Preface

Haipeng (Allan) Chen, University of Kentucky
Giana M. Eckhardt, King's College London
Rebecca Hamilton, Georgetown University

The 53rd Annual Conference of the Association for Consumer Research (ACR) was held at Sheraton Downtown in Denver, Colorado from October 20-22, 2022. The theme of this conference was Together. It marked the reconvening of our community in a face-to-face setting after being virtual in both 2020 and 2021, allowing reconnections with friends and colleagues and the opportunity to meet new collaborators and friends. We wanted to celebrate this by facilitating all benefits that can come from a shared, in-person conference experience.

In addition to celebrating being physically together again, our conference theme advocated for coming together across sub-disciplines to address important theoretical and substantive issues. Two such issues, the Post-Pandemic Sharing Economy and the Misinformation Infodemic, were highlighted in our plenary Perspectives and Prospects panels. Multiple methods were showcased in a series of Methods Workshops. For special sessions, competitive sessions, working papers, and roundtables, we particularly welcomed submissions that highlighted connections across theoretical perspectives and methodologies. And, when creating sessions of competitive papers and films, we created sessions around substantive topics rather than common methods, so that some sessions combined papers and films, and many sessions combined CCT work with experimental work.

Finally, we wanted to honor and facilitate connections among our diverse, international association of consumer researchers. We did this by offering a single track throughout the conference online, so that those who could not come to Denver could still participate.

The conference attracted over 1,100 participants from 36 different countries across the globe. We received 854 total submissions and accepted 513, which represents a 60.07% acceptance rate. At this year's conference, 240 competitive papers (acceptance rate of 52%), 51 special sessions (62% acceptance), 200 working papers (68% acceptance), 9 films (82% acceptance), 3 roundtables (75% acceptance), 2 plenary Perspectives and Prospects sessions, and 4 method workshops were presented. We congratulate our two new ACR Fellows, Joel Huber and Wes Hutchinson, who gave addresses at the conference.

We thank our generous sponsors: Sheth Foundation, BEAR - University of Toronto, King's College King's Business School, Georgetown University McDonough School of Business, University of Kentucky Gatton College of Business & Economics, Journal of the Association for Consumer Research, Journal of Consumer Research, SONA Systems, the Marketing Science Institute (MSI), and the American Psychological Association.

Many wonderful people worked tirelessly to help us make this conference possible. We thank our Program Committee, Associate Editors, Competitive Paper Reviewers, Working Paper Reviewers, and Videography Reviewers for carefully reviewing the 854 submissions to the conference. For their enthusiasm, creativity, and organization, we wish to thank Eileen Fischer and Gita Johar (Perspectives and Prospects Session Chairs), Steven Spiller, Uma Karmarkar, and Fleura Bardhi (Methods Workshop Chairs), Finola Kerrigan and Eric Li (Film Festival Chairs), Ana Babic Rosario, Irene Scopeletti and Echo Wen Wan (Working Paper Chairs), Aric Rindfliesch (Networking Lunch Chair), Nicole Mead and Lawrence Williams (Doctoral Symposium Chairs), Luca Cian, Nailya Ordayeva and Alison Xu (Early Career Workshop Chairs), Rebecca Reczek and Markus Giesler (Mid Career Workshop Chairs), Melissa Akaka (Saturday Gala event coordinator), Cristal Russel (wellbeing coordinator), and Kelley Cours Anderson (social media manager).

Special gratitude goes to ACR Executive Director Rajiv Vaidyanathan, our Conference Planners Paula Rigling, and ACR Executive Assistant Amy Ledin. Last but not the least, we wish to sincerely thank Jen Argo, ACR President 2022, for giving us the opportunity to organize the ACR conference and for her guidance during the entire journey.

Here, we present the abstracts from all the sessions, as a record of the vibrant exchange of ideas that took place at the conference. We hope you are inspired to approach your topics of interest in different ways, in the spirit of bringing consumer research subdisciplines together.

Haipeng (Allan) Chen, University of Kentucky

Conference Committees & Reviewers

2022 ACR Presidential Address

Jennifer Argo, University of Alberta, Canada

Perspective	1
-----------------------	---

2022 ACR Fellows' Address

The Power of a Strong Research Culture	4
<i>Joel Huber</i>	

Competitive Papers—Full

Consumer Cynicism Through the Lens of Bourdieu	9
<i>Dr. Indirah Indibara, (Indian Institute of Management Raipur)</i>	
<i>Dr. Sanjeev Varshney, (XLRI Jamshedpur)</i>	
The Material Possessions Stereotype	13
<i>Tabitha Thomas, Unaffiliated</i>	
Brand Nomadicity: Redefining Consumer-Brand Relationships in Liquid Modernity	18
<i>Sarah Schwarz, University of Innsbruck</i>	
<i>Christiane Aufschnaiter, MCI-The Entrepreneurial School</i>	
Ugly is the New Pretty: Motivations Behind the Acceptance of Ugly Fashion Trends	24
<i>Tabitha Thomas, Unaffiliated</i>	
<i>Dolphy Abraham, Independent Researcher</i>	
The “Supportive Consumption” Movement in Japan: Consumers’ Age and Distance of Beneficiaries in Ethical Consumption	29
<i>Takeshi Matsui, Hitotsubashi University, Japan</i>	
<i>Akiko Masuda, Senshu University, Japan</i>	
<i>Masayuki Tsumura, Kanagawa University, Japan</i>	
Consumer Noncompliance in Compliance-Dependent Services	35
<i>Mr. Jared Wong, Yale University, USA</i>	
<i>Dr. Stephanie Dellande, Menlo College, USA</i>	
Myth	40
<i>Dr. Jonatan Södergren, Sweden</i>	
<i>Dr. Niklas Vallström, Kristianstad University, Sweden</i>	
<i>Dr. Ileyha Dagalp, Gothenburg University, Sweden</i>	
<i>Mr. Thomas Broberg, Sweden</i>	

“Sharing in” Practices among Lower-Middle Class Urban Families in Brazil	46
<i>Prof. Barbara Levy, Pontifical Catholic University of Rio de Janeiro - PUC-Rio, Brazil</i>	
<i>Prof. Angela Da Rocha, Pontifical Catholic University of Rio de Janeiro - PUC-Rio, Brazil</i>	
<i>Prof. Ana Raquel Rocha, UFF - Fluminense Federal University, Brazil</i>	
Market-centric pathways for racial inclusion: the case of #MyBlackReceipt.	49
<i>Dr. Olivier Sibai, Marketing lecturer, Birkbeck, University of London, UK</i>	
<i>Prof. Katja Brunk, Professor of Marketing, European University Viadrina, Germany</i>	
<i>Dr. Marcia Christina Ferreira, Senior Lecturer in Marketing and Operations, Brunel University London, UK</i>	
<i>Prof. Meriam Belkhir, Professor of Marketing, University of Sfax, Tunisia</i>	
<i>Dr. Myriam Brouard, Assistant professor, University of Ottawa, Canada</i>	
<i>Dr. Mario Campana, Marketing lecturer, University of Bristol, UK</i>	
<i>Dr. Marlon Dalmoro, Assistant Professor, Univates, Brazil</i>	
<i>Dr. Bernardo Figueiredo, Associate Professor, RMIT University, Australia</i>	
<i>Dr. Daiane Scaraboto, Associate professor, University of Melbourne, Australia</i>	
<i>Dr. Andrew Smith, Associate professor, Suffolk University, USA</i>	
Prosocial Nudges and Visual Indicators Increase Social Distancing but Authoritative Nudges Do Not	55
<i>Mr. Mohin Banker, Yale University, USA</i>	
<i>Dr. Moses Miller, Reichman University (IDC), Israel</i>	
<i>Dr. Guy Voichek, Yale University, USA</i>	
<i>Prof. Dafna Goor, London Business School, UK</i>	
<i>Dr. Tamar Makov, Ben-Gurion University, Israel</i>	
Technoism: A New Form of Consumer Prejudice and Discrimination	58
<i>Dr. Moritz Joerling, Emlyon Business School, France</i>	
<i>Prof. Nico Heuvinck, IESEG School of Management, France</i>	
<i>Dr. Gwarlann De Kerviler, IESEG School of Management, France</i>	
<i>Dr. Derek Rucker, Northwestern University, USA</i>	
Between Two Worlds: Consumption of Private Schools by Low-Income Families	63
<i>Prof. Estefanie Nascimento, Pontifical Catholic University of Rio de Janeiro - PUC-Rio, Brazil</i>	
<i>Prof. Angela Da Rocha, Pontifical Catholic University of Rio de Janeiro - PUC-Rio, Brazil</i>	
<i>Prof. Ana Raquel Rocha, UFF - Universidade Federal Fluminense, Brazil</i>	
A machine learning approach for the prediction of individual and market level demand from retail loyalty program data:	66
<i>Mr. Cameron Mcrae, McGill University, Canada</i>	
<i>Prof. Laurette Dubé, McGill University, Canada</i>	
Evaluative Dynamics: Summarizing Customer Journeys, Interviews, and Lives	70
<i>Prof. Julian De Freitas, Harvard Business School, USA</i>	
<i>Ms. Pechthida Kim, Harvard University, USA</i>	
<i>Prof. Tomer D. Ullman, Harvard University, USA</i>	
How Coherent Nature Makes Natural Products Attractive:	74
<i>Dr. Hajar Fatemi, University of Windsor, Canada</i>	
<i>Prof. Laurette Dubé, McGill University, Canada</i>	
When and how virus anthropomorphism intensifies consumer stigma toward patients	78
<i>Mr. Jiancai Liao, Aalto University School of Business, China</i>	
<i>Ms. Jingya Huang, Shanghai Jiao Tong University, China</i>	
<i>Dr. Lei Su, City University of Hong Kong, Hong Kong</i>	
In Limbo: Liminality Narratives of Young Adults Returning to the Family Home	79
<i>Ms. Ugne Greivyte, Independent Researcher, Austria</i>	
<i>Prof. Andrea Hemetsberger, University of Innsbruck, Austria</i>	
Tower of Babel: Thematic Cohesion in Online Consumer Conversations	83
<i>Mr. Denis Utochkin, Norwegian School of Economics, Norway</i>	
<i>Prof. Ivan Belik, Norwegian School of Economics, Norway</i>	
Cause-Related Marketing Accelerates Satiation	87
<i>Mr. Han Young Jung, University of Minnesota, USA</i>	
<i>Dr. Joseph Redden, University of Minnesota, USA</i>	

Pool More, Drive Less: An In-Depth Qualitative Investigation of Barriers and Motivators of Ride-Pooling in Autonomous Vehicles 90
Dr. Annalisa Stefanelli, University of Applied Sciences North Western Switzerland, Switzerland
Ms. Nora Studer, University of Applied Sciences North Western Switzerland, Switzerland
Ms. Nicole Haiderer, University of Applied Sciences North Western Switzerland, Switzerland
Prof. Dorothea Schaffner, University of Applied Sciences North Western Switzerland, Switzerland
Prof. Alexander Erath, University of Applied Sciences North Western Switzerland, Switzerland
Dr. Michael Van Eggermond, University of Applied Sciences North Western Switzerland, Switzerland

The Use of Ownership Language and Its Consequences on Evaluation. 94
Mr. Myojoong Kim, Virginia Tech, United States
Dr. Juncai Jiang, University of Central Florida, United States
Dr. Mario Pandelaere, Virginia Tech, United States

When Loneliness Impedes Compliance with COVID-19 Prevention Guidelines. 98
Dr. Ainslie Schultz, Providence College, United States
Dr. Kevin Newman, Providence College, United States

What Is ‘Average’? 100
Prof. Ray Charles “Chuck” Howard, Texas A & M University, USA
Mr. Amin Shiri, Texas A & M University, USA

My Two Cents: Assistance During Financial Decision Making Increases Consumer Sentiment and Gamma Brainwaves. 102
Samuel B. Barnett, ThinkAlike Laboratories, USA

Transforming Impoverished Consumer Subjectivity. 106
Dr. Meredith Rhoads Thomas, Florida State University, USA
Dr. Alexander Mitchell, University of South Florida, USA

Competitive Papers—Extended Abstracts

Consumer Cynicism Through The Lens Of Bourdieu 111
Dr. Indirah Indibara, Indian Institute of Management Raipur, India
Dr. Sanjeev Varshney, XLRI Jamshedpur, India

Emotions as Drivers of Empowerment and Destigmatization in Disability Sport 114
Dr. Sheila Matson-Barkat, Rennes School of Business, France
Dr. Petya Puncheva, Rennes School of Business, France

<i>Ms. Tinka Krüger, Kiel University, Germany</i>	
<i>Dr. Wassili Lasarov, Kiel University, Germany</i>	
<i>Prof. Stefan Hoffman, Kiel University, Germany</i>	
Motivated Fake News: Understanding how ideology and competitive context influence misinformative posts on social media	144
<i>Ms. Xiajing Zhu, University of California, Irvine, USA</i>	
<i>Dr. Connie Pechmann, University of California, Irvine, USA</i>	
Barriers to social change: Unconscious complicity and a distributed form of power woven throughout the social space.	147
<i>Dr. Paul Henry, The University of Sydney, Australia</i>	
<i>Dr. Marylouise Caldwell, The University of Sydney, Australia</i>	
<i>Dr. Babak Amiri, The University of Sydney, Australia</i>	
Closing the Attitude-Behavior Gap: A Novel Measure to Predict Ethical Consumption.	149
<i>Prof. Brandon Reich, Portland State University, USA</i>	
<i>Prof. Hong Yuan, University of Oregon, USA</i>	
<i>Prof. Lamberto Zollo, Università degli Studi di Milano, Italy</i>	
<i>Prof. Riccardo Rialti, Università degli Studi di Milano, Italy</i>	

Sentimental Value: Use it & Grow it	151
<i>Dr. Daniel Grossman, University of Missouri-St. Louis, USA</i>	
<i>Dr. Ryan Rahinel, University of Cincinnati, USA</i>	
Using Benchmarks to Mitigate Overhead Aversion and Increase Donations	153
<i>Dr. Burcak Bas, WU Vienna, Austria</i>	
<i>Prof. Zachary Estes, City, University of London, London, UK</i>	
<i>Prof. Aradhna Krishna, University of Michigan, USA</i>	
Production Enjoyment Asymmetrically Impacts Buyers' Willingness to Pay and Sellers' Willingness to Charge	154
<i>Dr. Anna Paley, Tilburg University, Netherlands</i>	
<i>Dr. Robert Smith, Tilburg University, Netherlands</i>	
<i>Dr. Jacob Teeny, Northwestern University, USA</i>	
<i>Dr. Daniel Zane, Lehigh University, USA</i>	
Describing Rosé: Measuring Consumer Preferences for Hedonic Experiences.	156
<i>Dr. Anirban Mukherjee, Cornell University, USA</i>	
<i>Dr. Hannah H. Chang, Singapore Management University, USA</i>	
Secondbrand Exchange: When Traditional Retail Brands Resell Used Products	158
<i>Mr. Peter Silverstein, Unaffiliated, USA</i>	
<i>Dr. Catherine Armstrong Soule, Western Washington University, USA</i>	
<i>Dr. Sara Hanson, University of Richmond, USA</i>	
Personal Growth is More Enjoyable than Consumers Expect.	161
<i>Ms. Emily Powell, New York University Stern School of Business, USA</i>	
<i>Dr. Adam Alter, New York University Stern School of Business, USA</i>	
"It happened to my friend": How story source and victim characteristics shape consumer responses to stories about marketplace injustice	163
<i>Dr. Anne Hamby, Boise State University, USA</i>	
<i>Dr. Davide Orazi, Monash University, Australia</i>	
<i>Mr. Patrick Moreau, Muse Storytelling, USA</i>	
Extended Warranties Protect the Consumer, Not Only the Product	164
<i>Dr. Liat Hadar, Tel Aviv University, Israel</i>	
<i>Dr. Ronit Montal-Rosenberg, The Hebrew University of Jerusalem, Israel</i>	
<i>Prof. Shai Danziger, Tel Aviv University, Israel</i>	
Product Face Ratios, Stereotypes, and Political Orientation: Field Data on Consumer Evaluations	165
<i>Dr. Boram Lim, University of Kansas, USA</i>	
<i>Dr. Michael Lash, University of Kansas, USA</i>	
<i>Dr. Ahreum Maeng, University of Kansas, USA</i>	
<i>Dr. Pankaj Aggarwal, Rotman School of Management, University of Toronto, Canada</i>	
How do Emojis Shape Conversations in Digital Environments?	167
<i>Ms. Yiming Li, HEC, Lausanne, University of Lausanne, Switzerland</i>	
<i>Prof. Tobias Schlager, HEC, Lausanne, University of Lausanne, Switzerland</i>	
<i>Prof. Joandrea Hoegg, Sauder School of Business, University of British Columbia, Canada</i>	
Luxury Content Becoming Viral Online: The Positive Role of Lexical Sophistication.	170
<i>Mr. Zitian Qiu, HEC, Lausanne, Switzerland</i>	
<i>Prof. Felicitas Morhart, HEC Lausanne, Switzerland</i>	
<i>Prof. Andreas Lnaz, HEC Paris, France</i>	
<i>Dr. Daniel Shapira, Ben-Gurion University, Israel</i>	
Creative Gift Systems: An Autonetnography Among Writers	172
<i>Ms. Isabella Ciampa, HEC Paris, France</i>	
The status signaling function of wasting food	174
<i>Ms. Evelyn Devos, Ghent University, Belgium</i>	
<i>Ms. Daphne Ribbers, Ghent University, Belgium</i>	
<i>Dr. Mario Pandelaere, Virginia Tech, USA</i>	
<i>Prof. Anneleen Van Kerckhove, Ghent University, Belgium</i>	

Disposing of Dior: The Impact of Luxury Goods on Disposal Decisions	176
<i>Dr. Jennifer Stoner, University of North Dakota, USA</i>	
<i>Dr. Ashley Stadler Blank, Xavier University, USA</i>	
<i>Dr. Navdeep Athwal, University of Leicester, UK</i>	
Donate Your Work: Framing a Monetary Donation Request as Donating Work Increases Donor Responsiveness	178
<i>Dr. Robert Smith, Tilburg University, Netherlands</i>	
<i>Dr. John Costello, Notre Dame, USA</i>	
<i>Dr. Alix Barasch, Insead, France</i>	
The Unintended Consequences of Raising Awareness: Knowing About the Existence of Algorithmic Racial Bias Widens Racial Inequality	180
<i>Dr. Shunyuan Zhang, Harvard Business School, Harvard University, USA</i>	
<i>Dr. Yang Yang, University of Florida, USA</i>	
Frugality versus Thriftiness: The Gender Difference in Consumer Saving Behaviors	182
<i>Dr. Ying Bao, University of Illinois at Urbana-Champaign, USA</i>	
<i>Dr. Alex Yao, San Diego State University, USA</i>	
<i>Dr. He (Michael) Jia, The University of Hong Kong, Hong Kong</i>	
<i>Dr. Chen Gong, Nanjing University of Science and Technology, China</i>	
The Inclusive Minimalism Effect: Increased Preference for Minimalist Aesthetics in Choices for Shared Consumption.	183
<i>Ms. Cary Anderson, University of Pittsburgh, USA</i>	
<i>Dr. Peggy Liu, University of Pittsburgh, USA</i>	
<i>Dr. Lauren Min, University of Kansas, USA</i>	
How does Local-global Identity Impact Consumer Preference for Leisure over Work? The Perspective of Production Orientation	185
<i>Mr. Yu Pan, Shanghai University of Finance and Economics, China</i>	
<i>Dr. Huachao Gao, University of Victoria, Canada</i>	
<i>Prof. Xiaoyu Wang, Shanghai University of Finance and Economics, China</i>	
<i>Ms. Yamei Liu, Shanghai University of Finance and Economics, China</i>	
Don't trust what you see: The consequences of deepfake videos for consumer evaluation of firms and their representatives.	187
<i>Mr. Jeremy Fannin, HEC Lausanne, University of Lausanne, Switzerland</i>	
<i>Prof. Tobias Schlager, University of Lausanne, Switzerland</i>	
<i>Dr. Gita Johar, Columbia University, USA</i>	
BOGO Frees You: Promotions and Adventurous Product Choices	190
<i>Mr. Junha Kim, The Ohio State University, USA</i>	
<i>Dr. Joe Goodman, The Ohio State University, USA</i>	
<i>Dr. Selin Malkoc, The Ohio State University, USA</i>	
A Consumer's Perspective on Online Search When Using a Search Engine	193
<i>Dr. Sarah Whitley, University of Georgia, USA</i>	
<i>Dr. Anindita Chakravarty, University of Georgia, USA</i>	
<i>Ms. Lan Anh Ton, University of Georgia, USA</i>	
<i>Dr. Pengyuan Wang, University of Georgia, USA</i>	
The Design Communication Assessment Scale (DCAS): Assessing and Adjusting the Effectiveness of Product Design Communications	195
<i>Dr. Kevin L. Sample, University of Rhode Island, USA</i>	
<i>Dr. John Hulland, University of Georgia, USA</i>	
<i>Prof. Julio Sevilla, University of Georgia, USA</i>	
<i>Dr. Lauren I. Labrecque, University of Rhode Island, USA</i>	
Disentangling Product Comparisons with the Attribute-Hedonic Model	196
<i>Dr. Zac Arens, Oklahoma State University, USA</i>	
Consumers' Reaction to Taste-based Product Modification	198
<i>Ms. Elisa Solinas, University of Southern California, USA</i>	
<i>Prof. Francesca Valsesia, University of Washington, USA</i>	
<i>Prof. Joseph C. Nunes, University of Southern California, USA</i>	

À Vous, but not For You: Multiple Languages on Product Labels Reduce Purchase Intentions	199
<i>Dr. Eugene Chan, Ryerson University, Canada</i>	
<i>Ms. Vanessa Hunter, Griffith University, Australia</i>	
<i>Dr. Gavin Northey, Griffith University, Australia</i>	
<i>Dr. Patrick Van Esch, Kennesaw State University, USA</i>	
Windfall Moments: Framing Tax Refunds to Increase Credit Card Debt Repayments among Indebted Consumers.	201
<i>Prof. Simon Blanchard, Georgetown University, USA</i>	
<i>Prof. Beatriz Pereira, Iowa State University, USA</i>	
<i>Dr. Remi Trudel, Questrom School of Business, Boston University, USA</i>	
Adoption of New Technology Vaccines.	203
<i>Dr. Laura Zimmermann, IE Business School, Spain</i>	
<i>Dr. Jeeva Somasundaram, IE Business School, Spain</i>	
<i>Ms. Barsha Saha, Indian Institute of Management, Shillong, India</i>	
Visual Storytelling: How Images Transport Us into the Narrative World	205
<i>Ms. Olesia Nikulina, Maastricht University, Russian Federation</i>	
<i>Prof. Allard Van Riel, UHasselt, Belgium</i>	
<i>Prof. Jos Lemmink, Maastricht University, Netherlands</i>	
<i>Prof. Martin Wetzels, EDHEC Business School, France</i>	
Cryptic Signalling: Hidden Markers of Inclusivity in Service Environments	207
<i>Dr. Kelly Choong, Edith Cowan University, Australia</i>	
<i>Dr. Gavin Northey, Griffith, University, Australia</i>	
<i>Ms. Vanessa Hunter Griffith, University, Australia</i>	
<i>Dr. Rory Mulcahy, University Of The Sunshine Coast, Australia</i>	
<i>Dr. Patrick Van Esch, Kennesaw State University, USA</i>	
<i>Dr. Eugene Chan, Ryerson University, Canada</i>	
Effects of Personalization and Ad Algorithm Disclosure on Perceived Creepiness	208
<i>Mr. Kevin Krause, Saarland University, Germany</i>

Special Sessions

Consumption Sacrifices in Relationships: When and Why Consumers Give Up Money, Time, and Preferences for Others 507

Chair: Peggy J. Liu, University of Pittsburgh, USA

Paper #1: The (In)Visibility of Consumption-based Sacrifice

Ximena Garcia-Rada, Texas A&M University, USA

Tami Kim, University of Virginia Darden School of Business, USA

Peggy J. Liu, University of Pittsburgh, USA

Paper #2: Choosing More Food for Others

Ignazio Ziano, Grenoble University, France

Peggy J. Liu, University of Pittsburgh, USA

Paper #3: When Mine Becomes Ours: Caregiving and the Effects of Choices Made for Others on Subsequent Choices for the Self

Kelley Gullo Wight, Indiana University, USA

Peggy J. Liu, University of Pittsburgh, USA

Lingrui Zhou, Duke University, USA

Gavan J. Fitzsimons, Duke University, USA

Receptiveness: Antecedents and Consequences 511

Chair: Mr. Mohamed Hussein, Stanford GSB, USA

Paper #1: Receptive Language Transmits Throughout Conversations and Improves Conflict Outcomes

Julia Minson, Harvard Kennedy School, USA

Michael Yeomans, Imperial College London, UK

Hanne Collins, Harvard Business School, USA

Francesca Gino, Harvard Business School, USA

Paper #2: How Partisan Identity Reverses the Benefits of Receptiveness to Opposing Views

Mohamed A. Hussein, Stanford GSB, USA

S. Christian Wheeler, Stanford GSB, USA

Paper #3: Ascribing Affective Attitude Bases Forestalls Political Word of Mouth: An Inference-Making Process Through Perceived Openness

Jacob D. Teeny, Kellogg School of Management at Northwestern University, USA

Richard E. Petty, Ohio State University, USA

Paper #4: (Mis)perceptions of Support-Oppose Framing for Message Senders Versus Recipients

Rhia Catapano, Rotman School of Management at University of Toronto, Canada

Zak Tormala, USA

On ethics and sludge: Consumers' perceptions of and reactions to the use of behavioral science by organizations 516

Chair: Ms. Daniella Turetski, Rotman School of Management, University of Toronto, Canada

Paper #1: Why Do People Condemn and Appreciate Experiments?

Burcak Bas, Bocconi University, Italy

Rachele Ciulli, University of Pennsylvania (Wharton), USA

Joachim Vosgerau, Bocconi University, Italy

Paper #2: An Experimental Investigation Into Whether Choice Architecture Interventions Are Considered Ethical

Daniella Turetski, Rotman School of Management, University of Toronto, Canada

Renante Rondina, Rotman School of Management, University of Toronto, Canada

Bing Feng, Rotman School of Management, University of Toronto, Canada

Dilip Soman, Rotman School of Management, University of Toronto, Canada

Paper #3: Everyday Administrative Burdens and Inequality

Lucie Martin, University College Dublin School of Economics and Geary Institute for Public Policy, Ireland

Liam Delaney, London School of Economics Department of Psychological and Behavioural Science, UK

Orla Doyle, University College Dublin School of Economics and Geary Institute for Public Policy, Ireland

Paper #4: Obfuscation and Choice Architecture in Online Donations

Nathaniel A. Posner, Columbia Business School, USA

Kellen Mrkva, Hankamer School of Business, Baylor University, USA

Andrey Simonov, Columbia Business School, USA

Eric J. Johnson, Columbia Business School, USA

Social Phenomena and Marketplace Signaling in a Changing World 522

Chairs: Jared Watson, New York University, USA

Evan Weingarten, Arizona State University, USA

Paper #1: The Upsides and Downsides of Gatekeeping

Evan Weingarten, Arizona State University, USA

Rachel Gershon, University of California, San Diego, USA

Amit Bhattacharjee, University of Colorado, Boulder, USA

Paper #2: Sexual Misconduct, Scientific Fraud, and Citation Penalties

Giulia Maimone, University of California, San Diego, USA

Gil Appel, George Washington University, USA

Craig R. M. McKenzie, University of California, San Diego, USA

Ayelet Gneezy, University of California, San Diego, USA

Paper #3: George Floyd’s Murder and Yelp: Product Reviews as a Compensatory Process

Siddharth Sharma, Indian School of Business, India

Justin Frake, University of Michigan, USA

Jared Watson, New York University, USA

Paper #4: Racial-Justice-Branding and Racial Privilege

Broderick Turner, Virginia Tech, USA

Esther Uduehi, University of Washington, USA

Gifting-Dynamics That Do Not Fit the Mold—Challenges and Resolutions 527

Chairs: Soo Kim, Nanyang Technological University

Theresa A. Kwon, University of Pittsburgh

Peggy J. Liu, University of Pittsburgh

Paper #1: Self-Gifting Hesitation

Soo Kim, Nanyang Technological University, Singapore

Theresa A. Kwon, University of Pittsburgh, USA

Peggy J. Liu, University of Pittsburgh, USA

Kate E. Min, Wheaton College, USA

Paper #2: Constraining the Unconstrained: Gift Versatility and Financial Perceptions

Lingrui Zhou, Duke University, USA

Denny Huynh, Duke University, USA

Keisha Cutright, Duke University, USA

Eugenia Wu, University of Pittsburgh, USA

Paper #3: The “I Hear You” Effect: Support-Givers’ Inflated Preference for Consolation Gifts that Signal Non-Avoidance of Support-Seekers’ Struggle

Soo Kim, Nanyang Technological University, Singapore

Lauren Min, University of Kansas, USA

Kate Min, Wheaton College, USA

Helen Chun, Cornell University, USA

Paper #4: Givers Can Handle the Truth: Givers React to Recipients’ Honesty About Disliked Gifts Better Than Recipients Expect

Yanyi Leng, Washington University in St. Louis, USA

Elanor F. Williams, Washington University in St. Louis, USA

Religion and Consumer Behavior 533

*Chairs: Yafei Guo, University of Illinois at Urbana Champaign, USA
Yu Ding, Stanford University, USA*

Paper #1: “This Is My Commandment, That You Love One Another”: The Interplay Between Cultural and Religious Orientation Predicts Prosocial Behavior

*Hyewon Oh, Stevens Institute of Technology, USA
Carlos J. Torelli, University of Illinois at Urbana Champaign, USA
Jennifer L. Stoner, University of North Dakota, USA*

Paper #2: Minimal or Universal: Religious Prosociality from A Political Ideology Perspective

*Yafei Guo, University of Illinois at Urbana Champaign, USA
Carlos J. Torelli, University of Illinois at Urbana Champaign, USA*

Paper #3: The Impact of God Salience on Algorithm Aversion

*Mustafa Karataş, Nazarbayev University, Kazakhstan
Keisha Cutright, Duke University, USA*

Paper #4: Science Denial: Rooted in Religious Intolerance and Lack of Religious Diversity

*Yu Ding, Stanford University, USA
Gita V. Johar, Columbia University, USA
Michael Morris, Columbia University, USA*

The intersection of political ideology and social identity: Impact on consumption and anti-consumption 539

Chair: Dr. Hyun Euh, University of Illinois at Urbana-Champaign, USA

Paper #1: Ideological differences in identity-reinforcing response in the face of the identity threat

*Hyerin Han, Carl H. Lindner College of Business, University of Cincinnati, USA
Joshua Clarkson, Carl H. Lindner College of Business, University of Cincinnati, USA*

Paper #2: How uncertainty shapes conservatives’ and liberals’ hedonic consumption

*Jihye Jung, Alvarez College of Business, University of Texas at San Antonio, USA
Daniel Fernandes, Católica-Lisbon School of Business and Economics, Universidade Católica Portuguesa, Portugal
Nailya Ordabayeva, Dartmouth College, USA
Kyuhyong Han, Korea University Business School, Korea University, South Korea
Vikas Mittal, Jones Graduate School of Business, USA*

Paper #3: National-level consumer boycott movement: The role of political dynamics on short-term and long-term consumer boycott engagement

*Kiju Jung, The University of Sydney Business School, Australia
Sanghyo Kim, Korea Rural Economic Institute, South Korea
Jaehyun Choi, Korea Rural Economic Institute, South Korea
Donnel Briley, The University of Sydney Business School, Australia
Nulpurum Seo, The University of Sydney Business School, Australia
Shai Danziger, Collier School of Management, Tel Aviv University, Israel*

Paper #4: We live in different Americas: Political ideology shapes perceptions of American culture and iconic brands

*Hyun Euh, Gies College of Business, University of Illinois at Urbana-Champaign, USA
Maria A. Rodas, Gies College of Business, University of Illinois at Urbana-Champaign, USA
Carlos J. Torelli, Gies College of Business, University of Illinois at Urbana-Champaign, USA
Sharon Shavitt, Gies College of Business, University of Illinois at Urbana-Champaign, USA*

New Perspectives on Censorship: Reacting to Censorship Decisions, Deciding What to Censor, and Censoring the Self. 545

Chair: Mr. Mohamed Hussein, Stanford University, USA

Paper #1: The Psychology of Consumer-Driven Media Censorship

*Polina Landgraf, The University of Virginia, USA
Tami Kim, The University of Virginia, USA*

Paper #2: How Pronoun Use Shapes Censorship Decisions

*Mohamed A. Hussein, Stanford University, USA
Zakary L. Tormala, Stanford University, USA*

Paper #3: Understanding Self-Censorship When Delivering Moral Feedback

*Yena Kim, The University of Chicago, USA
Emma E. Levine, The University of Chicago, USA*

Paper #4: When (Are) Online Relationships Real and Influential – An Evaluative Context Model

*Nirajana Mishra, Boston University, USA
Carey Morewedge, Boston University, USA*

Broadening the Scope of Consumer Research on Food. 550

Chair: Sherrie Y. Xue, INSEAD, France

Paper #1: The Start Stop Food Journey Framework for Consumer Eating Decisions

*Kelly L. Haws, Vanderbilt University, USA
Peggy J. Liu, University of Pittsburgh, USA
Brent McFerran, Simon Fraser University and Deakin University, Canada
Pierre Chandon, INSEAD, France*

Paper #2: Open Science Online Grocery: A Description and Application

*Holly S. Howe, Fuqua School of Business, Duke University, USA
Amanda Makara, Children's Hospital of Philadelphia, USA
Gavan J. Fitzsimons, Fuqua School of Business, Duke University, USA
Peter A. Ubel, Fuqua School of Business, Duke University, USA
C. Alix Timko, Children's Hospital of Philadelphia, USA*

Paper #3: Expiration Date Perception and Food Choices for Later Consumption

*J. Christine Kim, McIntire School of Commerce, University of Virginia, USA
Young Eun Huh, KAIST, South Korea
Brent McFerran, Simon Fraser University and Deakin University, Canada*

Paper #4: Ordering More and Eating Less: Effects of Preservation Containers on Food Ordering and Consumption Decisions

*Sherrie Y. Xue, INSEAD, France
Stephanie C. Lin, INSEAD, France
Pierre Chandon, INSEAD, France
Andde Indaburu, INSEAD, France*

“Seeing Stars: Novel Insights on how Consumers Generate and Use Product Ratings”. 555

Chair: Quentin André, Leeds School of Business, University of Colorado Boulder, USA

Paper #1: The Influence of Mean Product Ratings on Review Judgments and Search

*Daniel Katz, Booth School of Business, University of Chicago, USA
Dan Bartels, Booth School of Business, University of Chicago, USA*

Paper #2: Would you Use a South-Pointing Compass? Consumers Underestimate the Informativeness of Systematic Disagreement

*Quentin André, Leeds School of Business, University of Colorado Boulder, USA
Samuel Hirshman, Norwegian School of Economics, Norway
Nicholas Reinholz, Leeds School of Business, University of Colorado Boulder, USA*

Paper #3: Set Aside: Consumers Neglect Set Size when Evaluating Ranked Products

*Uri Barnea, Bocconi School of Management, Bocconi University, Milan, Italy
Alice Moon, The Wharton School, University of Pennsylvania, USA
Jackie Silverman, Lerner College of Business, University of Delaware, USA*

Paper #4: Cold, Rain, and Snow: Trouble for Star Ratings

*Matt Meister, Leeds School of Business, University of Colorado Boulder, USA
Nicholas Reinholz, Leeds School of Business, University of Colorado Boulder, USA*

Novel Insights on Prosocial Behaviors. 560

Chair: Minzhe Xu, Iowa State University

Paper #1: To Donate or Not: Providing Fewer Options Increases Donation Amounts

*Bowen Ruan, University of Iowa, USA
Minzhe Xu, Iowa State University, USA
Zoe Y. Lu, Tulane University, USA*

Paper #2: When Donation Feels Like Volunteering, People Give: A “Donateer” Fundraising Method

*Adelle X. Yang, National University of Singapore, Singapore
Oleg Urminsky, University of Chicago, USA*

Paper #3: What is Impact? Inter-Temporal Trade-offs in Donation Behavior

*Aparna Labroo, Northwestern University, USA
Uzma Khan, University of Miami, USA*

Paper #4: Outcomes (vs. Impact) Framing Makes People More Likely to Reduce Background Risk in Prosocial Decisions

*Randy Yang Gao, New York University, USA
Joshua Lewis, New York University, USA
Lucius Caviola, Harvard University, USA*

Consumer Interdependence: Decision Making With and For Others	565
<i>Chairs: Ms. Amanda Geiser, University of California, Berkeley, USA</i>	
<i>Prof. Rachel Gershon, University of California San Diego, USA</i>	
<i>Ms. Emily Powell, New York University Stern School of Business, USA</i>	
Paper #1: Friends with Health Benefits: A Field Experiment

<i>Dr. Alice Moon, The Wharton School, University of Pennsylvania, USA</i>	
Paper #4: Measuring Stable Noise in Consumers’ Intertemporal Preferences	
<i>Dr. Antonia Krefeld-Schwalb, Rotterdam School of Management, Erasmus University, Netherlands</i>	
<i>Dr. Eric J. Johnson, Columbia Business School, USA</i>	
Lay Beliefs about What Machines Can Do Better than Humans (and Vice Versa).	575
<i>Chairs: Almira Abilova, Erasmus University, the Netherlands</i>	
<i>Jimin Nam, Harvard Business School, USA</i>	
Paper #1: Robo-Journalism: Robo-Journalism Decreases Perceptions of Bias by Increasing Perceptions of Comprehensiveness	
<i>Jimin Nam, Harvard Business School, USA</i>	
<i>Adam Waytz, Northwestern University, USA</i>	
<i>Michael I. Norton, Harvard Business School, USA</i>	
Paper #2: To Delegate, or Not to Delegate: Consumers Prefer to Delegate Decisions to Algorithms (vs. Humans)	
<i>Sarah Lim, University of Illinois at Urbana-Champaign, USA</i>	
<i>Gizem Yalcin, The University of Texas at Austin, USA</i>	
<i>Stefano Puntoni, Wharton School of the University of Pennsylvania, USA</i>	
Paper #3: Stigma Against AI Companion Applications	
<i>Julian De Freitas, Harvard Business School, USA</i>	
<i>Anya Ragnhildstveit, University of Utah, USA</i>	
<i>Ahmet K. Uğuralp, Bilkent University, Turkey</i>	
<i>Zeliha Oğuz, Bilkent University, Turkey</i>	
Paper #4: Antecedents of Lay Beliefs about Job Automation	
<i>Almira Abilova, Erasmus University, the Netherlands</i>	
<i>Mirjam Tuk, Erasmus University, the Netherlands</i>	
<i>Stefano Puntoni, Wharton School of the University of Pennsylvania, USA</i>	

Structural Effects On Motivation	580
<i>Chair: Holly Howe, Duke University, USA</i>	
Paper #1: The Watch List Effect: How Loose Plans Make Consumers Feel Productive	
<i>Scott Wallace, University of Washington, USA</i>	
Paper #2: Quantitative Feedback Increases Social Comparison Motivation	
<i>Holly S. Howe, HEC Montréal, Canada</i>	
<i>Jordan Etkin, Duke University, USA</i>	
<i>Szu-chi Huang, Stanford University, USA</i>	
Paper #3: Work-to-Unlock Rewards: Leveraging Goals in Reward Systems to Increase Consumer Persistence	
<i>Marissa A. Sharif, University of Pennsylvania, USA</i>	
<i>Kaitlin Woolley, Cornell University, USA</i>	
Paper #4: Stuck in a Rut: The Behavioral Entrenchment Effect	
<i>Alicea Lieberman, University of California, Los Angeles, USA</i>	
<i>On Amir, University of California, San Diego, USA</i>	
<i>Ziv Carmon, INSEAD, France</i>	
For a Greener World: Consumers' Attitudes and Behaviors toward Sustainable Practices.	585
<i>Chair: Ms. Sylvia Chang, University of Washington, USA</i>	
Paper #1: Affording Disposal Control: The Effect of Circular Take-Back Programs on Psychological Ownership and Valuation	
<i>Anna Tari, Boston University, USA</i>	
<i>Remi Trudel, Boston University, USA</i>	
Paper #2: You're More Expendable: Consumers' Perceptions and Usage of Repurposed Products	
<i>Sylvia S.E. Chang, University of Washington, USA</i>	
<i>Jennifer D'Angelo, Texas Christian University, USA</i>	
<i>Francesca Valsesia, University of Washington, USA</i>	
Paper #3: The Effect of Perceived Control on Local Consumption	
<i>Arani Roy, McGill University, Canada</i>	
<i>Ashesh Mukherjee, McGill University, Canada</i>	
Trust Issues in the Daily Coexistence with Advanced Technology.	589
<i>Chair: Ms. Sonia Kim, Columbia Business School</i>	
Paper #1: The Effect of Digitally Altered Images on Consumers	
<i>Szu-chi Huang, Stanford Graduate School of Business, USA</i>	
<i>Jen H. Park, UBC Sauder School of Business, British Columbia</i>	
<i>Liyin Jin, Fudan University School of Management, China</i>	
Paper #2: The Consequences of Relying on YouTube Recommendation Algorithms	
<i>Sonia S. Kim, Columbia University, USA</i>	
<i>Jaeyeon Chung, Rice University, USA</i>	
<i>Gita V. Johar, Columbia University, USA</i>	
Paper #3: Does Automation Lower Meaningful Work?	
<i>Sarah Ward, Gies College of Business, University of Illinois at Urbana-Champaign, USA</i>	
<i>Roshni Raveendhran, Darden School of Business, University of Virginia, USA</i>	
<i>Tami Kim, Darden School of Business, University of Virginia, USA</i>	
Paper #4: Preferring People but Listening to Algorithms: Anticipated Preferences vs. Utilization of Algorithmic Advice	
<i>Jennifer M. Logg, Georgetown University, USA</i>	
<i>Rachel J. Schlund, Cornell University, USA</i>	

Customer Response to New Digital Technologies in Public and Private Sectors 594

Chair: Ms. Jianna Jin, The Ohio State University, USA

Paper #1: Overgeneralization of Failures of Artificial Intelligence in the Government

Chiara Longoni, Boston University, Questrom School of Business, USA
Luca Cian, University of Virginia, Darden School of Business, USA
Ellie J. Kyung, Wharton School, University of Pennsylvania, USA

Paper #2: Conversations with Machines: The Impact of Self-presentation Concerns on Consumer Engagement when Interacting with Chatbots versus Human Service Providers

Jianna Jin, The Ohio State University, USA
Jesse Walker, The Ohio State University, USA
Rebecca Walker Reczek, The Ohio State University, USA

Paper #3: “Click to Read More” Biases Consumers’ Memory and Preference

Jen H. Park, Stanford Graduate School of Business, USA
Szu-chi Huang, Stanford Graduate School of Business, USA

Paper #4: A Feast for the Eyes: How Augmented Reality Influences Food Desirability

William Fritz, Saïd Business School, University of Oxford, UK
Rhonda Hadi, Saïd Business School, University of Oxford, UK
Andrew Stephen, Saïd Business School, University of Oxford, UK

Consumer Behavior in the Field: Semblances of Success and Heterogenous Effects 599

Chair: Mr. Rafael Batista, The University of Chicago Booth School of Business, USA

Paper #1: The Semblance of Success in Nudging Consumers to Pay Down Credit Card Debt

Benedict Guttman-Kenney, University of Chicago Booth School of Business, USA
Paul Adams
Stefan Hunt
David Laibson, Harvard University, USA
Neil Stewart, Warwick Business School, UK

Paper #2: Understanding Co-Holding Through Informational Nudge Abstract

Rafael M. Batista, University of Chicago Booth School of Business, USA
Ella Mao, Stanford University, USA
Jessica Min, Princeton University, USA
Abigail Sussman, University of Chicago Booth School of Business, USA

Paper #3: Nudging Misperceptions

Walter W. Zhang, University of Chicago Booth School of Business, USA
Sanjog Misra, University of Chicago Booth School of Business, USA

Paper #4: Using Information Architecture to Address Individual Behavioral Differences and Reduce Retirement Savings Gaps

Stephen Shu, Cornell University; Digital Nudging Tech, USA
Hal Hershfield, UCLA, USA
Shlomo Benartzi, UCLA, USA
Richard Mason, Carnegie Mellon University; Voya Financial, USA

Decoding the Language of Success. 603

Chairs: Matthew D. Rocklage, D’Amore-McKim School of Business, Northeastern University, USA

Shiri Melumad, The Wharton School, University of Pennsylvania, USA

Paper #1: Beyond Sentiment: The Value and Measurement of Consumer Certainty in Language

Matthew D. Rocklage, D’Amore-McKim School of Business, Northeastern University, USA
Sharlene He, John Molson School of Business, Concordia University, Canada
Derek D. Rucker, Kellogg School of Management, Northwestern University, USA
Loran Nordgren, Kellogg School of Management, Northwestern University, USA

Paper #2: Style, Content, and the Success of Ideas

Jonah Berger, The Wharton School, University of Pennsylvania, USA
Grant Packard, Schulich School of Business, York University, Canada
Reihane Boghrati, W.P. Carey School of Business, Arizona State University, USA

Paper #3: The Effects of Diverse Language in Reference Group Associations

Jeffrey K. Lee, Kogod School of Business, American University, USA

Paper #4: Now That I Say it, I’ll Have the Escargot: How Speaking Alters Preferences

Shiri Melumad, The Wharton School, University of Pennsylvania, USA
Robert Meyer, The Wharton School, University of Pennsylvania, USA
Yoon Duk Kim, The Wharton School, University of Pennsylvania, USA

Out of Touch? Multi-Methodological Approaches to the Evolving Role of Haptics in Consumers' Experiences	609
Paper #1: Coping with the Loss of Touch During the COVID-19 Pandemic: Insights from A Longitudinal Qualitative Study of Shoppers	
<i>Joy Shields, Pepperdine University, USA</i>	
<i>Cristel Russell, Pepperdine University, USA</i>	
<i>Clark Johnson, Pepperdine University, USA</i>	
<i>Joann Peck, University of Wisconsin-Madison, USA</i>	
Paper #2: Am I Confident in the Weight? Conveying Product Weight in Digital Media using a Hand	
<i>Subhash Jha, University of Memphis, USA</i>	
<i>M. S. Balaji, Nottingham University Business School China, China</i>	
<i>Joann Peck, University of Wisconsin-Madison, USA</i>	
Paper #3: Consumer Responses to Haptic Augmentation of Brand Storytelling	
<i>Rhonda Hadi, University of Oxford, UK</i>	
<i>Ana Valenzuela, Baruch College, CUNY & ESADE Ramon Llul, USA</i>	
<i>Karthik Sridhar, Baruch College, CUNY, USA</i>	
<i>O. H. Groth, Baruch College, CUNY, USA</i>	
The Financial Consequences of Change	613
<i>Chair: Ms. Jocelyn Grabke, Northwestern University, USA</i>	
Paper #1: Untouchable Lockbox or Rainy-Day Fund? The Effect of Generosity of Employers' Retirement Plan Contributions on Leakage from Cashing Out at Job Separation	
<i>John G. Lynch Jr., University of Colorado, USA</i>	
<i>Yanwen Wang, University of British Columbia, British Columbia</i>	
<i>Muxin Zhai, Texas State University, USA</i>	
Paper #2: Precedented Times and Purse Strings: How Perceived Stability in Financial Well-Being Affects Money Disordered Behaviors	
<i>Jocelyn Grabke, Northwestern University, USA</i>	
<i>Aparna Labroo, Northwestern University, USA</i>	
Paper #3: Get your head out of the sand! Reconciling disparate findings on the ostrich effect.	
<i>Matthew Hilchey, University of Toronto, Canada</i>	
<i>Dilip Soman, University of Toronto, Canada</i>	
Paper #4: Psychological Ownership of Money and Other Resources: A Scale	
<i>Stephanie Tully, University of Southern California, USA</i>	
<i>Eesha Sharma, San Diego State University, USA</i>	
<i>Suzanne Shu, Cornell University, USA</i>	
Fresh Insights into Consumer Food Choice and Perceptions in the Emerging Post-Pandemic Normal	618
<i>Chair: Dr. Lane Peterson, Georgia State University, USA</i>	
Paper #1: Digital Technologies and Food Ordering: Using Digital Devices for Restaurant Orders Leads to Indulgent Outcomes	
Paper #2: Unitized Food Choice in Public – Understanding and Mitigating Unintended Consequences in the New Normal	
Paper #3: Good Things Come To Those Who Wait: How Waiting Increases Perceptions of Food Healthiness	
Paper #4: Fueling Against Stress: How Fuel Snacks Affect Consumers at the Intersection of Stress and Gender	
<i>Authors:</i>	
<i>Ms. Marina Cozac, Florida State University, USA</i>	
<i>Dr. Lane Peterson, Georgia State University, USA</i>	
<i>Dr. Annika Abell, University of Tennessee, Knoxville, USA</i>	
<i>Dr. Dipayan Biswas, University of South Florida, USA</i>	
<i>Dr. Maura Scott, Florida State University, USA</i>	
<i>Dr. Martin Mende, Florida State University, USA</i>	
<i>Dr. Brennan Davis, California Polytechnic State University, USA</i>	
<i>Dr. Myla Bui, Loyola Marymount University, USA</i>	
<i>Dr. Lama Lteif, University of New Mexico, USA</i>	
<i>Dr. Lauren Block, Baruch College/CUNY, USA</i>	

Socializing in the Virtual Realm: Emerging Social Technologies and Implications for Firms and Consumers	624
<i>Chair: Eric Park, Columbia Business School, USA</i>	
Paper #1: How Watching Livestreams Creates Connection and Enhances Enjoyment	
<i>Nofar Duani, New York University, Stern School of Business, USA</i>	
<i>Alixandra Barasch, New York University, Stern School of Business, USA</i>	
<i>Adrian Ward, University of Texas at Austin, USA</i>	
Paper #2: The (Virtual) Crowd: Speed of Synchronous Chat affects Popularity in Livestreams	
<i>Eric Park, Columbia Business School, USA</i>	
<i>Gita V. Johar, Columbia Business School, USA</i>	
Paper #3: Influence of Livestreaming Viewership on the Life Cycle of Entertainment Products: Evidence from Twitch and Steam	
<i>Travis Tae Oh, Yeshiva University, USA</i>	
<i>Jeunghyun Kim, Korea University, South Korea</i>	
Paper #4: Consumers Are More Trusting of Influencers When They Know They're Human: The Effects of CGI Influencers on Consumer Trust and the Moderating Role of Consumer Gender	
<i>Michelle Van Solt, Valparaiso University, USA</i>	
<i>Tessa Garcia-Collart, University of Missouri-St. Louis, USA</i>	
Navigating the New Normal: Uncovering Costs and Benefits of Technology-Enabled Communication	629
<i>Chair: Dr. Melanie Brucks, Columbia University, USA</i>	
Paper #1: From Stressful to Playful: How Conversational Chatbots Improve Financial Planning Experiences	
<i>Meike Zehnle, University of St. Gallen, Switzerland</i>	
<i>Christian Hildebrand, University of St. Gallen, Switzerland</i>	
Paper #2: How Voice-Based Interaction between Consumers and Intelligent Virtual Agents Influences Recommended Product Decisions	
<i>Zhen Yang, Creighton University, USA</i>	
<i>Yanliu Huang, Drexel University, USA</i>	
<i>Barbara Kahn, University of Pennsylvania, USA</i>	
<i>Jianguan He, University of Tennessee, Knoxville, USA</i>	
Paper #3: Uncanny Communications: Minor Video-call Glitches Undermine Persuasion and Connection	
<i>Jacqueline Rifkin, Cornell University, USA</i>	
<i>Melanie Brucks, Columbia University, USA</i>	
<i>Jeff Johnson, University of Missouri-Kansas City, USA</i>	
Paper #4: I Share, Therefore I Know? Sharing Online Content—Even Without Reading It—Inflates Subjective Knowledge	
<i>Adrian F. Ward, University of Texas at Austin, USA</i>	
<i>Jianqing (Frank) Zheng, University of Texas at Austin, USA</i>	
<i>Susan M. Broniarczyk, University of Texas at Austin, USA</i>	
Ambiguity in Times of Uncertainty: Bridging Uncertainty Research Across Consumer Domains	634
<i>Chairs: Amin Shiri, Texas A&M University, USA</i>	
<i>Donald R. Gaffney, Vanderbilt University, USA</i>	
Paper #1: Ambiguity Aversion and the Perceived Nature of Uncertainty	
<i>Craig R. Fox, University of California Los Angeles, USA</i>	
<i>David Tannenbaum, University of Utah, USA</i>	
<i>Michael Goedde-Menke, University of Münster, Germany</i>	
Paper #2: The less you know the better: How persuasion knowledge increases preference for products with ambiguous attributes	
<i>Amin Shiri, Texas A&M University, USA</i>	
<i>Keith Wilcox, Texas A&M University, USA</i>	
Paper #3: Inference in Times and Types of Uncertainty: The Case of COVID-19 and Free Will	
<i>Donald R. Gaffney, Vanderbilt University, USA</i>	
<i>Bryan M. Buechner, Xavier University, USA</i>	
<i>Noah VanBergen, University of Cincinnati, USA</i>	
Paper #4: Uncertainty about Stability of Romantic Relationship Increases Preference for Renting (vs. Buying)	
<i>Yuechen Wu, Oklahoma State University, USA</i>	
<i>Jared Watson, New York University, USA</i>	
<i>Ali Faraji-Rad, University of Maryland, USA</i>	

Mapping Consumer Mental Processes and Representations Across Diverse Marketplaces 639

Chairs: Zhihao Zhang, Darden School of Business, University of Virginia

Nicolette Sullivan, London School of Economics and Political Science

Paper #1: Pairing in-store and on-line experiences induces price primacy in information search

Nicolette Sullivan, London School of Economics and Political Science, UK

Ling-Ling Zhou, Duke University, USA

Courtney Lee, Duke University, USA

Gavan Fitzsimons, Duke University, USA

Paper #2: Isolating representations from processes: An application for quantifying product imitation without self-report

Zhihao Zhang, University of Virginia, USA

Femke van Horen, Vrije Universiteit Amsterdam, Netherlands

Andrew Kayser, University of California, San Francisco, USA

Ming Hsu, University of California, Berkeley, USA

Paper #3: Congruence in charitable request features elicits greater giving through positively experienced affect: Process evidence from neural data

Alexander Genevsky, Erasmus University, Netherlands

Brian Knutson, Stanford University, USA

Ting-Yi Lin, Erasmus University, Netherlands

Steve Shaw, University of Michigan, USA

Carolyn Yoon, University of Michigan, USA

Paper #4: Neural signals of advertisement liking: Insights into the psychological processes of consumer valuation and their temporal dynamics

Hang-Yee Chan, University of Amsterdam, Netherlands

Maarten A.S. Boksem, Erasmus University, Netherlands

Roeland C. Dietvorst, NN Investment Partners, Netherlands

Christin Scholz, University of Amsterdam, Netherlands

Khoi Vo, DIRT, Los Angeles, USA

Vinod Venkatraman, Temple University, USA

Emily B. Falk, University of Pennsylvania, USA

Ale Smidts, Erasmus University, Netherlands

Win-win interventions for healthier eating 645

Chair: Dr. Romain Cadario, Erasmus University, Netherlands

Paper #1: Unlimited Self-Customization as a Win-Win Strategy for Consumer Health and Firm Profit: Evidence from a Field Study

Ilyung Cheong, Korea Advanced Institute of Science and Technology, South Korea

J. Christine Kim, McIntire School of Commerce, University of Virginia, USA

Young Eun Huh, Korea Advanced Institute of Science and Technology, South Korea

Ralf van der Lans, HKUST, Hong Kong

Paper #2: Healthy in the Wrong Way: Mismatching of Marketers' Food Claim Use and Consumers' Preferences in the United States but not France

Pierre Chandon, INSEAD, France

Romain Cadario, Erasmus University, Rotterdam School of Management, Netherlands

Paper #3: More Value from Less Food? Cross-Cultural Effects of Epicurean Labeling on Portion Control

Pierre Chandon, (INSEAD, France

Yann Cornil, University of British Columbia, Sauder School of Business, British Columbia

Paper #4: Partitioned Plates: Nudging Healthy Eating through Incompleteness Perceptions

Linda Hagen, University of Southern California, USA

Miaolei Jia, University of Warwick, UK

Xiuping Li, National University of Singapore, Singapore

Aradhna Krishna, University of Michigan, USA

Assembling Technological Practices 651

Chair: Nathan B. Warren, BI Norwegian Business School

Paper #1: Automation Assemblages in the Internet of Things: Discovering Qualitative Practices at the Boundaries of Quantitative Change

Thomas P. Novak, Center for the Connected Consumer, George Washington University School of Business, USA

Donna L. Hoffman, Center for the Connected Consumer, George Washington University School of Business, USA

Paper #2: How Practices Co-evolve: The Case of AI Induced Practice Disruptions

Francesca Bonetti, London College of Fashion, UK

Matteo Montecchi, King's College London, UK

Kirk Plangger, King's College London, UK

Hope Jensen Schau, University of Arizona, USA

Paper #3: Tech Gone Wild: The Fraught Meanings and Altered Material Competences of Digital Practices in Wilderness Settings

Nathan B. Warren, BI Norwegian Business School, Norway

Jared Offei Lartey, BI Norwegian Business School, Norway

Linda L. Price, University of Wyoming, USA

Paper #4: Resisting Entropy: How Consumers and Objects Share the 'Work' Involved in Sustaining the Continued Use of Tech-Products

Paolo Franco, Radboud University, the Netherlands

Robin Canniford, KEDGE Business School, France

Marcus Phipps, The University of Melbourne, Australia

Amber Epp, University of Wisconsin-Madison, USA

Psychological Layers in the Consumption of Status Goods: Drivers, Forms, and Consequences 657

Chair: Felix Jan Nitsch, INSEAD

Paper #1: Do stress and social-self threat increase the preference for status goods?

Felix Jan Nitsch, INSEAD and Paris Brain Institute (ICM), France

Zsofia Margittai, Heinrich-Heine-Universität Düsseldorf, Germany

Gideon Nave, Wharton, University of Pennsylvania, USA

David Dubois, INSEAD, France

Tobias Kalenscher, Heinrich-Heine-Universität Düsseldorf, Germany

Hilke Plassmann, INSEAD and Paris Brain Institute (ICM), France

Paper #2: Contentment and Satisfaction with Life as a Status Signal

Evrin Yanar, University of Lausanne, Switzerland

Felicitas Morhart, University of Lausanne, Switzerland

Keith Wilcox, Texas A&M University, USA

Paper #3: Gaining Less by Giving More: The Disempowering Nature of Luxury Gifts

Maren Hoff, Columbia Business School, USA

Dafna Goor, London Business School, UK

Nader T. Tavassoli, London Business School, UK

Field Experiments: A Practical Tutorial 663

Chairs: Stephen Anderson, University of Texas at Austin, USA

Rajesh Chandy, London Business School, UK

Organized by: Praveen K. Kopalle, VP-External Relations, ISMS, INFORMS Society for Marketing Science, USA

The Psychology of Price: Advances in Pricing and Payment Perceptions in Consumer Decision Making	664
<i>Chair: Mr. Junha Kim</i>	
Paper #1: The Fees Paradox	
<i>Ms. Maren Hoff, Columbia Business School, USA</i>	
<i>Dr. Vicki Morwitz, Columbia University, USA</i>	
Paper #2: \$29.99 or \$19.99 - \$29.99? When Does Range Pricing Backfires?	
<i>Mr. Junha Kim, The Ohio State University, USA</i>	
<i>Dr. Selin Malkoc, The Ohio State University, USA</i>	
<i>Ms. Lily Johnson, The Ohio State University, USA</i>	
Paper #3: The Upside of Incompetence: When Low Brand Competence Signals Low Prices	
<i>Dr. Ryan Hamilton, Emory University, USA</i>	
<i>Dr. Morgan Ward, Emory University, USA</i>	
<i>Dr. Kathleen Vohs, University of Minnesota, USA</i>	
<i>Dr. Karen Anne Wallach, University of Alabama – Huntsville, USA</i>	
Paper #4: “Nothing Matters”: A “0%” Option Increases Consumers’ Voluntary Payments	
<i>Ms. Shirley Bluvstein Netter, New York University, USA</i>	
<i>Dr. Priya Raghuram, New York University, USA</i>	
Algorithms? Robots? Virtual Influencers?: How Algorithms in Different Forms Impact Consumer Decision Making in Service Contexts	669
<i>Co-chairs: Wenyan Yin, Drexel University, USA</i>	
<i>Yanliu Huang, Drexel University, USA</i>	
Paper #1: Conversational AI Design: How Initiation Modalities Shape Consumer Experience & Firm Perception	
<i>Christian Hildebrand, University of St. Gallen, Switzerland</i>	
<i>Donna Hoffman, George Washington University, USA</i>	
<i>Tom Novak, George Washington University, USA</i>	
Paper #2: I Do Not Want What You Have! The Mpnct of Mind Perception On Engagement With AI Influencers	
Paper #3: When Art Meets Artificial Intelligence: Consumers’ Valuation of Creative Products Made By AI	
<i>Ilyung Cheong, KAIST, South Korea</i>	
<i>Xuying Leo, KAIST, South Korea</i>	
<i>Young Eun Huh, KAIST, South Korea</i>	
<i>Stefano Puntoni, Erasmus University Rotterdam, Netherlands</i>	
Paper #4: The Effect of Production Mode (Human- Vs. Robot-Made) On Consumer Food Calorie Estimation and Choice	
It’s the “Quantity” that Counts: Quantity Cues in Decision-Making	674
<i>Chair: Ms. Elina Hur, Cornell University, USA</i>	
Paper #1: Cutting Your Cake and Having More of It: A Discretization Account of the Effects of Partitioning on Quantity Perceptions	
<i>Dr. Pierre Chandon, INSEAD, France</i>	
<i>Ms. Maria Langlois, INSEAD, France</i>	
<i>Mr. Andde Indaburu, INSEAD, France</i>	
<i>Dr. Natalie Rigal, Universite Paris Nanterre, France</i>	
Paper #2: Quantity Allocation and Its Influence on Hedonic Decline in Multi-Block Consumption Settings	
<i>Mr. Jinwoo Kim, Carnegie Mellon University, USA</i>	
<i>Dr. Jeff Galak, CMU, USA</i>	
Paper #3: Too Much of a Good Thing: Frequent Checking Decreases Subjective Performance Evaluation	
<i>Ms. Shannon Duncan, The Wharton School, University of Pennsylvania, USA</i>	
<i>Dr. Marissa Sharif, University of Pennsylvania, USA</i>	
<i>Dr. Jordan Etkin, Duke University, USA</i>	
Paper #4: When Less is More: Adopting Consummatory Motives to Reduce Overconsumption	
<i>Ms. Elina Hur, Cornell University, USA</i>	
<i>Dr. Kaitlin Woolley, Cornell University, USA</i>	

The World of Consumer Reviews: Analyzing the Production and Consumption of Reviews	679
<i>Chair: Mr. Daniel Katz, The University of Chicago Booth School of Business, USA</i>	
Paper #1: “I like it” vs. “You’ll like it”: The Use of Personal Pronouns in Online Reviews	
<i>Wenyan Yin, Drexel University, USA</i>	
<i>Yanliu Huang, Drexel University, USA</i>	
<i>Jonah Berger, University of Pennsylvania, USA</i>	
Paper #2: Valence and Arousal in Consumer Reviews: Effects on Evoked Emotion and Product Evaluations	
<i>Daniel Katz, University of Chicago, USA</i>	
<i>Abigail Sussman, University of Chicago, USA</i>	
<i>Daniel O’Leary, Udemy, USA</i>	
Paper #3: Incentives Increase Relative Positivity of Review Content and Enjoyment of Review Writing	
<i>Kaitlin Woolley, Cornell University, USA</i>	
<i>Marissa Sharif, University of Pennsylvania, USA</i>	
Paper #4: Negative Word of Mouth: The Role of Consumer Characteristics and Failure Type	
<i>Seyedjavad Mousavi, University of Arkansas, USA</i>	
<i>Surendra N. Singh, University of Kansas, USA</i>	
 Consuming Lethality: Fear, Gunfluencers, and Morality in American Gun Culture	 684
<i>Tonya Williams Bradford, University of California, Irvine, USA</i>	
Paper #1: Fear Made Me Buy It: American Gun Culture, Policymakers, and Market Messaging	
<i>Kevin D. Bradford, PhD, University of California, Irvine, USA</i>	
<i>Jacob Williams, Doctoral Student, University of California, Irvine, USA</i>	
<i>Tonya Williams Bradford, PhD, University of California, Irvine, USA</i>	
Paper #2: Digital Curation in Contested Markets: How Gunfluencers Enable the Platformization of Second Amendment Ideology	
<i>Jenna Drenten, Loyola University Chicago, USA</i>	
<i>Lauren Gurrieri, RMIT University, Australia</i>	
<i>Aimee Huff, Oregon State University, USA</i>	
<i>Michelle Barnhart, Oregon State University, USA</i>	
Paper #3: The (Ir)Responsible American Consumer: Examining Morality and Responsibilization for Armed Self-Defense	
<i>Michelle Barnhart, Oregon State University, USA</i>	
<i>Aimee Dinnin Huff, Oregon State University, USA</i>	
<i>Inara Scott, Oregon State University, USA</i>	
 Antecedents of and Remedies to the Spread of False Information.	 688
<i>Chairs: Gizem Ceylan, Yale School of Management, USA</i>	
<i>Yu Ding, Stanford University, USA</i>	
Paper #1: Habitual, Not Lazy or Biased: Sharing False News Depends on Social Media Users’ Habits	
<i>Gizem Ceylan, Yale School of Management, USA</i>	
<i>Ian Anderson, University of Southern California, USA</i>	
<i>Wendy Wood, University of Southern California, USA</i>	
Paper #2: How Intolerance of Uncertainty Shapes Sharing of Misinformation	
<i>Amin Shiri, Texas A&M University, USA</i>	
<i>Keith Wilcox, Texas A&M University, USA</i>	
<i>Xiang Wang, University of Florida, USA</i>	
Paper #3: Source Memory Is More Accurate for Opinions Than for Facts	
<i>Daniel J. Mirny, UCLA Anderson School of Management, USA</i>	
<i>Stephen A. Spiller, UCLA Anderson School of Management, USA</i>	
Paper #4: Factchecking Matters: A Novel Crowdsourcing Approach for Improving the Information Ecosystem	
<i>Yu Ding, Stanford University, USA</i>	
<i>Gita V. Johar, Columbia University, USA</i>	

More or Less? How Consumers Make Predictions and Inferences About Unobservable Attributes Based on Numeric Cues . . . 693

Chair: Michelle Kim, University of California, San Diego, USA

Paper #1: Less Is More (Natural): The Effect of the Number of Ingredients on Preferences and Naturalness Perceptions

Michelle Kim, University of California, San Diego, USA
Tianqi Chen, Boston University, USA
Rachel Gershon, University of California, San Diego, USA
Sydney E. Scott, Washington University, St. Louis, USA
Daniella Kupor, Boston University, USA
Remi Trudel, Boston University, USA

Paper #2: Opposing Effects of Company Size Metrics on Product Quality Evaluations

Kaitlin Woolley, Cornell University, USA
Daniella Kupor, Boston University, USA
Peggy J. Liu, University of Pittsburgh, USA

Paper #3: Choice Set Size Neglect in Predicting Others' Preferences

Beidi Hu, University of Pennsylvania, USA
Alice Moon, University of Pennsylvania, USA
Eric VanEpps, University of Utah, USA

Paper #4: Overinflated Expectations from Maximizing with Unreliable Information

Edward Yuhang Lai, Virginia Tech, USA
Mario Pandelaere, Virginia Tech, USA
Daniel Villanova, University of Arkansas, USA

Photos Speak Louder: What Consumers Convey about Themselves and Brands by Using Visuals 698

Chair: Gizem Ceylan, Yale School of Management, USA

Paper #1: Share the Fame, Take the Blame: How Social Media Feedback Influences Brand Perceptions

Lucas Nann, University of Lucerne, Switzerland
Gabriela Funk, University of Lucerne, Switzerland
Reto Hofstetter, University of Lucerne, Switzerland
Leslie John, Harvard University, USA

Paper #2: Color analytics for data-driven brand management

Daria Dzyabura, New Economic School and Skolkovo School of Management, Russia
Renana Peres, The Hebrew University, Israel

Paper #3: Words Meet Photos: When and Why Visual Content Increases Review Helpfulness

Gizem Ceylan, Yale School of Management, USA
Kristin Diehl, University of Southern California, USA
Davide Proserpio, University of Southern California, USA

Paper #4: Striking Visual Salience in Social Media Brand Posts: Implications for Consumer Sharing

Stefania Farace, Luiss Guido Carli University, Italy
Francisco Villarroel Ordenes, LUISS Guido Carli University, Italy
Dhruv Grewal, Babson College, USA
Ko de Ruyter, Kings College London, UK

New Perspectives on Experiential Consumption	703
<i>Chair: Jean Zhang, University of California San Diego, USA</i>	
Paper #1: Doubling Down on Losses—How Experience Unavailability Leads to Choice of Lesser Alternatives	
<i>Jean Zhang, University of California San Diego, USA</i>	
<i>Gal Smitizsky, University of California San Diego, USA</i>	
<i>On Amir, University of California San Diego, USA</i>	
Paper #2: Expecting a Better Subsequent Experience Inhibits Adaptation to a Negative Experience	
<i>Guy Voicheck, Yale University, USA</i>	
<i>Minju Han, Hanyang University, South Korea</i>	
<i>Ravi Dhar, Yale University, USA</i>	
Paper #3: It Could Be Better” Can Make It Worse: When and Why People Mistakenly Communicate Upward Counterfactual Information	
<i>Xilin Li, University of Chicago, USA</i>	
<i>Christopher Hsee, University of Chicago, USA</i>	
<i>Ed O’Brien, University of Chicago, USA</i>	
Paper #4: Consuming Experiences in a ‘Materialistic’ Way Leads to Less Happiness	
<i>Isabella Bunosso, The Ohio State University, USA</i>	
<i>Jesse Walker, The Ohio State University, USA</i>	
<i>Selin Malkoc, The Ohio State University, USA</i>	
<i>Joseph Goodman, The Ohio State University, USA</i>	
“Encouraging Repair: Bringing Together Behavioral Perspectives on a Sustainable Consumption Practice”	708
<i>Chair: Dr. Donald Lehmann, Columbia University, USA</i>	
Paper #1: “Replace or Repair?: How Companies Can Signal Unused Utility and Decrease Product Replacement”	
<i>Nathan Allred, Pennsylvania State University, USA</i>	
<i>Karen Winterich, Pennsylvania State University, USA</i>	
Paper #2: “Reluctance to Repair: Perceived Relative Income and Entitlement as barriers to DIY Repair”	
<i>Aprajita Gautam, University of Texas – Austin, USA</i>	
<i>Rajagopal Raghunathan, University of Texas – Austin, USA</i>	
Paper #3: “Materializing Sustainable Service Delivery Through an Ethos of Repair”	
<i>D. Matthew Godfrey, University of Massachusetts Amherst, USA</i>	
<i>Linda L. Price, University of Wyoming, USA</i>	
Text as a Window into Past Motivations and Future Behaviors	713
<i>Chairs: Amir Sepehri, ESSEC Business School, France</i>	
<i>Jonah Berger, University of Pennsylvania, USA</i>	
Paper #1: Passive voice and Consumer Complaints	
<i>Amir Sepehri, ESSEC Business School, France</i>	
<i>Jonah Berger, University of Pennsylvania, USA</i>	
Paper #2: How Motivations Affect the Language of Informative versus Social User Generated Content	
<i>Yiping Li, Manning School of Business, University of Massachusetts, USA</i>	
<i>Ann Kronrod, Manning School of Business, University of Massachusetts, USA</i>	
Paper #3: The Language of (Non)Replicability	
<i>Michal Herzenstein, Lerner College of Business and Economics, University of Delaware, USA</i>	
<i>Sanjana Rosario, Columbia Business School, Columbia University, USA</i>	
<i>Shin Oblander, Columbia Business School, Columbia University, USA</i>	
<i>Oded Netzer, Columbia Business School, Columbia University, USA</i>	
Paper #4: Deescalating Arousal in Social Media Complaints: Using Active Listening and Empathy to Enhance Customer Gratitude	
<i>Dennis Herhausen, Vrije Universiteit Amsterdam, Netherlands</i>	
<i>Lauren Grewal, Dartmouth College, USA</i>	
<i>Krista M. Hill, Babson College, USA</i>	
<i>Anne L. Roggeveen, Babson College, USA</i>	
<i>Francisco Villarroel Ordenes, LUISS Guido Carli University, Italy</i>	
<i>Dhruv Grewal, Babson College, USA</i>	

Joint Decisions and Joint Consumption: When and How Consumers Prefer, Communicate About, and Choose What to Share . 719

Chair: Ms. Nikkita Sarna, University of Texas at Austin

Paper #1: It Takes One to Buy but Two to Say Goodbye: Preferring Others' Involvement at Different Customer Decision Journey Stages

Theresa A. Kwon, University of Pittsburgh, USA

Peggy J. Liu, University of Pittsburgh, USA

Kelly L. Haws, Vanderbilt University, USA

Paper #2: Beyond Persuasion: Developing a Framework of Communication Patterns in Joint Decision Making

Kelley Gullo Wight, Indiana University, USA

Holly S. Howe, HEC Montreal, Canada

Danielle J. Brick, University of New Hampshire, USA

Gavan J. Fitzsimons, Duke University, USA

Paper #3: You Must Have a Preference: The Impact of No Preference Communication on Joint Decision Making

Nicole Kim, Hong Kong Polytechnic University, Hong Kong

Yonat Zwebner, Reichman University, Israel

Alix Barasch, New York University, USA

Rom Schrift, Indiana University, USA

Paper #4: Choosing for Joint Consumption: How Avoiding Appearing Selfish Can Be Worse for Everyone

Nikkita Sarna, University of Texas at Austin, USA

Andrew D. Gershoff, University of Texas at Austin, USA

"A Change in Perspective" in Context Effects. 724

Chair: Eric Park, Columbia University & Ozgun Atasoy, University of Basel, Switzerland

Paper #1: Preferential Attraction Effects Occur with Quantitative Perceptual Attributes, but Break Down with Qualitative Perceptual Attributes

Miguel Brendl, University of Basel, Switzerland

Ozgun Atasoy, University of Basel, Switzerland

Coralie Samson, University of Basel, Switzerland

Paper #2: When Does The Attraction Effect Occur?: A Case for Value Construction in Attraction Effect

Eric Park, Columbia University, USA

Martijn Willemsen, Eindhoven University of Technology, Netherlands

Eric J. Johnson, Columbia University, USA

Paper #3: The Upscaling Effect: How the Decision Context Influences Tradeoffs between Desirability and Feasibility

Ioannis Evangelidis, ESADE, Universitat Ramon Llull, Spain

Jonathan Levav, Stanford Graduate School of Business, Stanford University, USA

Itamar Simonson, Stanford Graduate School of Business, Stanford University, USA

Paper #4: Skewed Stimulus Sampling is Distorting Our Understanding of Consumers

Hannah Perfecto, Washington University in St. Louis, USA

Gut Feelings: Consumers' Intuitive Judgments of Companies 729

Chair: Mr. Mohin Banker, Yale University, USA

Paper #1: Dual Process Intuitions: Consumers' Beliefs About Persuasion Processing Drive Morality of Marketing Communications

Zarema Khon, University of Bath, UK

Yi-Ju Chen, University of Bath, UK

Samuel G. B. Johnson, University of Warwick, UK

Yetta Simonyan, University of Bath, UK

Haiming Hang, University of Bath, UK

Paper #2: Asymmetric Reactions to Erroneous Punishments and Rewards

Eitan Rude, University of California, Los Angeles, USA

Franklin Shaddy, University of California, Los Angeles, USA

Paper #3: Consumers' Lay Beliefs around Company Profitability

Mohin Banker, Yale University, USA

Ravi Dhar, Yale University, USA

Nathan Novemsky, Yale University, USA

Paper #4: The Effect of Political Ideology on Consumer Response to Company Silence

Andy Li, University of Maryland, USA

In-Hye Kang, University of North Carolina at Greensboro, USA

Rosellina Ferraro, University of Maryland, USA

Amna Kirmani, University of Maryland, USA

Looking at the World Through a New Lens: How Categorization Can Improve Motivation and Well-Being 735

Chair: Rebecca Chae, Santa Clara University, USA

Paper #1: Categorizing Tasks Around a Break Ruminates and Improves Task Performance

*Rebecca Chae, Santa Clara University, USA
Kaitlin Woolley, Cornell University, USA
Marissa Sharif, University of Pennsylvania, USA*

Paper #2: Categorization & Leisure: When Consumers Prefer to Spend Time on Leisure Activities

*Siyuan Yin, University of Pennsylvania, USA
Marissa Sharif, University of Pennsylvania, USA*

Paper #3: Monetizing Paid Vacation Shifts Employment Preferences

*Ashley Whillans, Harvard University, USA
Lauren Howe, University of Zurich, Switzerland*

Paper #4: Losing Weight but not Feeling Like Yourself? A Transformation Mindset Facilitates Consumer Authenticity

*Jaehwan Song, Stanford University, USA
Melanie Brucks, Columbia University, USA
Szu-chi Huang, Stanford University, USA
Margaret Campbell, University of Colorado Boulder, USA*

Leveraging Unstructured Data for Consumer Insights: Novel Perspectives on Text, Image, and Video Analytics 740

Chair: Dr. Christian Hildebrand, University of St. Gallen, Switzerland

Paper #1: Should You Really be Creative on Social Media? A Machine Learning Approach to Examine Originality of Video Content from TikTok

*Marc Bravin, University of Lucerne, Switzerland
Melanie Clegg, University of Lucerne, Switzerland
Reto Hofstetter, University of Lucerne, Switzerland
Marc Pouly, University of Applied Sciences Lucerne, Switzerland
Jonah A. Berger, The Wharton School, USA*

Paper #2: “Love the Shape, But Hate the Weight”: Leveraging Word Embeddings To Identify Product Innovation Opportunities

*Francesc Busquet, University of St. Gallen, Switzerland
Anouk Bergner, University of St. Gallen, Switzerland
Christian Hildebrand, University of St. Gallen, Switzerland*

Paper #3: Quantifying Imitation in Crowdsourcing: A Contrastive Learning Approach

*Reto Hofstetter, University of Lucerne, Switzerland
Harikesh Nair, Stanford University, USA
Sanjog Misra, University of Chicago, USA*

Paper #4: Following the rules of AI: A Justice Perspective

*Claire Linares, HEC Paris, France
Anne-Laure Sellier, HEC Paris, France
Ran R. Hassin, Hebrew University of Jerusalem, Israel*

Political Ideology and Consumption 745

Chairs: Pureum Kim, University of Arizona, USA

Gustavo Schneider, Salisbury University, USA

Paper #1: Small Donors Political Slacktivism: Buying Political Merchandise Decreases the Likelihood of Other Political Behavior

*Pureum Kim, University of Arizona, USA
Gustavo Schneider, Salisbury University, USA
Anastasiya Pocheptsova Ghosh, University of Arizona, USA*

Paper #2: Political Ideology and Consumer Activism

*Serkan Saka, University of Illinois-Chicago, USA
Adam Duhachek, University of Illinois-Chicago, USA*

Paper #3: Political Ideology and Negotiation: Does Political Ideology Affect Negotiation?

*Archer Pan, Cornell University, USA
Manoj Thomas, Cornell University, USA*

Paper #4: New for the Sake of Status: Political Ideology and Really New Products

*Erick Mas, Indiana University-Bloomington, USA
Jesper Nielsen, University of Arizona, USA
Steve Hoeffler, Vanderbilt University, USA*

Consumer Interactions with Different Types of Languages	751
<i>Chair: Jessie Rui Du, Baruch College, Marymount Manhattan College, USA</i>	
Paper #1: English as a Lingua Franca Promotes Interpersonal Closeness and Sympathy	
<i>Jessie Rui Du, Baruch College, Marymount Manhattan College, USA</i>	
<i>Steve Gould, Baruch College, USA</i>	
<i>Sankar Sen, Baruch College, USA</i>	
<i>Marlone Henderson, the University of Texas at Austin, USA</i>	
Paper #2: Local and Global Status Concerns Independently Predict Jargon Use Among Psychologists	
<i>Zack Brown, Hong Kong University of Science and Technology, China</i>	
<i>Eric Anicich, USC Marshall School of Business, USA</i>	
<i>Adam Galinsky, Columbia Business School, USA</i>	
Paper #3: Language Transfer in Word of Mouth -How Genderedness of Native Language Influences Reviews in Foreign Language of a Bilingual Reviewer	
<i>Grace Yu-Buck, University of Houston Clear Lake, USA</i>	
How Language Impacts Communication	755
<i>Chairs: Demi Oba, Duke University</i>	
<i>Jonah Berger, University of Pennsylvania</i>	
Paper #1: How Hedging Shapes Persuasion	
<i>Demi Oba, Duke University, USA</i>	
<i>Jonah Berger, The Wharton School, University of Pennsylvania, USA</i>	
Paper #2: How “Want” versus “Need” Framing Influences Responses to Crowdfunding Appeals	
<i>Lei Su, Hong Kong Baptist University, Hong Kong</i>	
<i>Jaideep Sengupta, Hong Kong University of Science and Technology, Hong Kong</i>	
<i>Yiwei Li, Lingnan University, Hong Kong</i>	
<i>Fangyuan Chen, Hong Kong Polytechnic University, Hong Kong</i>	
Paper #3: I Didn’t Have Time: The Language of Goal Failure	
<i>Luis Abreu, Duke University, USA</i>	
<i>Holly Howe, Duke University, USA</i>	
<i>Jordan Etkin, Duke University, USA</i>	
Paper #4: Writing in Consumer Research: Villains, Traps, and How to Escape Them	
<i>Pureum Kim, University of Arizona, USA</i>	
<i>Caleb Warren, University of Arizona, USA</i>	
Sex, Lies, and AI: Consumer Beliefs About the “Mental” Representations of Algorithmic Recommendations	760
<i>Chairs: Ana Valenzuela, Baruch College and ESADE-Ramon Llul</i>	
<i>Valentina Pitardi, University of Surrey</i>	
Paper #1: Consumer Reactions to Algorithms: A Meta-Analysis	
<i>Meike Zehnle, University of St. Gallen, Switzerland</i>	
<i>Christian Hildebrand, University of St. Gallen, Switzerland</i>	
Paper #2: How to Overcome Algorithm Aversion: Learning from Mistakes	
<i>Taly Reich, Yale University, USA</i>	
<i>Sam Maglio, University of Toronto, Canada</i>	
<i>Alex Kaju, HEC Montréal, Canada</i>	
Paper #3: Mitigating Inequalities Caused by Awareness of Algorithmic Bias	
<i>Sang Kyu Park, HKUST</i>	
<i>Yang Yang, University of Florida, USA</i>	
<i>Shunyuan Zhang, Harvard University, USA</i>	
Paper #4: Following the rules of AI: A Justice Perspective	
<i>Valentina Pitardi, University of Surrey, UK</i>	
<i>Ana Valenzuela, Baruch College and ESADE-Ramon Llul, USA</i>	

Working Papers

Teenagers and Brands on Instagram: An Analysis of Brand-related Teenagers’ Posts - D7	766
<i>Mrs. Laurence Dubé-Beaudin, Ipsos, USA</i>	
<i>Dr. Amélie Guèvremont, École des Sciences de la Gestion, Université du Québec à Montréal, Canada</i>	
Why Switch? The Impact of Visual Boundaries on Variety-Seeking Behavior - G6	766

2022 ACR Presidential Address

Jennifer Argo, University of Alberta, Canada

Perspective

Perspective matters. It's all a matter of perspective.

As professors we teach our students that companies need to understand how consumers perceive their product as it may not match the companies intended position; understanding what the consumers see, and not what they look at, is critical for success.

As researchers, many of us have been trained to try and understand our participants prior to data collection by pretesting our materials to ensure they are interpreted as intended.

For those of you who have children, we often encourage our kids when in a disagreement to take the perspective of the other person involved because there is usually more than one side to the same experience.

Finally, I can certainly promise you that the perspective I am seeing right now standing up here is different from the perspective you are seeing from your tables. In order to capture this truly unique perspective I'd like to take a photo. Now, if anyone is curious to see what the next 15 minutes or so looked like through my eyes, I can show you.

Many, if not all of us, regardless of which hat we might be wearing and the context in which we find ourselves, have likely considered the fact that perspective matters. Admittedly, usually when I'm thinking it, I am struggling to understand why my partner can't see it from "my" correct perspective. While I might believe that my perspective is right, it is certainly limited and failing to consider other perspectives is in my humble opinion a missed opportunity.

So today I would like to talk about perspective and how seeing things with a different lens is important. In particular, I will highlight three different instances in which I think perspective matters. In order to bring each instance to life I will illustrate a corresponding personal experience that really taught me the value of considering a different perspective. My hope is that at least one of these ideas will resonate with you and encourage you to think about the notion of perspective.

"Fairy Tales always have a happy ending.' That depends... on whether you are Rumpelstiltskin or the Queen."

— Jane Yolen, Briar Rose

My first example focuses on considering the perspective of other people, trying to understand their point of view and what it would be like in their shoes, and importantly recognizing that this effort is a continuous journey – you can always do better.

We are all different. Diversity is on everyone's mind these days. Some of us are old, young, Black, White, male, female, non-binary, tech savvy, tech ignorant, introverted, extroverted, lovers, fighters, you name it. Whatever defines us makes us individually special or unique, but also different from others.

The recognition that we are not the same is not new. For instance, we can look back to Joe Alba's presidential address when he reminded us that our participants are not always like us and that in fact "approximately half of the population is below average in intelligence".

Importantly, failing to recognize and understand that we are different can have implications. To illustrate, in the book *Invisible Women: Exposing Data Bias in a World Designed for Men* the author, Caroline Criado-Perez, presents evidence that product designers have been using a one-size-fits-all for a plethora of products – wherein the products in the marketplace were designed to fit men even if they are used by women. The author argues that the focus

on males is not meant to be deliberate and malicious, rather it arises because of the "way of thinking" that has driven society for centuries and thus it is really a product of a kind of not thinking. But this not thinking has downstream implications beyond simply poor fitting. Indeed, Dr. Alyson McGregor discusses in her book "Sex Matters..." how the use of male as the focus over the years in medical research can actually endanger women's lives.

So, we KNOW that we are different and thus by extension we have different perspectives, but sometimes it is difficult to remember this, to anticipate these different perspectives, and to respond accordingly.

Recently I had a vivid reminder that I am not always good at seeing the world through someone else's eyes – that I have to keep working on it.

In the spring I experienced the worst moment of my career, I got a rejection. Sure, over the years I have received piles of rejections, each leaving me yelling about how ignorant the reviewers were, unreasonable the AE and unfair the Editor. I don't think anyone likes to learn that their work is not good enough. But this rejection was different.

Briefly, the manuscript in question dealt with consumer groups who have been marginalized by society. I felt, along with my coauthors, that the research in our field has been overwhelmingly based on people who comprise the majority, and that a step, any step towards gaining some insight into less understood groups was a step in the right direction. I believe we had good intentions and yet...

When the reviews came back, one reviewer's report in particular took my breath away. It contained an entire section that was under a subheading that read "PREJUDICIAL PERSPECTIVE AND LANGUAGE" in all caps.

In reading this, I experienced anger at the reviewer, outrage at the Editor, gosh darn it I was angry at the world. I put the review away because thinking about it made me want to cry, to scream. I wanted to write a letter to anyone and everyone who would listen about the injustice I felt both my coauthors and I had experienced.

And then I stopped. Realization flooded over me. The review was not a personal attack but rather a clear message that despite our efforts to be sensitive, we had not gone far enough. Ultimately, we had still crafted the manuscript through the eyes and language of a majority perspective that could offend the very groups we were interested in understanding. So, if my anger and disappointment should have been directed anywhere, it should have been directed to myself.

In hindsight this conclusion seems so obvious (Reviewer 3 would certainly agree), we should have recognized our biases and limitations. We could and should have solicited the help from members of the various groups we were studying by at the very least asking them to give our work a friendly read. However, we thought we had a solid understanding of what it was like to be a member of our focal groups, we had read the literature, we thought we had it under control. We were wrong.

Even though this happened in the early spring, it still bothers me and I continue to think about it. This reaction is not just because I'm Canadian and I feel compelled to apologize to everyone, but rather I really do believe that we didn't deliver, we didn't push enough to truly grasp another person's perspective.

This first example focuses on the fact that not only is it important to take the perspective of others and consider what it is like in their shoes, but also that doing so is hard and is something that needs continuous vigilance. While the instance I discussed that really opened my eyes had me in the role of an author, this is not the only instance when taking the perspective of others is so important. For example, the next time you write a review, I encourage you to read that review out loud and ask yourself how you would feel being the recipient of the words that appear on the page. It is not hard to write critical and overly harsh reactions, we've been trained to identify weakness in work. But I can assure you that it is very HARD for many of us to receive such words. It takes true skill to be able to provide honest feedback in a tactful and empathetic way. As another example, the next time you are providing feedback to a student (undergrad, masters, or PhD) or drilling, I mean politely asking, a presenter questions, consider how the recipient of your thoughts or questions might feel. I'm not convinced that the expression "what doesn't kill us makes us stronger" works for everyone and I am fairly confident that public humiliation can be pretty awful.

Perspective taking is hard. Sometimes we will do a good job and yet other times we will completely miss the mark. If I've learned anything from the experience I recounted, it is that perspective taking is a journey, something we have to continue to work at. If we believe we "totally get it", we completely understand what it is like to be in someone else's shoes, chances are we don't. We always have more to learn.

"The greatest risk to man is not that he aims too high and misses, but that he aims too low and hits."

— **Michaelangelo**

My second example focuses on considering perspectives that take you outside of your comfort zone.

As an academic I feel like I SHOULD be smart. I am in the business of creating and disseminating knowledge, I have reached the pinnacle of education with degrees to prove it, and if I needed a more salient reminder of how smart I SHOULD feel, all I have to do is look at the three Jedi stripes that appear on my convocation gown. Given this, from an ego perspective I find it absolutely terrifying to enter a situation where someone might realize that while I might be sort of smart, that smartness is confined to a very narrow sliver of a large field and that outside that area, I may be the one asking the "stupid" question.

Several years ago, I was invited by Leonard Lee and Jeff Inman to join a group at the Choice Symposium. As someone who does not typically study consumer choice nor do I know much about the consumer journey, the focus of the session, I wasn't sure how I would fit in but I agreed because I hoped they had more confidence in my value to the group than I did. My lack of expertise on the topic became even more apparent on the first day of the symposium when our group sat down to talk and we went around the room indicating our research areas of interest – mine was different and I began to worry about how I could APPEAR smart, without really knowing what we were talking about.

Later that morning we broke into smaller groups each set with a different task. Already stressed and wondering how I could offer insight to the larger group from a theoretical angle, to this day I'm not sure what motivated me but, the group I decided to sit with was comprised of only modelers. I'm not saying there is anything wrong with quant researchers, they are absolutely lovely people many of whom are sitting in this room, but my decision to join their group put me 100% outside my comfort zone. Give me t-tests and ANOVAs, experimental design and I could talk for hours. But, quant?? Ahh! I do not speak quant language at all – it really, truly is all Greek to me!

Thank goodness Don Lehman who was a member of this group knew how to speak my language and had the patience to do so.

Without a doubt that was one of the most intimidating, humbling, yet most rewarding group think sessions I've ever been a part of. Approaching the research question from a quant perspective was SO different - it completely disrupted the way I would have automatically structured the ideas in my mind based on my own training. It forced me to approach and consider the question from a different angle.

From that experience I learned so much more than simply the research task on which we were focused. In particular, I realized that there is a lot to be gained by considering more than one methodological lens. Let me be clear – I am an experimentalist through and through and I am not suggesting that I can or should approach a research question with a quantitative or for that matter a qualitative perspective – these methodologies are not part of my toolbox and training. BUT what I am suggesting is that collaborating with people who use different methodological approaches, or even broader different theoretical frameworks will enrich our understanding of consumer behavior. Since, this experience at the Choice symposium I have been a strong advocate for getting outside of one's comfort zone by talking to people who share an interest in a substantive area but who tackle it from a different lens. Given this, I was delighted when I learned that this year's conference Co-Chairs had decided to create sessions that brought together researchers studying the same phenomena or topic area regardless of their methodological approach. I think this is a fantastic learning opportunity and I hope that when you are in the sessions you appreciate the awesomeness of bringing folks together with different perspectives. I personally have worked on projects that are methodologically outside of my comfort zone, they are hard, but very rewarding. Importantly they can and do get published!

This second example focuses on the importance of getting outside of one's comfort zone by considering different perspectives. While the experience I shared arose primarily due to different methodological lenses, there are certainly other ways we can put ourselves into situations where a different perspective is present and can challenge us. Within our schools, we share our building, floors, and sometimes hallways with academics studying different disciplines within business– think about attending their seminar series, talk to them about research ideas. Within our universities, we share our curiosity and passion for discovery with academics from not just foundational disciplines related to consumer research such as psychology, anthropology, sociology and economics, but also music, engineering, linguistics, the fine arts, computer science, to name a few. We have lots to learn from the researchers in these disciplines, and they from us.

I encourage you to leave your comfort zone and reach out to researchers who have different perspectives from those you are used to. It is true that in doing so there might be a cost: you might feel uncomfortable, you might have to learn a new "language", and yes, you might not be the smartest person in the room. In leaving your comfort zone it might feel like you have entered the Danger Zone, BUT that's good, I firmly believe that doing so will help us grow as that is where the magic happens.

"Happiness can be found, even in the darkest of times, if one only remembers to turn on the light." Dumbledore

My final example focuses on flipping your perspective on its head. In other words, I want to encourage you to do a 180, consider the opposite. Doing so, I believe can open up new opportunities.

A few years ago, I was working on a project that I really loved but which was labour, time, and money intensive as it was done in

a retail context, one person at a time. When we received a revision opportunity that required additional data we decided to be more time and money efficient, and so we moved our study online and then later into a sterile lab where we ran large groups of participants. Months, and several attempts later, we were left with studies that did not work. We had what I thought was “crappy” data. Later in preparation for a presentation I was going to give on the project it occurred to me that MAYBE we had perhaps not been thinking about our data and the results from the right perspective.

In our field I think it is fair to say that we have a fixation on significance. Over the years, I have had many studies that produced null results. When this happened, I used to have a kneejerk like reaction and I would cast my “failed” experiments aside, as in the case of the project I just told you about. But what if I considered the opposite. In particular, what if I thought about those experiments not as failures and thus dead ends, but rather as potential directions for future research?

I would like you to imagine the following situation: You are reading someone else’s work and when you are finished you say to yourself, while I believe the effect, I bet it does not work under condition X. So, curious, you run an experiment and lo and behold you find out that you were right, you have identified a situation in which the previous researcher’s work does not hold. How do you respond? I suspect many of you, like myself, would get excited and proclaim you have identified an important boundary condition. You would then go and run a series of additional studies, write up a paper, and submit your research identifying this boundary condition as the MAIN contribution of the work. Yet, when it comes to our own research, when we find a null effect, we often do not allow for such an interpretation. Instead, we label the study as a failure. Sometimes that is true, but I honestly believe that is not always the case.

I want to refer back to the project I was talking about before. I mentioned that when we had started the data collection for the revision we had moved from running our study one participant at a time to running it in large groups. As someone who has spent a significant portion of my career studying social influences it should have occurred to me that given we were studying a highly social context, participants’ responses might differ if they are in a group as compared to by themselves. Indeed, when we reverted back to our original methodological approach of running one participant at a time, our effects worked as before. This suggests that we might have found a cool boundary condition for our basic effect that we could pursue in future research.

Since this project, I have worked to change the lens through which I see my results. Now, when I have a null effect I pause and consider the possibility that perhaps I have found a boundary condition for an effect I have yet to identify (in the case of a new research project that I have just started), or for an effect that I already know. I would encourage you to see if your null effects have something to teach you. Do a 180 – maybe they don’t represent a loss, rather they might be telling you something interesting you had not previously considered.

This final example focuses on the importance of considering the opposite perspective. That doing a 180 can present new opportunities, it might enhance our creativity. While the instance I highlighted focused on a different interpretation of null effects, I think that considering opposites in other ways can enhance our idea generation – it can push our projects in directions we might not have otherwise pursued. Flip your thoughts: if you were focusing on positive outcomes now consider negative implications, reverse the pattern and make the effect the cause, interview older instead of younger adults, focus on disposal rather than acquisition, consider what happens if you in-

crease as opposed to decrease a given quantity, change whether you are alone or with others. I think you get my point. In short, whatever you are doing, ask yourself what is the opposite, and then test it. I think doing a 180 can open up so many new research directions.

Let me close by saying that I am certainly not an expert at taking different perspectives – I try but I’m obviously not always successful. I’m working on it. Taking a different perspective, or using a different lens is hard. Sometimes, we have to consciously identify our biases, our natural responses in situations, some of which may not be flattering. It can make us feel uncomfortable and can threaten to take our ego down a notch or two. But I certainly think the effort is worth it.

I’ve shared three personal instances in which I learned how much perspective matters: Trying to walk in the shoes of others, failing, and then remembering it is an ongoing process that I must continue to work on, stepping outside of my comfort zone at the potential short term cost of feeling a little less smart in order to reap the long term benefits of learning so much more, and doing a 180 when considering my results and new ideas. I think that a different point of view can be highly beneficial – a different perspective can enhance communication, it can teach us different approaches, and it can spur creativity. At a broader level, remembering that perspective matters can help us show compassion and understanding, build bridges, and present an opportunity where one may not have seemed to otherwise exist. I firmly believe that considering a different point of view can help us grow to be better academics and perhaps to be better people.

Thank you.

2022 ACR Fellows' Address

The Power of a Strong Research Culture

Joel Huber

My talk today is about the value of a strong research culture. What it meant for me and what it can mean for you. An effective culture can bridge theoretical frameworks, combine multiple methods, and span regional differences. It encourages scholars to be part of a vibrant research tradition with strong interpersonal bonds, constructive reviews, and effective collaborative processes. The ultimate goal is to foster sustained individual intellectual growth, and to support outstanding mentorship of students and colleagues.

The Power of a strong research culture

- What is a research culture?
- How did it help me?
- How research culture is changing
- Ways to improve culture

However, a strong research culture is rare and takes effort. That effort is the focus of my talk. Rather than promote my research victories, this talk will focus on the positive research practices that made such an impact on my life. In this talk the medium is the message; culture is the sea in which we swim. It enables us to flourish or drown. I will begin with a brief review of the research culture I experienced, and how it was critical to my own work. Throughout, I will provide suggestions for personal, university, and organizational strategies that have become increasingly important for all of us today.

Psychometrics in the early 70's
Can we apply physics to human preferences?

- How to measure values of objects?
- Choice vs. ratings?
- Metric values from choices .?

Duncan Luce J B Kruskal

My first love was psychometrics, seeking ways to measure human judgments in mathematical terms. Beautiful minds, elegant ideas like those of L. L. Thurstone and S. S. Stevens. Ken Arrow defined the principal of irrelevant alternatives that was central to Duncan Luce's elegant model of individual choice. The psychometricians searched for ways to estimate ratio scales of value from simple preference judgments. J. B. Kruskal developed a program called MONANOVA, which took rank orders of preferences on items and estimated the optimal rescaling of those orders that best predicted choices.

My thesis under Paul Green tested the ability of psychometric analysis to estimate stable values for a real product, Lipton iced tea, created with different amounts of sugar. It was like a conjoint but instead of reacting to verbal attributes of alternatives, subjects tasted different samples of tea. In keeping with psychometric norms each respondent made over 250 different judgments on 23 tea samples. Thus, there was a great deal of data on each subject.

What did I find? First, Luce's binary choice model did not predict as well as 5-point preference differences. Indicating that there is predictive value in those 5-point ratings. Second, Kruskal's monotone rescaling of these differences increased internal fit, but consistently decreased prediction to holdout pairs. Finally, I found that the different predictive models, such as additive, ideal point, and spatial models, all predicted well but none did consistently better than the others.

What did I learn? I gained from the thesis a sense of excitement from deep explorations into individual choice models. I also learned the benefits of using holdout choices to validate models. While I published a couple of articles from my dissertation, very few people read them. Psychometric theory, if it's any good, tends to be both simple and universal. By contrast, practical consumer prediction is messy. Important insight comes from differences across consumers. From the elegant psychometricians I learned how to measure values, but quickly moved marketing research that focused on individual differences using adaptive computer interviews and multivariate techniques.

Trail of Schools

Graduating from Wharton, my first job was at the Krannert School at Purdue where I learned so much from Frank Bass, Mike Pessemier and Jack Jacoby. Krannert had resources that enabled it to attract a strong faculty and outstanding Ph.D. students. It distributed working papers and provided plentiful conference support. Frank Bass was the editor of the *Journal of Marketing Research* and involved us in reviewing manuscripts at an early stage of our careers.

For me, Purdue was ideal. It brought me close to innovative researchers and showed me how bright Ph.D. students can excel when challenged by emerging questions in the field. The culture simply buzzed with ideas, resulting in a number of papers with the Ph.D. students including John McCann, Dave Reibstein, Abel Jeuland, Dick Wittink, and Don Lehmann.

After three years at Purdue I was blessed by a transformative year at Columbia. There I saw the outstanding leadership of John Howard and Don Lehmann, and worked with Barbara Kahn and Morris Holbrook. A year later John McCann and I joined the marketing group at Duke. Within three years we had successfully recruited two rookies: Julie Edell from Carnegie Mellon and Marion Moore from UCLA and soon thereafter recruited their thesis advisors, Rick Staelin and Jim Bettman, as chaired professors. I have remained at Duke for more than 40 years, with later sabbaticals at Columbia and Wharton.

Here is my favorite image of the Duke marketing group, taken nearly 20 years ago.

What a crew! Of the 17, four have left us: Wagner Kamakura, Kurt Carlson, and then to my right, Darryl Banks, and next to him the indomitable, John Lynch. Ours was a small group working together in both teaching and research. We also did administrative work that helped Fuqua grow. Bill Boulding is now Fuqua's dean. Wilfred Amaldos is our current area coordinator, Rick Staelin, Mary Frances Luce, Jim Bettman, Debu Purohit, Preyas Desai and I served as associate deans. Many of us also served the field as journal editors: Jim Bettman and Mary Frances Luce at JCR; Rick Staelin and Preyas Desai, at *Marketing Science*, Wagner Kamakura and I, at JMR, and recently Chris Moorman at *Journal of Marketing* and Carl Mela at QME.

Speaking of productivity, here is an image showing 28 Duke Ph.D.s. What a super Zoom call they would make!

The research in our area was leveraged by their presence. We worked hard to recruit the best Ph.D.s. to Duke, identifying a few of 100 applicants that applied each year, and inviting then to a weekend at Duke. The Ph.D. teaching was outstanding, led by master men-

tors, Rick Staelin and Jim Bettman. Gavin Fitzsimmons and Tanya Chartrand ran a lab which encouraged students to work together. We expected much from them and did our best to instill in them a culture of cooperation. They work together in a open area the encouraged joint efforts. They serve as hosts for outside speakers and provided summaries of audience reactions to their seminars. The students also set up a supportive internal monthly lunch to present research to each other. Finally, to focus their efforts, we altered the university rule replacing a comprehensive exam that tested many topics learned in classes with a deep review paper exploring a theoretical area that could form the focus of a valuable thesis.

Let's now shift to organizations, especially our own Association for Consumer Research.

ACR's Big Tent

Here you see a poster presentation meeting at an ACR conference. You can sense the enthusiasm and positivity in the room. Much of reviewing for the conference is done by younger scholars reflecting the bottom-up nature of ACR's culture, one that is accepting of so many different ideas, methods and modes of presentations.

Conferences are fun, a chance to see friends, experience outstanding presentations, have spirited conversations and enjoy enthusiastic parties. Of course, there is work; preparing as a reviewer, presenter or discussant, or being part of many task forces. I recall returning in a plane to Indianapolis from an early ACR. I was sitting next to Jack Jacoby, who was on the faculty in cognitive psychology at Purdue. As read my novel, I noticed Jack making extensive notes on what he had seen and penning letters to people he had met. We spoke about what he had learned, and how he had prepared beforehand by setting up meetings. He was like a scout looking for talent at a baseball game, while I was at the same game feeling like a happy but clueless fan. I came to understand how important it is to prepare before, actively engage during, and follow up after each conference.

A different kind of journal

- Focuses on four different topics per year
- Leading scholars edit each issue
- 2 years from announcement to publication
- Editor-in-chief has little power
- Issue editors know the topic

JACR was an important test of ACR's ability to grow and adapt to emerging needs of its members. While I am proud of being its first editor, I am prouder still of the research culture that propelled its

6 / The Power of a Strong Research Culture

success. From the start JACR was a different kind of journal. Eleven years ago an ACR steering committee considered various new journals: a journal focused on deep psychological theory, consumer welfare, creativity and aesthetics, as well as various managerial or social problems. Our solution was to have one topic per issue thereby generating four different ones each year. The schedule required publication for each issue two years from its announcement, the first year to recruit submissions and the second year to whip them into shape.

Early challenges

- Recruiting editors
- Encouraging submissions
- Managing the review process
- Support bonding among authors
- Encouraging citations and growth

The first problem was recruiting editors. No one knew whether JACR would work. The first editors were outstanding scholars willing to take the risk: Russ Belk, Linda Price, Angela Lee, David Stuart, and Norbert Schwarz. Their task was to pitch the topic at ACR meetings and on the JACR website. Each editor sent between 20 to 50 personalized emails to potential contributors asking for an abstract, a finished document, or a willingness to review. Because editors were established in their fields, they could shape the articles with support from fewer reviewers. The results for the first two years were predictable. Timing was difficult for all involved. JACR published some articles that were up to the standards of JCR and JCP but not consistently so. However, the process did help authors bond to each other through their joint efforts creating and promoting each issue.

To succeed, JACR pushed a number of innovations that encouraged citations and growth of emerging ideas. The most important motivator was a subscription to JACR along with membership, so that each quarter an issue was mailed to around 1,500 ACR members. Additionally, Chicago Press helped develop a creative cover and encouraged the use of colorful graphics. Further, the press allowed editors to select one article that could be freely accessed in each issue, and provided press releases and free access for articles with unusually heavy downloads.

Current success

Vicki Horwitz: Editor in Chief

James Ellis: Managing Editor

Rajiv Viadyanathan: Executive Director

JACR is now in its 8th year, with 32 completed issues, and 8 more in process. Angela Lee took over from me and now Vicki Morwitz is in charge. Citations, downloads, and request to generate issues are way up. Major gains came when Scopus brought JACR into their system and when Clarivate included it in its Emerging Sources Citation Index.

It is important to give credit to Andy Seagram, Chicago Press Publishing Manager and particularly to James Ellis, JACR's managing editor. James keeps track of the size of each issue and the likelihood that the submissions would be revised on time. He is the one who smooths the paths for authors dealing with editors, reviewers or copy editors. He also displays his artistic side to negotiate the unique set of images.

Finally, finally let's not forget the role of Rajiv Vaidyanathan. He does so many things for ACR including organizing its books and conferences, and was critical for success of JACR. He makes sure that organizational meetings for upcoming JACR issues occur both at the main and local ACR conferences. From the start, he met with me and Angela Lee each year to discuss the journal and get reports from the support staff at Chicago Press. Simply put, JACR would not have been possible without the joint support of the Chicago Press and research culture at ACR, enabling it to expand into new areas of research and reach scholars from different regions with varying backgrounds.

I like to think of the Journal as you would think of a journal you write to record new ideas or proposed ones. The Journal of the Association for Consumer Research serves that organizational purpose, allow us to try our new ideas, train editors and form cohorts. It could not have been done without the support of the ACR board, Chicago Press and the supportive culture of ACR.

Four ways to improve your research culture

- Understand three cultural shifts
- Improve research interactions
- Form research cohorts
- Achieve personal balance

This next section asks what the culture of research can do for you. I'll begin by noting three important evolutionary changes that I believe provide both challenges and opportunities for us.

Three Cultural Shifts

- Increased obsolescence of skills
- Decreased role of the solitary scholar
- Increased role of non-tenure faculty

The first shift arises as the rate of change in our field continues to accelerate. You can be sure within 15 years that new research skills you develop will either be adopted by others, or worse, rendered obsolete. We are moving from a culture with a few dominant theories, a few standard methods, and a few articulated goals to one with multiple theories, incompatible methods, and fractured goals. Put differently, we cannot let up on our need to continuously adapt and learn.

The second change is a shift in the role of the individual in scholarship. Hiring and promotion used to focus on the unique skills and achievements of the solitary scholar, with schools counting articles with sole authorship more than those with coauthors. That has changed for the better. Perhaps schools have come increasingly to realize that the most valuable colleague may not be the one with the best mind, but the one with broadest ability to help others prosper.

The third change is a disturbing rise in non-tenure track faculty in business schools, often replacing scholars with professors-of-the-practice who can provide valuable teaching at a lower cost. Recently, the status and pay of those non-tenure track positions has risen, particularly if they appear on TV, have active blogs or are published in the New York Times. Their greater status has been encouraged by students and the firms who recruit them that desire job related insights. If that trend continues, it suggests that talented individuals may be as satisfied and productive in an enhanced non-tenure track position as those in lifetime tenure.

These three changes define a scary world, one where what you know now will be less valuable in the future, where the individual is not the focus, and the prospect of lifetime tenure may become more scarce and less attractive for our brightest minds.

How do we prepare for those changes? Let's begin by considering .ways to get more out of interactions with others

Effective Research Interactions

- Preparing for interactions
- Official and unofficial meetings

Let's start by thinking about interactions in conferences like this one. Here, we interact joyfully with so many people. Many encounters are random, offering the exciting chance to learn about different ideas or research methods. Too often we are passive about those we meet, rather than setting up meetings and dinners with joint goals. I spoke earlier about the importance of preparation before, work during, and effort after a conference. The same principle goes for all interactions. If a visiting scholar comes to talk at your school, it is important to read the paper ahead so that you can understand and comment appropriately. Prepare for your personal visit, focusing first on the visitor before discussing your individual problems. Then follow-up with a brief email.

Not all meetings are part of a visit or a national conference. An unplanned Duke conference occurred during my second year at Duke that had an outsized influence on my research. Chris Puto, John Payne and I had been testing the asymmetric dominance effect and were amazed and puzzled by early results. In 1981 dean Tom Keller allowed us to coordinate a 3-day off-campus meeting with 25 scholars to discuss the impact of item similarity on choice. Eight papers were presented, each taking an hour with 30 minutes of comment and discussion. Those attending included John Hauser, Amos Tversky, Steve Shugan, Glen Urban, and Bob Meyer. Amos really liked the asymmetric dominance effect, but said it should be called the attraction effect, to evoke the fact that greater similarity among alternatives takes share from the target, the opposite of attraction. John Hauser wrote an elaborate comment showing that the attraction effect is inconsistent with Tversky's Elimination by Aspects and with Luces' Choice Axiom. He also suggested satisficing and tournament explanations. The support these 25 scholars positioned what might have been a narrow theoretical result to one that has since encour-

aged many studies of competitive context in marketing decisions. The lesson is simple. Group think matters, and group think among smart and focused thinkers matters even more.

Research cohorts are vital

Why are cohorts needed?

What makes an effective cohort?

How to nourish and build cohorts?

Now let's consider cohorts. Cohorts are groups of researchers exploring a substantive topic, a developing theory, or a promising methodology. Newly emerging cohorts tend to have fewer members, but they are easy to identify as groups of people who congregate at special sessions and cite each other's work. Cohorts generally lack formal alliances, and indeed there is an appropriate tension among researchers competing to resolve emerging issues.

Personally, I have been involved in different cohorts at various times. As examples, I have been part of substantive cohort that applies survey methodology and economics to understand household recycling, a methodological cohort exploring eye tracking of decisions, and a theoretical cohort making sense of asymmetric dominance.

Why are cohorts important? They matter because they support the publication of articles on a topic, thus helping to establish the credibility of ideas and the authority of their members. Effective cohorts need at least 30 members, assuring sufficient numbers to review and cite the articles from the group.

Joining cohorts is an important component of a research strategy particularly for young scholars. Choose a cohort whose growth fits the skills you have or want to have. Being identified as part of a cohort increases the likelihood of being chosen as a reviewer that enables you to understand and guide the evolution of an emerging field. Perhaps more important, cohort members are likely to write credible letters supporting promotion.

Apart from JACR there are a number of ways to build ties to a cohort. Great value comes from ACR conferences, particularly being part of a special session or a round table. For me, my regular attendances at the Sawtooth Software conference put me in contact with marketing research firms, their corporate clients and a remarkable group of academics. It helped me develop internet-based marketing research skills and have a central role developing conjoint and choice models.

Achieving Personal Balance

- Growth vs. decline
 - Skills
 - Cohorts
 - Topics
- Career vs. self
 - Body and health
 - Friends
 - Family

So far, I have spoken about the power of interpersonal culture in fostering success. Next, consider personal strategies to develop balance between your career and yourself. Within a career, one of the

8 / The Power of a Strong Research Culture

most difficult questions we all face is determining where we should put our efforts, determining which projects, which co-authors, which cohorts should consume our time and energy. Matching capability against need is difficult because ideas, methods and researchers go through life cycles which start slowly, then grow stronger, and then as we all do, mature. Coauthors can increase efficiency, giving jobs to those with best skills. The work slows considerably when a co-author or a student is running an elaborate study, and can become overwhelming when the results are not as predicted. It is helpful to have some slack to allow for focused attention when needed.

Now let's consider the even more difficult balance between your career and yourself. Teaching, research, and administrative demands of an academic career limit your ability to keep fit, be healthy, and emotionally refreshed. We all need time for exercise, greater control over what we consume, and the support of good friends. Good friends are critical for walks, sports, and delightful evenings. The benefit is even greater if your activities are with colleagues, co-authors or Ph.D. students. Having a walk or exercise buddy increases the likelihood of carrying it out. Having a group of friends who regularly go out to dinner together or go to a movie has the same positive effect. Both healthy behavior and friendships are virtuous habits that are fortified when they are a regular part of your schedule and your social network.

Finally, let's turn to families. Greater mobility has scattered many of us from our parents, siblings, and even our children who leave home. That splintering of families is especially common among academics. Occasional weddings and funerals are fine, but

provide limited ways to really bring people together. Stay in touch with family with phone calls, holiday cards, Facebook or a personal website. Encourage your families to visit your home or travel with you. Part of the solution is to incorporate families into the university fabric. Get to know their spouses, children and even parents, providing for them the same kind of accepting bonds that unite actual families.

Preparing for this talk I examined my publications searching for the intellectual breakthroughs I could share. The more I thought about my achievements, the more I realized the critical value of the people and the culture around me, of being blessed by people who could see more clearly, those who had the skills I lacked, and those with the energy I needed. Finally, the cultures of the marketing groups at Penn, Purdue, Columbia and Duke, and my associations of ACR, ACP and Sawtooth have made clear to me the value of getting together in open discussions that allow us to laugh with and learn from each other.

My final message is to urge you to support and treasure your interactions with each other. If there is a weakness in the people in our field today, it is a reluctance to build lasting interactions that support the research culture. Search out groups, meetings, and friends who share ideas with wisdom and joy. Go forth, my fellow researchers, work together, and prosper.

Competitive Papers—Full

Consumer Cynicism Through the Lens of Bourdieu

Dr. Indirah Indibara, (Indian Institute of Management Raipur)

Dr. Sanjeev Varshney, (XLRI Jamshedpur)

INTRODUCTION

Over time, consumers have become increasingly distrustful of the businesses and the marketplace. Many researchers have focused on various negative attitudes a consumer develops towards a firm or the marketplace to study this trend. Consumer cynicism (CC) that a consumer might harbour for the marketplace actors is one of the emerging areas of study in this domain (Helm, Moulard and Richins, 2015).

CC is conceptualized as a negative attitude that a consumer develops toward a firm (Chylinski and Chu, 2010) or the whole marketplace (Helm, Moulard, and Richins, 2015) due to the attribution of some hidden motives behind its actions. Due to the severity of the consequences of a cynical consumer's behavioural outcomes, it becomes imperative to understand the concept of CC, its driving factors, and its resulting behaviours.

RESEARCH GAP

To date, researchers have studied CC as either a personality trait or an individual's attitude. Both conceptualizations have given more importance to the individual, i.e., the subject, rather than the surrounding circumstances, i.e., the object of the study. This indicates a subject-object dichotomy prevalent in the literature. Though both subject and object are essential aspects and can be studied individually, scholars have called for an integrated approach to understanding any phenomenon in its entirety (Overton, 1997).

RESEARCH OBJECTIVE

We take the help of Bourdieu's concepts of habitus, field and capital (Bourdieu, 1987) to study CC in an integrated subject-object approach. Fields are social arenas that specify precise guidelines of conduct that require an individual to acquire specific skills to traverse the same (Holt 1997). The individuals gain these skills as various economic, social, and cultural capital to compete for status within fields (Holt 1997). Automatic internalization of the interaction between the capital and the field dynamics results in habituated tendencies and generative predispositions in an individual, defined as habitus by Bourdieu (Saatcioglu and Ozanne, 2013; Wacquant, 2016).

We propose that an individual's habitus, which evolves continually due to various life experiences, will determine the type of inter-field movement a person resorts to when moving between the social and consumption fields. The inter-field movement (Coskuner-Balli and Thompson, 2013) is also predicted to be determined by the person's cultural capital. Cultural capital combines "tastes, skills, knowledge, and practices" that distinguish individuals from others (Holt, 1998). Individuals are classified as high cultural capital (HCC) or low cultural capital (LCC) person based on the amount of cultural capital they possess (Holt, 1998; Saatcioglu and Ozanne, 2013).

As already established in the existing literature, inferring negative motives behind someone's actions is the defining characteristic of a cynical person. 'Negative Inferred Motive' (NIM) is conceptualized as the belief that a firm will try to take leverage of the customer and increase its earnings (Balaji et al., 2018). Unless someone

suspects negative motives behind the market player's actions, they won't turn cynical towards it (Indibara and Varshney, 2020). Hence, we posit that individuals develop CC when they infer negative motives while undergoing adverse inter-field movement experiences.

Borrowing from the extant literature (Helm 2004; Chylinski and Chu, 2010; Odou and Pechpeyrou, 2011 and Helm, Moulard and Richins, 2015), four different types of behaviour are predicted as a consequence of CC – defensive, offensive, subversive and withdrawal. While defensive behaviour leads a person to protect themselves from the marketplace, offensive behaviour results in the consumer trying to take advantage of the firm by displaying opportunism. Subversive behaviour motivates the person to treat firms and the market with sarcasm, thus creating negative word-of-mouth communication for others. And withdrawal behaviour results in complete withdrawal from the marketplace (Odou and Pechpeyrou, 2011).

METHODOLOGY

A mixed-method approach was adopted to understand the effect of habitus on CC and its consequent behaviours. Two studies, one qualitative and the other quantitative, were conducted for the same.

Study 1

The qualitative study using fourteen in-depth interviews was conducted to understand the phenomenon. The interviewees were purposely sampled to target consumers falling under LCC and HCC groups to better understand the distinct behaviours an individual displays according to their social upbringing. The approach was exploratory, with questions on respondents' upbringing and their social and consumption experiences. The interviews were conducted in English, Hindi and Odiya, averaging 75 minutes. All interviews were digitally recorded and transcribed to ensure trustworthiness, and guidelines were followed as suggested for in-depth interviews (Strauss and Corbin, 1990; Fournier, 1998). Collectively, 195 consumption stories were generated for analysis.

The life incidents were first arranged chronologically for each respondent to understand how childhood experiences get manifested in habitus, which then determines subsequent consumption decisions. Open, axial and selective coding was done in phases focusing on increasing levels of analysis, similar to the process recommended by McCracken (1988). Individual mind maps were also created for each respondent. The second level of interpretation involved cross-person analysis, which was to discover patterns across consumption episodes and individuals. The consolidated framework was proposed after analyzing all fourteen interviews and mind maps, as shown in Figure 1.

FINDINGS (STUDY 1)

It was found that an individual's childhood experiences and the resulting habitus significantly impact their adulthood consumption patterns. Depending on the childhood notions of justice and social comparisons, respondents displayed varying levels of social aspirations. The successful or unsuccessful achievement of the social growth and the reasons attributed for the same determine the type of movement between the social and the consumption field (hori-

zontal, upward or downward) that a person usually resorts to. The eight types of inter-field movements based on a person's social field habitus (HCC or LCC) and the type of consumption they resort to (HCC or LCC) are represented in Table 1.

If individuals cannot fulfil their desired social aspirations, they attribute the failure to society or their fate. Respondents who attributed their present LCC state to Karma or fate went for a status-quo consumption per their LCC habitus (voluntary horizontal inter-field movement). They seldom purchased anything aspirational. If these individuals were forced to overspend on their self-consumption (involuntary upward movement), they developed NIM and CC towards the particular market player and resorted to defensive behaviour due to the feeling of powerlessness.

But people who blamed society for their thwarted social growth continuously aimed to fulfil their aspirations in the consumption field, displaying a voluntary upward inter-field movement. If their upward movement in the consumption field was blocked, they inferred negative motives behind the market player's actions, turned cynical and displayed offensive behaviour towards the market player.

Suppose the individuals were not blocked in the social field while trying to fulfil their aspirations and could achieve their desired HCC social position. In that case, they tend to display voluntary simplicity (voluntary downward movement) and withdrawal behaviour in the marketplace.

In contrast, the individuals who were never blocked in the social field but are yet to fulfil their social aspirations see the consumption field as a signalling strategy for their achieved HCC status. Most of the time, they display a status-quo HCC consumption (voluntary horizontal movement), symbolizing their social growth. If these respondents faced any negative experience in the marketplace, they resorted to subversive behaviours.

Thus, it was found that an individual's voluntary or involuntary inter-field movement, upward, downward or horizontal, determines whether successful incorporation of consumption experience will occur or not in the person's habitus. And suppose the negative consumption experience led to inferring negative motives behind the market player's actions. In that case, CC is developed, resulting in four types of behaviour: defensive, offensive, withdrawal, and subversive.

Study 2

The second study was a scenario-based experiment designed to test the findings of Study 1 in two stages. The online surveys of both stages were shared with the students, alumni, and faculty members of two premier management institutions in India. The offline survey was conducted through personal face-to-face interaction with low-income employees of three organizations in India. A convenience sampling method was used, and the respondents were selected due to their accessibility to the researcher.

Stage 1

The first stage was a survey to capture the respondents' demographic information. The socio-economic classification (SEC), both childhood and present-day, was done for the respondents following the latest Indian SEC classification criteria depending on the education of the family's primary earner and the consumer durables that the family possesses.

The cultural capital of the respondents was calculated using the formula:

$$\text{Cultural Capital} = (\text{Respondent's Education} + \text{Respondent's Occupation}) + (\text{Father's Education} + \text{Father's Occupation})/2 + (\text{Mother's Education} + \text{Mother's Occupation})/2$$

The respondents were categorized into two groups – high and low based on the median values of the cultural capital, childhood SEC and current SEC scores. Those individuals who belonged to at least two high groups among the three median split categorizations were considered the HCC individuals. Others, who had all the low categorizations in the three cases or had only one high score and two low categorizations, were considered LCC individuals for further analysis.

The respondents were also asked to choose between a high-priced branded t-shirt (HCC product) and a low-priced unbranded t-shirt (LCC product) to understand their default consumption choice. Of the 545 responses collected in the first stage, 384 respondents chose the LCC product, and 161 chose the branded HCC product.

The respondents' inherent CC level was also captured, along with the above information. The scale developed by Helm, Moulard and Richins (2015) was used to operationalize the CC construct.

Stage 2

The second stage was a factorial design survey-based experiment. The 545 respondents were assigned to four experimental scenarios (two voluntary consumption groups treated as the control groups and two involuntary consumption groups treated as the manipulation groups). In the two voluntary consumption scenarios, the respondents were allowed to freely consume their desired cultural capital product – high or low as chosen in the first stage. In the two involuntary scenarios, respondents were asked to assume that they would consume their unpreferred consumption choice.

Out of the 161 individuals who had chosen the HCC product in the first stage, 80 were assigned to the involuntary LCC consumption scenario (Scenario 1), and 81 were assigned to the voluntary HCC consumption scenario (Control Group 1). Similarly, out of the 384 respondents who had chosen the LCC product in the first stage, 192 were assigned to the involuntary HCC consumption scenario (Scenario 2). The rest, 192, were assigned to the voluntary LCC consumption scenario (Control Group 2). Based on the social field HCC or LCC classification and the consumption choice assigned in the experiment, eight inter-field movements are captured, as shown in Table 1.

The second stage survey was sent to the 545 respondents after one month to reduce the recollection bias they might display due to the repetitive nature of the CC scale. Out of the 545 respondents who had filled the questionnaire in the first stage, 505 respondents reverted in the second stage of the study, indicating a response rate of 92.66%. 78 of these responses were from scenario 1 respondents, 79 from control group 1, 175 from scenario 2 and 173 from control group 2.

NIM (Joireman et al., 2013) and CC (Helm, Moulard and Richins, 2015) were measured with the help of established scales. Further, we developed a scale to measure the individual's behavioural intention (BI) and the same was tested for reliability and validity. Four categories of consequent behaviour proposed in the study were defensive, offensive, withdrawal and subversive. Statements that captured these behaviours were selected from the literature, and the BI questionnaire consisted of 21 questions.

Findings (Study 2)

Using a one-way ANOVA test, we found that the participants' NIM, CC, defensive, offensive, withdrawal, and subversive BI significantly vary across the eight consumption groups. Individuals who consumed a product of their choice (voluntary movement) inferred significantly lower negative motives behind the firm's actions and displayed a significantly lower level of CC and defensive, offensive,

withdrawal and subversive BI than participants who had to consume a product unwillingly (involuntary movement).

The data analysis indicates that the LCC individuals displayed a significantly higher level of NIM, CC, and defensive, offensive, withdrawal and subversive BI when experiencing the adverse scenario despite having a significantly lower CC than the HCC persons before the experiment. This indicates that the LCC individuals have a higher sensitivity toward the negative experiences in the marketplace. LCC individuals whose desired HCC consumption was thwarted in the experiment and who were forced to consume the LCC product unwillingly displayed the highest NIM, CC and defensive, offensive, withdrawal and subversive BI among the eight groups.

Regression analysis was done to test the effect of NIM on CC and of CC on four BIs. NIM was established as a significant predictor of CC, the beta value was 0.558, and the model R-square value was 0.393. CC was found to impact the four BIs significantly in the case of involuntary consumption scenarios. The beta values for defensive, offensive, withdrawal and subversive BI were 0.464, 0.589, 0.11 and 0.484, respectively. The above findings prove the causative effect of NIM on CC and CC on the four BIs in involuntary consumption situations as a support for our hypotheses.

IMPLICATIONS

Our study contributes to the stream of research that analyses consumption as a practice using Bourdieu's concepts of field, capital and habitus. CC, to date, studied as an individual's personality or attitude was looked at from a socio-cultural perspective. This helped us transcend the subject-object dichotomy that exists in the literature.

Gaining insight into how the childhood habitus and subsequent life experiences shape the consumption pattern of individuals and how the inter-field movement between the social and consumption fields results in CC will help the marketers take care of their actions that result in an involuntary downward, upward or horizontal movement.

For example, the focus should be on bridging the gap between the two fields, i.e., the firms should try to provide product and pricing options that match the mental schemas and habitus of the HCC and LCC individuals. However, at the same time, care should be taken about providing aspirational products to LCC consumers and low-priced options to HCC voluntary simplifiers.

Since CC can result in severe negative consequences (Helm, 2006; Chylinski and Chu, 2010; Odou and Pechpeyrou, 2011; Helm, Moulard and Richins, 2015), identifying instances when defensive, offensive, withdrawal and subversive behaviours get triggered will help the firms control the adverse impact of negative behaviours to a great extent.

LIMITATIONS AND FUTURE RESEARCH

Restrictions can be imposed on the findings because of the sample characteristics because the study was done in India. Cross-cultural research is suggested to test how developed economies differ from emerging markets in this context.

The conditions under which the four types of BI get converted into actual behaviour need to be studied, focusing on the role and importance of an individual's perception of 'powerlessness' in the marketplace.

Though manipulating the price and brand of the product was found to have a significant effect on the experimental groups, future studies should consider additional variables like individuals' consumption baskets and usage habits while studying the impact of the inter-field movement on CC and consequent behaviours.

The Material Possessions Stereotype

Tabitha Thomas, Unaffiliated

INTRODUCTION

A few years ago, I had to present my work in front of an audience. I recall ending my talk by saying, “when you ask children to draw and describe pictures of physically attractive and less attractive individuals, children perceive attractive individuals to own more quantity of things than less attractive individuals”. During the question-and-answer session, an audience member had the following to say to me. “Does it happen the other way round? That is if you were to ask children to draw and describe a person based upon the number of possessions – e.g., lots of things versus few things – would children then say people who own many possessions are more beautiful than people who own fewer things”. The motivation for this article comes from that specific feedback that I received many years back. The present research proposes a conceptual framework to understand the material possessions stereotype in children using perspectives from the status signaling dimensions of distance (Bellezza 2021), the sociocultural theory (Vygotsky 1978), and the halo effect (Thorndike 1920).

THE MATERIAL POSSESSIONS STEREOTYPE

In this article, the material possessions stereotype has been defined in the following manner. The stereotype occurs when a person, let's call them X (the one stereotyping) forms certain judgements about an unacquainted person, say Y (the one who is being stereotyped) based on the material things X observes Y consuming. The material possessions stereotype like any other negative stereotype can be an inaccurate judgement of an individual. For example, X may consider Y who is not rich to be wealthy because they notice Y wearing designer clothing and driving a luxury automobile. At the same time, in a different context, X can also wrongly mistake Y who is a wealthy person to be not affluent because they witness Y taking public transport or shopping at an inexpensive store. The material possessions stereotype is different from Veblen's (1899) conspicuous consumption in a subtle but significant way. According to the conspicuous consumption theory, Y uses specific material possessions to signal their identity or status to others who may be either acquainted or unacquainted with Y. The material possessions stereotype, on the other hand, is a stereotype wherein others form opinions about Y whom they do not know personally based on the consumption patterns that they see Y displaying.

The present research examines the material possessions stereotype in children because (1) children have been understudied within the consumer behavior literature compared to adults; and (2) children are vulnerable consumers who are still in their developmental stages and do not yet possess the cognitive abilities to discern between what is right or wrong. Therefore, understanding the material possessions stereotype in children is crucial for their future well-being.

STATUS SIGNALING BEHAVIOR IN CHILDREN

Children, like adults, use objects to signal their status and identity to others (Chaplin and John 2005; 2007). Status signaling behaviors are normally found to be higher in children who are exposed to advertising messages than those who are not (Goldberg, Gorn, Peracchio, and Bamossy 2003). Children who give importance to material things are also typically seen to nag their parents to buy them stuff and throw tantrums when their parents do not adhere to their purchase requests than others (Goldberg et al 2003).

Research shows that when children do not own expensive material things e.g., branded/status-related goods, they are often ridiculed by their peers at school (Wooten 2006). Studies in the extant literature have mostly focused on the relationships children have with material possessions and how these relationships impact children's well-being either positively or negatively (e.g., Chaplin and John 2005, 2007; Goldberg et al 2003; Kasser 2005; Wooten 2006). The present research does not examine the relationships children have with material possessions. Rather, this study examines how a child perceives an individual based on the material possessions that they see the specific individual consuming.

Prior research, that is closest to the present work, is a study that was conducted by Chan (2006) who explored children's perceptions of others who owned one particular possession, namely, toys. Chan's (2006) findings reveal that children consider individuals with expensive toys to have higher status among peers compared to those with fewer toys. The present research is different from Chan's (2006) research in the following ways. Chan (2006) explored children's perception of other children who owned lots of new and expensive toys versus those who did not have many toys. The present research takes a broader perspective on the subject matter compared to Chan (2006). That is, in this research children are not just confined to defining others based on one single possession, namely, toys. But the current study considers how different types of possessions can influence children's perception of others. Also, in this study, I have not defined material possessions for the children, instead, children have defined material possessions on their own.

METHOD

Drawing Method: To explore the material possessions stereotype in children, drawings were considered as an ideal method. This is because psychologists have argued that through drawing one can dive deeply into a child's mind and understand their inner most thoughts which children otherwise find hard to articulate (Cherney, Seiwert, Dickey, and Flichtbeil 2006).

Participants: 55 children (47% females, *Age* = 8.96), in the 6–12-year-old age range, were recruited from a large public school. Most participants belonged to lower to middle-income families. The study was ethically approved and required permissions were taken from concerned authorities before starting this research.

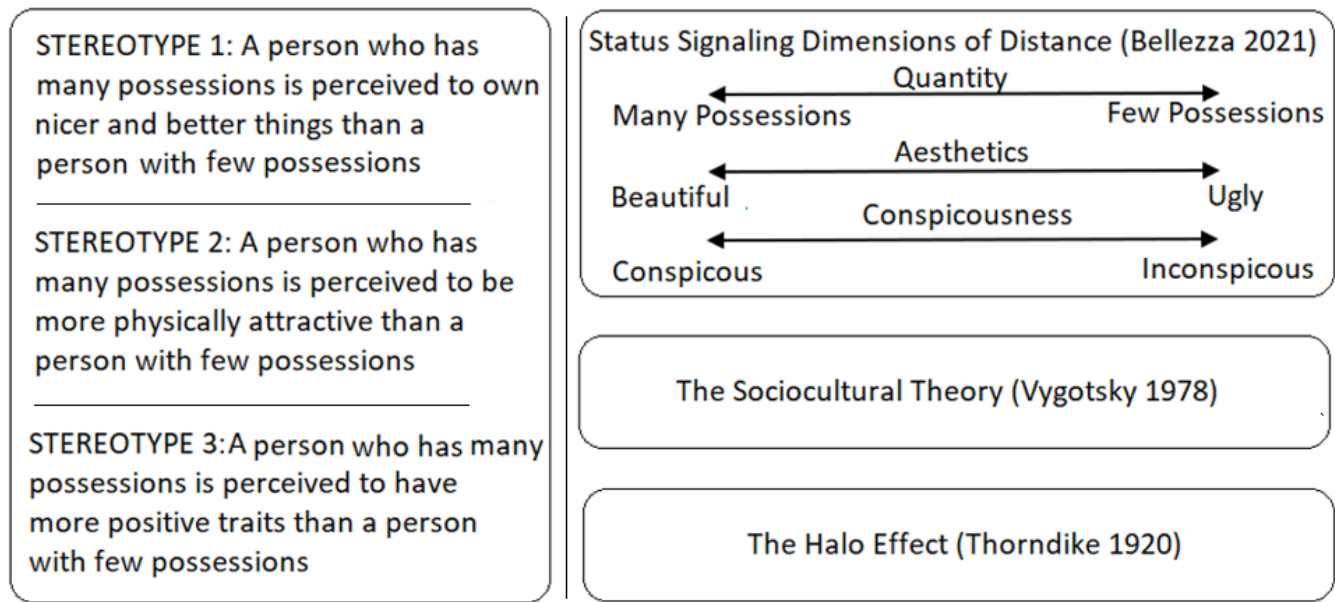

Procedure: The steps followed in this study have been adapted from Chan (2006) and Thomas (2021). The participants were seated in a classroom. Two participants shared a table. They were then given a sheet of A3 size paper, a box of twelve color pencils, and asked to draw two pictures. The first picture was that of a girl/boy who had lots of things and the second picture was that of a girl/boy who had few things. After the drawing activity was completed, the participants were asked to describe the characters present in their pictures. The entire task took approximately around 60 minutes. The participants were asked to keep the box of color pencils as an incentive for taking part in the study.

Analysis: A total of 110 drawings (i.e., each child drew two pictures) and descriptive words were analyzed. The analysis was a back-and-forth process and was done using Braun and Clark's (2006 p 87) thematic analysis guidelines that consisted of “(1) familiarizing the data, (2) generating initial codes, (3) searching for themes, (4) reviewing themes, (5) defining and naming themes, and (6) producing the report”.

FINDINGS AND DISCUSSION

The findings are interpreted through the lens of the status signaling dimensions of distance (Bellezza 2021), the sociocultural theory (Vygotsky 1978), and the halo effect (Thorndike 1920).

Figure 1. The Material Possessions Stereotype Framework

FRAMEWORK TO UNDERSTAND THE MATERIAL POSSESSIONS STEREOTYPE

STEREOTYPE 1: A person who has many possessions is perceived to own nicer and better things than a person with few possessions

To explain this stereotype, Bellezza’s (2021) status signaling dimensions of distance namely quantity, aesthetics, and conspicuousness have been adapted in this research. Quantity is defined in terms of the number of possessions i.e., many versus few that children have assigned to the characters in their respective pictures. Aesthetics is exemplified by how beautiful or ugly the drawings of the possessions appear in the child’s picture. Conspicuousness is concerned with the visibility features e.g., generosity in the usage of colors, patterns, and designs to enhance the visual effects present in the drawings. For example, in Figure 2, a 10-year-old girl and boy have used colors to depict aesthetics and conspicuousness and to highlight the differences that exist between the characters in their pictures. The drawings reveal that children associate things like money, a big house, cars, expensive clothes, shoes, accessories, closets/wardrobes, television, computers, phones, and toys with the person who has lots of possessions. In contrast, a person with few possessions is described as being poor and owning things such as coins, a small house, broken toys, torn clothes, and plain shoes (see Figures 2 and 3).

During face-to-face conversations with the participants, it was found that if someone is imagined having lots of things, the objects that they own or consume are also perceived to be better and nicer than that of an imagined person who has lesser things. These finding may have emerged because of the importance society places on the quantity of material possessions a person owns. Children are picking up cues from the environment as a result of social learning (Bandura1971). Children then internalize these cues and use the knowledge gained to form stereotypes. For instance, children learn at a young age that those who belong to poorer families or marginalized communities have limited resources compared to others. And

so, when you ask a child to imagine an individual with few possessions the stereotypical knowledge that they have learned is what comes out (see Figures 2 and 3). The findings show that the material possessions stereotype is so strongly engraved in a child’s mind that they are unable to think that the person with few possessions may actually be wealthy and own goods that are beautiful, nice, precious, or exclusive (e.g., minimalists).

Figure 2. Drawings done by children aged 10

STEREOTYPE 2: A person who has many possessions is perceived to be more physically attractive than a person with few possessions

The drawings exemplify (see figure 3) how the contemporary culture has influenced children's perceptions of material possessions and beauty ideals. Digital and traditional media outlets bombard us with images of perfect-looking people living the material-good-life (Dittmar 2007). Research shows that constant exposure to such images results in us internalizing body ideals and linking material possessions with happiness, success, and fame (Ashikali and Dittmar 2012). How we define material objects and beauty standards are therefore highly influenced by what is learned from social agents such as the mass media, peers, parents, and the cultures that are prevalent in the world at large. This reverberates with sociocultural theory (Vygotsky 1978) i.e., how social learning

impacts society and how society then contributes to an individual's development.

The findings clearly show how society has made children think of beauty ideals and material possessions in the most obvious manner. For instance (see figure 3), a 12-year-old girl has drawn the picture of the girl with lots of things to be more adult looking i.e., her waist is relatively smaller compared to her hips. The character has skinny arms and legs and is shown wearing a body-hugging dress that is paired with high heeled shoes. On the other hand, the 12-year-old girl has drawn the picture of the girl with a few things to appear more like a child who has messy hair, tears, and is sketched wearing a dress with patches and flat plain shoes. As you can see,

the 12-year-old girl has overtly linked physical attractiveness and happiness (smiley face versus sad face) to quantity of possessions. Likewise, a 7-year-old boy has drawn the picture of the boy with

lots of things to have an adult-like looking muscular body whereas the picture of the boy with few things is portrayed to have a non-human-like shape.

Figure 3. Drawing done by a 7-year-old boy and a 12-year-old girl

STEREOTYPE 3: A person who has many possessions is perceived to have more positive traits than a person with few possessions

The findings reveal children associating positive traits with the picture of the person with many possessions and negative traits with the picture of the person with lesser possessions. For example, the words used to describe the girl/boy with lots of things were “smart”, “not mean”, “kind”, “good”, “helpful”, “popular”, “happy”, “shares things”, and “clean”. In contrast, the girl/boy with few things was described as “stupid”, “unhappy”, “mean”, “rude”, “bully”, “bad”, “does not share things”, and “dirty”. A reason for this type of cognitive bias can be attributed to the halo effect (Thorndike 1920). Halo effect is an error in reasoning, wherein a person’s character is assessed based on a single trait (e.g., physical attractiveness) that they possess. This effect is also known as the beautiful-is-good stereotype (Dion, Berscheid, and Walster 1972). That is, if an individual is seen to be physically attractive, they are also perceived to have more positive traits than an individual who is normal-looking or unattractive (Griffin and Langlois 2006). In the context of the present research, the halo effect led children to think of the individual who

owned many things to have more favorable traits than the individual who owned fewer things.

CONCLUSION

The present research identified three main stereotypes relating to material possessions. The first stereotype is that a person who has many possessions is perceived to own nicer and better things than a person with few possessions. The second stereotype is that a person who has many possessions is perceived to be more physically attractive than a person with few possessions. And the third stereotype is that a person who has many possessions is perceived to have more positive traits than a person with few possessions.

Practical Implications: An important message this article would like to convey is that every person deserves to be treated properly with respect despite what they own or how they appear. Public policymakers, educational institutions, teachers, and parents have a significant role to play in identifying stereotypes in children and rectifying them as early as possible. One way to do this is by

making children aware and teaching them not to hold any prejudice or bias related negative attitudes against any individual or a group based on what they see on the exterior.

Future Research Arenas: Certain cultures put greater emphasis on the concept of minimalism. And so, it would be interesting to see how children raised in minimalist homes would perform on the drawing and description task. In the present research, children drew pictures of individuals who were the same gender as their own. Future research can look at considering cross-gender pairing to study material possessions and traits related stereotypes i.e., boys draw and describe girls and vice-versa. Future research can also consider examining gender-neutral scenarios. For example, instead of using the phrase “draw this boy or girl”, the phrase “draw this person” can be used.

Brand Nomadicity: Redefining Consumer-Brand Relationships in Liquid Modernity

Sarah Schwarz, University of Innsbruck

Christiane Aufschnaiter, MCI-The Entrepreneurial School

INTRODUCTION

Societal changes have ushered in an era of liquidity (Bauman 2000) where consumer culture underlies a nomadic logic. With its hypermobile and hyperconnected nature, postmodernity lauds consumption as detached from traditional markers of solidity—endurance, ownership, and materialization (Bardhi and Eckhardt 2017). Accordingly, consumers embrace liquid relationships to the material world (Bardhi, Eckhardt, and Arnould 2012) as they strategically enable their navigation in uncertainty. Research challenging the linking value ascribed to products and services (Cova 1997) has even foregrounded the rationale of publicity (Arvidsson and Caliandro 2016) and visibility (Eckhardt and Bardhi 2020) permeating consumption. Drawing a more colorful picture of liquid consumer culture, recent studies have pointed to the centrality of solid structures (e.g., Caldwell and Henry 2020), such as in the form of anchors conveying both social and material stability (Aufschnaiter, Schwarz, and Hemetsberger 2021). Reminiscent of Bauman's (2000, ix) claim that "the quest for the solidity of things and states [...] triggered, kept in motion, and guided their liquefaction," these scholars have implied conceptualizing consumption as occurring at the interplay between liquidity and solidity.

In this light, we aim to provide a more nuanced account of the roles brands as solid anchors assume to nurture consumer life in liquid modernity. Research has noticed the altering relationships to brands in consumption contexts (Wegerer 2018) and foregrounded that technological advancements call for "the 'blurring' and 'broadening' of branding boundaries" (Swaminathan et al. 2020, 25) requiring a reassessment of branding research from the perspectives of firms, consumers, and society. Brands are shifting away from single ownership to shared ownership, as heightened access to information and people is allowing more stakeholders to cocreate brand meanings and experiences alongside traditional brand owners and managers. Moreover, hyperconnectivity has allowed existing brands to expand their geographic reach and societal roles, while new types of branded entities (ideas, people, places, and organizational brands). However, while these insights have hinted at the detachment of consumers from branded objects, Bardhi and Eckhardt (2017, 591) emphasize the lack of "empirical research on the nature of relationships to brands and brand communities from a liquid perspective." To cater to this gap in extant scholarship on liquid versus solid consumption, we employed a netnographic approach. We used content analysis of Twitter data revolving around Moleskine—a brand representing "around the world, a symbol of contemporary nomadism" (Moleskine booklet information). This study ultimately introduces the concept of brand nomadicity, illuminating how consumers relate to brands while experiencing uncertainty.

THEORY

Consumer-Brand Relationships

Since Fournier's (1998) pioneering work on consumer-brand relationships, relational approaches to branding have contributed to our understanding of how and why people connect to brands in ways similar to their social relationships (e.g., Alvarez, Brick, and Fournier 2021; Fournier and Alvarez 2012). These strong connections to branded objects are intertwined with consumers' development of a sense of selfhood (MacInnis and Folkes 2017) and com-

munal belonging (Muniz and O'Guinn 2001), providing security, stability, and continuity (Fournier 1998; Muniz and O'Guinn 2001). More recently, major shifts such as the omnipresence of digital technologies and platforms (Caliandro and Anselmi 2021) challenge the continuing importance of consumer-brand relationships. Liquid perspectives have suggested that as "[c]onsumers may not want committed relationships or emotional attachments" (Bardhi and Eckhardt 2017, 590), brands become an easily disposable tool. Research has questioned the role of brands in sustainably forming identity projects or establishing enduring interpersonal relationships (Caliandro and Anselmi 2021). Still, evidence has suggested that in liquid times—when society no longer provides frames of reference—strong consumer-brand relationships become even more essential sources of solidity (Biraghi 2017; Minina and Holmqvist 2021). Similarly, Epp, Schau, and Price (2014) highlight how brands remain relevant in liquid contexts if they become integral to consumers' new practices. Therefore, current conceptualizations vary from *liquid brands* (Hewer 2020) continuously adapting to ever-changing demands to *grounding brands* (Eichinger, Schreier, and van Osselaer 2021) offering connectivity to places, people, or their past.

Materializing Brands

The digitization of (nearly) every sphere of our life—be it possessions (Belk 2013), social connections (Borgerson and Miller 2016), or identity projects (Schau and Gilly 2003)—questions the prevailing role of the material. Concomitantly, research risks taking for granted material aspects and, thus, neglecting their capacity to shape consumer culture (Mardon and Belk 2018; Miller 2010). Attending to the concept of materiality (Borgerson 2013; Miller 1987), which foregrounds the co-constitutive interactions between subjects and objects, allows analyzing relationships between consumers and their brands. Through continuous co-creation processes, consumers and brands "are made into entities that perform certain roles" (Borgerson 2013, 128). Several studies have demonstrated the fruitfulness of investigating consumers' interactions with branded objects from a materiality perspective. For example, in their analysis of a plastic shoe brand, Ferreira and Scaraboto (2016) point out how the brand's material substances, design, and marketing efforts either open or limit the space to engage with consumption objects. As detailed accounts of brand roles in hypermobility and hyperconnectivity are still lacking (Bardhi and Eckhardt 2017; Swaminathan et al. 2020) requiring a reassessment of branding research from the perspectives of firms, consumers, and society. Brands are shifting away from single ownership to shared ownership, as heightened access to information and people is allowing more stakeholders to cocreate brand meanings and experiences alongside traditional brand owners and managers. Moreover, hyperconnectivity has allowed existing brands to expand their geographic reach and societal roles, while new types of branded entities (ideas, people, places, and organizational brands, we applied the concept of materiality to understand brands and "the powerful aesthetic, affective, and embodied encounters they create" (Rokka 2021, 118) more holistically.

METHODOLOGY

To acknowledge the room digital affordances provide for contemporary consumer-brand relationships (Swaminathan et al. 2020), this exploratory study built upon Kozinet's (2020) netnographic ap-

proach. We examined the roles and qualities of branded objects in liquid modernity by drawing attention to Moleskine due to its philosophy of catering to liquid existences: This brand “encompasses a family of nomadic objects dedicated to our mobile identities, versatile tools for both everyday and extraordinary journeys” (Moleskine LinkedIn profile). Over four months, starting in October 2021, we engaged with written and visual content demonstrating consumers’ interaction with Moleskine on Twitter, Facebook, and Instagram. This allowed us to obtain a first glance into how relationships between liquid consumers and brands come into being, are nourished over time, and occasionally fade away. We subsequently conducted a qualitative content analysis of textual data published by Moleskine consumers on Twitter—a platform suited to delve into digital narratives that center around perceptions of a brand (Aufschnaiter 2020). The Netlytic application (“Moleskine” as a keyword) granted us access to a pool of 649 tweets, which consumers posted from November to December 2021. We interpreted inductively, following categorization, abstraction, and iteration (Spiggle 1994).

FINDINGS

Our findings show that to master uncertainty, consumers embrace relationships to brands that go beyond sheerly fulfilling either liquid or solid demands. Since societal sources of security and continuity fade (Bauman 2000), consumption occupies the middle ground between the poles of liquidity and solidity. This study conceptualizes brands as concurrently constituting liquid motors and solid anchors to cater to the needs of consumers in hypermobility and hyperconnectivity. As such, branded objects, on the one hand, *lend wings* by displaying boundless availability and mirroring ephemeral and non-materialized qualities of liquidity based on access (Bardhi and Eckhardt 2017). On the other hand, branded objects *provide roots*, giving back access to sources of stability by incorporating qualities of solidity—endurance, ownership, and materialization (Bardhi and Eckhardt 2017). While the brand qualities of liquid motors and solid anchors act like two gear wheels turning in opposing directions with minimal interplay only, the movement of one ultimately contributes to the continuation of the respective other. Considering this, our findings foreground a concept—brand nomadicity—to address the entanglement between liquidity and solidity within contemporary consumer-brand relationships (figure 1).

Borrowing the nomadicity notion from computer scientists (Kakihara and Sørensen 2001; Kleinrock 1996) who argue for a wider interpretation of mobility in the digital era, we introduce the brand nomadicity concept to detail how consumers play with the spatiality, temporality, and contextuality of brands in liquid modernity. Since branded objects draw from qualities of liquidity and solidity simultaneously, they provide opportunities for living in the here or alternative realities and reflecting upon the past, indulging in the present, or fantasizing about the future. Through their offline and online manifestations, brands may re-shape the contextual nature of interactions. Similar to Kakihara and Sørensen (2001, 33), who find the nomadicity notion to account for “new configurations of social-technical relationships,” we use it to explain consumers’ relationships to objects—such as brands—in hypermobility and hyperconnectivity. Our analysis unveils four roles that branded objects assume when embedded in nomadicity and drawing from both liquid and solid qualities: creator, communicator, connector, and companion (table 1).

The brand as a *creator* crystallizes in references revolving around the various processes of creative artwork immersion that go beyond promising a calming pastime. Providing space for craftsmanship, Moleskine fosters activities “to which the consumer typically brings skill, knowledge, judgment[,] and passion while being mo-

tivated by a desire for self-expression” (Campbell 2005, 23). This role becomes paramount when branded objects not only foster practices of indulgence by supporting mental regeneration or emotional treatment but also act as a contributor in framing, manifesting, and reconfiguring identity projects. Consumers also pursue relationships to Moleskine as a creator brand due to its power to evoke flow-like experiences (Csikszentmihalyi 2017), allowing spiritual growth and care. While being limited by material affordances such as the fixated page size and numbers, the expressive components of the brand unlock consumers’ creative self-production in unlimited ways.

Turning into a vehicle for representations in front of others, the brand’s role as a *communicator* mediates formations between consumers and a public audience (Arvidsson and Caliandro 2016). As such, Moleskine is embedded in values of sophistication and cosmopolitanism, which results in pursuits of displaying consumption and affiliation to the branded object. The communicator role puts the signaling power of objects to the fore in that it showcases the consumer-brand relationship as a cultural signifier of the creative class. Similarly, Moleskine provokes practices for showing off intellectual superiority and educational status. Consumers in today’s attention economy also perform what reminds of Abidin’s (2016) visibility labor through exploiting the capacity of interactions with (branded) content to expose themselves. As a communicator, Moleskine produces consumer-perceived luxury products that are, rather than being exclusively cherished for intrinsic validation, symbols of differentiation.

Foregrounding the linking value of branded objects as they “express and mediate the relationship to other people” (Miller 1998, 46), the brand as a *connector* enables meaningful connections. These social connections manifest in consumers forming communities or tribes (Cova 1997; Muniz and O’Guinn 2001) around Moleskine as they engage in virtual conversations and articulate their sense of belonging to fellow brand users while distancing from others. Consumers use branded objects to materialize connections to particular people, conveying the social nature of consumption and revealing that brands contribute not only to establishing but also to nurturing sociality and expressing hedonic attachment. Consumers engage in gift-giving practices and, thus, materialize experiences and feelings involving others. However, the brand also facilitates connections to additional branded objects since consumers oftentimes apply particular objects like Kaweco pens in combination with Moleskine products.

The brand as a *companion* manifests in consumers’ references to Moleskine as a relationship partner, highlighting the importance of branded objects in and of themselves (Fournier 1998) as opposed to their role in mediating and expressing social connections. Consumers describe how they continuously take along and use the brand. More than that, they express a deep sense of belonging to Moleskine objects they possess or have access to. Practices such as personalizing, grooming, or fearing the loss of these objects reveal that consumers incorporate the brand into their extended self (Belk 1988). Anthropomorphizing practices (Aggarwal and McGill 2012) further substantiate the companion role, as consumers attribute human-like characteristics to branded objects in ways being rather common among humans. Overall, consumers’ references to Moleskine as a cherished relationship partner over an extended time suggest that the brand even surrogates hard-to-achieve stable social connections.

Across all roles, the brand provides consumers with distinct qualities which ensure continuous consumer-brand relationships in hypermobility and hyperconnectivity. Our findings reveal that despite the *ephemerality* of consumer-brand interactions on social media, certain connections between consumers and the self, the pub-

lic, other human and non-human actors, as well as the brand itself assume *enduring* value. Moleskine illustrates how consumers draw on *access-based* and *dematerialized* modes of interacting with the brand through digital media while at the same time appreciating *ownership* of *material* objects central to their practices. Rather than solely encouraging imaginative plays in the mind, the brand roles inspire consumers to embody their ideas as expressed by textual and visual artifacts. Ultimately, exploring the interplay of the brand as liquid motor and solid anchor brings to light how Moleskine manages to provide consumers with needed functionalities and emotional links as well as the freedom to unfold and the structure to ground themselves.

DISCUSSION

This study puts forward the concept of brand nomadicity to open the dialogue on how consumer-brand relationships develop in times that Bauman (2000) aptly terms liquid modernity. Our theoretical contribution to scholarship on branding and materiality is twofold: First, we shed light on the entanglement between liquidity and solidity—being traditionally labeled as the conceptual extreme poles along a consumption spectrum (Bardhi and Eckhardt 2017). Doing so allows us to propel the notion that rather than emerging in a co-existent and continuous manner, liquid and solid aspects argue for a symbiotic interplay. Therefore, this study concurs with Bauman's (2000 ix) idea to “view those two conditions as a couple locked, inseparably, by a dialectical bond,” which describes liquidity and solidity as mutually reinforcing. Second, we pick up the thread of Aufschnaiter et al.'s (2021) research on material anchors trans-

mitting stability and security in that our study stresses the materialization of brands that support consumers navigating the liquid-solid interplay. We understand branded objects as creatively uniting not only material but also social anchors, illustrating how different roles and qualities grant mobility and connectivity alike across temporal, spatial, and contextual axes in the offline and online world. With that, we add to previous work (Mardon and Belk 2018; Miller 2010), underlining the power of materiality in forming consumer culture.

Overall, this study introduces the concept of brand nomadicity to provide a first account of the nomadic logic dominating branded objects that cater to consumers in hypermobility and hyperconnectivity by embodying liquid motors and solid anchors alike. Playing with the boundaries of branding, the concept reconciles the paradox that brands either manifest as adaptations to the unpredictable nature of today's world (*liquid brands*; Hewer 2020) or contain solid facets linking to places, people, and bygone times (*grounding brands*; Eichinger et al. 2021). We apply the notion of nomadicity (Kleinrock 1996) to the consumer research realm and hope to spur debate on the necessity of reflecting openly upon the spatial, temporal, and contextual mobility of brands in uncertainty.

An avenue for subsequent studies could be to examine consumer-brand relationships longitudinally to better comprehend the transitional points invigorating the different brand roles and qualities liquid consumers strive for. Since our concept only revolves around the Moleskine brand, future research efforts could also be directed toward detailing more cases to reveal navigations between liquidity and solidity from a multifaceted angle.

TABLE 1
FINDINGS

ROLES	PRACTICES	ILLUSTRATIVE TWEETS	QUALITIES LIQUID MOTOR & SOLID ANCHOR Inspired by Bardhi and Eckhardt (2017)
BRAND AS A CREATOR Relationship: Consumer → Brand → Self	Indulging Oneself	T#537: #Birthday noir: Tomorrow is my birthday, Sunday, December 5, 2021. And today I got myself an early present: a 2022 @Moleskine daily planner. Hell #YES! https://instagram.com/p/CXDmSAIvKj_/	Ephemeral consumer-brand interactions on social media & enduring connections to others and other brands Emphasis on <i>use-value</i> and <i>access</i> to the brand & <i>attachment</i> to and <i>ownership</i> of branded objects Centrality of <i>dematerialized</i> modes of relating with the brand & <i>material</i> affordances of branded objects
	Building Identities	T#22: Almost 20 years of @moleskine notebooks. Cataloguing my growth as a person. Recording who I really am. Speaking to future readers. #NFTcreator #Writer #Artist #HumanBeing #HumanDoing	
	Experiencing Flow	T#80: [camera emoji] This is your sign of manifestations [cyclone emoji] Spirit wants to communicate so it can grand you its gifts and make way for your blessings. Get a journal, or simply listen. It's always trying to reach out.. [speaking head emoji] ~ Sailor Moon Journal by @moleskine ~... https://t.co/Oiq0CW1qgN	
BRAND AS A COMMUNICATOR Relationship: Consumer → Brand → Public	Providing Intellect	T#544: Considering doing a bit where I go to bars and play a character—eg. guy who brought his Moleskine to the bar because he wants everyone to know he's a writer	
	Signaling Status	T#1: I used to save my money to buy moleskine sketchbook and never used that because i didnt like its paper and just realized the size was small and bought because my cool seniors used that and i thought i would be cool like them too	
	Performing Visibility Labor	T#528: #graphite #portrait on #moleskine #paper photo ref. by Alexandr Ivanov on @pixabay https://t.co/8dV75zyHls	
BRAND AS A CONNECTOR Relationship: Consumer → Brand → Others and Other Brands	Expressing Communal Belonging	T#153: Today I learned both Bengals coach Zac Taylor and I exclusively use Moleskine notebooks and Pilot Pens. .07. Never related more to a person in my life. Via The Athletic: https://t.co/HKaovyrMxL https://t.co/RNY1nFvoL0	
	Materializing Social Connections	T#255: @snoozeoof thank you so much for the moleskine, it has reignited my journal writing [smiling face with hearts emoji] T#640: Love letters to my kids in my @Moleskine Sketchbook - (2011). A decade of scribbles. https://t.co/3ids1ckXJx	
	Connecting to Other Brands	T#414: some movies make you want to grab your moleskine and a pen and start recalling your most formative childhood memories and that is LICORICE PIZZA for me baby	
BRAND AS A COMPANION Relationship: Consumer → Brand	Continuously Using	T#404: @coldbrewedtool Truth. Moleskine got me through my Master's degree. Hell, I've got one in my work bag right now. Along with a good Kaweco fountain pen. Great for my carpal tunnel.	
	Incorporating the Brand	T#455: when I stop having thoughts then I'll stop buying journals (if they don't have a moleskine store in hell) https://t.co/zkLCpjWgUd T#137: I've lost my moleskine diary and tbh I feel like I've lost an arm???	
	Anthropomorphizing the Brand	T#506: Like a security blanket ... Happy to be reacquainted with the @moleskine journal I was working in as the pandemic and remote work took over my life in March 2020. Retrieved from the office on Friday. @hathitrust @mnylc @NNIPHQ @netinclusion @SPARC_NA @LibraryFreedom ... https://t.co/Pi3InKPHMa

Ugly is the New Pretty: Motivations Behind the Acceptance of Ugly Fashion Trends

Tabitha Thomas, Unaffiliated

Dolphy Abraham, Independent Researcher

INTRODUCTION

Have you watched supermodels walk down the runway in designer clothing? If yes, then have you ever wondered, who in their right state of mind would buy and wear such hideous-looking ridiculously-expensive clothes in real life? When popular fashion designers are posed with the same question, they often respond by saying, “my designs and clothes are only meant for those who can appreciate art and creativity in its purest form”. Yet it is not quite a convincing answer to an overly conservative aunt who insists that clothes need to be pretty and not the opposite. However, her nephew/niece contradicts the opinion by saying that there is no such thing as what you call ugly. Rather what one person perceives as being soreness to sight is viewed to be a masterpiece in another’s eyes. The aunt, however, ignores her nephew/niece’s viewpoint and continues to adamantly stick to her own. Although the conversation between the conservative aunt and her nephew/niece is a hypothetical situation. It seems like the beautiful versus ugly debate has been going on forever. In fact, ancient philosophers, and poets, e.g., Aristotle, Plato, Plotinus, Theocritus Idylls have never come to a consensus on the subject matter (Langlois et al. 2000).

While we know that beauty has managed to get a lot of positive attention in history, ugly, in comparison, has not. However, recently, this specific trend appears to be changing especially within the fashion industry. The digital and print media, in particular, have reported that ugly fashion is becoming ubiquitous, and that people are acknowledging ugly as the new pretty (Vogue 2020). For instance, consumers are associating style and coolness with clothing items that are oversized, ill-fitted, unmatched, and loud, e.g., bright color and jarring prints (The Hollywood Reporter 2017). But why is this change happening? The present research contributes to the extant literature by providing a theoretical framework to answer this question. The primary objective of the current work is to explore why people are now all of a sudden gravitating towards ugly fashion which was not the case or scene years ago.

WHAT IS UGLY?

Some of the synonyms used for the word ugly are awful, bad-looking, beastly, disfigured, disgusting, evil, foul, gross, horrid, horrendous, monstrous, repulsive, and violent (thesaurus.com 2022). The simplified definition of ugly in the extant literature is that “ugliness is everything that beauty is not” (Chinchilla 2012, p. 323). Kant called wars and destruction ugly (Gladkova and Romero-Trillo 2021). Plotinus equated ugly to a body rolling in mud (Henderson 2015). Ugliness has also been compared to a weed in a garden that should be removed and not find its place in architecture, artworks, landscapes, and even in human beings (Forsey and Aagaard-Mogensen 2019). Why is ugly despised so much? A common belief acknowledged by philosophers is that ugly negates, depreciates, and destroys beauty (Henderson 2015). Rosenkranz (1853) put it this way; we often see or refer to something as being ugly only because its counterpart beauty exists.

NOTIONS OF UGLY IN THE CONSUMPTION CONTEXT

In the consumption related context, the stereotype is that ugly individuals are perceived to own more cheap material possessions than expensive ones (Thomas 2020). When young children are asked

to describe the types of things that they think a less attractive person could possibly own, their responses include words and phrases such as broken toys, torn clothing, spiders, lizards, bugs, pictures of demons, and garbage (Thomas 2021). Lately, however, the idea of seeing ugly as being bad is changing particularly in the context of food consumption (e.g., Lombart et al. 2019; Mookerjee et al. 2021; Yuan, Yi, Williams, and Park 2019). Scholars found that when humans are educated about the high nutritional values of ugly-looking fruits and vegetables they become more receptive and acceptive towards ugly produce (Qi, Penn, Li, and Roe 2022; Yuan et al. 2019). But can the same rationale work in other contexts such as fashion?

Prior research tells us why people are open to consuming ugly food items (e.g., Mookerjee et al. 2021). However, the extant literature does not provide us with clear reasons as to why people are keen on following ugly fashion trends. According to societal standards, the norm is that clothing and other related items are supposed to be not obnoxious but rather the contrary. When a societal rule is broken even if the rule is unwritten or unrecorded, the ramifications that follow are often in the form of judgments or punishments (Cialdini and Trost 1998). For example, an individual is susceptible to be ridiculed by others for their ugly clothing choices. Despite the criticisms, people are still gravitating towards the consumption of ugly fashion. The objective of this article is to investigate why this happens.

METHOD

Digital resources are considered to be great data sources for conducting consumer research (Kozinets 1998, 2002). And so, in the current study, to understand the rise of ugly fashion trends, articles published in fashion, entertainment, lifestyle, educational, and news websites were analyzed. These articles included perspectives from consumers, journalists, freelance writers, bloggers, fashion experts, celebrities, influencers, and social elites. Articles that appeared during 2017-2021 were chosen, in particular, because it corresponds to the timeframe when ugly fashion became a trend among the common man (see Table 1).

Discourse analysis was conducted on 70 articles. Discourse is “a specific ensemble of ideas, concepts and categorizations that are produced, reproduced, and transformed in a particular set of practices and through which meaning is given to physical and social realities” (Hajer 1995, p.44). In discourse analysis, written texts are analyzed to understand different meanings and perspectives on a specific subject matter (Johnstone 2017). The overall process followed to conduct the discourse analysis is summarized in Figure 1.

Figure 1. The Data Collection and Analysis Process

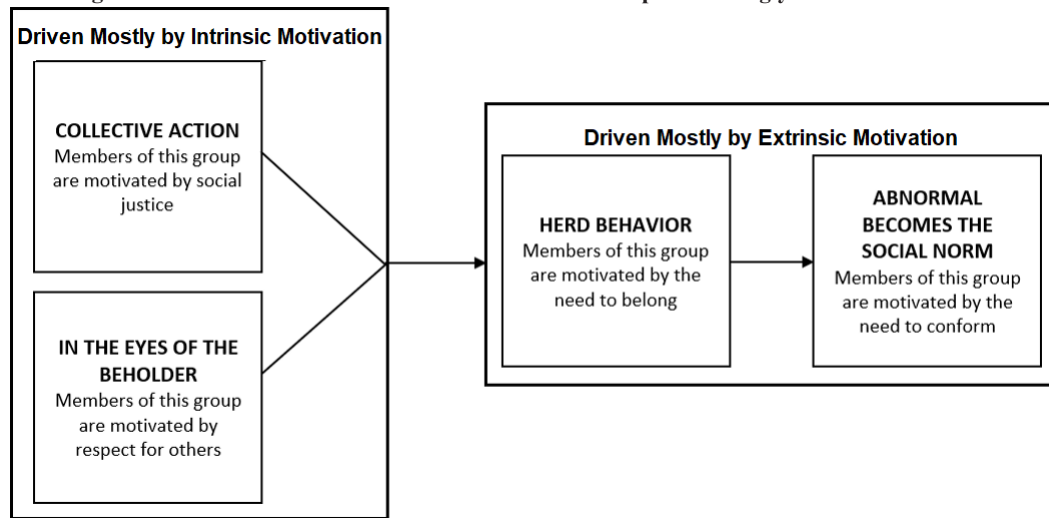

Phase 1	Phase 2	Phase 3	Phase 4
<p>- Internet search engines were used to look for articles published in fashion, entertainment, lifestyle, educational, and news websites.</p> <p>- The keywords entered into the search engines were texts/phrases such as "ugly trends", "ugly fashion", "ugly chic", "ugly luxury", "ugly designer brands", "celebrities into ugly fashion", "ugly is cool", "ugly is pretty", "ugly style", "ugly is elegant", and "ugly is popular"</p>	<p>- To make the data collection and analysis process more manageable, only those articles that appeared on the first ten pages of the search results published between 2017 and 2021 were taken into account for analysis.</p> <p>- A total of 100 articles were downloaded based on the title. Out of which 30 articles were removed because these articles were irrelevant to the topic or if they were relevant, they had the year, date, or author-related information missing. Finally, 70 articles that met the required criterion were chosen for the study.</p>	<p>- The initial analysis consisted of reading and re-reading the first 30 articles that appeared on the search results page.</p> <p>- Initial thoughts and ideas were put down and codes were generated.</p> <p>- The coded data was then collated and categorised into potential themes.</p>	<p>- The same steps were followed for the next 25 articles. The saturation point was reached after analyzing 55 articles.</p> <p>- To make sure the analysis was accurate, and that the themes were telling the right story 15 more articles were analyzed.</p> <p>- In total, 70 articles were analyzed (see Table 1). The analysis was a back-and-forth process done until the themes were clearly defined, and the storyline was well-organized about the data and topic.</p>

FINDINGS AND DISCUSSION

Figure 2. Motivations involved in the Creation and Acceptance of Ugly Fashion Trends

Discourse analysis resulted in the formation of the framework presented in Figure 2. Human behavior is driven by intrinsic and extrinsic motivations (Self-Determination Theory; Ryan and Deci 2002). Intrinsic motivation is when people engage in behaviors solely for internal rewards (e.g., growth, inner satisfaction) whereas extrinsic motivation is driven by external rewards (e.g., praise from others, popularity). The findings show that members of the collective action and in the eyes of the beholder groups embrace ugly fashion for internal rewards. In contrast, the herd followers and those that adhere to social norms get into the ugly fashion trends because of external rewards. These motivations are discussed in detail below.

Collective Action

Members of this group are motivated by social justice. Collective action is often a response to injustice, inequality, or a condition of disadvantage (Van Zomeren, Postmes, and Spears 2008). Wright, Taylor, and Moghaddam (1990) state that “a group member engages in collective action any time that he or she is acting as a representative of the group and where the action is directed at improving the conditions of the group as a whole” (p. 995). In the context of the present research, when the outgroup – the ugly/low-status group – is discriminated or treated unfairly; the outgroup members experience emotions like anger and sadness, which then propels them to take action to bring about the required social change (Social Identity Theory; Tajfel and Turner 2004). For example:

“What’s behind the staying power of ugly fashion? Some say it’s a reaction to decades of oversexualized women’s clothing, from high heels to bustiers and formfitting styles. Or in an era of Instagram influencers and selfies, it’s just another way to stand out in the feed or make a statement about nonconformity. It may be practical – some ugly fashions are pretty comfy – or a sign of a growing collective confidence with women wearing what they want. Whatever the cause, this fashion shift is giving women license to express individuality once deemed “unfashionable” – Kami Phillips, September 12th, 2019, CNN

Collective action redefines the low-status group and gives them a whole new identity. For instance, people are rejecting perfection and accepting imperfections. Some call ugly fashion a revolution or revolt against society’s unrealistic beauty standards. Ugly fashion

promotes inclusivity and diversity which makes people feel real and seen. Hence, people now want to be a part of the underrated group. This is exemplified in the following quote:

“The world at large is adopting the principle of embracing people who may otherwise be discriminated or marginalized by their differences or disabilities... In fashion, this can be likened to clothing and accessories typically worn by the “uncool kids” (think fanny packs and bucket hats) ...plus-sized (yay to more oversized clothing!) ... and even the poor (ripped clothing, anyone?) ... Inclusivity has become the new pop culture and the fundamental ethos in today’s world. Ugly fashion is just one evidence of that” – Natalie Khoo, May 30th, 2018, First Class

In the Eyes of the Beholder

Members of this group are motivated by respect for others. This group may not necessarily take part in a social protest. However, they do not tolerate any form of injustice or discrimination against others. The group strongly believes that change happens at an individual level. That is, each individual’s actions or choices impact society as a whole. In the context of the present research, the ideology of this group is that they see beauty in everything. They do not like to call anything ugly. These people argue that style is a personal statement and that one can express their identity in whatever way one wishes to. This group endorses the concept of feeling comfortable in one’s skin. The following quote captures these thoughts:

“What does “ugly” even really mean? We all have our own personal styles, and just because something is viewed as ugly by many doesn’t mean there aren’t people who think it is amazing. People choose to wear “ugly” clothes all of the time, whether they themselves agree that they are ugly or they see them as a genuine fashion statement...Those who embrace and express their true selves and true style, and choose to wear what they love, despite the opinions of others--and isn’t that what fashion is really about? Since we all have our own tastes, nothing can really be “ugly” – Maddie Casey, July 16th, 2018, The Avenue

Herd Behavior or The Bandwagon Effect

Members of this group are motivated by the need to belong. When prominent individuals, e.g., celebrities, the elite, influencers in society become a part of the collective action or in the eyes of the beholder group, people who admire these individuals decide to join the respective groups as well. This results in herd behavior (Banerjee 1992; Raafat, Chater, and Frith 2009; Shiller 1995) or what scholars refer to as the bandwagon effect (Leibenstein 1950).

Herd behavior or the bandwagon effect involves imitating or copying what everyone else is doing. In other words, I go where everyone else goes regardless of what I think. People tend to mimic the behaviors of others at both conscious and nonconscious levels (Bargh, Chen, and Burrows 1996; Chartrand and Bargh 1999; Van Baaren, Holland, Kawakami, and Van Knippenberg 2004). People also compare themselves with others whom they think are either similar or better than them (Social Comparison Theory; Festinger 1954). When popular celebrities, influencers, and the elites start promoting ugly fashion; their fans observe the behavior and immediately begin to do the same. Thus, ugly fashion suddenly becomes a cool trend that everyone is into. This is typified in the following quotes:

“Enter the ‘ugly’ trends that may have once been unflattering, but are now hot hot hot (thanks to our favorite A-listers)” – Brooke Hardington, August 29th, 2021, She Finds

“Celebrities have the kind of influence that turns totally unfashionable items fashionable. Whether it’s their innate sense of style or a really good stylist, they help us see the potential of a certain fashion item and how we can style it ourselves... Whenever celebs post outfit of the day (OOTDs) on Instagram featuring something we initially thought was hideous, our opinion immediately changes, and we proceed to imagine how the outfit would look on us. It’s like stars are saying, “Don’t knock it until you style it.” – Bluesky Quianzon, August 6th, 2018, The Fashion Spot

Abnormal Becomes the Social Norm

Members of this group are motivated by the need to conform. Herd behavior or the bandwagon effect results in the majority accepting the unusual trend. Members of this group realize that – non-confirming behaviors are rewarding (Bellezza, Gino, and Keinan 2014) – i.e., wearing clothing that was once despised can actually lead to others seeing them as being trendy, authentic, and cool. At this stage abnormal becomes the new normal. And so, the fourth reason behind the growth of ugly fashion can be credited to the change in social norms.

Social norms determine how people are supposed to behave or not behave in the world (Cialdini, Kallgren, and Reno 1991; Cialdini et al. 2006; Cialdini and Goldstein 2004; Cialdini and Trost 1998). Social norms change when society’s perception of a certain subject matter changes (Cialdini et al. 2006). For example, in the first half of the nineteenth century, the social norm was for women to wear tightly-laced corsets, dresses, and other clothing items that displayed high levels of femininity (Crane 1999). Women who broke this norm by wearing masculine garments, e.g., trousers or pant suits were labeled as defiant and arrogant (Crane 1999). However, in the second half of the nineteenth century as a result of the feminist and women empowerment movements, the attires that were once forbidden is no longer rejected by society. Today trousers/pants are a staple piece in a woman’s closet. People are hoping for the same change to take place concerning ugly fashion. People believe that if ugly trends be-

come popular or ubiquitous, then what was once perceived as abnormal becomes the social norm.

“Aesthetics be damned. Discerning eyes will adjust to the aesthetics; they always do. It takes time and patience, but now shredded jeans look normal and so do oversize silhouettes” – Robin Givhan, July 19th, 2018, The Washington Post

“There is something organic about ugly fashion. It springs up, like weeds growing in sidewalk cracks, and spreads outward until it’s consumed the entire parking lot—or, at least, until it begins to look less ugly, until our eyes become used to the eyesores” – Katy Kelleher October 30th, 2018, The Paris Review

FINAL THOUGHTS

The current research identifies the factors that influence people’s approval of ugly fashion trends. As noted in the beginning of this paper, philosophers believe that ugly negates beauty and that ugly exists only because beauty does. The collective action and eyes of the beholder groups aim to go against these historical and cultural notions of beauty in order to bring about diversity, equality, and inclusion within society. The motivation of the collective action and eyes of the beholder groups are intrinsic because they chose to embrace ugly fashion despite being prone to receiving negative responses/judgements from society. The motivation of the members of the other two groups – i.e. people who follow the herd and adhere to norms – are extrinsic because the intentions for adopting ugly fashion trends is clearly based on social acceptance.

In conclusion, yes! once ugly fashion becomes normalized, it is not likely to be viewed as pathbreaking as it once was. It can also be posited that ugly becomes the new beautiful. What happens next? Well, something that is deviant from the norm will be identified as the new unacceptable and the process of turning the ugly duckling into a beautiful swan is repeated.

The “Supportive Consumption” Movement in Japan: Consumers’ Age and Distance of Beneficiaries in Ethical Consumption

Takeshi Matsui, Hitotsubashi University, Japan

Akiko Masuda, Senshu University, Japan

Masayuki Tsumura, Kanagawa University, Japan

INTRODUCTION

The COVID-19 pandemic has impacted consumer behaviors enormously (Kirk and Rifkin 2020; Sheth 2020). One of the emerging movements observed in Japan is a form of ethical consumption called *ouen shohi* (supportive consumption; SC hereafter), which is defined as “consumption activities in which products and other items are purchased to support people, companies, and communities” (Kobayashi 2020). The SC movement has its origins in the 2011 Tohoku earthquake and tsunami crisis (Hidaka, Stanislawski, Mizukoshi, and Ohira 2021; Mizukoshi and Hidaka 2021). The term SC became so popular after the pandemic that it was selected as one of the Nikkei Marketing Journal (NMJ)’s hit products/trends of 2020 (Nikkei Marketing Journal 2020a, 2020b). Through the diffusion process of the word, the term SC has changed to mean helping those nearby in addition to others far away (e.g., the victims of the earthquake and tsunami), according to the text analysis of newspaper coverage of SC (Matsui, Masuda, and Tsumura 2020). Therefore, the term, which was coined approximately ten years ago, now implies support to both those near and far: some support restaurants and shops in their neighborhood by purchasing their take-out dishes and merchandise; NMJ reported that “the sentiment of not wanting to see the loss of a safe, favorite place to go has enlivened ‘supportive consumption’” (Nikkei Marketing Journal 2020b). Others support farmers and fishermen/women in distant places by purchasing their produce, as reported by NMJ: “supporting producers and others hit by the new Coronavirus” (Nikkei Marketing Journal 2020a).

The present study involves an exploratory survey regarding this relatively new ethical consumption phenomenon and contributes to the theories on whether consumers support those far away or near them. Previous studies have revealed various factors that motivate consumers to help distant others (Cavanaugh, Bettman, and Luce 2015; Wang, Kirmani, and Li 2021; Winterich, Mittal, and Ross 2009). We expect to provide novel evidence to update the discussion on beneficiaries’ distance. We surveyed consumers’ experience with SC and conducted quantitative analysis as well as interpretive and automated textual analysis.

We do not position this context as unique in Japanese or Eastern cultures; rather, this helping movement can be recognized as a representation of both Eastern and Western cultures, because Japanese society is in the middle of a transition to Westernization. It was said that giving behavior in Japan was less active compared to that in other developed countries (Ouchi 2004). However, the major natural disasters constantly experienced in Japan over the last two decades resulted in institutional development in the nonprofit sector, and there is currently a growing momentum to help others in various ways (Okuyama and Yamauchi 2015). For example, young people in Japan have little experience in consuming ethically compared to the elderly (Consumer Affairs Agency 2020), but they are actively involved in SC (NHK 2021).

Therefore, this exploratory study sheds light on the age of ethical consumers. One of the current study’s findings is supported by previous research: the younger generation are more self-interested, and the older generation are more altruistic (Gilg, Barr, and Ford 2005; Granzin and Olsen 1991; Roberts 1996). More importantly, the analysis shows that the former tend to support those in their immedi-

ate neighborhood, and the latter also grow to help those in distant places. The study also suggests that older ethical consumers have a broader perspective than do younger consumers. The results of our analysis contribute to the theory of ethical consumption and the distance of beneficiaries by showing the dimensional importance of the age of consumers.

Distance of Beneficiaries and Ethical Consumers’ Age

Previous studies have demonstrated that consumers are more inclined to help those nearby than those far away (Cavanaugh et al. 2015; Wang et al. 2021; Winterich et al. 2009). However, various factors motivate them to support distant others, such as feminine and moral identity (Winterich et al. 2009), a feeling of love (Cavanaugh et al. 2015), and residential mobility (Wang et al. 2021). CRM researchers are also interested in the impact of the geographic proximity of the cause on consumers’ attitudes toward CRM firms, and the findings reveal that consumers think the local causes are more important than the national and global causes (Grau and Folse 2007; Varadarajan and Menon 1988).

The context on which we focus suggests that age can also be a booster of supportive behavior toward distant others. The influence of the factor of consumers’ age has not always received sufficient attention in studies concerning ethical consumption, while there has been a fair amount of research on organizational age and their intention to give to charity (Bekkers and Wiepking 2011). Some exceptional studies show that the age of consumers explains differences in ethical consumption. Older generations are more likely to donate and prefer reusable products (Granzin and Olsen 1991), to buy somewhat more responsibly (Roberts 1996), and to be more committed environmentalists (Gilg et al. 2005) when compared to younger generations. Contrary to these findings, the research on volunteering shows that younger generations are more likely than older generations to perceive career benefits and a sense of accomplishment in volunteering (Briggs, Peterson, and Gregory 2009). However, this finding suggests that the younger generation are more self-interested than the older generation. In addition to these studies on ethical consumption, the meta-analyses of psychological studies reveal that the elderly are altruistic (Sparrow et al. 2021). However, much remains unclarified about the relationship between distance from the person being helped and the age of the supporter.

METHODOLOGY AND DATA

We conducted an explanatory questionnaire survey with consumers who had experienced SC, following which we carried out quantitative analysis and interpretive and automated textual analysis of the survey results. To understand the context better when designing the questionnaire, we scrutinized 120 newspaper articles on this topic by searching using the keyword *ouen shohi* (supportive consumption) in Nikkei Telecom between January 2011 and September 2020.

The dependent variable in the quantitative analysis was the motivation for SC. We adopted the SHIFT framework, which is a comprehensive framework for conceptualizing sustainable consumer behavior change (White, Habib, and Hardisty 2019). The acronym SHIFT reflects the five factors that encourage more sustainable

consumer behaviors: "Social influence," "Habit formation," "Individual self," "Feelings and cognition," and "Tangibility" (White et al. 2019). A total of 19 items from the five factors were replaced with questions that fit the context of SC based on our review of the newspaper articles (see Table 1). For example, the item Self Efficacy, which is one of the important factors when it comes to doing good (Västfjäll, Slovic, Mayorga, and Peters 2014), is defined as "beliefs that the individual can engage in the required action and that carrying out the behavior will have the intended impact" (White et al. 2019, p. 28). It was replaced with the statement "Because I thought that my supportive consumption would definitely help those in need." The respondents were asked to specify the extent to which they agreed with each statement on a five-point Likert scale.

Through the exploratory analysis, attitude toward SC and age were ultimately selected as independent variables. We used the Helping Attitude Scale (HAS) to assess the attitude; this is a 20-item measure of broader helping attitudes regarding helping beliefs, feelings, and behaviors (Nickell 1998). These questions are also accompanied by a five-point Likert scale. Following the previous study that used HAS (Kwak and Kwon 2016), we divided the respondents into two groups by median value of the score. We labeled them as High or Low, respectively. The respondents were also categorized, based on their age, into three groups to show the big picture of the influence of age on SC: Young for those in their 30s or younger, Middle for those in their 40s to 50s, and Old for those in their 60s or older.

This survey was conducted online in February 2021 among people aged 15 and older residing in Japan. From a panel of 4,000 consumers, equally allocated by gender and age, we obtained 1,235 samples who had experienced at least one SC and agreed to join the survey. We then excluded invalid respondents such as those who selected the same options for all the questions, including reverse score items, and those who gave unmeaningful answers to the free-answer question. The final screened data set comprised 777 samples (mean age of 42.7 years, 406 females and 371 males).

In addition to the multiple-choice questions on the SHIFT and the HAS scales, the free-answer question "What is your most memorable story about SC?" was also asked.

FINDINGS

Quantitative Analysis: Motivation for SC

With regard to analysis, the applicable items from the 19 SHIFT items were categorized as altruistic or self-interest motivations (Table 1). The former were "Self-concept" (S9), "Self-consistency" (S10), and "Self-efficiency" (S12), while the latter were "Social desirability" (S3), "Incentive" (S7), "Self-interest" (S11), "Negative emotion" (S13), "Positive emotion" (S14), and "Framing" (S17).

We first conducted ANOVA to identify differences in the motivation for SC between the High and Low HAS score groups. The significant motivation was altruistic. The altruistic variable ($\alpha=.628$) was more significant in the High group ($M_{\text{high}}=3.54$ $SD=.648$) than in the Low group ($M_{\text{low}}=3.02$ $SD=.706$; $F(1, 775)=114.216$, $p<.001$). However, the self-interest variable ($\alpha=.757$) was not more significant for the High group ($M_{\text{high}}=2.86$ $SD=.762$) than for the Low group ($M_{\text{low}}=2.79$ $SD=.686$; $F(1, 775)=1.656$, $n.s.$). These results are natural because High is altruistic enough to have a strong motivation for SC.

Second, we conducted ANOVA to identify differences in the motivation for SC by age group. In the case of altruistic motives, the younger generation ($M_{\text{young}}=3.22$ $SD=.841$) were characterized by lower scores than the older generation ($M_{\text{middle}}=3.28$ $SD=.647$; $M_{\text{old}}=3.42$ $SD=.539$; $F(2, 774)=2.720$, $p=.067$). On the other hand, for self-interest motives, the younger generation ($M_{\text{young}}=2.99$ $SD=.739$)

scored higher than the older generation ($M_{\text{middle}}=2.69$ $SD=.705$; $M_{\text{old}}=2.73$ $SD=.618$; $F(2, 774)=16.566$, $p<.001$).

The analysis showed that the younger generation had a stronger self-interest motivation than the older generation. They were more likely to engage in SC because of the "Social desirability" (S3) to impress others and show that they are good people ($F(2, 771)=9.053$, $p<.001$). They also engaged in SC because of "Incentives" (S7), such as rewards, discounts, and prizes ($F(2, 771)=25.395$, $p<.001$). It was also evident that they performed SC because they felt "Negative emotion" (S13), such as guilt for not providing support ($F(2, 771)=4.531$, $p=.011$). Furthermore, they performed SC due to "Framing" (S17), when they learnt that, if they did not offer support, they would not be able to obtain that product or service in the future ($F(2, 771)=5.510$, $p=.004$). These were all self-interest motives, with higher results for the younger generation than for the older generation.

The younger generation also engaged in SC for reasons other than self-interest and altruism. "Social identities" (S2) was a factor that prompted the respondents to engage in SC when they knew their close friends and others did as well ($F(2, 771)=6.973$, $p=.001$). "Labeling" (S16) was also a reason for SC when the label "supportive consumption" was used in the description of the product ($F(2, 771)=6.242$, $p=.002$). Younger consumers responded more to the influence of others and the label SC than did older generations.

Interpretive and Automated Text Analysis: Stories of SC

In order to assess the answers to the free-answer question regarding stories of SC, we applied a mixed method. We first conducted interpretive analysis; three co-authors from different genders and generations coded, interpreted, and discussed the text data

(Belk, Fischer, and Kozinets, 2013). Automated text analysis was then applied with the KH Coder – the most widely used freeware for morphological analysis and text mining of the Japanese language (Higuchi 2014).

The top ten most frequent words in the answers were “purchase” (268 times), “think” (144 times), “buy” (136 times), “support” (116 times), “Corona” (105 times), “restaurant” (90 times), “supportive consumption” (85 times), “store” (84 times), “product” (81 times), and “vegetable” (81 times). These major keywords reflect the characteristics of the SC movement.

We conducted correspondence analysis to understand how the different categories of respondents based on HAS and age answered the question. For this purpose, we created six categories of respondents by combining the two categories of HAS (High and Low) and the three age categories (Young, Middle, and Old). Each of the six categories was labeled as in Figure 1: for example, L_Y refers to the Young with a Low HAS score. The keywords closest to each group were their expressions in their responses.

The analysis showed that the young generation tend to support relatively local businesses, while the older generation tend to help those in the distance.

The keywords “Take-out,” “Lunch bag,” “Local,” and “Friend” were positioned around the area where H_Y, H_M, and L_Y were located (Figure 1). These positionings suggested that the younger generation tend to support local business and their acquaintances. One of the L_Y answered that “A person I know runs a restaurant business, so I bought a lunch box to help him/her as much as possible.” Similar answers were found in the young and middle age groups: “I heard that a local Chinese restaurant was in danger of closing, so I continued to buy dinner for one person from the early days of their take-out service” (H_Y), and “My favorite restaurant was hit hard by the coronavirus and was on the verge of extinction, so I ate the most expensive course meal out of a desire to support the

restaurant.” (H_M). Some of these consumers, however, also supported distant others. For example, one of the H_M answered that “Because I learned that the producers of the foods I usually buy were affected by the earthquake and typhoon. I bought seafood and fruits several times.”

On the other hand, the keywords “Disaster-hit area,” “Fukushima,” “The Great East Japan Earthquake,” and “Region” were positioned around the area where H_O was located (Figure 1). The results show two different and overlapping perspectives shared among the older generation. First, the first three keywords suggested that they have their gaze on victims who are far away rather than those who are closer to them. For example, one of the H_O respondents stated that “After the Great East Japan Earthquake, harmful rumors spread about Fukushima due to radiation leaks, so I bought Fukushima produce every month. The inspection results of the agricultural products were fed back to me.” Second, the contrast whereby “Region” was positioned around the older generation and “Local” was positioned nearby the younger generation suggested that the older respondents have a broader perspective and worldview than do the younger ones. One of the H_O group answered, “When I saw a news report that apples in Aomori Prefecture were being left unharvested because there were not enough buyers, I wanted to support them as much as possible, so I informed everyone in the community association, and we made a joint purchase. I became friends with the local people in the association, and we decided to purchase apples every year. I think it helped a little.” This respondent works with others in his local communities to support those in the distance. Such a broad perspective and scope of action, which includes the distant and the near, is difficult to find among the younger generations.

FIGURE 1

Correspondence Analysis of Free-Response Question: Your Story of SC

DISCUSSION

The results suggest that another dimension should be incorporated into the theoretical framework on ethical consumption and beneficiaries' distance: age. To summarize the above findings, the younger generation consumers support from a self-interested motive perspective. They tend to support those in their immediate neighborhood, while the older generation help those in distant places as well as those nearby. The findings further suggest that older ethical consumers have a broader perspective on society than do their younger counterparts. These findings on SC contribute to the theoretical development of consumers' charitable behaviors and CRM. The extraordinary situations created by COVID-19 overturned the assumption of the extant research; as shown in our case, not only beneficiaries but also supporters became victims, being, for example, deprived of their freedom of movement, and so charitable behaviors in such situations should be treated as a multifaceted phenomenon (Nowakowska 2021).

Because the SC movement in Japan is a relatively new phenomenon, we employed the explanatory approach to gain first-hand insights into the various aspects of the movement using quantitative and text-analysis methods. However, this study has three limitations to overcome. First, in our qualitative analysis, we showed only a correlation of the motivation for SC between the High and Low HAS score groups and age groups, and we need to illustrate their causality. Second, we adopted only three age categories to gauge the big picture of age differences, and we need to conduct our analysis using ages as a continuous variable. Third, although we treated this single context as a representation of both Eastern and Western cultures, we need to observe other contexts to achieve a comparative analysis, such as differences between the East and the West. Based on such extended observation, further theorization on the relationship between ethical consumers and the recipient of their support will be needed.

Consumer Noncompliance in Compliance-Dependent Services

Mr. Jared Wong, Yale University, USA

Dr. Stephanie Dellande, Menlo College, USA

INTRODUCTION

Service researchers and practitioners often face the challenge of gaining consumer compliance necessary for the provider to complete the service delivery process and for the customer to achieve their goal (e.g., become debt free, improve physical fitness, etc.). While consumers may recognize the value of compliance (Bowman and Seetharaman 2004), noncompliance with a recommended protocol can be more likely than compliance for certain long-term services (Celsi et al. 2017), particularly for compliance-dependent services (CDS). CDS are long-term services in which the customer participates in co-creation during the face-to-face provider-customer exchange and must continue to carry out their role for an extended amount of time once away from the provider to realize the desired outcome (e.g., weight loss or completing undergraduate education) (Dellande and Nyer 2013). However, even in life-and-death situations, noncompliance may be as high as 80% (Hausman 2001).

Noncompliance to recommended protocols in certain CDS may lead to consequential, less-than-ideal outcomes (e.g., a poor running automobile), whereas noncompliance in other types of CDS (e.g., substance abuse) may lead to detrimental, harmful outcomes (Trujillo Torres and Dellande 2015). The present investigation focuses on service provisions with noncompliant outcomes that are consequential but not detrimental, such as in the case of auto maintenance.

Consideration of how consumers neutralize their noncompliant behavior advances our understanding of why consumers fail to follow the recommended protocol prescribed by the service provider. Specifically, the present research details 14 key neutralization (i.e., rationalization) themes that arose from a qualitative study of non-compliant participants, which contrasts with extant research that has primarily examined noncompliance as an outcome of the provider's characteristics or attributes (e.g., provider expertise or attitudinal homophily) (Dellande, Gilly, and Graham 2004). The insights gained from this investigation may be instructive as researchers and practitioners design more effective service delivery processes for CDS.

Neutralization Theory

The theoretical framework used in this investigation into non-compliance stems from neutralization theory, which provides a conceptualization of the way individuals rationalize or justify their behavior. Neutralization theory has been applied to the consumer behavior context (Brunner 2014; Gruber and Schlegelmilch 2014; McGregor 2008; Sharma 2020), whereby researchers have considered neutralization of fraudulent consumer behavior for liberal return policies (Rosenbaum and Kuntze 2003) and for personality-based antecedents for consumer misbehavior (Harris and Dumas 2009), including consumer alienation, Machiavellianism, sensation seeking, aggressiveness, and self-esteem (Daunt and Harris 2011).

We find neutralization theory to be a useful framework for understanding consumer noncompliance behavior, as noncompliance can be reasonably classified as a form of misbehavior (i.e., not fol-

lowing a recommended protocol). The present research takes the perspective of the consumer to investigate the ways individuals neutralize their noncompliant behavior in the context of a consequential CDS.

METHODOLOGY

Through qualitative methods, we elicit the rationale—as conceptualized through the framework of neutralization theory—consumers give for their noncompliance. The consequential (but not detrimental) example of auto maintenance is a fitting context that provides a domain for an investigation into noncompliance, as the use of a vehicle is a wide-spread practice throughout the world, yet many individuals do not follow a recommended auto maintenance protocol (e.g., regularly rotating tires, changing oil and filter, etc.) (Malaj 2016). The Pew Research Center found that 89% of Italians, 88% of Americans, and 83% of South Koreans own at least one car (Poushter 2015). Given the near-ubiquitous use of personal vehicles for transportation purposes in many countries, auto maintenance is an applicable and practical CDS for which to explore consumer non-compliance.

Participants and Methods

A qualitative instrument was distributed through Amazon's Mechanical Turk (MTurk); women comprised roughly 40% of the 43 participants ($M_{age}=25-34$, $M_{income}=\$26,501-\$65,300$, $M_{price\ of\ daily\ car}=\$0-\$10,000$). The qualification for participating in the study was that the respondent owns an automobile but does not follow a regular auto maintenance routine (examples of auto maintenance protocols were given, such as regularly checking tire pressure). We used a projective technique found in past consumer behavior research (Marshall and Rossman 2014), as the context represented instances in which consumers may have difficulty expressing their feelings (e.g., in the case of noncompliance) (Hofstede et al. 2007). Two scenarios were administered: First, the participants were shown an image of a woman standing next to a broken-down car and were asked to construct a story based on the image provided. Next, the participants were given a secondary projective scenario, without an image, based on the description of a man who needed to get to work but whose car is experiencing mechanical issues. Participants were asked to construct a story for both scenarios. Justification for the choice of the stimuli comes from the desire, within-subject, to provide both visual and written projective scenarios, in addition to including both male and female stimuli (the inclusion of which, explored later, in itself resulted in a neutralization theme). Respondents were required to write at length (over 1,000 characters).

Following the recommendation for thematic analysis (Colaizzi 1978), special attention was given to the rationale behind reasons for noncompliance or the projected context onto the hypothetical situations that led to noncompliance. Ultimately, 14 major themes emerged from the projected descriptions from the 43 participants (see Table).

Table

The 14 Themes of Neutralization of Noncompliant Behavior

Code Number and Title	Description	Examples
1. Lack of financial resources	Noncompliance behavior due to lack of money to engage in prescribed regimen	1. "She didn't have a lot of money to take care of everything properly" (Participant 1) 2. "She can't afford any extra expenses right now..." (Participant 16) 3. "...she doesn't have enough funds at the moment..." (Participant 7)
2. Bad timing	Observation that noncompliance consequences occur at inconvenient times	1. "...as she was late for a meeting." (Participant 41) 2. "She will be late for her interview." (Participant 40) 3. "Sally knew she would be late for her big presentation." (Participant 15)
3. Possible prevention	There is personal agency in taking responsibility for the consequence	1. "If you do not pay attention to vehicle maintenance your vehicle is at higher risk for major faults developing in the engine and other components." (Participant 25) 2. "This is a type of situation that could have been easily prevented if the women had done regular inspections and service for her Car [sic]..." (Participant 30) 3. "All of this could have been avoided had Becky learned some basic car knowledge and upkeep." (Participant 34)
4. Random event	Regardless of maintenance, the consequence would have occurred	1. "It's not possible to know whether routine maintenance would have helped her avoid this situation." (Participant 18) 2. "...most likely the maintenance wouldn't have found this problem anyway." (Participant 42) 3. "However, it is also possible that some other issue has occurred that may have been a breakdown not caught by preventative maintenance." (Participant 23)
5. Transportation alternatives	Alternatives, such as a taxi, friend, or ride-share service, are readily available	1. "She called her sister to pick her up." (Participant 4) 2. "Then he will have to take a taxi to school..." (Participant 5) 3. "...so I picture him getting an Uber..." (Participant 6)
6. Available information	Information from Google or YouTube are easily obtainable	1. "He was able to check the transmission fluid after watching a youtube [sic] video..." (Participant 22) 2. "...Thomas looks up 'car won't start' videos on Youtube..." (Participant 33) 3. "...does a google search for what causes a car to not start." (Participant 43)
7. Impede quality of life	Noncompliance consequences significantly disrupt life	1. "Becky removed the radiator cap only to sustain severe burns to her left hand." (Participant 34) 2. "He is going to have to cancel some plans later that day and maybe even later that week if he has no car." (Participant 6) 3. "He still lives at home [and] has some stress issues..." (Participant 34)
8. Reliance on insurance companies	Companies, such as AAA, are always there to help	1. "...she realized that she had AAA...[and] dialed the number that was on the card." (Participant 4) 2. "...she called AAA and have [sic] them details of her location." (Participant 14) 3. "...she then called AAA (thank goodness she renewed that membership!) to tow her car" (Participant 21)
9. Gendered asymmetric expectations	Different compliance behavior and levels of knowledge based on gender	1. "...I know women are not that savvy in car maintenance..." (Participant 2) 2. "...she has no idea what to do, being a woman and all." (Participant 37) 3. "This would most likely be a man because she thinks they are the most knowledgeable about cars." (Participant 39)
10. Resolution of changed behavior	A promise to comply to the regimen in the future	1. "...she wouldn't let it happen again." (Participant 8) 2. "Tom vows to never ignore any warning lights again..." (Participant 21) 3. "Thomas learned a lesson the hard way and will absolutely pay attention to the car's check engine light in the future." (Participant 14)
11. Lack of knowledge	Noncompliance due to not knowing how to perform the prescribed regimen	1. "...he realizes that he really doesn't understand any of the components or even know what to look for." (Participant 19) 2. "Thomas can pretend that he can try to find the culprit under the hood, but he really has no idea what to do." (Participant 21) 3. "He doesn't have the first idea about cars at all." (Participant 40)
12. Financial damage	Noncompliance leading to costly consequences	1. "...she was looking at big repair bill [sic]." (Participant 26) 2. "The cost might exceed the value of the car." (Participant 28) 3. "He couldn't really afford this and was forced to move back with his parents." (Participant 34)
13. Emotional distress	Noncompliance leading to stress	1. "...was panicking thinking her car was on fire." (Participant 31) 2. "Feeling enraged, frustraed [sic] and yet utterly defeated..." (Participant 33) 3. At the shop she gets the bill and cries." (Participant 38)
14. Reliance on auto shop/mechanic	Auto shops or mechanics always available for help	1. "Next she needs to call her mechanic..." (Participant 43) 2. "...so he has to trust the mechanic and they might even rip him off and there's nothing that he can do." (Participant 6) 3. "...so he calls a mechanic to see if he can give him a jump..." (Participant 7)

As seen in the Table, each code is accompanied with an operationalization that provides the definitional requisite for the theme.

Results and Discussion

We propose 14 key themes through thematic analysis that differ from how noncompliance has previously been conceptualized in the literature. Through allowing the participants to write at length about different auto maintenance scenarios—and using neutralization theory as the basis for the analysis—major themes pervasive in the data were identified, capturing the most prevalent rationales for noncompliance. Below are the five (of the 14; see Table) most prominent themes from the analysis.

Possible Prevention. By and large, the most common theme in the writing samples were mentions that the hypothetical situations proposed could have been prevented. To note, these responses were from consumers who do *not* follow the recommended protocol for auto maintenance. Nonetheless, the majority of the respondents explained that auto maintenance works to prevent possible issues. There was a willingness to admit the need for maintenance, and yet the cognitive acknowledgement does not transfer into behavior. Thus, noncompliance does not stem from ignorance: If so, the respondents would likely not so readily admit that prevention is even a possibility. On the other hand, a small minority of respondents did feel this way. For example, Theme 4 (random event) stands in direct opposition to possible prevention. As Participant 18 explains, “It’s not possible to know whether routine maintenance would have helped her avoid this situation.” This reluctance to connect maintenance and successful outcomes may be the most obvious explanation for noncompliance. A consumer who does not believe that the prescribed protocol would benefit them will naturally avoid completing the regimen. This, however, does not capture what the data reveal. Instead, noncompliant consumers are, on average, not unaware of the potential benefits of the protocol. Rather, they fail to comply despite knowing that an unfortunate event may result from their inaction. Some consumers, however, neutralize their noncompliant behavior by suggesting that compliance does not lead to goal fulfillment as a method of justification; others use different neutralization techniques explored below.

Transportation Alternatives. With the proliferation of rideshare companies such as Uber or Lyft (Dudley, Banister, and Schwanen 2017), what appears is a general feeling that this alternative provides an easy and accessible option that removes the necessity for auto maintenance. The presence of readily available alternatives provides an example of another neutralization technique that consumers use. There is always a backup plan and therefore compliance is not necessary. In an era without these services, one can surmise that there may have been a greater emphasis placed on maintaining one’s car, as that car represented the only readily available option for transportation other than public transportation. Now, with access to transportation through one’s smartphone, auto trouble simply could mean deferring to rideshare companies to get around. More broadly speaking, noncompliance may be a viable option for consumers if there exists an alternative that is readily available. In other cases of readily available alternatives, gastric bypass surgery may stand in as an easier alternative for weight loss, and e-cigarettes may be an alternative for smoking cessation. These alternatives are not without drawbacks: Taking an Uber may be expensive, weight loss surgery has many health complications (Podnos et al. 2003), and e-cigarettes still may be harmful (King et al. 2020). However, the existence of an alternative removes the absolute necessity for protocol adherence and instead yields opportunities for noncompliance.

Lack of Knowledge. In past compliance research, it has been demonstrated that an important determinant for compliance is the

service provider’s knowledge and expertise (Dellande et al. 2004). However, compliance may also depend on the consumer’s level of knowledge. One rationale for noncompliance is that the consumer did not know what to do, who to go to, or when to go for help. While a knowledgeable consumer may know when a car gives off an indication (through sounds, on-screen computers, etc.) that the car needs maintenance or inspection by a professional, an unknowledgeable consumer may simply not be able to recognize these signals. This may lead to noncompliance out of ignorance. It is important to note, however, that this is not the same as not knowing that compliance can lead to prevention. Instead, this theme specifically describes when consumers do not know the recommended protocol or when the protocol should be followed. These consumers, on the other hand, may still acknowledge that compliance can be a preventative measure. In this context, an ignorance neutralization is used to justify noncompliance.

Financial Damage and Emotional Distress. A major result of noncompliance, according to the respondents, is the financial damages incurred from the cost of repairing the car. Some note that these financial damages may exceed the cost of following the protocol (i.e., regular maintenance). It is interesting to note that financial damages were only one of the reported consequences of noncompliance. The other was emotional distress. These together were the expected outcome of not following the protocol. For the consumer, noncompliance could result in a large bill or increased stress. Likewise, these constructs are not mutually exclusive. It was noted that stress can arise from financial damages but also that financial damage could arise from stress; nevertheless, noncompliance prevailed.

Asymmetric Gendered Expectations. The most surprising theme that came from the data was misogynistic comments that peppered the writing samples. Some writing samples expounded women were, in some sense, given a pass for noncompliance in auto maintenance, citing different gendered expectations between men and women for the assumed knowledge or interest in cars. There is an equal need for transportation for men and women. In this sense, both men and women should have equal need in maintaining a working car. However, some respondents discounted the fact that women can also follow a recommended protocol of auto maintenance. Other contexts of compliance may also be influenced by these gendered expectations. For an example in which men may get a pass for noncompliance is in the context of weight loss, in which there is more societal pressure for women to be slim (Stice, Trost, and Chase 2003). These societal expectations do not obfuscate the fact that men still incur many health complications from being overweight, including liver or heart disease. As such, one neutralization technique is to absolve one’s responsibility to comply by pointing out supposed gender differences.

General Discussion and Limitations

We investigated how consumers neutralize their own noncompliant behavior in the context of a CDS (auto maintenance). Five primary ways unique to how consumers neutralize noncompliance were identified: (1) *transportation alternatives*—participants state that there is always a backup plan and therefore compliance is not necessary, (2) *possible prevention*—participants admitted to the need for auto maintenance, and yet the acknowledgement does not lead to behavior, (3) *lack of knowledge*—such that the consumer did not know what to do, who to go to, or when to go for help, (4) *financial damage and emotional distress*—study participants noted that stress can arise from financial damages but also that financial damage could arise from stress; nevertheless, noncompliance prevailed, and (5) *asymmetric gendered expectations*—some participants indicated that women were given a pass for noncompliance in auto

maintenance, citing different gendered expectations between men and women.

Consideration of noncompliance from the perspective of the consumer allows both researchers and practitioners to move beyond the focus on provider characteristics (e.g., provider expertise or attitudinal homophily) (Dellande et al. 2004); instead, the service delivery process can address consumers' neutralization of noncompliance. Specifically, whereas past research may suggest that consumer compliance should be gained through increasing the level of expertise exhibited by the service providers (e.g., through employee education programs), our research findings offer alternative managerial implications, such as engaging in degendered marketing communications that emphasize the need for *all* consumers to, for instance, check their tire pressure (i.e., not just men). Furthermore, firms can acknowledge alternatives to their services but express the financial costs that are incurred from these alternatives (e.g., auto repair centers can emphasize the cost of using a ride-share service if one's car is malfunctioning).

One limitation of the study includes investigating only a single type of CDS. Future research could examine other contexts, such as smoking cessation, weight loss, education, or dental care. In addition, future research could investigate the stress consumers experience associated with being noncompliant, particularly due to resource constraints, like the time limitation of a manager or financial constraint of a low-wage worker. Yet still, the importance of material value may play a role in noncompliance. For example, the cost of a consumer's car may predict noncompliance, where someone who can afford a luxury car may not be as adversely impacted by noncompliance with the auto maintenance protocol, as they may have more than one functioning car. Alternatively, consumers with an expensive car may be more compliant given that the financial costs from noncompliance are higher for luxury cars.

This study is also limited by the lack of comprehensive psychometric measurements of the consumers to explore what personality attributes or characteristics are most associated with noncompliance. Indeed, perhaps certain personality traits can predict noncompliance, in which case, these personalities may benefit from alternatives to uninterrupted long-term compliance. As Jiang, Dellande, and Canniff (2020) determined, consumers can take a break from compliance and still be successful at goal completion. In fact, counterintuitively, service providers might plan for potential acts of noncompliance in their service delivery process. In sum, the findings of how consumers neutralize their noncompliant behavior in which the outcome of noncompliance is merely less than ideal, such as in automotive care, may prove useful to providers of CDS.

Myth

Mr. Thomas Broberg, Sweden

INTRODUCTION

Myths, symbols and signs embedded in modern life that naturalise hidden ideologies and implicit meanings that affect our thought and behaviour (Barthes 2009), entered the field of marketing and consumer research with Levy's (1981) inaugural paper. Myth today is an integral part of marketing theory and practice. Advertisers draw on myths to smooth over cultural contradictions and anxieties and make consumers feel better about their identities (Holt 2004). But, as Thompson (2004, p. 162) writes, "mythologies are not just for advertising anymore."

One could think of myth as a deeply held belief that is shared by a group of people (Levy 1981). Myths are often described as commonly told tales that hold a social group together (Hirschman 2000; Luedicke, Giesler, and Thompson 2010; Stern 1995). These stories (e.g. royals have blue blood) are passed down through millennia, inspiring writers and artists as versatile as Shakespeare and Walt Disney. As Stern (1995, p. 183) points out, myths "are as old as humanity, yet constantly renewed to fit contemporary life." Myths are central to all cultures across history, and are deeply embedded in the cultural DNA of the West (see, for example, Fry 2017). Consumers invoke myths as a response to the vast levels of disenchantment that saturate modern life (Brown, Kozinets, and Sherry 2003). Alongside cultural narratives and ideologies, myths also constitute an essential topic in CCT (Arnould and Thompson 2005). However, few attempts have been made to synthesise the stream of consumer research on marketplace mythology.

We begin with a brief review of previous research on marketplace mythology, highlighting the distinction between consumer myths and commercial mythmaking. The findings are presented around nine interrelated themes that were derived from 301 articles published in the *JCR*. We conclude with suggestions for future research on marketplace mythology in terms of brand storytelling, co-mythologisation, and the role of myth in the polarisation of consumer culture.

MARKETPLACE MYTHOLOGY

"Mythologies," Thompson (2004, p. 162) argues, "permeate consumer culture." They consist of universal archetypes and plot-lines that serve as metaphors for consumers to navigate between different ideological agendas. More precisely, Thompson (2004) draws on the natural health marketplace to illustrate the interrelationship between cultural mythologies, marketplace structures, and consumers' interpretive strategies. To make sense of the market offerings (e.g. alternative medicine, Hummer cars), Thompson (2004) found that consumers would often rely on metaphors, such as mythic constructions of nature vs. technology, that circulate in mass media and the marketplace (also Canniford and Shankar 2013).

From this perspective, marketplace mythology consists of communal beliefs that certain lifestyles are associated with higher levels of stress (Belk and Costa 1998), postmodern alienation (Firat and Venkatesh 1995), and disenchantment (Kozinets 2002). Marketplace mythology shaped by enterprises is largely the marketer's attempt to tap into consumer beliefs. For example, Thompson (2004) highlights the myth of humanity's fall from grace, as represented in the tale of Adam and Eve, and its enduring influence on Western cultural

beliefs. Natural health marketplace mythology, Thompson (2004) points out, draws from this archetypal cultural narrative to distinguish itself from mainstream science medicine.

Moreover, the same marketplace mythology may generate different metaphoric alignments serving conflicting ideological agendas, which leads to mythological instabilities and polarisation of consumer culture (Södergren 2022). In other words, ideological conflict can arise between different mythic formations (Luedicke, Giesler, and Thompson 2010). As an example, Thompson (2004) illustrates ideological conflict within the natural healthcare mythology, which, on the one hand, is based on the Romantic revenge-of-nature trope; and, on the other hand, a Gnostic perspective that science and technology are divine tools that enable humanity to attain her rightful dominion over nature. In today's consumer culture, such polarisation ranges from topics including attitudes towards electric scooters (Choron and Sakran 2019), food diets (Östberg 2003), and plastic surgery (Chalmers and Price 2009) to anti-vaxxers vs. supporters of vaccination (Berman 2020). In our increasingly polarised consumer culture, mythic interpretations are constantly contested by countervailing ideological discourses, which calls for rejuvenated attention to marketplace mythology.

Consumer Myths

Stern (1995) draws on the work of literary theorist Northrup Frye to demonstrate that four mythic plots—tragedy, irony, comedy, and romance—structure consumers' self-mythologising narratives. Following Stern (1995), myths are seen as the stories consumers tell to uncover the consumer values that advertising stories tap. From this structural perspective, consumer interpretation is subconsciously informed by universal stories of "birth/death/rebirth associated with nature's seasons and the human life cycle" (Stern 1995, p. 166).

For example, advertisements that appeal to consumers' sentimental or nostalgic longings are often successful because of the associations consumers make to romantic plots and narratives. Likewise, Brown, McDonagh, and Shultz (2013) illustrate how tragic plots of disaster and death (e.g. Titanic) resonate with consumers because of their ambiguous endings. Stern (1995, p. 167) summarises,

"Comedy ends in joy, and its correspondent value is happiness; tragedy ends in sadness, and its value is wisdom; romance ends in nostalgia, and its value is ideal peace or beauty; and irony ends in surprise, and its value is excitement."

In their study of consumption rituals during Thanksgiving, Walendorf and Arnould (1991) describe how consumer myths include elements of all plots in Frye's taxonomy. In one family, for example, the father cut himself with a knife while carving the traditional stuffed turkey, whereupon the holiday is associated with disaster. Hence, Stern (1995, p. 178) notes that advertisements that appeal to tragedy often use "a fear approach to enable the user to prevent an unhappy outcome." What is more, consumer stories are not limited to rituals; Stern (1995, p. 183) concludes that "the analysis of myths across consumer stories, including those told about nonceremonial occasions, everyday product purchases, and deviant consumption, is a promising direction for future research."

Brown, McDonagh, and Shultz (2013, p. 596) point out that previous consumer research has provided two explanations to why certain myths are “eagerly embraced by consumers and integrated into their lives, whereas others fail to strike a chord and ring true.” The first is rooted in *structuralism* and the notion of universal plots and archetypes (Stern 1995). A second explanation is more *post-structural* and related to consumer identity projects vis-à-vis social institutions and discourses of power (Thompson 2004). A few scholars, including Russ Belk, have studied consumer myths from an *existential* perspective (Belk and Costa 1998; Higgins and Hamilton 2019). However, the existential research stream on consumer myths remains relatively scant compared to structural and poststructural approaches.

Commercial Mythmaking

Commercial actors also compete to create myths that shape popular memory, offering identity value for consumers. When marketing the American South, for example, Thompson and Tian (2008) demonstrate how marketing agents selectively omit contentious racial politics, lynchings, poverty, etc., focusing instead on the cosmetic gloss of barn dances and barbecues. Thompson and Tian (2008, p. 596) define commercial mythmaking as

“the efforts of advertisers, brand strategists, tourist promoters, and other marketing agents to situate their goods and services in culturally resonant stories that consumers can use to resolve salient contradictions in their lives and to construct their personal and communal identities in desired ways... commercial mythmaking can also function as an ideological process that [creates] a particular interpretive rendering of the past and its sociocultural meaning.”

In postmodern consumer culture, brands compete in mass-mediated myth markets rather than product markets (Holt 2004). To succeed, it is often more crucial for brands to engage with cultural ideologies and embody compelling identity myths rather than produce quality goods. According to Holt (2004), iconic brands like Harley-Davidson and Volkswagen assert compelling stories that resolve acute cultural contradictions and help people feel better about their identities. For example, by incorporating bohemian mythology in their marketing communications, Volkswagen managed to shake off the associations with Nazi Germany (that still haunted the brand in the 1960s) and gained legitimacy in American culture. Moreover, by being perceived as a credible insider in the art world, the brand was endowed with cultural authenticity (Holt 2004).

Crockett and Davis (2015) note that far less is known about commercial mythmaking than mythmaking among consumers. Nevertheless, Brunk, Giesler, and Hartmann (2018) highlights the role of commercial mythmaking in the marketisation of a consumable past. More precisely, they note how East German brands after the reunification were imbued with socialist nostalgia for how things were “better back then” (p. 1325). They suggest that cultural production is crucial in the commercial side of mythmaking. For example, they point to the 2003 movie *Good Bye, Lenin!*, which “shifts socialist camaraderie and care to the level of brand consumption” (Brunk, Giesler, and Hartmann 2018, p. 1336). Films and TV shows are powerful tools in disseminating cultural myths and counter memories that shape popular memory (Thompson and Tian 2008). Advertisers often flirt with films and other forms of popular culture to imbue their market offerings with mythic and sociocultural meaning (Holt 2004).

METHOD

The *Journal of Consumer Research (JCR)* is one of the most prominent journals in our field. A search for the term “myth” yields 343 results in the *JCR* database. Out of these, 301 original articles were included in the final sample of this study. Some articles merely cited a reference that included the term “myth” and were therefore excluded. Other exclusions were editorials, tutorials, and articles that only touched upon the topic tangentially.

The final sample consists of papers that address myths and marketplace mythology in a meaningful way. We recognise the limitation of using articles from only one journal. However, the included sample (n = 301) seems rich compared to other conceptual papers of this type.

In our findings, we present each thematic category around a couple of papers that serve as exemplars of the theme in question. The first author downloaded and skimmed through all articles before choosing those (n = 18) that were read in more detail by both authors (Table 1). The aim of this procedure was not to be as extensive as possible, but to provide an overview of previous consumer research on marketplace mythology.

Table 1. Articles Included in the Detailed Analysis

Title	Year of Publication	Author(s)	Mythological Context
Politicizing Consumer Culture: Advertising's Appropriation of Political Ideology in China's Social Transition	2008	Xin Zhao and Russell W. Belk	Advertising Plots and Narratives
Images in Advertising: The Need for a Theory of Visual Rhetoric	1994	Linda M. Scott	Advertising Plots and Narratives
License to Assemble: Theorizing Brand Longevity	2019	Chloe Preece, Finola Kerrigan, and Daragh O'Reilly	Brand Evaluations
The Starbucks Brandscape and Consumers' (Anticorporate) Experiences of Glocalization	2004	Craig J. Thompson and Zeynep Arsel	Brand Evaluations
Demythologizing Consumption Practices: How Consumers Protect their Field-dependent Identity Investments from Devaluing Marketplace Myths	2011	Zeynep Arsel and Craig J. Thompson	Consumer Identity Work
Space as a Resource in the Politics of Consumer Identity	2021	Andre F. Maciel and Melanie Wallendorf	Consumer Identity Work
Therapeutic Servicescapes and Market-mediated Performances of Emotional Suffering	2019	Leighanne Higgins and Kathy Hamilton	Consumer Well-being
Chronic Consumer Liminality: Being Flexible in Precarious Times	2021	Laetitia Mimoun and Fleura Bardhi	Consumer Well-being
The Regeneration of Consumer Movement Solidarity	2021	Andreas Chatzidakis, Pauline Maclaran, and Rohit Varman	Consumption Rituals and Collectives
"We Gather Together": Consumption Rituals of Thanksgiving Day	1991	Melanie Wallendorf and Eric J. Arnould	Consumption Rituals and Collectives
The Politicization of Objects: Meaning and Materiality in The U.S. Cannabis Market	2021	Aimee D. Huff, Ashlee Humphreys, and Sarah J. S. Wilner	Legitimation of Consumption Practices
Social Emotions and the Legitimation of the Fertility Technology Market	2021	Laetitia Mimoun, Lez Trujillo-Torres, and Francesca Sobande	Legitimation of Consumption Practices
Hermeneutics and Consumer Research	1994	Stephen J. Arnold and Eileen Fischer	Myths about the Scientific Procedure
Scientific Style and the Conduct of Consumer Research	1985	Elizabeth C. Hirschman	Myths about the Scientific Procedure
Paths to Respectability: Consumption and Stigma Management in the Contemporary Black Middle Class	2017	David Crockett	Socio-political or Gendered Myths
Almost Equal: Consumption under Fragmented Stigma	2022	Christian A. Eichert and Marius K. Luedicke	Socio-political or Gendered Myths
Networks of Desire: How Technology Increases Our Passion to Consume	2017	Robert Kozinets, Anthony Patterson, and Rachel Ashman	Technology Myths
We Are What We Post? Self-Presentation in Personal Web Space	2003	Hope Jensen Schau and Mary C. Gilly	Technology Myths

FINDINGS AND CONCLUSIONS

We found that consumer research in marketplace mythology can be classified into nine interrelated themes:

- Advertising Plots and Narratives (e.g. Scott 1994; Stern 1995; Zhao and Belk 2008);
- Brand Evaluations (e.g. Brown, McDonagh, and Shultz 2013; Preece, Kerrigan, and O'Reilly 2019; Thompson and Arsel 2004)
- Consumer Identity Work (e.g. Arsel and Thompson 2011; Luedicke, Giesler, and Thompson 2011; Maciel and Wallendorf 2021)
- Consumer Well-being (e.g. Higgins and Hamilton 2019; Hill 1991; Mimoun and Bardhi 2021);
- Consumption Rituals and Collectives (e.g. Belk and Costa 1998; Chatzidakis, Maclaran, and Varman 2021; Wallendorf and Arnould 1991);
- Legitimation of Consumption Practices (e.g. Huff, Humphreys, and Wilner 2021; Humphreys 2010; Mimoun, Trujillo-Torres, and Sobande 2021);
- Myths about the Scientific Procedure (e.g. Arnold and Fischer 1994; Hirschman 1985; Wells 1993);
- Socio-political or Gendered Myths (e.g. Crockett 2017; Eichert and Luedicke 2022; Thompson 1996);
- Technology Myths (e.g. Kozinets 2008; Kozinets, Patterson, and Ashman 2017; Schau and Gilly 2003).

These constitute our main findings and are summarised in Table 2. Based on these interrelated themes, possible avenues for future consumer research on marketplace mythology include brand story-

telling; co-mythologisation; and the role of myth in the polarisation of consumer culture.

Table 2. Summary of Findings

<i>Mythological Theme</i>	<i>Brief Description</i>
Advertising Plots and Narratives	Advertising plays a myth-like role in making certain market ideologies seem natural
Brand Evaluations	Brands facilitate different mythic interpretations to alleviate cultural anxieties and provide consumers with identity value
Consumer Identity Work	Myths are important drivers in consumers' identity projects and resolve ideological tension
Consumer Well-being	Myths have emotional and restorative qualities that can be therapeutic and improve one's sense of well-being
Consumption Rituals and Collectives	Consumers collectively gather around myths and rituals to feel a sense of togetherness
Legitimation of Consumption Practices	Commercial mythmaking is important in the legitimation of stigmatised consumption practices
Myths about the Scientific Procedure	Marketing departments in business schools have instituted their own mythology based on physics envy
Socio-political or Gendered Myths	Our understanding of socio-political identities (e.g. what it means to be a woman) are often based on myths
Technology Myths	Myths were originally oral stories but are nowadays mass-mediated by means of technology

Brand Storytelling

Aaker (2018) distinguishes between six types of commercial storytelling. First, a *founder story* tells something about the heritage of the brand. For example, as Brown, Patterson, and Ashman (2021, p. 421) points out, “Hollister’s backstory is a thing of beauty... not a word of it is true, however.” Second, an *offering story* illustrates the magical powers of a commodity. For example, for over twenty years, Red Bull used “Red Bull gives you wings” as its catchy slogan. Third, a *brand story* is a cohesive narrative that encompasses the facts and feelings that are created by a brand and often inspires a strong emotional reaction. Fourth, a *customer story* (e.g. BMW drivers are always friendly) reveals compelling traits and characteristics that other consumers can identify with, often strengthening the social ties in a brand community. Fifth, a *growth strategy story* (e.g. Elon Musk’s growth story before the first Tesla car was shipped) provides credibility and inspiration to employees and investors. Lastly, a *borrowed story* denotes a brand drawing on myths in popular culture to convey meaning. Aaker’s (2018) typology of brand storytelling offers a potentially novel framework for understanding and advancing theory on commercial mythmaking.

In practical terms, Aaker (2018) shows how to apply the power of storytelling to strategic marketing. It seems that commercial mythmaking will be an increasingly vital topic in the age of digital marketing where storytelling is key to successful branding. Future research on how myths are conveyed in brand storytelling can include:

- What stories will be effective in promoting different types of brands?
- How can stories be told in the digital age? In ancient Greek, the myths were originally oral traditions.
- What are the consequences when mythic stories are increasingly passed on through social media?

- What cultural anxieties need to be alleviated through commercial myths on social media, through more immersive technologies, and future iterations of the internet?
- Is commercial mythmaking as relevant to business-to-business marketing as it is to consumer marketing?
- What if brand stories fail to generate the ideological power of myths? Will such failure undermine the perceived authenticity of the brand?

Co-mythologisation

The distinction between consumer myths and commercial myth-making offers opportunities for future studies on co-creation of meaning where both consumers and commercial actors partake in the myth-making process. Beverland (2018) points out that the consumer is a co-creator in a brand’s identity. In other words, consumers actively partake in the construction of myths around the brand. Consider, for example, the case of Burberry and ‘Chav’ culture (Hayward and Yar 2006). Chav culture came to be known as a type of fashion that involved designer brands, tacky jewellery, and bad taste; when Burberry became associated with this term, it greatly affected the brand and its story by plummeting sales to an all-time low.

Further research should study co-mythologising practices between brands and different types of consumer collectives such as brand communities (Muñiz and O’Guinn 2001), consumer tribes (Cova, Kozinets, and Shankar 2007), and subcultures of consumption (Schouten and McAlexander 1995).

The Role of Myth in the Polarisation of Consumer Culture

Lastly, the recent polarisation of consumer culture (Ulver 2021) calls for further attention to marketplace mythology in consumer research. For example, more research is needed to unpack the various ideological conflicts that may arise from myth markets, espe-

cially by employing non-dialectical theoretical frameworks such as Bakhtinian dialogism and heteroglossia (Fowler, Das, and Fowler 2022). From a macro-level perspective, it would also be interesting to study the role of public policy on the shaping of marketplace mythology beyond consumer myths (i.e. micro-level) and commercial mythmaking (i.e. meso-level) that have guided most of the previous research in this domain. For example, should it be criminalised to spread misinformation about certain topics such as anti-vaccination? As a final note, we call for more research employing existential or phenomenological frameworks to complement the majority of extant research, which is based on structuralism (Stern 1995) and poststructuralism (Thompson 2004).

“Sharing in” Practices among Lower-Middle Class Urban Families in Brazil

Prof. Barbara Levy, Pontifical Catholic University of Rio de Janeiro - PUC-Rio, Brazil

Prof. Angela Da Rocha, Pontifical Catholic University of Rio de Janeiro - PUC-Rio, Brazil

Prof. Ana Raquel Rocha, UFF - Fluminense Federal University, Brazil

INTRODUCTION

Sharing is defined as “the act and process of distributing what is ours to others for their use and/or the act and process of receiving or taking something from others for our use” (Belk, 2007, p. 127). Sharing can occur in both abundance and scarcity situations. Open sharing (also called altruistic sharing) happens when there is no need to ask, whereas demand sharing occurs when one must ask of another, such as when children ask their parents for food (Belk, 2010, 2014; Peterson, 1997). When sharing happens within the extended family, or among friends or neighbors, it is called “sharing in”; when it is done with outsiders, it is called “sharing out” (Belk, 2010). In both “sharing in” and “sharing out” there is no transfer of ownership of the shared good, nor is there expectation of compensation, aspects that differentiate sharing from gifting and buying (Belk, 2014). Reciprocity in sharing is typically asymmetrical (Price, 1975), creating “a weak obligation to reciprocate”, characterized by “indifference to the time, quality and quantity of the return” (Peterson, 1997, p.173).

Recent marketing studies on sharing have focused mainly on “sharing out” situations. A recent literature review of studies on sharing (Ryu et al., 2019) covering almost 300 papers showed that, despite examining a wide range of products and services, the extant literature, focuses mainly on the so-called “sharing economy”. In addition, the review showed a growing interest on “sharing out” associated with some form of monetary compensation. However, the original concept of sharing advanced by Belk (2010) in his study on consumption was much broader, encompassing traditional sharing, as well as new forms of sharing in affluent societies, particularly “sharing out” with outsiders or strangers. In fact, several authors have recently criticized the use of the term “sharing economy” because it frequently refers to practices that are far from expressing true sharing (e.g., Hellwig et al., 2015; Kuper & Edinger-Schons, 2020).

“Sharing in” can be traced to ancient societies, but it appears in all contemporary societies as well (Belk, 2017; Belk & Llamas, 2012), often without being noticed. The sharing of resources by families and communities works as a collective possession of property; it “requires no invitation, generates no debt, and may entail responsibilities as well as rights” (Belk, 2010, p.717). In spite of this, the use of resources is not homogeneous within the family, nor is the power that each actor exercises concerning the use of shared goods in the context of the family relationship (Belk, 2010; Belk & Llamas, 2012). It is often the case that sharing is unconditionally expected from other family members, and a refusal to share may be punished by some form of verbal or nonverbal sanction. Each society has its own practices of sharing, including with whom one is supposed to share, and what types of goods, services or spaces are expected to be shared.

The present study aimed to investigate “sharing in” among members of lower-middle class urban families in Brazil. The reason for choosing this economic group was that, despite the restrictions on consumption they routinely face, consumers in this segment have access to a reasonable variety of goods, while those belonging to the lower class often fight for survival, with income barely covering basic food and housing expenses. Therefore, sharing among members of the lower-middle class segment is to a large extent optional, compared to families at the bottom of the social pyramid.

The following research question was addressed in the study: *What is the nature of sharing as a consumption practice in lower-middleclass urban Brazilian families?* Our contribution is threefold. First, we look at lower income families, a group that has been largely neglected by researchers in consumer behavior. Indeed, most studies from developed countries have looked specifically at affluent families and individuals, even though there are many more families in the world similar to the ones we studied in our research. Therefore, the present study contributes to the extant literature by examining sharing practices within this specific social group from an emerging market. Second, we contribute to the understanding of sharing practices by examining a context in which the extended family predominates, and not the nuclear family. Third, we investigate differences in sharing practices within families, an issue that “is not available in most ethnographies” (Ember et al., 2018, p. 384), nor in consumer behavior studies on sharing.

METHOD

Our research adopted an interpretive lens to examine the phenomenon under study. The unit of analysis was the extended family, conceptualized as individuals with blood or relational ties who live in the same household. The households were located in less-affluent areas on the periphery of the city of Rio de Janeiro, Brazil, but not in the slums. We interviewed 15 families and a total of 48 individual family members. All interviews were conducted in the families’ homes. The interviews were recorded with the informants’ permission and later transcribed. Data analysis consisted of two steps. First, we analyzed the interviews held with each family member and wrote a short report for each family, using a set of categories extracted from the literature, combined with those that emanated from the field. The second step consisted of a comparison of the 15 families in order to determine the similarities and differences among them. The third step included a comparison of the patterns identified in the study with those in the extant literature.

FINDINGS

Sharing is a daily practice within the families we studied. The extent of sharing, however, showed significant variations. Some families claimed that they shared “everything”, because “everything belongs to everyone.” Nevertheless, even members of these families mentioned exceptions to the “everything for everyone” rule. Other families stated that most goods were for everyone’s use, but that there were spaces and items for private, individual use, and “others do not touch.”

The informants used different terms to describe sharing. Some terms considered the buying situation as the backdrop for the practice of sharing, such as “shopping together”, or “buying for the whole family.” Other terms denoted ownership, such as certain items “belonging to everyone in the home” or “to the family.” The terms “mine” or “his/her” were rarely employed, because “what is mine is his and what is his is mine”, or “it belongs to nobody.” Sharing was also understood as permission to use: family members could use the objects “whenever they want”, sometimes taking turns, or even using them together, or with another one. Thus, anyone can “take”, “use”, or “enjoy” the shared object. Other terms were used to designate negative occurrences associated with the practice of sharing,

such as “getting everything mixed up” or “tangled up”, “invading” what belongs to the other, “stirring”, “abusing” or “confusing.” Informants also mentioned items for private, individual use that were not shared. The financial outlay for the acquisition and maintenance of goods guaranteed their privatization unless the owner chose to share them. For some, non-shared items had a well-defined owner (“what’s yours is yours”) or there were separate owners for similar items (“everyone has his/her own”). Those that were not included in the sharing carried an implicit prohibition against being used (“no-body should take it”).

There were basically three levels of sharing in these families. Some objects were typically shared in all families, others were shared only in some families, and still others were rarely shared at all. Among the items rarely shared were towels and underwear, but even those could be shared in some cases. Cellular phones were also among the objects that were rarely shared unless the owner kept the chip and shared only the device. Clothes, on the other hand, were often shared, particularly among siblings, but also between mothers and daughters. Even so, the younger members of the families sometimes avoided using their siblings’ clothes because they feared that this could be regarded by outsiders as an indication of poverty, or perhaps because they saw it as deindividuation.

There were also three categories of spaces: public spaces, which were open to visitors; private spaces, which were reserved for family members, and intimate spaces, which were reserved exclusively for one or more family members and no one else. There were very few of these (e.g., a couple’s bedroom), and in some homes there were none at all. Intimate possessions were reserved for the owner’s exclusive use and were not a cause of dispute, but other goods that were not meant for sharing might eventually be used without permission by others in the family, particularly siblings. In such situations, the informants reported practices to prevent this from happening, such as hiding the goods, locking them in a closet, or carrying them in a backpack.

In addition to the limitations on sharing pointed out in the marketing literature, such as possessiveness or attachment to a particular object, materialism and scarcity, our study revealed three additional limitations (although they varied from one family to the next): interest limitations, suitability limitations, and situational limitations. Interest limitations refer to a lack of interest in using a shareable item, even if available, due to differences in life cycle stages, or preferences for different styles, models, or sizes. Suitability limitations refer to the judgment of an object as being inappropriate for use by others, such as adult items to be used by children. Situational limitations are temporary factors that could lead to resistance to sharing, such as when an item had not yet been used by the individual who purchased it. In addition, what was shared among the family members residing in the home could not be automatically shared with other individuals even if they belonged to the extended family but did not live under the same roof. The limitations on with whom to share were thus well-defined and common to all the families we studied; shared goods were non-transferable outside the home. Losing a shared item – particularly a more expensive one – could result in the user being temporarily excluded from sharing until he/she proved to be trustworthy again. Exclusion could in some cases be due to failing to abide by explicit or implicit rules of conduct.

Another characteristic of sharing discussed in the literature is the connection between sharing and reciprocity. In our study, some families considered sharing to be an act that did not imply receiving anything in return for it, but other families explicitly expected some form of reciprocity, although of the same kind: “If it’s shared, it must be reciprocal. If he shared with me, I must share with him.” Even in

these cases, reciprocity was not expected to be immediate, nor was there any control on how much one should share with others. Even in the families that did not report any expectation of reciprocity, however, there was also an implicit understanding that members would share, because this was a common moral value. Thus, the practice of sharing seemed to create some sort of future moral obligation to also share one’s goods when and if the situation allowed, although limited control was exerted on this issue. However, children were taught that they were expected to share toys with their siblings.

Finally, there were differences among family members concerning their status as users of shared possessions. Usage rights were not the same for everyone, nor for all uses. Among family members, it was often the elders who decided priorities, sometimes on behalf of younger children. Also, the power to decide who was going to use the possession, and when, could also rest in the hands of whoever paid for it. However, the hierarchy was not so clear when the object was purchased by one family member as a gift to another, leaving open the discussion on priority of use.

DISCUSSION AND FINAL CONSIDERATIONS

This study provides an in-depth view of how lower-middle class families use sharing in their everyday life. Our findings are in line with the literature on “sharing in” as “the oldest form of mutual distribution” (Belk, 2017, p.249). In our study, “sharing in” appeared as a value associated with the concepts of family unity and belonging. The study unveiled several nuances to “sharing in” as a social practice by lower-income Brazilian families (Table 1).

Table 1 – Nature of Sharing among the Families Studied

Issue	Extent of Application
Family values	Sharing with the family is a moral value learned and transmitted from one generation to the next.
Scope	Sharing is limited to members of the extended family living under the same roof. Families differ in the extent of sharing.
Reciprocity	Expectations of reciprocity can be explicit or implicit, and even pass unnoticed.
Refusal to share	What one has the right to refuse to share varies from one family to the next.
Hierarchy and power	Decisions on sharing can follow the family hierarchy or be made by the provider of the shared object.
Exclusion of sharing	One can be excluded from sharing for failing to accept sharing rules, damaging/loosing the shared object, or not abiding by the obligation of sharing.

Sharing is learned and transmitted as a family value; no one is exempt from sharing at some point. In some families there is an explicit expectation that every family member living under the same roof should share his/her possessions in due course and according to his/her financial and material means. In other families this assumption is implicit and even, in some cases, not expressed at all. This type of asymmetrical reciprocity has often been identified in the anthropological literature, particularly ethnographic studies (e.g., Peterson, 1997; Pierce, 1975). Nonetheless there are limits on sharing. In our study, with whom one has to share was physically limited to those that live together and did not apply to other members of the extended family residing in other places. This is not the typical sharing practice, according to a large-scale study of 98 non-industrial societies (Ember et al., 2018), which showed “beyond-household sharing” as a ubiquitous practice.

In our study, sharing included both hierarchical and egalitarian aspects. Egalitarianism is seen in the use of a shared possession by several family members in similarity of conditions, but it is mostly a hierarchical practice, which tends to follow the family hierarchy, both the parental dominance and the higher status of the provider. If sharing entails giving up some control by those who make the shared good available, it also means gaining control by those who benefit from sharing. Control is associated with responsibility. One must take care of the object, one must not abuse it to the detriment of others, and one must make it available again in useable condition. Failure to respect these rules may result in the temporary or permanent exclusion of the right to enjoy certain shared goods. Sharing can even be denied when demanded, this power being reserved for the owner of the object if the situation allows him or her not to share. And when an object in high demand is not shared, a strategy to avoid unauthorized use may entail hiding it, as reported in ethnographic studies. For example, eating some of the food while collecting it was a strategy used by members of some hunter-gatherer societies to avoid sharing (Petersen, 1997). In sum, within the context of lower-middle class families, sharing must be understood as a practice that generates rights and obligations, in which rules of conduct tend to be informal, implicit or explicit and, at times, ambiguous.

INTRODUCTION

Marketing research has established that race continues to play an important role in the functioning of markets (Grier, Thomas, and Johnson 2019) and that markets are racialized at their core (Henderson, Hakstian, and Williams 2016; Poole et al. 2020; Tilley and Shilliam 2018). Questioning historical conceptions of markets as “free” or “fair” (Johnson et al. 2019), extant research has provided ample empirical evidence of ongoing racial discrimination and exclusion in a variety of consumption contexts (Ainscough and Motley 2000; Bennett, Lee-Treweek, and Vandeyar 2015). Many such studies have focused on systemic racial disparities that lead to exclusionary market practices (Bone, Christensen, and Williams 2014; Brumbaugh and Rosa 2009; Crockett, Grier, and Williams 2003). Together, these studies highlight that existing public policy measures have failed to fully alleviate racial disparities and point to the urgency of better understanding pathways for racial inclusion at the intersection of the market and society.

The following empirical investigation contributes to this timely and relevant body of research by studying an underexplored pathway in the battle against racial exclusion. Drawing on our empirical analysis of the initiative #MyBlackReceipt, we describe additional tactics that racial minorities can employ to activate that pathway and challenge systemic inequality in markets.

LITERATURE: IDENTIFYING EXISTING PATHWAYS FOR RACIAL INCLUSION

From our critical review of existing scholarship on marketing and race we identified two different pathways toward fighting market exclusion, defined as “the mechanisms through which certain individuals and communities are barred from the resources and opportunities provided by the market to other citizens” (Saren, Parsons, and Goulding 2019, 2).

In the first pathway, which we labeled *managing stigma*, the market is a space of continuous racial conflict where minorities face discrimination and stigma. Subsequently, affected consumers employ a range of tactics to cope with or mitigate their exclusion and change themselves to fit to the market, such as 1) dissimulating their racial identity through assimilation and appropriation of the dominant race’s consumption codes (Bone et al. 2014; Harris, Henderson and Williams 2005); 2) signaling cultural capital and achieving respectability through status-enhancing consumption (Crockett 2021, 2017; Poole et al. 2020); 3) deliberately avoiding stigmatized consumption goods, services and practices (Crockett 2017; Crockett and Wallendorf 2004) and 4) embracing counternarratives by reinterpreting the dominant stigmatized narrative (Crockett 2017; Milner and Howard 2013). While these tactics may alleviate exclusion for some individual consumers, they do little to change discriminating market mechanisms or address other systemic issues of racial exclusion.

The second pathway, which we labeled *developing positive representation*, sees consumers trying to change markets that render their ethno-racial identity invisible or devalued. Here, the market is seen as an uncivilized space that needs to be moralized and exposed to the principles of racial equality and inclusion. In contrast to *managing stigma*, where individual consumers are the agents and focus of transformation, here, activist consumers and the marketers that respond to them are the key actors promoting transformation at the market level. They reform marketing practices by restraining forces of exclusion and fostering adherence to the principles of racial equality and inclusivity (Mirabito et al. 2016). This pathway includes tactics such as 1) ethno-racial targeting, e.g. offering particular products for the needs of ethnic-minority consumers (Crockett 2021; Lamont and Molnár 2001; Peñaloza 2018); and 2) selling diversity through multiracial communications and creating value enhancing narratives for ethnic minorities (Crockett 2008; Moorman 2020; Vredenburg et al. 2020).

The described pathways entail tactics that impact racial exclusion at the individual and market level. However, by focusing on either improving individual consumers’ position in the market or attempting to moralize existing marketing practices, the scope of both pathways confines their impact on the broader objective of achieving market inclusion. In this paper we argue that hashtag initiatives such as #MyBlackReceipt are evidence of a promising third pathway to fight racial exclusion. In contrast to *managing stigma*, where it is up to the individual consumer to achieve change, and in contrast to *developing positive representation*, where racial minorities are offered token inclusion in the market, this approach is a collective effort of various market actors who *leverage within market boundaries* in attempting to redress racial inequalities. Our summary is presented in the findings section, contrasting the two existing pathways and their tactics, which we conceptualized from the literature, with the third pathway emanating from our empirical analysis.

RESEARCH CONTEXT: #MYBLACKRECEIPT

We empirically investigated a recent initiative enacted in the United States: #MyBlackReceipt. Aligned with the broader #Buy-Black movement and other racial movements that manifest in the digital space (e.g. #BlackLivesMatter), #MyBlackReceipt was launched in June 2020 by Kezia Williams. Through her company The Black upStart and social media platforms, Williams calls consumers to buy from Black-own businesses, and promotes financial literacy in Black communities. To launch #MyBlackReceipt, Kezia set up a website where consumers, businesses, and investors upload receipts that serve as proof of purchases from or investments made in Black businesses. The original goal was to generate receipts valuing \$5 million in 17 days, which was exceeded considerably. The key logic of the initiative is one that has long been drawn upon by Black

activists: to keep the money circulating and build wealth in the Black community.

#MyBlackReceipt is a recent instantiation of efforts to build Black wealth that have a long history in the USA and persistently faced challenges. A prominent challenge is racist backlash, responsible for the demise of historic efforts like Black Wall Street, a powerful and prosperous African-American community of the 1920s in Tulsa, Oklahoma (Fain, 2017). Thus, consumers and Black business owners may be reluctant to engage in #MyBlackReceipt fearing backlash or stigmatization. Moreover, some Black entrepreneurs and businesses may also have limited financial know-how, business acumen, and resources, and therefore be less competitive than others in attracting consumers.

METHODOLOGY

We conducted an empirical qualitative study of the #MyBlackReceipt initiative taking a non-participant approach by collecting archival data publicly available on traditional media and social media (Fischer and Parmentier 2010). We engaged in Thematic Analysis (Gibbs 2018; Miles, Huberman and Saldaña 2018) to guide our analytical process.

Data Collection We collected media articles from mainstream media outlets as well as blogs and independent publishers, and archival data from social media platforms. We searched for the hashtag #MyBlackReceipt on Factiva for media articles, complementing results with a Google search for the News feature using the same keyword. For social media, we used the applications 4K Stogram (Instagram) and Tweet Deck (Twitter) and the embedded search mechanisms on Facebook and YouTube, all searching for the same hashtag (#MyBlackReceipt). We collected all textual and visual information publicly available on social media pages. Additionally, we collected information on the official website for the initiative (MyBlackReceipt.com). Data was collected between August and November 2020 and covered the period from the first announcement of the initiative, June 1st, to October 31st, 2020. In total, our data set consists of 16,900 Instagram posts, 2,100 Facebook posts, 45 single-spaced pages of Tweets, 125 pages in PDF of website content, 25 media articles, 12 YouTube videos.

Data Analysis We conducted thematic analysis (Gibbs 2018) of the textual dataset including illustrated messages, transcripts and comments for YouTube videos; posts and comments on Facebook, Twitter, and Instagram. Starting with a subset of our data, we identified the main themes related to how the market was mobilized to fight racism, which were: goals, strategies, tactics and outcomes. We then coded and classified them further into different types. By iterating between our data and the literature we eventually focused our analysis on the tactics employed by the initiatives of #MyBlackReceipt in search for theoretically meaning patterns (Locke, Feldman, and Golden-Biddle 2020). During this iterative process authors independently classified excerpts, analyzed data exemplars, and utilized different types of data for triangulation purposes (Spiggle 1994). We engaged in negative case analysis, debated discrepancies until we agreed on descriptors that best represented the patterns in our data. As a result, the identified six tactics offer a grounded theoretical understanding of the phenomenon.

FINDINGS: LEVERAGING WITHIN MARKET BOUNDARIES

In contrast to the two pathways and related tactics synthesized by our literature review, the #MyBlackReceipt initiative is a collective, concerted and strategic effort that leverages various market actors, practices, and resources to fight racial exclusion. In line with

#MyBlackReceipt's previously described goal and overall strategy, the initiative creates a highly participative market space *within* the existing market. To activate this market space, members of the initiative employ six tactics: *educate*, *facilitate*, *embolden*, *partner*, *normalize*, and *champion*. Each of the tactics mobilizes a particular set of actors, resources and practices. We briefly describe each of these tactics below. Illustrative examples from our dataset are shown in the data table in the Appendix. The following figure outlines and contrasts the three pathways including their goals, level of action, as well as the involved market actors and their tactics.

Educate is a tactic that aims at teaching and advancing business skills as well as expanding Black business owners, entrepreneurs and consumers' understanding of market processes and the importance of keeping the money in the Black community. It is expected that, if Black business owners develop better financial and business acumen, they will thrive, create employment for Black people, and serve customers better. When educating, #MyBlackReceipt leaders leverage market resources and marketing tactics, e.g. free samples of educational resources.

Despite their general willingness to support the overall cause, consumers reported that researching and locating Black-owned shops in their vicinity was challenging. Additionally, it was often-times difficult to identify which branches of large businesses (e.g. McDonalds or 7eleven) are Black-owned. The tactic *Facilitate* addresses these difficulties and assists consumers in locating Black-owned businesses either through using the searchable directory on the myblackreceipt.com website or via the hashtag #MyBlackReceipt. Similarly, Black business owners can publicize and list their products, facilitating access to consumers. By sharing recommendations, lists and directories via social media and employing a wide range of buy-Black-related Hashtags beyond #MyBlackReceipt, this tactic expands the reach of Black-owned businesses and exposes Black consumers to a wider selection of brand, products and services.

Through the tactic of *Embolden*, leaders and supporters of #MyBlackReceipt encourage consumers to identify as "unapologetically Black" and openly support Black businesses. They do so through emboldening messages and calls for action that appeal to positive (e.g. pride, hope) or negative (e.g. anger) emotions. At the same time, businesses are encouraged to publicize their Black ownership (e.g. Yelp offered window tags). This tactic aims to strengthen Black confidence resulting in more participative, empowered and engaged market actors, such as consumers who can fully enact their boycotting consumption power (Shaw, Newholm, and Dickinson 2006).

The tactic of *Partner* refers to establishing connections with non-marginalized, non-Black allies to increase the initiative's presence, reach and impact. In so doing #MyBlackReceipt leverages the powerful influence of prominent market actors (e.g. celebrities, brands, sponsors, data platforms). This tactic legitimizes Black consumers and business owners, creates connections to the mainstream market and activates consideration for the needs and preferences of the Black community. This is in contrast to pathway two (developing positive representation) because here, Black-owned businesses are empowered by their "marketer partner" to participate on their own terms.

Another tactic of the initiative that serves the goal of keeping the money in the Black community is to *Champion* committed market actors, who are identified based on their shared views (Kozinets and Handelman 2004; Weijo, Martin, and Arnould 2018). Drawing on the prevalent consumer ethics to "vote with your purchase" (Shaw, Newholm, and Dickinson 2006), here #MyBlackReceipt calls on Black consumers to commit their financial resources to ex-

Figure 1: Market-centric pathways for racial inclusion

	Managing stigma	Developing positive representation	Leveraging within market boundaries
Level of action	Individuals cope with racial exclusion in the market by changing themselves to fit with the dominant cultural codes.	Marketers aim to better represent racial minorities in the market by responding to moral appeals of activist groups calling for more inclusive marketing practices.	Racial minority groups challenge systemic inequality by leveraging within market boundaries and creating a highly participative space within the existing market.
Goals	To be included in the market by adjusting to dominant cultural codes and norms.	To suppress forces of exclusion in the market.	To fight against systemic racial exclusion by leveraging market mechanisms.
Tactics employed	Avoidance, Dissimulation, Signaling, Embracing counternarratives	Ethnic targeting, Selling diversity	Educate, Facilitate, Embolden, Partner, Champion, Normalize
Actors mobilized	Individual racialized consumer	Marketers Consumer activists	Consumers, Business owners, Social movements and activist groups
Actors benefitting	Individual minority consumers	Minority consumer groups	Minority communities including consumers <u>and</u> businesses

clusively support Black businesses. Similarly, Black entrepreneurs are called to develop businesses that serve the Black community, and celebrated when they do so. At the same time, oppressors of the Black community and inauthentic Black-owned businesses are named and consumers asked to withdraw their support. The tactic is operationalized through the “receipt counter” featured on the initiative’s website, showcasing the collective catalysis (Kozinets, Ferreira, and Chimenti 2021) that the initiative has organized.

Finally, *Normalize* seeks to turn “buying Black” from a one-off protest into an internalized long-lasting practice. Discursive motivation occurs by associating the buying Black rationale with other known selective patronage initiatives, e.g. buying local; consuming in a more sustainable way (Hinrichs and Allen 2008). Such associations are impactful as they convey the message that societal change is possible.

The six tactics we identified by empirically studying the initiative #MyBlackReceipt were simultaneously implemented by its leaders and supporters. While the tactics in itself are complementary and some of them may be present in other forms of market activism, the hashtag aggregates them to achieve broader reach, visibility and impact (Johnson et al. 2019), creating a distinct pathway to pursue market inclusion. The tactics target a variety of Black consumers and entrepreneurs’ positions in the market. While some need encouragement to support the cause or education about the advantages of keeping dollars within the Black community, others may only need their choices facilitated.

DISCUSSION

Our paper contributes to consumer research on marketing and race by: 1) synthesizing and critically reviewing previous work on mitigating racial exclusion at the individual consumer and market

level and its limitations in terms of creating sustainable change; and 2) arguing for a promising complementary, multi-actor collective pathway that leverages market forces.

The newly identified pathway of *leveraging within market boundaries* offers an opportunity to pair the agency of racialized actors with market tools to help the intersectional issue of economic inequality that contribute to some aspects of racial exclusion in markets. Here, racialized Black consumers can funnel their resources toward building a sustainable future and in so doing move away from reactive toward creative tactics to combat racial exclusion. Unlike pathways one and two, this will benefit not only Black consumers, but also Black entrepreneurs and businesses, therefore creating wealth for the entire community.

When compared to the pathway of managing stigma, the new pathway recruits previously oppressive market actors to be allies in helping to combat exclusion. When compared to the pathway of developing positive representation, the new pathway offers ethnic minority actors the opportunity to develop marketing practices that prevent instrumental woke-washing and inadequate adaptations of their culture and ethos.

Our findings can serve to develop market-based guidelines for promoting inclusion and are relevant for policy makers, social institutions, consumers and consumer movements as well as marketers and businesses. As #MyBlackReceipt is a fairly recent initiative, a longitudinal investigation would complement our research to evaluate whether the initiative’s short-term impact can be turned into long-lasting sustainable change. Future research may also explore differences between historical Black movements efforts that failed, such as Black Wall Street, and hashtag initiatives like #MyBlackReceipt.

Appendix: Data Table

DATA TABLE: Tactics of Pathway "Leveraging the market"					
Educate	Facilitate	Embolden	Partner	Champion	Normalize
<p>"We're coming back in august with skill house youtube [...] so we call it classrooms for the culture and because we wanted to be accessible to all people we host these classes for free via instagram live we're probably going to be moving on to a different platform so people can access the information for free and then they can pay for the replay at a later date so we've talked about how you can buy your first home with no money down we've talked about how you can invest in the stock market with less than a hundred dollars and we've talked about how you can take advantage of all aspects of the stimulus plan not just the 1200 paycheck if you qualify [...] we have so many websites and we're consolidating y'all."</p> <p>SOURCE: Youtube https://www.youtube.com/watch?v=LiAhFXKCI74</p> <p>"I mean the biggest thing is honestly you have to be a knowledge [...] seeker, you can't swim in an ocean of knowledge and drown in ignorance. We're in the information economy right now so at the other side of your fingertips is an opportunity for you to qualify your black excellence with black knowledge."</p> <p>SOURCE: Youtube https://www.youtube.com/watch?v=LiAhFXKCI74</p> <p>"Black entrepreneurs should make more of the products that Black people buy disproportionately. The Nielsen Consumer Index Report noted that we over-index in spending on ethnic hair care & beauty products, women's fragrances, feminine hygiene products, refrigerated juices and drinks, gum, detergents. This is why the incredible success of J.I.V.E. Juice Company, and the Honey Pot and also True Laundry Detergent is nearly guaranteed. They capitalize on the Black dollar and also provide a service that others want too. We need more Black-owned companies making products in these categories and more. When we make the products and provide the services that we buy, our \$1.3 trillion becomes an investment and not a blank check for every other company to endorse but our own."</p> <p>SOURCE: News, Forbes https://www.forbes.com/sites/ianysun/2020/06/18/black-ownership-founder-still-cas-white-people-purchase-like-they-protest/?sh=7f6dacc9d266</p>	<p>"Javier Martinez @__javi__ Jun 8 Do you want to know how you can help @OpenTable & @Yelp? Prosocial Nudges and Visual Indicators Increase Social Distancing but Authoritative Nudges Do Not

Mr. Mohin Banker, Yale University, USA

 Prof. Dafna Goor, London Business School, UK
 Dr. Tamar Makov, Ben-Gurion University, Israel

INTRODUCTION

Public health guidelines for social distancing are designed to reduce COVID-19 transmission and save lives. Although social distancing guidelines are relatively straightforward – keep six feet apart from others – following them is not always simple. To boost compliance with social distancing guidelines, simple visual indicators such as floor markings at six-foot intervals are often provided. Yet, information alone does not guarantee the behavior it is intended to promote (Hollands et al. 2016). To encourage social distancing, visual indicators are frequently accompanied by short messages, i.e., *nudges*. Different nudges have been widely employed during the pandemic to encourage social distancing and other COVID-19 risk-mitigating behaviors, including handwashing, mask-wearing, and vaccination. In many cases, these nudges highlight how compliance benefits oneself and others (Ceylan and Hayran 2021; Jordan, Yoeli and Rand 2021; Milkman et al. 2021; Rabb et al. 2021)³ or emphasize the medical expertise and authority behind the promoted behavior (Abu-Akel, Spitz and West 2021; Birnbach et al. 2017; Díaz and Cova 2021).

Although research suggests that nudges focusing on oneself or others foster preventive behaviors, it is often survey-based. Furthermore, results are inconclusive with respect to the relative effectiveness of nudges that emphasize benefits to oneself compared to nudges that emphasize benefits to others (Ashworth et al. 2021; Ceylan and Hayran 2021; Favero and Pedersen 2020; Jordan et al. 2021; Luttrell and Petty 2020; Rabb et al. 2021, Lu et al.2021)³. Relatedly, despite their ubiquity in public health messaging, it is unclear how authoritative nudges affect compliance with health guidelines and whether they trigger psychological reactance causing contrarian behavior (Díaz and Cova 2021, Krapen and Dolan 2021).

To address this knowledge gap, we tested whether social distancing is affected by visual indicators accompanied by nudges emphasizing personal benefits, public benefits, or authority in a field study at a major U.S. airport. During a ten-day period in January 2021, we collaborated with a private company to monitor the minute-by-minute locations of 57,146 travelers and track how social distancing varied in response to nudges presented on displays throughout a terminal (see Table 1).

Table 1: Nudge text by condition. Conditions were randomly assigned to two 24-hour periods during the study, balancing between weekdays and weekends. Crowd monitoring system displays as well as airport wayfinding and check-in monitors showed the condition’s message (i.e., nudge) to travelers throughout the terminal while color-changing poles presented crowdedness levels at each gate.

Condition	Nudge Text	Date
Baseline	N/A	Sunday, January 17 Tuesday, January 19
Generic	<i>Go towards green for less crowded areas</i>	Saturday, January 16 Wednesday, January 20
Self	PROTECT YOURSELF <i>Go towards green for less crowded areas</i>	Friday, January 15 Thursday, January 21
Others	PROTECT OTHERS <i>Go towards green for less crowded areas</i>	Thursday, January 14 Friday, January 22
Authoritative	DON’T BREAK CDC COVID-19 GUIDELINES <i>Go towards green for less crowded areas</i>	Sunday, January 17 Tuesday, January 19

Analysis

To analyze the effect of visual indicators and nudges on social distancing, we examine the proportion of travelers who maintained social distancing and were at least six feet apart from other travelers, excluding airport employees and groups traveling together. We repeat this analysis at both the whole terminal and gate level.

Results

Using a non-parametric approach, we first match observations across conditions by the number of travelers, and then compare average social distancing compliance between conditions over 30-minute time periods by estimating bootstrapped means, confidence intervals, and p-values. Table 2 presents results of pairwise comparisons at the (i) terminal level and (ii) the gate level.

First, to isolate the effects of visual indicators, we compare social distancing between the baseline and generic conditions. We find

that social distancing in the generic condition was marginally higher than the baseline in the terminal-level analysis ($p < .10$) and significantly higher in the more granular gate-level analysis ($p < .01$).

Next, we compare social distancing between conditions (i.e., self, others, and authoritative) to examine the effectiveness of the nudges. Both analyses indicated that social distancing compliance was higher in the others and self conditions compared to the generic condition (see Table 2). In contrast, social distancing was not statistically different between the authoritative and generic conditions.

Finally, we examine the consistency of social distancing differences between conditions across crowdedness levels at each airport gate. *Crowdedness* is the number of travelers at the gate divided by the gate’s capacity. *Gate capacity* is the maximum number of travelers that can occupy the gate while maintaining social distancing.

As depicted in Figure 1, for lower crowdedness levels (between 15% and 25%), social distancing was higher in the self and others

conditions (72%) compared to the generic condition (66%; $p < .05$). As gates become more crowded, differences in social distancing between conditions become more apparent. For example, between 70% and 80% crowdedness, social distancing in the self (68%) and others (66%) conditions remained higher than in the generic condition

(60%; $p < .05$). In contrast, at those crowdedness levels, the authoritative nudge decreased social distancing (57%; $p < .05$).

With the persistence of new cases and hospitalizations, COVID-19 remains dangerous around the world. Our findings demonstrate how nudges can promote or hinder COVID-19 preventive behaviors.

Table 2. Differences in percentage of travelers complying with social distancing guidelines between condition pairs. Each value is social distancing compliance of the latter condition subtracted from the former condition. CI and p-values were bootstrapped with 10,000 iterations. Observations were aggregated into 30-minute intervals and matched between conditions by number of travelers.

Comparison	Analysis	
	Terminal level	Gate level
Generic vs. Baseline	3.1*	4.4***
Others vs. Generic	7.9***	4.8*
Self vs. Generic	5.0***	5.0**
Authoritative vs. Generic	-2.0	-1.8
Others vs. Self	2.3	1.1
Observations	247	472

* $P < 0.10$, ** $P < 0.05$, *** $P < 0.01$.

Figure 1. Social distancing as a function of condition across gate crowdedness levels. Lines represent moving averages at 10% intervals for the share of travelers maintaining social distancing. Shaded areas represent bootstrapped 95% CI with 10,000 iterations. Vertical lines mark the crowding thresholds for visual indicators to change colors (from light green to dark green at 65%, orange at 105%, and red at 165%).

Technoism: A New Form of Consumer Prejudice and Discrimination

Dr. Moritz Joerling, Emlyon Business School, France

Prof. Nico Heuvinck, IESEG School of Management, France

Dr. Gwarlann De Kerviler, IESEG School of Management, France

Dr. Derek Rucker, Northwestern University, USA

INTRODUCTION

We introduce technoism, a new construct, to capture consumer's prejudice and discrimination toward technology. Consumers show prejudice against technology with objectively superior performance because of perceived human superiority. Three studies, across multiple contexts, demonstrate technoism exists, varies among consumers, and affects consumers' response to and use of technology.

Our data is publicly available at the following link: https://osf.io/8y3m6/?view_only=7e3a67c31d214b6db9e22e6fcc4284c2

Machines have become integral to consumer decision making from the mundane to the meaningful. Algorithms now make everyday recommendations from the household goods consumers buy to the movies they watch. Algorithms also influence potentially life-altering decisions related to consumer financial investments (Kou et al., 2014), whether to grant criminals parole (Dressel & Farid, 2018), and even triage decisions related to COVID-19 (Hao, 2020). In the modern age, this would seem a blessing as algorithms have exhibited the ability to outperform human decision making when it comes to desired outcomes (Dietvorst et al., 2015).

On the surface, machine algorithms seem a ripe and vibrant crop ready for harvest and further sowing. However, if one stirs up the soil and looks deeper, a long deeply held belief system seems to have taken root. Despite the superior performances of algorithm forecasts, research suggest humans exhibit apprehension, concern, and even distrust of algorithms (Longoni et al., 2019). People exhibit a preference for their fellow humans even when algorithms objectively exceed human performance (Dawes, 1979; Dietvorst et al., 2015; Longoni et al., 2020). On the surface such behavior might appear perplexing, however, it reflects a long active observation of human behavior: we distrust those that are different.

Across the course of history, humanity has exhibited prejudice and discrimination against those that are different, regardless of their merits. For example, some individuals or societies suppress others simply because of their gender or race, which is called sexism and racism (Masequesmay, 2020; Smedley, 2021). More generally, research has suggested that even when strides are made to bring humanity together it leads to other forms of prejudice and discrimination. For example, research on "speciesism" suggests that people deny basic rights to animals because of the belief that humanity is a superior species. In the case of machines, algorithms, and eventually artificial intelligence, this poses a risk that people may set aside factually better performance or decisions, purely based on the fact the recommendation comes from technology.

In this paper, we explore the idea that some people exhibit prejudice and discrimination against recommendations purely because the recommendations come from technology, which we term technoism. Technoism does not describe absolute refusal of technology but the value that an individual allocates to technologies in relation to humans. We propose, similar to racism, sexism, speciesism, and other forms of discrimination, that this level of intrinsic superiority over technology varies between individuals.

Our core research question is whether technoism exists and whether individual variation within it predicts prejudice and discrimination toward technology and, in this paper, algorithms. To test this hypothesis, we measured technoism by adapting items from

the speciesism construct (Caviola et al., 2019), originally measuring individuals' perceived superiority over animals, to the technology context. For example, technoism is assessed via items such as "An ideal society weights the opinion of human beings stronger than the opinion of technology.", "Humans should dominate technology", "Morally, technology always count for less than humans"; measured on a 7-point likert scale from "totally disagree" to "totally agree".

CONSTRUCT VALIDATION

In a first step, we tested for technoism's discriminant validity (preregistered: https://aspredicted.org/L6P_4B1) from the speciesism construct (Caviola et al., 2019) and from other perceptions related to technology (i.e., computer anxiety (Venkatesh, 2000), computer liking (Loyd & Gressard, 1984), technology optimism (Parasuraman & Colby, 2015), technology

insecurity (Parasuraman & Colby, 2015), perceived usefulness (Davis, 1989), perceived ease of use (Davis, 1989)). We collected 159 US participants ($Mage = 40.97$; 56.0% female) via Cloudresearch. All constructs demonstrated good reliability (range of $\alpha = 0.73 - 0.97$), except for computer liking ($\alpha = 0.46$). We calculated the average variance extracted for technoism ($AVE = 0.66$) and its zero order correlations with all other included constructs (see supplement Table S1 for complete correlation matrix). Technoism correlated the highest with perceived usefulness ($r = 0.379$). Thus, square root of the technoism's AVE (0.81) was bigger than technoism's correlation with all other constructs, demonstrating the construct's discriminant validity (Fornell & Larcker, 1981).

STUDY 1

Study 1 tested for technoism on the acceptance of algorithm input. More specifically, we tested whether the usage of algorithm input is perceived as less correct than the usage of human input if both inputs are qualitatively equal (i.e., same average accuracy in making correct predictions).

From an objective standpoint, the outcomes are similar, and thus if focused solely on ability no differences in perceived correctness should occur.

We collected 218 ($Mage = 38.91$, 47.7% female) participants from the US via Cloudresearch. Participants read about an employee that made investment decisions for an investment fund. For these decisions the employee received recommendations from a computer algorithm and a financial analyst, which have on average the same accuracy but differ in their recommendations. Depending on the experimental condition, participants learned either that a) the employee followed the computer algorithm's instead of the financial analyst's or b) the employee followed the financial analyst's decision instead of the computer algorithm's. Participants evaluated the employee's decision on a 7-point semantic differential with the two anchor points "not acceptable" and "acceptable". Subsequently, participants completed the technoism scale ($\alpha = .73$).

No main effect of condition was observed ($Malgorithm_instead_of_human = 5.80$, $SD = 1.14$; $Mhuman_instead_of_algorithm = 5.99$, $SD = 1.11$; $b = -0.195$, $SE = 0.153$, $p = .204$); however, we found a significant interaction ($b = -0.443$, $SE = 0.143$, $p = .002$). In both conditions, technoism significantly predicted perceived cor-

rectness of the employee's action. The higher a participants' score on technoism the more acceptable they thought the analysis was for following the human instead of the algorithm ($b = 0.210$, $SE = 0.105$, $p = .049$). In contrast, the higher a participants' score on technoism the less acceptable they thought the employee was for following an algorithm instead of a human ($b = -0.233$, $SE = 0.097$, $p = .018$); Moreover, individuals that scored relatively high on technoism perceived following an algorithm instead of a human recommendation as significantly less correct than following a human instead of an algorithm recommendation (Johnson-Neyman significance region for Technoism > 5.25 ; 42.20% of participants).

STUDY 2

In Study 2 (preregistered: https://aspredicted.org/VN7_H5S), we tested for technoism in the form of differential blame of a decision maker for a negative outcome that resulted from following an algorithm (vs. human) recommendation. Our experimental design consisted of four conditions: 1) a decision maker followed the recommendation of an algorithm instead of a human, 2) a decision maker followed the recommendation of a human instead of an algorithm, 3) a decision maker followed the decision of an algorithm in isolation, or 4) a decision maker followed the decision of a human in isolation. These latter two conditions allowed us to explore whether technoism led to bias in the absence of choosing between a human or algorithm or only when a decision maker makes a tradeoff.

All participants read a scenario that described a bank employee, who follows a recommendation (depending on the condition) to invest the participants' money. In all conditions, the average accuracy of human and algorithm recommendations was kept constant with 95%. We collected 366 US participants ($Mage = 37.92$; 51.6% female) via Cloudresearch. After reading the scenario, participants evaluated how much they would blame the decider, if their investment failed. We measured blaming of the decider with three items ($\alpha = .95$) adapted from an established scapegoating scale (Rothschild et al., 2012) and technoism as in Study 1 ($\alpha = .66$). We found no differences in blaming as a function of condition ($M_{algorithm_instead_of_human} = 4.43$, $SD = 1.72$; $M_{human_instead_of_algorithm} = 4.25$, $SD = 1.52$; $M_{isolated_algorithm} = 4.43$, $SD = 1.77$; $M_{isolated_human} = 4.39$, $SD = 1.54$; all $ps > .1$). However, we observed significant conditions by technoism interactions (interaction 1 "Algorithm_instead_of_human vs. Human_instead_of_algorithm x technoism": $b = -0.616$, $SE = 0.245$, $p = .012$; interaction 2 "Algorithm_instead_of_human vs. Human_isolated x technoism": $b = -0.662$, $SE = 0.217$, $p = .003$; interaction 3 "Algorithm_isolated vs. Human_isolated x technoism": $b = -0.451$, $SE = 0.228$, $p = .049$). Specifically, we found technoism led people to blame the employee more when they followed the algorithm instead of human ($b = 0.667$, $SE = 0.151$, $p < .001$). Moreover, technoism led people to blame the employee more when they followed the algorithm in isolation ($b = 0.457$, $SE = 0.175$, $p = .011$). In contrast, we found no relationship between technoism and blame when the employee decided to follow a human recommendation over an algorithm ($b = 0.051$, $SE = 0.181$, $p = .778$) or a human recommendation in isolation ($b = 0.006$, $SE = 0.147$, $p = .968$). Results of the interaction suggests technoism is prejudice against algorithms as opposed to favoritism toward humans.

STUDY 3

In Study 3 (preregistered: https://aspredicted.org/6SC_J3V), we tested whether the effect of technoism on decision maker blame is affected by the accuracy of the recommendation sources. As technoism describes the discrimination of technology irrespective of its

merits, we hypothesized that people may show bias against algorithms even if the algorithm recommendation is *more* accurate than the human recommendation.

Participants read a scenario about a doctor making treatment decisions for cancer patients. Here, the doctor receives an algorithm and a human recommendation to make the decision. We manipulated between-subjects three conditions: (i) the two recommendations have on average the same accuracy, (ii) the algorithm recommendation is *more* accurate on average (95%) than the human recommendation (75%), (iii) the human recommendation is more accurate on average (95%) than the algorithm recommendation (75%). In all conditions the doctor followed the algorithm recommendation.

We collected 325 US participants ($Mage = 28.91$; 73.8% female) via Prolific. Participants rated how much they would blame the decider if the chosen treatment would fail ($\alpha = .92$) and completed the technoism scale ($\alpha = .65$). We observed a main effect of condition; participants blamed the doctor more when he followed a less accurate algorithm ($M_{algorithm_low} = 4.89$, $SD = 1.39$) over a human decision than a more accurate algorithm over a human decision ($M_{algorithm_high} = 3.16$, $SD = 1.49$) or over a human decision with identical accuracy ($M_{control} = 3.57$, $SD = 1.48$, $p < 0.05$). Of central interest to technoism, the higher individuals scored on technoism the more they blamed the doctor for a negative outcome after following an algorithm recommendation even if the algorithm recommendation was significantly more accurate than the human recommendation ($b = 0.314$, $SE = 0.143$, $p = .031$). Technoism did not affect blaming of the decider if the human was more accurate than the algorithm ($b = 0.053$, $SE = 0.139$, $p = .704$); in essence everyone blamed the doctor the same for choosing the less accurate algorithm. The relation between technoism and decider blaming did not reach significance in the control condition ($b = 0.154$, $SE = 0.132$, $p = .246$) but was additionally established in Studies 4 – 9, outlined in the supplement material.

GENERAL DISCUSSION

We demonstrate across multiple contexts that appreciation of algorithm usage substantially depends on the individual beliefs (cf. technoism) and not only the decision context (Castelo et al., 2019; Granulo et al., 2020; Longoni et al., 2019). In essence, just as people have exhibited prejudice and discrimination toward their fellow humans because of sex and race, so do some discriminate against technology. Of note, this technoism is distinct from other constructs related to technology. Moreover, this work suggests that technoism can lead to bias even in situations where technology, in this case algorithms, perform objectively better than humans. Just as scholars have suggested that a careful monitoring of technology input is needed to avoid systematic discrimination of people by technology (Obermeyer et al., 2019), this work suggests that, as humans, we may need to be mindful of not discriminating against technology.

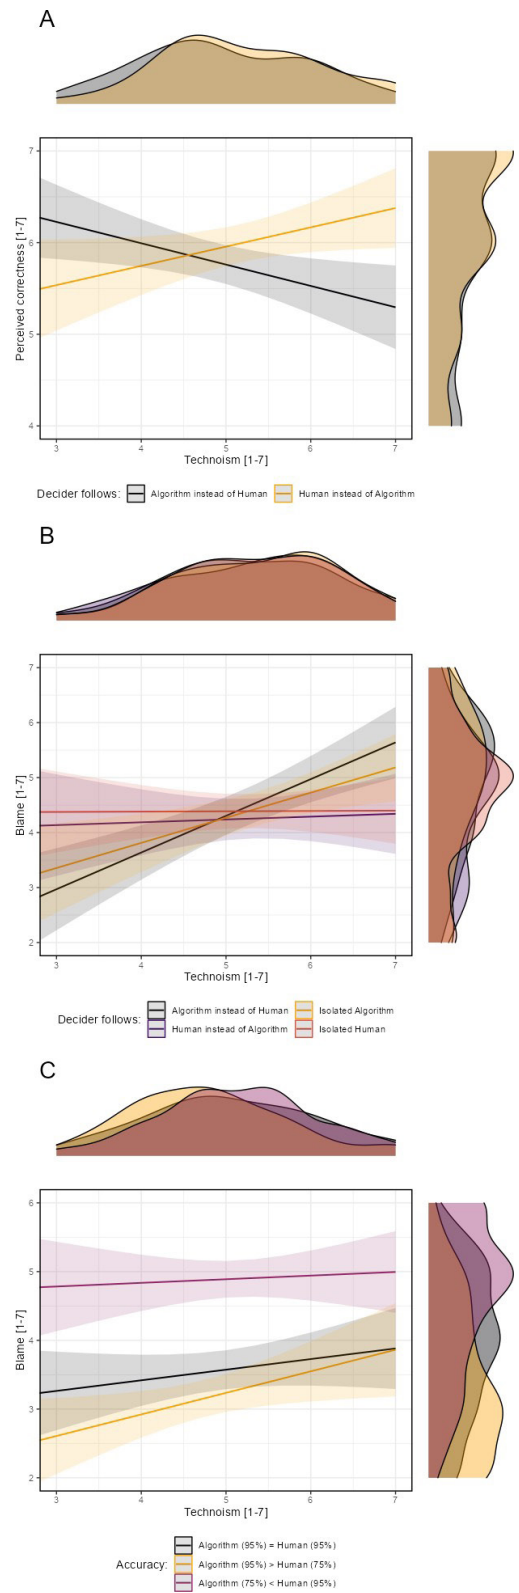

Figure 1. Regression plots for technoism in Study 1 – 3.

Plot (A) shows the effects of Study 1, the impact of technoism on perceived correctness depending on the recommendation source the decider followed. Plot (B) shows the effects of Study 2, the impact of technoism on blaming of the decider for a negative decision outcome, depending on the recommendation source the decider followed. Plot (C) shows the effects of Study 3, the impact of technoism on blaming of the decider for a negative decision outcome after following an algorithm recommendation, depending on the accuracy of the algorithm and human recommendation source.

Between Two Worlds: Consumption of Private Schools by Low-Income Families

Prof. Estefanie Nascimento, Pontifical Catholic University of Rio de Janeiro - PUC-Rio, Brazil

Prof. Angela Da Rocha, Pontifical Catholic University of Rio de Janeiro - PUC-Rio, Brazil

Prof. Ana Raquel Rocha, UFF - Universidade Federal Fluminense, Brazil

INTRODUCTION

We examine education as a form of consumption by low-income families in Brazil that have risen economically in recent years. The study adopts the view of consumption as a symbolic activity. Goods are bought, consumed, or used more for their symbolic value than for their utilitarian purposes. It is through the appropriation of meanings residing in goods that individuals categorize their position in the social world (McCracken, 1988). At the heart of consumption as a symbolic activity is the understanding that consumers use goods as extensions of the self (Belk, 1988). As stated by Baudrillard (1996), goods are never possessed, but rather abstracted from their function and their meaning incorporated to the individual. Holt (1995) adds that consumption can be understood as experience, play, integration, and classification.

One of the most striking social and economic phenomena in recent times has been the entry in the global consumer society of large fractions of the world population that have gained access to products and services that neither them nor their ancestors had ever consumed before. Although this new consumption at first was often directed towards traditional consumer goods, other desires followed, finally entailing the consumption of services such as leisure and education. These phenomena have been observed in several emerging economies, such as India (Chudgar and Creed, 2016; Sermeels and Dercon, 2021) and Uganda (The Economist, 2022). In this context, the following research question guided the study: *How do low-income Brazilian families, residing in poor communities that have improved their economic situation in recent years, use private education as a means and a symbol of social ascent?* We depart from a Bourdieusian perspective of education (Bourdieu, 1984, 1986, 2007), as well as from Holt's (1995, 1998) and Üstüner and Holt's (2010) contributions by incorporating Bourdieu's perspective to the understanding of status consumption into the marketing research agenda.

The contribution of our study derives from the scant attention given to education from the perspective of symbolic consumption in the field of marketing. Most studies, particularly in economics and education, see education as an investment, either public or private (e.g., Santibañez et al., 2021), even when recognizing there is also a consumption component to it. The literature also addresses the benefits of education on consumption, that is, individuals' access to goods and services, or their ability to use them because of education (e.g., Cheng, 2021). To our knowledge, few marketing studies have examined education as symbolic consumption in the context of low-income families that have improved their social standing (an exception is Costa Filho and Rocha, 2020). However, due to the very logic of scarcity, one can expect that consumption by this social fraction presents meanings that are different from those of consumers who exercise this role in the context of abundance. By examining the phenomenon, we concur with Rocha et al.'s (2020, p.2) view that "as an emerging economy, Brazil offers a fertile research landscape" to study the consumption of the less-privileged members of society.

METHOD

The study is qualitative and interpretive. The informants were fathers and mothers of lower-middle class families with children enrolled in private elementary schools, residents of *favelas* (slums), who improved their economic situation in recent years. The *favelas*

are typically located in the hills of the city, side by side with wealthier areas where the upper classes reside. Despite proximity, the two worlds are quite segregated, except that the *favela* residents often work in stores, other types of services, or as domestic employees in the homes of the wealthy. Twenty-four in-depth interviews were conducted with parents of 14 families. Informants were first asked to tell their family history, and then to describe their choices of private education for their offspring. Each parent was interviewed separately to search for occasional differences in their views of the experience. All names were disguised. The analytical method used was thematic analysis (Braun and Clarke, 2006). Each family was analyzed separately and then compared with the others and the final results with the literature.

RESULTS

Contrasting different worlds

Metaphors of private education have emerged in systematic contrast to public education. The backdrop is that public schools are meant for the lower class and are suitable for the more "ignorant" and "poorer," and "for the worst people," whereas private schools are seen as a place frequented by the middle class, by children of liberal professionals, who belong to "more structured families," consisting of "better people," who, even if poor, are "concerned about their kids." The contrasts that these two worlds represent – one rejected and the other coveted by the informants – extend to all aspects of the school. The private school is protective, quiet, ventilated, organized, disciplined and progressive. The public school, on the other hand, is threatening, a place of shouting and disorder, a place of disrespect and aggression, pure "chaos."

Making symbolic differences tangible

Ease of access to teachers and principals were highly valued and were seen as a tangible symbol of parents' status. Such was the case of Mário, who stated: "In private schools you have a more humane contact. You know the teacher; you know the principal; I just think it's better." And Rebeca, who had easy access to her son's teacher: "I know the teacher. I have her phone number, her email address, and her Facebook. I can make an appointment and go there and talk to her whenever I want to." A good physical infrastructure was also seen as a tangible sign of school quality. And to display the symbols of their social ascent, the parents often used social media to share photos depicting diplomas, attendance at extracurricular activities typical of the elite, and school uniforms.

Compensating inequality

Putting children in a private school meant giving them the opportunity to move forward in the process of social ascension initiated by their parents, by acquiring social and cultural capital. Regarding the acquisition of social capital, the private school offered the opportunity to interact with those "from the street" (those who live in urban areas of the city), as opposed to those "from the hill" (that is, those who live in the *favelas*), which was a common demarcation among the informants, who, for the most part, were born and raised in Rio's *favelas* on the city's hillsides. Interacting with those "from the street" made it possible to acquire different habits, attitudes,

and behaviors. “We look for what is best for him... because [there are] these things that go with the school and with socializing with friends. The school offers some things like outings, trips abroad. [...] We want him to participate in those things too, to have that interaction with friends” (José).

The acquisition of cultural capital was manifested by the refinement of musical, artistic, culinary and fashion tastes. The children consumed activities typical of the elite, such as ballet and language classes, visits to museums and exhibitions, or even trips abroad. The different tastes, preferences, and interests, as well as the polite manners and language obtained through private education, were also mentioned on a recurring basis. Cultural activities were well regarded by the informants, as explained by Raiane, who sought to take her daughter to children’s theater plays: “I go there, and I want to cry because I never had that. And she is there completely happy because for her, it’s normal.”

Among the activities, learning English was the highlight. Most of the private schools offered the discipline as part of their curriculum, but some of the families paid for an additional English course for their children. In the Araújo family, for example, Jaqueline attended ballet, swimming, and jazz classes, as well as an English class. The same was true of Laura, of the Ribeiro family: her school offered English classes as part of the curriculum, but the father planned to enroll Laura in an English course because “English taught there is different; it’s stronger.” Learning English meant inserting their children into a globalized world, giving them the opportunity to access other worlds unknown to their parents.

Circumscribing a new social logic

Forming circles of friendship with classmates and parents from other social classes, which extends beyond the boundaries of the school, was seen in a very positive light by the informants, who never had had the opportunity to interact in environments frequented by members of higher classes, except in situations of subservience. Another advantage provided by interacting with children from other classes related to future prospects. Instead of thinking about professions without much promise, such as manual labor, or aiming to be

a thief or a drug dealer (“like many youngsters in the *favelas*”), children learn to want “more dignified” careers, such as being a professor, a doctor, or an engineer. Mário pointed out: “Although they are children, they talk about pursuing a profession; they talk about going to college. I didn’t have that when I was in school.” Fausto synthesized his wishes for his son: “What I want for my son is not what I had. I don’t want him to have to go to work when he’s only thirteen, like I had to. [...] What I really want is for him to graduate, get a master’s degree, and have a cool profession – not one like mine.”

Private education was therefore an instrument of distinction for both parents and children. The distinction between parents who put their children in a private school and those who did not was articulated as a symbolic expression of love, as a testimony to the structure and solidity of the family and its social ascension:

“The public school caters to the lower class. Not that I’m from the upper class; we, ourselves, are from the lower class; but there are people from every layer. Even here in [the slum], there are spots that are worse than others. Then the kid goes to school with those influences. As long as I can, I’m keeping mine in the private school, so she can interact with others... I’m not saying they’re any better – we can’t judge people. But at least their parents think as we do. They want the best for their kids.” (Ricardo)

In the Vieira family, the son acquired tastes, preferences and behaviors considered distinct from those of the other boys in the community and similar to those of their schoolmates, in such a way, that he “...doesn’t even act like he’s from here [the slum].” The parents themselves created barriers by forbidding their children from playing with the others in the streets and alleys of the *favela*. Ricardo compared his daughter with other children in the community: “When she’s around other children, she’s even a bit withdrawn because she doesn’t know how to play the games of the children who are being raised without much supervision.” Thus, the informants saw their offspring assimilating the lessons from the “other world” and becoming, at least to some extent, part of that world.

DISCUSSION AND FINAL CONSIDERATIONS

Table 1 summarizes the main findings of the study.

Table 1 – Main findings

CLASSIFICATION		EXPERIENCE	INTEGRATION
<i>Contrasting different worlds</i>	<i>Making symbolic differences tangible</i>	<i>Compensating inequality</i>	<i>Circumscribing a new social logic</i>
- Who goes there - Who are their parents/ families - What social rules are enforced - What are the performance requirements	- Ease of communication with schoolteachers and principal - Quality of physical infrastructure - Use of social media to display distinction	- Socializing with “the street” - Acquiring superior role models - Acquiring taste - Experiencing the unexperienced	- Assimilating tastes and preferences - Becoming part of the “other world”

Embedded in a consumer society (Baudrillard, 1970), low-income consumers use private education to classify, experience, and integrate (Holt, 1995). Classification is rooted in the contrast between private and public schools, representing two opposite worlds that mirror the inequality in Brazilian society. While the private school is seen as the territory of the rich and privileged, the public school is represented as a place of poverty, exclusion, and deviant behavior. Such representation of the public school, albeit overstated and stereotyped, recognizes some of the problems identified by previous research in Brazil (e.g., Saisi, 2016). On the other side, the

representation of the private school pictures an idealized world of respect, organization, and progress, to which our informants aspire to belong. Thus, symbolic consumption of education serves to classify adults, children, and places of attendance. An invisible hierarchy is established in which the family and its members stand out from the rest because they can consume private education. They symbolically leave the “hill” and start to experience the “street,” but they are still on the boundaries between the two worlds.

These parents wanted to offer a set of experiences, social and cultural, to their offspring, and by doing so, vicariously experience

it themselves. The informants assumed that the tastes, attitudes, and preferences of the upper classes formed a set of codes that should be mastered to ascend. Since they, themselves, did not have this social and cultural capital to transmit to their children, they used private education, through which, in their understanding, several resources – attitudes, skills, preferences and behaviors – could be obtained and internalized (Bourdieu, 1986). By consuming private education (and its accessories), the appropriate cultural and social capital could then be transferred, owned, and accessed, when necessary, by their offspring. Thus, our informants were willing to make sacrifices to provide the relevant social markers to their children.

The child's socialization in a private school serves the family's plans for social ascension. It is necessary to build a network of relationships that transcends the social world of the "hill" and that can only be found on the "street," where the wealthiest people live because, although it is necessary to "live" on the hill, there is no need to "interact" there. This subtle territorial demarcation is in line with Üstüner and Thompson (2012, p.801), who noted that "consumers further assert their privileged social status position by setting strict boundaries on the range of normatively acceptable social interactions."

In Brazil, private education, from which the poorest segments have been systematically excluded, has become a symbol of belonging to the middle class and an aspiration of the lower classes. Therefore, examining the acquisition of this object of desire provides some relevant insights into how private education conveys meanings associated with distinction, status, and social ascension, and how parents appropriate these meanings and transfer them to their children. Aware of their limitations, the families in our study sought an education that would provide the tacit acquisition of the cultural and social capital necessary for the social ascent of the next generation so that the parents' own histories of childhood deprivation would not be repeated.

The study has several limitations. We examined a group of families living in the slums on the hillsides of the city of Rio de Janeiro, a cosmopolitan urban center, where poor communities live side by side with the wealthy areas. Although segregated, members of poor families do interact with the wealthier part of the population, mainly as service providers, and thus they can observe and learn about their lifestyles and tastes. Wherever segregation is more complete, the issues investigated here may show a different turn. In addition, the families examined had left poverty – in some cases extreme poverty – to have a discretionary income. They have experienced lifestyle changes in recent years that may have stimulated their desire for further ascent. Thus, they may differ from others that have remained in poverty. Future research should seek to understand the continuity of the processes used to socially ascend by low-income families, both through education – as in the case of higher education – and through the search for and access to other goods and services. It would also be interesting to investigate families with similar characteristics whose children have remained enrolled in public schools.

A machine learning approach for the prediction of individual and market level demand from retail loyalty program data:

Analytic models and discussion of possible behavioral and business practice mechanisms

Mr. Cameron Mcrae, McGill University, Canada

Prof. Laurette Dubé, McGill University, Canada

INTRODUCTION

Consumers walk many paths. Every decision requires the integration of several factors, be they economic, biological, or social, that complement and compete in terms of importance given the context of the decision (Brehmer, 1992; Dubé et al., 2014). Some decisions can also be emotionally charged, impulsive, and a little irrational (Amos, Holmes, & Keneson, 2014). Thus, the decision-making process results in heterogeneous consumer journeys, which makes predicting behavioral outcomes a unique challenge.

Behavioral prediction models at aggregate market levels are already well-established in the market and perform quite well. Methods such as the autoregressive-integrated moving average (ARIMA) model have been around since the 1970s and perform accurate predictions of aggregate market demand (e.g., total sales) at daily, weekly, monthly, or yearly scales (Box & Pierce, 1970). Yet, these models typically only use historical time-lagged sales data to predict future sales and require extensive transformations to address the non-linearity and seasonality of factors driving demand. Modern machine learning (ML) techniques for predictive modelling can overcome some of these limitations, while also affording superior accuracy of aggregate demand forecasts with a greater number of predictor variables (Bajari, Nekipelov, Ryan, & Yang, 2015).

Despite the technological advances in ML and its recent uptake in consumer research (Mariani, Perez-Vega, & Wirtz, 2022), little research has applied these methods to the prediction of food demand. Food choices are particularly complex due to the interplay of individual factors, ideals, resources, social frameworks, and the environmental context that influence consumer value negotiations, strategies, and choices throughout their lifecourse (Furst, Connors, Bisogni, Sobal, & Falk, 1996). Despite heterogeneity at the individual level, demand at the market level is a lot more predictable. Traditional statistical models have fared well at predicting the market demand for fresh foods on daily and weekly time scales (Arunraj & Ahrens, 2015; Marmier, Gonzales-Blanch, & Cheikhrouhou, 2009). ML approaches like non-linear autoregressive exogenous neural networks (Lutoslawski et al., 2021), artificial neural networks (Çetinkaya & Erdal, 2019; Huang, 2013), support vector regression (Rincon-Patino, Lasso, & Corrales, 2018), decision trees and random forest (Evers, Tavasszy, van Duin, Schott, & Gorte, 2018) have also been applied to predict market demand. Yet, common among all the ML approaches applied previously, the demand models were built using features constructed from historical sales, often without the incorporation of marketing or consumer variables. None of these models have been tested at predicting demand for food products at the individual level. Therefore, we seek to answer the following three research questions: (1) can ML methods be applied to predict food demand using marketing data from retail loyalty programs?, (2) can such models be applied at both the market and consumer levels?, and (3) what features are most important for prediction?

The objective of this article is to present two consumer demand prediction models that are useful and actionable for marketers working in food retailing today: (1) prediction of weekly sales at brand-level, and (2) prediction of monthly individual-level sales on a given brand. One million randomly selected purchase decisions within the

context of grocery retailing over a two-year period are used to train five machine learning (ML) models capable of predicting demand at both levels. Predictors included in the model are core to marketing, including over 70 variables that cover price, promotion, placement, product, and consumer characteristics. The results reveal two actionable models for marketers capable of predicting brand-level weekly demand for branded food products with an r-squared of 99% and individual-level monthly demand with 54%, based on the manipulation of marketing variables within the control of a marketer. An investigation into the contribution of each feature to the prediction model uncovers differential pathways of demand prediction, where marketing strategies like price discounts and flyer promotions contribute more to the market level sales prediction than those at the consumer level.

DATA AND CONTEXT

Loyalty program data was obtained from a large retail chain that operated 256 grocery stores located in the province of Quebec, Canada for a 23-month period ranging from February 1, 2015, to December 30, 2016. Each row of the dataset corresponds to one item purchased at a grocery store checkout by one of the retailer's loyalty cardholders, which can be linked to time-bound product, store, marketing, and consumer information from other tables defining the context.

Brand marketing managers are the target audience for our prediction models. Focusing on 22 individual food brands under the portfolio of three of the world's largest multi-national corporations (MNCs), which includes 3815 unique product codes (UPCs), we form a full dataset that spans 757.8 million purchase transactions by 657,261 loyalty program cardholders (an additional 138,136 were removed by isolation forest as outliers). Predicted outcome measures (weekly brand-level and monthly individual-level sales on an individual food brand) were aggregated across the full dataset and matched to the individual transaction representing a single purchase decision. A random sample of one million transactions was taken from the full dataset to train the five ML prediction models to conserve computational costs like system RAM, training time, and prediction time.

Each of the one million transactions was linked using search query language (SQL) to a timestamp, consumer information, and product, placement, price, and promotion (4 Ps) marketing data defining the context at the point of sale within the retail loyalty program data. This process yielded 77 predictor variables: (i) *time* variables: holiday, season of year x 4, year, week of year, month of year; (ii) *product* variables: MNC corporate brands x3, individual food brands x 22, product size in grams or milliliters, product category x 18; (iii) *placement* variables: retail banner x 4, urban or rural; (iv) *price* variables: regular price, discount, final price; (v) *promotion* variables: number of loyalty points awarded, location of promotion in flyer (front, inside major, inside minor, back), digital promotion, in-store price-cut or sell-off; and (vi) *consumer* variables: days registered in loyalty program, length of relationship with brand in days, cluster number (predicted with k-means clustering), and neighborhood socioeconomic indicators for income, unemployment, education, and household composition from the 2016 Canadian census.

Note that the consumer variables were only used for the individual-level predictions, not the brand-level.

We first conducted principal component analysis (PCA) and k-means clustering to identify distinct segments of cardholders based on past expenditures, with the Silhouette score being used as an evaluation metric to determine the optimal number of clusters. This process resulted in each loyalty cardholder being assigned to one of two clusters, which was used as a predictor for the individual-level demand model. All predictor variables were standardized using the sklearn StandardScaler python package. Machine learning models implemented for the sales predictions include linear regression, random forest, eXtreme gradient boosting (XGBoost), k-nearest neighbors (kNN), and multi-layer perceptron artificial neural network (aNN). The kNN optimally used the 10 nearest neighbors for both models. The aNN was constructed using two layers (73 neurons, 37 neurons) for the market level model and two layers (75 neurons, 50 neurons) for the consumer level model, both using a Rectified Linear Unit (ReLU) activation function. Shapley values were used to determine the importance of each feature to the predictions (Jia et al., 2019). The random sample of one million transactions was partitioned to 70% for training and 30% for testing the machine learning models. Root Mean Square Error (RMSE), Mean Absolute Error (MAE), r-squared, training time, and prediction time were used as performance metrics. All data analyses were conducted using Python 3.7 on Google ColabPro+. Data were stored on Google Drive and connected to virtual machines running our Python code. The following open-source libraries were used: *numpy*, *pandas*, *matplotlib*, *seaborn*, *sklearn*, *xgboost*, *shap*, and *yellowbrick*.

RESULTS

Two principal components explained 97.794 (SD= 0.35%) of the variance in sales. Using these two components to feed into the k-means clustering algorithm, we observed that the optimal number of clusters is two, which yielded the highest silhouette score of 0.655. The first cluster ($k=0$) contains 75% of cardholders ($n=491,409$) who consistently spend more on the 22 food brands, whereas the second cluster ($k=1$) contains the remaining 25% ($n=165,852$).

A summary of the predictive results is provided in Table 1. For brand-level monthly sales, random forest (RF) regressor is the best performing algorithm with the lowest RMSE and MAE, highest R-squared, and decent training and prediction running times. Remarkably, RF can predict brand-level weekly sales with 99.96% accuracy given the 73 marketing predictors. The MAE for RF predictions of weekly sales across all 256 stores is only \$1,228.90. aNN also performs well but has a slightly higher error and substantially longer training times (33x longer than RF in seconds). kNN also achieves high accuracy at 95.60% but suffers from a long prediction time. Linear regression is the worst performing, only explaining 68.90% of the variance in weekly sales at the brand level.

Regarding monthly individual-level spending, aNN performs best. The aNN algorithm achieves 53.4% accuracy and the lowest RMSE and MAE, despite longer training times. Given the 78 predictors used for the consumer model, aNN can predict an individual’s monthly spending within a \$12.02 margin of absolute error. RF performs second best and is approximately 2% less accurate than aNN but benefits from a shorter training time. Again, we observe the linear model performs worst at individual demand predictions but is not that much worse than the best-performing non-linear aNN model.

Table 1. Performance metrics (n = 1,000,000)

ML method	Weekly Brand-level Sales					Monthly Individual-level Sales				
	RMSE	MAE	R ² (std dev)	Train time (s)	Predict time (s)	RMSE	MAE	R ² (std dev)	Train time (s)	Predict time (s)
linear regression (LR)	1,146,805.73	694,981.41	68.90% (1.47%)	2	0	16.92	13.35	47.10% (0.14%)	5	0
random forest (RF)	34,218.88	1,228.90	99.96% (0.01%)	518	7	16.18	12.32	51.42% (0.18%)	1,568	32
eXtreme gradient boosting (XGBoost)	711,745.21	445,724.92	88.14% (0.25%)	129	1	16.48	12.72	49.90% (0.21%)	158	1
k-nearest neighbors (kNN)	415,984.28	136,353.49	95.60% (0.18%)	0	4,147	16.8	12.82	47.64% (0.24%)	0	4,286
multi-layer perceptron artificial neural network (aNN)	266,454.86	124,019.54	95.38% (0.10%)	17,200	4	15.85	12.02	53.40% (0.10%)	4,107	1

Shapley values were computed for each of the one million observations in the dataset. The Shapley value for a feature represents how much the model prediction changes the feature is observed versus unknown, which is measured in units of dollars. We present these results in a beeswarm plot in Figure 1, where each observation is represented by a single dot on each feature row. The position of the dot on the x-axis is determined by the Shapley value, whether it has a negative or positive impact on the prediction. Dots “pile up” to show density, while the colour shows the original value of the feature as high or low (e.g., 0 would appear blue whereas 1 would appear red for a binary indicator).

Notable differences exist among the top ten features contributing to the brand and consumer-level predictions. For the brand

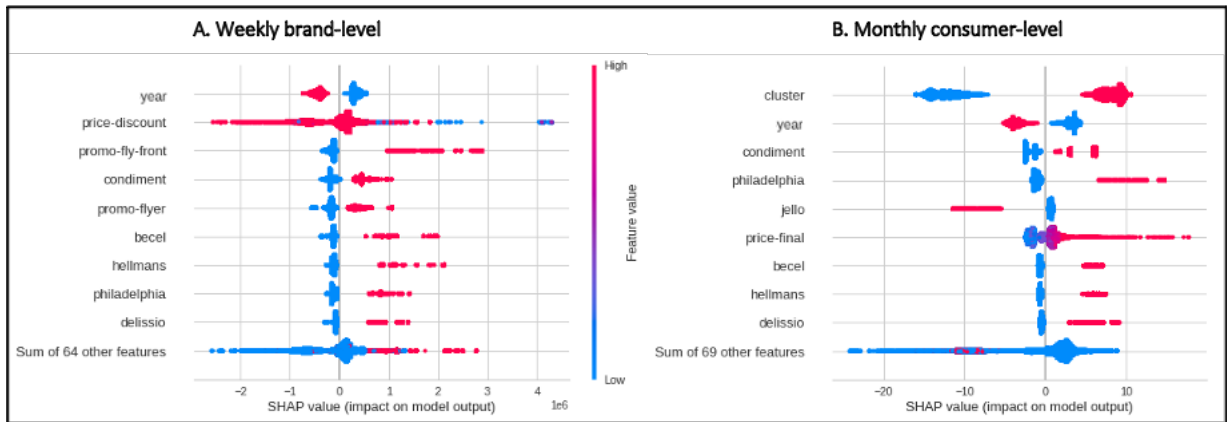

model, time (year) is the most important predictor, followed by the magnitude of price discount, and whether the product was on promotion on the front-of-flyer or not. Price discounts and flyer promotions have strong positive impacts on predictions of weekly sales for branded food products.

Conversely, for the consumer-level model, cluster number is the most important predictive feature. The importance of the cluster number in contributing to individual demand predictions highlights the utility of quantitative segmentation approaches, such as the one done with k-means clustering at the start of this article. Other important features include time (year), brand name, and the final price. Only the final price appears in the top 10 predictors, suggesting that the final price, regardless of a discount or not, is most predictive of

monthly consumer sales. Individual brand names (e.g., Philadelphia) appeared within the top 10 predictors, which are synonymous with frequently purchased brands with strong and lasting market share.

The strength of individual brand names and categories seems to overcome the impact of marketing on predictions at an individual level in this model.

Figure 1. Top 10 feature importance by SHAP value for (a) brand-level and (b) consumer-level (n = 1,000,000)

DISCUSSION

These analytical results align with previous research that has demonstrated the use of machine learning models for predicting the demand of food products at a market level. However, our model only uses marketing features that describe the food environment at the point of sale to make brand-level predictions of weekly sales with an r-squared of 99.96%. This model can be extremely useful for marketers and brand managers in practice. After selecting one of the 22 food brands in one of the 18 product categories, one can manipulate any of the 5 placement, 3 price, 9 promotion, or 1 product variables to experiment with predictions of market-level outcomes for the brand, for any week of the year, given the scenario in mind.

Marketers should continue to pay careful attention to the magnitude of a price discount, which is one of the most influential features of our model. The distribution of the Shapley scores for price discounts does suggest that some discounts may not actually boost overall revenues for a brand; marketers could use our model to predict the impact of price changes on market outcomes so as to guide their marketing program strategies. Even in the consumer-level model, the final price paid (which factors in the price discount) is among the top ten predictors of an individual's spending on a particular brand in any given month.

Our results also reveal the difficulty in predicting individual behaviors. The best performing ML model for monthly consumer spending, the multi-layer perceptron artificial neural network (aNN), achieved an r-squared of 53.40%, meaning that our model accounts for about half the variance in individual sales. The consumer model also integrates consumer-specific variables defining the length of the relationship the consumer has with the retailer and the food brand, as well as neighborhood-level socioeconomic characteristics, none of which appear among the top ten predictors of individual-level sales. The most important feature, rather, is the cluster number which was assigned using a k-means clustering analysis based on all-time consumer expenditure across the 22 food brands. This points to the usefulness of quantitative segmentations in marketing practice, and how nested ML approaches can yield superior predictive results. These benchmark individual prediction models can now open the door for future research that employs other methods of segmentation, which do show promise in improving the low r-squared.

Clearly, the other half of the variance not explained by the consumer model must be explained by factors outside our model, which could be tied more so to the biological, psychological and social context that is specific to an individual at a point in time. Possible other factors include hunger (Hoeftling & Strack, 2010), lifecycle events and experiences (Furst et al., 1996), social influences (Shepherd, 1999), emotions (Gutjar et al., 2015), impulsivity (Mishra & Mishra, 2010), neurocognitive evaluations of value (Petit et al., 2016), risk perceptions and risk preferences (Lusk & Coble, 2005), decision-making under uncertainty (Tonkin, Coveney, Meyer, Wilson, & Webb, 2016), weight management and dietary goals (Lowry et al., 2000), dietary habits (Hackett et al., 2008), or other behavioral mechanisms. Future work, for example, could incorporate measures of these facets as features for segmentation via clustering, which could also likely enhance the accuracy of behavioral predictions for the individual-level model.

Future research may consider implementing optimization algorithms to tune marketing parameters to achieve desired outcome measures. At the consumer level, this optimization is a key pathway for personalized marketing or precision retailing (Dubé, Soman, & Almeida, 2021). Using this model, price discounts and promotions could be tailored to maximize an individual's spending on a particular food brand in each month. However, this also raises questions of fairness, welfare, and equity around personalized pricing that are still to be addressed in marketing practice, particularly for food (Kallus & Zhou, 2021). The optimization of individual spending on a branded food product also raises a secondary ethical issue with societal relevance: should we implement an individual-level ML optimization algorithm on branded food products, when, at the same time, processed foods have been found to increase the risk of overweight/obesity, cholesterol levels, and metabolic syndromes (Pagliai et al., 2021)? Perhaps this optimization approach would be more suitable for boosting the consumption of healthy foods that are notoriously under-consumed, such as vegetables (Ma, McRae, Wu, & Dubé, 2021), as a pathway enabling the convergence of food, health, and wealth (Dubé, Pingali, & Webb, 2012).

Evaluative Dynamics: Summarizing Customer Journeys, Interviews, and Lives

Prof. Julian De Freitas, Harvard Business School, USA

Ms. Pechthida Kim, Harvard University, USA

Prof. Tomer D. Ullman, Harvard University, USA

INTRODUCTION

Life is filled with experiences over time that we undergo twice: once in the living, and once in the recounting. When we go on a week-long vacation, we have the moment-by-moment experience of that vacation. But when a friend asks us how the trip was, we do not give them a week-long tale. Summarizing and compressing experiences is an essential part of learning and decision-making, both in consumption and management.

How do people summarize continuous experiences? Take a customer journey (Edelman and Singer 2015), consisting of how a customer felt across their various touch points with a firm, such as when they first saw the firm's ad, logged on to its website, received information about the product, installed the product, and so forth. How does a consumer summarize how satisfying an entire customer journey was? One idea is to literally "sum up" the affect experienced over the course of the journey—say, by plotting happiness over time and then taking the area under the curve (integral). However, researchers have suggested people instead weigh the peak and end moments most heavily (Fredrickson and Kahneman 1993), or consider the trajectory's velocity (Hsee, Abelson, and Salovey 1991), acceleration (Hsee, Salovey, and Abelson 1994), or improvement and deterioration (Bhargave and Montgomery 2013; Loewenstein and Prelec 1993).

Previous work has studied how people summarize trajectories by testing the importance of only one or two features at a time (e.g., peaks and velocity), and by considering lines that simplify the complexity of real-life trajectories, such as how consumers feel when shopping for a product or how managers feel when listening to an interviewee (Bhargave and Montgomery 2013; Carmon and Kahneman 1996; Fredrickson and Kahneman 1993; Hsee et al. 1994; Kahneman et al. 1993; Loewenstein and Prelec 1993). The current work significantly builds and expands on this previous work by considering 27 differently patterned trajectories and quantifying the relative extent to which 20 features of these trajectories predict people's summaries.

The features we chose capture both the literal characteristics of each trajectory and more semantic features based on participant's descriptions of the trajectories. Literal features include how much the trajectory was improving or deteriorating over time (various weighting of the first derivative, or slope), whether such changes are fast or slow (various weighting of the second derivative, or acceleration), what the peak, valley, and end values of the line are, the combined content contained by the trajectory (integral, area under the curve), and the number of peaks, valleys, and total extrema. Semantic features include how interesting the trajectory is (as represented by the number of unique words used by different participants to describe the trajectory), the semantic meaning of these words (as generated from a trained neural network), and the valence of these words (as calculated by a sentiment model).

Here we explore the possibility that more than one of these features is important, because they inform an evaluation of how well or poorly the trajectory is going overall. This evaluative representation is how consumers naturally represent the trajectory, perhaps because such a psychological representation is more compact and useful than keep tracking of all the literal features of the pattern (e.g., its peaks, troughs, integral, velocity, and so on). This evaluation is also what ultimately informs how people rate the experience, such as how satisfying a customer journey is, whether to hire someone based on their interview performance, or how meaningful a life is.

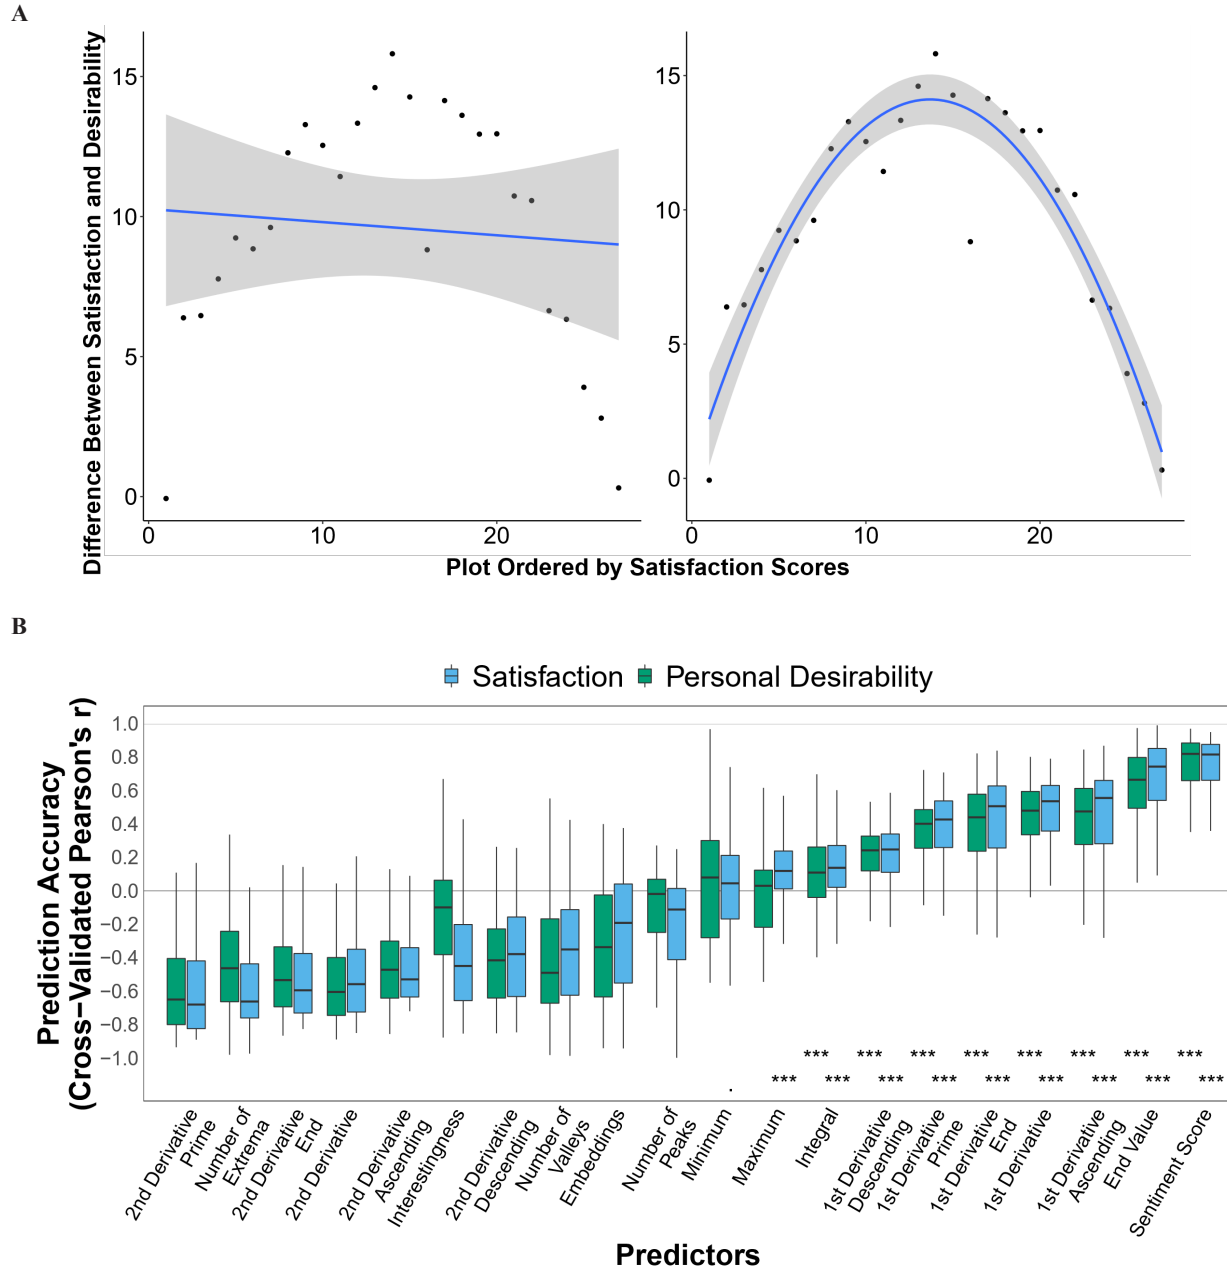

Study 1 examined how consumers judge the satisfaction of 27 customer journeys, derived from a range of basis functions and common narrative arcs of stories (Vonnegut 1995). The plots captured a fictional customer's experience with a solar panel firm named *Solaro*, with "Happiness" plotted on the y-axis and "Customer Touchpoint" plotted on the x-axis. After seeing each pattern, participants (296 recruited, 119 excluded) answered questions about how satisfied and desirable the customer journey was, and how willing they would be to pay for the service (DVs in all studies were on 0–100 scales). Participants also described the journey using a single word.

Patterns of customer satisfaction resembled that of desirability and willingness to pay (satisfaction: $r = .42, p < .001$; personal desirability: $r = 0.39, p < .001$). Notably, participants' summaries of satisfaction and personal desirability depended on the *pattern* of the trajectory ($b = 0.17, p < .001$). Participants also differentiated between how satisfying and desirable a customer journey was ($b = 9.61, p < .001$), with satisfaction scoring significantly higher than personal desirability ($M = 43.37 (29.64)$ vs. $M = 33.75 (31.58)$; $t(4778) = -46.75, p < .001$). Moreover, we noticed an interesting pattern between summaries of satisfaction versus desirability: When we plotted satisfaction and desirability scores arranged in ascending order of satisfaction, the differences were initially small, then increased, then decreased again (Figure 1A). Indeed, when we regressed the difference between satisfaction and personal desirability on customer journey numbers ordered by the average satisfaction scores, we found that a linear model fit the data poorly ($b = -0.05, p = .672$), whereas a quadratic model fit them well (quadratic $b = -0.07, p < .001$; quadratic $>$ linear, $p < .001$). Thus, although customer journeys were generally viewed as more satisfying than personally desirable, satisfaction and personal desirability converged for journeys that were viewed as either extremely full or devoid of satisfaction. While consumers acknowledged that ups and downs could lead to satisfying experiences, they preferred to avoid fluctuations themselves in favor of experiences that were consistently good or improving.

To quantify how well each feature predicted summaries of satisfaction and personal desirability, we used a leave-one-subject-out cross-validated procedure. Summaries were significantly predicted by (from best to worst) the sentiment scores of the word descriptors, followed by the end value, various first derivatives, integral and maximum value (Figure 1B).

Figure 1

LINEAR AND QUADRATIC FITS TO THE DIFFERENCE BETWEEN SATISFACTION AND PERSONAL DESIRABILITY RATINGS (A) and PERFORMANCE OF FEATURES IN PREDICTING Satisfaction AND PERSONAL DESIRABILITY (b) in study 1

Note. (A) Points arranged by increasing satisfaction scores. (B) Feature score boxplots depict the median and 25th and 75th percentiles. Features are ranked by how well they predict satisfaction (blue). The thin line above the plot depicts the noise ceiling, an estimate of the maximum possible performance of our predictors, given the reliability of the data (obtained by randomly splitting the participants in half, finding the average rating per lifeline for each half, correlating the two halves, and correcting with the Spearman-Brown Prophecy Formula: $r_{full} = 2(r_{half}) / (1 + r_{half})$, where r_{half} = split-half reliability and r_{full} = full-length estimation). The noise ceiling encompasses the range of values between the 25th and 75th percentiles of all split-half correlations. Stars beneath boxes indicate whether the distribution of correlations is significantly different from a null distribution, via a Wilcoxon signed-rank test. Absence of a star indicates non-significance. * = $p < .05$, ** = $p < .01$, *** = $p < .001$.

Study 2 asked participants (296 recruited, 78 excluded) to describe the same patterns from Study 1 *without* also summarizing how satisfying or desirable they were, or how much they would pay for them. In short, participants were merely asked to describe each customer journey using one word and one sentence. We hypothesized

that, even when participants are not explicitly asked to evaluate experiences, they use highly evaluative language to describe trajectories, such that a sentiment score of their natural descriptions in this study correlates highly with their sentiment scores in the previous study, and again predicts satisfaction ratings.

We first ran the same sentiment analysis used in Study 1 on the words participants provided. We then ran a Pearson's correlation between their sentiment scores in this study and their analogous scores from Study 1. We found near-perfect correlations, both when correlating the sentiment scores of this study's full sentences ($r = .92, p < .001$) and single words ($r = .99, p < .001$).

We next tested whether the sentiment scores for both words and sentences from this study predicted participants' summaries from Study 1 by utilizing the leave-one-out cross-validation procedure outlined in Study 1. Our predictors were the average sentiment scores for words and sentences from the current study. Both sentiment score types significantly predicted satisfaction (sentences: mean $r = .73, p < .001$; words: mean $r = .73, p < .001$) and personal desirability (sentences: mean $r = .68, p < .001$; words: mean $r = .72, p < .001$) ratings from Study 1, even though Studies 1 and 2 involved different groups of participants. These results suggest that consumers' representations of customer journeys are *naturally* evaluative.

Studies 3 and 4 extended these findings into two new domains respectively: hiring a candidate based on interview performance (Study 3) and summarizing the meaningfulness of a life (Study 4). While seemingly different, all domains involved summarizing experiences over time.

In Study 3, the plots captured a fictional candidate's perceived interview performance for a teaching position at a university called *Northridge College*, with "Perceived Performance" plotted on the y-axis and "Time" plotted on the x-axis. Participants (295 recruited, 155 excluded) then rated how likely it was that they would hire the candidate and were asked to describe the experience using one word.

In Study 4, the plots captured entire lives, with "Happiness" plotted on the y-axis and "Age" plotted on the x-axis. Participants (203 recruited, 79 excluded) rated how meaningful the person's life was overall, how much the life was personally desirable, and how they would describe the life with one word.

Both studies replicated the main findings of Study 1. At the same time, there was interesting variation in the ordering of the best-performing features, depending on the domain. Over short periods, such as an interview or customer journey, ends and slope mattered a lot, suggesting that people expect interviewees and firms to deliver an improving experience that ends climactically. Over long periods, such as a lifetime, integrals mattered more, suggesting that people were more forgiving of lives without peaks, perhaps because people have less control of an entire life. Yet again, the most predictive feature was a sentiment score of the words people use to describe these patterns.

Finally, we also found that meaningfulness ratings in Study 4 were highly correlated with satisfaction ratings from Study 1 ($r = .93, p < .001$), as were personal desirability ratings from the two studies ($r = .93, p < .001$).

GENERAL DISCUSSION

Experiences over time are ubiquitous in consumption, management, and life, and they can be summarized in various ways. Yet how do people ordinarily do so? Is there any consistency in how they summarize events over time across various practical domains? In three different domains—determining whether a customer journey is satisfying, an interviewee should be hired, and a life is meaningful—we found that 1) people's summaries were affected by the patterns of the trajectories; 2) people's judgments were best predicted by a sentiment score of the words they used to describe the patterns, followed by the area, slope, and end value of the pattern; and 3) over short periods, ends and first derivatives mattered a lot, quantitatively supporting previous work (Carmon and Kahneman 1996;

Fredrickson and Kahneman 1993a), while over long periods such as a lifetime, integrals were more important. Apparently, people in consumer, managerial and everyday life settings are likely to represent continuous events in evaluative terms.

The fact that consumers spontaneously evaluated experiences over time using a valence judgment significantly extends classic work on evaluation (Fazio et al. 1986; Osgood 1952, 1962), with practical implications for the specific domains we tested. Previous work has found that consumers represent concepts (Osgood 1952), entities (De Freitas et al. 2017, 2018), and counterfactuals (Folkes and Lassar 2015; Tsiros and Mittal 2000; Wiggin and Yalch 2015) in evaluative terms. Adding to this list, we find that consumers are also highly evaluative in how they naturally summarize information over time. Perhaps, the evaluative dimension is a particularly useful and compact way to represent experiences, informing the summaries consumers need to make of them without the need to keep track of all the literal features of a trajectory. In this vein, future work could also investigate whether consumers are better able to remember evaluative details of a trajectory than its literal features.

Limitations and Future Directions. One drawback of our design is that the patterns were artificially constructed, and our 'measures of success' were provided by participants rather than collected 'from the wild', e.g., using journal citations or how much profit a movie made. It would be worthwhile to test whether the current results replicate using real-world data, such as customer reviews or movie ratings. In a separate pilot study, we tested whether we could predict movie ratings based on the sentiment arcs of their scripts but did not find promising results. One likely reason may be that ultimately the most relevant predictor of a movie's rating is not the trajectory of its content but that of the viewer's *mental experience* of it.

The current work also leaves open several other exciting questions, including what factors moderate people's summaries of trajectories, whether the duration of the trajectory matters (e.g., a shorter life may be viewed as more tragic than a longer one), and whether there are some domains that diverge from the consistency found across the three studied here.

Implications. Managers care about what makes some customer journeys more successful than others (Edelman and Singer 2015; Lemon and Verhoef 2016) and about how to make good hiring decisions (Arvey 1979), and candidates care about what patterns of performance are most likely to get them hired. The current work uncovers the types of experience patterns, as well as the features of those patterns, that are most likely to lead to success. For instance, candidates should end their interviews positively, display either consistently or increasingly positive impressions, and make a deep impression at a "peak" point of their interview.

The results have further implications for each of the specific domains we tested. For instance, our results both confirm and diverge from previous theoretical positions on customer journeys. One debate is whether customer journeys should be smooth (Edelman and Singer 2015) or constantly fluctuating (Siebert et al. 2020), given that the latter may be more exciting. Supporting the smooth view, we find that consistently positive trajectories are viewed as most satisfying, meaningful, desirable, and likely to lead to a hire. Of course, in practice it is hard to sustain this level of service, so managers and candidates may want to take note that people rate almost as positively those experiences which end pleasantly, constantly improve, or have a distinct peak. But note that not all fluctuations from perfection are equally effective. In this vein, our results also provide mixed support for the strong fluctuation view, since we find that people do not personally desire experiences that fluctuate, even if they recognize that such experiences may be satisfying or meaningful.

A broader implication is that customer experience managers may want to think of creating certain *patterns* of experience and tracking what patterns their consumers are in fact having. Luckily for them, something as simple as a sentiment score of the consumer's natural language description of their customer journey can be highly indicative of whether these efforts are working.

How Coherent Nature Makes Natural Products Attractive: The Moderating Role of Centrality of Naturalness in Category Representation

Dr. Hajar Fatemi, University of Windsor, Canada

Prof. Laurette Dubé, McGill University, Canada

INTRODUCTION

We investigate the underlying cognitive process and a boundary condition for evaluation of natural products. Our findings highlight consumers' lay belief about coherence in nature and suggest higher inter-attribute coherence and, thus, better product evaluation for natural products, but only if being natural is a central attribute in those products. Natural products have become increasingly popular among consumers but our understanding of consumers' lay beliefs and underlying cognitive processes about these products remains limited. We propose that consumers hold a belief on nature having coherent characteristic, which is transferred to natural products and increases their inter-attribute coherence, i.e., more aligned and consistent attributes. Our findings in an Implicit Association Test (IAT) and two experimental studies confirm these propositions and show that naturalness improves inter-attribute coherence and consequently willingness to purchase of natural products. Our proposed effects are limited to the products in which naturalness is a central attribute. The naturalness literature is mainly in psychology and environmental studies and outside the context of marketplace. These studies look primarily at how individuals interact with nature, either in experiences like hiking and surfing (Canniford & Shankar, 2013) or in exposure to natural elements in living environments (Shanahan et al., 2015). The studies that look at naturalness in the context of marketplace build mainly on general preference for nature and within a limited number of product categories (Roman et al., 2017; Prada et al., 2017; Berry et al., 2017; Scott et al., 2020). These studies mostly did not provide an underlying mechanism for the effect of naturalness on product evaluation that can get generalized across different product categories. Our paper tries to fill this gap in the current literature by proposing a mediator along with a boundary condition for explaining the impact of naturalness on product evaluation. Unlike previous studies, the application of our reasoning is not limited to a selected number of product categories and can be generalized to all types of products. Naturalness is commonly defined as being close to nature, i.e., the biological and physical world around us (Thompson, 2011), as opposed to that which is man-made (Wachsmuth, 2012; Rozin, 2005; Lanier et al., 2013). We highlight the consumers' lay belief about interconnected and integrated whole, i.e., coherent, characteristic of nature. Humans hold a widespread belief that characterizes nature as coherent, bringing integrity among diverse, ever-changing, and sometimes competing components (Thompson, 2011, 2004; Deangelis & Waterhouse, 1987; Wu & Louks, 1995). In coherent nature, all entities are believed to be highly interrelated in harmony and uniformly create a single whole, unless they get disrupted by human interruption (Wilson, 1993). We propose that the coherent qualities of nature transfer to natural products and make them to have more coherent attributes. This implies more interconnected, aligned, consistent and less conflicting attributes for natural products. Therefore, we propose:

Hypothesis 1: Nature is commonly perceived to have higher coherence compared to man-made developments.

We propose that consumers evaluate natural products as having coherent attributes. In another words, we expect the perception

of coherence to transfer from the mental representation of nature to the evaluation of natural products. Contrastingly, as man-made developments are associated with having lower coherence compared to nature, we expect consumers to evaluate man-made products as having fewer coherent attributes compared to natural products. Previous studies showed that naturalness is not evaluated the same across products (Scott et al., 2020). We contribute to these results and propose that the centrality of naturalness, i.e., the degree to which the internal structure and the coherence of that product depends on naturalness (Sloman et al., 1998; Gershoff & Frels, 2015), is different across product categories. This difference in the degree of centrality is linked to how naturalness improves the coherence of product attributes and eventually product's preference. We propose that when naturalness is central in defining a product, it increases the inter-attribute coherence of that product. We do not expect to find the same impact in a product where naturalness is not a central attribute. Unlike earlier studies (Rozin et al., 2004; Scott et al., 2020), the application of our reasoning is not limited to a selected number of product categories and can be generalized to all types of products.

Hypothesis 2: Being natural, compared to being man-made, increases inter-attribute coherence only in products in which naturalness is a central attribute.

A high degree of coherence between intrinsic attributes of a product entails lower trade-offs, i.e., receiving costs in the outlay of using the benefits (Anderson, 1971, 1981; Miyazaki et al., 2005). Confirming the results of previous studies (Wang et al., 2010; Khan et al., 2011; Hedgcock & Rao, 2009), we expect to find a better evaluation of a product, i.e., willingness to purchase, as the result of its lower inter-attribute coherence due to lower trade-offs. Hence, we propose that inter-attribute coherence mediates the effect of naturalness on willingness to purchase. In line with Hypothesis 2, we expect the positive impact of naturalness on product evaluation (which is the result of higher inter-attribute coherence) to exist only for products in which naturalness is a central attribute.

Hypothesis 3-1: Naturalness, compared to being man-made, increases willingness to purchase only in products in which naturalness is a central attribute.

Hypothesis 3-2: A product's inter-attribute coherence mediates the effect of naturalness on willingness to purchase.

Figure 1 shows our research model.

Figure 1: Research Model

Figure 1 Research Model

Study 1

Beliefs about nature are for the most part strong engrained beliefs (Kellert, 1993; Wilson, 1993). Studies describe individuals'

responses towards natural elements as evolutionary, universal, and innate (Hale, 2016; Ulrich, 1993). Therefore, we expect that individuals' beliefs about nature and naturalness can best be captured using the implicit association test (IAT). We use the IAT in Study 1 to measure implicit association of nature with coherent attributes.

Sixty-one (61) individuals participated in this study on the MTurk website. They had to categorize words in the middle of the screen into either left or right categories by pressing the A or L keys. Their response time in milliseconds was recorded. The words that appeared in the middle of the screen belonged to any of four categories: nature, man-made, coherent, and incoherent. We used Carpenter et al. (in press) to create the IAT, including 7 trial blocks.

The results of our pretest confirmed that participants perceived the words in the coherent condition as more coherent than the words in the incoherent condition ($M_{\text{Coherent}} = 6.11$, $M_{\text{Incoherent}} = 3.92$, $F(1,49) = 18.12$, $p < .01$) (and different from neutral: (single sample t-test) $t(49) = 7.20$, $p < 0.1$). Moreover, participants perceived the words in the nature condition to be related to nature versus man-made ($M_{\text{Nature}} = 7.6$, $M_{\text{Man-made}} = 0.31$, $F(1,49) = 884.17$, $p < .01$) (and different from neutral $t(49) = 22.76$, $p < 0.1$).

Using Greenwald et al.'s (2003) improved algorithm we found that the mean response latency in the hypothesis incongruent critical blocks was significantly larger than the mean response latency in the hypothesis congruent critical blocks ($M_{\text{congruent}} = 1062.41$, $M_{\text{incongruent}} = 1180.06$, $F(1,57) = 11.14$, $p < .01$). The IAT D score was also significantly different from zero ($D = -.21$, $SD = .44$, $t(57) = -3.60$, $p < .01$). Therefore, the participants responded significantly faster when they grouped man-made related words with incoherent words and nature related words with coherent words, compared to the time when they grouped man-made related words with coherent words and nature related words with incoherent words. These results provide support for H1 and suggest an implicit association in consumers' mind between nature versus man-made and coherent versus incoherent words.

Study 2

Study 2 highlights the role of centrality of naturalness and investigates the effect of naturalness on inter-attribute coherence (Hypothesis 2) and willingness to purchase (Hypotheses 3-1, 3-2) across the products where naturalness is (is not) a central attribute.

Two-hundred (200) individuals took part in Study 2 on the MTurk website. The participants answered questions regarding one of the four products, i.e., a package of chocolate cookies or a bottle of pain-relief pills, either in the natural or the man-made conditions in a 2*2 between subject design. First, the participants saw a generic product with no specific indication of naturalness and wrote down some attributes that they might consider in purchasing the product. Next, they saw the same products as those in the first task but with a label (containing additives/pharmaceutical formula, produced in laboratory for man-made containing only natural ingredients with no additives or preservatives/100% natural formula for natural condition) to manipulate naturalness. The participants evaluated those products on the same series of attributes that they indicated in the first task.

In a pretest, we measured the centrality of naturalness for cookies and pills. We asked if a cookie (pill) is natural, how similar will it be to an ideal version of a cookie (pill), how important is naturalness to a cookie (pill) and to what extent is naturalness a defining characteristic of a cookie (pill) (adapted from Gershoff & Frels, 2015). We found out that naturalness is a central attribute for a chocolate chip cookie as it received a score that is significantly higher than 5 (neutral) ($M_{\text{Cookie}} = 6.20$, $SD_{\text{Cookie}} = 2.01$, $t(50) = 4.27$, $p < .01$), but it is

not a central attribute for a pain-relief pill ($M_{\text{Pills}} = 4.75$, $SD_{\text{Pills}} = 2.17$, $t(50) = -.79$, $p > .43$).

We calculated a score for inter-attribute coherence of each product based on the rating scores that each participant gave for evaluating the attributes of each product. We considered an attribute positive (negative) when it received a score higher (lower) than 4. To calculate the final coherence score, we divided the number of aligned attributes (whether positive or negative) by the total number of attributes. For example, a product with the rating scores of 2, 7, 6, 5 on its attributes has a coherence score of 0.75, i.e., three positive attributes (higher than 4) divided by 4, likewise for a product with the rating scores of 7, 1, 2, 3 on its attributes, i.e., three negative attributes (lower than 4) divided by 4. Larger coherence scores showed higher degree of inter-attribute coherence. We found out that naturalness improved inter-attribute coherence in the products in which naturalness is a central attribute and marginally decreased inter-attribute coherence in the products in which naturalness is not a central attribute (for cookies: $M_{\text{Man-made}} = .70$, $M_{\text{Natural}} = .83$, $F(1,175) = 4.10$, $p < .05$); for pills: $M_{\text{Man-made}} = .76$, $M_{\text{Natural}} = .65$, $F(1,175) = 2.82$, $p < .1$).

Naturalness improved willingness to purchase only for products in which naturalness is a central attribute (for cookies: $M_{\text{Man-made}} = 7.53$, $M_{\text{Natural}} = 7.97$, $F(1,175) = 5.41$, $p < .03$). There was no significant difference between the willingness to purchase for products in which naturalness is not a central attribute in the natural compared to the man-made condition (for pills: $M_{\text{Man-made}} = 7.22$, $M_{\text{Natural}} = 7.15$, $F(1,175) = .27$, $p > .58$). Using Hayes' (2013), we found the significant moderated indirect effect of naturalness on willingness to purchase through inter-attribute coherence (Index of moderated mediation: .21, $BootSE = .09$, $LLCI = .01$, $ULCI = .42$, with 95% confidence interval).

One explanation for our findings is positivity-bias. To measure the degree of positivity of products, we divided the number of product's attributes that received the score of neutral or better than neutral by the number of attributes. We found significantly higher degree of positivity in natural compared to man-made conditions for products in which naturalness is a central attribute (for cookies: $M_{\text{Man-made}} = .78$, $M_{\text{Natural}} = .96$, $F(1,175) = 8.45$, $p < .01$). However, we did not find this effect for products in which naturalness is not a central attribute (for pills: $M_{\text{Man-made}} = .79$, $M_{\text{Natural}} = .85$, $F(1,175) = .77$, $p > .38$). Entering the level of positivity as a covariate, we confirmed a significant indirect effect of inter-attribute coherence (Index of moderated mediation: .22, $BootSE = .09$, $LLCI = .06$, $ULCI = .42$, with 95% confidence interval, 5000 bootstraps). This finding showed that the mediation role of inter-attribute coherence existed despite the positivity bias towards nature.

Study 3

Study 3 provides further support for the findings of Study 2. Two-hundred (200) participants took part in Study 3 on the MTurk website. We used the same procedure as Study 2. We changed the products to a t-shirt and a lice-killing shampoo to make sure that the results of Study 2 were not confounded by the healthiness attribute of the products. The t-shirt was labeled as made with 100% natural material and the shampoo was labeled as using 100% natural formula in the natural condition. In the man-made condition, the t-shirt was labeled as made with synthetic material and the shampoo was labeled as using a pharmaceutical formula. We then asked participants to evaluate the products. We replaced willingness to pay in Study 2 with product evaluation to make sure that our results were not biased by the perceived prices of the products.

The results of our pretest showed that naturalness is a central attribute for a t-shirt as it received a score that is significantly higher

than 5 (neutral) ($M_{T\text{-Shirt}}=6.13$, $SD_{T\text{-Shirt}}=1.67$, $t(49)=4.79$, $p<.01$), but it is not a central attribute for a lice shampoo ($M_{Lice\text{-Shampoo}}=4.83$, $SD_{Lice\text{-Shampoo}}=2.07$, $t(49)=-.59$, $p>.57$).

Using the same procedure as in Study 2 we found out that naturalness improved the interattribute coherence of the products in which naturalness is a central attribute and decreased (but not significantly) the inter-attribute coherence of the products in which naturalness is not a central attribute (for t-shirt: $M_{Man\text{-made}}=.54$, $M_{Natural}=.74$, $F(1,185)=6.97$, $p<.01$); for lice-shampoo: $M_{Man\text{-made}}=.72$, $M_{Natural}=.71$, $F(1,185)=.001$, $p>.9$).

Naturalness improved product evaluation of the products in which naturalness is a central attribute and decreased (but not significantly) the inter-attribute coherence of the products in which naturalness is not a central attribute (for t-shirt: $M_{Man\text{-made}}=4.17$, $M_{Natural}=4.90$, $F(1,185)=7.35$, $p<.01$); for lice-shampoo: $M_{Man\text{-made}}=5.20$, $M_{Natural}=4.95$, $F(1,185)=.88$, $p>.3$).

Using Hayes' (2013) we found a significant moderated indirect effect of naturalness on product evaluation through inter-attribute coherence (Index of moderated mediation: .25, $BootSE=.14$, $LLCI=.03$, $ULCI=.50$, with 90% confidence interval). Next, using the same procedure as Study2, we checked for the role of positivity-bias. Our results confirmed the findings of Study2, and we found a significant mediation role of inter-attribute coherence even after controlling for the level of positivity (Index of moderated mediation: .17, $BootSE=.11$, $LLCI=.001$, $ULCI=.39$, with 90% confidence interval).

Our findings show that consumers' belief of coherent nature impacts the evaluation of natural products by increasing the inter-attribute coherence of these products. Our results suggest a novel boundary condition for the effect of naturalness on product evaluation and show that this effect is not the same across all products but is according to the centrality of naturalness.

This paper contributes to the current literature on naturalness (Thompson, 2004; Rozin et al., 2012; Scott et al. 2020) by highlighting consumers' lay belief about coherent nature and natural products. Previous studies either mostly did not delve into a mechanism for the effect of naturalness on product evaluation or limited their explanation to general preference for naturalness (Rozin et al., 2004; Berry et al., 2017). Unlike previous studies, e.g., Scott et al., 2020, that limited their focus on explaining the role of naturalness in products with specific goals, our paper explains the role of naturalness in evaluation of products in different categories and providing any types of benefits. Our findings have important marketing and public policy implications.

When and how virus anthropomorphism intensifies consumer stigma toward patients

Mr. Jiancai Liao, Aalto University School of Business, China

Ms. Jingya Huang, Shanghai Jiao Tong University, China

Dr. Lei Su, City University of Hong Kong, Hong Kong

INTRODUCTION

Governments, companies, and individuals worldwide are accustomed to depicting infectious diseases as a person during the COVID-19 pandemic. For instance, the World Health Organization anthropomorphizes the coronavirus and calls on people to destigmatize patients in the fight against COVID-19. In addition, enemy metaphors are frequently used in public discussions about infectious diseases. Even academic journals sometimes represent virus as an anthropomorphized enemy. Advertisements also commonly anthropomorphize viruses. Although virus anthropomorphism might attract more attention and thus increase consumers' adoption of protective measures, could doing so potentially harm people suffering from the virus? This is the primary research question.

Over the past two decades, scholars have conducted a great deal of research on anthropomorphism, which is defined as the tendency to attribute human-like characteristics, intentions, and behavior to nonhuman objects (Aggarwal and McGill 2007). Overall, virtually all the extant empirical research on anthropomorphism explores bilateral relationship scenarios: how consumers react to anthropomorphized agents or how anthropomorphized agents influence consumers. In other words, consumer is an *actor* in the relationship. However, little is known about the effect of anthropomorphism in a tripartite relationship context, i.e., consumer become an *observer* in the relationship. To paraphrase, we focus on how the process of imbuing life into viruses (i.e., anthropomorphized agents) affects observers' (i.e., consumers) evaluation on victims (i.e., stigmatized patients).

Stigma is defined as “a *mark* placed on a person, place, technology, or product associated with a particular attribute that identifies it as different and deviant, flawed or undesirable” and results in elevated risk perceptions (Kasperson, Jhaveri, and Kasperson 2001, p. 19). We argue that an anthropomorphized virus (vs. non-anthropomorphized) is less random and more likely to serve as a social marker. This makes sense because anthropomorphism has been proved as a powerful tool to access human schema (Epley, Waytz, & Cacioppo 2007), apply social norm (Chen, Sengupta & Zheng 2022) and make social belief more available (Wan, Chen, & Jin 2017). Therefore, we predict virus anthropomorphism (vs. non-anthropomorphism) can lead to greater stigma toward patients.

We further demonstrate that defensive attribution is the underlying mechanism. Defensive attribution theory states that an observer attributes the causes for a negative event to minimize their fear of being a victim (e.g., attribute the patient's suffering to their own dispositions). A strong hypothesis from this theory is observer would assign more culpability to the victim who are dissimilar to the observer compared with those who are similar to the observer (e.g., Grubb and Harrower 2008). Virus anthropomorphism (vs. non-anthropomorphism), as a stronger presence of mark, would increase consumers' dissimilarity perception from patients, which in turn increases the likelihood of defensive attribution and thus induces more stigma toward patients.

Six studies, including a text analysis, a field experiment and 4 online experiments, are combined to examine our hypotheses. Study 1, text mining on 139, 845 tweets, offers evidence that “tripartite relationships” do exist in practices and provide preliminary support for the main effect through testing consumers' engagement on anthropomorphized (vs. non-anthropomorphized) donation appealing tweets.

Study 2 provides real-life confirmation on the main hypothesis using a field experiment on Facebook. Under the background of COVID-19, we published a campaign to prevent and address social stigma toward COVID-19 patients. An actual expression of addressing the stigma problem—the click rate of the ad appeal on Facebook—was the dependent variable of interest.

Four laboratory studies follow. For each study, in the anthropomorphism condition, the introduction was written in a first-person language (e.g., “I am Tubercle Bacillus. If people infect with me...”). Conversely, people in the control condition read the introduction in the third-person language (e.g., “This is Tubercle Bacillus. If people infect with it...”). In the context of pulmonary tuberculosis, Study 3 reveals that virus anthropomorphism increases stigma toward infectious disease patients. Study 4 demonstrates the mediating mechanism of attribution bias. Study 5 shows that the main effect attenuates for diseases which are difficult to generate an internal attribution since it is harder to produce attribution bias in this situation. Study 6 confirms the moderating role of group identity based on intergroup attribution bias. The negative effect of virus anthropomorphism on prosocial behaviors toward patients occurs only for outgroup members but not in-group members.

Overall, by exploring how the process of imbuing life into viruses (i.e., anthropomorphized agents) would affect observers' (i.e., consumers) evaluation on victims (i.e., stigmatized patients), our research provides novel contributions to the anthropomorphism literature through a new perspective such that consumer become an observer rather than actor. Defensive attribution as an underlying mechanism is verified. Our study has significant implications in many domains including media design of governments' campaigns to decrease disease stigma and NGO's campaigns raising money for stigmatized patients.

In Limbo: Liminality Narratives of Young Adults Returning to the Family Home

“It opened doors.” Mandy, 28

Ms. Ugne Greivyte, Independent Researcher, Austria
Prof. Andrea Hemetsberger, University of Innsbruck, Austria

INTRODUCTION

Modern life trajectories (Elder, Johnson and Crosnoe 2003) are messy and non-linear (Shirani and Henwood 2011). Increasingly, fluid life courses include overlapping, intermingling transitions and even reversals (Shanahan 2003; Turner 1977). This is especially true of emerging adulthood (Arnett 2014), which has a “tremendous variation in timing of life course transitions” (Weinberger, Zavisca and Silva 2017: 334) and is characterized by instability and ambiguity (Harrington, Bielby and Bardo 2011). ‘Boomerang kids’—young adults returning to the parental home after a period of independence—are a rising global phenomenon, amplified by the recent pandemic (theguardian, 18th of October 2020). This reverse transition marks a regression of the normative progression to adulthood (Sassler, Ciambone and Benway 2008; Settersten 2003), accompanied by tensions between the established adult identities and the child-like state of living with parents, between autonomy and dependence (Lewis, West, Roberts and Noden 2016; Severson and Collins 2020).

Previous studies on young adults returning to the parental home have primarily focused on identifying the drivers that lead to their return (Billari and Liefbroer 2007; Holdsworth 2000; South and Lei 2015; Stone, Berrington and Falkingham 2014) and how they negotiate adulthood as a result of the move (Lewis et al. 2016; Sassler et al. 2008; Severson and Collins 2020). This study investigates ‘returning home’ pathways and the role of consumption in navigating the ambiguities that accompany the return to living with parents. Based on life-course and liminality literature and substantiated by in-depth interviews with young adults, this study presents three ‘returning home’ narratives and corresponding consumption transitions ‘in limbo’.

THEORY

Moving back home

Individual life trajectories are varied and take unexpected paths. Young adults’ return to the family home often goes hand in hand with completing education, becoming unemployed or the dissolution of a partnership (Stone, Berrington and Falkingham 2014). In the UK, this trend has been made more prominent with the dramatic rise in housing costs and the recent SARS-CoV-2 pandemic (Bell, Codreanu and Machin 2020). Life-course literature recognizes these reversals of life transitions (McMillan and Eliason 2003; Shanahan 2003), potentially ending in a feeling of regression (Shirani and Henwood 2011).

Returning to the parental home has strong implications on young adults’ independence. Lewis et al. (2016) found that most returners struggled with a sharpened sense of dependence and being treated as a child by their parents when living together. A child-like self co-exists and competes with the adult self (Lewis et al. 2016; Sassler et al. 2008; Severson and Collins 2020), marking a *dividual* (Appau et al. 2020) state of self in transition. Further, Lewis et al. (2016) note that periods of co-residence are usually of uncertain duration, which renders the ‘betwixt and between’ state even more delicate. Yet, while young adults want to be treated as equals and aspire to recover their independence, Sassler et al. (2008) find that young adults also benefit from the domestic and economic support of their

parents. Hence, transition reversals are experienced as highly ambiguous and liminal (Turner 1977; van Gennepe 1960)—a transition-in-transition—waiting to be mastered and recovered.

Consumption in Transition

Progression from childhood to adulthood marks a coming-of-age transition that is rooted in identity tensions between reliance and autonomy, chaos and organisation (Drenten 2013). Consumption plays a key role in helping young adults navigate and fulfil the desires latent between these tensions. Stability-seeking consumption (Noble & Walker 1997) self-gifting, compulsive consumption, indulgence and increased materialism (Rindfleisch, Burroughs and Denton 1997) constitute common coping strategies related to transition. Weinberger, Zavisca and Silva (2017), for example, found that the period after gaining residential independence is characterised by heavy investment in exploratory experience as a means to build cultural capital. In parting from the “old” self, the separation from possessions and consumption practices that represent the past can facilitate the transition (Martin Young 1991). In the transition to adulthood (Cody 2012; Hemetsberger, Bauer, von Wallpach and Broger 2013), consumption practices that represent the old selves are shed, while some childhood brands become therapeutic and alleviate the transition to a new role. However, consumption can also prolong or stall liminality (Darveau and Cheikh-Ammar 2021) when it hinders the self-development of a future self (see Yau and Christidi 2018). Appau et al.’s (2020) study of Pentecostal converts shows that individuals in transition can be even stuck in an ongoing cycle of incorporation and separation consumption practices when liminality turns permanent. Considering these different possible pathways, this study aims to understand the ambiguity inherent in re-transitions from independent life to home and uncover the role of consumption in alleviating or stalling young adults’ return to independence.

METHODOLOGY

Our exploratory study includes 10 narrative interviews and collages to elicit individuals’ biographies and to gain a nuanced understanding of reverse transition narratives of young adults and related consumption patterns in regaining balance and independence (Flick 2018). The collages were used as autodiving technique helping participants to elicit rich life narratives and consumption patterns associated with their past, present and prospective future selves. The UK context was chosen to capture the rising trend of Generation Boomerang. Participants were recruited personally, via Gumtree and Reddit using maximum variation sampling (Patton 2014). Interviews were conducted in February and March 2020 online via video Zoom calls, lasting on average 75 minutes each. Following grounded theory, this study analyzed verbatim transcripts and developed narrative themes through an iterative process of categorization and abstraction (Charmaz 2006; Spiggle 1994).

FINDINGS

Young adults’ transition to the parental home unfolded in the context of their broader past-present-future narratives that are deeply entangled with their former lives and current life contexts. We identified three key narratives and accompanying changes in consumption

patterns: (1) *interruption* narrative, (2) *fruitful interval* narrative and (3) *uneasy perpetuity* narrative.

Figure 1

Narrative Distribution According to Time Living with Parents

(1) The *interruption narrative* portrays young adults who experienced the return to the family home as an interruption to their otherwise ‘normative’ life trajectories (Settersten 2003). Prior to moving in, life was on a stable path, independence a matter of course. Moving back home is therefore a big adjustment and feels like going back in time – “I had that feeling of like, ‘oh, God living with my parents again’” (James, 32). Thus, staying with parents is characterized by strong tensions between the former independent self and the present child-like status. Yet, escaping the family home, similar to ‘disengagement’ coping strategies identified by Yau and Christidi (2018), offers temporary relief.

Still, moving back to the parental home and being cared for has its draws, as it has helped participants save a bit of money and they expect their future trajectories to progress as planned once they return to living independently. Despite the tensions and the strong intention to move out, there is an overall appreciation of the support offered and the convenience of living at the parental home. At times, this turns into an indulgence in their former selves, potentially stalling the transition (Darveau and Cheikh-Ammar, 2021). For Harriett (30), living with her mum is a time in which she can indulge by playing the role of a child (Martin Young, 1991) before she plunges back into adulthood.

The moving out date is in sight, thus rather than negotiating their place as adults in their family home, the young adults put their lives ‘on hold’, *suspend* self-oriented consumption and mostly adhere to parental consumption patterns and rituals. Some more active strategies of coping include *future-oriented* and *imagined* consumption. Maria, living out of boxes in her childhood room at the time of the interview, dreams of decorating her new home with pictures and plants, “It gives you a sense that the space is yours, and that you live there ... a stamp of your personality in your place” (Maria, 27). Harriet, about to move out, has been trying to spend as little as possible so she can save up for her new home. Accordingly, interruptors’ view of the future is optimistic and confident and their prospective consumption is detailed.

(2) Young adults in the *fruitful interval narrative* view the return to the parental home as a transformative and productive period in their lives, allowing them to build strength, take control and gather the necessary resources to achieve their future goals. For some it is a purposeful and significant turning point in their life trajectories: “I actually did make the decision to like – when I moved home to change my life around” (Mandy, 28). Often, young adults described their time living independently as liberating and tumultuous, characterised by abandoned consumption and loss of control. Adam describes the time before moving back to live with his parents as “living by like feeling, like doing whatever felt good. And then, just you know, paying the consequences for it afterwards.” (Adam, 33). Returning home is a consequent and constructive move, giving them the security and the freedom to pursue their careers and dreams. While the sense of freedom expressed by returners seems paradoxical

and contradicts prior findings (Lewis et al. 2016; Severson and Collins 2020), it marks a deliberate decision of the young adults to restructure their lives, as Mandy (28) expresses: “So, yeah, I just got a really strong support system. So, I think that’s why I feel comfort, in a sense being home. Because I feel like I can take my time deciding what I’m going to do with my life,”.

Their longer stay at the parental home gives them scope to negotiate their independence in the family home. *Reciprocity* as a coping strategy (Yau and Christidi 2018) is more prevalent and is keeping the parent-child relationship in balance. Mandy pays rent and Alia helps out extensively around the home. The young adults also express a strong sense of agency (Elder et al. 2003; Gecas 2003), viewing their parents as partners on a common mission.

Accordingly, consumption while living at home focuses on self-investment in the future and has therapeutic qualities in prospect of an independent life. Consumption strategies encompass *deconsumption* and *saving* behavior. Future orientation also emerges in other, less tangible areas, such as career-planning, living a healthier life, building up mental resilience or having the opportunity to learn from past mistakes – “So, when you’ve got your basic needs sorted, then you can go high-level thinking and reflecting and become more enlightened I suppose” (Adam, 33).

(3) The *uneasy perpetuity narrative* is the most challenging of the three. It applies to young adults who return to the parental home as a course of necessity and do not have the resources to progress to independent living, despite their desire to do so. Similar to lives preceding a fruitful interruption, time living independently was characterised by living in the moment, purposelessness and lack of control. Accordingly, consumption is indulgent, impulsive and oblivious. The underlying theme in their narratives is of loss of control and structure, which brings them back home. Lacking field-dependent capital (Appau et al. 2020; Üstüner and Holt 2007) to make the desired transition to independence leaves them in limbo. In uneasy perpetuity, the lack of financial resources but also less tangible means such as health, mental wellbeing and employability weigh heavy on them.

Participants have been living with their parents for an extended period (the longest stay in the sample is 11 years), with little hope of moving out in the future. This is problematic as they are stuck in an awkward limbo where they are neither at ease with their current state nor are they propelled to their desired state. Living in a state of permanent liminality (Appau et al. 2020; Szokolczai 2014; Thomassen 2009) participants feel immobilised, depressed and without enthusiasm for their futures. This shows up as stagnation and lack of structure while co-residing with parents. The lack of perceived self-efficacy and agency is palpable in their narratives: “and I think to myself, the future is going to happen whether I make it happen or whatever happens.” (Wim, 35). Adam is plagued by uncertainty, which is reflected in the vagueness of his future outlook and narrative, “I don’t know. I mean I just don’t know what the future holds.” (Adam, 32).

This state of paralysis is reflected in consumption habits as well. Rather than focusing on gaining independence, attention is centred around more achievable goals, self-improvement and focus on the here and now. Wim (38) likes to look for interesting, short-term work via Gumtree. Chance over choice (Drenten 2013) plays a big role in their future narratives. Wim (35) dreams of winning the lottery, while Roberto hopes his cryptocurrency investment will earn a substantial return and help him become more independent – “[that would] change my life” (Roberto, 28). Yet, daydreaming without agency leaves them in uneasy perpetuity of *investments in moments* of living and *risky investments* as coping strategies.

DISCUSSION

Our study illuminates the role of consumption in transition, specifically reversals, and contributes to the literature on the life course trajectories of young adults. We identified three distinct narratives and related consumption patterns surrounding the return to the parental home. Sampling a broad variation in life trajectories, a striking divergence in the role of a reversal in an individual’s life course is revealed: from being framed as a temporary reversal or a pause (*interruption*) to a crucial consolidating and productive stage in one’s life course development (*fruitful interval*) to a seemingly permanent, pernicious reversal (*uneasy perpetuity*) (Appau et al. 2020; Szokolczi 2014). Thereby our study supports prior views of reverse transitions as being conceptually different from regular phases of liminality (Thomassen 2009; Turner 1977; van Gennep 1960).

Within the three narratives, distinctive consumption patterns unfolded. The *interruption* narrative exhibits *bridging* consumption patterns, suspending and reducing consumption related to independence and adapting to the demands of their new role. In the *fruitful interval* narrative, a shift from living in the moment to *future-oriented and imagined consumption* patterns characterizes a phase of productive consolidation and preparation for re-transitioning, akin

to the ‘turning point narrative’ in first-time motherhood (Hemetsberger, von Wallpach and Bauer 2015). *Uneasy perpetuity* is framed by future uncertainty, thus consumption reflects *living in the moment* and coping with uncertain outcomes, as a result of a permanent, liminality-induced paralysis (Üstüner and Holt 2007; Shirani and Henwood 2011). *Deconsumption* emerged as a key consumption practice throughout the narratives—not as an ideological statement but rather as a pragmatic, potentially future-oriented strategy (Wilczak, 2018).

Our study also contributes to the broader literature on life transitions and liminality (van Gennep 1960; Elder et al., 2003) with three potential transitions in the context of broader past-present-future narratives. In reconciling independent selves, role-dependent tensions are either negotiated, compensated or result in paralysis and permanent liminality (Appau et al 2020). However, in contrast to the loss of control over oneself and one’s environment (Drenten 2013) as dominant themes in the literature on reverse transitions (Lewis et al. 2016; Sassler et al. 2008; Severson and Collins 2020), we find that reverse transitions also exhibit a constructive and liberating character as reflected in the freedom rhetoric of the fruitful interval or, as our informant Mandy phrased it: “It opened doors”.

Table 1: Findings
Key Narratives of Young Adults Returning to Live With Their Parents

Narrative	<i>Interruption</i>	<i>Fruitful Interval</i>	<i>Uneasy Perpetuity</i>
Duration	Short	Extended	Permanent
Description	A momentary interruption in / a reversal of their life trajectory. “Yeah, I just come back, have a little sort of semi-holiday back in my home country for a few months, and then go back to China.” (James, 32)	A period to recover, build strength and gather resources for the future. “[I] actually did make the decision to like-- when I moved home to change my life around” (Mandy, 28)	A seemingly permanent state, marked by stagnation. Lacking the means to progress to independence. “I’m staying with my parents, it’s not too good, but I can’t afford the rent. It’s not too good to be staying with parents, I’m going to be 36 soon.” (Wim, 35)
Consumption while living independently	Liberating, exploratory, relational consumption. Ascetic consumption framed by budgetary constraints. Investment in the future.	Indulgent, abandoned, exploratory, relational consumption. Ascetic consumption framed by budgetary constraints.	Indulgent, impulsive, relational, careless consumption. Ascetic consumption framed by budgetary constraints.
Consumption while living with parents	Suppression of individual consumption and conforming to family consumption habits. Indulgence in home comforts and family support. Delayed consumption.	Self-investment. Future-orientated saving and de-consumption. Strategic consumption of family support and reciprocation.	Living and investing in the moment. Self-improvement. Saving as a coping , precautionary strategy rather than an investment in the future.

Tower of Babel: Thematic Cohesion in Online Consumer Conversations

Mr. Denis Utochkin, Norwegian School of Economics, Norway

Prof. Ivan Belik, Norwegian School of Economics, Norway

INTRODUCTION

In the 2021 Andy Weir science fiction novel *Project Hail Mary* (2021), a human and an alien meet in space and, in a matter of weeks, learn each other's languages so well that very few misunderstandings ever occur in their communication. The speed with which they manage to advance from establishing a common understanding of words like 'yes' and 'no' to accurately conveying fuzzy concepts such as 'grief' or 'grace' is all the more impressive given how seemingly incompatible the two languages are: while human tongues are represented by English, the alien language in the book is constructed from sequences of musical notes. Although several explanations are conceivable of this unlikely triumph of desire for mutual understanding, one would be wise to mainly attribute it to the simple fact that the author felt the need to sacrifice a degree of realism in order to move the plot forward (Hutchinson, 2021). Alas, it appears that real life either lacks an omnipotent author that can ensure well-paced plot progression for all characters in the story or else, that communication problems of mere mortals do not score high on the priority list of said author. A vastly more common experience for most of us is one of conversing with other humans and slowly realizing that no side seems to really grasp what the others are saying: much like in the myth of the Tower of Babel, too much is often lost in translation, even when all parties in the conversation are fluently speaking the same language.

The problem of mutual (mis)understanding is a universally human one, but its many manifestations are of interest to marketing and consumer researchers as much as to linguists or psychologists. When word of mouth is said to propagate throughout a network of consumers, can one assume that information contained in the original message does not quickly morph, like in a game of 'whisper down the lane', into something so different that it ceases to be of relevance to the marketer? When studying large-scale consumer collectives, how does one differentiate superficial consumer-to-consumer interactions, which are 'conversations' in name only (Arvidsson & Calianadro, 2016), from such interactions in which meaningful communication does occur and which lead to opinions changing (Colleoni et al., 2014) or communal bonds emerging (Cova et al., 2011)?

In this paper, we pave the way to answering these questions by developing an approach to analysing changes over time in thematic foci in conversations that occur on the popular social media platform Reddit. Specifically, our methodology involves measuring thematic similarity between consecutive comments and building an understanding of common ways online conversations develop with a combination of a topic modeling algorithm (Blei et al., 2003), Jensen-Shannon measure of mutual information (Manning & Schutze, 1999), and k-means clustering (Hartigan & Wong, 1979).

We test our approach on a dataset of over 200,000 conversations on Reddit. We gain insight into the structural organization of consumer conversations and identify three archetypes of online conversations with distinct overarching structural organizations. Interestingly, we find that most often, users do not converge on a shared understanding of the topic of the conversation and in cases that they do, this thematic convergence tends to happen relatively late in the conversation. We conclude with a discussion of implications of these findings for researchers, marketers, and platform holders.

DATA

The data for this study come from Reddit, a popular social media platform that is structured as an assortment of hundreds of thousand communities. These communities, many of which are brand-centric, are called *subreddits* and are created, maintained, and moderated by Reddit's users.

Reddit can be seen as a collection of rooted discussion trees, each comprised of several nodes, or postings. There are two types of postings. First type is *submission*, which is the root node of each discussion tree. Submissions contain a title and a "main body", which can be text, hyperlinks to external websites, or rich media (e.g., images, GIFs, videos). The second type of postings is called *comments*. These are all the other nodes in the discussion tree. Each comment is placed as a direct reply to a higher-level node, which can be either another comment or, in case of top-level replies, the submission itself.

We collected all activity from 1,027 subreddits centered around various brands, platforms, and consumption practices in the video game industry. We chose to focus on the video game industry in particular due to several factors. First, it is a booming industry, with just the US share of the market trumping global box office and global streaming services revenues (Shieber, 2019; Wijman, 2019). Second, many of Reddit's largest communities are devoted to video game-related topics and the website's user base has been shown to be more technologically inclined than those of other social media (Gevers, 2019). The dataset is comprised of a total of 251 mil. comments across 21 mil. submissions posted by 6.7 mil. users in 2019.

Here and elsewhere in the text, we use the terms *conversation* and *discussion* interchangeably to refer to a single full *comment branch* of a discussion tree that starts at the root node (i.e., submission) and ends with the final comment (i.e., a comment to which there are no further direct replies). We filter our dataset and only keep discussion trees with a minimum comment length of 10 words or more. From among these trees, we keep comment branches of length five or more. The motivation for these filtering thresholds is elaborated on in the following section.

METHOD

3.1. Topic Modeling

Topic discovery is the method of using statistical models to divide a collection of text documents (in our case, Reddit posts and comments) into thematic clusters. We develop a topic model of the postings in the dataset and identify 200 topics. To do so, we make use of Latent Dirichlet Allocation, or LDA, a well-established unsupervised machine learning technique often used for topic discovery (Blei et al., 2003). In order for LDA to better pick up on the latent semantic patterns in the texts, we filter out comment branches with comments shorter than 10 words, leaving in 382,620 branches.

At this step, our unit of analysis is a single user's posting. LDA represents each posting in the dataset as a mixture over a set of latent underlying topics. When given a new posting, the algorithm assigns to it a set of probabilities of that posting containing each of the identified topics in the entire dataset. As a result, for each posting, the LDA model produces a vector of probabilities, whose length is equal to the number of topics the model identified (200 in the case of our

model). These numeric vectors can be thought of as individual thematic signatures of each particular posting.

3.2. Jensen-Shannon Divergence

As discussed previously, each branch, or conversation, is composed of subsequent postings. In order to estimate thematic similarity between two subsequent postings (i.e., a posting and the immediate reply to it), we employ Jensen-Shannon divergence – a metric of mutual information commonly used for measuring the degree of similarity of two probability distributions (Manning & Schütze, 1999).

In subsection 3.1, we produced, for each posting pair, two probability vectors of length 200 that represent the postings' respective thematic signatures. Computing Jensen-Shannon divergence between these two vectors produces a variable ranging from 0 to 1, with value of 0 corresponding to perfect thematic similarity and value of 1 signifying absolute thematic dissimilarity within a 'posting-reply' pairing. Jensen-Shannon distance close to 0 is observed for postings that are very similar semantically as well as thematically (direct quotes of one another at the extreme), whereas moderately high values are indicative of 'productive' discussions whose participants operate in a similar thematic space and successfully build on and add to the arguments proposed earlier in the previous postings. Finally, high thematic dissimilarity between a posting and a reply to it tells us that consumers participating in the conversation were not successful in establishing a common understanding of the topic they are discussing.

Following the logic described above, the Jensen-Shannon divergence is calculated for the entire conversations (i.e., branches of postings). Each conversation can be seen as sequences of 'parent-child' pairs, such that the 'child' part of the first pair becomes the 'parent' part of the second pair and so on. We sequentially perform pairwise comparisons of thematic similarity within consecutive 'parent-child' posting pairs, starting from the similarity between the root node (submission) and a direct reply to it and ending with a comparison of thematic signatures of the penultimate and final comments in the branch. We repeat this process for each branch (i.e., conversation) of length five or more, for a total of 235,804 branches.

3.3. K-means Clustering

Computing Jensen-Shannon distances at the previous step allowed us to create representations of individual Reddit discussions as vectors of thematic similarity between adjacent comments (i.e., postings). The next, and final, step of our analysis involves looking for commonalities between the organisational structure of thematic (dis)similarities over the course of a conversation across all branches in the dataset. To do so, we perform k-means clustering on the resulting vector representations of the discussions. *k*-means is a local search procedure for minimising within-cluster variances. The core idea behind the algorithm is to assign each data point to one of *k* clusters so that the distance between each data point in the cluster and the cluster centre would be minimal (Hartigan & Wong, 1979).

Since the branch lengths vary greatly within our dataset, we resized all vectors to length 100 by using nearest-neighbour interpolation (Han, 2013) for upscaling branches shorter than 100 postings long. The few discussions of length greater than 100 postings (41 out of 235,804 branches) were discarded. We also remove very short discussions (branches with fewer than five comments), resulting in the final sample of 235,773. Using *k*-means clustering, we then divided the resized vector representations of Reddit conversations into three archetypes with distinct patterns of thematic cohesion or, conversely, thematic divergence of consecutive postings. In the next section, we present a discussion of the obtained results.

4. Results and Discussion

Using the approach described in the previous section, we clustered over 200,000 Reddit conversations based on their particular 'signature' of thematic cohesion, or stability. We were able to identify three clusters, or archetypes, which are visualised in Figure 1. Each of the three bars corresponds to a different archetype and can be thought of as a 'progress bar' (ranging from 1 to 100) for the chronology of conversations of that type, with each vertical slice *n* representing thematic similarity between *n*-th and *n-1*-th comments. A short summary of the results is presented in Table 1.

Conversations that match the first archetype resemble the plot of the parable of the blind men and an elephant (Saxe, 2016): although participants in such conversations were brought together by the same Reddit posting and are clearly sending and receiving information to one another, they tend to operate in vastly different thematic spaces and fail to ever converge on a common understanding of the topic of the conversation. Over 60% of the discussions in the dataset correspond to this archetype.

The second archetype paints a more optimistic picture of online discourse: the proverbial 'blind men' in conversations of this type similarly start out in a place of mutual misunderstanding, but eventually succeed in converging on a common set of topics, albeit the first steps towards this thematic convergence are typically not taken until the second half of the conversation. Such discussions are least frequent, with just under 18% of the analysed discussions being assigned to this archetype.

One might be tempted to assume that the first and second archetype correspond to conversations symptomatic of, respectively, a clash between several echo chambers and healthy discourse that occurs in a Habermasian public sphere (Habermas, 2020), but it is important to note that further analysis would be needed to corroborate that intuition. As it stands, our analysis speaks not to the ability of consumers conversing on Reddit to agree with one another about a specific issue, but rather to the difficulty they experience in even agreeing on what the issue *is*. Converging on a shared thematic space is a necessary condition for communication characteristic of public sphere, but not a sufficient one.

Finally, while the second archetype can be thought of as having two acts (act one: mutual misunderstanding; act two: gradual thematic convergence), conversations matching the third archetype (21.7% of all discussions) roughly follow a three-act structure (Field, 1982): mutual misunderstanding is followed by thematic convergence, but then, intriguingly, thematic cohesion, which is achieved by the speakers by the first fifth of the conversation, starts dissolving in the second half. Notably, lack of agreement about the thematic focus that we observe in the first act of conversations of this type tends to be less pronounced compared to the cacophonous chatter in the early stages of the first two archetypes. However, by the end of the third act, archetype-III conversations achieve a higher level of discord that the one seen between the first few utterances. One possible interpretation of this finding is that, having exhausted the topic by the end of act two, consumers lose interest in maintaining focus, although only further research could illuminate the actual reasons behind the dissolution of these conversations' thematic cohesion in the last act.

We conclude with a brief discussion of implications of these findings for researchers, marketers, and platform holders and some possibilities for future research. We found that consumer conversations on Reddit often have little thematic cohesion and so may have limited value to marketers that, for example, look to leverage electronic word of mouth to disperse brand-relevant information. This finding calls into question validity of the implicit assumption of immutability of information that is passed through a network of

individuals (Yap & Lim, 2017, p. 216) – an assumption that goes into much of the research of the phenomenon of social influence (Katz & Lazarsfeld, 1955; Pei et al., 2014; Watts & Dodds, 2007). A follow-up study could also illuminate the factors that may determine along which archetypal course a particular online conversation will develop, thus enhancing our understanding of conditions conducive

to healthy online discourse. Finally, further research could test external validity of the study by conducting similar analyses with data collected from other social media platforms in order to understand if conversation archetypes outlined in this paper (or their prevalence) are considerably shaped by the affordances of the different social media platforms.

Archetype	Organisational Structure	Number of conversations / Share among all conversations
Archetype I	Consistently very low thematic similarity over the entire course of the conversation; participants do not arrive at a shared understanding of the topic of the discussion.	142,284 / 60.3%
Archetype II	Very low thematic similarity in the first half of the conversation; gradual thematic convergence in the second half of the discussion.	41,576 / 17.6%
Archetype III	Low thematic similarity in the first fifth of the conversation; high thematic similarity achieved by the end of first fifth; dissolution of thematic cohesion in the last third of the discussion.	51,913 / 22.1%

Table 1: Summary of the archetypes of consumer conversations on Reddit

Cause-Related Marketing Accelerates Satiation

Mr. Han Young Jung, University of Minnesota, USA

Dr. Joseph Redden, University of Minnesota, USA

INTRODUCTION

Imagine that you went to a Krispy Kreme Doughnuts store to buy a box of donuts. The cashier tells you that 1% of your payment goes to a charity that helps people in poverty. You decide to buy the box of donuts and you start eating them. How much do you think you will enjoy eating the first bite of the donuts? How long do you think any effect of the charitable giving would last as you continued to eat the donuts? More generally, how does giving to a cause affect enjoyment?

The example describes cause-related marketing (CRM) that many companies engage in. It is a donation-based promotion that links product sales with a donation (Winterich and Barone 2011; Andrews et al. 2014). For example, Patagonia, which is well known for CRM, donates 1% of sales for each product sold to environmental charities. It is widely believed that CRM helps businesses build strong brands, and also benefits both firms and consumers.

Consistent with this belief, research on CRM shows that CRM positively influences the utility of a product, product attitude, purchase intention, and even attitude towards the brand (Arora and Henderson 2007; Andrews et al. 2014; Gupta and Pirsch 2006). The research suggests that a warm glow feeling explains the effectiveness of CRM on choice and purchase intention. People choose to purchase CRM products because they feel good about themselves when choosing them.

However, less is known about whether consumers indeed enjoy consuming CRM products after the choice. Although one past work suggests that consumers with positive attitudes toward CRM have less regret with their purchase of CRM products (Galan-Ladero et al. 2013), how they influence the ongoing consumption experience, especially how long their enjoyment lasts, remains unclear.

On the one hand, it could be that consumers enjoy consuming CRM products in the long run because people feel good about themselves by helping others in need (Andreoni 1990; Dunn et al. 2008). Moreover, research suggests that consumption of socially responsible products, such as green products, makes an accompanying consumption experience more enjoyable by increasing positive emotions (Tezer and Bodur 2020). Thus, it is possible that the positive emotion that CRM products elicit may spill over and make consumption experiences more enjoyable over time.

Nevertheless, we predict that consumers' enjoyment with a product will drop more quickly when it is linked to a cause than when it is not. Past research suggests that considering external benefits of consumption undermines enjoyment (e.g., Maimaran and Fishbach 2014; Etkin 2016). For instance, children consumed fewer carrots and rated them as less tasty when external benefits of eating carrots (e.g., helping them know how to read and count) were highlighted (Maimaran and Fischbach 2014). While consuming a CRM product, consumers may think more about how their consumption can benefit people whom they have decided to help. That is, they will be concerned about others' needs during consumption. This, in turn, could make a repeated consumption experience seem like work rather than a relaxing break. Therefore, we predicted that, over the course of repeated consumption, CRM will lead to faster drops in enjoyment.

Hypothesis 1: People will satiate faster with a product with a cause than a product without a cause.

Hypothesis 2: Faster satiation rate with a cause-related product is mediated by increased concern about other's needs and an increased feeling that consumption feels like work.

Study 1: We recruited 150 participants (Female: 37 percent, $M_{age}=40.07$) from Amazon MTurk. Participants received 75 cents as compensation. Study 1 had 3 (between: cause, no-cause, and control conditions) causal treatments \times 6 (within: trials) repetitions in a mixed design.

Participants viewed and rated a painting in the study. In the cause condition, participants were told that the painter drew the painting to support wildlife animals and that they will need to donate 5 cents to a wildlife animal charity (WWF) to view the painting. In the no-cause condition, participants were told that they will need to pay a commission fee of 5 cents to Adobe, which owns the copyright, to view the painting. In the control condition, participants were not given any information about payment. They were just asked to view the painting.

After the manipulation, participants in all conditions started viewing a lesser-known painting by Paul Cezanne. They viewed the painting six times repeatedly, and at each trial, they were asked to report how much they enjoyed viewing the painting (0-Not at all to 100-Very much). Lastly, we measured participants' donation frequency, and general interests in artworks as covariates to control for their influence on enjoyment.

The mean enjoyment ratings for three conditions across six trials are plotted in Figure 1. Data were analyzed using a linear mixed effect model. The model included the covariates of donation frequency and general interests in artworks. First, results indicated that there was no significant difference in enjoyment across the conditions at trial 1, $M_{cause}=66.90$ vs. $M_{no-cause}=64.67$ vs. $M_{control}=67.91$, $\beta=-.49$, $p=.85$. There was a significant main effect of trial, $\beta=-3.48$, $p<.001$, which indicated decreased enjoyment over time in all three conditions.

Most importantly, the condition \times trial interaction was significant, $b=-1.14$, $p=.04$. Planned contrasts showed that enjoyment dropped more quickly for the cause condition compared to the control condition, $b=-2.26$, $p=.039$. However, there was no difference between the no-cause condition and the control condition, $b=-0.37$, $p=0.73$. Lastly, the difference in the slopes between the cause condition and the no-cause condition was marginally significant, $b=-1.89$, $p=.08$. That is, enjoyment decreased faster in the cause condition than in the conditions without a cause. The results remained consistent without the covariates.

Consistent with the hypothesis, Study 1 showed that people satiated faster when the painting was linked to a cause than when it was not. The satiation rates did not differ between the control and the no-cause conditions, which suggests that pain associated with payment did not explain the results. However, it is possible that participants in the cause condition satiated faster because they were forced to donate their money to the designated charity and hence became more annoyed over the course of the experience. To rule this out, in Study 2, we asked people to choose the charity or the image provider to receive the 5 cents they paid. In addition, we examined the underlying mechanism of the effect in the next study.

Study 2: We recruited 120 participants from Amazon MTurk (Female: 38 percent, $M_{age}=42.69$). Participants received 75 cents as compensation. Study 2 had a 2 (between: cause and no-cause conditions) causal \times 6 (within: trials) repetitions mixed design.

Unlike in Study 1, participants in Study 2 were able to choose the charity or the image provider. In the cause condition, participants chose one charity out of three (WWF, Charity:Water, and Feeding America) to whom they would like to donate their 5 cents. In the no-cause condition, participants chose one image provider out of three (Adobe, Getty Images, and Shutterstock) to whom they would like to pay their 5 cents. They were told that the painting will be selected based on the charity or provider that they choose. However, they viewed the same painting regardless of their choice.

As in Study 1, participants viewed the painting six times and reported enjoyment after each trial. After viewing the final painting, participants reported how much they concerned about the needs of others while viewing the painting (one-item; 1-not at all to 7-very much), and how much they felt viewing the painting seemed like work (two-items; 1-not at all to 7-very much). Lastly, donation frequency and general interests in artworks were measured, which served as covariates.

The mean enjoyment ratings across six trials are plotted in Figure 1. As in Study 1, data were submitted to a linear mixed effect model. The model included the two covariates. The results showed that there was no significant difference of enjoyment between the conditions at trial 1, $M_{cause}=71.43$ vs. $M_{no-cause}=70.05$, $\beta=3.79$, $p=.41$. There was a main effect of trial, $\beta=-3.44$, $p<.001$, which indicated that participants in both conditions satiated over time.

More critically, the predicted condition \times trial interaction was significant, $b=-2.16$, $p=.04$. This result indicates that enjoyment in the cause condition dropped more quickly than that in the no-cause condition. The results remained consistent without the covariates.

In addition, the main effect of choice (i.e., options of the charities and image providers), the interactive effect between choice and trial, and the interactive effect among condition, choice, and trial on enjoyment were all not significant, $ps>.21$.

Next, we conducted a serial mediational analysis to test whether CRM leads to faster satiation by increasing concerns about others' needs, and feeling that consumption was viewed as work. To capture the satiation rate, we used the estimated slope for each participant from the linear mixed effect model. A serial mediational analysis (Model 6, Hayes, 2017) indicated that concerns about others' needs and the extent to which consumption felt like work sequentially mediated the effect, $b=-.08$, 95% CI $[-.33, -.001]$. More specifically, participants in the cause condition showed greater concern about others' needs while viewing the painting compared to those in the no-cause condition, $b=.91$, $p=.01$. Greater concern about others' needs led participants to see consumption as more like work, $b=.15$, $p=.04$. Lastly, viewing consumption as work predicted greater satiation rates (smaller values indicate greater satiation rates), $b=-.59$, $p=.06$. Thus, the results supported our hypothesis. The results again remained consistent without the covariates.

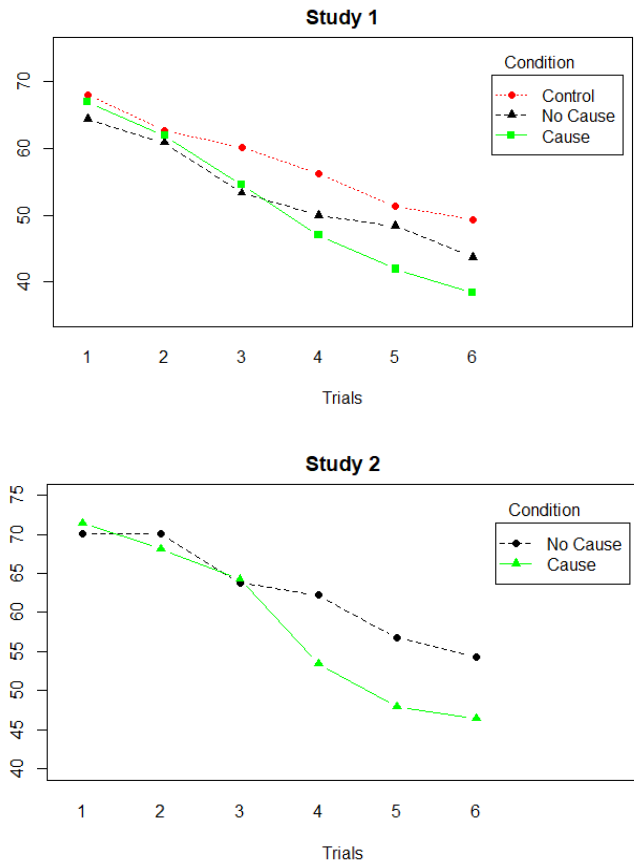

Study 2 showed consistent evidence that CRM accelerated satiation. More specifically, CRM increased concerns about others' needs during the consumption, which in turn led people to view the experience as work, and in turn predicted greater satiation. We ruled out the possibility that forced choice of charity might have accelerated satiation by letting participants choose the charity that they would like to support.

Across two experiments, we demonstrated that CRM led to faster drops in consumption enjoyment. Our findings make several contributions. First, this is the first work to examine how CRM influ-

ences consumers' consumption experiences over time. Second, unlike past works that demonstrate positive effects of CRM (e.g., Andrews et al. 2014), our work shows long-term costs that such practice can produce, which is a faster decrease in consumption enjoyment.

Future studies will test this effect using different stimuli (e.g., songs), and examine interventions that can attenuate the faster satiation for CRM products.

Figure Mean Enjoyment Ratings Across the Trials.

INTRODUCTION

Technological developments – digitization, automation, and electrification – allow for radical changes in the mobility market. Especially, the advancement of autonomous vehicles (AVs) pushes this wave of innovation. AVs are expected to make traffic flow more efficiently, especially on motorways. However, recent simulation results show that unregulated use of AV can lead to an increase in travel demand and to more congestion (Hörl et al., 2019). Ride-pooling combined with AV technology has the potential to mitigate these problems by combining the advantages of public transport (higher vehicle occupancy) and private vehicles (direct trips). Further, ride-pooling allows for substantial accessibility gains, especially in areas and during times of the day for which conventional public transport services cannot be efficiently operated.

A number of current studies is related to the acceptance of ride-pooling in AVs: What risks do passengers associate with ride-pooling in AVs? What are expected benefits? Answers to these questions are required to produce credible estimates of the potential of ride-pooling and to advance our understanding on how to promote pooling in AVs. In addition, results may inform transportation service providers, policymakers, AV designers, and other stakeholders about behavioral and service-design factors that will impact the uptake of pooled AVs.

Ride-pooling

Ride-pooling (RP) describes pooled on-demand mobility where travelers may share a ride with other passengers during the whole or a certain part of the trip. The service is provided by professional operators and thus differs from carpooling, which is a service where private people offer a shared ride (Sonneberg et al., 2019). The pick-up and drop-off of rides can happen at existing public transport stops, virtual stop points or at a specific address (door-to-door). This depends mostly on the service operator and the geography where the mobility service is offered. So far, most RP services, i.e., the usage of vehicles with four to eight seats for shared taxi services, have only been tested in pilots with conventional vehicles and with professional drivers. More efforts are needed to achieve a large-scale implementation. MOIA for instance, a RP transport service in Hamburg, Germany operated a fleet of 250 vehicles in 2019 and served on average about 6 000 trips per day. With an average occupancy rate of 1.33, the service served only about 0.11% of all trips and remained a niche product (MOIA, 2021). This example shows that the potential of RP is still very high and can further be exploited.

Ride-pooling in Automated Vehicles

Automated vehicles (AVs) in their most advanced stage permit fully automated driving and aim at being more efficient and safer than driver-operated vehicles, and even increase resource utilization by enabling new car sharing models (Thrun, 2010). In the case of ride-pooling in AVs a driver becomes obsolete and the space in the vehicle can be used otherwise. Mobility on-demand, especially RP in AVs, could provide the best option for an inexpensive service

which will contribute for very much needed sustainable solutions (Kramers et al., 2013; Martinez & Viegas, 2017) as well as for a facilitation of multimodality (Krueger et al., 2016).

Previous Insights into Acceptance of AVs and RP

In the past few years, several studies have addressed the psychological factors influencing behavior related to riding AVs such as perceptions of safety and technology adoption (e.g., Bansal & Kockelman, 2018; Zmud et al., 2017)

Concerning RP research has addressed this very specific mobility service as described above in combination with psychological factors (de Ruijter et al., 2021; König et al., 2018; König & Gripenkoven, 2019) ride-pooling platforms can potentially lead to reduced congestion levels without adversely prolonging travel times. While previous studies concluded that shared rides can offer substantial benefits, initial evidence suggests low adoption levels. We postulate that previous studies that investigated the potential of ride-pooling failed to account for the trade-off that users are likely to make when considering a shared ride. We address this shortcoming by formulating user net benefit stemming from sharing as a compensatory function where the additional travel time and on-board discomfort need to be compensated by the price discount for a traveller to choose a shared ride over a private ride. The proposed formulation is embedded in a method for matching travel requests and vehicles. We conduct a series of experiments investigating how the potential of ride-pooling services depends on travel demand characteristics, user preferences and the pricing policy adopted by the service provider. In particular, the impact of various behavioural settings in terms of users' willingness to share their ride and delay aversion on service adoption and its operational efficiency is assessed. Our results suggest that the total vehicle mileage savings found by previous studies is only attainable when users are very willing to share their ride (i.e. attach low premium to private rides. Additionally, insights about carpooling and ridesharing can shed light on determinants that can be related to RP. Studies have shown that barriers and motivators might exist regarding the trip purpose (i.e., long or short distances; leisure or work; etc.), the usage of an app or other tools while planning (i.e., usability and data privacy), personal and social attitudes (i.e., norms; socializing; flexibility; etc.), travel and waiting time, and number of passengers (see e.g., Adélé & Dionisio, 2020; Alonso-González et al., 2020; Hörl et al., 2020; Kang et al., 2021; König & Gripenkoven, 2019)

More recently, studies focusing on individuals' attitudes found several factors that influence behavior of using RP in AVs, such as accessibility, technology improvements, cost-saving, information, improving the built environment, reliability, adoption of technology, security (Etminani-Ghasrodashti et al., 2021) trust in the AV (Hörl et al., 2019; Nordhoff et al., 2020) comfort, time, perceived costs (Stoiber et al., 2019) and anxiety in social situations (Dolins et al., 2021).

Development of these technologies are fast paced. Likewise, consumer's knowledge, experiences and preferences with regards to using AVs and RP are shaped by these current developments and

need to be tracked and continuously investigated to understand and better predict consumers attitudes and behavior. Our study contributes to filling the gap of current determinants influencing the intention to use RP in AVs. Further, an in-depth analysis of the barriers and motivators related to RP in AVs can provide a deeper and more differentiated understanding of the determinants to use these services.

METHODS

Research Approach

To investigate barriers and motivators related to RP in AVs, we adopted a qualitative exploratory approach. Semi-structured qualitative interviews allow for exploratory data collection and permit an in-depth investigation of factors such as attitudes and behavioral tendencies (Brinkmann, 2014). Furthermore, the time perspective (talking about hypothetical scenarios in the future, such as using RP in AVs) is a challenge that can be overcome by applying specific interview methods, such as the narrative approach (Sools, 2020).

Sample and data collection

We conducted 19 semi-structured qualitative interviews. Participants were people living in the German-speaking part of Switzerland who were either mostly public transport user (n=9), both public transport and private car user (n=3), or mostly private car user (n=7). Participants were balanced in terms of gender (male, n= 9; female, n=10) and aged between 21 and 61 years. The interviewees received a monetary incentive for their participation.

Each interview took between 45-60 minutes and was conducted remote via Zoom. The interviews were conducted by trained inter-

viewers following a pre-tested semi-structured interview-guideline. All the interviews were recorded and transcribed.

Analysis:

The transcribed interviews were analyzed using the software MAXQDA based on the procedures of structured content analysis (Nielsen et al., 2015; Radke et al., 2011). In a first step, interview-transcripts were coded by two independent coders along the main categories based on the findings from the literature research.

In a second step, subcategories were identified and classified as either a barrier, a motivator or a neutral factor. This resulted in a two-level structure of the coding system: (1) main categories (deductive coding), (2) subcategories that are classified as either a barrier, a neutral factor, or a motivator (inductive coding).

RESULTS

Relevant determinants were categorized into 21 main categories (Table A: Appendix). The results of the present study replicate results from previous studies, confirming the relevance of several determinants such as safety, security, availability, or privacy concerns etc.

Analysis based on the subcategories revealed a variety of barriers and motivators that are relevant to explain the intention to use RP in AVs. Frequently mentioned determinants are found in the categories: safety, time, availability, flexibility of the offer, environment, socializing, and reliability. The determinants *security* and *reliability* are discussed in further detail below. Table 1 lists the valence (i.e., barriers and motivators) of the identified subcategories for the two determinants.

Table 1. Subcategories and valence of safety and reliability

Determinant	Barriers (B)	n (B)	Motivators (M)	n (M)
Safety	Feelings of insecurity at the beginning	14	Trust due to growing familiarity	18
	Distrust in technical functionalities		Trust in technical functionalities	
	Difficulties at handing over control to a machine		Safety standards: Trust and information	
	General fear, fear of accidents and/or technical issues		Less susceptible to human errors	
	Helplessness in case of technical issues		Presence of driver or other passengers	
	Feelings of uneasiness			
	Safety issues for other road users			
	Concerns about unforeseen situations			
	Guilt in case of accident			
Reliability	Unreliable	10	Reliable (2)	9
	Less reliable than public transport		Suitable for journeys without fixed appointments (2)	
	Unpredictability of vehicles available		On-time when planning and enough information available	

Notes: B = Barriers; M = Motivators; n = Number of interviewees, stating arguments in this category.

Safety

Safety is defined as feeling safe regarding technology and infrastructure. The barriers related to safety include feelings such as fear of accidents and technical issues, helplessness in case something happens, general uneasiness, and guilt in case of an accident (see Table 1). Unforeseen situations as well as concerns about other road users seem also to be an issue. The former can be related to extreme weather situations (“I am still critical how such technology [works] with black ice and slush. And how the sensors work in bad weather

and bad conditions.”) or unforeseen situations (“It would be dangerous, if the AV would not be able to detect and recognize animals or people [...] and put, any animal or anyone in danger, then I would not use it in any case.”) The same applies to the control that passengers need to give up when riding in AVs .

When it comes to technical functionalities, we see controversy. On the one hand, some participants experienced distrust related to technical functionalities (“The car thinks for you and that is just dangerous.”). On the other hand, participants reported trust in tech-

nical functionalities. Trust in safety standards is generally very high, and for some, information about safety standards builds trust. AVs are often perceived as less susceptible to human errors and thus safer than driver-operated vehicles (“*Nevertheless, technology is more reliable than people. I am convinced of this.*”). A general sense of unfamiliarity at the beginning is common due to this new mode of transport. Also, riding with others evokes a positive feeling of safety (“*When something happens, I am not alone. Actually, it’s exactly the same. But you’re not alone in the boat. You are kind of together and it changes the feeling. It gives more security.*”).

Reliability

Reliability refers mainly to issues related to punctuality and predictability. A large share of participants perceives RP in AVs as being unreliable (“*In terms of planning, the problem is that it doesn’t always leave reliably at [a specific time]*”; “*For example, if I know I have to be in town on time at a certain time, I don’t know if that would be the service for me.*”). Only a few perceive RP in AVs a reliable service (“*Yes, I think that is very punctual and you can rely on it*”). For few participants public transportation is more reliable than RP in AVs (“*With the bus, I know exactly when it leaves. I don’t have to do anything, it’s there. It has a fixed, predictable schedule.*”) and one participant argued that the unpredictability about the availability of vehicles hinder him or her to choose the service.

GENERAL DISCUSSION

Due to its potential to solve transportation issues such as pollution or congestions, RP in AVs is a promising mobility service. Understanding consumers’ preferences is of fundamental importance when it comes to accelerating the adoption of innovations in the marketplace. Furthermore, it is very important to be able to differentiate consumers’ (changing) attitudes to keep pace with the fast-developing industry. In our in-depth qualitative investigation, we could verify 21 different determinants that influence the use of RP in AVs. We were able to replicate the findings regarding the mere determinants already assessed in prior research (Adelé & Dionisio, 2020; Alonso-González, van Oort, et al., 2020; Dolins et al., 2021; Etmnani-Ghasrodashti et al., 2021; Hörl et al., 2020; Kang et al., 2021; König & Gripenkoven, 2019; Nordhoff et al., 2020; Stoiber et al., 2019). However, the market share of their pooled version (ridesharing, e.g., UberPOOL or LyftLine). However, instead of categorizing the determinants into barriers or motivators, we went a level deeper and were able to gain a more differentiated understanding for each of the 21 determinants by identifying for each determinant three subcategories: barriers, neutral arguments, and motivators.

We described two determinants: *security and reliability* in more detail. The in-depth analysis from the qualitative interviews allowed us a more differentiated view of the factors driving the intention to use RP in AVs and uncovered several controversial motivators and barriers. For instance, regarding safety, some participants reported to feel secure and to trust the technical functionalities of an AV, whereas the opposite was true for others. This shows a much more differentiated process of assessing the own preferences and suggests that to identify consumers’ preferences, we need to dive more deeply into the argumentation of costumers.

A similar picture was found for reliability. From our in-depth interviews we can conclude that people are concerned with issues such as punctuality and predictability. There is a tendency to perceive RP in AVs as being unreliable. However, this issue becomes less relevant, if RP in AVs is used for non-time-sensitive trips such as leisure trips, where arriving at a specific time is not very important. Another argument that can be seen as a motivator for RP in AV is when the trip can be planned well in advance.

The discussed examples show that determinants can be used in the argumentative process and the individuals’ construction of preferences as a barrier as well as a motivator. Thus, the preferences and resulting behavior do not merely depend on the general attitude towards RP in AVs but are very much related to specific situations and needs.

From these findings we can derive several recommendations that may inform policymakers, transportation planners and mobility providers likewise on how to design and promote RP in AV: E.g., providing reliable information about the trip (pick-up / drop-off) may reduce uncertainty and increase perceived reliability of mobility service. Or by offering test rides might increase familiarity with new mobility service and reduce insecurities.

Finally, we need to acknowledge the limitations associated with the present study. Likewise, to all research endeavors concerning innovative services that are not yet available to test and experience, findings are limited to the extent of participants’ capabilities to foresee their future preferences. Also, the qualitative methodology was designed to uncover and explore barriers and motivators genuine to the acceptance of RP in AVs. Future research is needed to confirm the proposed relationships and different target groups using a quantitative approach.

Despite its limitations results of this study may inform transportation service providers, policymakers, AV designers, and other stakeholders about behavioral and service-design factors that will impact the uptake of pooled AVs.

The Use of Ownership Language and Its Consequences on Evaluation

Mr. Myojoong Kim, Virginia Tech, United States
Dr. Juncai Jiang, University of Central Florida, United States
Dr. Mario Pandelaere, Virginia Tech, United States

INTRODUCTION

Consumers often use ownership language to signal that a given item is theirs and belongs to them (Peck & Shu, 2018; Pennebacker, Mehl, & Niederhoffer, 2003). For instance, when listing items on used item selling websites, people often describe the items to be sold using ownership language (e.g., my car, this sofa is mine, etc.). Consumers' use of ownership language is not limited to tangible products. They often feel that intangible products, such as ideas, digital goods, and even computer codes, are 'theirs' (Belk, 2013) and use ownership language to indicate the items belong to them.

Despite the prevalence of the use of ownership language in the marketplace, less research attention has been paid to examining its impact on consumer evaluation. Instead, little research has indirectly investigated this issue, implying using ownership language can have diverging effects on consumer evaluation. For instance, Dai and Hsee (2013) found that ownership status can influence motivated judgments, such that hungry consumers perceived the exact cake as larger when it did not belong to them. This work suggests using ownership language may lead to enhanced consumer evaluation. In contrast, territorial research found that using territorial marking to communicate a claim over one's ideas inhibited others' intrinsic motivation and creativity (Brown & Baer, 2015). In the context of ownership transfer, like the present research, this finding implies that using ownership language may ward off prospective buyers.

With these two opposing predictions, the present research demonstrates that ownership language use decreases prospective buyers' evaluation due to perceived barriers to future ownership. Our prediction is based on the notion that the use of ownership language makes it difficult for prospective buyers to feel that they would know the target items better than anyone else (e.g., owners), resulting in perceived barriers to future ownership.

Our contributions are manifold. First, it contributes to our understanding of psychological ownership by examining how using ownership language could influence item evaluation because prior findings are only suggestive (Brown & Baer, 2015; Dai & Hsee, 2013). Second, this research reveals that the effect of the use of ownership language takes place for tangible and intangible items. Although a growing number of studies are asking if the impact of psychological ownership depends on product type (Peck & Shu, 2018), we find that the effect is quite universal. Lastly, our research provides practical implications as well. For instance, marketing managers (e.g., open-source platforms, second-hand goods websites) can leverage our findings to promote more consumer sharing.

STUDY 1A

Study 1A aims to examine the effect of using ownership language on the evaluation of intangible items (i.e., projects) using secondary data from the open-source code-sharing platform, Scratch.com. This platform helps users to program creative multimedia projects, which can be shared with others on the platform. In most cases, the shared projects were presented with a brief description which might include ownership-related language. For instance, typical project descriptions could be written like "my project is about my favorite things" or "Hi, this is my project!"

Users of the platform could express their interest in particular projects in many ways. Specifically, interested users could view

projects and put loves or favorites. In addition, they could download and modify the shared projects as they wanted. Many users found it interesting because they could make improvements by adding to the work of others. Our dataset has information about how many loves, favorites, downloads, and views each project received. Also, the dataset tells us whether the project has been remixed or modified by other users, and these measures were used as proxies for evaluation (i.e., project).

Method

We analyzed a dataset of 1,677,493 projects shared on the platform between 2007 and 2012. We used the Linguistic Inquiry and Word Count language analysis program (LIWC) to analyze the percentage of words within these project descriptions that could potentially signal ownership status. We draw upon a review of the literature on psychological ownership, developmental psychology, and communication (Hay, 2006; LeBarr & Shedden, 2017; Pennebaker et al., 2003; Sun, Schwartz, Son, Kern, & Vazire, 2020), and created a custom dictionary that captured how ownership status could be expressed. Specifically, the dictionary counted (1) the use of possessive pronouns 'my,' 'mine' and (2) the use of first-person singular pronouns 'I,' 'me.' A descriptive analysis shows that 22.1% of the projects shared on the platform contained words that could express ownership status.

Results

We used multiple measures as proxies for project evaluation to examine the effect of using ownership language on project evaluation. These measures include the number of loves, favorites, downloads, and views for each project and whether the project has been remixed or modified by other users (i.e., remixing likelihood).

Using a Tobit regression model and controlling for the project-level characteristics and time shocks, we find that the use of ownership language in project descriptions had a negative association with the project evaluation. To be specific, as more ownership language was used in project descriptions, the projects were viewed less ($\beta = -.74$, $SE = .01$, $t(1,677,471) = -72.92$; $p < .001$), given fewer loves ($\beta = -.25$, $SE = .003$, $t(1,677,471) = -70.03$; $p < .001$), fewer favorites ($\beta = -.20$, $SE = .003$, $t(1,677,471) = -66.19$; $p < .001$), and downloaded less ($\beta = -.36$, $SE = .004$, $t(1,677,471) = -85.18$; $p < .001$).

We also find a similar result for the remixing likelihood. Logistic regression was used to analyze the relationship between the use of ownership language in project descriptions and the remixing likelihood. The result shows that the odds of projects getting remixed by other users decreased by 3% (95% CI [-.029, -.026]) for one percentage increase in the use of ownership language, indicating the negative relationship between the use of ownership language in project descriptions and project evaluation.

STUDY 1B

Study 1B also examines our prediction using different field data. Specifically, we analyzed repositories (i.e., projects) on Github, a web-based platform where people can collaborate on public repositories. Like in Scratch.com, users of Github can express their interest in repositories by giving stars. Moreover, interested users can also download the repository and tweak it into a new one, which is called a fork.

Method

We analyzed a dataset of over 31,330,441 repositories on Github. As in Study 1A, we quantify the extent to which descriptions contain ownership-related words using the LIWC software.

Results

Next, we tested the effect of ownership language on the evaluation of repositories (i.e., projects) using two different measures. First, we use the number of stars each repository received within the three-month window after it was launched to GitHub. Receiving a star is akin to receiving a like or thumb-up on social media. Second, the number of forks (i.e., how many times a particular repository got modified by other users) is used as another proxy for evaluation.

We ran a Tobit regression analysis to examine how the use of ownership language in the descriptions affected the number of stars received. We controlled for the project-level characteristics. The result indicates that using ownership language had a negative influence on the number of stars repositories received ($\beta = -.67$, $SE = .026$, $t(31,330,421) = -25.60$; $p < .001$). This result didn't change when we use the six-month window instead of the three-month window ($\beta = -.77$, $SE = .029$, $t(31,330,421) = -26.53$; $p < .001$).

A separate Tobit regression analysis was conducted for the number of forks made. We find that the use of ownership language in project description negatively affected the number of forks made for repositories ($\beta = -.23$, $SE = .007$, $t(31,330,421) = -29.79$; $p < .001$). This result holds when we control for total word count and when only the percentage of possessive pronouns is counted (e.g., "my," "mine") as the use of ownership language.

To summarize, Study 1A and 1B provide initial evidence that our prediction holds in field settings. Using various measures of project evaluation, both studies found that using ownership language in the descriptions can negatively influence the evaluation of intangible products.

STUDY 2

The primary purpose of Study 2 is to replicate the findings of Study 1A and 1B in the controlled lab setting. In addition, unlike Study 1A & 1B, Study 2 focuses on the effect on the evaluation of tangible products (e.g., used sofa).

Method

120 US participants ($M = 39.21$ years, $SD = 10.31$ years, Female = 45.00%) were recruited on MTurk and assigned to one of the two conditions in a single factor (ownership language: control vs. used) between-subjects design.

We asked participants to imagine that they were considering purchasing a used sofa. Browsing a website where people listed their used sofa for sale, they found one they were interested in potentially purchasing. Then, we showed a description of the used sofa where we manipulated the number of ownership-related words included. Depending on the condition, a different percentage of ownership language was used in the product description.

In the control condition, we did not include any ownership-related words in the description, thus, resulting in zero percentage of ownership language used. In contrast, in the experimental condition, about 15.0% of total words were ownership-related (e.g., "I bought my sofa bed four months ago. My sofa bed can be converted into a sofa or a lounge. Buy my sofa bed to relax your body!").

Subsequently, participants were asked to answer three items assessing if the manipulation worked as intended (e.g., "the person seems to feel that the sofa bed belongs to him/her") and then to indicate their willingness to pay for the product. To be specific, we told them the listed price for the product was \$150 and that they were asked

to indicate the percentage of the price they wanted to pay for the sofa bed (Fedorikhin, Park, & Thomson, 2008).

Results

Our manipulation of ownership language ($\beta = 5.20$ (1.31) vs. $\beta = 5.98$ (.81)) worked as intended. Participants in the control (vs. used) condition reported they felt fewer (vs. more) ownership-related words used in the description ($\beta = .39$; $t(118) = 3.95$; $p < .001$).

We conducted a linear regression analysis to examine the effect of ownership language on the willingness to pay for the product. As predicted, ownership language used in the description significantly decreased consumers' willingness to pay for the used sofa ($\beta = -4.51$; $t(118) = -2.43$; $p = .016$). Specifically, participants in the control condition reported significantly higher WTP for the product than those in the ownership language used condition ($M = 78.15$ (14.07) vs. $M = 69.13$ (25.02), $p = .016$), suggesting the detrimental effect of ownership language on product evaluation.

Our results show that we successfully replicated the findings of Study 1A & 1B. That is, the more ownership language used in the description, the lower consumers' evaluation of the focal item. Importantly, in Study 2, our focal item was a used sofa, a tangible product. This suggests that the detrimental effect of ownership language occurs not only for intangible products (e.g., ideas, projects) but also for tangible ones.

STUDY 3

Study 3 aimed to test the mechanism by which the use of ownership language decreases product evaluation. We argue that the effect takes place because prospective buyers perceive barriers to future ownership, which, in turn, leads to decreases in evaluation. In order to test this, we introduced a new factor, the acquisition mode (Dustin Harding, Hildbrand, Kramer, & Lasaleta, 2019). The idea behind this is that prospective buyers would be less (vs. more) likely to be affected by ownership language when deciding to rent (vs. purchase) items. This is because when renting something, people expect to relinquish ownership of the items at some point in time. As a result, the use of ownership language may be less viewed as a barrier to future ownership when renting.

Method

Participants were 201 US participants ($M = 37.97$ years, $SD = 11.93$ years, Female = 40.80%) recruited on MTurk. Study 3 is almost identical to Study 2, except that we included another factor, acquisition mode. As a result, we used a 2 (acquisition mode: rent vs. purchase) X 2 (ownership language: control vs. used) between-subjects design. To manipulate acquisition mode, we told half of the participants that they were considering renting (vs. purchasing) a used guitar. We manipulated ownership language by using a varying number of ownership-related words in a product description, as we did in Study 2.

As our primary dependent variable, we measured consumers' evaluation of the used guitar using three items (e.g., "how good/appealing/favorable do you think the guitar is?"; $\beta = 5.13$ ($SD = 1.12$)). These items were summed and averaged to form an index of item evaluation. Then, participants answered the same manipulation check items as well as several demographic questions, and the survey ended.

Results

Manipulation checks were successful. We found only a significant main effect of ownership language ($\beta = .57$; $t(197) = 6.02$; $p < .001$; $M = 4.69$ (1.59) vs. $M = 5.85$ (1.04)). The main effect of acquisition mode ($\beta = -.05$; $t(197) = -.58$; $p = .565$) and the interaction between ownership language and acquisition mode ($\beta = -.16$; $t(197) = -1.64$; $p = .010$) were not significant.

In order to examine whether the detrimental effect of ownership language is moderated by acquisition mode, we ran a regression analysis in which the use of ownership language, acquisition mode, and their interaction served as independent variables and the index of item evaluation as a dependent variable. The results supported our prediction. The regression analysis revealed that none of the main effects were significant (ownership language: $\beta = .03$; $t(197) = .42$; $p = .678$; acquisition mode: $\beta = .04$; $t(197) = .45$; $p = .650$). However, the interactive effect of ownership language and acquisition mode on product evaluation was significant ($\beta = -.19$; $t(197) = -2.34$; $p = .02$). Specifically, in the purchase condition, using ownership language did not influence item evaluation ($\beta = -.15$; $t(197) = -1.36$; $p = .18$). In contrast, in the renting condition, ownership language increased item evaluation ($\beta = .22$; $t(197) = 1.96$; $p = .05$). The results are illustrated in Figure 1.

GENERAL DISCUSSION

Across four studies, this research shows that using ownership language can have a detrimental effect on consumer evaluation. Specifically, we found that the ownership language used in the description lowered the evaluation of intangible items (Study 1A & 1B) and tangible items (Study 2 & 3). We used various evaluation measures, including WTP, the number of favorites, loves, views, etc., and the remixing likelihood, suggesting that the effect is quite robust. Also, we tested our predicted mechanism (i.e., perceived barriers to future ownership) using a moderation study (Study 3).

There are, of course, still some questions to be answered. One such question is why respondents in Study 3 who were told that they were making renting decisions indicated increased item evaluation when ownership language was used. We speculate that they might take it as an indication of how knowledgeable the owner was about his/her possession, which could reduce the uncertainty associated with the decision itself. However, given that there's research showing that owners' expression of attachment can deter prospective buyers (Graul & Brough, 2021), future studies need to investigate how the expression of ownership/attachment may yield different outcomes.

TABLE 1. Results summary

Study	Method	Sample Size	Dependent Variable	Key Covariates	Main Findings
Study 1a.	Field Study.	1,677,493 samples.	# of views, # of loves, # of favorites, # of downloads, remixing likelihood.	Percentage of ownership-related words in the description.	Ownership language decreased (1) # of views ($\beta = -.74$, SE = .01, $t = -72.92$; $p < .001$), (2) # of loves ($\beta = -.25$, SE = .003, $t = -70.03$; $p < .001$), (3) # of favorites ($\beta = -.20$, SE = .003, $t = -66.19$; $p < .001$), (4) # of downloads ($\beta = -.36$, SE = .004, $t = -85.18$; $p < .001$), (5) remixing likelihood (The result shows that the odds of projects getting remixed by other users decreased by 3% (95% CI [.964, .973]) for one percentage increase in the use of ownership related words).
Study 1b.	Field Study.	31,330,441 samples.	# of stars, # of forks.	Percentage of ownership-related words in the description.	Ownership language decreased (1) # of stars ($\beta = -.67$, SE = .026, $t = -25.60$; $p < .001$), (2) # of forks ($\beta = -.23$, SE = .007, $t = -29.79$; $p < .001$).
Study 2.	Experiment.	120 respondents	WTP	The use of ownership language.	Using ownership language significantly decreased consumers' WTP for the used sofa ($\beta = -4.51$; $t(118) = -2.43$; $p = .016$).
Study 3.	Experiment.	201 respondents	Evaluation	The use of ownership language, acquisition mode (rent vs. purchase).	The use of ownership language interacts with acquisition mode to influence consumer evaluation ($\beta = -.19$; $t(197) = -2.34$; $p = .02$). Specifically, in the purchase condition, using ownership language did not influence item evaluation ($\beta = -.15$; $t(197) = -1.36$; $p = .18$). In contrast, in the renting condition, ownership language increased item evaluation ($\beta = .22$; $t(197) = 1.96$; $p = .05$).

FIGURE 1. Acquisition mode moderates the impact of the use of ownership language on item evaluation (Study 3).

Note: Item evaluation was measured using three items (e.g., how good/appealing/favorable do you think the guitar is?).

When Loneliness Impedes Compliance with COVID-19 Prevention Guidelines

Dr. Ainslie Schultz, Providence College, United States

Dr. Kevin Newman, Providence College, United States

INTRODUCTION

To slow the spread of COVID-19, the CDC instituted a series of prevention guidelines, including urging individuals to physically distance themselves from people outside their immediate household, frequently wash their hands, and wear face masks. However, some individuals have been reluctant to comply with these guidelines. The current research investigates whether feelings of loneliness influence consumers' willingness to comply with COVID-19 prevention guidelines. The experience of loneliness is pertinent to the study of pandemics, as the physical distancing and quarantine efforts encouraged during them require people to stay home and limit face-to-face socialization. Furthermore, most scientists believe that COVID-19 is unlikely to disappear due to reduced immunity and the emergence of new COVID-19 variants. Thus, a holistic understanding of compliance may prevent further transmission of COVID-19 and provide insights into how to handle future pandemics.

Using reciprocal altruism theory as a guide, we suggest that investing in collective behaviors, like wearing a mask, washing hands vigilantly, and physically distancing from others, may be less worthwhile for lonely individuals (Trivers, 1971). Loneliness decreases one's ability to experience the social benefits of altruistic behavior such as higher social standing and increased access to shared group resources (Miller, 2000; Zahavi, 1975). As such, we might expect lower compliance with COVID-19 prevention guidelines among lonely individuals as opposed to non-lonely individuals because they have a lower sense of obligation to reciprocate.

Experiment 1 tested whether lonely (vs. non-lonely) individuals report lower willingness to comply with COVID-19 prevention guidelines. 147 undergraduate students participated in a lab study. The experiment was set up such that participants were told they would take part in two separate experiments, although in actuality, the experiments were connected. In the "first" experiment, participants were randomly assigned to one of two loneliness manipulations from Jiao and Wang (2018). In the lonely condition, participants wrote about a time in their life when they felt socially isolated, while in the non-lonely condition, participants wrote about a time when they felt socially connected.

In the "second" experiment, participants were asked in the next week, do you plan to... 1) practice social distancing; 2) thoroughly wash your hands with soap and water; and 3) wear a mask when you are around others (outside your immediate household) (1 = Never to 5 = Always). These items were combined to measure willingness to comply with COVID-19 prevention guidelines ($\alpha = .67$).

Analyses showed that individuals primed to feel lonely (vs. non-lonely) were less willing to comply with COVID-19 prevention guidelines ($M_{\text{lonely}} = 4.23$ vs. $M_{\text{non-lonely}} = 4.46$; $F(1, 145) = 4.74$, $p = .03$).

Experiment 2 examined the psychological mechanism (sense of obligation to reciprocate). 186 undergraduate students participated in a lab study. The experiment was set up such that participants were told they would take part in two separate experiments, although in actuality, the experiments were connected. In the "first" experiment, participants were randomly assigned to the loneliness manipulation (lonely vs. non-lonely) from Experiment 1. In the "second" experiment, participants answered the willingness to comply with COVID-19 prevention guidelines from Experiment 1. Afterward, participants answered the reciprocity scale ($\alpha = .92$) (from Jami et

al., 2021), which served as our mediator. Participants indicated how "obligated," "indebted," "appreciative," "thankful," and "grateful" they felt at that moment (1 = Feel very little to 7 = Feel a lot).

Analyses showed that individuals primed to feel lonely (vs. non-lonely) were less willing to comply with COVID-19 prevention guidelines ($M_{\text{lonely}} = 2.87$ vs. $M_{\text{non-lonely}} = 3.19$; $F(1, 184) = 6.43$, $p = .01$). To explore the underlying mechanism, we used Process Model 4 (Hayes, 2017). As expected, the pathway from loneliness to willingness to comply with COVID-19 prevention guidelines through obligation to reciprocate was not significant (indirect effect = $-.05$, 95% CI $[-.10, -.01]$), demonstrating full mediation. Thus, Experiment 2 demonstrated that lonely (vs. non-lonely) individuals experience a lower sense of obligation to reciprocate, which in turn, reduces their willingness to comply with COVID-19 prevention guidelines.

Experiment 3 tested whether the use of communal or agentic advertising appeals would impact consumers' willingness to comply with COVID-19 prevention guidelines. Given that we expected lonely consumers to experience a lower sense of obligation to reciprocate than non-lonely consumers, we also expected lonely consumers to be less persuaded by communal appeals that heighten the social aspect of compliance with COVID-19 prevention guidelines. Conversely, we predicted that when exposed to agentic-focused appeals, consumers both higher and lower in loneliness would show no difference in willingness to comply with COVID-19 prevention guidelines.

210 undergraduate students participated in a lab study. The experiment consisted of a between-subjects design with one manipulated factor (appeal type: agentic or communally focused) and one measured variable (loneliness). The experiment was set up such that participants believed they would take part in two separate experiments, although in actuality, the experiments were connected. In the "first" experiment, participants viewed an advertisement that used either an agentic or communally focused appeal type. In the "second" experiment, participants completed the same willingness to comply with COVID-19 prevention guidelines scale ($\alpha = .67$) from Experiments 1 and 2. Last, participants completed a filler task and loneliness scale (Russell et al., 1980) ($\alpha = .88$).

Analyses showed a significant two-way interaction of loneliness and the advertisement appeal type ($\beta = .23$, $t(1, 206) = 2.06$, $p = .04$). As an individual's level of loneliness increased, they were significantly less willing to comply with COVID-19 prevention guidelines when exposed to an ad using a communally focused appeal ($\beta = -.34$, $t = -2.24$, $p = .03$). Most importantly, though, when the ad used an agentic-focused appeal, the difference in willingness to comply with COVID-19 prevention guidelines between individuals higher and lower in loneliness was no longer significant ($\beta = .12$, $t = .73$, $p = .47$).

Overall, our results suggest that lonely individuals may be less inclined to comply with COVID-19 prevention guidelines, but that agentic advertising messages can encourage lonely consumers' compliance. We hope our findings will inspire additional research about loneliness and provide insights valuable to the current and future pandemics.

What Is ‘Average’?

Prof. Ray Charles “Chuck” Howard, Texas A & M University, USA
Mr. Amin Shiri, Texas A & M University, USA

INTRODUCTION

Consumers rely on their perception of what is ‘average’ to make several consequential decisions, including financial predictions, product choices, probability judgments, personal valuations of public goods, and evaluations of past experiences (Fisher, Newman, and Dhar 2018; Fisher and Keil 2018; Howard et al. 2022; Kahneman 2003). This begs the question, *what do consumers perceive to be average?* Intuition suggests that when people estimate an average they try to imagine the *mean* of the distribution of relevant outcomes. And indeed, research suggests that humans are adept at perceptual mean identification in contexts as diverse as numbers (André, Reinholtz, and de Langhe 2022), object size (Ariely 2001), gender (Haberman and Whitney 2007), and facial expressions (Haberman and Whitney 2009). However, very little research has systematically manipulated the skewness of sequential outcomes in a way that shows when consumers’ perceived average accurately represents the mean and when it might be biased. The goal of the present research is to address this gap in the literature by examining the effect of skewness on consumers’ perceived average of sequential outcomes.

We examine the effect of skewness on perceived average in several contexts, including plain numbers, percentages, expenses, and income. Our core hypothesis is that when consumers encounter a positively (negatively) skewed distribution of sequential outcomes, their perceived average systematically underestimates (overestimates) the true mean. The logic underlying this hypothesis is that a consumer’s perception of what is average overweight’s typical outcomes (Howard et al. 2022). Typical outcomes are represented by the mode of a distribution, so if this logic is correct, underestimation should occur when mode < mean, overestimation should occur when mode > mean, and estimates should be relatively accurate when outcomes are normally distributed with mode = mean.

We tested our hypothesis in a series of 20 pre-registered experiments ($N = 8,748$). In a typical study, participants were presented with 52 values, one at a time, every 1.2 seconds (André, Reinholtz, and de Langhe 2022). The primary manipulation was that the values were drawn in random order, without replacement, from either a positively skewed, normal, or negatively skewed distribution. Importantly, the mean, standard deviation, minimum value, and maximum value were held constant across conditions to let us isolate the effect of skewness on perceived average. After viewing the 52 values, participants answered the question “What is the average of the numbers you just saw?” using a free response text box. As per our pre-registrations, our primary analysis was a set of one-sample t-tests comparing the mean estimate in each condition to the true mean of each condition.

Studies 1–11 tested our core hypothesis with varying degrees of skewness. In each of these experiments participants were randomly assigned to one condition in a 3 cell between-subjects design (distribution: positively skewed vs normal vs negatively skewed). The true mean in each condition was 150, the minimum value was 110, and the maximum value was 190. Participants consistently underestimated the true mean in the positive skew conditions, accurately estimated the true mean in the normal conditions, and overestimated the true mean in the negative skew conditions.

Studies 12–16 tested the generalizability of our findings by changing study specifications like the number of values shown (26 rather than 52), interval width (130, 135, . . . , 170 instead of 110, 120, . . . , 190), display time (0.8s or 1.6s rather than 1.2s), and question wording (estimating the “mean” instead of the “average”). The

effect of skewness on perceived average was replicated in each of these studies.

Studies 17–20 examined the robustness of the effect by actively trying to make it go away. Study 17 was a 3 (distribution: positively skewed vs normal vs negatively skewed) \times 2 (forewarning: yes vs no) design. Participants in the no forewarning conditions received the same study instructions as in previous studies. In the forewarning conditions, we told participants we would be asking them to estimate the average before we presented them with the values. We did this because it is reasonable to ask if the effect will go away when participants know in advance what the focal task is. It did not.

Study 18 was a 3 (distribution: positively skewed vs normal vs negatively skewed) \times 2 (true mean = 150 vs 200) design. The shape of the distribution in each pair of true mean conditions was identical, but shifting the true mean of each distribution from 150 to 200 meant that most values in the true mean = 200 positive skew condition started with 2 (e.g., 200, 210, 220, and so on) whereas most values in the true mean = 200 negative skew condition started with 1 (e.g., 190, 180, 170, and so). In contrast, all values in each true mean = 150 conditions started with 1. We reasoned that the effect might go away when the true mean is 200, because consumers have a left-digit bias (e.g., Thomas and Morwitz 2005), which should draw their attention to higher (lower) values in the positive (negative) skew condition, and thus correct under (over) estimation in the skewed conditions. Nonetheless, the main effect was replicated in both the true mean = 150 and true mean = 200 conditions.

Study 19 was a 3 (distribution: positively skewed vs normal vs negatively skewed) \times 2 (estimate delay: yes vs no) design. Participants in the no delay conditions completed the study as usual. In the delay conditions, we made participants wait 30 seconds before estimating the average because a short delay in judgment can help people retain learned information (Posner and Keele 1970), which would presumably improve estimation accuracy. However, the effect was replicated in both the delay and no delay conditions.

Study 20 was a 3 (distribution: positively skewed vs normal vs negatively skewed) \times 2 (incentive: yes vs no) design. Participants in the incentive compatible conditions were told in advance that accurate estimates would be rewarded with entry into a draw to win one of three \$100 prizes. Participants in the non-incentive compatible conditions received the same information, but after they provided their estimate. Introducing an incentive did not improve accuracy.

My Two Cents: Assistance During Financial Decision Making Increases Consumer Sentiment and Gamma Brainwaves

Samuel B. Barnett, ThinkAlike Laboratories, USA

INTRODUCTION

Financial decisions are arguably the most challenging tasks faced by consumers daily. Specialized skills are increasingly required to make decisions regarding household budgets, investment products, insurance plans, and many other aspects of our financial lives (Lusardi 2008). To address this need, an entire service industry exists for the sole purpose of providing consumers with financial advice as they navigate these complex, emotionally laden, and highly uncertain choices (Calcagno and Monticone 2015).

Behavioral finance and marketing researchers have repeatedly found that consumers benefit emotionally from receiving professional financial advice. Consumers of these advisory services report feeling happier and more confident regarding their financial decisions (Robb, Babiarz, and Woodyard 2012; Xiao and Porto 2016). Some economists even argue that impartial financial advice plays a critical role in protecting consumers (Inderst 2011).

Financial decisions present a unique interplay of biological processes, statistical calculations, and emotional preferences and biases (Bosschaerts 2009, Frydman and Camerer 2016). Research incorporating consumer psychology, neuroscience, marketing, and economics has resulted in additional tools to better study financial decision making (Peterson 2007; Bosschaerts and Murawski 2015).

This work seeks to further these interdisciplinary efforts, combining behavioral research with neuroscience techniques. Participants watched a video of hypothetical financial scenarios and answered survey questions while undergoing electroencephalography (EEG) sampling brain activity. The video varied whether each financial scenario was presented with or without advice to determine the impact assistance has on participants' subjective and neural responses.

Specifically, we measure the power of neural oscillations (i.e., brainwaves) in the gamma frequency range, which have been positively linked to numerous cognitive tasks (Fitzgibbon et al. 2004). Neuroscientists have associated gamma power with attention and visual information processing (Gruber et al. 1999; Müller, Gruber, and Keil 2000), working memory (Jokisch and Jensen 2007; Lozano et al. 2014), imagination of actions (De Lange 2008), and language comprehension (Wang, Zhu, and Bastiaansen 2012).

The purpose of this work is to better understand the emotional and neural effects of advice during complex decision making. We hypothesize that the presentation of financial advice will elevate gamma power in real time and lead participants to feel more financially secure, confident, and at ease with their decisions.

METHODS

Data Collection

The data analyzed here was collected as part of a corporate consulting project commissioned by Northwestern Mutual, a Fortune 500 company specializing in consumer financial services (The Northwestern Mutual Life Insurance Company, 2017). This section summarizes the methods ThinkAlike Laboratories utilized in the original data collection as well as our current analysis.

Participants

A participant recruiting service assembled a diverse sample ($N = 41$; 18 females) in terms of age (45.98 ± 11.12 years), ethnicity (76%

white, 15% black, 5% Asian, 2% Hispanic, 2% other), and marital status (68% married, 24% single, 5% divorced, 2% living with significant other).

Given the interest in likely consumers of financial services, all participants were required to have a college degree (37% additionally reported having post-graduate education) and two-thirds of the participants had annual incomes of \$100,000 or more. Additionally, participants were asked about the importance of managing their finances; on a Likert-style scale ranging from one to five, 95% selected five (i.e., extremely important) and 5% selected four (i.e., important).

Participants could fluently speak and read English and had normal (or corrected-to-normal) vision and hearing. Participants were paid for their participation and provided informed consent.

Task

Participants underwent EEG recordings while watching a narrated video of financial scenarios and answering questions when intermittently prompted. The scenarios were developed in consultation with Northwestern Mutual.

In total, the video was 52.57 minutes in length. After 30 seconds of baseline recordings (presentation of a fixation cross, followed by an extended period of eyelid closure), the video was broken into four financial decision-making scenarios commonly faced by consumers: (1) budget allocation (14.68 minutes), (2) college tuition investment (10.41 minutes), (3) home purchase (20.88 minutes), and (4) retirement planning (11.63 minutes).

Each scenario began with the narrator providing an overview of the hypothetical situation to be considered. For example, in the budget allocation scenario, participants were first presented with a monthly after-tax income of \$7,000 and a list of various monthly expense categories (housing, medical, transportation, entertainment, etc.) totaling \$6,455. Participants were intermittently prompted to make decisions in response to the scenario at hand (e.g., changing the amount of money allocated to a particular expense category), and they wrote their responses on paper. At some point during each scenario, the video presented optional advice (e.g., a decision-making framework).

In our analysis, we refer to the portions of the financial scenarios with and without advice as the "assisted" and "unassisted" conditions, respectively. The video did not explicitly distinguish between these assisted and unassisted conditions in order to make the decision-making processes as seamless and natural as possible for the participants. The first three scenarios each presented one unassisted condition and one assisted condition; the fourth scenario (retirement planning) presented one unassisted condition and two assisted conditions.

Subjective Data

Sentiment Ratings. Participants provided numerous survey responses regarding the financial scenarios presented by the video. In this work, we analyzed the participants' subjective feelings about their financial decisions (as opposed to the specific decisions themselves). Participants were asked to rate their sentiment in various ways following each scenario/condition pair (e.g., scenario: budget allocation; condition: unassisted). In two of the four scenarios, participants were asked how "financially secure" they felt after making their decisions. In the other two scenarios, the phrasing was varied to ask how "confident" they felt and how "difficult" the decisions were for them. Each

of these responses were rating on a Likert-style scale ranging from one to five.

Analysis. For each participant and scenario, we compared the reported sentiment from the unassisted versus assisted conditions using participant-matched (i.e., paired), single-tail t-tests.

Neural Data

Acquisition. Participants’ neural data were recorded using 32-channel EEG systems (Ag/AgCl scalp electrodes; Brain Products GmbH, Gilching, Germany) at a sampling rate of 250 Hz. The electrodes were distributed uniformly and symmetrically across the scalp in a commonly-used configuration (montage: actiCAP 64Ch Standard-2, green holders) with ground and reference electrodes at AFz and FCz, respectively. Washable conductive saline gel was placed on each electrode to minimize impedance during the data acquisition.

Processing. These neural data sets were imported into MATLAB (MathWorks, Natick, Massachusetts) via EEGLAB (Swartz Center for Computational Neuroscience, University of California, San Diego). We use a Short-Time Fourier Transform (STFT) to isolate the power of the gamma oscillations (32-100 Hz) at every one-second epoch from the raw neural data at each electrode. Next, for each participant and each second, we calculated the mean gamma power across all electrodes. Then, at each second, we calculated the median power value across participants, which yields a time series of the central tendency of the participants’ whole-brain gamma power. We further processed this aggregated time series by applying a ten-second span moving average. Finally, we normalized the time series values to an intuitively meaningful range (i.e., zero to one, reflecting the minimum to maximum observed aggregate gamma power; no effect on statistics).

Analysis. We calculated the mean and standard deviation of the normalized gamma power for each subset of the aggregate time series corresponding to each scenario/condition pair. We performed statistical comparisons between subsets of the normalized gamma power time series using independent (i.e., unpaired), single-tail t-tests.

RESULTS

We observed statistically significant differences between assisted and unassisted conditions with respect to both the neural and subjective data. The individual results from the four scenarios (budget allocation, college tuition investment, home purchase, and retirement planning) were consistent with each other as well as the combined results of all scenarios (see Summary Table at the end of this section).

Increased Gamma Power in Assisted Condition

For each scenario and in aggregate, normalized gamma power was significantly higher in the assisted condition compared to the unassisted condition ($p < .01$). Within each scenario, gamma power tended to be 26.41% ± 9.21% higher in the assisted condition versus the unassisted condition. Overall, normalized gamma power was significantly higher ($p < .01$) during assisted conditions (.48 ± .18) than during unassisted conditions (.39 ± .15).

Increased Positive Sentiment in Assisted Condition

We observed increased positive sentiment (indicated by increased ratings of “financial security” or “confidence” and decreased ratings of perceived “difficulty” of the decisions) for the assisted condition in each scenario.

For the budget allocation and home purchase scenarios, we found 6.91% and 8.21% increases in “feeling financially secure” (each statistically significant, $p = .02$) following the assisted condition versus the unassisted condition.

Regarding the college tuition investment scenario, we observed a statistically significant ($p < .01$) increase of 19.08% in reported confidence after the assisted condition versus the unassisted condition. We also saw a 9.22% decrease in perceived difficulty of the decisions, which was directionally consistent with the prior result, but statistically insignificant ($p = .15$).

In the retirement planning scenario, each participant was presented with one unassisted condition (as was the case with the other scenarios), but two different assisted conditions.

For the first version of the assisted condition, we observed statistically significant ($p < .01$) changes in both sentiment metrics, with a mean increase of 9.71% in confidence and a mean decrease of 26.97% in perceived difficulty. The reported confidence levels ($4.73 \pm .55$) were the highest of any scenario/condition pair in the study, near the maximum of the one-to-five scale. Similarly, the rated difficulty values (1.76 ± 1.28) were the lowest of any scenario/condition pair tested.

The second version of the assisted condition had directionally consistent, albeit weaker, results. Confidence increased by 2.84% and perceived difficulty fell by 1.66% relative to the unassisted condition (however, neither change was statistically significant; $p = .17$ and $p = .42$, respectively).

When combining all scenarios, there were statistically significant differences between the assisted and unassisted conditions for each sentiment metric. For the assisted conditions in aggregate (relative to the unassisted conditions in aggregate), financial security ratings were 7.27% higher ($p = .01$), reported confidence tended to increase by 14.58% ($p < .01$), and perceived difficulty decreased by 14.06% on average ($p = .03$).

High Correlation between Gamma Power and Sentiment

Figure 1 shows that normalized gamma power was highly correlated ($r = .87$, $p < .01$) with sentiment (combining the similar ratings of “financial security” and “confidence” into one complete set). Furthermore, we noted that the first scenario/condition pair (budget allocation, unassisted) had both the lowest sentiment values (rating of financial security: $3.18 \pm .69$) and lowest normalized gamma power levels ($.28 \pm .14$). Relatedly, for the first assisted condition in the retirement planning scenario, we recorded both the highest sentiment ratings (confidence: $4.73 \pm .55$) and highest normalized gamma power levels ($.61 \pm .18$).

Scenario	Condition	Neural Response	Subjective Response		
		Normalized Gamma Power	Financial Security	Confidence	Difficulty
Budget Allocation	Unassisted	.28 ± .14	3.18 ± .69	-	-
	Assisted	.35 ± .15	3.40 ± .67	-	-
College Tuition Investment	Unassisted	.36 ± .11	-	3.46 ± 1.10	2.71 ± 1.33
	Assisted	.48 ± .12	-	4.12 ± .81	2.46 ± 1.31
Home Purchase	Unassisted	.45 ± .12	3.41 ± .74	-	-
	Assisted	.51 ± .17	3.69 ± .65	-	-
Retirement Planning	Unassisted	.45 ± .14	-	4.22 ± .96	2.41 ± 1.41
	Assisted, Version 1	.61 ± .18	-	4.73 ± .55	1.76 ± 1.28
	Assisted, Version 2	.57 ± .12	-	4.34 ± .91	2.37 ± 1.51
All Scenarios (Average)	Unassisted	.39 ± .15	3.30 ± .72	3.84 ± 1.09	2.56 ± 1.37
	Assisted	.48 ± .18	3.54 ± .67	4.40 ± .81	2.20 ± 1.39

Summary Table: Increased Gamma Power and Positive Sentiment in Assisted Condition. For each scenario/condition pair, the means and standard deviations are presented for each metric. In the assisted condition of each scenario, bolded values indicate a statistically significant ($p < .05$) difference from that metric corresponding to the unassisted condition of the same scenario.

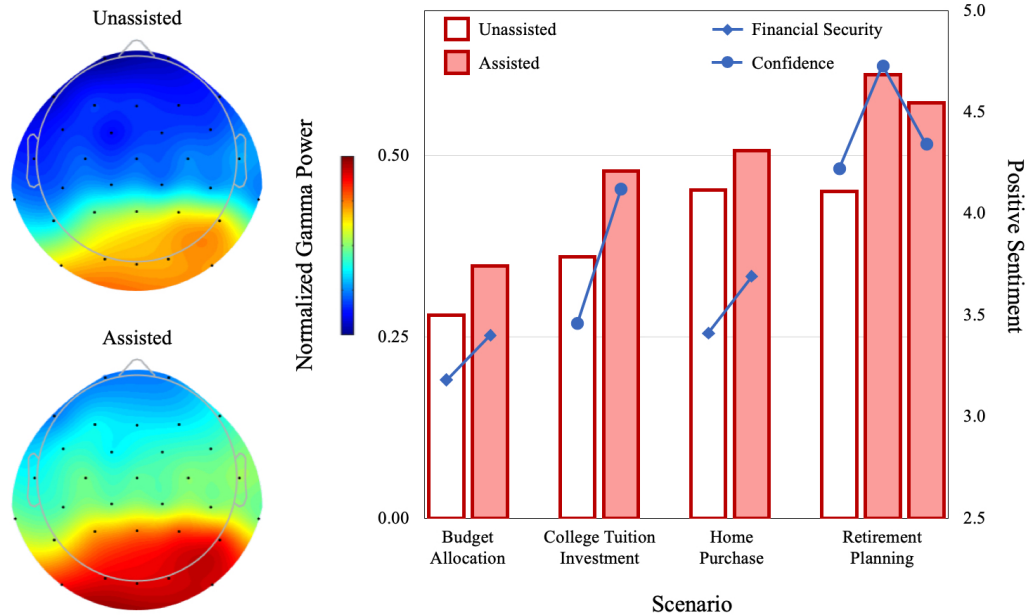

Figure 1: Relationships between Gamma Power, Assistance, and Positive Sentiment.

The right side of the figure graphs the normalized gamma power for each scenario/condition pair as vertical bars corresponding to the values on the left axis. The outlined bars represent the unassisted condition whereas the shaded bars represent the assisted condition. The blue markers correspond with the positive sentiment values on the right axis for each scenario/condition pair (diamonds for ratings of feeling “confident” and circles for ratings of feeling “financially secure”). The left side of the figure presents topographic maps (looking down at the top of the head) of the mean normalized gamma power for all scenarios in the unassisted and assisted conditions. The colors range from dark blue (.25) to dark red (.50).

DISCUSSION

Consistent with previous research (Robb et al. 2012; Xiao and Porto 2016), the results supported our hypothesis that assistance with financial decisions enhance consumers’ subjective experiences. Additionally, we observed sizable elevations in gamma power during scenarios with assistance, and these increases were highly correlated with the consumers’ positive sentiment ratings. Even just educating people about a decision-making framework had a measurably positive impact on both their neural activity and reported sentiment. Linking neural and subjective data provides base knowledge for researchers to incorporate EEG in future research on decision making.

Future Directions

The impact of financial advice on consumer behavior deserves more attention. This work furthers the notion that consumers indeed benefit from such services, both emotionally and cognitively, and that the effects can be observed in real time. This study offers a foundation for future research on financial advice and decision making. Specifically, researchers could measure moment-to-moment gamma power as a real-time proxy for the effect of financial advice on neural processing. Researchers could assess the effectiveness of various approaches to financial advice without interrupting participants to ask questions or

relying on potentially inaccurate subjective reflections. Furthermore, researchers could attempt to pinpoint the moment that a certain piece of advice “clicks” with consumers.

One natural extension to this work is to attempt the same paradigm with other categories of consumer decision-making tasks. Would an assisted condition for a simpler consumer choice, such as the selection between different tangible products (e.g., cell phones), have as strong of an effect?

Our results also support prior literature about the meaningfulness of gamma oscillations during conscious decision making. The gamma frequency spectrum is relatively understudied compared to lower-frequency oscillations (e.g., alpha waves), and given our findings of a potent correspondence between gamma power and complex cognitive tasks, further study is worthwhile.

Relatedly, there is little consensus in the literature regarding the precise frequency range that should be considered “gamma.” We utilized 32-100 Hz, but future work could refine this range into one or more tighter subsets. Likewise, we also computed gamma power across the entire scalp, but it will be fruitful to analyze smaller regions (e.g., posterior locations of the scalp where it appears that there is higher gamma power versus anterior locations; see left side of Figure 1).

Limitations

We recognize several limitations in this work. For example, since financial decisions are inherently complex, the presentation of each scenario was over ten minutes long, which ultimately limited the number of scenario/condition pairs (i.e., trials) that could be tested during the course of an hour (a reasonable amount of time for participants to engage with hypothetical financial decisions).

Although data was collected about participants’ educational background and income levels, we did not control for these variables in our analysis, preferring to study the full participant population ($N = 41$) rather than subdividing the participants’ into smaller segments.

However, such factors may have affected participants' familiarity with the tasks or receptivity towards financial advice.

It is also possible that participants learned, even subconsciously, that they would be offered assistance at some point during each scenario, which may have affected participants' effort. Effort was not directly measured (other than asking participants to report their perceived difficulty in making certain decisions), which could have confounded the behavioral or neural findings. Moreover, even asking about "difficulty" seemed less precise than other surveyed sentiment metrics. The "difficulty" ratings had higher standard deviations than those of "financial security" or "confidence," which may explain why we found fewer statistically significant differences among "difficulty" values.

Conclusion

In this study, we found that receiving advice improved consumers' subjective opinions about their decisions regarding hypothetical financial scenarios (rating that the decision-making processes seemed easier, and they felt more financially secure and confident after making their decisions). At the same time, we observed significant increases in gamma power across participants' brains. Interestingly, the advice was not actually recommending any specific decision nor did it present extensive reasoning behind the guidance. Rather, the assisted condition presented simple suggestions to help consumers approach the decision at hand in a more professional, organized manner. Consumers can make their own choices, even complex ones, but being offered a new way to consider a task improves confidence and impacts decision making, even at the neural level.

Transforming Impoverished Consumer Subjectivity

Dr. Meredith Rhoads Thomas, Florida State University, USA

Dr. Alexander Mitchell, University of South Florida, USA

INTRODUCTION

The US federal poverty level (FPL) was developed in the 1960s to measure the degree of poverty experienced by US citizens. The FPL is a measure of the annual gross income a citizen requires to afford the basic consumption necessary for survival, and is used to track poverty reduction through qualifying federal aid programs such as food stamps, loan assistance, and other supports (Hauver, Goodman and Grainer 1981). According to recent data, roughly 13% of US households (approximately 16 million) are living at or below the FPL of \$25,100 (United Way 2020).

However, the FPL has not kept up with changing consumption conditions. For example, a mobile phone has become necessary to function in contemporary society but is not considered as essential under FPL standards. Further, the FPL does not accurately reflect the rising costs of essential goods or housing, nor does it reflect stagnation in wages. In 2018, the average budget for a US family with two adults and two children was greater than \$67,476, three times the FPL (United Way 2020). In other words, many consumers who do not qualify as living in poverty may still fall well short of being able to afford basic needs. Consumers in this category, referred to as Asset Limited, Income Constrained, Employed (ALICE) or more commonly “the working poor,” make up approximately 35 million households (29%) (United Way 2020).

In this project, we investigate an anti-poverty program, entitled *Getting Ahead in a Just Gettin’ By World* (hereafter *Getting Ahead*), which helps consumers in the ALICE population address and overcome their own impoverishment. *Getting Ahead* is not a support group, which typically presents a prescribed list of actions to change or a step-by-step program (Moisio and Beruchashvili 2010), nor is it a policy-driven subsistence program providing material resources to meet individuals’ immediate needs. *Getting Ahead* addresses poverty through a process of self-driven subjectivity transformation rooted in an entrepreneurial mindset (Sarasvathy 2001, 2022). In terms of policy, *Getting Ahead* is not a top-down approach to resource distribution that risks depleting the resource (as the CEO of the organization explained it to the researchers). It is a community-based program sponsored by social service organizations that receive funding from local, state, and federal governments that approaches poverty alleviation from the bottom up, addressing the needs and circumstances of individuals.

Getting Ahead is a type of educational program in which participants are encouraged to evaluate their current resources and use them to make decisions in the short term that contribute to longer term, sustainable goals. We draw inspiration from Reuber et al. (2016, 539) who note the possibilities for extending effectuation theory by examining how entrepreneurs might learn effectuation approaches in educational settings. Effectuation theory is a theory of entrepreneurial expertise that emphasizes decision making that focuses on the possible effects an entrepreneur can generate with current resource endowments (Sarasvathy 2001). Learning how to effectuate involves a subjectivity transformation by which individuals gain new understanding of their own capabilities and potential (Sarasvathy 2022). Understanding the process through which individual subjectivity is transformed can inform consumer research on how consumers may pursue and achieve self-sufficiency and sustainable well-being.

THEORY

The nature and transformation of consumer subjectivity is at the core of consumer research (Firat and Venkatesh 1995; Holbrook and Hirschman 1982; Vargo and Lusch 2004). In general, consumer subjectivity is thought of as a collective concept, with research focusing on ways in which subjectivity emerges. For example, empirical studies have explored how powerful entities such as marketers and governments shape subjectivity through mythologically-infused discourses (Coskuner-Balli 2020; Dion and Borraz 2017; Giesler and Veresiu 2014). Alternatively, studies of consumers explore the ways in which consumer groups acquire or pursue forms of subjectivity, often aligned with ideology or other collective belief systems (Crockett 2017; Crockett, Grier and Williams 2003; Crockett and Wallendorf 2004; Holt 1998, 2002; Mikkonen, Moisander and Firat 2011).

We argue that ALICE consumers exist within effectual problem spaces (Sarasvathy 2022, 63), wherein it is difficult for individuals to know what elements of their situations to focus on, the future is difficult to predict, and their own preferences are not necessarily well structured. As a theory of entrepreneurial expertise, effectuation focuses on so-called micro foundations, consisting of processes and mechanisms (Gross 2009; Stinchcombe 2005), that alter the subjectivity of the individual and that alter the scope of their social connections (Sarasvathy 2022). Rather than entrepreneurship from an evolutionary view, where entrepreneurs are important only to the extent that they create different types of goods or services through exploration or exploitation (March 1991), effectuation pays attention to individual level differences in expertise, both tacit and learnable (Sarasvathy 2022, 12), through which entrepreneurs create opportunities.

As a form of expertise, effectual approaches alter how reality is perceived, which in turn impacts how individuals construct their understanding of the problems they face, how they conceive of the types of alternatives available to them, and how they perceive the nature of their constraints (Sarasvathy 2022, 18). The emphasis is on how effectuating entrepreneurs “fabricate opportunities from mundane realities of their lives” (Sarasvathy 2022, 12).

CONTEXT AND METHOD

Getting Ahead is a 15-week curriculum designed to help individuals living in poverty or unstable situations. The program addresses micro-level issues by teaching participants, referred to as investigators, how to identify where they can make changes and create opportunities for personal growth and advancement. The course curriculum is structured in weekly meetings in which a small group of 15 investigators gather for a discussion led by a trained facilitator. Participants are referred to as investigators because the program encourages them to explore various dimensions of their own lives, including their finances, time usage, and social networks. It also addresses the more macro forces that shape their circumstances based upon education, race, gender, as well as social and family structures. There is no standardized process, but rather, investigators are expected to analyze their idiosyncratic challenges, and then form plans to address those challenges and pursue their own life goals.

In this study, we adopt a grounded-theoretic approach (Charmaz 2006; Glaser and Strauss 2017) to explore how consumers generate transformative change and alleviate various forms of poverty in their

lives. The primary data source is fieldwork with the Getting Ahead program, through participant observation and depth interviews with those who have experienced the program. The first author was a participant observer/investigator in the class, attending weekly, 2-hour class meetings, where she immersed herself in the experience. Following each class, the second author debriefed the first author about the experiences in that evening's class. Debrief interviews lasted between 40 and 65 minutes. Additionally, the first and second authors conducted depth interviews with Getting Ahead graduates, mentors, class facilitators, social service directors, and conducted a focus group with Getting Ahead graduates and mentors.

We adopt an iterative-interpretive approach consistent with hermeneutics (Arnold and Fischer 1994; Thompson 1997) whereby the authors work back and forth between data and theory to develop processual explanations (Giesler and Thompson 2016; Spiggle 1994). Both authors coded raw data and debated emergent themes using the 'devil's advocate' approach (McAlexander and Schouten 1998), evaluating themes for their power to explain ways in which the Getting Ahead program assisted with subjectivity transformation consistent with our conceptual framework.

FINDINGS

Our findings illustrate a process of subjectivity transformation, rooted in the development of an effectual entrepreneurial expertise (Sarasvathy 2001, 2022).

Step 1: The Power of "No"

In the first stage of the Getting Ahead process, investigators are prompted to identify the pressing challenges they are facing to meet immediate needs, and find ways to create time and space to see beyond the present. The class describes poverty as extending far beyond economics alone. It includes poverty of time, social connection, physical health, emotional health, spiritual well-being, etc. Participants identify the responsibilities or relationships that demand their time and keep them from moving beyond the current moment. The facilitators then encourage participants to engage in establishing symbolic boundaries to alleviate stress and expand their resources.

And I guess I was just thinking about how I don't even respond to (a friend's) calls anymore, in a lot of cases. And just, and then, like, it feels great. Just, like, "No, I'm not gonna answer." But I probably need to get better about just saying no instead of just not answering, because, like—not answering—all it does is, like, create more questions. But saying no is, like, a clear answer, you know?
(first author, investigator debrief interview)

In an effectual approach, the practice of creating symbolic boundaries is a mechanism (Gross 2009; Stinchcombe 2005) that transforms who an individual is and what they know. In the above verbatim, the first author reflects on her practice of not answering calls. This would be a typical avoidance coping strategy, whereas explicitly stating 'no' acts as a confrontational strategy (Mick and Fournier 1998). The latter solves a problem in ways the former does not, with the effect that saying no to others settles the issue, whereas avoiding the conversation leaves the caller to speculate and expect an eventual reply and explanation.

She explains that saying no is "a clear answer" that provides a definitive response, dealing with the problem in the current moment rather than passing it off to a future time. This opens up more temporal resources. Effectually this is helping the investigator understand the means they already have to create particular effects.

Step 2: Reflexive Interrogation

In the Getting Ahead text, participants are asked to complete something referred to as "page 19." This page is intentionally blank, and investigators are asked to reflect on their everyday choices in relation to their current circumstances. They write down all of the factors that contribute to the conditions that are holding them back as an exercise in identifying and accepting the issues as a first step to addressing them.

Overall, the goal is for people to realize that you are human, you have a past, you have a future, and you have a present. And in order for you to become a better you, there are some things that you have to acknowledge, talk about, and let go. Because, believe it or not, some of the things that we walk around and hold in keeps us kinda stuck. And in order for you to become unstuck, you gotta talk about it and let it go. And it's not always easy. (Serena, Getting Ahead graduate and facilitator)

Serena explains that part of the challenge of moving beyond the stuck is to identify and document their own barriers to change. This exhaustive list of issues serves as a reference which they may use to understand what the class calls the "tyranny of the moment." For investigators, acknowledging the disparate challenges that are being faced at the same time can be an enlightening and even shocking revelation. In most cases, this forces investigators to acknowledge that their limited resources could never allow for them to address all of these issues at once, explaining their discouragement and fatigue.

From their "page 19," investigators begin to identify how to tackle their issues, and what they must put aside or let go of altogether. In effectual terms, investigators are establishing affordable loss – investigators commit in advance to what they are willing to lose – which serves as the beginning of subjectivity transformation. In contrast to consumers who avoid reflexivity in order to pursue "regenerative escapes from the self" (Scott, Cayla and Cova 2017, 22), here reflexivity is pursued critically (Thompson, Henry and Bardhi 2018) by investigators, with the intention of revealing barriers and the forms of loss required to become "unstuck."

Step 3: What Can I Do With What I Have Now?

Through identifying acceptable losses, investigators generate resources by freeing up time and space. The next step is to identify achievable actions that help pursue desired outcomes, as Serena, a Facilitator and Getting Ahead graduate explains:

Serena: And so what we suggest is that you don't do it all at once. Because I had somebody, "Oh, I wanna go to school. I wanna buy a car. I wanna buy a house." Fine. We're great and we're happy, but you gotta do it in stages. You can't do it... What is most important, do that first. And then what's next, and then do that. Because if you try to do it all at once, you become overwhelmed and you do nothing, and nothing gets accomplished.

Interviewer: So how do you help them...or do you help them identify what to do first then or, like, what could be in stage one?

Serena: We ask them how.

In establishing an entrepreneurial approach to transformation, Getting Ahead investigators are not given a generalized series of steps or practices to use to guide them toward their goals. Instead, they are asked to present their goals and then are pushed to think through how they will begin. Serena explains here the simple, per-

sistent way the facilitators teach investigators to proceed in their change process. By repeatedly asking, “How?,” they apply the effectual principle known as “the bird in the hand principle,” where they force investigators to generate and prioritize the next actionable task on their way to change.

Step 4: Interpreting the Social Arrangements of Class

Once investigators have assessed their current circumstances and the challenges that they believe are holding them back, the curriculum begins to explore the macro structures that shape the environments and circumstances in which investigators find themselves. This includes discussions on social class, race, gender, and politics, and how these social distinctions have been sources of inequality, discrimination and exclusion.

By taking this perspective, the class acknowledges the barriers to social mobility that investigators may have faced in the past, and may continue to face going forward. This is in contrast to a responsabilizing approach (Giesler and Veresiu 2014) in which investigators would be largely implicated in creating their own impoverished circumstances. The curriculum focuses on the socio-historic patterning of class norms and behaviors (Allen 2002), including the composition and scope of class-based social networks. In this way, the course develops expertise in the form of “domain-specific heuristic principles,” (Saravathy 2022, 14) which investigators can use to chart their own idiosyncratic change projects.

Step 5: Making Sense of the Future

In contrast to the emerging adults of Weinberger et. al. (2017) whose resource endowments afford them opportunities to voraciously consume in the present and allow for a clearer sense of their futures, ALICE consumers are mired in the tyranny of the moment. However, by step 5, investigators are able to imagine a pathway forward. The final step involves investigators laying out a more formal plan for their future, including what steps will come next, how this accumulation of steps can help them reach their goals, and how they can leverage their stakeholder networks to co-create desired outcomes. Consistent with effectual expertise, the future story they imagine is organized with an understanding that it is co-created with their economic, social and cultural environments.

DISCUSSION

This ongoing research project offers insights into transforming consumer subjectivity. The Getting Ahead process assists investigators in the pursuit of idiosyncratic life projects by way of subjectivity transformation. This approach to poverty alleviation has implications for policy and theory.

For theory, this study explores subjectivity reconstruction through developing the expertise of the individual rather than large-scale programs that require adherence to ideological or moral commitments (Giesler and Veresiu 2014). We interpret this process using an entrepreneurial framework (Saravathy 2022) to explore how participants develop skills in establishing symbolic boundaries, acquire domain-specific heuristics to help with prioritizing choices and problem-solving, and gain insights into the ways in which macro and meso social arrangements contribute to limiting social mobility. In developing these skills, participants expand their possibilities and learn how to manifest immediate changes – create outcomes from means already at their disposal – to work in the direction of longer term goals.

Competitive Papers—Extended Abstracts

Consumer Cynicism Through The Lens Of Bourdieu

Dr. Indirah Indibara, Indian Institute of Management Raipur, India

Dr. Sanjeev Varshney, XLRI Jamshedpur, India

EXTENDED ABSTRACT

Over time, consumers have become increasingly distrustful of the businesses and the marketplace. Many researchers have focused on various negative attitudes a consumer develops towards a firm or the marketplace to study this trend. Consumer cynicism (CC) that a consumer might harbour for the marketplace actors is one of the emerging areas of study in this domain (Helm, Moulard and Richins, 2015).

CC is conceptualized as a negative attitude that a consumer develops toward a firm (Chylinski and Chu, 2010) or the whole marketplace (Helm, Moulard, and Richins, 2015) due to the attribution of some hidden motives behind its actions. Due to the severity of the consequences of a cynical consumer's behavioural outcomes, it becomes imperative to understand the concept of CC, its driving factors, and its resulting behaviours.

RESEARCH GAP

To date, researchers have studied CC as either a personality trait or an individual's attitude. Both conceptualizations have given more importance to the individual, i.e., the subject, rather than the surrounding circumstances, i.e., the object of the study. This indicates a subject-object dichotomy prevalent in the literature. Though both subject and object are essential aspects and can be studied individually, scholars have called for an integrated approach to understanding any phenomenon in its entirety (Overton, 1997).

RESEARCH OBJECTIVE

We take the help of Bourdieu's concepts of habitus, field and capital (Bourdieu, 1987) to study CC in an integrated subject-object approach. Fields are social arenas that specify precise guidelines of conduct that require an individual to acquire specific skills to traverse the same (Holt 1997). The individuals gain these skills as various economic, social, and cultural capital to compete for status within fields (Holt 1997). Automatic internalization of the interaction between the capital and the field dynamics results in habituated tendencies and generative predispositions in an individual, defined as habitus by Bourdieu (Saatcioglu and Ozanne, 2013; Wacquant, 2016).

We propose that an individual's habitus, which evolves continually due to various life experiences, will determine the type of inter-field movement a person resorts to when moving between the social and consumption fields. The inter-field movement (Coskuner-Balli and Thompson, 2013) is also predicted to be determined by the person's cultural capital. Cultural capital combines "tastes, skills, knowledge, and practices" that distinguish individuals from others (Holt, 1998). Individuals are classified as high cultural capital (HCC) or low cultural capital (LCC) person based on the amount of cultural capital they possess (Holt, 1998; Saatcioglu and Ozanne, 2013).

As already established in the existing literature, inferring negative motives behind someone's actions is the defining characteristic of a cynical person. 'Negative Inferred Motive' (NIM) is conceptualized as the belief that a firm will try to take leverage of the customer and increase its earnings (Balaji et al., 2018). Unless someone

suspects negative motives behind the market player's actions, they won't turn cynical towards it (Indibara and Varshney, 2020). Hence, we posit that individuals develop CC when they infer negative motives while undergoing adverse inter-field movement experiences.

Borrowing from the extant literature (Helm 2004; Chylinski and Chu, 2010; Odou and Pechpeyrou, 2011 and Helm, Moulard and Richins, 2015), four different types of behaviour are predicted as a consequence of CC – defensive, offensive, subversive and withdrawal. While defensive behaviour leads a person to protect themselves from the marketplace, offensive behaviour results in the consumer trying to take advantage of the firm by displaying opportunism. Subversive behaviour motivates the person to treat firms and the market with sarcasm, thus creating negative word-of-mouth communication for others. And withdrawal behaviour results in complete withdrawal from the marketplace (Odou and Pechpeyrou, 2011).

METHODOLOGY

A mixed-method approach was adopted to understand the effect of habitus on CC and its consequent behaviours. Two studies, one qualitative and the other quantitative, were conducted for the same.

Study 1

The qualitative study using fourteen in-depth interviews was conducted to understand the phenomenon. The interviewees were purposely sampled to target consumers falling under LCC and HCC groups to better understand the distinct behaviours an individual displays according to their social upbringing. The approach was exploratory, with questions on respondents' upbringing and their social and consumption experiences. The interviews were conducted in English, Hindi and Odiya, averaging 75 minutes. All interviews were digitally recorded and transcribed to ensure trustworthiness, and guidelines were followed as suggested for in-depth interviews (Strauss and Corbin, 1990; Fournier, 1998). Collectively, 195 consumption stories were generated for analysis.

The life incidents were first arranged chronologically for each respondent to understand how childhood experiences get manifested in habitus, which then determines subsequent consumption decisions. Open, axial and selective coding was done in phases focusing on increasing levels of analysis, similar to the process recommended by McCracken (1988). Individual mind maps were also created for each respondent. The second level of interpretation involved across-person analysis, which was to discover patterns across consumption episodes and individuals. The consolidated framework was proposed after analyzing all fourteen interviews and mind maps, as shown in Figure 1.

Findings (Study 1)

It was found that an individual's childhood experiences and the resulting habitus significantly impact their adulthood consumption patterns. Depending on the childhood notions of justice and social comparisons, respondents displayed varying levels of social aspirations. The successful or unsuccessful achievement of the social growth and the reasons attributed for the same determine the type of movement between the social and the consumption field (horizontal, upward or downward) that a person usually resorts to. The

eight types of inter-field movements based on a person's social field habitus (HCC or LCC) and the type of consumption they resort to (HCC or LCC) are represented in Table 1.

If individuals cannot fulfil their desired social aspirations, they attribute the failure to society or their fate. Respondents who attributed their present LCC state to Karma or fate went for a status-quo consumption per their LCC habitus (voluntary horizontal inter-field movement). They seldom purchased anything aspirational. If these individuals were forced to overspend on their self-consumption (involuntary upward movement), they developed NIM and CC towards the particular market player and resorted to defensive behaviour due to the feeling of powerlessness.

But people who blamed society for their thwarted social growth continuously aimed to fulfil their aspirations in the consumption field, displaying a voluntary upward inter-field movement. If their upward movement in the consumption field was blocked, they inferred negative motives behind the market player's actions, turned cynical and displayed offensive behaviour towards the market player.

Suppose the individuals were not blocked in the social field while trying to fulfil their aspirations and could achieve their desired HCC social position. In that case, they tend to display voluntary simplicity (voluntary downward movement) and withdrawal behaviour in the marketplace.

In contrast, the individuals who were never blocked in the social field but are yet to fulfil their social aspirations see the consumption field as a signalling strategy for their achieved HCC status. Most of the time, they display a status-quo HCC consumption (voluntary horizontal movement), symbolizing their social growth. If these respondents faced any negative experience in the marketplace, they resorted to subversive behaviours.

Thus, it was found that an individual's voluntary or involuntary inter-field movement, upward, downward or horizontal, determines whether successful incorporation of consumption experience will occur or not in the person's habitus. And suppose the negative consumption experience led to inferring negative motives behind the market player's actions. In that case, CC is developed, resulting in four types of behaviour: defensive, offensive, withdrawal, and subversive.

Study 2

The second study was a scenario-based experiment designed to test the findings of Study 1 in two stages. The online surveys of both stages were shared with the students, alumni, and faculty members of two premier management institutions in India. The offline survey was conducted through personal face-to-face interaction with low-income employees of three organizations in India. A convenience sampling method was used, and the respondents were selected due to their accessibility to the researcher.

Stage 1

The first stage was a survey to capture the respondents' demographic information. The socio-economic classification (SEC), both childhood and present-day, was done for the respondents following the latest Indian SEC classification criteria depending on the education of the family's primary earner and the consumer durables that the family possesses.

The cultural capital of the respondents was calculated using the formula:

$$\text{Cultural Capital} = (\text{Respondent's Education} + \text{Respondent's Occupation}) + (\text{Father's Education} + \text{Father's Occupation})/2 + (\text{Mother's Education} + \text{Mother's Occupation})/2$$

The respondents were categorized into two groups – high and low based on the median values of the cultural capital, childhood

SEC and current SEC scores. Those individuals who belonged to at least two high groups among the three median split categorizations were considered the HCC individuals. Others, who had all the low categorizations in the three cases or had only one high score and two low categorizations, were considered LCC individuals for further analysis.

The respondents were also asked to choose between a high-priced branded t-shirt (HCC product) and a low-priced unbranded t-shirt (LCC product) to understand their default consumption choice. Of the 545 responses collected in the first stage, 384 respondents chose the LCC product, and 161 chose the branded HCC product.

The respondents' inherent CC level was also captured, along with the above information. The scale developed by Helm, Moulard and Richins (2015) was used to operationalize the CC construct.

Stage 2

The second stage was a factorial design survey-based experiment. The 545 respondents were assigned to four experimental scenarios (two voluntary consumption groups treated as the control groups and two involuntary consumption groups treated as the manipulation groups). In the two voluntary consumption scenarios, the respondents were allowed to freely consume their desired cultural capital product – high or low as chosen in the first stage. In the two involuntary scenarios, respondents were asked to assume that they would consume their unpreferred consumption choice.

Out of the 161 individuals who had chosen the HCC product in the first stage, 80 were assigned to the involuntary LCC consumption scenario (Scenario 1), and 81 were assigned to the voluntary HCC consumption scenario (Control Group 1). Similarly, out of the 384 respondents who had chosen the LCC product in the first stage, 192 were assigned to the involuntary HCC consumption scenario (Scenario 2). The rest, 192, were assigned to the voluntary LCC consumption scenario (Control Group 2). Based on the social field HCC or LCC classification and the consumption choice assigned in the experiment, eight inter-field movements are captured, as shown in Table 1.

The second stage survey was sent to the 545 respondents after one month to reduce the recollection bias they might display due to the repetitive nature of the CC scale. Out of the 545 respondents who had filled the questionnaire in the first stage, 505 respondents reverted in the second stage of the study, indicating a response rate of 92.66%. 78 of these responses were from scenario 1 respondents, 79 from control group 1, 175 from scenario 2 and 173 from control group 2.

NIM (Joireman et al., 2013) and CC (Helm, Moulard and Richins, 2015) were measured with the help of established scales. Further, we developed a scale to measure the individual's behavioural intention (BI) and the same was tested for reliability and validity. Four categories of consequent behaviour proposed in the study were defensive, offensive, withdrawal and subversive. Statements that captured these behaviours were selected from the literature, and the BI questionnaire consisted of 21 questions.

Findings (Study 2)

Using a one-way ANOVA test, we found that the participants' NIM, CC, defensive, offensive, withdrawal, and subversive BI significantly vary across the eight consumption groups. Individuals who consumed a product of their choice (voluntary movement) inferred significantly lower negative motives behind the firm's actions and displayed a significantly lower level of CC and defensive, offensive, withdrawal and subversive BI than participants who had to consume a product unwillingly (involuntary movement).

The data analysis indicates that the LCC individuals displayed a significantly higher level of NIM, CC, and defensive, offensive, withdrawal and subversive BI when experiencing the adverse scenario despite having a significantly lower CC than the HCC persons before the experiment. This indicates that the LCC individuals have a higher sensitivity toward the negative experiences in the marketplace. LCC individuals whose desired HCC consumption was thwarted in the experiment and who were forced to consume the LCC product unwillingly displayed the highest NIM, CC and defensive, offensive, withdrawal and subversive BI among the eight groups.

Regression analysis was done to test the effect of NIM on CC and of CC on four BIs. NIM was established as a significant predictor of CC, the beta value was 0.558, and the model R-square value was 0.393. CC was found to impact the four BIs significantly in the case of involuntary consumption scenarios. The beta values for defensive, offensive, withdrawal and subversive BI were 0.464, 0.589, 0.11 and 0.484, respectively. The above findings prove the causative effect of NIM on CC and CC on the four BIs in involuntary consumption situations as a support for our hypotheses.

IMPLICATIONS

Our study contributes to the stream of research that analyses consumption as a practice using Bourdieu's concepts of field, capital and habitus. CC, to date, studied as an individual's personality or attitude was looked at from a socio-cultural perspective. This helped us transcend the subject-object dichotomy that exists in the literature.

Gaining insight into how the childhood habitus and subsequent life experiences shape the consumption pattern of individuals and how the inter-field movement between the social and consumption fields results in CC will help the marketers take care of their actions that result in an involuntary downward, upward or horizontal movement.

For example, the focus should be on bridging the gap between the two fields, i.e., the firms should try to provide product and pricing options that match the mental schemas and habitus of the HCC and LCC individuals. However, at the same time, care should be taken about providing aspirational products to LCC consumers and low-priced options to HCC voluntary simplifiers.

Since CC can result in severe negative consequences (Helm, 2006; Chylinski and Chu, 2010; Odou and Pechpeyrou, 2011; Helm, Moulard and Richins, 2015), identifying instances when defensive, offensive, withdrawal and subversive behaviours get triggered will help the firms control the adverse impact of negative behaviours to a great extent.

LIMITATIONS AND FUTURE RESEARCH

Restrictions can be imposed on the findings because of the sample characteristics because the study was done in India. Cross-cultural research is suggested to test how developed economies differ from emerging markets in this context.

The conditions under which the four types of BI get converted into actual behaviour need to be studied, focusing on the role and importance of an individual's perception of 'powerlessness' in the marketplace.

Though manipulating the price and brand of the product was found to have a significant effect on the experimental groups, future studies should consider additional variables like individuals' consumption baskets and usage habits while studying the impact of the inter-field movement on CC and consequent behaviours.

Emotions as Drivers of Empowerment and Destigmatization in Disability Sport

Dr. Sheila Matson-Barkat, Rennes School of Business, France

Dr. Petya Puncheva, Rennes School of Business, France

Dr. Clara Koetz, Rennes School of Business, France

Dr. Sophie Hennekam, Audencia Business School, France

EXTENDED ABSTRACT

This study examines destigmatization of disability in sport. We interviewed 12 disabled athletes and analyzed 221 comments on a paralympic advertising. Our results show that athletes and consumers use emotions as discursive resources to empower themselves and each other, facilitating their identity projects and reducing the stigma related to disability.

Many individuals possess social identities that carry a stigma. Research shows that the stigma associated with certain social identities, such as disability, tends to elicit unpleasant emotional responses such as pity and sadness, accentuating the sense of ‘otherness’ (Mick & Buhl, 1992). Although previous studies have explored the motivations for disability sports consumption (Cottingham, et al. 2014), we do not know how consumers and disabled individuals mutually and interactively empower each other and further their identity projects, thus serving to destigmatize disability. Further, little is known about the role marketing communications play in the destigmatization of stigmatized populations. This study aims to fill this gap, by shedding light on the narrated experiences and emotions of individuals with stigmatized social identities and of consumers who view advertising related to this social stigma.

Our two studies were based on an interpretative approach, which is particularly useful in research that aims to understand the subjective meanings of experiences and emotions (Ahuja et al., 2019; Holbrook & O’Shaughnessy 1988; Spiggle, 1994). Study 1 consists of 12 in-depth interviews with disabled athletes. The purpose of the interviews was to capture narratives of the personal experiences and emotions associated with participating in disability sports activities as well as the athletes’ perceptions of how their engagement in these activities resonates with viewers. Study 2 is based on archival social media data collected from YouTube comments on the ‘Yes I Can’ ad for the 2016 Paralympic Games in Rio, extracted in July 2018. The International Paralympic Committee adopted the ‘supercrip’ narrative in the conception of the advertising for the Rio 2016 Paralympic Games, where Paralympic athletes were represented as having superhuman qualities. The ad shows people with various backgrounds and disabilities, including Paralympic athletes, performing many activities (e.g., playing instruments, competing in sports, doing ordinary tasks).

The findings from our in-depth interviews and consumer comments reveal that disability sports athletes and consumers of disability sports advertising interactively empower themselves and each other through the experience of emotions, furthering their respective identity projects and leading to the destigmatization of disability. From the ad viewers’ perspective, watching and commenting on a disability sports ad can elicit a range of emotions, such as gratitude, pride, admiration, and inspiration. As the consumers shared their feelings and sometimes personal stories in the form of comments on YouTube, they emotionally connected with the disabled athletes depicted in the ad. Through these feelings of similarity and closeness, the commenters felt inspired and determined to act, dare and try. This is in line with previous research showing that social media viewers are inspired by portrayals of triumph over obstacles and exceptional successes (Dale et al., 2020; Uetake and Yang 2020).

Similarly, from the athletes’ point of view, our findings show that disabled athletes experienced emotions such as joy/happiness, pride, and feelings of belonging. Their achievements not only enhanced their self-confidence but also gave them a new, positive social identity to draw on, which aligns with previous research (Askegaard & Linnet, 2011). The positive comments on YouTube reinforced these emotions. In addition, the sports identity of the disabled athletes helped them restore their sense of self or overruled their stigmatized identity as a disabled person, and the consumers were also able to develop their identity projects as a result of their emotional connection with the individuals depicted in the ad.

We make two theoretical contributions. First, we contribute to the literature on stigma by showing how consumers indirectly contribute to the destigmatization of disability, even if they are not personally affected by this stigmatizing attribute. Second, we contribute to the emotions literature by highlighting the role of emotions in the process of empowerment. Consumers of media content and the individuals depicted in the ad indirectly empower themselves and each other in a mutual manner through joy, pride, inspiration, admiration, and feelings of belonging.

Our research has implications for social marketing managers who use advertising as a means of changing public opinion about stigmatized groups. The findings show that it is through sharing similar concerns, objectives, or personal experiences that consumers create emotional bonds. Whereas most research on advertising focuses on whether an ad elicits positive or negative emotions, our study reveals that the emotions in themselves are less important than the emotional bonds an ad can create. Thus, the success of an ad in this context should be evaluated on the basis of its ability to establish emotional bridges with the group represented in the ad. We suggest the use of ad narratives that focus on goals such as empowerment, self-realization, and belongingness.

Givers eschew gifts that are inferior to their own: How social norms, regulatory focus, and concerns about offending lead givers astray

Dr. Julian Givi, West Virginia University, USA

Dr. Gopal Das, Indian Institute of Management Bangalore, India

EXTENDED ABSTRACT

We show that gift-givers avoid giving gifts that compare unfavorably to their own possessions more often than recipients prefer. Further, we demonstrate that this arises because givers (recipients) are relatively more prevention-focused (promotion-focused), which leads them to overestimate how offended recipients feel receiving gifts that compare unfavorably to givers' products.

In the present research, we compare gift-givers' choices and gift-recipients' preferences when givers are considering a gift that is an inferior version of a product they own themselves (along with another gift). We show that givers are less likely to give gifts that are inferior versions of their own products than recipients prefer. Moreover, we show that this occurs because givers are more prevention-focused (less promotion-focused) than recipients, which leads them to overestimate how offended recipients feel receiving gifts that are inferior versions of givers' products.

Theoretical Development

As mentioned, we explore givers' and recipients' preferences when givers are considering a gift that is an inferior version of a product they own themselves. How might givers and recipients construe these decisions? According to regulatory focus theory (Higgins, 1998), consumers can approach a decision with either a prevention-focus (i.e., a concern about the negative) or a promotion-focus (i.e., a fixation on the positive). We suggest givers are more prevention-focused (less promotion-focused) than recipients, because givers, unlike recipients, are *accountable* for their choices (Teigen et al., 2005). That is, givers are both responsible for the consequences the gift has on the recipient and the ones who need to justify their decision in the event the gift misses its mark. And, critically, when consumers are held accountable, attention is drawn to prevention-focused information (Crowe & Higgins, 1997).

As a consequence of givers being more prevention-focused (less promotion-focused) than recipients, they could overestimate how *offended* recipients feel receiving gifts that compare unfavorably to givers' products. Said otherwise, there is a clear potential negative outcome associated with gifts that are inferior versions of givers' products: they could offend the recipient. But since givers are more prevention-focused (less promotion-focused) than recipients, they should concentrate more on this prospective negative outcome compared to recipients and, in turn, overestimate just how offended the recipient would feel receiving it.

Our theorizing suggests that givers overestimate how offended recipients feel receiving gifts that are inferior versions of givers' products, which leads them to shun such gifts more often than recipients prefer. If this is indeed the case, then we would expect givers' aversion to giving these sorts of gifts to have its limitations. Specifically, when a giver is considering a gift that is an inferior version of one of their own products but is aware the recipient *does not know of the giver's version of the product*, they should be relatively more likely to give that gift, because they do not have to worry about offending the recipient.

Below, we present three studies that tested the predictions outlined above.

Study 1

Participants listed a friend and then read about a website that sold two models—Model Y and Model X—of two products—air fryers and

coffee makers. The Model Y versions cost \$75 and were rated 4-stars by user reviews, whereas the Model X versions cost \$100 and were rated 5-stars. Participants assigned to the [*Giver/ Recipient*] condition indicated which of the two Model Y products [their friend/they] would like better.

Participants in the *Giver* condition then read a vignette in which they visited a website in search of a gift for their friend. The websites' air fryers and coffee makers caught their eye, as their friend had told them that they could use a new one of each. The air fryers and coffee makers were the models from earlier in the study (Model Y and Model X). The vignette explained they had a \$75 budget and thus were considering the two Model Y products. The vignette also explained they owned one of the two Model X products; specifically, they owned the Model X product that was from the same product category as the Model Y product they indicated earlier their friend would like better (e.g., if they indicated their friend would like the Model Y air fryer, the vignette explained they owned the Model X air fryer). The vignette further explained that their friend was aware they owned that Model X product. Givers then indicated which Model Y product they would give. Participants in the *Recipient* condition read the same vignette from the recipient's perspective and indicated which Model Y product they would rather receive. Givers were less likely to choose the gift that was an inferior version of the giver's product (*Giver*: 31% vs. *Recipient*: 48%; $p = .01$).

Study 2

The study was like Study 1, but with two differences. First, participants also completed two measures that assessed the extent to which they were prevention-focused versus promotion-focused during their decision (1-7 scale; combined to form a "Regulatory Focus Index," with higher scores indicating more promotion-focus). Second, participants also completed a set of three measures about how offended the recipient would be if the giver gave the gift that was an inferior version of the giver's product (1-7 scale; combined to form an "Offensiveness Index").

Givers were less likely to choose the gift that was an inferior version of the giver's product (*Giver*: 33% vs. *Recipient*: 56%; $p < .001$), responded higher on the Offensiveness Index ($M_{Giver} = 2.48$ vs. $M_{Recipient} = 1.85$; $p < .001$), and had lower Regulatory Focus Indices ($M_{Giver} = 1.61$ vs. $M_{Recipient} = 2.80$; $p < .001$).

Study 3

The study was like Study 1, but with three differences. First, the two product categories were sunglasses and headphones. Second, there was an additional condition (*Giver – Recipient Is Unaware*) wherein the friend did not know of the participant's Model X product. Last, participants also completed the Offensiveness Index from Study 2.

Participants in the *Giver* condition were less likely (30%) to choose the gift that was an inferior version of the giver's product than participants in the *Recipient* (63%; $p < .001$) and *Giver – Recipient Is Unaware* (62%; $p < .001$) conditions. Participants in the *Giver* condition responded higher ($M_{Giver} = 2.66$) on the Offensiveness Index than participants in the *Recipient* ($M_{Recipient} = 1.70$; $p < .001$) and *Giver – Recipient Is Unaware* ($M_{Giver - Recipient Is Unaware} = 1.95$, $p = .001$) conditions.

The Impact of Financial Infidelity Asymmetry on Couples' Financial and Relationship Well-Being

Dr. Hristina Nikolova, Boston College, USA

Dr. Jenny Olson, Indiana University, USA

Dr. Joe Gladstone, University of Colorado Boulder, USA

EXTENDED ABSTRACT

Financial infidelity (FI) is common within marriage. We examine how couple-level dynamics in FI-proneness influence couples' well-being. Three studies demonstrate that couples with greater FI asymmetry (greater divergence in the two partners' FI-proneness) report having misaligned financial goals, which predicts negative financial communication and, ultimately, lower financial and relationship well-being.

Recent research identifies a new type of prevalent infidelity among married consumers—*financial infidelity* (FI), defined as “engaging in any financial behavior expected to be disapproved of by one’s romantic partner and intentionally failing to disclose this behavior to them” (Garbinsky et al. 2020, p. 1). Although Garbinsky et al. (2020) propose that FI *potentially* poses harm to one’s partner or the couple as a whole, the authors remained agnostic as to the nature and amount of harm inflicted. The current research examines this question directly by considering FI dynamics within married couples. Within each couple, two spouses may have similar or dissimilar predispositions toward engaging in FI (“FI proneness”). Thus, we examine the effect of *FI asymmetry* on couples’ financial and relationship well-being. FI asymmetry refers to the degree of divergence in two partners’ FI proneness. In a couple with FI asymmetry, one partner might be willing to hide spending, debt, savings, and income from their spouse, while the other partner would not. Conversely, in a couple with FI symmetry, both spouses might exhibit equally low or equally high levels of FI proneness.

We propose that greater FI asymmetry predicts greater financial goal misalignment between two partners, which ultimately strains their communication about financial matters and, as a result, predicts lower financial and relationship well-being. First, we argue that greater partner divergence in FI-proneness impairs the couple’s ability to strive toward unified financial goals. This prediction is grounded in prior research showing that trait similarity enhances relationship cohesiveness and coordination of partners’ behaviors, which facilitates goal-directed behavior (Anderson et al., 2003; Gonzaga et al., 2007; Hatfield et al., 1994; Kenny & Kashy, 1994). Second, we propose that financial goal misalignment within couples impacts negatively their communication about financial matters (Gere & Schimmack, 2011; Gere et al., 2011; Jang & Danes, 2013). Within interdependent unions such as a marriage, financial goal misalignment poses a challenge because each partner is drawing upon a shared pool of financial resources (Fitzsimons et al., 2015). If one partner values saving for retirement, achieving that goal is compromised when the other partner values indulgences. Thus, misaligned financial goals may prompt challenging conversations and lack of coordination in conversations about financial matters. Finally, we propose that negative financial communication ultimately impacts couple-level outcomes. Within the financial realm, longitudinal evidence among entrepreneur-couples found that venture-related communication quality predicted better investment decisions (Jang & Danes, 2013). Furthermore, “high-maintenance interactions” are depleting and impair self-regulatory success on other, unrelated tasks (Finkel et al., 2006). Moreover, couples may be willing to compromise decision quality to smooth interactions and avoid confrontation (Dzhogleva & Lamberton, 2014). Thus, we propose that negative

financial communication may challenge a couple’s ability to make unified financial decisions like saving for their future, and result in lower financial and relationship well-being.

We provide evidence for our predictions across three studies featuring married couples, including via field data where we collect real financial account information from a money management mobile application. In studies 1-2, FI asymmetry is operationalized as the absolute difference between the two spouses’ FI proneness scores (Garbinsky et al. 2020); study 3 operationalizes FI asymmetry using objective bank account information (the absolute difference in the proportion of hidden accounts of two partners). We capture relationship well-being by the average relationship satisfaction of the two partners (Rusbult, Martz, and Agnew 1998). We measure financial well-being using the couple’s total accumulated assets and subjective financial well-being (e.g., “Are you happy with the amount you and your partner together are saving for the future?”).

Study 1 ($n = 165$ married couples) showed that couples’ FI asymmetry is a negative predictor of their relationship satisfaction ($b = -.44$, $SE = .11$; $t(163) = -4.04$, $p < .001$), total assets ($b = -.74$, $SE = .24$; $z = -3.09$, $p = .002$), and subjective financial well-being ($b = -.57$, $SE = .11$; $t(163) = -5.24$, $p < .001$). Financial goal misalignment mediated the effect of FI asymmetry on all three variables ($b = -19,300$, $SE = 8,808$, 95% CI = [-37,000, -2,000]; $b = -.24$, $SE = .07$, 95% CI = [-.369, -.115]; $b = -.45$, $SE = .09$, 95% CI = [-.627, -.276] respectively). Study 2 ($n = 307$ married participants) replicated the effects of FI asymmetry on relationship satisfaction ($b = -.91$, $SE = .13$; $t(306) = -6.86$, $p < .0001$) and subjective financial well-being ($b = -.26$, $SE = .08$, $t(306) = -3.27$, $p = .001$). Importantly, study 2 provides evidence of serial mediation through financial goal misalignment and negative financial communication on both DVs ($b = -.18$, $SE = .05$, 95% CI: [-.290, -.097]; $b = -.08$, $SE = .02$, 95% CI: [-.140, -.048] respectively). Study 3 ($n = 622$ married couples) used bank account data obtained from a couple’s money management app to capture both FI asymmetry (i.e., how many accounts partners hide from each) and total accumulated assets. Results again demonstrated that couples with higher FI asymmetry had lower accumulated assets ($b = -.42$, $SE = .12$, $z = -3.36$, $p = .001$) and marginally lower relationship satisfaction ($b = -.13$, $SE = .065$; $t(620) = -1.96$, $p = .051$).

Our research makes several contributions. First, we respond to calls for increased attention on dyad-level predictors of marital outcomes (Gottman & Notarius, 2002). While Garbinsky et al. (2020) examined FI-proneness as an individual-level variable, we examine the effect of FI asymmetry as a dyad-level variable on dyad-level outcomes. Importantly, our work demonstrates that it is not just the presence of FI, per se, but the differential levels of partners’ FI-proneness that pose harm to the couple. Second, our research is among the first to examine the effect of trait similarity on financial well-being. Lastly, while money is a major source of marital conflict (Dew et al., 2012), little is known about the antecedents and consequences of financial communication. We identify FI asymmetry as an important precursor to misaligned financial goals and negative communication, which ultimately predicts lower couple well-being.

Consumers' Support for Small Brands through Positive Electronic Word of Mouth

Ms. Anne Mareike Flawsinkel, Bielefeld University, Germany

Dr. Jan Klostermann, University of Cologne, Germany

Dr. Nicola Bilstein, Bielefeld University, Germany

Mr. Alexander Max, Bielefeld University, Germany

Dr. Reinhold Decker, Bielefeld University, Germany

EXTENDED ABSTRACT

While brands seek to become big in terms of market share and awareness, we show that increasing brand size negatively affects electronic word-of-mouth valence. This effect is driven by a stronger desire to help small brands and a perception of increased directness when sharing opinions about small brands.

Although marketing scholars and practitioners have spent significant time studying what drives consumers to express their opinions about products, services, and brands online in the form of electronic word-of-mouth (eWOM), little information is available on how specific brand attributes influence consumer review behavior. While gut instinct suggests that big brands receive a higher volume of eWOM due to bigger market share and consumer awareness, we wonder about the valence of these expressed consumer opinions and ask: Do big brands receive more positive or more negative eWOM ratings compared to their smaller competitors?

We find evidence that brand popularity is bought with negative valence in brand-related social media posts and lower star ratings on online review platforms and show that increasing market share and awareness, as well as being viewed favorably by consumers' eWOM articulations, are mutually contradictory objectives.

Hydock et al. (2020) showed that unhappy customers are unlikely to share their opinions directly "with" brands, while they are more likely to share indirectly "about" brands. Anticipated discomfort from conveying bad news (Tesser and Rosen 1975) may explain this tendency as trying to make unpleasant messages palatable is common for people (Sussman and Sproull 1999) and concerns on the recipient's well-being cause reluctance to transmit bad news (Folger and Skarlicki 2001). Consumers are therefore likely to experience negative emotions when sharing negative experiences directly with brands. The aversion to criticizing small brands directly should be stronger (than with big brands) if consumers have a feeling of direct communication.

Moreover, feeling that it is important to help others who are in need and being motivated by a desire to help the company (Hennig-Thurau et al. 2004), consumers intend to help brands they assume to have less market power. This can manifest in a higher likelihood of sharing a positive experience or a lower likelihood of sharing a negative experience. In light of these relationships, we expected more positive eWOM ratings for small (vs. big) brands on average.

To test our hypotheses, we conducted three field studies and two lab experiments. We first investigated the relationship between brand size and eWOM ratings in real-world settings while controlling for brand ratings. We derived brand size and brand rating for chain restaurant brands from YouGov's representative US brand panel. We measured eWOM rating by averaging the sentiment of all Twitter and Instagram posts related to the brands in 2019 and collected all Yelp reviews for a sample of major US cities for each brand. Brand size had a strong significant negative effect on eWOM rating. We replicated the findings for a second product category (i.e., hotel brands). By matching all brands tracked by YouGov and a public dataset on hotel ratings on TripAdvisor, we found a marginal significant negative effect of brand size on eWOM ratings. Afterwards, we replicated the effect in a within-brand setting (i.e., brand size chang-

ing over time). Estimating a panel model with year- and brand-fixed effects and brand rating as a control variable, we found a significant negative effect of brand size on eWOM rating.

In Study 2, we sought to test the relationship between brand size and brand rating on eWOM-sharing intention. Thus, we conducted an online experiment with a 2 (brand size: big vs. small) \times 2 (brand rating: positive vs. negative) between-subjects design. We showed a detailed description of a restaurant chain brand framed as either a big or a small brand. After describing an either positive or negative experience with the described brand, participants were asked to indicate their intention to share their (positive / negative) experience with the brand on social media or by posting an online review. We identified a significant negative interaction effect between brand size and brand rating for social media posts and online reviews, indicating that a positive rating is less likely to be articulated for big brands than for small brands.

With Study 3 we scrutinized the underlying cognitive process by including two possible mediators: Perceived need for help and perceived directness. Participants of this second online experiment which followed the same experimental design as Study 2 indicated perceived directness when interacting with the brand via social media or a review site and the valence of their articulation in the case of eWOM contribution for both venues. Participants in the small brand size condition stated to intend contributing eWOM with more positive valence. This effect was not found for social media eWOM under the negative brand rating scenario. We further showed a negative total effect of brand size on eWOM valence for both social media posts and online reviews. Perceived need for help was significantly lower for big brands and increased eWOM valence for small brands in a significantly positive way. In both cases, perceived need for help significantly mediated the effect of brand size on eWOM valence. Additionally, perceived directness was lower when contributing eWOM about big brands. Perceived directness only slightly affected eWOM valence on social media and, as a result, only slightly mediated the effect of brand size on eWOM valence for social media. For online reviews, we observed a positive effect of perceived directness on eWOM valence and a significant mediation.

In summary, we contribute to previous research on the relationship between brand size and eWOM (Paharia et al. 2014) by showing a negative effect of brand size on eWOM ratings. Perceived need for help explains this relationship in both cases, while perceived directness seems to play a more significant role for online reviews. Thus, variations in brand size might lead to misleading observations and conclusions, when using eWOM data for information. Therefore, companies should control for brand size if the analyzed data contains average eWOM ratings. The perception of direct communication when sharing eWOM about small brands discourages consumers from sharing negative feedback. Big brands should take advantage of this consumer aversion to direct criticism by communicating their commitment to processing the eWOM contributions they receive.

It's the Heart that Matters: The Effect of Benefactor Income on Perceived Motivation, Moral Elevation, and Donation Behaviors

Dr. Miranda Yin, California Polytechnic State University, USA

Dr. Jessica Li, University of Kansas School of Business, USA

Dr. Jenny Olson, Indiana University, USA

EXTENDED ABSTRACT

This research examines how people respond to observing a low- (vs. high-) income benefactor's donation behavior by donating themselves. We show that donations from a low- (vs. high-) income benefactor elicit greater generosity among observers and this effect is driven by perceived altruistic motivations, which enhances feelings of moral elevation.

The current research examines how observing a low- versus high-income benefactor's donation behavior influences observers' own charitable deeds. Charities often feature others' helping behaviors in their charity appeals and consumers' prosocial actions are often influenced by others (White, Habib and Dahl 2020). In this research, we study a specific benefactor characteristic—benefactor income. We propose that donations from a low-income benefactor elicit greater generosity than one from a high-income benefactor. We further suggest that this effect is driven by perceived altruistic motivations, which enhances feelings of moral elevation (i.e., a warm, uplifting feeling people experience after observing others' human kindness and goodness; Haidt 2000).

We further posit that observers' donation behavior in response to a low-income versus high-income benefactor depends on the perceived benefactor's donation motivation, such that the presence of high-income benefactor's altruistic motivation should elevate the feelings of moral elevation among observers and attenuate the effect of benefactor income bias on donations. Additionally, we suggest that revealing a high-income benefactor's personal connection to the cause (vs. not) would increase the perceived altruistic motivation of the benefactor, eliciting greater levels of moral elevation and donations.

Experiment 1 provides an initial test of the role of benefactor income on donations and the underlying mechanism of moral elevation. Students ($N = 1,037$) participated in a 3 benefactor income (low vs. high vs. control) X 3 types of charity cause (children charity vs. animal charity vs. environmental charity) between-subject design. Results revealed only a main effect of benefactor-income on donation likelihood ($F(2, 1028) = 91.66, p < .001$). No interaction effect ($p = .54$) or effect of charity ($p = .89$) was found. Participants were more likely to donate after observing a low-income benefactor donating than a benefactor in the control condition ($p < .001$) or a high-income benefactor ($p < .002$). No donation intention difference was found between the high-income benefactor and control conditions ($p = .62$). Mediation analyses (Hayes 2019, model 4) revealed significant indirect effects of moral elevation (low-income vs. control: 95% CI: -1.003, -.696; low-income vs. high-income: 95% CI: -.646, -.368).

Experiment 2 examines the serial mediation. Undergraduate students ($N=168$) read a scenario about a benefactor who was described as either being low-income or high-income. Consistently, results indicated a main effect of income on both donation likelihood ($F(1, 166) = 6.25, p = .013$) and donation amount ($F(1, 166) = 10.32, p = .002$). Participants were more likely to donate/donated more in response to a low-income versus high-income benefactor. Serial mediation models using benefactor income as the predictor, perceived motivation of the benefactor (M1) and the level of moral elevation observers experience (M2) as serial mediators were significant for both donation likelihood (95% CI: -.537, -.180) and donation amount (95% CI: -1.493, -.422).

Experiment 3 explores resource type as a possible boundary condition. MTurk participants ($N = 402$) participated in a 2 benefactor income (high vs. low) X 2 resource type (money vs. time) between-subject design. Results showed only main effects of benefactor income on both donation likelihood ($F(1, 398) = 12.22, p = .001$) and donation amount ($F(1, 398) = 7.95, p = .005$). Regardless of the resource type, participants who observed a low-income benefactor donating reported being significantly more likely to donate/donated more than those who observed a high-income benefactor donating. No interaction effect ($p = .48$) or effect of resource type ($p = .44$) was found. For mediation, consistently, the indirect effects of moral elevation were significant for both donation likelihood (95% CI: -.77, -.37) and donation amount (95% CI: -.07, -.03).

Experiment 4 (preregistered) tests benefactor's personal connection to the cause. MTurk participants ($N = 404$) participated in a 2 (benefactor income: high vs. low) X 2 (benefactor personal connection: present vs. absent) between-subject design. Results on donation likelihood showed no interaction ($p = .86$) but only a main effect of benefactor income ($F(1, 400) = 5.44, p = .02$), such that observing a low (vs. high) income benefactor donating led to greater donation likelihood. For donation amount, results showed a significant interaction ($F(1, 400) = 4.00, p = .046$), and a main effect of benefactor income ($F(1, 400) = 8.76, p = .003$). When benefactor personal connection was absent, people donated more money after observing a low (vs. high) income benefactor donating ($p < .001$). No donation amount difference was found when benefactor personal connection was present ($p = .50$). A moderated serial mediation analyses (model 85) using perceived benefactor motivation as the first mediator, moral elevation as the second mediator, and benefactor personal connection as the moderator was significant (95% CI: .002, .030).

In experiment 5 (preregistered), we directly manipulated the perceived motivation of the benefactor. Students ($N = 561$) participated in a 2 (Benefactor income: low vs. high) X 2 (Benefactor's altruistic motivation information: absent vs. present) between-subjects design. Results revealed a significant interaction between benefactor income and the availability of benefactors' altruistic motivation information ($F(1, 557) = 4.79, p = .029$) on donation likelihood. When the information about benefactor's altruistic motivation was absent, people donated more money after observing a low (vs. high) income benefactor donating ($p < .001$). This effect was attenuated when benefactor's altruistic motivation information was present ($p = .19$). Results also indicated a significant moderated mediation (Index = .496, 95% CI: .160, .836), such that the indirect effect of benefactor income (X) on donation likelihood (Y) via moral elevation (M) was moderated by benefactor's altruism motivation information (W).

Taken together, we show that a low income (vs. high) benefactor is more effective in eliciting donations among observers. The effect is driven by the perceived altruistic motivation of the benefactor and the level of moral elevation experienced among the observers. We demonstrate that the effect of benefactor income on donations can be attenuated by revealing the altruistic motivation of the benefactor. We contribute to research on moral elevation, build upon work examining moral judgments and provide insights to charities about what type of benefactor they should feature in motivating others to donate.

Owner Attribute Label Increases Perceived Competence for Marginalized Populations

Mrs. Nicole Davis, University of Georgia, USA

Dr. Tami Kim, University of Virginia, USA

EXTENDED ABSTRACT

Women-owned businesses now account for 36% of small businesses worldwide (Kuadli 2021). Although women-owned businesses are a rapidly growing sector, being a female business owner remains a challenge. Between 2014 and 2019, women-owned enterprises increased by 21%, leading market growth relative to all other businesses (American Express 2019b). Despite these trends, studies have shown that female business owners face many challenges, including accessing capital and markets and overcoming negative perceptions of working women (Bosse and Taylor III 2012). Women entrepreneurs also face challenges from consumers. Consumer attitudes toward this group have been shown to be generally negative and prevalent, illustrating “problematic stereotypes, perceptions and expectations of business and government leaders” (Hadary 2010).

While there have been growing calls for consumer behavior researchers to study topics that promote the interests of marginalized populations (Chandy et al. 2021; Wooten and Rank-Christman 2021), scant research has investigated strategies that individuals can implement to overcome barriers they will likely face in the consumer marketplace. Here, we examine one intervention—what we term owner attribute labels, such as “woman-owned business”—to help market women-owned businesses and benefit female entrepreneurs.

On one hand, making their gender identity salient could incite adverse outcomes for women. It could remind observers of the negative attributes stereotypically associated with this identity. Past research has also shown that individuals belonging to marginalized groups can face discrimination when observers infer their social groups based on cues such as names and extracurricular activities (Doleac and Stein 2013; Edelman, Luca, and Svirsky 2017; Milkman, Akinola, and Chugh 2015). These results suggest that women would benefit from concealing, rather than revealing, their demographic identity (van Veelen et al. 2020).

Here, we propose an alternative perspective. Drawing on prior work on social perception and impression management, we posit that the very act of asserting that one’s business is woman-owned can counteract traditional stereotypes of women as low in competence (Fiske et al. 2002) and engender positive business outcomes for female business owners. Across five preregistered studies involving 3,110 respondents, we study the impact of affixing an owner attribute label to marketing communications on consumer evaluations of the business, focusing specifically on consumer perceptions and evaluations of its competence and service quality.

We empirically test our theory across five preregistered experiments by applying an owner attribute label as a treatment in marketing appeals. We show that the label increases perceptions of competence, resulting in increased firm outcomes (Studies 1-4). In addition, we examine two moderating factors: industry experience (Study 3) and industry type (Study 4), and demonstrate the generalizability of the findings (Study 5).

We began by examining whether affixing an owner attribute label (e.g., “woman-owned business”) versus no label will improve perceptions of brand competence and therefore service quality. We recruited 200 participants on Amazon’s Mechanical Turk (46% Female, $M_{age} = 49.96$, 84% White, <https://tinyurl.com/5xxcxyt4>). The study was a two-condition, between subjects (label vs. no-label) design. Participants were randomly assigned to one of the two conditions and then presented with a description of a business owner and the accompa-

nying logo. Participants then completed a four-item service quality scale including items such as “Is this a service that you would want to use?” and “How willing are you to pay for this service?” ($\alpha = .89$). Next, participants rated the warmth (warm, sincere, and good-natured; $\alpha = .92$) and competence (competent, confident, and competitive; $\alpha = .86$) of the brand (Fiske et al. 2002). All items were administered on a 1-7 Likert scale.

Results revealed that perceptions of service quality was significantly higher for the brand with the label ($M = 4.99$) relative to no label ($M = 4.43$; $t(198) = -3.125$, $p = .002$, $d = .44$). Perceived competence also was significantly higher for the brand with the label ($M = 5.38$) relative to no label ($M = 4.84$; $t(198) = -3.263$, $p = .001$, $d = .46$). There was no significant effect of condition on warmth ($t(198) = -.482$, $p = .63$), suggesting that affixing an owner attribute label does not harm perceptions of warmth while allowing female founders to boost perceptions of competence. A mediation analysis using PROCESS Model 4 (Hayes 2018) with 10,000 resamples revealed that competence significantly mediated the increase in service quality (indirect effect = .47, $SE = .14$, 95% CI = [.18, .75]). These findings provide initial support for our account that affixing an owner attribute label increases perceptions of service quality, and that this effect is driven by an increase in perceived competence of the brand.

In Study 2, we test whether the effectiveness of our proposed intervention would vary by race or remain robust across different racial categories. Stereotyping literature has shown that competence judgements can fluctuate based on race (Fiske et al. 2002; Fiske 2018). Six hundred and two participants (50.3% Female, $M_{age} = 40.64$, 81.8% White, <https://tinyurl.com/yfd7wnad>) were randomly assigned to one of six conditions in a 2 (label vs. no-label) x 3 (race of woman: White vs. Black vs. Asian), between-subjects design. The design was similar to that of Study 1. Those in the no-label condition read about a female business founder along with her company logo, while those in the label condition read, in addition, that the founder has decided to affix a “woman-owned business” label on her marketing materials. We varied the race of the business owner by including a head shot of a founder who is White, Black or Asian and included their race in the description. We measured service quality, competence, and warmth of the business using the same measures from Study 1. Participants also rated the attractiveness of the founder.

A 2 x 3 between-subjects ANOVA revealed that there was no main effect of race ($F(2, 596) = .29$, $p = .75$) and no significant interaction ($F(2, 595) = .02$, $p = .98$). Importantly, there was a main effect of label condition, such that service quality was higher for those in the label condition ($M = 5.00$) than those in the no-label condition ($M = 4.52$; $F(1, 595) = 23.50$, $p < .001$, $\eta_p^2 = .038$). We found the same pattern for perceived competence such that there was no significant main effect of race ($F(2, 596) = .12$, $p = .89$) and no significant interaction ($F(2, 596) = .07$, $p = .94$). Importantly, there was a main effect of label condition, with participants perceiving the firm that included a label to be more competent ($M = 5.56$) than the firm without the label ($M = 5.11$; $F(1, 596) = 22.22$, $p < .001$, $\eta_p^2 = .036$). As for warmth, there was no significant main effect of race ($F(2, 596) = 1.62$, $p = .20$), no main effect of condition ($F(1, 596) = .45$, $p = .51$), and no significant interaction ($F(2, 596) = .83$, $p = .44$). As in Study 1, competence mediated the relationship between the owner attribute label and service quality (indirect effect = .36, $SE = .08$, 95% CI = [.21, .52]). In sum, the effectiveness of an owner attribute label on expected service quality of the brand

persisted across different racial groups. Controlling for attractiveness revealed the same patterns of results.

Study 3 explored industry experience as a moderator. We suspected that presenting an owner attribute label can serve as an effective signal of one's competence, especially in situations where other signals of competence are absent (e.g., there is no indication of the founder's industry experience). However, in situations where such signals of the founder's competence are present, affixing an owner attribute label should not serve as an effective intervention to boost consumers' perceptions of the founder's competence.

Eight hundred and three participants (49.8% Male, $M_{age} = 36.97$, 80.7% White, <https://tinyurl.com/bdctcjjw>) were randomly assigned to one of eight conditions in a 2 (label: label vs. no-label) x 4 (industry experience: no information vs. 1 year vs. 5 years vs. 15 years) between-subjects design. Those in the no information condition were simply given a description about a female founder who owns an interior decorating business. Those who were given information about the business owner's experience (i.e., 1 year, 5 years, and 15 years conditions) were also informed: "She currently has (1 year, 5 years, or 15 years) of experience, which is (below average, average, or above average, respectively) for an interior decorator in her area." In the label present condition, participants were also informed that the founder "has decided to make it known that her business is a woman-owned business". We assessed service quality and competence using the same items from Studies 1 and 2. As there was consistently no effect of warmth in previous studies, we did not measure warmth in subsequent studies.

A 2 x 4 ANOVA revealed a main effect of label ($F(1, 795) = 50.76$, $p < .001$, $\eta_p^2 = .060$) and a main effect of industry experience ($F(3, 795) = 18.78$, $p < .001$, $\eta_p^2 = .066$) for service quality. Importantly, these effects were qualified by a significant interaction ($F(3, 795) = 4.26$, $p = .005$; $\eta_p^2 = .016$). Service quality was higher for those in the label condition than the no-label condition when participants (1) were not given any information about the founder's industry experience ($M_{present} = 5.01$ vs. $M_{absent} = 3.95$; $F(1, 795) = 36.63$, $p < .001$, $\eta_p^2 = .044$), (2) read that the founder's industry experience was below average ($M_{present} = 4.33$ vs. $M_{absent} = 3.62$; $F(1, 795) = 17.02$, $p < .001$, $\eta_p^2 = .021$), and (3) read that the founder's industry experience was average ($M_{present} = 4.86$ vs. $M_{absent} = 4.35$; $F(1, 795) = 8.54$, $p = .004$, $\eta_p^2 = .011$). However, when industry experience was above average (i.e., 15 years), the difference between the label ($M = 4.97$) and no-label was not significant ($M = 4.78$; $F(1, 795) = 1.31$, $p = .25$, $d = .15$).

We conducted the same analysis on competence. The analysis revealed a main effect of label ($F(1, 795) = 62.24$, $p < .001$, $\eta_p^2 = .073$) and a main effect of industry experience ($F(3, 795) = 25.64$, $p < .001$, $\eta_p^2 = .088$) for perceived competence. Importantly, these effects were qualified by a significant interaction ($F(3, 795) = 4.69$, $p = .003$; $\eta_p^2 = .017$). Competence was higher for those in the label present condition than the label absent condition when participants (1) were not given any information about the founder's industry experience ($M_{present} = 5.48$ vs. $M_{absent} = 4.39$; $F(1, 795) = 43.41$, $p < .001$, $\eta_p^2 = .052$), (2) read that the founder's industry experience was below average ($M_{present} = 4.82$ vs. $M_{absent} = 4.08$; $F(1, 795) = 20.42$, $p < .001$, $\eta_p^2 = .025$), and (3) read that the founder's industry experience was average ($M_{present} = 5.39$ vs. $M_{absent} = 4.87$; $F(1, 795) = 10.31$, $p = .001$, $\eta_p^2 = .013$). However, when industry experience was above average (i.e., 15 years), the difference between the label present ($M = 5.55$) and the label absent was not significant ($M = 5.32$; $F(1, 795) = 2.12$, $p = .15$, $\eta_p^2 = .003$).

We conducted a moderated mediation analysis (PROCESS Model 8; Hayes 2018) using label as the independent variable, competence as the mediator, and industry experience as the moderating factor (dummy-coded; moderating the path from the independent variable to the mediator). Differences in competence mediated the effect of label

presence on service quality, but this effect decreased as the years of industry experience increased. Specifically, the indirect effect in the no-information condition was .84 ($SE = .13$, 95% CI = [.59, 1.09]), while it was .57 ($SE = .13$, 95% CI = [.31, .84]) and .41 ($SE = .14$, 95% CI = [.14, .68]) for the 1-year and 5-years conditions, respectively (moderated mediation indices: no information vs. 1 year = $-.27$ ($SE = .18$, 95% CI = $[-.62, -.07]$); no information vs. 5 years = $-.43$ ($SE = .19$, 95% CI = $[-.79, -.08]$). Importantly, the indirect effect was the smallest in the 15-years condition at .19 ($SE = .12$, 95% CI = $[-.06, .42]$); moderated mediation index: no information vs. 15 years = $-.65$ ($SE = .17$, 95% CI = $[-1.00, -.32]$).

Study 3 found that affixing an owner attribute label can be an effective intervention when there are no other signals of competence present. In Study 4, we explored industry type as another moderator. While both warmth and competence are important to consumers, consumers may especially value competence when choosing a service in certain industries (e.g., white collar businesses such as interior design) than others (e.g., blue collar businesses such as house cleaning). If so, an owner attribute label might be very effective for women-owned businesses operating in industries where competence is highly valued. Study 4 tested this idea.

One thousand and four participants (50.3% Female, $M_{age} = 39.68$, 80.4% White, <https://tinyurl.com/2p8ju9sf>) were randomly assigned to one of four conditions in 2 (label: no label vs. label) x 2 (industry: house cleaning vs. interior decorating) between-subjects design. We measured service quality and competence of the business using the same measures from the previous studies.

A 2 x 2 ANOVA revealed significant main effects of label ($F(1, 1199) = 53.76$, $p < .001$, $\eta_p^2 = .043$) and industry type ($F(1, 1199) = 21.67$, $p < .001$, $\eta_p^2 = .018$). Importantly, these main effects were qualified by a significant interaction ($F(1, 1199) = 5.08$, $p = .024$, $\eta_p^2 = .004$). Specifically, amongst participants in the interior design condition, service quality was higher in the label condition ($M = 4.91$) than the no-label condition ($M = 4.21$; $F(1, 1199) = 46.06$, $p < .001$, $\eta_p^2 = .037$). This gap was smaller amongst participants in the house cleaning condition such that service quality was higher in the label condition ($M = 5.09$) relative to the no-label condition ($M = 4.72$; $F(1, 1199) = 12.86$, $p < .001$, $\eta_p^2 = .037$); however, affixing an owner attribute label for a house cleaning service was still effective in boosting service quality of the business.

For competence, perceptions of competence increased for the label condition ($M = 5.43$) relative to the no-label condition ($M = 4.83$; $F(1, 1199) = 72.33$, $p < .001$, $\eta_p^2 = .057$). There was also a significant main effect of industry. Perceived competence was higher in the house cleaning condition ($M = 5.21$) than in the interior decorating condition ($M = 5.05$; $F(1, 1199) = 6.15$, $p = .013$, $\eta_p^2 = .005$). However, the interaction was not significant ($F(1, 1199) = 1.97$, $p = .16$). Competence mediated the relationship between the owner attribute label and service quality (indirect effect = .48, $SE = .06$, 95% CI = [.37, .59]), suggesting that while an owner attribute label may be notably effective for certain industries inherently more associated with competence such as interior decorating than house cleaning, it still serves as an effective intervention to boost perceptions of competence, and therefore, service quality of the business.

Finally, in our last study we demonstrate the generalizability of owner attribute labels by examining "Black-owned" and "minority-owned" in addition to "woman-owned" relative to no label across five different industries. Our theory hinges on the notion that the very act of affixing a woman-owned business label serves as a display of competence; if so, we should also observe affixing other types of owner attribute labels to improve business outcomes as well. The results demonstrate that the very act of affixing an owner attribute label sig-

nals attributes associated with competence. In sum, all owner attribute labels boosted perceived competence of the business relative to using no label across five industries.

While previous work has primarily focused on documenting workplace barriers for women and intervention that organizations can utilize to reduce those barriers, we join a small but growing number of researchers focused on identifying interventions at the individual-level (e.g., Kirgios et al. 2022). We also respond to the recent and growing calls for consumer behavior researchers to study topics that promote the interests of marginalized populations (Chandy et al. 2021). Finally, we provide practical take aways for female business owners that aim to abridge traditional gender stereotype perceptions by implementing a WOB label as an interceding marketing strategy.

TABLE 1. SUMMARY OF STUDIES

	Study1	Study2	Study3	Study4	Study5
Sample Size	200	602	803	1,004	501
Mean Age	49.96	40.64	36.97	39.68	34.98
Gender	46%Female	50.3%Female	49.8%Male	50.3%Female	64.3%Female
t-value	-3.125*				
F-statistic for main effect					55.42**and 103.85**
F-statistic for interaction		22.22*	8.54*	5.08**	
Summary of findings	Affixing an owner attribute label increases expected service quality of the business. This effect is driven by an increase in perceived competence of the brand.	The effectiveness of an owner attribute label on service quality of the brand persists across different racial groups and is mediated by perceived competence.	Affixing an owner attribute label can especially be an effective intervention when there are no other signals of competence present.	While an owner attribute label may especially be effective for certain industries inherently more associated with competence such as interior decorating than house cleaning, it still serves as an effective intervention to boost perceptions of competence, and therefore, service quality of the business.	Owner attribute labels increase perceptions of competence and warmth across five different industries and across three different owner attribute labels.

A Consumer Perspective on the Implications of Contrived Electricity Scarcity

Dr. Pia A. Albinsson, Appalachian State University, USA

Dr. B. Yasanthi Perera, Brock University, Canada

Dr. Sarita Ray Chaudhury, Humboldt State University, USA

Dr. Merlyn A. Griffiths, University of North Carolina Greensboro, USA

EXTENDED ABSTRACT

This study examines extended Public Safety Power Shutoffs from a consumer perspective. Electricity is a taken-for-granted utility, which when disrupted negatively impacts consumers' wellbeing. Findings reveal that consumers' intersectional vulnerabilities influence their level of electricity dependency and increase their powerlessness in their ability to navigate the disruptions in the marketplace.

In 2019, 639,000 Californians and 93,000 businesses experienced the state's largest planned electricity disruption. Noting that the increasing frequency and intensity of wildfires makes pre-planned disruptions a necessity, utility companies frame them as proactive de-energization or Public Safety Power Shutoffs (PSPS), which are safety measures undertaken during extreme weather conditions that exacerbate wildfires (e.g., high winds, high temperatures). Critics note that beyond weather challenges, PSPS are partly precipitated by utility companies' failure to maintain their infrastructure. Becoming a part of consumers' lived experience, planned disruptions impact market actors' ability to provide and access food, safety and shelter (Baker 2009). While manipulated scarcity is widely accepted and economically justified in some industries, scarcity of essential utilities necessary for everyday consumption practices (Arnould 2007) and survival (Hill and Sharma 2020) is ethically problematic. There is limited research on PSPS from the perspective of consumers' lived experiences. Situating this research within the vulnerability, resilience, and scarcity literature streams, we examine the following research questions: How do customers respond to and cope with contrived (e.g., manipulated) scarcity of an essential service? What strategies do consumers employ to self-protect and minimize vulnerability and dependence on utility service providers?

Circumstances that affect essential services like electricity may exacerbate consumers' vulnerabilities. While vulnerability can be experienced as a result of conditions, capacities, and internal factors (e.g., physical and mental states) (Hill and Sharma 2020), external factors such as those occurring in the changing marketing environment can create situational vulnerability. In this study, situational vulnerability stems from utility companies disrupting electricity supply thereby affecting businesses' ability to provide goods and services, coupled with individuals' personal characteristics (e.g., age, economic standing, health condition), which exacerbate the effects experienced. Studies examining vulnerability during crises, often regard those affected as having homogenous identities. Intersecting characteristics, which introduces variability into how a crisis is experienced, are unexplored. Resilience for example, which entails physical and mental toughness, the capacity to avert danger and rebound from damage should it occur, adds variability to the lived experience. Vulnerability and resilience are not interdependent, rather they are discrete entities though they exist side by side (Turner et al. 2003).

Data collection began with the compilation of archival data (e.g., news media, company reports, Facebook posts). Semi-structured interviews, conducted via telephone and video-conferencing, were digitally recorded and transcribed. Data analysis utilizing MAXQDA software followed prescribed qualitative methodology (Bradford 2021). Coding was based on a combination of emic themes from the data and terms from extant literature including con-

sumer research, and news sources. Member checks with select informants were conducted.

Findings and Discussion: Consumer Resilience during PSPS

Much of the scarcity literature focuses on physical products, including luxury goods. With manipulated scarcity of resources such as electricity, those affected cannot change the outcomes through their efforts, nor can they pre-plan (e.g., cannot store electricity for future use). Unable to satisfy the desire to access resources through typical means, consumers innovate and adapt (e.g., siphon petrol, creatively use equipment to circulate heat, rely on spirituality) As alternative sources are sought (e.g., gasoline powered generators or ice as means of refrigeration), sometimes, scarcity of one resource creates others. For instance, scarcity of electricity exposes scarcity related to finances, fresh air (pollution from gasoline powered generators), water (accessed through electric water pumps), thereby increasing their importance to consumers (Mardon and Belk 2018).

Strength Together: Rural and remote regions are especially vulnerable to manipulated scarcity and the collective resilience of the community is instrumental in surmounting challenges. Indicative of community unity (Albinsson et al. 2021), analysis indicates that area residents used resources efficiently through sharing. Further, community members checked in on one another, and formulated plans to become more self-sufficient and less reliant on external parties including PG&E (e.g., energy alternatives, food gardens).

Accumulated Strength to Fight Power Dynamics: Based on their inability to effect change in PG&E's decision making, informants' accounts conveyed a sense of powerlessness. While residents of high-risk geographical areas are disproportionately affected by climate change, decisions made by corporations (Mehta 2001) that may not prioritize customer/ societal wellbeing (Griffiths et al. 2019) makes them more vulnerable. Some claim that PSPSs are partly necessitated by PG&E's neglect of infrastructure maintenance. Subpar systems that create contrived scarcity of essential services, counters duty of care and corporate social responsibility claims. Thus, policy makers, businesses, and civil servants have a responsibility to identify and mitigate risks and reduce vulnerability through preventative management of hazardous events (e.g., disaster management).

Word-of-Mouth Marketing Can Backfire for Luxury Products: Diminished Feelings of Uniqueness Lower Luxury Product Attitudes

Ms. Seo Young Myaeng, Northwestern University, USA

Dr. Jacob Teeny, Northwestern University, USA

EXTENDED ABSTRACT

Luxury products encountered through word of mouth (WOM) recommendations are evaluated more negatively than luxury goods encountered absent a recommendation (e.g., through consumers' own discovery), because WOM reduces feelings of uniqueness, an essential characteristic of luxury products. Notably, factors that shift attention away from uniqueness attenuate the effect.

As an informal consumer-to-consumer communication on products, services, or brands, word of mouth (WOM) has been widely touted as a powerful form of marketing (Berger 2014). However, the current research highlights one area where the influence of WOM might be less effective. People develop less favorable attitudes toward *luxury products* encountered through a recommendation (vs. in the absence of it), because WOM reduces the feelings of uniqueness experienced from luxury goods.

Consumers' luxury product purchase motivation is partly explained by the items' symbolic role in expressing different aspects about the owners' identity (Belk 1988; Berger and Heath 2007; Hudders and Pandelaere 2012). One aspect with particular relevance to WOM is signaling uniqueness: consumers often buy luxury products to fulfill their need for uniqueness and to differentiate themselves from others (Dubois and Duquesne 1993; Dubois et al. 2001). In other words, one of the consumption goals of luxury products is centered around product uniqueness and how these offerings allow the owners to feel unique. We predicted that if a luxury product is introduced to consumers through a WOM recommendation, its feelings of uniqueness will be dampened, consequently leading to negative attitudes toward the item.

Past research suggests the positive effects of WOM on consumer attitudes result from WOM providing assurance of product quality (e.g., Lee and Lee 2009). However, as quality is generally assured for luxury products (Vigneron and Johnson 2004), WOM's signal on uniqueness is expected to be more salient instead. WOM is expected to signal reduced uniqueness of the target product, because it could signal that the product is used by other consumers (Cheema and Kai-kati 2010) and that consumer's autonomy in choice is being somewhat restricted by the recommendation (Imajo 2002; Maslach, Stapp, and Santee 1985; Worchel 2004). Thus, WOM for luxury (vs. non-luxury) products is expected to produce more negative attitudes toward the items. Seven studies were conducted to test this hypothesis.

Studies 1a-c established that people perceive luxury products encountered through a recommendation (vs. in the absence of it) less favorably. Participants imagined encountering either a luxury or non-luxury target product in the presence (vs. absence) of a recommendation and then evaluated their product attitude. Results showed that participants were more favorable toward the recommendation-present (vs. -absent) non-luxury items but less favorable toward the recommendation-present (vs. -absent) luxury items.

Studies 2 and 3 tested for the mediating process of reduced feelings of uniqueness. In study 2, participants recalled and evaluated either two luxury or two non-luxury clothing items they purchased in the past, one of which was recommended to them and one that they found on their own. Results showed more negative attitudes toward the recommended luxury (vs. non-luxury) item and an overall negative effect of WOM on feelings of uniqueness for both luxury and non-luxury items. However, within-subject mediation analyses showed that feel-

ings of uniqueness only mediated the effect of the product encounter (recommendation-present vs. recommendation-absent) on attitudes for luxury products, but not for non-luxury products.

Study 3 provided further evidence for the mechanism through moderation. Based on our theorization, WOM should not backfire for luxury products when uniqueness is no longer prioritized. To test this effect, half of the participants were primed to care less about product uniqueness, whereas the other half were not. Participants then imagined choosing between either two luxury or two non-luxury dress shirts, one of which was recommended, and the other was not. Results showed that within the non-luxury shirts, no difference between the uniqueness conditions was found. However, within the luxury shirts conditions, the uniqueness unimportant condition (vs. control) displayed greater preference for the recommended shirt relative to the found shirt.

Study 4 tested whether a different type of WOM would also result in the same negative consequences for luxury products. While studies 1-4 focused on recommendation WOM, there is another form of WOM, mere mention, where consumers talk about the product without specific recommendations (Berger 2014), which should show an attenuated negative effect of luxury WOM. To test this moderator, participants were asked to read tweets that either recommended or mentioned a target luxury or non-luxury wine and indicated their willingness to pay (WTP) for it. Results showed that for non-luxury wine, WTP did not differ between the two types of WOM. However, for luxury wine, WTP was lower for the recommended (vs. mentioned) item.

Study 5 identified another boundary condition: political orientation. We expected liberals (vs. conservatives), who are more sensitive to product uniqueness signals (Ordabayeva and Fernandes 2018), to display an even more negative response to luxury WOM when WOM communicates even lower uniqueness (i.e., WOM from a social media influencer vs. a friend). In the study, Democratic and Republican participants were asked to indicate their WTP for either luxury or non-luxury headphones recommended by either an influencer or a friend. The Republican participants did not differ in their WTP for an influencer-recommended vs. friend-recommended headphones for both luxury and non-luxury conditions. In contrast, although the Democratic participants' WTP did not differ between a friend-recommended and influencer-recommended non-luxury headphones, their WTP was lower for an influencer-recommended (vs. a friend-recommended) luxury headphones.

Across seven studies, our research examines the costs of WOM marketing for luxury products, making theoretical advancement in the WOM literature and offering managerial implications on whether WOM marketing is the most effective for luxury goods. An additional contribution is made by showing how WOM can take on a different meaning for people depending on what considerations are more salient (i.e., uniqueness vs. quality). We further contribute to the luxury literature by showing how the product encounter plays an important role in determining consumers' luxury product attitudes. Finally, based on insight provided by the moderating role of political orientation and types of WOM, marketers may also reconsider consumer targeting as well as the forms of WOM they generate in their marketing campaigns for luxury goods.

Predicting Against Judgment: When People Fail to Predict What They Believe to Be Most Likely to Arise

Mr. Chengyao Sun, Washington University in St. Louis, USA
Prof. Robyn Leboeuf, Washington University in St. Louis, USA

EXTENDED ABSTRACT

We document a robust discrepancy between predictions and likelihood perceptions. When the most likely outcome seems unlikely (e.g., it is objectively most likely but has only a 20% chance), people are less likely to predict that it will arise than when it seems likely (e.g., has an 80% chance).

Consumers often predict the outcome of an event from a set of alternatives. For example, a gambler predicts which roulette number will come up; a basketball fan predicts which team will win the title, and so on. It is widely accepted that such predictions can be biased. However, research usually assumes that predictions correspond to people's likelihood assessments, such that people select as their prediction the outcome that seems most likely to them. Thus, if Ray thinks Kansas is most likely to win March Madness, one might assume that he would predict Kansas as the winner. Less research has examined whether likelihood assessments and predictions diverge. We demonstrate a novel disconnect between the two.

Consider Ray again. If he thinks Kansas has a 90% chance of winning, he can easily predict that Kansas will be the champion. However, if he thinks Kansas only has a 10% chance, he might hesitate to predict Kansas, even if he thinks all other teams have a lower chance, because there remains substantial uncertainty.

Normatively, Ray should focus on the relative likelihoods of the teams. No matter how likely Kansas is to win, Ray should predict Kansas if he believes Kansas is more likely than any other team. However, we find that people often incorporate absolute likelihoods into their predictions: they consider not only what is *most* likely but also *what is likely*. When the most likely outcome is likely to arise, they regularly predict that it will arise. However, when the most likely outcome is unlikely, meaning that no outcome is truly likely, they less regularly predict that outcome. This may happen because events seem unpredictable when the most likely outcome is unlikely, so people may make arbitrary predictions using gut feelings or random guesses. We explore this effect in 7 studies (all preregistered except Study 1).

In Study 1, 222 undergraduates each randomly (virtually) drew a ball from one of two sets of nine balls. In one set, two balls were labeled "1", and the others were labeled "2" to "8". In the other set, six were labeled "1" and the others were labeled "2" to "4". Participants knew the composition of their sets. They either predicted which number they would draw or indicated which they were most likely to draw. With six "1"s, nearly everyone identified "1" as most likely and nearly everyone predicted they would draw a "1" (98.1% vs 94.7%, $p=.663$). With two "1"s, although nearly everyone identified "1" as most likely, significantly fewer predicted "1" (94.7% vs 74.5%, $p=.007$). Thus, people were less likely to predict "1" when it was unlikely to arise—even though they knew that it was most likely to arise. Study 2 ($n=600$) replicated these findings with monetary incentives for correct predictions.

Study 3 ($n=300$) replicated Study 1 in a within-subject design where participants both indicated the most likely number from the set with two "1"s and predicted what number they would draw. Nearly everyone (88.0%) identified "1" as most likely, but only 59.7% predicted "1" ($p<.001$).

Next, we sought evidence from real-world predictions. In Study 4, 602 participants predicted which team would win 2022 March

Madness. They also estimated the probability of each team winning. Participants were less likely to predict the team that they estimated to have the highest probability when that probability was lower ($p<.001$).

In Study 5, 601 participants predicted the 2022 NBA championship. They indicated which team was most likely to win the title and whether that team had a high or low absolute chance of winning. Among people who thought their team had a high (low) absolute chance of winning, 76.8% (54.2%) predicted that their most-likely team would win the title, $p<.001$. That is, people were less likely to predict their most-likely-winner when they believed that this team was unlikely to win in an absolute sense.

If our effect arises because people consider absolute likelihood, reducing the sense that the most likely outcome is unlikely may attenuate the effect. In Study 6 ($n=290$), participants played the version of Study 1's game where there were only two "1"s. They were also asked to imagine 1000 people playing the same game. They estimated which number would be drawn most often across the 1000 players. We theorized that this intervention would make drawing a 1 seem less unlikely because people could imagine hundreds of players drawing a 1. As predicted, considering 1000 plays reduced the effect. After (before) imagining 1000 plays, 74.7% (55.6%) predicted that a "1" would be drawn when they played the game themselves. ($p<.001$).

One might also attenuate our effect by increasing the relative-likelihood advantage. In Study 7 ($n=586$), participants considered a set of balls that contained either 10 balls (2 labeled "1" and 8 labeled "2" to "9") or 100 balls (20 labeled "1" and 80 labeled "2" to "81"). In both sets, "1" had a 20% chance of being drawn and was most likely. Notably, "1" was twice as likely as any other number in the 10 set, but 20 times as likely in the 100 set. Regardless of whether the relative-likelihood gap was large or small, most participants identified "1" as most likely (88.6% vs. 86.3%, $p=.676$). However, participants more often predicted "1" with the 100 (vs. 10) set (75.0% vs. 53.2%, $p<.001$).

We document a robust discrepancy between what people predict and what they believe to be most likely. This disconnect may suggest a new angle on predictions and probability judgment.

How Polarizing Discourse Varies Around the World and Throughout the US: The Influence of Strong Societal Norms

Prof. Peter Nguyen, Miami University, USA
Prof. Jessie J. Wang, Miami University, USA

EXTENDED ABSTRACT

This research shows societies with strong norms express more polarizing discourse. The effect is robust across countries and US-states, manifests in reviews and microblogs, and is salient (reversed) for topics with permissive (restrictive) subjectivity. The authors argue this polarization phenomenon is a compensatory manifestation of highly structured and restraining environments.

In recent years, the prevalence of polarizing discourse in the online social space has become particularly discernable. Although the prevalence of polarizing word-of-mouth (WOM) is well documented (Hu, Zhang, and Pavlou 2009; Schoenmueller, Netzer, and Stahl 2018), little is known about why and how polarizing WOM varies across different geographic regions around the world. Accordingly, the main objective of this research is to investigate the relationship between societal cultures and polarizing WOM.

In our research, we define *polarizing WOM* as the degree of extremity and variance expressed in content generated by users and that is intended to be shared with others. Our societal factor of interest is cultural tightness-looseness (Gelfand, Nishii, and Raver 2006; Harrington and Gelfand 2014; Uz 2015). *Cultural tightness-looseness* refers to variation in the strength of norms and tolerance for norm deviance among different consumer groups. Tight [loose] cultures have strong [weak] norms and low [high] tolerance for deviant behavior; e.g., Bangladesh, Egypt, and Indonesia [Belgium, Mexico, and Sweden]. We argue that tightness-looseness influences expressions of polarizing WOM.

Myriad research shows that people have, to one degree or another, a need to be unique (Tian, Bearden, and Hunter 2001; Cheema and Kaikati 2010). However, highly structured and restraining environments of tight cultures, by nature, largely limits one's ability to express their uniqueness. As such, individuals of tight societies behave modestly and similarly in the public limelight (Gelfand et al. 2011; Harrington and Gelfand 2014). We argue that this incongruity between restraining environments of tight cultures and individuals' need for uniqueness drives people from tight cultures to seek external outlets, such as social media and online discussion boards, for self-expression. More importantly, we argue that the expression itself is manifested in a compensatory manner (Khan and Dhar 2006; Rucker and Galinsky 2008), i.e., with greater polarity, which is in sharp contrast to the conspicuous societal alignment of tight cultures.

We test our main hypothesis across four studies: one behavioral and three field studies. Study 1 (Booking.com) leverages online review data and tests whether the hypothesized relationship between tightness-looseness and polarizing WOM is a global phenomenon. The main dependent variable is polarizing WOM, i.e., the degree of extremity expressed in the review post. Polarizing WOM is operationalized based on the sentiment of reviews (Hansen et al. 2011); specifically, the magnitude of standard deviations of sentiment of a review, relative to all reviews for a given hotel. As robustness of measurement, we also computed polarizing WOM by the assigned rating – i.e., variance in a rating relative to all ratings for a given hotel.

The main independent variable is cultural tightness-looseness (CTL)—i.e., the degree to which societies tolerate deviant behavior. CTL scores, at the country level, are provided by Uz (2015), which contain the combined-index CTL scores across 63 countries. A number of other predictor variables were included as controls: (a) other major cultural factors (Hofstede, Hofstede, and Minkov 2005) and (b) economic-

related factors, such as gross domestic product per capita and education level.

Mixed-effects regression shows that greater degree of country tightness is associated with more polarizing discourse ($b=.027$, $se=.010$, $p<.01$). Most notable, across all culture and economic predictor variables, cultural tightness has the *most pronounced effect* on review polarity (Cohen's $f^2=.40$), well above any other variable. All results of polarizing WOM operationalized based on written reviews are replicated and robust with assigned ratings.

Study 2 was conducted in the lab to test and provide support for the causal relationship from cultural tightness to polarizing WOM. Students ($N=152$) from a large public University in the Midwest participated in the experiment (77 males, $M_{age}=19$). Tightness [looseness] was manipulated by asking participants to write three reasons to support [argue against] the statement “there should be clear expectations of what behaviors are appropriate or inappropriate in most situations in our society”. After the manipulation, participants were asked to recall a recent restaurant experience and consider the extremity of their review writing behavior, using a four-item, seven-point scale ($\alpha=.69$). A general liner model with extreme review behavior as the dependent variable, and looseness/tightness as the independent variable, revealed a significant main effect of looseness/tightness manipulation ($F(1, 143)=3.90$, $p=.05$). Pairwise comparison show that participants in the tightness (vs. looseness) condition tend to be more extreme when reviewing their restaurant experience ($M_{tightness}=3.96$, $M_{looseness}=3.57$, $p=0.05$, Cohen's $d=.33$).

Studies 3 (Twitter) and 4 (New York Times) show that the effect of cultural tightness on polarizing WOM extends to a more granular geographic level, US states (Cohen's $f^2=.27$). More importantly, in Study 4, we examine an important boundary condition—permissive subjectivity of topic—for the effect of tightness on polarization. We define *permissive subjectivity* as the degree to which a topic is conducive to self-expression, diverse ideas. Its counterpoint is *restrictive subjectivity*, the degree to which a topic is deemed fact-based, objective. A pre-test demonstrates that *op-ed*, *sports*, and *travel* [*politics*, *science*, and *Washington*] categories of news are deemed to have permissive [restrictive] subjectivity. Accordingly, comment sections across these six news categories are collected from the New York Times, a major US news outlet. Polarizing WOM is operationalized by variance in the sentiment of comments generated by users from each state by news article.

Regression results show a significant interaction between tightness-looseness and topic subjectivity ($b=.121$, $se=.038$, $p=.001$). We find that the effect of cultural tightness on polarizing discourse is salient [reversed] for comments in the *op-ed*, *sports*, and *travel* [*politics*, *science*, and *Washington*] news categories (permissive subjectivity: $b=.068$, $se=.030$, $p=.024$) [(restrictive subjectivity: $b=-.053$, $se=.024$, $p=.025$)]. Further, pairwise comparison demonstrates that changes in polarizing WOM is driven by tightness ($|\Delta_{tightness}|=.075$), not looseness ($|\Delta_{looseness}|=.022$, $p=.007$).

To conclude, this research contributes to the research stream on polarizing WOM, demonstrating how language polarity systematically varies by geographic regions around the world. Across multiple contexts (online reviews, microblogs, news forums), WOM formats (written text, assigned ratings), and geographic granularity (country, US state), we show that individuals from tight (vs. loose) cultures—i.e., societies with strong norms and low tolerance for deviant behavior—express more polarizing WOM.

Ownership Unwanted: Identity Signals and Preferences to Consume Without Owning

MX. Tyler MacDonald, Questrom School of Business, Boston University, USA

Dr. Remi Trudel, Questrom School of Business, Boston University, USA

Dr. Carey Morewedge, Questrom School of Business, Boston University, USA

EXTENDED ABSTRACT

Ownership is usually desirable. Consumption trends are evolving, however, replacing private ownership with access based consumption of goods. Declining ownership has its costs, but we identify an upside. Consumers prefer access-based consumption to private ownership when goods confer a negative identity signal; it buffers the self from their use.

Consumers often prefer to purchase products that allow them to affirm desired identities and communicate those identities to others (Berger & Heath, 2007; Bodner & Prelec, 2003). With the rise of the sharing economy, however, legal ownership of private goods is being replaced with legal access to shared goods, the many benefits conferred by psychological ownership appear to be on the decline (Morewedge et al., 2020). We examine a potential benefit to the rise of access-based consumption.

We argue when goods produce negative identity signals, consumers prefer forms of consumption that minimize psychological ownership because such “access-based” consumption feels less diagnostic of their true preferences. When a good is associated with undesired identities (e.g., a rival team or political party), consumers will then prefer to rent than purchase the product, even at the same price, as the negative identity signal outweighs the benefits of ownership. Access-based consumption allows consumers reap the consumption utility of “off-limits” products without incurring the negative identity signal that ownership would produce.

METHODS & RESULTS

In **Study 1** ($N=404$) we requested an online panel of Democrats ($N = 201$; 53% female) and Republicans ($N = 203$; 48% female). Participants imagined needing a book to complete an assignment for an online course. In the identity relevant (neutral) condition, participants were told that they needed was «The Art of the Deal» by Donald J. Trump («Getting to Yes» by Roger Fisher”).

Consistent with our preregistered hypothesis, Democrats were significantly more likely to rent when the book conflicted with their identity than when it did not (94% vs. 69%; Wald $\chi^2 [1] = 17.62, p < .001$), whereas Republicans did not differ in their likelihood of renting (Wald $\chi^2 [1] = 0.06, p = .81$), yielding a significant interaction (Wald $\chi^2 [1] = 12.12, p < .001$).

Study 2a ($N=249$) was a field study to examine this effect in an incentive compatible setting. University students were either given a neutral pencil (i.e., plain) or identity conflicting pencil (i.e., logo of rival university) to complete a short survey. After completing the survey, students were offered to keep the pencil as a gift for participation. The key dependent variable was whether the student chose to keep (i.e., own) the pencil, which was secretly recorded.

All students used the pencil to complete the survey (i.e., engaged in access-based consumption). However, as predicted, significantly more students chose to own the pencil, when it was identity neutral (i.e., plain red; 73%) than when it was identity conflicting (i.e., logo of rival university's; 32%; $\chi^2 [1] = 42.77, p < .001$).

In **Study 2b** ($N=306$), student participants imagined needing an umbrella during an unexpected rainstorm. The umbrella available was either: identity-confirming (i.e., logo of the alma mater university), identity-neutral (i.e., plain umbrella) or identity-conflicting (i.e., logo of a rival university).

Consistent with our preregistered hypothesis, students were more likely to rent a product when it conflicted with their identity (63.1%)

than when the product was identity-neutral (31.4%; Wald $\chi^2 (1) = 19.96, p < .001$) or when the product was identity-confirming (36.6%; Wald $\chi^2 (1) = 13.95, p < .001$).

Study 3 ($N=202$) tested our proposed mediator: product-self connection (Escalas & Bettman, 2003). Participants from New England imagined a going to see a football game where it unexpectedly started to rain. In the identity conflict (confirming) condition, participants were told that the concession stand only had “New York Jets” (“New England Patriots”) ponchos available.

As predicted, significantly more participants chose to rent the identity conflicting product (79%) than the identity consistent product (47%; $\chi^2 (1) = 21.97, p < .001$). Critically, this effect was mediated by product-self connection (Indirect Effect = 1.37, 95% CI [0.89, 2.05]; Model 4; Hayes, 2017).

In **Study 4** ($N=300$), participants imagined being cast in a local play and that they needed to acquire a costume. Participants were told that they had either been cast in the role of Darth Vader (confirmation), a Roman statesman (neutral), a Roman statesman, or Adolf Hitler (conflict). Finally, participants indicated their preference to rent or buy the costume at the same price.

Consistent with our preregistered hypothesis, significantly more people preferred to rent the conflicting costume compared to the neutral costume (87% vs. 64%; Wald $\chi^2 (1) = 13.04, p < .001$) or the confirming costume (87% vs. 59%; Wald $\chi^2 (1) = 18.57, p < .001$). Critically, we found that this effect was mediated through product-self link (Model 4; Hayes, 2017).

We have suggested that consumers prefer to access identity conflicting products because the more ambiguous form of ownership confers less diagnostic identity signals. Therefore, we would expect those renting an identity conflicting item to be less likely to engage in compensatory consumption, consumption which aims to cope with identity threat (Rucker and Galinsky 2013). In **Study 5** ($N=400$), participants imagined buying (renting) luxury apparel to attend an opera and responded to the self-authenticity scale (Goor et. al. 2020). Finally, participants read that the next night they wanted to go out to dinner and choose from two restaurant options: 1) a fancy burger restaurant with high-class offerings [authenticity threatening; non-compensatory]; or 2) a no-frills burger joint with simple down-to-earth offerings [authenticity restoring; compensatory].

Consistent with our preregistered hypothesis, the interaction between ownership and self- authenticity was significant (Wald $\chi^2 (1) = 5.24, p = .02$). Buying the luxury apparel caused a positive relationship between feelings of inauthenticity and compensatory consumption ($B = .50, \text{Wald } \chi^2 (1) = 19.51, p < .001$). However, preferences for the compensatory choice were not affected by feelings of inauthenticity for those who rented ($B = .14; \text{Wald } \chi^2 (1) = 1.73, p = .19$).

CONCLUSION

Consumers avoid purchasing products that conflict with their identities. However, we find that consumers may be more willing to consume identity conflicting products when they do not feel like they own them. Access-based consumption appears to create a weaker identity-signal than private ownership. As a result, it allows consumers to enjoy the consumption utility off “off-limits goods” while avoiding the negative self-signal they evoke.

Bleed from Extraordinary Experiences

Dr. Tom Van Laer, University of Sydney, Australia

Dr. Davide Orazi, Monash University, Australia

EXTENDED ABSTRACT

The present ethnography of live action role-playing explains how consumers return from extraordinary experiences and how this process differs depending on consumers' subjectivity. The emic term "bleed" captures the trace that extraordinary frames and roles leave in everyday life. The subjective tension between the extraordinary and the ordinary intensifies bleed.

"I took the hat off, clinging to it all the way home, thinking about being back in this strange, therapeutic, enlightening experience, where the hosts seemed to understand me better than I did. I wanted to go back; despite the small panic attack and emotional exhaustion that washed over me, I wanted to do it all again" (Alexander 2017).

Accessing an alternative realm beyond the everyday where they can be someone else has captured consumers' imagination for centuries. Fascination with utopian worlds and possible selves continues to the present day (Kozinets 2002; Schouten 1991), and consumer experiences with fictional or virtual places offer a new frontier for innovative companies (Bertele et al. 2020). Contemporary consumer society is brimming with opportunities to join extraordinary experiences that allow for the exploration of different settings and roles—from reenacting the fur trade in modern mountain men's rendezvous (Belk and Costa, 1998), to immersion into vampire narratives during the Whitby Goth Weekend (Goulding and Saren 2016), to the decelerated experience that a Camino de Santiago pilgrimage promises (Husemann and Eckhardt 2019).

Returning from such experiences can be challenging. Modern mountain men's "romantic nostalgia" (Belk and Costa 1998, 233), Whitby Goths' "trace" (Goulding and Saren 2016, 221), and pilgrims' "post-Camino syndrome" (Husemann and Eckhardt 2019, 1158) all suggest that coming back to reality is difficult. What this challenge exactly looks like, however, is still a question. How the kinds of lives consumers are leading influences the process of returning from extraordinary experiences also remains underexplored. Previous scholarship examines subjective understandings of consumers' everyday life mainly as a motivation to engage in the experience (Kozinets 2002; Tumbat and Belk 2011), leaving uncharted how individual differences influence the process of returning. Yet the consequences of experiential consumption are likely as idiosyncratic as its antecedents (Tumbat and Belk 2011). Scholarship thus needs a better understanding of what happens when consumers leave extraordinary experiences and reintegrate into everyday life, and how subjective understandings of the tension between "extraordinary" and "everyday" influence this process.

This paper examines the challenge of returning from extraordinary experiences in the context of live action role-play (LARP), an extraordinary experience during which consumers explore fantastic frames within which they assume the roles of invented characters (Orazi and Cruz 2019). Since frames and roles characterize what consumers detach from when returning to everyday life, these Goffmanian (1974) concepts enable us to unpack the emic term "bleed" as the process through which consumers' experience in the extraordinary seeps into the ordinary, like dye colors bleed into one another. Unpacking bleed is theoretically relevant to advance understanding of the process by which consumers return from extraordinary experiences. As a result, we make three contributions to the literature: We (1) identify the critical dimensions of bleed to provide greater insight

into what happens when consumers return from extraordinary experiences, (2) explain how consumers' subjective understandings of the tension between the extraordinary experience and their everyday lives can influence bleed's intensity, and (3) formalize a transformative recursive process that captures the diverse trajectories consumers can take when returning from extraordinary experiences. Our model of bleed offers a more nuanced understanding of the traces and tensions generated by extraordinary experiences, and how individual consumers take different routes along the extraordinary-ordinary continuum to return, cope, and transform their everyday lives.

Failure Counts (but Success Doesn't): Evidence for an Attributional Asymmetry in the Evaluation of Others' Financial Outcomes

Mr. Alexander Fulmer, Yale University, USA
Dr. Taly Reich, Yale University, USA
Dr. Sam Maglio, University of Toronto, Canada

EXTENDED ABSTRACT

When evaluating others' successes or failures, are we more influenced by how big the success or failure was or how many times it occurred? This research reveals a novel asymmetry; the number of occurrences matters more than magnitude for failure, and for success, neither magnitude nor occurrences carry more weight.

When evaluating others' successes or failures, are we more influenced by how big the success or failure was or how many times it occurred? The current research ($N=1,740$) illuminates that the number of occurrences of an outcome can be a stronger psychological input to observers' evaluations of an actor than the magnitude of occurrences depending on the valence of the outcome.

A tenet of a classical attribution theory, the Covariation Model of attribution, proposes that dispositional attributions of observed outcomes should increase with higher consistency among the observed outcomes. This model would predict that greater numbers of outcomes of the same valence (whether the outcomes are successes or failures) would be attributed increasingly to an actor's disposition. However, we propose that people readily infer that either one or two financial successes arise from internal ability; the number of successes provides no further cue to diagnosticity. Conversely, people attribute a single financial mistake to external forces but only make dispositional inferences after observing multiple financial failures.

We build our prediction on three lines of research. The first is work on attribution theory, demonstrating that observers tend to attribute a single success of another to internal ability, whereas observers tend to attribute a single failure of another to external factors. The second is from the realm of mistake correction, hinting that multiple failures move the attribution needle. Such work has demonstrated that when an actor committed and corrected the same mistake twice, people were relatively less likely to attribute the multiple mistakes to external circumstances compared to a single mistake, albeit attributions did not crossover from external to dispositional. The third concerns the Evaluative Information Ecology model, which proposes that positive information (in the present studies, observance of one or more financial successes) is perceived as more similar to other positive information than negative information (in the present studies, observance of one or more financial failures) is to other negative information. We predict multiple mistakes gone uncorrected shift attributions from external to dispositional with negative downstream consequences.

Study 1

Participants considered a debtor who successfully paid back[failed to pay back] one loan of \$20,000 alongside a debtor who successfully paid back[failed to pay back] two separate loans of \$10,000.

The omnibus was significant for attributions ($\chi^2(df=1, N=199)=24.47, p<.001$). Participants perceived the debtor failing once as more financially proficient (86.9%) vs. the debtor failing twice (13.1%; $\chi^2(1, N=99)=53.83, p<.001$). Participants perceived no difference in proficiency between the debtor succeeding twice (45.0%) vs. once (55.0%; $\chi^2(1, N=100)=1.00, p=.317$).

The omnibus was significant for lending likelihood ($\chi^2(1, N=199)=36.17, p<.001$). Participants preferred to grant a future

loan to the debtor failing once (84.8%) vs. twice (15.2%; $\chi^2(1, N=99)=48.09, p<.001$). Participants did not prefer to grant a future loan to the debtor succeeding twice (56.0%) vs. once (44.0% $\chi^2(1, N=100)=1.44, p=.230$).

Study 2

In a 2(failure vs. success) x 2(one vs. two) between-subjects design, participants considered an individual debtor who successfully paid back[failed to pay back] one loan of \$20,000[two separate loans of \$10,000].

The interaction was significant for attributions; $F(1, 823)=7.21, p=.007$. Participants made more dispositional attributions when the debtor failed twice ($M=4.25$) vs. once ($M=3.65$; $F(1, 823)=16.96, p<.001$). Attributions did not differ between the debtor succeeding once ($M=4.69$) vs. twice ($M=4.74$; $F(1, 823)=.12, p=.733$).

Attributions to the debtor who failed once were lower than the 7-point-scale's midpoint ($M=3.65, t(203)=-3.66, p<.001$), but attributions to the debtor who failed twice were higher than the midpoint ($M=4.25, t(206)=2.53, p=.012$). In contrast, both attributions to the debtor who succeeded twice ($M=4.74, t(208)=6.69, p<.001$) and attributions to the debtor who succeeded once ($M=4.69, t(207)=6.62, p<.001$) were higher than the midpoint.

The interaction was significant for lending likelihood; $F(1, 823)=9.60, p=.002$. Participants were more likely to give a loan to the debtor failing once ($M=18.26$) vs. twice ($M=13.03$; $F(1, 823)=9.49, p=.002$). There was no difference in lending likelihood between the debtor succeeding once ($M=88.15$) vs. twice ($M=90.33$; $F(1, 823)=1.67, p=.196$).

Bootstrapping revealed that in the failure conditions[but not the success] number of occurrences increased dispositional attributions, leading to differences in lending likelihood [95% CI: 2.12, 6.19].

Study 3

In a 2(failure vs. success) x 2(skill vs. chance) between-subjects design, participants considered a gambler who lost[won] \$100 in a single session of blackjack[roulette] alongside a gambler who lost[won] two \$50 gambles in two separate sessions of blackjack[roulette].

The interaction was significant for attributions; $b=.65, SE=.32, p=.040$. In the game of skill(blackjack), the higher evaluations of gambling proficiency of the person with one occurrence was stronger in the failure condition (73.1% vs. 2 failures: 26.9%) than in the success condition (52.9% vs. 2 successes: 47.1%), $p<.001$. In the game of chance(roulette), there were no differences in proficiency between the two outcome conditions (success=63.4%; failure=68.5%), $p=.299$.

The interaction was significant for who to give \$25 to gamble; $b=.64, SE=.32, p=.046$. In blackjack, choice of the person with one occurrence was stronger in the failure condition (73.7% vs. 2 failures: 26.3%) than in the success condition (56.4% vs. 2 successes: 43.6%), $p<.001$. In roulette, there were no differences in choice between the two outcome conditions (success=64.5%; failure=67.5%), $p=.547$. This result offers evidence inconsistent with the alternative explanation that the asymmetry demonstrated in Studies 1-2 was due

to low base rates of defaulting on loans given that base rates of losing a hand of blackjack at a casino are higher than base rates of winning.

This research extends attribution theory's predictions beyond patterns of single events to attributions of multiple successes and failures. In doing so, it qualifies a tenet of the Covariation Model of attribution, demonstrating that the influence of outcome consistency on dispositional attributions differs based on outcome valence (success versus failure). Further, it builds upon work demonstrating that the presence of negative information may not be as damaging as one might expect but that making and correcting multiple mistakes is relatively less attributed to external causes. The present investigation shows that multiple failures without subsequent correction are attributed to internal disposition in absolute terms with negative downstream implications.

On Scarcity, Self-threat, and the Avoidance of Financial Advice

Dr. Jane So, City University of Hong Kong, Hong Kong
Prof. Nidhi Agrawal, University of Washington, Hong Kong

EXTENDED ABSTRACT

This paper investigates the psychological reasoning the avoidance of financial advice (e.g., financial services, money management books) that money-scarce consumers have. In four experiments, this paper shows that money scarcity, relative to time scarcity, leads to avoidance of financial advice.

Consumers are often confronted with situations that make them feel that their money is scarce. However, interventions to assist people in making financial decisions seem to have little appeal, especially to those who experience greater financial constraints (Fernandes, Lynch, and Netemeyer 2014; NFCS 2018).

This research suggests why money-scarce consumers are more reluctant to seek help to improve their financial decisions and strategies for overcoming this aversion. Specifically, we propose that money-scarce people avoid financial advice, such as financial services, money management apps, or self-help books, because the domain of financial advice leads to defensiveness. In contrast to other forms of resource scarcity (e.g., time scarcity), money scarcity will lead people to perceive financial advice as a psychological threat to their negative self-perception. Feeling money scarcity is an unpleasant experience that people would like to avoid (Griskevicius et al. 2013; Paley et al. 2019; Sharma and Alter 2012). When experiencing money scarcity, they may feel less ‘worthy’ since money can be an important tool in proving their competence and maintaining positive self-views (Zhang 2009). However, we expect that people who experience time scarcity may not respond defensively to financial advice because time scarcity may not be such a negative state that people want to avoid compared to money scarcity (Bellezza et al. 2017; Gershuny 2005).

Furthermore, we propose two ways of minimizing the defensiveness of money-scarce consumers: reducing the threat from money scarcity and reducing the supposed threat from financial advice. First, we suggest that the threat from money scarcity can be reduced if money-scarce consumers are presented with the opportunity to buffer their threat (Hall et al. 2014). Research shows that self-affirmation can buffer the threat allowing people to respond less defensively to situations that are threatening (Aronson, Cohen, and Nail 1999; Hall et al. 2014; Steele 1988). Another approach to reducing the defensiveness of money-scarce people is to discount the threat stemming from financial advice through message framing. That is, when financial advice aids money-scarce consumers to cope with the threat, by helping the money-scarce consumers devalue the threat from the message (Gibbons, Benbow, and Gerrard 1994; Tesser 1988), people would no longer consider the financial advice as a threat and show lower defensive processing.

In study 1, we test defensive processing by measuring people’s distrust toward financial advice. Participants in the money-scarcity and time-scarcity conditions first performed an episodic recall task (adapted from Roux et al. 2015). Following that, participants were instructed to view a financial service advertisement and answer the questions. We found a significant effect on the financial advice acceptance such that the money scarcity condition showed lower financial advice acceptance than the time scarcity condition ($M_{\text{money}} = 4.93$, $SD = 1.96$ vs. $M_{\text{time}} = 5.45$, $SD = 1.79$; $F(1, 443) = 8.59$, $p = .004$, $\eta_p^2 = .019$). We also found that the money scarcity condition showed greater distrust toward the advertisement than the time scarcity condition ($M_{\text{money}} = 4.01$, $SD = 1.86$ vs. $M_{\text{time}} = 3.67$, $SD = 1.73$; $F(1, 443)$

$= 4.04$, $p = .045$; $\eta_p^2 = .009$). We found that distrust significantly mediated the scarcity effect on the financial advice acceptance ($B = -.26$, $SE = .12$, 95% CI = $[-.510, -.011]$).

In study 2, we examine the moderating effect of self-affirmation. A 2 (scarcity: money scarcity vs. time scarcity) \times 2 (self-affirmation: present vs. absent) between-subjects design was used. Participants were asked to evaluate advertisements for self-help books (money management book, time management book, stress management book). They were asked to choose one book that they would like to read and rate how likely they would purchase the books. The chi-square test result showed that when participants were self-affirmed in the money scarcity condition, they chose money-management books significantly more than those not self-affirmed ($\chi^2(2, 161) = 11.84$, $p = .003$). A 2 (scarcity: money scarcity vs. time scarcity) \times 2 (self-affirmation: present vs. absent) \times 3 (book: money-management vs. time-management vs. stress management) mixed repeated-measures ANOVA demonstrated a significant three-way interaction $F(1, 316) = 9.16$, $p = .003$, $\eta_p^2 = .03$.

Study 3 evaluates whether money (vs. time) scarce consumers’ defensiveness toward financial advice can be mitigated through message framing. This study used a 2 (scarcity: money scarcity vs. time scarcity) \times 2 (message framing: stressed vs. strapped) between-subjects design. The analysis revealed a significant interaction between the scarcity and message framing ($F(1, 833) = 4.11$, $p = .04$, $\eta_p^2 = .005$), and a significant interaction between the scarcity and message framing ($F(1, 833) = 6.43$, $p = .011$, $\eta_p^2 = .008$). Moderated mediation analysis showed a significant result ($B = .33$, $SE = .16$, 95% CI = $[.004, .654]$).

In study 4, we used a 2 (scarcity: money scarcity vs. time scarcity) \times 2 (message framing: stressed vs. strapped) \times personal relevance between-subjects design. Phase 1 consisted of a survey measuring the financial advice relevance. Phase two study was carried out one week later. The procedure of phase 2 was identical to that of study 3. The three-way interaction (Model 3, Hayes 2017) was significant ($B = .51$, $SE = .24$, $t = 2.11$, $p = .036$). Consistent with our prediction, when the relevance is low (-1 SD), interaction between scarcity and message framing was not significant ($F(1, 326) = .22$, $p = .64$). However, when the relevance was high (+1 SD), the interaction between scarcity and message framing was significant ($F(1, 326) = 13.24$, $p < .001$).

Our findings suggest that feeling money scarcity is a negative state that makes people act defensively toward financial advice, which is perceived as a further threat. We test this notion by comparing money scarcity with time scarcity, which is a relatively less aversive state than money scarcity. Furthermore, this research reveals that money scarcity can be moderated.

EXTENDED ABSTRACT

This research investigates fact-checking measures inoculating consumers against fake news threatening brands. First, it identifies that the ambiguity of current labeling countermeasures is harmful to the targeted brands. More importantly, it shows that less-ambiguous fact-checking labels can be beneficial in overturning the adverse consequences of fake news into attitudinal resistance.

Fake news threatens brands of all sizes, causing them to lose profit and reputation, but despite numerous real-life incidents (e.g., United Airlines, McDonald’s, Starbucks, Pepsi), the research overlooks downstream marketing consequences of fake news. There is a reasonable analogy between the spread of fake news and viruses (Kucharski 2016) as fake news, defined as verifiably false news articles (Allcott and Gentzkow 2017), circulates six times faster than real news on social media (Vosoughi, Roy, and Aral 2018), creating the urgency of inoculating people against fake news. However, this is not easy, as people are more likely to start believing fake news the more often they see it, the so-called illusory truth effect (ITE) (Pennycook, Cannon, and Rand 2018).

Although fact-checking is increasingly prevalent in the fight against fake news, the recent evidence hints that widely-used fact-checking measure (“disputed by third-party fact-checkers”) has severe shortcomings in preventing the ITE (Pennycook et al., 2018), and its impact on the downstream marketing consequences is unknown. Seemingly, its inefficiency lies in the ambiguity of the label. Building on the inoculation theory (McGuire 1964), this research investigates (un)ambiguity of the fact-checking labels in generating resistance to fake news persuasion. In a series of experiments, we contrast ambiguous (“disputed”) vs. unambiguous (“false”) labels attached to corporate fake news and assess their potency in preventing biased judgments for the next time consumers see fake news without any help from those labels.

Study 1 (N=1400, Prolific) utilizes a 2x3 mixed design experiment with the fake news exposure (repeated vs. novel) manipulated as a within-subject factor and label (no-label, “disputed”, “false”) manipulated as a between-subjects factor. Repeated news had the label manipulation to assess the effect of labels on the next unlabeled exposure to the same fake news. Participants rated accuracy judgments (1=“not at all accurate”, 4=“very accurate”) and brand evaluations (1=“negative”, 7=“positive”) about several corporate fake news denigrating well-known brands. We find that the “false” label does not only eliminate the ITE but also overturns the harmful impact of repeated fake news exposure to an immunizer as it reduces the accuracy perceptions for the next time participants come across the same fake news ($M_{\text{repeated}}=1.77$ vs. $M_{\text{novel}}=2.02$, $p < .001$). Also, it prevents the drop in brand evaluations better than the widely-adopted “disputed” label ($M_{\text{false}}=3.83$ vs. $M_{\text{disputed}}=3.65$, $p = .010$), while the “disputed” label is not different from not labeling fake news at all ($p = .522$). Furthermore, accuracy judgments restrict brand evaluations ($B = -.36$, $SE = .05$, $p < .001$). Study 2 (N=994, Prolific) demonstrates that inoculation with a “false” label can endure over time, as the same results hold even three days after the first exposure to the fake news.

Study 3 (N=134, undergraduate students) shifts the focus to actual behavior. In a behavioral lab, after repeatedly being exposed to fake news, participants chose among four connected watch brands, one of which was denigrated by fake news at the earlier stage of the experiment. On top of confirming our previous findings, we find that the “false” label leads to a higher choice rate of the victim brand (40.9%) than the “disputed” label (33.3%). Also, the choice of the victim brand is guided by brand evaluations ($B = .47$, $SE = .15$, $p = .002$), which is shaped by perceived accuracy ($B = -.52$, $SE = .14$, $p < .001$). We observe this indirect effect only for the “false” label (vs. unlabeled, $B = .12$, $SE = .09$, $CI_{95\%}$ does not include 0) but not for the “disputed” label (vs. unlabeled, $B = .08$, $SE = .07$, $CI_{95\%}$ includes 0).

Study 4 (N=888, Prolific) includes brand reactions by contrasting different strategic approaches about how they can counter fake news. Specifically, we explore whether removing fake news is better for victim brands than labeling. We manipulated the victim brand’s social media response: the brand denied the fake news either (i) when fake news is removed, (ii) “false” labeled, or (iii) unlabeled. We confirm the previously observed inoculation effect of the “false” label as it reduces accuracy perceptions when news is not removed ($M_{\text{unlabeled}}=33.36$ vs. $M_{\text{false}}=17.23$, $p < .001$), but removing the news later cancels this initial inoculation effect of the “false” label ($M_{\text{unlabeled}}=32.20$ vs. $M_{\text{false}}=31.04$, $p = .751$). We do not observe a significant effect on brand evaluations; effects are predominant in accuracy perceptions.

Our research provides important implications. First, we identify the ambiguity of current measures as a problem for eliminating ITE and brand-related responses. We show that unambiguous labels inhibit the ITE more effectively and can even be beneficial to overturn adverse consequences into attitudinal resistance the next time consumers see the same fake news. Second, and relevant for managers, we demonstrate that this imprint on brands has a lasting effect and is even detectable some days after being aware of fake news. Third, for the first time, this research sheds light on the downstream consequences of fake news on brands. Even when consumers notice that news denigrating a brand is fake, seeing such a message next time inflates not only their accuracy judgments but also lowers their brand evaluations and choices. Remarkably, the label widely used by social media platforms (“disputed”) seems to prevent distorted accuracy judgments but provides no additional benefit of inoculation. Our findings are generalizable to various brands from various industries (consumer goods, digital platforms, fashion, retailing) as each study tests several factually false news, all having unique denigrating content (e.g., about moral issues, product safety). We also suggest that the strategy of removing fake news has to be employed cautiously because removing also implies eliminating a cue that could otherwise generate resistance to fake news persuasion.

Motivated Fake News: Understanding how ideology and competitive context influence misinformative posts on social media

Ms. Xiajing Zhu, University of California, Irvine, USA
Dr. Connie Pechmann, University of California, Irvine, USA

EXTENDED ABSTRACT

We investigate how context motivates people to post misinformation on social media. In four field and lab studies, we find that in a competitive context, conservatives (vs. liberals) tend to post more political misinformation because of higher motivated ingroup favoritism. A cooperative context nullifies this effect.

As the most profound type of misinformation, political misinformation is spread by both political conservatives and liberals (Vosoughi, Roy, and Aral, 2018; Hochschild and Einstein, 2015). However, who is more likely to post political misinformation online; political conservatives or liberals? Past research on political misinformation has mainly focused on why people believe political misinformation (Tucker et al., 2018), neglecting consumers' active role in political misinformation spread. Furthermore, while there has been some research on how consumers' political ideology impacts general misinformation sharing (Jost et al., 2018; Grinberg et al., 2019), virtually none of that research has addressed the sharing of political misinformation. In addition, the limited research on how political ideology may affect the spread of political misinformation (Pennycook and Rand, 2019; Osmundsen et al., 2021) has overlooked possible contextual factors that may motivate liberals and conservatives to engage in this behavior. Despite the prevalence of competitive contexts that both conservatives and liberals experience (Green-Pedersen, 2007), its impact on posting political misinformation has been neglected in the literature. Thus, in this research, we investigate how and why a competitive context may impact people's posting of political misinformation on social media. Our predictions are as follows:

Hypothesis 1: In a competitive context, conservatives (vs. liberals) will be more likely to post negative political misinformation; while in a cooperative context, conservatives and liberals will be equally likely to post negative political misinformation.

Hypothesis 2: Motivated ingroup favoritism will mediate the effects of political ideology and competitive context on the posting of political misinformation. In a competitive context, conservatives (vs. liberals) will be more likely to post negative political misinformation because of conservatives' higher ingroup favoritism, but this mediating effect will be weakened in a cooperative context.

In a pre-study, we explored the prevalence of competitive contexts in political discussions between conservatives and liberals. Using secondary datasets from the Pew Research Center (2019, 2020), we found that U.S. conservatives and liberals were highly divided and therefore competitive in 11 of the 13 political contexts studied, such as whether to increase government spending on health care ($p < 0.001$) and education ($p < 0.001$). The two groups agreed in only two contexts: spending on veteran benefits (between-group difference, $p = 0.947$) and on combatting the federal budget deficit ($p = 0.599$).

Study 1 examined how political ideology and discussion context competitiveness affected post misinformativeness. We used a public dataset called LIAR (Wang, 2017), which contained political posts from 2007 to 2016 that were compiled by a fact-checking website (PolitiFact.com). All statements were rated on a 6-level scale that ranged from "true" for accurate posts to "pants-on-fire" for highly misinformative

posts. Based on our pre-study, we identified posts from this website that represented known competitive contexts (e.g., that supported spending on healthcare) or cooperative contexts (e.g., that supported spending on veterans), which amounted to 3532 posts. As predicted, conservatives' posts were more misinformative than those of liberals in the competitive contexts ($p < 0.001$), while the misinformativeness of posts was comparable for liberals and conservatives in the cooperative contexts ($p = 0.133$).

Study 2 also used actual posts but shed light on the underlying mechanism. We scraped public posts from both a conservative Facebook group and a liberal Facebook group that were posted between January 2020 and June 2021. This period encompassed both a highly competitive political context, the U.S. presidential election, and a more cooperative political context in which congressional conservatives and liberals reached numerous agreements related to the COVID pandemic (Galston, 2020). Two researchers working independently coded whether each post contained political misinformation (1) or not (0), agreement = 90.61%. Ingroup favoritism conveyed in the posts, the posited mediator, was analyzed using the automated textual analysis software LIWC (Sterling et al., 2020). In the competitive context, conservatives had stronger ingroup favoritism ($p < 0.001$) and, moreover, posted significantly more political misinformative information than did liberals ($p < 0.001$). However, in the cooperative context, liberals and conservatives expressed similar levels of ingroup favoritism ($p = 0.219$) and, moreover, posted similar amounts of political misinformation ($p = 0.935$). The index of moderated mediation was significant (95%CI 0.0005, 0.0539), indicating that the mediating effect of ingroup favoritism was stronger in the competitive context than in the cooperative context.

In study 3, we conducted a lab experiment using a 2 (political ideology, between-subjects) x 2 (context, within-subjects) mixed design. Participants indicated their political ideology and then read two misinformative attack posts based on their ideology, one representing a competitive context (the U.S. election) and the other representing a cooperative context (the COVID pandemic), in random order. After reading each post, participants indicated their intention to make similar posts, their ingroup favoritism (Scheepers et al., 2003; Chen and Kirmani, 2015), and the perceived competitiveness of context as a manipulation check. The manipulation was successful. In addition, in the competitive context, conservatives reported greater ingroup favoritism ($p = 0.048$) and a higher intention to post misinformation than did liberals ($p = 0.014$). In contrast, in the cooperative context, liberals and conservatives did not differ in their ingroup favoritism ($p = 0.817$) nor in their intention to post political misinformation ($p = 0.256$). The mediation results showed that ingroup favoritism only mediated the effect of political ideology on the intention to post political misinformation in the competitive context (95% CI .0024, 1.0248), not in the cooperative context (95% CI -.2006, .8059).

To summarize, this research finds that conservatives (vs. liberals) experienced higher ingroup favoritism in competitive contexts and, therefore, posted more political misinformation to attack opponents. In contrast, in cooperative contexts, conservatives and liberals experienced similar ingroup favoritism, and their intentions to post political misinformation did not differ. This research provides several theoretical insights for the literature as well as managerial implications for the public, as we strive to understand the pervasiveness of political misinformation spread in today's highly polarized political environment.

Barriers to social change: Unconscious complicity and a distributed form of power woven throughout the social space

Dr. Paul Henry, The University of Sydney, Australia
Dr. Marylouise Caldwell, The University of Sydney, Australia
Dr. Babak Amiri, The University of Sydney, Australia

EXTENDED ABSTRACT

Social movements face significant barriers to change. One barrier lies in the clash of tacit understandings that stem from everyday interactions between people with differently configured habitus(es). We illustrate the emotional frictions that stem from such clashes by analyzing reader comments in response to newspaper articles on the #MeToo movement.

We draw on reader comments in response to 55 New York Times articles where the #MeToo social movement was the central subject of the story. Many comments exhibit sympathy, support and understanding. Others exhibit skepticism and hostility. Overall, we saw an ideological battleground. In the #MeToo case there have been numerous references to adversarial reactions, typically framed as “backlash” (Hillstrom 2019). The term was first coined by Faludi (1991) in her book “Backlash” which examined hostile reactions by conservatives to feminist advances across the 1960-70’s. In a recent interview Faludi was asked if she felt that a similar backlash was happening post #MeToo. Her response was in the affirmative; “The assault on women’s rights and feminist gains is loud and clear, and embodied in one obvious figure of fury: Hard to imagine a backlash expressed more literally than in Donald Trump’s reflexive need to humiliate and attack any strong women who challenges him” (Faludi et al. 2020, p. 337). Here Faludi identifies associations between ideological stance, emotionally charged dispositions and the resulting (political) actions that impede goals of women’s social movements.

In this paper, we focus on the cultural mechanisms that retard the advancement of social movements through an analysis of reader comments, which reveal a range of morally charged opinions. We employ Bourdieu’s (1984) theory of social practice to explore the distribution of power across the social space. We demonstrate how emotionally charged social interactions (dis)empower in an unconsciously shared complicity that impedes social change. We argue that this complicity is not simply reducible to two opposing parties that divide into advocates and adversaries. Rather, this unconscious complicity is woven into the social fabric.

METHODS

We drew down the entire body of reader comment text that were posted in response to the 55 articles published in the NYT between October 2017 and October 2019. The final data set comprises 26,000 comments posted by 12,646 commenters. The total corpus word count was 1,857,883 words. We then employed a mix of qualitative and quantitative approaches. First, we employed the text mining suite of tools—Voyant—to explore the text (see voyant-tools.org). We next employed Word-Network Topic Modelling WNTM (Zuo, Zhao and Xu 2016). We followed the technical specification for WNTM detailed in Zuo et al. (2016). Following multiple runs, we settled on a six-topic version. We then iteratively moved between text and Bourdieusian theory to examine the question as to barriers of unconscious complicity faced by the #MeToo social movement.

FINDINGS

The six topics include: Topic 1 - The casting couch metaphor: Focusses on discussion of cultural norms in the film industry. Topic 2 – Justice and due process: Focusses on justice for those accused of as-

sault, rape and harassment. However, others are more concerned about the possibility of false accusations and trial by media. Topic 3 – Speaking out (or not): Focuses on people either speaking out or remaining silent on rape and harassment. A variety of opinions range from credit for speaking out or being blamed for remaining silent. Topic 4 – Polarized political positions: Focuses on disparaging opposing political parties which involve accusations of hypocrisy on the part of opposing party’s political leaders. Topic 5 – Experiences of female readers: Commenters describing their past experiences of sexual harassment in workplaces. Topic 6 – Abuse of power: Features references to exercise of power. Opinions as to power abuse spans Hollywood, the wider workplace and broader society.

DISCUSSION

The foundational idea of Bourdieu’s habitus stems from repetitive performance. Dispositions and preferences generate patterns of behavior in which we feel a natural and comfortable fit. These patterns of behavior encompass our daily social interactions, which vary in terms of the level of distinction endowed on those with whom we interact (Probyn 2004). We behave in ways that convey deference to some and fear of others. We feel a sense of comfort around our equals and disdain for others. Similarly, those with whom we interact, also respond in a like way based on relative distinction. These repetitively performed behaviors across social interactions reinforce such behavior; and take on an unconsciously performed character. For example, Harvey Weinstein expressed bemusement as to his wrongdoing, even after he was convicted (Ransom 2020). He had become used to being lauded and fawned upon by those around him. Others reacted with fear and deference at his power position. His pattern of behavior saw him regularly being rewarded and reinforced by the reactions of others. This applied to most all the people working in the Hollywood sphere and, also applied in the wider social and political environment that Weinstein inhabited. Similarly, deferential behaviors of those seeking to accrue distinction are also reinforced with repeated performance of deference. The following reader comment goes some way in expressing unconscious complicity born: “Most of us don’t tell. Not because we’re protecting a career. Just because telling and being doubted, is worse than keeping quiet. You’re not even aware that you’re a part of the problem.”

We illustrate how cycles of emotionally-based actions and reactions are embedded across everyday life; and operate across the social space. We argue that a form of power resides within and across the cycle of interactions and that this power can be likened to the sum of the threads that bind a tapestry. The sum of the interactions that trigger the myriad of everyday emotional reactions can be thought of as the threads that hold a society together in a stable manner. Such stability works against those that seek social change. Our analysis of power reveals that a characterization which polarizes imagined opponents into a simple struggle between advocates and adversaries is illusionary. This characterization of power spotlights the self-sustaining nature of social systems. This is not to say that social change does not happen, but it demonstrates how desired progress of social movements can be retarded. This is evident in the case of movements seeking to promote gender equality where well-publicized backlash is translating into concerted actions to wind back hard-fought gains (Faludi et. al 2020).

Closing the Attitude-Behavior Gap: A Novel Measure to Predict Ethical Consumption

Prof. Brandon Reich, Portland State University, USA

Prof. Hong Yuan, University of Oregon, USA

Prof. Lamberto Zollo, Università degli Studi di Milano, Italy

Prof. Riccardo Rialti, Università degli Studi di Milano, Italy

EXTENDED ABSTRACT

An attitude-behavior gap in ethical consumption presents a pervasive challenge to socially responsible marketing. In response, this research seeks to develop a novel tool measuring consumers' *implicit* ethical consumerism. Through rigorous development, findings show that our implicit measure (based in the Affect Misattribution Procedure) predicts ethical consumption beyond explicit attitudes.

Consuming ethically is socially desirable and reporting favorable attitudes does not incur any personal cost. Thus, consumers have incentives to explicitly state their favorable attitudes and intentions toward ethical products despite a host of barriers to actual purchase. This attitude-behavior gap in ethical consumption presents a pervasive challenge to the theory and practice of socially responsible marketing. A litany of theoretical explanations for this gap in ethical consumption has been offered. This research seeks to draw from these existing explanations and—based on extant research in psychometrics and the psychology of attitudes—develop a novel measurement tool based on the Affect Misattribution Procedure (AMP). We aim to capture consumers' *implicit* ethical product attitudes which have otherwise evaded marketing practitioners and scholars. Further, the current research examines the predictive power of this measurement tool in predicting consequential ethical consumption choices.

Study 1

A pretest recruited 98 US residents from Prolific to rate 20 ethical product labels in terms of ethicality and familiarity (1=Not at all ethical/familiar, 9=Highly ethical/familiar). We summed these ratings for each label into an index and retained the five top-rated labels: *Rainforest Alliance Certified*, *Free Range*, *Fair Trade*, *Cruelty Free*, and *Forest Stewardship Council (FSC) Certified*. The main study (N=366) presented a modified AMP including these ethical labels and five common non-ethical product labels for control. Each label was displayed for 1 second, followed by a randomly selected Chinese pictograph, followed by a gray square with a single item below asking participants to rate the visual pleasantness of the Chinese pictograph (1=Very unpleasant, 6=Very pleasant). Participants' average ratings following the five ethical labels should represent an implicit measure of ethical consumerism. Participants also responded to measures of explicit ethical consumerism and socially desirable responding. Lastly, participants engaged in a shopping task where they used a Prolific bonus to choose between ethical and non-ethical versions of four product. Each ethical (non-ethical) choice was scored as 1 (0), creating an index of ethical purchase (range: 0–4). Participants were informed that they would be entered into a drawing to receive the products they chose.

The main analysis employed hierarchical linear regression, treating the ethical purchase index as the dependent variable. At step 1, only implicit ethical consumerism was entered as a predictor, and results showed a positive significant effect ($\beta=.23, p<.001$). At step 2, we entered the average implicit scores associated with the non-ethical labels as a predictor ($\beta=.11, p=.08$), and implicit ethical consumerism remained significant ($\beta=.18, p=.003$). At step 3, we added the two method factors pertaining to the randomization of Chinese pictographs (both $ps>.15$) and social desirability ($p=.79$), and implicit ethical consumerism's effect remained ($\beta=.17, p=.004$). Lastly, at step 4, we added the explicit ethical consumerism item ($\beta=.41, p<.001$), and the effect of our implicit measure remained significant ($\beta=.14, p=.01$). Overall, these results suggest that our implicit measure predicts consequential

choices in an ethical (vs. non-ethical) product purchase task over and above the effect of an explicit measure. Moreover, our study suggests that the implicit measure's effect is robust to method factors and socially desirable responding.

Study 2

Study 2 included a more behavioral measure of ethical consumption and tested our measure's effects among consumers in Italy. We repeated the pretest procedure among 70 Italian consumers recruited from Prolific. Participants rated a series of eight actual ethical labels in terms of familiarity and ethicality. These two ratings were summed for each label and sorted in descending order, and the five labels rated most highly were retained for the main study: *Consumo Energetico A+++*, *Cartone Riciclabile*, *Confezione Riciclabile*, *Legambiente*, and *Plastica in meno*.

Participants in the main study (N=414), as before, completed our modified AMP, the four-item explicit ethical consumerism scale ($\alpha=.87$), and the Social Desirability Scale, in randomized order. Next, a product search task was presented in which participants imagined themselves considering options of a popular Italian delivery service, Just Eat. They were told that six service options would be displayed, one at a time, in order from least to most environmentally friendly. For each option, participants chose whether to continue learning about the subsequent options or to stop searching and skip to the end. Because participants knew that the latter options were more ethical, their search effort (operationalized as the number of times they chose to continue searching, ranging from 0–5) represented a behavioral measure of ethical consumption. In addition, search effort was consequential because Prolific participants are motivated to complete each study as quickly as possible.

A hierarchical linear regression was conducted, treating search effort as the dependent variable. At step 1, only implicit ethical consumerism was entered as a predictor, and results further support its predictive validity via a positive significant effect ($\beta=.13, p=.008$). At step 2, we added the two method factors ("set" and "type") pertaining to the randomization of Chinese pictographs (both $ps>.18$) as well as social desirability ($p=.15$), and implicit ethical consumerism's effect remained significant ($\beta=.12, p=.02$). Lastly, at step 3, we added the explicit ethical consumerism scale which served as only a marginally significant predictor ($\beta=.09, p=.09$), whereas the effect of the implicit measure remained significant ($\beta=.10, p=.049$).

DISCUSSION

The attitude-behavior gap in ethical consumption presents a pervasive challenge to socially responsible marketing. The current research, informed by literatures in ethical consumption and the psychology of attitudes, offers a novel measurement tool aimed at capturing consumers' *implicit* ethical product attitudes which have otherwise evaded marketing practitioners and scholars. Through a rigorous development process, findings across two national contexts converge to show that our implicit measure predicts ethical consumption beyond the effects of other variables, including explicit attitudes. Further, our AMP-based implicit measure is relatively easy for researchers to implement using standard survey software and basic regression analyses.

One limitation of this research is that, while results showed the unique (study 1) and superior (study 2) predictive power of the implicit measure, our studies were not conducted in a field setting. Although the tasks were designed to be consequential, participants were still aware that they were participating in a research study.

Sentimental Value: Use it & Grow it

Dr. Daniel Grossman, University of Missouri-St. Louis, USA

Dr. Ryan Rahinel, University of Cincinnati, USA

EXTENDED ABSTRACT

Three studies demonstrate that the usage of sentimentally valuable possessions causes the sentimental value imbued in those possessions to increase over time. Process evidence suggests that this happens because repeated-use causes the object's source of sentimental value to be more highly integrated with the owner's self-concept.

Sentimental value stems from an object's association with a special event, time, or person in a consumer's life, and as a result, objects with sentimental value are cherished greatly by their owners (Yang and Galak 2014; Givi and Galak 2017). Sentimental value generally does not wane over time (Yang and Galak 2015); however, it is unclear as to what factors might systematically stimulate its growth.

Past literature suggests that as a consequence of the great emotional value attached to sentimentally valuable objects, consumers often avoid using them in an effort to protect the object and/or the memories it is associated with (Belk 1995; Zauberan et al., 2009). For example, a consumer who bought an engraved ceramic bowl while on vacation may choose to simply display it above his/her/their fireplace as a decorative piece rather than regularly using it to warm up his/her/their afternoon soup. We empirically confirmed this with a pilot study, which found that consumers are far less likely to actively use their sentimentally valuable items as compared to their other possessions (all p 's < .001).

We propose that this tendency to avoid using sentimentally valuable objects causes consumers to miss out on an opportunity to naturally grow their objects' sentimental value over time. This notion stems from the idea that that repeated-usage of a possession can self-signal one's identity based on the characteristics of the possession (O'Brien 2021). For example, a person who always has his/her/their morning cup of coffee from a mug that portrays the logo of his/her/their alma mater may more greatly identify with his/her/their alma mater over time. As people repeatedly interact with sentimentally valuable objects, the object's associations (i.e., the object's source of sentimental value) become a more salient characteristic as compared to its benefit-based features (Yang and Galak 2015). These two points suggest that repetitive use of a sentimentally valuable object can self-signal to the user that the associations the possession holds are more tightly knit to his/her/their identity, which subsequently enhances the object's sentimental value over time. We tested this hypothesis in two studies.

In study 1 we operationalized participant's most recently purchased souvenir as their sentimentally valuable possession due to souvenirs having the inherent purpose of being a memento of a special place/time and being a commonly used example of a sentimentally valuable possession in past work (e.g., Belk 1991; Yang and Galak 2015). We first measured the sentimental value imbued in the souvenir (1) at the time it was acquired, and (2) in the present moment. This was followed by a measure of usage frequency, which served as our independent variable. A repeated measures ANOVA with sentimental value over time (sentimental value at the time of acquiring vs. sentimental value in the present) as a within-subjects factor and usage frequency as a measured continuous predictor revealed that the only significant effect was the two-way interaction between usage frequency and sentimental value over time ($F(1, 113) = 4.42, p = .04$). Contrasts revealed that high usage frequency led the object

to have higher sentimental value in the present ($M = 5.09$) than the sentimental value the object had at the time of acquiring ($M = 4.53; t(113) = 2.56, p = .01$). However, when there is low usage frequency, we found no such difference between the object's sentimental value in the present ($M = 4.39$) and sentimental value at the time of acquiring ($M = 4.30; t(113) = .41, p = .68$). In sum, this pattern of results provides evidence of a link between the usage of sentimentally valuable objects and the growth of sentimental value over time.

Study 2 was preregistered on aspredicted.org (https://aspredicted.org/DXN_NIR). We repeated the first part of study 1 by asking participants to share with us their most recently purchased souvenir. The dependent measure tapped into the change in sentimental value of the souvenir by asking whether sentimental value had increased, decreased, or remained the same since the initial purchase (1 = much less now, 7 = much more now). We measured the proposed mediator with three items that asked whether the time/place the souvenir is associated with had become more closely integrated with the owner's self-concept over time. Finally, consumers were presented with the same independent variable from study 1, which asked about how frequently participants actively used the souvenir.

Basic Effect. We conducted a regression analysis in which we inserted usage frequency as the predictor and inserted change in sentimental value as the dependent variable. Our analysis found that usage frequency has a strong positive relationship with change in sentimental value ($b = .21, t = 3.27, p < .01$).

Process Evidence. We averaged the mediator items to create a self-concept integration index ($\alpha = .87$). Next, we conducted a mediation analysis using model 4 of Hayes's PROCESS macro estimate the indirect effects. Usage frequency was entered as the independent variable, change in sentimental value was entered as the dependent variable, and the self-concept integration index was entered as the mediating variable. The analysis revealed that the self-concept integration index yielded an indirect effect with a confidence interval that did not contain zero (LLCI = .0336, ULCI = .1473), indicating a significant mediating pathway for this model. In addition, the direct effect was non-significant (LLCI = -.0107, ULCI = .1550), suggesting strong mediation.

Taken in tandem, these studies provide evidence for core effect by demonstrating that greater usage frequency leads sentimental value to grow over time. Our process evidence suggests this occurs because repeated-use leads owners to integrate the association the object holds into their self-concept. Thus, it seems consumers' lay inclination to avoid regular-use of sentimentally valuable objects is causing them to miss out on an opportunity to organically grow the object's sentimental value, and by doing so failing to maximize the value (Liu et al. 2020; Yang and Galak 2014) and other benefits that could be derived from such objects (Belk 1991; Coleman and Wiles 2020; Curasi et al. 2004; Grossman and Rahinel 2022; Price et al. 2000; Yang and Galak 2015).

Using Benchmarks to Mitigate Overhead Aversion and Increase Donations

Dr. Burcak Bas, WU Vienna, Austria

Prof. Zachary Estes, City, University of London, London, UK

Prof. Aradhna Krishna, University of Michigan, USA

EXTENDED ABSTRACT

Donors avoid charities with high operational expenses (“overhead aversion”). Four preregistered studies demonstrate that benchmarking (i.e., providing the average overhead of similar charities) mitigates overhead aversion and increases donations, by increasing perceived charity efficiency. We add to prior work on the drivers of overhead aversion and provide guidelines for charities.

A major hindrance for charitable donations is *overhead aversion* - the tendency to donate less to charities that have high overhead costs (e.g., Gneezy, Keenan, & Gneezy, 2014). Although such overhead costs are often unavoidable, donors think of them as “a diversion of funds from program expenses” (Tinkelman & Mankaney, 2007, p. 42). This is problematic as overhead aversion can ultimately lead charities to underinvest in their organizational infrastructure (Gregory & Howard, 2009) and render them less effective in the long run (Lecy & Searing, 2015).

In this research, we argue that overhead may not be inherently aversive and that overhead related information can be strategically disclosed to create a competitive edge for certain charities, because what matters to donors may not be the charity’s overhead ratio, per se, but rather how low its overhead is, relative to peer charities. In four preregistered studies (<https://researchbox.org/553&PEER-REVIEW-passcode=RHQFUM>), we reveal a novel, simple, and effective strategy - benchmarking (i.e., providing the average overhead of similar charities) - to increase donations, while also considering donor perceptions of charity efficiency as a driver of overhead aversion.

Study 1 ($N = 398$) tested whether providing an overhead benchmark that is higher than a given charity’s overhead increases donations to that charity. As predicted, providing a high (50%) overhead benchmark ($M = 5.16$; $SD = 1.21$) had a positive and significant effect on willingness to donate, compared to both an equal (30%) benchmark ($M = 4.80$; $SD = 1.25$), $t(265) = 2.36$, $p = .019$, $d = .29$, and a low (10%) benchmark ($M = 4.65$; $SD = 1.36$), $t(263) = 3.22$, $p = .001$, $d = .40$. The equal and low benchmark conditions did not differ significantly, $t(262) = .95$, $p = .341$, $d = .12$.

Study 2 ($N = 200$) tested whether perceived charity efficiency mediates the effect of an overhead benchmark on donations, while also measuring perceived personal impact for comparison. As predicted, willingness to donate was higher when the benchmark overhead was 50% (i.e., high benchmark; $M = 4.82$; $SD = 1.29$) than when it was 20% (i.e., low benchmark; $M = 3.25$; $SD = 1.48$), $t(199) = 8.00$, $p < .001$, $d = 1.13$. Importantly, the effect of benchmarking on willingness to donate was significantly mediated by not only perceived personal impact, $B = .53$, $SE = .13$, $CI95 = (.30, .80)$, but also perceived charity efficiency, $B = .48$, $SE = .17$, $CI95 = (.17, .85)$.

Study 3 ($N = 200$) tested incentive compatible whether benchmarking can reverse overhead aversion, while pitting perceived charity efficiency against personal impact. Participants viewed two charities (i.e., Kids Korps and charity:water), which were randomly assigned across “low overhead (=15%), lower benchmark (=5%)” and “high overhead (=25%), higher benchmark (=35%)” conditions, and were asked to choose which should receive a \$100 donation. As predicted, significantly more participants (64%) chose to donate the \$100 to the high overhead, higher benchmark charity than to the low overhead, lower benchmark charity, $\chi^2(1, 200) = 15.68$, $p < .001$, d

$= .59$. Remarkably, people chose to donate to the charity with higher overhead costs, indicating that they made their choices based on (relative) charity efficiency rather than (absolute) personal impact.

Study 4 ($N = 600$) tested in a more comprehensive manner the effect of benchmarking via perceived charity efficiency. As predicted, a 2 (overhead) \times 2 (benchmarking) ANOVA on willingness to donate revealed that overhead and benchmarking had a significant interaction effect on willingness to donate, $F(1, 596) = 20.89$, $p < .001$. In the control condition, when there was no benchmark, willingness to donate was higher with low overhead ($M = 5.25$; $SD = 1.22$) than with high overhead ($M = 4.89$; $SD = 1.37$), $t(298) = 2.42$, $p = .016$, $d = .28$, demonstrating overhead aversion. In contrast, when the benchmarks were provided, willingness to donate was higher in the high overhead-higher benchmark condition ($M = 5.07$; $SD = 1.28$) than in the low overhead-lower benchmark condition ($M = 4.42$; $SD = 1.55$), $t(298) = 3.97$, $p < .001$, $d = .46$. The index of moderated mediation was significant for both personal impact, $B = .20$, $SE = .08$, $CI95 = (.06, .36)$, and charity efficiency, $B = .53$, $SE = .12$, $CI95 = (.31, .77)$. In the control conditions, both personal impact, $B = -.11$, $SE = .05$, $CI95 = (-.22, -.02)$, and charity efficiency, $B = -.16$, $SE = .07$, $CI95 = (-.31, -.03)$, significantly mediated the effect of overhead ratio on willingness to donate. Importantly, for the present purposes, in the benchmark conditions, charity efficiency significantly mediated the effect of overhead ratio on willingness to donate, $B = .37$, $SE = .08$, $CI95 = (.21, .54)$, but personal impact did not, $B = .09$, $SE = .05$, $CI95 = (-.01, .19)$, demonstrating the role of perceived charity efficiency in underlying overhead aversion.

Our findings point to the role of charity efficiency perceptions and suggest that using benchmarks is an effective strategy to mitigate overhead aversion.

Production Enjoyment Asymmetrically Impacts Buyers' Willingness to Pay and Sellers' Willingness to Charge

Dr. Anna Paley, Tilburg University, Netherlands
Dr. Robert Smith, Tilburg University, Netherlands
Dr. Jacob Teeny, Northwestern University, USA
Dr. Daniel Zane, Lehigh University, USA

EXTENDED ABSTRACT

Production enjoyment (the perception that a seller enjoys producing a product/service) increases buyers' willingness to pay (and choice likelihood) and lowers sellers' willingness to charge for the product/service. This asymmetry in pricing judgments occurs because production enjoyment signals high quality to buyers and a lower need for compensation to sellers.

The marketplace has experienced a proliferation of opportunities for buyers and sellers to directly connect and conduct business (e.g., peer-to-peer marketplaces). These buyers can access personal information about sellers, and these sellers can share information about the production processes behind their products or services. We examine the impact of an understudied yet fundamental attribute that sellers can communicate and that both buyers and sellers use to help determine the value of a product or service: the seller's enjoyment of the production process, or *production enjoyment*. We find that buyers are willing to pay *higher* prices for products and services that are high in production enjoyment because of inferences about quality. In contrast, sellers are willing to accept *lower* prices and charge less for products and services high in production enjoyment, because they require compensation for the unpleasant emotional labor invested in the production process.

In study 1, we examined the impact of production enjoyment on buyers' willingness to pay and sellers' willingness to charge for the 100 most common consumer-facing jobs (bls.gov). MTurk participants were randomly assigned to imagine that they needed to hire someone with a particular job (buyer condition) or that they had a particular job (seller condition). For each job, buyers (and sellers) indicated whether they were willing to pay (charge) more if the seller really didn't enjoy doing the work or if the seller really did enjoy doing the work. A paired samples t-test revealed that buyers were willing to pay more for high production enjoyment (relative to low production enjoyment), while sellers were willing to charge less for high production enjoyment (relative to low production enjoyment (job-level analysis $t(99)=41.39, p<.001, d=4.14$).

Study 2 investigates sellers' own jobs and addresses the possibility that the buyer-side results are driven by an increased liking of happy people (Bell 1978). First, sellers with jobs outside of MTurk named their job and one task core to their job that they enjoyed more than other people and one that they enjoyed less. They then indicated the minimum amount of money they would need to be paid per hour to do each task. Sellers' jobs and the two tasks were then yoked to MTurkers who imagined wanting to hire someone to do the tasks, and these buyer-side participants indicated their maximum willingness to pay for each task. Results revealed that buyers were willing to pay more for tasks high (vs. low) in production enjoyment, while sellers were willing to accept less for tasks high (vs. low) in production enjoyment (interaction $F(1,180)=67.38, p<.001, \eta_p^2=.27$).

Study 3 examines the process driving this pricing asymmetry. MTurk participants were randomly assigned in a 2(marketplace role: buyer vs. seller) x 3(enjoyment: high vs. neutral vs. low) between-subjects design. Sellers imagined that they were a local baker who sold brownies while buyers imagined they were buying a brownie from a local baker, and they each read about how much the seller

enjoyed baking brownies. Participants indicated their willingness to pay/accept on a sliding scale from 0 and 5 dollars, and indicated the quality of the brownies and how much compensation is necessary for the baker's experience during the process of making brownies. Again, buyers were willing to pay significantly more for higher enjoyment and sellers were willing to accept significantly less for higher enjoyment (interaction $F(2,1091)=41.18, p<.001, \eta_p^2=.07$). Mediation analyses using the two parallel mechanisms revealed that the positive effect of production enjoyment on buyers' WTP was driven by perceptions of higher quality, and the negative effect of production enjoyment on sellers WTA were driven by perceptions of an increased need for compensation.

Study 4 compares the relative strength of a production enjoyment signal to other information that buyers often have about sellers in the marketplace. We conducted a choice-based conjoint experiment where participants (acting as buyers) viewed information about three photographers and chose their most preferred option, repeated this choice task 12 times. In each trial, the three photographers randomly varied across five different attributes: production enjoyment, effort towards job, number of reviews, amount of advertising, and price (low, high, or no information). A Hierarchical Bayes analysis revealed that production enjoyment was significantly more important than each other attribute for driving choice. Buyers were willing to pay approximately \$40 more for a photographer who enjoys taking photos (vs. the no information control).

In study 5, we conducted a field study through Facebook to examine whether consumer responses to advertising were affected by a seller's mention of high production enjoyment. We created two ads for an SEO specialist and randomly presented one of the two ads to Facebook users associated with small business ownership. In the control condition, the ad read: "Need SEO Help? I have a lot of experience." In the production enjoyment condition, the ad additionally stated, "I really enjoy SEO." Results revealed that the enjoyment ad led to a significantly higher click-through rate (control=.72%, enjoyment=1.01%; $\chi^2(1)=9.47, p=.002$).

The current research demonstrates a novel factor (i.e., production enjoyment) that produces a consequential asymmetry in pricing judgments between buyers and sellers. This work contributes to and connects disparate streams of literature that examine the role of enjoyment in consumer behavior (e.g., Alba and Williams 2013), buyer/seller asymmetries in pricing (e.g., Carmon and Ariely 2000), and how marketplace cues and subsequent inferences guide decision making, especially cues relating to the creation process (e.g., Kirmani and Rao 2000). On a practical level, this work offers guidance for sellers seeking to maximize their profits and reveals how high production enjoyment might lead sellers to miss out on available profit, since it increases buyers' willingness to pay, but instead lowers the prices that sellers charge.

Describing Rosé: Measuring Consumer Preferences for Hedonic Experiences

Dr. Anirban Mukherjee, Cornell University, USA
Dr. Hannah H. Chang, Singapore Management University, USA

EXTENDED ABSTRACT

We develop an approach to measure preferences whereby anticipated hedonic experiences are presented to participants in written (unstructured) prose, akin to the real-life marketplace. Our method decomposes consumer preferences for experiences into product-attributes shaping these experiences. To illustrate, we present a large-scale study across Australia, New Zealand, and the US.

Many products and services (henceforth, ‘products’) are typically described and presented to consumers in prose. Prominent examples include products that consumers choose, buy, and use primarily for the hedonic consumption experience provided (Holbrook and Hirschman 1982), such as entertainment, travel, and hospitality. As consumer experiences are rich and nuanced, descriptions of these products are best delivered in prose—restaurants describe their ambience, travel operators describe the sight-seeing experience at an exotic locale, and theme parks describe the exhilaration of a roller-coaster ride. Similarly, tasting notes of wines are presented in natural language to capture the sensory experience of wine consumption. In extant methods to measure consumer preferences (e.g., conjoint analysis), hedonic experiences are described to participants and portrayed in the utility model as a list of product attributes (Green et al. 2001; Toubia et al. 2007). This format is also common in many extant consumer decision-making studies, wherein hedonic options are listed by their product attributes in tabular formats (e.g., Chang and Hung 2018).

In this research, we propose a novel approach wherein products are described to participants in natural language, akin to how they are presented to consumers in real-life marketplace. To do so, we construct a novel embeddings-based utility model that incorporate product embeddings and leverage the utility model to analyze participants’ choices of hedonic experiences (described in natural language) to infer their preferences. The model is based on the mathematical theory of an embedding—an injective map (i.e., a one-to-one function) from a set of objects to points on a normed vector space, the axes of which encode important and relevant information about the objects—as applied to products. Our proposed approach is based on prior research in three distinct literatures, including (1) hedonic consumption in consumer behavior, (2) embeddings in computer science and machine learning, and (3) choice modeling in quantitative marketing. Specifically, we propose a two-component approach where we first derive the product embeddings which numerically represent (verbally described) experiences by extracting latent features. Next, we incorporate the product embedding in the utility model to form an embedding-based utility model. We estimate the utility model on participants’ choices to infer preferences.

We use our method to investigate consumer preferences for wines made in 427 wine-growing regions in 44 wine-growing countries, from 708 wine-grape varieties, in Australia, New Zealand, and the United States (henceforth, “US”). In our empirical application, we first obtained a large-scale dataset of wine descriptions with the name, region, country, varietal (or blend), and tasting notes of 119,955 wines from 44 countries. We constructed product embeddings using this product dataset. We compared the performance of three methods in constructing product embeddings: (1) a model with the probabilistic (non-neural) embedding; (2) a model with the feed-forward embedding; and (3) a model with the recurrent embedding. We then conducted three choice experiments among regular wine consumers in three countries—the US, Australia, and New Zea-

land—to demonstrate our proposed method and the generalizability of the approach among English-speaking markets. Participants sequentially evaluated 32 pairs of randomly selected wines and chose their preferred wine in each pair. Each presented wine included its name and a prose description of the tasting experience. To provide a conservative test of our proposed approach, for each participant, the wines were randomly selected from the complete set of tasting experiences of 119,955 wine (which we collected for the product dataset). We estimated utility models based on the three embeddings methods and additionally estimated three benchmark models based on extant research: (a) a benchmark model that includes region, country, and grape varietal fixed effects; (b) a benchmark model with Latent Semantic Analysis (LSA) feature loadings (Eliashberg et al. 2007); and (c) a benchmark model with Latent Dirichlet Allocation (LDA) topic intensities (Toubia et al. 2019). Our findings show that, the model with the recurrent embeddings consistently fits the choice data across the three markets the best (in LOOIC and WAIC); this model also performs best at predicting participants’ choices (highest AUC and the lowest MSE) among all models.

Relative to extant methods, our proposed method can provide three key benefits. First, describing products in prose enhances study realism. Extant consumer behavior studies have shown that presenting the same product information in different formats (e.g., numerically vs. verbally, matrix display vs. written sentences) alters consumers’ decision processes. Therefore, for participant responses in a preference measurement study to reflect real-world behavior, products should be presented in the same manner in a study as they are presented in the real-world marketplace (e.g., Morales, Amir, and Lee 2017).

Second, it enables products to be described in prose, and hence more completely than if they were described using categorical variables (Toubia et al. 2019). For example, it is challenging to construct a categorical system to capture the flavors and sensory properties of all the hedonic experiences (such as wine) available in the market; this is particularly likely for hedonic experiences, as they are characterized by rich, nuanced, and complex sensory descriptions (Chang and Mukherjee 2022). Even if such a categorical system could be derived, it likely would have far too many attributes and attribute-levels to be useful in a self-contained market research study (i.e., curse of dimensionality; pp. 233–237, Toubia et al. 2007b).

Third, it enables a more detailed measurement of consumer preferences. If products are described to participants using categorical variables, there is a natural limit to how many attributes and attribute-levels can be included in a study. While much progress has been made in the development of more efficient study designs including adaptive self-explicated conjoint designs (Netzer and Srinivasan 2011), the use of many categorical attributes increases the amount of required participant data. These issues are particularly salient for products with many nuanced, sensory characteristics (such as wines). Our method facilitates the specification of a much more parsimonious embedding-based utility model, thereby reducing data requirements and enhancing cost-effectiveness.

Secondbrand Exchange: When Traditional Retail Brands Resell Used Products

Mr. Peter Silverstein, Unaffiliated, USA

Dr. Catherine Armstrong Soule, Western Washington University, USA

Dr. Sara Hanson, University of Richmond, USA

EXTENDED ABSTRACT

This paper explores consumer behavior in the novel context of secondbrand exchange, which is defined as traditional “firsthand” retail brands directly engaging in the reselling of used items. The authors introduce framework of item transformation and connect theory from brand extension and contagion literatures to this circular consumption marketing practice.

INTRODUCTION AND MOTIVATION

Can previously used products ever be “better than new” as Patagonia, an outdoor gear and clothing manufacturer, suggests to consumers on its website? We call this practice secondbrand exchange—when traditional brands directly reselling their own used goods. Rethinking linear consumption patterns, addressing overconsumption, and attempting to mitigate negative environmental impacts, brands as varied as Walmart, Nordstrom, Levi’s, REI, and others make strategic choices about acquisition, transformation, communication and distribution of used products. In this paper, we uncover the theoretical foundations connected to this novel brand strategy, present exploratory descriptive marketplace data, and offer research propositions to investigate the impact on consumer perceptions of the new and used products as well as the brand itself.

The secondhand market is experiencing an exponential rise (thredUP 2020), motivated by the climate change imperative and supported by technological advances and consumers’ shifting preferences (Ertz, Durif, and Arcand 2017). Because the vast majority of research exists within the linear economy paradigm wherein brands make new goods to be sold directly to consumers, these practices are both novel and understudied. This research contributes to the stream focused on circular and more fluid or liquid consumption practices (Bardhi and Eckhardt, 2017), but is distinctly separate from access-based consumption (Bardhi and Eckhardt, 2012) as ownership in secondbrand exchange is transferred.

CONCEPTUAL FOUNDATIONS

Defining Secondbrand Exchange: The Space Between New and Used

Secondhand reselling has existed for centuries in many forms, from flea markets to donation-based providers like Goodwill to for-profit thrift and consignment shops to informal consumer-to-consumer exchange such as classifieds and garage sales. More recently, web and app-based interfaces like Poshmark, thredUP, The RealReal, Depop, StockX, as well as social media-hosted C2C communities have appeared as technological advances break down geographic and logistical barriers. Secondbrand exchanges are defined as those mediated and hosted within one traditional, firsthand retailing brand (Nordstrom vs. thredUP) where the category remains the same (clothing remains clothing vs. clothing altered into recycled packaging). Because secondbrand exchanges are facilitated within one brand landscape, we must consider its differences from both traditional firsthand and secondhand retailers.

We introduce an organizational framework around secondbrand positioning matched with four main consumer motivations for buying secondhand: sustainability, durability, frugality, and fashionability. Another key aspect of secondbrand exchange is product transformation, defined as the magnitude of item change performed by

the secondbrand before resale, ranging from refresh (cleaning and/or merchandising) to renew (refresh+repair or other substantive change) to remake (refresh/renew+full recreation of new item from old item(s)).

Mapping Secondbrand in the Marketplace

To provide a snapshot of current secondbrand exchange activities in the marketplace, exploratory research identified twenty-nine large traditional brands in the online retail space. Some main findings from qualitative coding indicated difficulty in locating the used items (3.59 on a 5-point scale), a common (78%) display of actual (vs stock) item, and most (84%) displayed the new MSRP as a reference price for the used item. Secondbrands most often used sustainability positioning (approximately 2/3 of the brands), followed by durability (21%), and fashionability and frugality being infrequent (both at approximately 7%). Renewal activities were the most common level of product transformation (55%) and remaking was the least (17%). Only 17% engaged in more than one level of transformation. It was very unusual for the brand to share information about previous owners (single instance). Extending from these exploratory findings, we draw theoretical connections in two primary domains: brand extension and contagion.

THEORY DEVELOPMENT

Brand Extension

Brand extension refers to the introduction of new products/services by established brands (Keller and Aaker 1990). The question of whether brand extensions will help or harm parent brands and which factors affect these outcomes has been researched in depth (Aaker and Keller 1990; Keller 2002). The two main factors resulting in brand extension success are quality of the parent brand (Aaker and Keller 1990) and “fit” between the brand category and the extension category (Boush and Loken 1991; Dawar 1996; Herr, Farquhar, and Fazio 1996). In secondbrand exchange, perceptions of similarity may be bolstered based on category match (i.e., both firsthand and secondhand items are apparel) as well as item transformation level (i.e., reducing the perceived difference between new and used items). Further, consumers’ perceptions of fit may be influenced through the match within the four appeal types discussed above, brand position, and target consumers’ motives for shopping secondhand.

Contagion

The Law of Contagion refers to a phenomenon wherein objects transfer certain properties to another object upon coming into contact (Nemeroff and Rozin 1994) and is therefore pertinent to secondhand contexts. Physical contagion refers to perceived contamination through germs, dirt, and other disgusting material (Nemeroff and Rozin 1994), is perceived negatively by consumers, and is an important deterrent to secondhand consumption (e.g., O’Reilly et al. 1984) and driven by disgust and risk (Bezaçon, Guiot and Le Nagard 2019). Magical contagion, in contrast, refers to a transfer of essence from one entity to another and can be perceived as positive or negative depending on whose essence is transferred (Nemeroff and Rozin 1994). Positive magical contagion has been shown to increase the perceived value of items, make them feel more special, and to even imbue the new owner with certain abilities from the previous user (Kramer and Block 2014; Lee et al. 2011; Newman and

Bloom 2014; Newman, Diesendruck, and Bloom 2011). We suggest that it may be possible for secondbrands to strategically enhance positive magical contagion through transference of brand identity or prior owner identity and reduce negative physical contagion through product transformation level, merchandising and presentation/communication choices.

CONTRIBUTIONS AND CONCLUSION

This paper introduces the unique consumer context of second-brand exchange, a second-order market that blurs the line between new and used, entering a perceptual space that must be explored with continued research. After considering the phenomenon itself, presenting a spectrum of item transformation and drawing connections between brand extensions and contagion, we present seven research propositions organized around consumer perceptions of used products, new products and the brand itself.

Personal Growth is More Enjoyable than Consumers Expect

Ms. Emily Powell, New York University Stern School of Business, USA

Dr. Adam Alter, New York University Stern School of Business, USA

EXTENDED ABSTRACT

In ten studies, we demonstrated that growth experiences (i.e., leisure experiences meant to change, develop, or improve oneself) provided more meaning than, and just as much enjoyment as, purely fun experiences. Despite these dual benefits, people expect growth-experiences to be relatively unenjoyable and, consequently, often avoid them.

Imagine its Friday night and you are deciding between attending an improv comedy class and a stand-up comedy show. How should you decide? When making decisions like these, many choose the option they expect will maximize well-being, such as enjoyment (pleasure; Kahneman et al. 1997) or meaningfulness (a sense of purpose, value, and significance; Steger 2018). Thus, your decision might rest on how enjoyable and meaningful you expect each option will be.

Yet, such predictions are often inaccurate, and can produce faulty decisions (Wilson and Gilbert 2003). In this work, we examine how accurately people forecast the enjoyment and meaning they will derive from growth experiences (those meant for self-development, like an improv class; Ryff 1989) and compare these to those of fun experiences (like a stand-up show).

We propose that people underestimate their enjoyment of growth (but not meaningfulness). Growth experiences are designed to highlight gaps in knowledge. Once people notice such gaps, it creates drive-like curiosity that persists until the gap is bridged (Loewenstein 1994), leading them to feel highly absorbed by the experience (Kashdan et al. 2004). However, people often don't realize how drive states like this one will influence their behavior and feelings (Loewenstein 1996). Consequently, they tend to overlook how easily curiosity immerses them in growth experiences. Since engagement is a key driver of enjoyment, this disconnect leads people to underestimate their enjoyment of growth (but not fun). Further, we expect this will lead people to choose fun rather than growth experiences, despite the dual benefits of growth.

In Study 1, we examined the relationships between our constructs of interest. We found a positive relationship between growth and both predicted ($r=.200$, $p=.028$) and actual meaning ($r=.547$, $p<.001$). People expected a negative relationship between growth and enjoyment ($r=-.153$, $p=.095$) but instead, we found no relationship ($r=.039$, $p=.676$), indicating both high and low growth were similarly enjoyable. There was also a negative relationship between growth and purchase likelihood ($r=-.262$, $p=.004$).

In Study 2, we measured expected and actual enjoyment and meaning for the same experience (learning to draw an illusion). Study 2a was within-subjects, 2b measured only post-experience ratings, and 2c was between-subjects. Participants generally correctly predicted meaningfulness (2a: predicted $M=35.04$ v. actual $M=41.31$, $t(185)=5.39$, $p<.001$; 2b: average rating ($M=1.15$) v. midpoint, $t(115)=.64$, $p=.522$; 2c, predictor $M=36.03$ v. experiencer $M=37.96$, $t(195)=.64$, $p=.52$). In contrast, they underestimated enjoyment (2a, predicted $M=51.92$ v. actual $M=64.25$, $t(185)=6.41$, $p<.001$; 2b average rating ($M=16.04$) v. midpoint, $t(115)=8.28$, $p<.001$; 2c, predictor $M=52.74$ v. experiencer $M=60.53$, $t(195)=2.30$, $p=.022$).

In study 3a, we compared growth (documentary films) to fun (comedy films) experiences. While documentaries were considered more meaningful (predicted $M=69.23$; actual $M=76.82$) than comedies (predicted $M=48.92$; actual $M=51.68$), $F(1, 307)=100.15$, $p<.001$, prediction accuracy did not differ by film type ($F<2$). In

contrast, enjoyment accuracy did, $F(2, 614)=2.72$, $p=.067$. Predicted enjoyment of documentaries ($M=58.23$) was lower than actual enjoyment ($M=69.75$, $t(306)=5.22$, $p<.001$) whereas predicted enjoyment of comedies ($M=64.68$) was more similar to actual enjoyment ($M=70.28$), $t(306)=2.37$, $p=.015$).

In study 3b, participants chose which film from study 3a they wanted to watch. More selected a comedy (70.1%) than a documentary (29.9%), $\chi^2=18.88$, $p<.001$, even though the documentaries contributed more to well-being in study 3a.

Study 4 showed that the underestimation of enjoyment of growth (v. fun) was mediated by differences in how easily participants expected to become engaged in the experiences (indirect effect=.53, 95% CI[.15, .94]). Study 5 showed that adding a distraction to a growth experience moderated prediction accuracy, $F(1, 428)=4.70$, $p=.01$. We replicated previous findings in the control condition (predicted $M=5.96$ v. actual $M=6.83$, $F(1, 428)=31.31$, $p<.001$) but found the underestimation of enjoyment was reduced in the distracted condition (predicted $M=5.79$ v. actual $M=6.18$, $F(1, 428)=6.02$, $p=.015$).

In Study 6a we debiased predictions. Participants read an article stating that becoming engaged is easier than expected (v. an unrelated article) before they did the same experience from study 2, $F(1, 407)=5.22$, $p=.023$. We replicated our findings in the unrelated condition (predicted $M=4.98$ v. actual $M=5.69$, $F(1, 407)=25.08$, $p<.001$) but found that predicted enjoyment ($M=5.62$) was more similar to actual enjoyment ($M=5.89$) in the engagement condition, $F(1, 407)=3.69$, $p=.055$.

In Study 6b, we used the same article manipulation and measured participants likelihood of choosing growth (learn to draw activity) versus fun (play a video game). After reading the engagement article, participants rated their likelihood of choosing the growth experience as higher ($M=6.09$) than after reading the control article ($M=4.92$), $t(254)=2.34$, $p=.02$.

We demonstrate that people underestimate enjoyment of growth experiences, which can be both highly meaningful and highly enjoyable. We argue that this error occurs because people overlook how easily they become immersed in growth experiences. Further, this misprediction leads people to avoid growth experiences, preferring more fun experiences despite the dual benefits of growth.

“It happened to my friend”: How story source and victim characteristics shape consumer responses to stories about marketplace injustice

Dr. Anne Hamby, Boise State University, USA

Dr. Davide Orazi, Monash University, Australia

Mr. Patrick Moreau, Muse Storytelling, USA

EXTENDED ABSTRACT

People often hear stories about marketplace injustice from someone who was not the actual victim. The current work examines how exposure to a story told by one person, that is subsequently revealed to have happened to another person, influences the audience's willingness to take retaliatory action against an offending retailer.

Researchers and practitioners alike agree that telling an engaging story is an effective way to inspire action (Monarath, 2014). However, people routinely tune out messages based on initial judgments of the person communicating the message, particularly in emotionally charged contexts, rendering the message less persuasive (Parks-Stamm et al., 2008). Separately, consumer ethics research has also overlooked the role of storytelling in galvanizing consumer action. Specifically, while prior consumer ethics research has focused on how consumer (Cowan & Yazdanparast, 2021) and business characteristics (Hornsey et al., 2021) influence retaliation behaviors such as boycotts (Hahn & Albert, 2017), whether and how the characteristics of the source of a story of marketplace injustice influence retaliation behavior remains little understood. Addressing this gap in the consumer ethics literature is especially relevant in light of (1) rising concerns about customer ethnic and racial biases (Linzmajer et al., 2020) and (2) the growing prevalence of social media messages about marketplace injustice told by people who are not necessarily the victims of the incident (Chen et al., 2019).

Against this background, the aim of this work is to examine how the race of both the source of and the victim in a story of marketplace injustice influence a consumer audience's desire to retaliate against a focal retailer featured in the story. Three experiments using professionally acted and produced media examine the dynamic interplay of revealing information about the race of a victim (which is separate from that of the story source) *after* exposure to a story. Our findings confirm that both the race of the story source and victim (white vs. black) interact to influence the audience's desire to retaliate (studies 1-3). When the source is black, revealing the victim of the incident (black vs. white) does not lead to significant differences in the audience's willingness to retaliate against discrimination. When the source is white, however, respondents are significantly less likely to support a white victim compared to a black victim. This effect occurs despite exposure to identical story content, is serially mediated by differential levels of victim trustworthiness and ensuing perceptions of moral violation (study 2), and disappears when the victim race is revealed at the beginning (rather than the end) of the story (study 3).

Our research offers two key contributions to existing literature on consumer ethics and injustice in the marketplace. First, we extend current consumer ethics research focusing on consumers' retaliation in response to transgressions. While previous scholarship investigates the role of audience (Cowan & Yazdanparast, 2021) and business characteristics (Hornsey et al. 2021; Russell, Russell & Honea, 2016) in influencing retaliation behaviors, we are the first to focus on consumer-to-consumer transmission of stories about marketplace injustice. In doing so, we demonstrate how specific features of the story source and victim influence the audience's perceptions of moral violation and ensuing vicarious retaliation intentions against the offending service provider. Second, we extend research on service transgressions by unveiling a distinct form of racial bias from that

which is found in customer-employee interactions. Recent research on racial and ethnic bias demonstrates that a white majority of customers is negatively biased toward a non-white minority of employees and reports “less positive behaviors in interethnic service” (Linzmajer et al., 2020, p. 194). Our findings instead demonstrate that the retaliatory intentions individuals develop after being exposed to a story of marketplace injustice depend on the race of both the story source and the victim of the story, such that white audience members are positively biased towards the stories of non-white story sources and victims. Together, these contributions enrich our understanding of how the race of both the source and the victim of a story of marketplace injustice influence intentions to retaliate against the offending service provider, and provide avenues for future research on how to mitigate the responses and regulate communications.

Extended Warranties Protect the Consumer, Not Only the Product

Dr. Liat Hadar, Tel Aviv University, Israel

Dr. Ronit Montal-Rosenberg, The Hebrew University of Jerusalem, Israel

Prof. Shai Danziger, Tel Aviv University, Israel

EXTENDED ABSTRACT

We propose that consumers experiencing greater choice process induced negative affect wish to avoid repeating the choice experience. They purchase extended warranty plans because it eliminates future product choice for the plan's duration. We discuss practical implications and theoretical implications for research on choice-induced affect and avoidant behavior.

Product Face Ratios, Stereotypes, and Political Orientation: Field Data on Consumer Evaluations

Dr. Boram Lim, University of Kansas, USA

Dr. Michael Lash, University of Kansas, USA

Dr. Ahreum Maeng, University of Kansas, USA

Dr. Pankaj Aggarwal, Rotman School of Management, University of Toronto, Canada

EXTENDED ABSTRACT

Prior findings show a positive relationship between a product's facial width-to-height ratio (*fWHR*) and consumers' perceptions of its dominance and evaluations. The current research employs actual car review data and an experiment to replicate this effect, and show that this effect reverses for Asian brands and moderated by political orientation.

Product appearance influences a product's initial impressions and overall evaluations (Hollins and Pugh 1990). Recent research suggests that much like human face width-to-height ratio (*fWHR*): bizygomatic width divided by upper-face height), product *fWHR* too signals dominance. Further, products with high *fWHR* are evaluated positively since dominance traits signal higher status (Maeng and Aggarwal 2018). Given the different racial stereotypes especially the submissive stereotype associated with Asians, prior research shows that dominance ratings of a minority race are suppressed compared to that of the white race (Maeng and Aggarwal 2022). This current research examines if racial stereotypes are also applied to products made by Asian companies and how it affects product evaluations. Finally, prior research notes that people's political orientation affects the extent to which they endorse racial stereotypes (Nosek et al. 2007). Employing field and experimental data, we examine whether the effect of *fWHR* on product evaluations for Asian versus American brands depend upon consumers' political orientation.

STUDY 1

To investigate these effects, data was obtained from a car review website, Cars.com. Data contain the review text, exterior style rating, and the consumer's location. We obtain review data of 34 car models from 16 distinct manufacturers over 15 years via a web-scraper. We also obtain front-facing car images for each model for each year (689 total photos).

Variable Operationalization

Dependent variable for our analysis is reviewers' exterior style ratings assessed on a discrete scale of 1-5 -- e.g., $y_{icyt} \in \{1,2,3,4,5\}$.

Primary independent variables of interest are: car *fWHR*, Asian car branding, and reviewer political orientation. The front-facing car images were annotated with landmarks *a*, *b*, *c*, and *d*. The $fWHR_{cy} = (a-b)/(c-d)$, where the landmarks indicate the left edge (*a*), right edge (*b*), top of the hood (*c*), and undercarriage (*d*).

To investigate the moderating effect of Asian branding on *fWHR* we define a binary variable for a car as $AsianBrand_c = 1$ if $make_c \in \{Toyota, Honda, Hyundai, Lexus, Genesis, Acura\}$ and 0 otherwise, where $make_c$ is the manufacturer of car *c*. To investigate the moderating effect of political orientation on *fWHR*, we define a variable using reviewers' self-reported location information as a proxy for political orientation. $Conservative_i = 1$ if reviewer *i* is located in a conservative-voting state (2016 presidential election).

Control variables. We include a rich set of control variables that may affect consumers' ratings of a car's exterior including review characteristics, car use, and other car specifications.

Empirical Analysis

Effects are investigated via a linear ordered logit model consisting of specific combinations of our defined covariates: $y_{icyt}^* = \beta_1 fWHR_{cy} + \beta_2 fWHR_{cy} \times Conservative_i + \beta_3 fWHR_{cy} \times AsianBrand_c + \beta_4 AsianBrand_c \times conservative_i + \beta_5 fWHR_{cy} \times AsianBrand_c \times Conservative_i + \Gamma X_{icyt} + \eta_i + \omega_{brand} + \nu_{generation} + \Phi_y + \Psi_t + \epsilon_{icyt}$. β_1 captures the main effect of car *fWHR* on the exterior rating y_{icyt} , β_2 captures the moderating effect of political identity, and β_3 captures the moderating effects of Asian branding on *fWHR*. The three-way interaction, β_5 captures the interacting effects of political affiliation, Asian branding, and *fWHR*. X_{icyt} is a vector of control variables; state/brand/generation/time fixed effects are also included.

RESULTS

(a) *The effects of fWHR*. Consistent with prior findings (Maeng and Aggarwal, 2018), our results show that *fWHR* positively affects consumers' evaluations of the car exterior ($\beta_1 = .104; p < .01$). (b) *The effects of political orientation*. Results reveal a significant positive interaction effect ($\beta_2 = .033; p < .01$) between product *fWHR* and preferences among conservatives. (c) *The effects of Asian brands*. Our model reveals a negative interaction effect between *fWHR* x Asian Brand ($\beta_3 = -.685; p < .01$), reversing the overall positive effect of *fWHR* ($\beta_1 = .104; p < .01$). These results provide evidence supporting our hypothesis that stereotypes associated with Asians bias consumer perceptions of Asian car brands. (d) *The effects of Asian branding and political orientation*. We see a significant negative interaction effect ($\beta_5 = -.313; p < .01$) showing that conservatives suppress the dominance cues of Asian-branded product faces more than liberals.

STUDY 2

The purpose of study 2 is three-fold. First, we replicate the effects of study 1 in a controlled experiment to ensure internal validity. Second, we test our hypothesis using individual-level political orientation measures. Finally, we examine the causality of the proposed effects using moderated mediation analysis. The *fWHR* of five automobile front faces were manipulated to high-low levels, yielding a total of 10 automobile faces. 581 M-Turk participants evaluated the automobile faces presented as either Asian or American brands on three liking and three dominance measures as well as participants' political orientation on a 5-item scale (Evans, Heath, & Lalljee, 1996).

Consistent with the results of Study 1, there was a three-way interaction between *fWHR*, Asian brand, and respondents' political orientation ($B = -.09, S.E. = .04, p < .05$). Political conservatives show a larger effect of *fWHR* on the dominance ratings of American brands ($B = .50, 95\% CI [.31, .68]$) than for Asian brands ($B = .23, 95\% CI [.03, .42]$). For liberals, *fWHR* has a larger impact on the dominance ratings of Asian brands ($B = .50, 95\% CI [.32, .68]$) than for American brands ($B = .35, 95\% CI [.16, .54]$). A similar interaction was observed for overall preference ($B = -.12, S.E. = .04, p < .05$), indicating that for conservatives *fWHR* has a significant effect only for American brands ($B = .37, 95\% CI [.15, .58]$) but not for Asian brands ($B = .08, 95\% CI [-.14, .31]$). For liberals, *fWHR* has a larger impact on Asian brand preference ($B = .48, 95\% CI [.27, .69]$).

but not for American brands ($B = .21$, 95% CI [-.01, .43]). Finally, a moderated mediation analysis revealed that dominance mediated the influence of $fWHR$ on the preference for automobile faces and that this effect was moderated by brand country of origin and respondents' political orientation ($B = -.056$, $p < .05$).

In sum, using actual field data and a controlled experiment, we show, for the first time, the effect of car $fWHR$ on consumer preference and the moderating effects of Asian stereotypes and consumer political orientation.

How do Emojis Shape Conversations in Digital Environments?

Ms. Yiming Li, HEC, Lausanne, University of Lausanne, Switzerland

Prof. Tobias Schlager, HEC, Lausanne, University of Lausanne, Switzerland

Prof. Joandrea Hoegg, Sauder School of Business, University of British Columbia, Canada

EXTENDED ABSTRACT

Conversations that take place online suffer from the lack of audio-visual cues. Using real conversation samples from Twitter and online experiments, the current study demonstrates that emojis shape online conversations such that people better understand each other and eventually engage in greater turn-taking behaviors (e.g., more conversation topics and turns).

Emojis can be considered the most important linguistic development of the past decades. In 2015, the Oxford Dictionaries chose, for the first time, an emoji as the word of the year (Dictionaries 2015). Emojis are a textual paralinguistic (Luangrath, Peck & Barger 2017), which is described as “visual textual paralinguistic elements”. Conversations in digital environments (e.g., on social media, chatbots, or forums) lack the non-verbal cues that are common in face-to-face conversations, which led to the development of surrogates for those missing cues (Byron & Baldrige 2007; Ganster, Eimler, & Krämer 2012; Walther 1996). Emojis, as paralinguistics in general, thus aid people in expressing themselves in digital environments.

Research on the effect of emojis on conversations and especially on the efficiency of conversations is sparse. Previous studies in the area of emojis focus on people’s interpretation of emojis (Na’aman, Provenza & Montoya 2017; Miller et al. 2016; Pohl, Domin & Rohs 2017; Barbieri, Ronzano, & Saggion 2016), the sentiment of emojis, their similarity (Novak et al. 2015; Ljubešić & Fišer 2016; Eisner et al. 2016), as well as their impact on customer outcomes, such as service relationships and purchase intentions (Hill 2016; Smith & Rose 2020). Finally, Li et al. (2019) showed that emojis could significantly affect the consumers’ perception of the warmth and competence of the service provider.

However, it is still unclear how emojis affect conversations and the work hitherto primarily uses non-experimental methods. At the same time, researchers across disciplines call for more work on language (Kronrod & Danziger 2013; Schellekens, Verlegh & Smidts 2010; Sela, Wheeler & Sarial-Abi 2012). An important gap is the impact of emojis on conversations in digital environments, which are hitherto predominantly using text. Specifically, such conversations lack nonverbal (e.g., facial expressions) and vocal cues (Kiesler, Siegel & McGuire 1984; Culnan & Markus 1987; Walther 1992). While this does not seem to be a major drawback, at first sight, the lack of verbal cues can lead to inefficient conversations coined by misunderstandings and longer information processing time (Herring 1999).

Considering the prior work, this work asks the broader research question: *How do emojis affect conversations?* We propose that emojis can increase the clarity of digital, text-based conversations and eventually lead to a better mutual understanding of the conversation partners. We propose that this results in greater turn-taking behaviors (i.e., more conversation turns) and higher dynamics of topic change (i.e., more conversation topics).

Study 1 investigates whether turn-taking conversations with emojis (vs. without emojis) lead to more topic changes in a real-life environment. We collected real random conversations via Twitter API and the *Tweepy* package (period: October-December 2020). To rule out the potential dynamics in conversations (i.e., different turns for each conversation and emoji frequency for each turn), we extracted three turns in each conversation. Further, we trained two topic clustering models (*Latent Dirichlet Allocation* [LDA] and K-

Means) to compare the topic modeling predictive performance in the conversations ($N = 6'719$, $N(\text{conversations with emojis}) = 1'905$ and $N(\text{conversations without emojis}) = 4'814$). To control selection bias and endogeneity problems, we choose the matching approach in Study 1 to compare the estimation difference between the emojis groups and non-emojis groups. We applied logistic regression on unmatched and matched samples to assess the effect of emojis on the probability of topic change dynamics. The estimated results showed that the main effect of emojis on the probability of topic change is robust after controlling for all covariates in three-turn conversations. Both unmatched and matched estimated results show that the group with emojis has a positive significant effect on topic change probability in online conversation ($b = 0.27, p < .001$ [unmatched conversation]; $b = 0.26, p < .001$ [genetic matching]; $b = 0.26, p < .001$ [nearest neighbor matching]; $b = 0.27, p < .001$ [subclass matching], $b = 0.25, p < .001$ [optimal matching]). The results of Study 1 showed that emojis can enhance turn-taking in conversations using real-world data.

In Study 2, we focused on the difference in responses in conversation, examining whether the likelihood of topic change is lower when only the recipient uses emojis (versus neither of the two communicators using emojis). We randomly collected conversations with two turns from Twitter ($N=6'954$). Results in Study 2 illustrated that recipient who used emojis is more likely to change topics than neither of the two communicators without emojis ($b_{\text{emojis}} = 0.55, p < .001$).

Studies 3 and 4 examine whether the use of emojis increases conversation turns and topics by enhancing better mutual understanding in conversations. In Study 3, participants [$N = 597$] were recruited from Amazon Mechanical Turk to imagine a conversation that would take place online. Participants were randomly assigned to assess five text messages in one of two conditions (emojis: [present vs. absent]). We selected five text messages with varying meanings, which are merely ambiguous lexicons in each. After that, we measured the perceived ambiguity and understanding level of the text messages. The indirect serial path through disambiguation and common understanding on willingness to take conversation turns has found to be positive significant in the Study 3 ($b = 0.027, p < .001$), $CI95\% = [0.012; 0.041]$, $SE = 0.007$). The results from study 3 support that, conversation with emojis increased the clarity of message content and mutual understanding, which led to more conversation turns in these effects. Study 4 replicated previous findings that people contributed more topics in conversations that included emojis compared to conversations with merely verbal texts.

The findings of four studies show that emojis can increase the efficiency of conversations online such that they cover more topics, and, at the same time, lead to a greater mutual understanding. Our current work highlights the importance of emojis as non-verbal cues on efficient conversations regarding turn-taking behaviors (e.g., conversation topics and turns) and message clarity.

Luxury Content Becoming Viral Online: The Positive Role of Lexical Sophistication

Mr. Zitian Qiu, HEC, Lausanne, Switzerland
Prof. Felicitas Morhart, HEC Lausanne, Switzerland
Prof. Andreas Lnaz, HEC Paris, France
Dr. Daniel Shapira, Ben-Gurion University, Israel

EXTENDED ABSTRACT

An analysis of 300,000+ brand-created tweets reveals that luxury brands' content using more sophisticated (vs. simple) words is more likely to be shared. This is because lexically sophisticated content is in line with high-status communication styles, thus enabling luxury brands' audiences to signal superior status by sharing such content online.

Nowadays, most well-known luxury brands are active on social media. How to increase content virality while maintaining a high-end brand image has become the focal point of contemporary luxury branders. Pancer et al. (2019) found that content using simple (vs. complex) words is more likely to be shared online. However, we propose such a strategy may not be suitable for luxury brands.

Keeping a psychological distance from the mass is a critical strategy for luxury branding (Kapferer and Bastien 2012). Sophisticated (vs. simple) words that are used less in daily contexts could reduce content's processing fluency, and hence, enlarge the psychological distance between a brand and its audiences (see Construal Level Theory; Alter and Oppenheimer 2008). Thus, sophisticated wording should align with luxury brands' communication styles. Besides, content-sharing behavior can be seen as a form of social interaction. Driven by impression management motives (Goffman 1959), users should prefer sharing content with more status signaling qualities. For example, people like to discuss high-status matters to signal that they belong to the elite (Berger 2014). Taken together, we predict that users prefer sharing lexically sophisticated content that is created by luxury brands (H1a) vs. non-luxury brands (H1b), because sophisticated luxury-branded content is more aligned with high-status brands' communication style (H2a), and thus, has more status signaling qualities (H2b).

Studies 1–2 were conducted by analyzing a dataset from the global watch industry containing 318,775 tweets and 119,593 images by 221 brands. The purpose of Study 1 was to explore how different levels of lexical sophistication would impact the virality of luxury versus non-luxury brands' content. We used the word's usage frequency cross-checked with existing frequency-checking corpora (e.g., Corpus of Contemporary American English) as a proxy for the sophistication level (Kyle, Crossley and Berger 2018). Then, we took the inverse of average word frequency to quantify each tweet's sophistication level and used the Linguistic Inquiry and Word Count 2022 (Boyd et al., 2022) and Google Cloud Vision API to capture each tweet's text- and image-specific features. Regression results revealed that increased lexical sophistication was positively correlated with the sharing volume of luxury brands' content (e.g., $\beta = .016$, $p < .05$; We determined a brand's status based on Deloitte's watch industry report; Deloitte 2021), but negatively correlated with the sharing volume of affordable (e.g., $\beta = -.033$, $p < .005$) and premium brands' content (e.g., $\beta = -.041$, $p < .001$). By extension, Study 2 was designed to show that sophisticated wording style is more status-relevant. Thus, we used a brand's (median) product price as the proxy for a brand's status (Lee 2021), regressed the natural log of the median price of each brand on the tweet's lexical sophistication level, and found that lexical sophistication was positively correlated with brand status (e.g., $\beta = .12$, $p < .001$).

To verify the main effect and the mediation path, we conducted Study 3, a one-factor experiment (lexical sophistication: unsophisticated vs. sophisticated) with a between-subject design. 153 MTurkers (45% female, $M_{age} = 33.5$) were randomly assigned to read either a sophisticated or unsophisticated post. After reading, participants rated their intention of sharing the post on social media (scale adapted from Pancer et al., 2019), the content's conformity to high-status communication norms (scale adapted from Bellezza, Gino and Keinan 2014), and the content's status signaling qualities (scale adapted from Locke, 2003). ANOVA results showed significant differences between conditions on sharing intention ($F(1, 151) = 10.22$, $p < .005$), conformity to high-status communication norms ($F(1, 151) = 184.66$, $p < .001$), and status signaling qualities ($F(1, 151) = 18.13$, $p < .001$). Next, we used Hayes's (2017) Model 6 to test the serial mediation model and found evidence of full mediation.

To conclude, our research explores the positive effects of lexical sophistication on the virality of luxury brands' content and sheds light on the mechanism behind the effect. Theoretically, this paper makes several contributions. First, some previously established virality-driving factors should be carefully revisited for high-status brands' digital marketing practices. Second, we provide empirical evidence that manifests people share high-status content to signal superior statuses. Third, we add to those studies (e.g., Pocheptsova, Labroo and Dhar 2010) that show the positive effects of processing disfluency. Managerially, luxury brands could create sophisticated social media content to ensure content virality while maintaining the brand's prestige.

Creative Gift Systems: An Autonetnography Among Writers

Ms. Isabella Ciampa, HEC Paris, France

EXTENDED ABSTRACT

This article details a creative gift system, investigating the relationships between a single giver and its recipients. Using an autonetnographic approach, it explores the author's experience on the social media of Wattpad, unpacking how different types of relationships affect the creative process of writing an original novel online.

INTRODUCTION

Nowadays, consumers share content on platforms like SoundCloud and WebToon (focusing on music and comic book production, respectively), creating alongside other creators and followers. This article explores a similar setting: I discuss the case of Wattpad, an online book community where writers share original creations, entrusting their creative development (e.g., books) to anonymous users. I focus on my own experience as a writer, using three years of autonetnography where I concurrently wrote and published a Fantasy novel on Wattpad. In those three years, I developed a relationship with my readers, which impacted the object of my giving – the novel being written. The article unpacks said relationships, that shaped the creative gift system in which I was embedded and that impacted the object of the giving. Furthermore, it explores the development of the creator's experience of a creative gift system through a specific social media platform.

LITERATURE REVIEW

Gift giving is a fundamental representation of social behavior (Mauss 1925), which encapsulates key cultural dimensions (Levi-Strauss 1949; McCracken 1986). Gift giving grasps the complexity of human behavior by showing a variety of non-utilitarian but paradoxical characteristics – generosity and reciprocity, as well as the attempt to impose oneself in a quest for power (the “dark side” of the gift, Sherry et al. 1993). Caillé (2000) summarizes Mauss' gift constructs in four main concepts: 1) gift giving as being about *alliance*, in particular about forming relationships with other individuals, 2) gift giving as *ritual obligation*, which implies reciprocity on the recipient's part, 3) gift giving as *generativity*, where it represents the giver's need for acknowledgment, and 4) the gift as a *quest for glory*, in which the parties involved in the exchange establish a particular hierarchy by imposing themselves.

Contemporary marketing research ties gift giving to the idea of marketplace exchange (Bagozzi 1975) and consumer behavior (Sherry 1983). Furthermore, marketing research uses it to study a multitude of relationships and exchanges: dyadic forms of relationships (Belk 1979; Belk and Coon 1993; Otnes et al. 1993; Lowrey et al. 2004), as well as sociological, communitarian but nonetheless reciprocal expressions of giving (Giesler 2006; Joy 2001; Kozinets 2002; Weinberger and Wallendorf 2012). In the last two decades, gift giving literature extended to exchanges in digital settings, uncovering the digital gift (Kwon et al 2017; Romele and Severo 2016) and representing the complexities of anonymous, digital gift systems (Giesler 2006). Nonetheless, still very few papers attempt to understand how gift systems are shaped around digital environments, in particular creative ones.

METHODOLOGY

I employ a mix of netnography (Kozinets 2002) and autoethnography (Ellis 1999): an autonetnography (Kozinets, Scaraboto and Parmentier, 2018; Villegas 2018) on Wattpad, a platform where users

can publish anything from fan fictions to original novels, through mobile app or desktop. Starting July 2016 until August 2019, I concurrently wrote and published a Fantasy novel on this social media. During these years, I interacted daily with the Wattpad community, where I built a tight knit group of writers and readers.

The introspective approach allowed me to study tenets of my experience. For the analysis, I scraped comments left by readers and myself on the story, from the day it was first published until the moment I decided to elaborate on my experience from an academic point of view (July 2019). On Wattpad, users can leave comments on single chapters, paragraphs, sentences, or even words. These comments appear as a small bubble to be clicked on, which incorporates readers' jokes, critiques, and opinions on the story, displayed alongside the main text. I collected over 40,000 comments in 58 book chapters published separately. In analyzing these comments, I followed an iterative, hermeneutic approach (Thompson 1997). I narrowed down the data to the months between July 2016 and December 2017, when I was the most active and the interaction with the community was at its peak. Overall, the dataset consists of 680 single-spaced pages, including 14,858 comments on the story, personal notes left as footnotes in the chapters, private messages with fellow wattpadders, and opinions and posts published in my profile's feed in the considered time frame. To corroborate my analysis, I then held five in-depth semi-structured interviews (lasting from 60 to 118 minutes) with writers, to explore their long-term experience before and after landing on Wattpad.

FINDINGS

A creative gift system is made of a multiplicity of relationships. On Wattpad, these relationships define specific types of interactions, which act as forces of change in the system. These forces shape the creative gift system and push it forward. I categorize two types of forces of change: *generative forces*, that arise out of the interaction between the creator and the platform, and *relational forces*, which spur from the various interactions between the creator and other consumers. Generative and relational forces of change impact the creative gift system at different stages. I develop a framework to identify four main steps: *Nesting*, when the creator approaches the new platform, learning its rules and userbase's habits; *Giving*, when the creator, out of a generative desire to be acknowledged, begins gifting its original, creative artifact; *Co-creating*, when the creator, through followers' feedbacks and comments (i.e., relational forces), shapes the artifact around the system; *Branching Out*, which marks the end of the cycle, when the creator feels the need to branch out of the platform, to generatively engage with a new one.

The status signaling function of wasting food

Ms. Evelyn Devos, Ghent University, Belgium

Ms. Daphne Ribbers, Ghent University, Belgium

Dr. Mario Pandelaere, Virginia Tech, USA

Prof. Anneleen Van Kerckhove, Ghent University, Belgium

EXTENDED ABSTRACT

While food waste instances are omnipresent, it remains unclear what the social consequences are for the individual who wastes food. Results show that wasting food increases one's financial status, yet also decreases one's social status in the eyes of others. The decrease in social status is driven by inconsiderateness perceptions.

While food waste has tremendous consequences on a large scale (WRI, 2019), it remains unclear what the possible social consequences are for the individual who wastes food. We fill this gap in the literature by examining how wasting food impacts one's ascribed status.

Extant literature identified several ways an individual can signal status to others, including consuming luxurious brands (Cannon & Rucker, 2019; Nelissen & Meijers, 2011), and performing non-conforming behavior (Bellezza et al., 2014). We add to this literature by exploring wasting food as an alternative status signal.

In contrast to the vast majority of status research, we specify status as a multidimensional concept by distinguishing between financial and social status. We define social status as the respect and esteem one enjoys from others (Magee & Galinsky, 2008), and financial status as the possession of financial resources (Nelissen & Meijers, 2011). We expected that wasting food increases one's financial status, yet decreases one's social status in the eyes of others (H1).

We focus on explaining the change in social status perceptions as little research considered it, despite it being crucial for one's social interactions and well-being (Anderson et al., 2015; Nelissen & Meijers, 2011). Wasting food is associated with harming others and is considered immoral behavior (Misiak et al., 2018). When individuals act against the common good their ascribed social status decreases (Keltner, 2016). Therefore, we propose that one's social status decreases because the observer believes the waster cares less about other humans (H2).

Study 1 ($N = 198$) tests H1 in a between-subjects design. Participants imagined helping a friend clean up leftover food (lobster) after a dinner party, and seeing their friend Alex throwing away the leftover (waste condition) or saving it for later (control condition). Afterwards, we measured participants' financial status perception (6 items; e.g. "Alex is financially wealthy"; $\alpha = .96$) and social status perception of Alex (6 items; e.g. "Alex is admired by others."; $\alpha = .92$) on a 7-point Likert scales ranging from 1 = "strongly disagree" to 7 = "strongly agree". Results showed that Alex was ascribed higher financial status ($M_{waste} = 5.50$) when he wasted the leftovers compared to when he stored it ($M_{control} = 5.09$; $t(185.84) = -2.91$, $p = .004$, $d = .42$). Yet, at the same time, ascribed Alex significantly lower social status ($M_{waste} = 4.86$ vs. $M_{control} = 5.26$; $t(196) = 3.25$, $p = .001$, $d = .47$).

Study 2 ($N = 221$), not reported here, shows that the effect is truly driven by wasting food rather than simply having leftovers one has to decide over.

Study 3 ($N = 250$), using a similar procedure and measures as study 1, tests whether the price of the wasted food (red wine) plays a moderating role. We employed a 2 (leftover use: wasteful vs. control) \times 2 (price: low [8\$] vs. high [65\$]) between-subjects design. As predicted, financial status perceptions ($\alpha = .96$). significantly in-

creased when wasting the red wine ($M_{waste} = 4.59$ vs. $M_{control} = 4.17$, $F(1,246) = 12.19$, $p = .001$, $\eta_p^2 = .047$) and serving the expensive bottle ($M_{expensive} = 5.04$ vs. $M_{cheap} = 3.72$, $F(1,246) = 119.69$, $p < .001$, $\eta_p^2 = .327$). Surprisingly, there was no interaction ($p = .215$). Social status perceptions ($\alpha = .90$) decreased when wasting the leftover wine ($M_{waste} = 4.49$ vs. $M_{control} = 4.83$, $F(1,246) = 13.14$, $p < .001$, $\eta_p^2 = .051$). We found no effect of price ($p = .271$) nor an interaction between price and leftover use on ascribed social status ($p = .520$).

Results from *study 4* ($N = 201$), not reported here, provides initial support for the underlying process ($ab = -.11$, Boot $SE = .06$, 95% CI [-.23, -.01], 10,000 bootstrap samples), yet in a different setting (observing a stranger in a restaurant).

The goal of *study 5* ($N = 312$) was to replicate the finding of study 4 and examine whether the amount of leftover food moderates the negative effect of wasting food on social status perception. Participants imagined seeing their friend David wasting (waste condition) or saving (saving condition) either one hotdog (low amount condition) or five hotdogs (high amount condition). Participants indicated their social status ($\alpha = .92$), and inconsiderateness perceptions of David (4 items; e.g. "David does not care about others."; $\alpha = .92$). Results show that participants ascribed significantly less social status to David when he wasted the hot dogs ($M = 4.73$) compared to when he saved them ($M = 5.06$, $F(1,308) = 8.97$, $p = .003$, $\eta_p^2 = .028$). Contrary to our contradictions, there was neither a significant effect of amount manipulation ($F(1,308) = 1.50$, $p = .221$, $\eta_p^2 = .005$) nor a significant interaction of amount and use manipulation ($F(1,308) = 2.04$, $p = .154$, $\eta_p^2 = .007$) on social status perceptions. Lastly, a mediation analysis confirmed that when observers saw David waste food they thought he had significantly less social status because they thought David was more socially inconsiderate ($ab = -.39$, Boot $SE = .08$, 99% CI [-.61, -.20], 10,000 bootstrap samples).

Study 6 ($N = 381$) further explores this mechanism by manipulating rather than measuring the mediator. To manipulate perceived inconsiderateness, we described a friend (Jack) who agrees or refuses to volunteer. We used a 2 (use: waste vs. control) \times 3 (perceived inconsiderateness: inconsiderate vs. considerate vs. control) between-subjects design. Most importantly, contrast analyses confirmed that social status perceptions decreased significantly more when Jack wasted the spaghetti (cf. saved it) if no information about Jack's (in)considerateness was available, versus when participants had additional information (contrast estimate = -3.72 , $F(1,375) = 4.53$, $p = .034$, $\eta_p^2 = .020$). Moreover, using only the control perceived inconsiderateness conditions, we confirmed our mediation hypothesis ($ab = -.70$, Boot $SE = .20$, 99% CI [-1.28, -.27], 10,000 bootstrap samples).

In sum, we demonstrate that observers ascribe higher financial status, yet, at the same time, lower social status to an individual who wastes food. Neither the price nor the amount of the wasted food attenuates the main effects. Observers confer less social status to a food waster because they believe that the individual is being inconsiderate of others.

Disposing of Dior: The Impact of Luxury Goods on Disposal Decisions

Dr. Jennifer Stoner, University of North Dakota, USA

Dr. Ashley Stadler Blank, Xavier University, USA

Dr. Navdeep Athwal, University of Leicester, UK

EXTENDED ABSTRACT

Building on the product disposal and sustainability literatures, we examine the disposal of luxury goods. We find that consumers make more (not less) sustainable disposal decisions for luxury goods because they consider the financial value. Furthermore, this effect extends to non-luxury goods that are disposed of at the same time.

Today, decluttering is considered an important self-care practice (Wang, 2021). This trend has led to the decluttering of homes, which leads consumers to dispose of a variety of goods, including both luxury and non-luxury items. Past research that examines product disposal identifies several disposal decisions, such as keeping, gifting, donating, trashing, and selling (Jacoby et al., 1977). Importantly, disposal decisions are closely linked to sustainability (Athwal et al., 2019). Recent research from thredUP (2021), an online consignment store, states that approximately 34 billion pieces of clothing get trashed each year when they could have been recycled or reused. Second, while keeping may initially seem to be a more sustainable option, hoarding items prevents unwanted goods from being redistributed to other consumers who may have bought a used item (rather than new) if it were available in the marketplace (Sarigöllü et al., 2021).

Existing literature on the secondhand market focuses primarily on the demand side of secondhand goods (e.g., motives for consuming secondhand goods) (see Turunen and Pöyry, 2019 as an example). Despite the sustainability benefits of the secondhand market, there is very little research on how unwanted goods end up in the secondhand market. Understanding the supply side is integral to the growth and success of secondhand markets (thredUP, 2021). Therefore, we question how consumers make disposal decisions for unwanted luxury goods as well as how these decisions affect disposal decisions for non-luxury goods.

Luxury goods are typically offered at a premium price and associated with exclusivity (Wang et al., 2021). Just like past research on the secondhand market, prior work on luxury goods largely studies the demand side (i.e., purchase and consumption of luxury goods) (see Wiedmann et al., 2009 as an example). Some of this research finds that luxury goods may lead consumers to engage in more selfish behaviors (Wang et al., 2021). We, therefore, might expect disposal decisions related to unwanted luxury goods to be more selfish in nature (e.g., trashing or keeping). However, we argue that disposal decisions for unwanted luxury goods make consumers focus on the financial value of the items and thus make more sustainable disposal decisions.

Study 1 had two between subject conditions (luxury/non-luxury). Participants imagined that they were decluttering when they found a fictitious brand scarf. In the luxury (non-luxury) condition the fictitious brand was described as a luxury (mass market) brand. Participants reported their disposal decision as well as their disposal motivation. We coded sell, give to someone, and donate as sustainable and keep and throw away as unsustainable disposal decisions. Participants in the luxury condition made more sustainable disposal decisions (88.9% vs. 75.0%, $\chi^2(1, N=101)=3.15, p<.08$). Participants in the luxury (vs. non-luxury) condition reported financial value as a more important motivation ($M=4.98$ vs. 3.43, $F(1,99)=12.38, p=.001$) and their own feelings ($M=3.31$ vs. 4.48, $F(1,99)=8.56,$

$p<.01$) and future use ($M=3.09$ vs. 3.95, $F(1,99)=5.15, p<.05$) as less important. All other motivations were not significantly different.

Study 2 attempts to replicate our results using real brand names as well as test mediation. Participants read a scenario similar to that in study 1. In the luxury (non-luxury) the accessory was a Coach (Target) brand wallet. Participants responded to the same items from study 1 and rated likelihood to make each type of disposal decision. Participants in the luxury condition made more sustainable disposal decisions (88.0% vs. 60.9%, $\chi^2(1, N=96)=9.41, p<.01$), and reported a higher likelihood to make sustainable disposal decisions ($M=6.12$ vs. 4.97, $F(1,94)=9.22, p<.01$). Participants in the luxury condition reported financial value, ($M=5.38$ vs. 3.26, $F(1,94)=23.16, p<.001$), their own feelings ($M=4.78$ vs. 3.39, $F(1,94)=12.22, p=.001$), and others' feelings ($M=5.32$ vs. 3.87, $F(1, 94)=15.48, p<.001$) as more important. Unexpectedly, participants in the luxury condition reported timelessness as less important ($M=2.67$ vs. 3.62, $F(1,94)=5.93, p<.05$). All other motivations were not significantly different. Financial value (95% CI of the indirect effect = .29, 1.29), their own feelings (.24, 1.14), and others' feelings (.38, 1.42) mediated the relationship between luxury good and sustainable disposal decisions (PROCESS model 4; Hayes, 2017).

In study 3, participants imagined getting rid of items as part of a decluttering exercise. They received a box containing seven items. Participants in the luxury (non-luxury) condition received a Coach (unbranded) scarf. Participants made disposal decisions and rated disposal motivations. Perceptions of luxury increased sustainable disposal decisions for the scarf ($\beta=.26, t(77)=2.36, p<.05$) as well as the disposal motivation of financial value ($\beta=.47, t(77)=4.66, p<.001$). All other motivations were not significant. Additionally, perceptions of luxury increased the number of sustainable decisions for the other goods ($\beta=.22, t(77)=2.02, p<.05$) demonstrating a spillover effect.

Donate Your Work: Framing a Monetary Donation Request as Donating Work Increases Donor Responsiveness

Dr. Robert Smith, Tilburg University, Netherlands
Dr. John Costello, Notre Dame, USA
Dr. Alix Barasch, Insead, France

EXTENDED ABSTRACT

Can a monetary donation feel more like a donation of time? Two field and four lab studies demonstrate that asking people to donate their pay from a day's work (vs. equivalent money) increases donor responsiveness, because it makes the requested donation feel both smaller and more representative of the donor.

Charities welcome donations of both money and time, and extensive research has examined the differences in how people think about these resources and potentially donating them to a charity. Expenditures of time and donations of time are considered more personally meaningful, more reflective of moral identity, and more virtuous to people than expenditures and donations of money (Johnson and Park 2021; Liu and Aaker 2008; Mogilner and Aaker 2009; Reed, Aquino, & Levy 2007). People therefore often prefer giving time to giving money (Brown, Meer, and Williams 2018; Costello and Malkoc 2022). Regrettably, donations of time involve more challenges for charities than donations of money (e.g., volunteer training, fungibility). We propose that charities can encourage donations of money by making it feel more like a donation of time. For example, they can ask people to donate a day of their work, where their take-home pay from a day's work at their job is donated to the charity. Six lab studies (three reported here) and two field studies conducted in partnership with actual charities demonstrate the benefits of this novel "money as time-worked" framing strategy. Asking people to "donate your work" increases donation rates and amounts because it makes the requested donation feel both smaller as well as more representative of the donor.

For study 1, we partnered with Tilburg University's fundraising office for their annual fundraising campaign. We randomly assigned alumni to receive either a Donate Money email which was created by the professional fundraisers at the university, or a Donate Work email which was identical, except that it included our money as time-worked framing manipulation, which read "For example, you can 'donate' one working day. With your salary for one day of work you can contribute to the realization of great projects and grants." The Donate Work email produced more positive engagement (e.g., clicks on links to learn about the University fund and how to support it; $p=.035$) and less negative engagement (i.e., clicks on the link to not be called during the fundraiser; $p=.002$).

For Study 2, we partnered with Doctors of the World UK to test whether money as time-worked framing would influence responsiveness to a charity appeal presented in a Facebook advertisement. We made two versions of a fundraising ad to help people affected by a large explosion in Beirut, Lebanon: a Donate Work ad where the appeal is framed as a request to "donate a day of your work," and a Donate Money ad which was otherwise identical but framed the request as "donate your money." The Donate Work ad produced a significantly higher click-through rate ($X^2=12.08$, $p=.002$) and a marginally higher donation rate (13 donations totaling £315) compared to the Donate Money ad (6 donations $X^2=3.35$, $p=.067$, totaling £170).

Participants in Study 3 imagined that they have a full-time job where they earn \$100 take-home pay per day. Participants then considered a donation request from the American Red Cross. Participants in the Donate Work condition read that, "The Red Cross

is asking you to donate a day's work, where your take-home pay from one day's work would go directly to helping victims of disasters." Participants in the donate money condition read that, "The Red Cross is asking you to donate \$100, where your money would go directly to helping victims of disasters." Participants in the donate work condition donated significantly more ($t(278)=4.303$, $p<.001$, $d=.52$), felt that the donation was more representative of themselves ($t(278)=-2.171$, $p=.031$, $d=.26$), and felt that the donation request seemed smaller ($t(278)=5.292$, $p<.001$, $d=.63$) than participants in the donate money condition. Both representativeness of the self and the perceived size of the request mediated the effect.

In study 4, we applied money as time-worked framing to other units of time beyond one day. Participants considered a donation request from UNICEF which was presented in a 2 (Donation Framing: Work vs. Money) X 2 (Requested Amount: Full Day vs. 6 Hours) between-subjects design. The full day conditions were functionally the same as in study 3; the 6 hours conditions were similar, except the requests were for them to "donate 6 hours of work, where your pay from 6 hours of work would go directly to helping children" versus "donate \$120...". The Donate Work condition again yielded significantly higher donations ($F(1,121)=4.402$, $p=.038$, $\eta_p^2=.035$) which was not moderated by the requested amount. Again, both representativeness of the self and perceived size mediated the main effect.

In study 5, we test whether money as time-worked framing is most effective for high wage donors. Participants indicated their daily wage amidst some filler questions, and we piped in the participant's exact daily wage in both conditions, which were otherwise similar to Study 3. Analyses revealed that framing the donation request as a donation of work again significantly increased total donations. This was significantly moderated by wage rate, such that it grew as participants' wage increased, with a floodlight analysis showing that the influence of condition is significant for people making more than \$48.30 per day (64% of the sample). Again, the main effect was mediated by both representativeness of the self and perceived size, with perceived size alone mediating the moderation effect.

These studies demonstrate that charities can increase donations of money when they frame that donation in terms of the time required to earn it. This research has theoretical implications for how consumers generally think about time versus money (Gino and Mogilner 2014; Mogilner and Aaker 2009), and introduces a relatively novel construct of thinking about money in terms of hours worked. Our investigation therefore contributes to several literatures, including research on the framing of charitable appeals, the psychology of time and money. Our work also offers fundraisers a simple yet effective strategy for increasing monetary donations—framing a request for money in terms of a day's work significantly boosts donor responsiveness in real-world donation appeals.

The Unintended Consequences of Raising Awareness: Knowing About the Existence of Algorithmic Racial Bias Widens Racial Inequality

Dr. Shunyuan Zhang, Harvard Business School, Harvard University, USA

Dr. Yang Yang, University of Florida, USA

EXTENDED ABSTRACT

Public awareness of algorithmic bias is important for motivating change, but a longitudinal Airbnb dataset and an experiment reveal an unintended consequence: raising awareness of algorithmic racial bias can deter Black consumers (but not white consumers) from using “good” (i.e., fair and beneficial) algorithms and exacerbate existing racial inequality.

Algorithms have revolutionized almost every industry, but they are not perfect. Algorithmic bias occurs when an algorithm generates unfair outcomes on the basis of sensitive attributes such as race and gender, a situation that threatens social welfare and equity. Algorithmic bias went largely unnoticed by the public—until May 2016, when ProPublica published a study exposing algorithmic racial bias: a widely used recidivism prediction algorithm was twice as likely to mistakenly predict a high risk of recidivism for low-risk Black defendants than for their low-risk white counterparts. The study went viral and triggered a nationwide outrage on social media. It also sparked a series of articles on racial bias in other algorithms, awakening a public horror that algorithms, just like humans, can exhibit racial bias.

Public awareness of algorithmic bias is certainly useful for putting pressure on firms and policymakers to correct injustice in algorithms. We argue, however, that raising public awareness of algorithmic bias may have unintended consequences. Specifically, awareness of algorithmic bias can affect consumers’ reactions to “good” algorithms, namely, algorithms that are fair (i.e., satisfying conditional statistical parity) and beneficial.

Across industries, many algorithms are fair and beneficial. For instance, Zhang et al. (2021) examined Smart Pricing, Airbnb’s free algorithm for hosts, by analyzing the algorithm’s price predictions and impacts on host revenue. The study found that Smart Pricing is both fair and beneficial. The algorithm is “fair” because it recommends similar price adjustments for similar properties, regardless of the host’s race; the algorithm is “beneficial” because hosts earn more when using Smart Pricing than when setting prices themselves.

While research has found that algorithms can be drastically different, we propose that the average consumer, unfortunately, has no insight into the differences among algorithms. Instead, they tend to view different algorithms as homogeneous, due to their lack of understanding of artificial intelligence. Building on the literature on overgeneralization and illusory correlation (Tversky and Kahneman 1974; Baron 1994; Hsee et al. 2019; Risen et al. 2007; Yang et al. 2021), we propose that, when consumers learn that some algorithms are biased against (toward) them, they may overgeneralize that information, and assume that other algorithms are also biased against (toward) them. If so, then awareness of algorithmic racial bias may deter Black consumers (but not white consumers) from adopting “good” algorithms, algorithms that are fair and beneficial, like Smart Pricing.

To understand how awareness of algorithmic racial bias may differentially influence the usage of “good” algorithms among white and Black consumers, we report an analysis of a longitudinal dataset of 8,175 unique Airbnb properties in the US. We investigated how the extensive media coverage of the ProPublica study in May 2016 influenced the usage of Smart Pricing (i.e., a “good” algorithm) among Black and white Airbnb hosts. We found that, before the media event, Black hosts were less likely than white hosts to use Smart Pricing;

after the media event, the racial gap in Smart Pricing usage widened by 61.2%.

We then report a controlled experiment that tested the causal effect of raising awareness of algorithmic racial bias. We found that awareness, whether experimentally-induced or naturally-occurring, discouraged Black consumers (but not white consumers) from using Smart Pricing. Moreover, awareness differentially affected the expected benefits of using the “good” algorithm along racial lines: it increased the expected benefit for white consumers and reduced the expected benefit for Black consumers.

The present studies contribute to several streams of research. First, while the nascent literature on algorithmic bias has greatly advanced our understanding of algorithmic bias per se (Caliskan et al. 2017; Simious et al. 2017; Kallus et al. 2021), no research, to the best of our knowledge, has studied public awareness of algorithmic bias and its consequences. The present research extends the scope of the algorithmic bias literature by investigating how public awareness of algorithmic racial bias may differentially affect the behaviors of consumers of different races. While the conventional wisdom suggests that raising public awareness of a problem should always be beneficial, we find that raising public awareness of algorithmic racial bias can backfire, discouraging disadvantaged consumers from using the technology that would benefit them.

Second, recent work in the consumer behavior literature finds that people may be reluctant to rely on algorithms decisions even when the algorithms clearly outperform humans. Prior research has identified several explanations: People have a lower tolerance for mistakes made by algorithms than for the same mistakes made by humans (Dietvorst et al. 2015). Also, people incorrectly believe that algorithms are less capable of accounting for consumers’ unique situations and characteristics (Longoni et al. 2019) and performing subjective tasks (Castelo et al. 2049). The current research contributes to the literature by discovering a novel cause of algorithm aversion: awareness of algorithmic racial bias. While the previously documented causes suppress the use of algorithms across all racial groups equally, the present research reveals that awareness of algorithmic racial bias deters only the disadvantaged group from adopting algorithms, thereby exacerbating the already-pronounced racial gap in technology adoption.

It is important to note that while overgeneralizing algorithmic bias can lead to serious negative consequences, we should not blame consumers for overgeneralizing, because overgeneralization in this case is entirely due to a lack of information: no firms, to the best of our knowledge, disclose fairness-related information about their algorithms directly to consumers when consumers make adoption decisions; media outlets rarely acknowledge the existence of fair algorithms when exposing unfair algorithms. Under this circumstance, overgeneralizing may be completely rational. Our research has implications for policymakers, firms, and media outlets. Policymakers should encourage firms to disclose fairness-related information to consumers. When consumers have adequate information to discern whether an algorithm is biased, they may be less likely to overgeneralize concerns about publicized instances of algorithmic bias to algorithms that are fair and beneficial. Policymakers should encourage the media to report on algorithmic bias more accurately and responsibly by providing examples of both biased and fair algorithms, raising awareness that not all algorithms are created equal.

Frugality versus Thriftiness: The Gender Difference in Consumer Saving Behaviors

Dr. Ying Bao, University of Illinois at Urbana-Champaign, USA

Dr. Alex Yao, San Diego State University, USA

Dr. He (Michael) Jia, The University of Hong Kong, Hong Kong

Dr. Chen Gong, Nanjing University of Science and Technology, China

EXTENDED ABSTRACT

This paper focuses on the gender difference in consumer saving behaviors. Using a multi-method approach, two studies reveal that females are generally thriftier and lean towards pro-consumption while males are generally more frugal and lean towards anti-consumption. We use experiments to show the generalization and the underlying mechanism.

We live in an era that witnessed rampant consumption, and most consumer research focuses on how to incentivize consumers to make more purchases. The life cycle hypothesis predicts that people choose a level of consumption they can maintain over the course of their lifetimes, independent of their current income. However, during the pandemic, we observed that consumer spending fell sharply, and saving increased more than ever before (Smith 2020). Increasing saving for retirement is one of the most important challenges as the aging population could render public retirement and pension funds insolvent in the future. Saving behaviors are encouraged not only for consumer financial well-being reasons but also for social welfare reasons. Thus, more research switches the focus from encouraging consumer spending to understanding consumer saving.

Related literature suggests two important dimensions of consumer saving behavior: frugality and thriftiness. Although both are used to achieve saving goals and lead to lower monthly spending, researchers argue that these two behaviors need to be distinguished from each other, as frugality is associated with reduced consumption, while thriftiness is associated with finding deals and, therefore, could potentially induce more consumption (Gatersleben et al., 2019; Evans 2011). However, the existing literature fails to examine the role of gender in saving behavior, although gender is an important indicator for many financial decisions (e.g., Gao et al., 2020). We extend the body of literature by examining whether the different saving styles differ systematically between men and women, if so, how and why.

In study 1, We collected data from a popular interest-based forum-like social media platform in China. The platform allows registered users to join groups with similar interests and share their opinions and ideas. Among all the groups, two most popular groups on this platform are “Federation of Female Savers” and “Federation of Male Savers.” While these two groups are for female and male users, respectively, members from both groups share their tips and experiences regarding saving and consumption. We have scraped more than 10,000 posts from both groups and used machine learning algorithms to identify whether female and male members approach the saving problem differently based on their posts. Following the literature (Evans, 2011; Gatersleben et al., 2019), we focused on two types of saving behaviors: frugality and thriftiness. Three steps were taken to classify whether each member is frugal or thrifty based on the posts s/he publishes. *Step 1: training set construction.* Because there is no available training set, we constructed our own training set by hiring three research assistants to label about 2000 subsample posts as “frugality” or “thriftiness.” *Step 2: data training.* We utilized the cutting-edge TF-IDF method for natural language processing to identify relevant keywords/phrases in each post. *Step 3: Topic classification.* We applied several powerful machine learning algorithms to classify the posts into frugality or thriftiness, in-

cluding two types of logistic regression and three types of support vector machine (SVM) analyses. The logistic regression model performs best, with a prediction accuracy of 97.02%. Given the classification results from the machine learning algorithm, we compared the percentage of “thriftiness” and “frugality” posts between female and male groups. Our results suggest that compared to males, female members are more likely to be thrifty (84.24% vs. 59.07%, $p < 0.01$). Compared to females, males are more likely to be frugal (40.93% vs. 15.76%, $p < 0.01$).

One potential limitation of Study 1 is that we used the field data in China to explore the gender difference in saving behaviors, and we do not know whether the results would hold in a different cultural background. To address this issue, we conducted a survey in the United States in Study 2a. Two hundred workers from Prolific were recruited, with 50% females and 50% males. We measured frugality versus thriftiness using a scale adapted from Rick et al. (2008) and used as DV. A regression analysis reveals that after controlling for age, household income, marital status, gender has a substantial and significant effect on frugality. In particular, males tend to focus more on frugality while females tend to focus more on thriftiness ($b = -0.61$, $p < 0.01$). To further explore the process of our main finding, we conducted another survey in the United States in Study 2b and used the ST-TW scale developed by Rick et al. (2008) to measure the pain of payment and find evidence that it mediates our main effect. Specifically, females generally experience a lower pain of payment ($b = 1.24$, $p < 0.1$), which is associated with thriftiness (lower level of frugality) ($b = -0.12$, $p < 0.01$).

This paper makes several contributions. First, it extends the consumer saving literature by providing empirical support for the gender difference. Our findings suggest a systematic difference between males and females in money-saving behavior, closely related to financial wellbeing. Moreover, we detect an important mediator of the gender effect in saving behaviors. These are important discoveries because although gender has been associated with a wide range of consumption-related attitudes and behaviors, its role in saving behavior is unexamined. Managerially, our findings provide important implications to practitioners and policymakers to improve consumer financial well-being and increase sustainability.

The Inclusive Minimalism Effect: Increased Preference for Minimalist Aesthetics in Choices for Shared Consumption

Ms. Cary Anderson, University of Pittsburgh, USA

Dr. Peggy Liu, University of Pittsburgh, USA

Dr. Lauren Min, University of Kansas, USA

EXTENDED ABSTRACT

We identify an “inclusive minimalism effect” wherein consumers believe minimalist (vs. maximalist) aesthetics are more broadly appealing and thus choose minimalist (vs. maximalist) products for shared (vs. solo) consumption. This research thus bridges the literatures on product aesthetics and shared consumption, demonstrating how choosing for shared consumption alters aesthetic preferences.

Though consumption is often social (Belk 2010; Liu, Dallas, and Fitzsimons 2019; Simpson, Griskevicius, and Rothman 2012; Wu, Moore, and Fitzsimons 2019), especially in the modern sharing economy (Eckhardt et al. 2019; Goldsmith and Lambertson 2020), literature on consumer aesthetics predominately focuses on how product aesthetics influence choices for only one person—generally the self (e.g., Batra and Ghoshal 2017; Sevilla and Townsend 2016; Wu et al. 2017). This research examines how consumers make aesthetic decisions for shared (vs. solo) consumption, focusing on choices between products with minimalist (e.g., clean lines, ample whitespace, simple color palettes (Wilson and Bellezza 2022)) versus maximalist aesthetics (e.g., complex textures, bold colors, excess ornamentation (Budds 2020)).

On the one hand, maximalism is historically associated with inclusivity (and minimalism with exclusivity) (Adamson 2019; Keats 2019). However, we predict and find the opposite: that consumers prefer relatively more minimalist (vs. maximalist) product aesthetics for shared (vs. solo) consumption. The “inclusive minimalism effect” occurs because consumers view minimalist products as more broadly appealing across diverse tastes, making them better suited for balancing multiple consumers’ preferences, and thus preferable for shared (vs. solo) consumption. Five pre-registered experiments ($N=2245$) test our hypotheses.

Experiment 1 ($N=371$) tests our key hypothesis that there is an increased preference for minimalist (vs. maximalist) aesthetics for shared (vs. solo) consumption. Participants considered shopping for furnishings for either a solo or shared office and indicated their aesthetic preference (1=maximalist, 6=minimalist). Demonstrating the inclusive minimalism effect, participants preferred minimalist (vs. maximalist) aesthetics more in the shared condition than the solo condition ($M_{\text{shared}}=4.41$, $SD_{\text{shared}}=1.18$ vs. $M_{\text{solo}}=4.04$, $SD_{\text{solo}}=1.40$; $t(369)=2.75$, $p=.006$, $d=.29$).

Experiment 2 ($N=368$) generalizes the inclusive minimalism effect to the increasingly relevant consumption context of the sharing economy. Participants considered decorating a shared (intended to be rented out via Airbnb) or solo vacation home, and viewed images of interior homes pre-defined as minimalist (three images) and maximalist (three images) by interior design tastemakers (Jones 2019; Nemoy 2016). They then selected the image that best represented the aesthetic they would choose when decorating a shared (solo) vacation home. Preference for a minimalist (vs. maximalist) aesthetic was significantly greater when participants considered decorating a home for shared (90.27%) than for solo consumption (63.93%) ($B=1.66$, $\chi^2(1)=38.00$, $p<.001$, $OR=5.23$).

Experiment 3 ($N=387$) examines the process underlying the inclusive minimalism effect. Participants were randomly assigned to consider shopping for a rug for a solo or shared office, before choosing a rug aesthetic (1=maximalist, 6=minimalist). Next, par-

ticipants responded to a 2-item ($r=.80$) mediator measuring focus on broad appeal involving addressing universal tastes. Participants in the shared (vs. solo) condition indicated greater preference for a minimalist (maximalist) rug, $M_{\text{shared}}=4.54$, $SD_{\text{shared}}=1.65$ vs. $M_{\text{solo}}=3.80$, $SD_{\text{solo}}=1.87$; $t(385)=4.15$, $p<.001$, $d=.42$). This effect was significantly mediated by focus on broad appeal ($B=.53$, $SE=.19$, 95% $CI=[.17, .91]$). Participants in the shared ($M=5.92$, $SD=1.04$) versus solo ($M=3.26$, $SD=1.73$) condition were more focused on choosing a product with broad appeal ($B=2.66$, $SE=.15$, 95% $CI=[2.38, 2.95]$), and a greater focus on broad appeal predicted a higher preference for the minimalist (vs. maximalist) option ($B=.20$, $SE=.06$, 95% $CI=[.08, .32]$).

Experiment 4 ($N=555$) tests a process-consistent moderator of the inclusive minimalism effect: the homogeneity (vs. heterogeneity) of aesthetic tastes in shared consumption groups. Participants were randomly assigned to one of three conditions (solo, shared with others with homogenous tastes known to be similar to one’s own, shared with others with heterogeneous tastes) and considered shopping for a wall art print for an office space. Replicating the inclusive minimalism effect, participants in the heterogeneous shared condition showed a greater preference for a minimalist ($M=4.52$, $SD=1.42$) art print, compared to participants in the solo condition ($M=3.80$, $SD=1.77$), $t(552)=4.20$, $p<.001$, $d=.44$. Additionally, participants in the heterogenous shared condition showed a greater preference for a minimalist aesthetic than participants in the homogenous shared condition, $t(552)=3.91$, $p<.001$, $d=.41$. There was no significant difference in aesthetic preference between the solo and homogenous shared conditions—thus, the inclusive minimalism effect is eliminated when the aesthetic tastes of anticipated co-consumers are known and homogeneous.

Experiment 5 ($N=564$) demonstrates that the inclusive minimalism effect is observed when choosing for multiple consumers (vs. one consumer) who will share in consumption, regardless of whether or not the decision-maker will also consume the product. Thus, we varied both whether participants were choosing for one consumer or multiple consumers and also whether they would take part in the consumption of the chosen product. Participants considered shopping for a wall clock that would either be used by one consumer (solo condition) or shared between multiple co-consumers (shared condition). Further, the participant would either be using the product (self-as-consumer) or not (self-not-consumer). Participants indicated their preferred aesthetic (1=maximalist, 6=minimalist) for a wall clock in their assigned consumption scenario. A 2(choice type: solo, shared) 2(self-as-consumer: yes, no) ANOVA on aesthetic preference revealed no significant interaction nor a significant main effect of self-as-consumer. Instead, the analysis revealed only a significant main effect of choice type, such that participants in the shared condition expressed a greater preference for minimalism ($M=4.65$, $SD=1.43$) than participants in the solo condition ($M=4.06$, $SD=1.73$), $F(1, 560)=19.79$, $p<.001$, $\eta^2_p=.034$.

Overall, this research shows that—counter to the historical notion of maximalism as more welcoming and inclusive—choosing for shared (vs. solo) consumption leads to a consistently greater preference for minimalism (vs. maximalism), a novel effect that we call the inclusive minimalism effect. Specifically, consumers believe that

minimalist products are more broadly appealing to diverse aesthetic tastes, and thus they are more likely to select them for shared (vs. solo) consumption. This research offers theoretical contributions to the literature on consumer aesthetics—by showing that consumers’ aesthetic decisions can vary based on whether consumption is shared—and to the burgeoning literature on choices for shared consumption (e.g., Liu et al. 2019; Simpson et al. 2012), by adding visual aesthetics to the identified set of dimensions affected by sharing.

How does Local-global Identity Impact Consumer Preference for Leisure over Work? The Perspective of Production Orientation

Mr. Yu Pan, Shanghai University of Finance and Economics, China

Dr. Huachao Gao, University of Victoria, Canada

Prof. Xiaoyu Wang, Shanghai University of Finance and Economics, China

Ms. Yamei Liu, Shanghai University of Finance and Economics, China

EXTENDED ABSTRACT

This research finds that global-identity consumers prefer work over leisure, whereas the opposite is the case for local-identity consumers. This occurs because global-identity consumers tend to hold stronger productivity orientation, which promotes work-related over leisure-related activities. Framing leisure as productivity-related reverse the proposed effect.

In modern human society, people tend to spend significant more time on work than leisure, leading to emotional exhaustion and cynicism, lower psychological wellbeing, and poorer life quality (Etkin and Memmi 2020; Reichl, Leiter and Spinath 2014). Thus, it is important to examine what factors may explain consumers' choice between work and leisure. Such an understanding not only advances the related literature, but also provides useful guidelines for organizations and public policy makers to enhance consumer wellbeing.

In a work-leisure trade off, work refers to activities that feel productive and provide primarily instrumental benefits (Laran and Janiszewski 2011), whereas leisure refers to activities that feel unproductive and provide primarily hedonic or experiential benefits (Etkin and Memmi 2020). Then, how does consumers' local-global identity impact their work-leisure tradeoffs?

Following Zhang and Khare (2009), we define a local identity as consumers' mental associations with local traditions, local culture, and people in the local community, whereas a global identity as consumers' mental associations with a global culture, exotic traditions, and people around the world. Accordingly, global-identity consumers tend to be more open to diversified experiences, ideas, and values from different parts of the world (Nie et al. 2022). They also tend to meet more unfamiliar people from different cultures, buy or use more unfamiliar products and services, and engage in more novel activities in their lives, compared with their local-identity counterparts (Gao et al. 2017). As a result, global-identity consumers are more likely to experience self-competence doubt due to broader social comparison, cultural or language barrier, or novel way of doing things. In contrast, local-identity consumers are less likely to have such experiences given their focus on their local community and neighborhood, which tend to be more familiar and less challenging (Zhang and Khare 2009).

Consequently, global-identity consumers are more motivated to address their competence challenges by focusing on productivity orientation, which is defined as the aspire for progress and achievements in multiple domains (Keinan and Kivetz 2011). Given productivity orientation encourages work and discourages leisure (Laran and Janiszewski 2011), we predict that global-identity consumers tend to be more productivity oriented, leading them to prefer work over leisure.

We test the theory with five studies. Study 1 utilized secondary data from a national tourist and leisure survey, which measured the average hours per day spent on leisure activities. We operationalized local-global identity with residential area with larger cities indicating stronger global identity (Gao et al. 2017). The results indicated that, consumers from larger cities (vs. rural area) or stronger global (vs. local) identity tend to spend less time on leisure activities.

Study 2 provided causal test for the effect with experimental design. We first manipulated local-global identity following Zhang and Khare (2009). Then, we asked consumers to choose between leisure versus work activities. The results indicated that global-identity consumers are more likely to choose work-related activities, whereas local-identity consumers are more likely to choose leisure activities. Study 3 further replicated the findings from Study 2. More importantly, Study 3 showed direct evidence for the mediating role of productivity orientation.

In Study 4, we tested the mediating role of productivity orientation by directly manipulating it. This study was a 2 (identity: local vs. global) \times 2 (leisure option: control vs. productive) between-subjects-designed experiment. Besides completing the local-global identity manipulation (Gao et al. 2017), we also framed the leisure option as either leisure (i.e., control) or a productive activity. The results replicated the effect of local-global identity on work-leisure preference in the control condition. In contrast, in the productivity condition, the effect was attenuated, supporting our prediction.

In Study 5, we tested the moderating role of open mindset. According to our theory, if we create a salient open mindset, all consumers regardless of their local-global identity levels should exhibit stronger productivity orientation and thus preference for work over leisure activities. In this study, we manipulated both local-global identity and open versus control mindset. Then, we measured consumers' preferences between work versus leisure activities. The results indicated that among local-identity consumers, manipulating open mindset significantly boosted their preference for work over leisure. In contrast, global-identity consumers showed similar work-leisure preference regardless of mindset, supporting our theory.

This research makes several contributions to the related literature. First, it contributes to the understudied phenomenon of work-leisure tradeoff by identifying consumer identity as a new antecedent. Second, it advances the local-global identity literature by introducing it into a new area of study. Third, we discover productivity orientation as a key mechanism behind the effect of local-global identity on work-leisure tradeoff, which extends the study on productivity orientation in marketing.

Furthermore, this research offers practically useful strategies for companies and public policy makers. For instance, in marketing leisure-focused products such as theme park, vocation package, or other entertainments, companies could benefit from activating consumers' local identity. For consumers with strong global identity, these companies may want to frame the leisure activities as a way to enhance productivity.

Don't trust what you see: The consequences of deepfake videos for consumer evaluation of firms and their representatives.

Mr. Jeremy Fannin, HEC Lausanne, University of Lausanne, Switzerland
Prof. Tobias Schlager, University of Lausanne, Switzerland
Dr. Gita Johar, Columbia University, USA

EXTENDED ABSTRACT

This paper studies the psychological and behavioral impact of deepfakes (i.e., synthetically generated content) on consumer evaluations. Through four studies, deepfakes negatively impact consumer evaluations of a CEO. Moreover, suspicion acts as an attenuation mechanism reducing the impact. However, consumers do not return evaluations to baseline even when warned beforehand.

INTRODUCTION

Imagine seeing Mark Zuckerberg tell you he wants to steal your data (Posters 2020), or Richard Nixon give a stirring speech on a failed moon landing (DelViscio 2020). While these events never happened, advancements in artificial intelligence technology have introduced the phenomenon of 'deepfakes', which produce realistic depictions of situations (Chesney and Citron 2018; Korshunov and Marcel 2018). Deepfakes are "hyper-realistic videos [audio files, and images], [synthetically] manipulated to depict people saying and doing things that never actually happened" (Westerlund 2019; pp.40). Much of the work involving deepfakes is technical (Albahar and Almalki 2005; Yang, Li, and Lyu 2019; Li and Lyu 2018) or aimed at the societal, political, and legal impact (Vaccari and Chadwick 2020; Dobber et al. 2021; Mara and Alexandrou 2018). This paper is one of the first to explore the impact on consumer responses at the individual level. Moreover, this paper applies non-technical intervention techniques utilizing psychological processes (i.e., suspicion) to attenuate the negative effects of exposure. Detection software has shown to be ineffective thus far (e.g., 65% accuracy for the Facebook competition; Collins and Ebrahimi 2021), therefore, a variety of approaches must be explored to appropriately respond to this novel phenomenon.

We conceptualize deepfakes as videos, audio files, or images that (1) realistically mimic a person's bodily movements, facial features, and voice patterns, (2) convey false and novel (i.e., surprising) information, (3) are incongruent with people's view of what the person would typically express, (4) and are nonconsensual, with harmful intent (i.e., negative as boundary condition). We show support for this conceptualization in Pilot Study 2, which for purposes of length is not included in this abstract. We utilize suspicion, which describes "a person's simultaneous state of cognitive activity, uncertainty, and perceived malintent about underlying information" (Bobko et al. 2014), as an important psychological process and attenuation mechanism. The following are results from three separate empirical studies.

Pilot Study 1

The aim of the pilot study is to provide preliminary evidence on the characteristics of deepfake videos. Three hundred and three US participants (Median_{age} = 35-44, 56.33% female) were recruited from MTurk for this within-subjects experiment. Participants were exposed to one fake news article found on politifact.com, then randomly exposed to 5 videos – a mix between real and deepfake. After the article and each video, participants responded to various measures including suspicion and surprise of the articulation of the message. Linear mixed models reveal that deepfake videos result in higher levels of suspicion compared to both fake news and real videos ($M_{\text{Deepfake}} = 5.22$, $M_{\text{FakeNews}} = 4.35$, $M_{\text{RealVideo}} = 3.27$; $B_{\Delta\text{Deepfake-FakeNews}} = 0.87$, $t = 8.12$, $p < 0.001$; $B_{\Delta\text{Deepfake-Real}} = 1.95$, $t = 17.87$, $p < 0.001$). In addition, deepfakes were significantly more surprising in terms of articulation of the message ($M_{\text{Deepfake}} = 4.30$,

$M_{\text{FakeNews}} = 4.07$; $B_{\Delta\text{Deepfake-FakeNews}} = 0.23$, $t = 2.55$, $p = 0.029$). Thus, this study gives us indications of two potential psychological processes of exposure (i.e., suspicion and surprise of articulation).

Study 1

This study aimed to observe deepfakes effect on consumer evaluations towards company representatives. Using 600 US participants (Median_{age} = 35-44, 53.41% female) on Mturk, participants were randomly assigned to one of the three conditions (video vs. text vs. audio), using a viral deepfake found online of Mark Zuckerberg (Posters 2020). A one-way ANOVA shows a significant difference in evaluations following exposure of a deepfake ($M_{\text{Audio}} = 26.65$, $M_{\text{Text}} = 28.81$, $M_{\text{Video}} = 23.25$; $F(2, 599) = 3.16$, $p = 0.043$). A Tukey post hoc test shows a significant difference between text and video ($M_{\text{Text}} = 28.81$, $M_{\text{Video}} = 23.25$, $95CI[-10.78, -0.32]$, $p = 0.034$), but not between video and audio. A separate one-way ANOVA shows a significant difference between type of fake content and suspicion ($M_{\text{Audio}} = 3.88$, $M_{\text{Text}} = 3.99$, $M_{\text{Video}} = 4.27$; $F(2, 599) = 9.88$, $p < 0.001$). A Tukey post hoc test supports this finding such that the video is significantly more suspicious than text (*Text-Video*: $95CI[0.06, 0.49]$, $p = 0.005$), as well as audio (*Video-Audio*: $95CI[0.17, 0.60]$, $p < 0.001$). Thus, Study 1 proved that deepfake videos are more impactful on consumer evaluations, as well as generate a higher level of suspicion.

Study 2

The aim of Study 2 was to observe the effect of suspicion by using a priming method found in Kirmani and Zhu (2007), to increase general suspicion prior to exposure. Four hundred and ninety-eight US participants (Median_{age} = 35-44, 62.37% female) were recruited from Mturk for this 2 (fake video vs. fake audio) x 2 (primed vs. not primed) + 1 control between-subjects experiment. To control for underlying biases towards Mark Zuckerberg, we developed a deepfake video and audio file of a fictitious CEO using the open-source generator, deepfakesweb.org. We built up both the CEO and brand using fictitious news articles. This study also manipulated suspicion by randomly priming individuals prior to exposure with general knowledge of media manipulation. Our results reveal that priming individuals with suspicion prior to exposure has a positive impact on evaluations of the targeted CEO ($M_{\text{Primed}} = 29.79$, $M_{\text{NotPrimed}} = 20.19$, $F(1,378) = 12.04$, $p = 0.0005$), regardless of medium ($F(1,376) = 0.10$, $p = 0.750$). However, we show that evaluations do not return to baseline control.

DISCUSSION

Through two studies and one pilot study, we have been able to show that deepfakes present a novel danger to the reputation of company representative. These insights are important for companies associated to human brands, such as Mark Zuckerberg and Facebook. A deepfake, regardless of medium, has the potential to significantly harm the reputation of these public figures. Our research also uncovers two potential psychological processes of exposure, suspicion and surprise. The former is an important attenuation mechanism reducing the impact of exposure. However, the main limitations to our studies thus far is the failure to return evaluations to baseline. Thus, further studies within this project and future projects must continue to explore non-technical intervention techniques which completely eliminate the negative effects of exposure to deepfake content.

BOGO Frees You: Promotions and Adventurous Product Choices

Mr. Junha Kim, The Ohio State University, USA

Dr. Joe Goodman, The Ohio State University, USA

Dr. Selin Malkoc, The Ohio State University, USA

EXTENDED ABSTRACT

Brands increasingly offer adventurous options (e.g., carrot ginger yogurt or cappuccino chips), and marketers often introduce new and novel variants to attract consumers' attention and satisfy variety-seeking needs. To encourage consumers to try these new products, marketers try to lower to cost to do so by employing various promotions (Kotler & Armstrong, 2010). Indeed, promotions can be effective tools to encourage consumers to switch brands, accelerate their repurchases, and stockpile, increasing basket sizes and ultimately consumer spending (Foubert & Gijbrecchts, 2007; Gupta, 1988; Kahn & Louie, 1990; Van Heerde, Gupta, & Wittink, 2003).

However, consumers' reactions to different types of promotional offers vary (Chen, Marmorstein, Tsiros, & Rao, 2012; Hardesty & Bearden, 2003; Kahn & Raju, 1991; Mishra & Mishra, 2011). For instance, while price discount promotions (e.g., 50% price off) and quantity discount promotions (e.g., buy-one-get-one-free or BOGO) offer similar levels of monetary savings to consumers, consumers' reaction to a "free" product is psychologically distinct (Shampanier, Mazur, & Ariely, 2007).

Building on this prior research, we propose and demonstrate that BOGO (vs. 50% off) can be more effective in driving adventurous product choices (controlling for the quantity purchased). This is because free entails no direct monetary cost, but only benefits, which invokes more positive affect and leads to affective (vs. cognitive) processing (Shampanier et al., 2007).

Critically, consumers who engage in affective processing are more likely to be risk-seeking and impulsive (Metcalfe & Mischel, 1999; Sloman, 1996), which suggests that BOGO promotions might be more effective in encouraging consumers to try novel and adventurous products.

Likewise, mental accounting literature shows that potential loss from free choices has relatively lower psychological value and thus might not require opening of a new account (Thaler & Johnson, 1990). Since there is no cost to open a new account, there is also no need to close the account with positive value (i.e., a positive outcome), allowing consumers to experiment with adventurous products that might have a potential downside. Taken together, we propose that a BOGO quantity promotion encourages consumers to engage in affective processing, which increases the choice share of adventurous options. In contrast, a 50% off pricing promotion encourages consumers to engage in cognitive processing because choices still entail cost, which decreases the choice share of adventurous options. Five studies provide empirical support for these predictions by demonstrating that a quantity discount increases the choice of adventurous options compared to a similar pricing promotion, while also testing the proposed process based on affective processing.

STUDY 1A

Method

In a 2 (promotion: BOGO vs. 50% off) between-subjects design, 320 undergraduates who were presented with ten yogurt flavors choose any combination of six. In the BOGO condition, three choices were made at regular price (simply labeled as yogurt 1, 2, and 3) and latter three choices were labeled as free. In the 50% off condition, all six choices were labeled as '50% off'. Among ten flavors, six (strawberry, peach, blueberry, raspberry, honey, and vanilla)

were pre-tested as more traditional and less adventurous while four (pumpkin, jalapeño, sriracha, and carrot ginger) were rated as less traditional and more adventurous. We used the number of adventurous flavors chosen as the dependent variable and analyzed it with a Poisson regression since the dependent variable had a non-normal distribution.

RESULTS AND DISCUSSION

As would be expected, there was no difference in the number of adventurous options chosen in the first three choices (labeled 'full price' or '50% off', respectively; $M_{\text{BOGO}} = .11$ vs. $M_{\text{50%off}} = .09$, $Wald\ x^2 = .27$, $p = .60$); however, in the last three choices (labeled 'free' or '50% off') participants choose more adventurous options in the BOGO condition ($M = .29$) than in the 50% off condition ($M = .18$, $Wald\ x^2 = 3.79$, $p = .05$). These results provide initial evidence that BOGO is driving adventurous product choices more than economically equivalent price discounts.

STUDY 1B

One potential explanation to the effect could be due to differences in assortment size, or changes in the perception of variety with unfamiliar options (Broniarczyk, Hoyer, & McAlister, 1998). To examine this potential explanation and test the generalizability of our effect, study 1B expanded and manipulated the assortment size.

Method

In a 2 (promotion: BOGO vs. 50% off) x 2 (assortment size: small vs. large) between subjects design, 196 undergraduates made six yogurt choices. To manipulate assortment size, participants chose from either 25 or 5 different flavors. In the large assortment condition 10 were more adventurous, and in the small assortment condition 2 were adventurous. In this study, we first asked participants to choose three yogurts without any information about promotional offers. After they made these three choices, participants were informed that there was a promotion going on (either BOGO or 50% off) and so they decided to buy three more yogurts and asked them to indicate what they would choose.

RESULTS AND DISCUSSION

Examining the first three choices, we found main effects of promotion and assortment size ($Wald\ x^2_{\text{promotion}} = .62$, $p = .431$; $Wald\ x^2_{\text{assortment}} = .50$, $p = .497$), as expected. There was also no interaction ($Wald\ x^2_{\text{interaction}} = .10$, $p = .754$). Nevertheless, we controlled for their first three choices (results did not change when we eliminated this control), and found that in the last three choices participants choose more adventurous options in the BOGO condition ($M = .52$) than in the 50% off condition ($M = .28$, $Wald\ x^2 = 14.67$, $p < .001$). The interaction with assortment size was not significant ($Wald\ x^2 = 1.12$, $p = .291$), suggesting that the effect generalizes to different assortment sizes.

STUDY 1C

Next, we examined the potential role of non-monetary opportunity cost. When facing "free" choices, consumers might focus solely on the lack of monetary costs and neglect associated opportunity cost. If so, realization of opportunity cost might lead consumers to perceive free choices psychologically differently, thus eliminating

the BOGO effect. In the next study, we test this potential psychological mechanism.

Method

In a 2 (promotion: price discount vs. quantity discount) x 2 (opportunity costs: small vs. large) between subject design, 322 undergraduates made six yogurt choices. In both conditions, we first asked participants to estimate the average price of yogurt. In the small opportunity cost condition, we told the participants that the actual average price of a yogurt was this number multiplied by 0.9. In the large opportunity cost condition, the multiplier was 1.5. This manipulation was designed to make the opportunity cost salient and we reasoned that when participants realize that the actual price is much higher than their estimation, they would be more thoughtful and possibly take less risks. After the estimation task and getting the feedback, participants saw the promotion and chose six yogurts from an assortment of 10 (as in study 1).

RESULTS AND DISCUSSION

For the first three choices, we did not observe main effects for promotion type or for opportunity cost ($Wald x^2_{promotion} = .02, p = .880$; $Wald x^2_{opportunity_cost} = .22, p = .641$). There was also no interaction ($Wald x^2_{interaction} = .43, p = .514$). Nevertheless, we controlled for the first three choices (results did not change when we did not include this control), and again found that in the last three choices participants choose more adventurous options in the BOGO condition (MBOGO = .39) than in the 50% off condition ($M_{50\%off} = .23, Wald x^2 = 6.56, p = .010$). The main effect of opportunity cost was not significant ($Wald x^2 = 1.21, p = .271$), nor was the interaction with opportunity cost ($Wald x^2 = .15, p = .700$). These results suggest that the effect does not depend on making the opportunity cost salient or not.

STUDY 2

Study 2 tested whether the effect was driven by BOGO increasing adventurous choices or 50% decreasing it, while also ruling out alternative accounts based on several individual differences (e.g., exploratory buying behavior, deal proneness, etc.).

Method

In a 3-cell (promotion: BOGO vs. 50% off vs. control) study, 443 Mturk participants were presented with the same assortment of 10 yogurt flavors. As in study 1B, participants made their first three choices in absence of a promotion. Upon the completion of this choice, they were informed that there was an ongoing promotion so they decided to buying three more yogurts. In the control condition, participants were simply told that they decided to buy three more yogurts. After making all choices, we measured individual traits, using scales of risk perception (Weber, Blais, & Betz, 2002), exploratory buying behavior (Baumgartner & Steenkamp, 1996), deal proneness (Lichtenstein, Burton, & Netemeyer, 1997), emotional stability and openness to experience (Gosling, Rentfrow, & Swann Jr, 2003), and tightwad-spendthrift (Rick, Cryder, & Loewenstein, 2007).

RESULTS AND DISCUSSION

We used orthogonal contrast coding to partition the sum of squares for the 3-cell design (contrast1: -1 = 50% off and control conditions, 2 = BOGO condition; contrast2: -1 = 50% off condition, 0 = BOGO condition, 1 = control condition).

We first looked at the first three choices (which did not receive the manipulation), and, unexpectedly, there was a significant difference on the number of adventurous options chosen ($Wald x^2 = 8.63, p = .013$): participants choose more adventurous options in the

BOGO condition ($M = .26$) than the other two conditions ($M_{50\%off} = .17, M_{control} = .14$; $b_{contrast1} = .18, SE = .06, Wald x^2 = 8.23, p = .004$). The 50% off condition and control condition did not differ ($b_{contrast2} = -.11, SE = .13, Wald x^2 = .71, p = .400$).

We next examined the last three choices (which received the manipulation), while also controlling for the first three choices, and found that participants choose more adventurous options in the BOGO condition ($M = .36$) than the other two conditions ($M_{50\%off} = .21, M_{control} = .27$; $b_{contrast1} = .13, SE = .05, Wald x^2 = 7.27, p = .007$). The 50% off condition and control condition did not differ ($b_{contrast2} = .12, SE = .10, Wald x^2 = 1.51, p = .219$). Not surprisingly, the number of adventurous options in the first three choices predicted the number of adventurous options in the last three choices ($b = .78, SE = .09, Wald x^2 = 82.80, p < .001$). However, the pattern of results remained the same when we did not control for the first three choices: Participants choose more adventurous options in BOGO than the other two conditions ($b_{contrast1} = .18, SE = .05, Wald x^2 = 14.01, p < .001$), and the 50% off and control conditions did not differ ($b_{contrast2} = .07, SE = .10, Wald x^2 = .54, p = .464$).

Further, none of the individual measures moderated this effect ($ps > .13$), suggesting that the effect generalizes beyond a subset of consumers. It is also preliminary evidence that the effect is not due to differences in chronic risk perception, exploratory buying behavior, deal proneness, openness to experience, or and tightwad-spendthrift beliefs.

STUDY 3

Studies so far established that BOGO encourages adventurous options more than 50% off and ruled out potential explanations. However, we have not yet provided evidence for “free” discount in BOGO driving the results via greater affective processing. Study 3 tested this mechanism by encouraging participants to engage in additional cognitive thought, which blocks consumers’ ability to engage in affective processing (Shiv & Fedorikhin, 1999). Thus, we expected the effect to be mitigated in the cognitive processing condition, where participants could not process affectively.

Method

In a 2 (promotion: BOGO vs. 50% off) x 2 (processing style: control vs. cognitive) between-subjects design, 284 undergraduates chose four chips from an assortment of twelve either under BOGO or 50% off promotion. A pretest showed that 7 flavors (classic, barbecue, salt & vinegar, sour cream & onion, lightly salted, wavy ranch) were less adventurous, and 5 flavors (cappuccino, cheddar bacon mac & cheese, Chesapeake Bay crab spice, chile limón, wavy mango salsa) were more adventurous. In the cognitive processing condition, we asked participants to write why they made their flavor choices – what they were thinking, and what consideration they had. In the control condition, participants were asked to write the last time they had chips.

RESULTS AND DISCUSSION

Using a Poisson regression controlling for the first two choices we again found that in the last two choices participants choose more adventurous options in the BOGO condition ($M = .57$) than in the 50% off condition ($M = .38, Wald x^2 = 5.38, p = .020$). Importantly, the interaction with type of processing was significant ($Wald x^2 = 5.70, p = .017$). Specifically, while BOGO led to significantly more adventurous choices in the control condition ($M_{BOGO} = .65$ vs. $M_{50\%off} = .28, p = .001$), this was not the case in the cognitive processing condition ($M_{BOGO} = .51$ vs. $M_{50\%off} = .50, p = .960$). Using a process-by-moderation approach (Spencer, Zanna, & Fong, 2005), this study

provides process evidence for affective as the driver of the increased adventurous option choices under BOGO.

GENERAL DISCUSSION

Across five studies we find that consumers are more likely to choose adventurous options with a quantity promotion (i.e., BOGO free) than an equivalent price promotion (i.e., 50% off). Study 1B and 1C provide robust evidence of the effect across different situations (when assortments are both large and small and when opportunity costs are made salient) and rule out alternative accounts. Study 2 suggests that it is the BOGO that increases adventurous choices rather than the 50% off decreasing adventurous choices. Further, study 3 shows that the effect of the BOGO was mitigated when consumers predominantly engage in a cognitive processing, suggesting that the effect is, at least partially, driven by processing type: promotions framed as “free” encourage consumer to engage in affective processing and the trial of new flavors/variants.

A Consumer's Perspective on Online Search When Using a Search Engine

Dr. Sarah Whitley, University of Georgia, USA

Dr. Anindita Chakravarty, University of Georgia, USA

Ms. Lan Anh Ton, University of Georgia, USA

Dr. Pengyuan Wang, University of Georgia, USA

EXTENDED ABSTRACT

We take a consumer's perspective on the process of online search via a search engine. In doing so, we find that how one feels (i.e., their emotion state) at search initiation drives the choice of words used in their search query, and that these words dictate paid search ad clicks.

51% of all online consumers use search engines for product or service search in any month (Global Web Index Report 2020), yet our understanding of this search behavior in marketing is not only limited but also primarily one-sided. Most of the work on online search via a search engine has focused on this ubiquitous search process from a managers' perspective, examining click rates and keyword targeting strategies (Ghose and Yang 2009; Rutz, Trusov, and Bucklin 2011; Joo, Wilbur, and Zhu 2016; Lu and Zhao 2014; Jerath, Ma, and Park 2014; Agarwal and Mukhopadhyay 2016). However, scant work has actually sought to investigate this search behavior from the consumer's perspective.

In this research, we examine online search via a search engine from the vantage point of the consumer, specifically with regard to what impacts the choice of words used to articulate what they are looking for on a search engine. We suggest that how a consumer feels (i.e., their emotion state) at the initiation of search influences the words they use to describe their desired product. Since search engines themselves promote an algorithmic form of search, such that consumers seek to evaluate search results in terms of their matching ability with their search query text, we suggest that the search process via a search engine is cognitive rather than affective in nature. Accordingly, we suggest that one's emotion state influences their online search process via the words chosen in their search query through a cognitive rather than affective process. Specifically, that one's emotion state primes emotion-related words in their available memory (i.e., affect priming; Forgas 1995), increasing the likelihood they will employ emotion-based descriptors in their search query to articulate their desired product (e.g., exciting book).

Product descriptors are consequential in the context of search engines as the words employed in one's search query text not only influence the organic search results a consumer obtains but also whether they are targeted by paid search advertising. Thus, a consumer's response to search results should also be contingent on elements of the words chosen to describe their desired product in their search query text. We suggest that the use of an emotion descriptor leads to the perception that the product they are seeking is perceived to be uncommon or unique, and as a result, consumers perceive targeted paid search ads in their search results for this unique search query to be more relevant, increasing their likelihood to click on the ads. Across nine studies, we examine this multi-stage process of online search via a search engine.

In a pilot test, 458 Mturkers were randomly induced into either a positive, negative, or neutral emotion, before being asked to think about a product they were currently interested in purchasing and told to write down (free response form) the text of the query they would put in the search bar. Responses were coded for containing emotion descriptors (i.e., emotion adjectives), and participants in a positive (19.0%; $Wald=2.76, p=.097$) and negative (19.9%; $Wald=3.49, p=.062$) emotion state were more likely to employ emotion descrip-

tors than those in a neutral state. We replicated this same pattern of findings using a more controlled design and search task for a water bottle (Study 1A) and book (Study 1B).

Study 2 tested for the cognitive process of affect priming driving the observed effect. We randomly induced 605 Mturk participants into a positive, negative, or neutral emotion state and assessed the perceived availability of emotion-based words in their memory by having them write down three adjectives that come to mind when thinking about a book. As predicted, a poisson regression examining the number of times participants used an emotion descriptor, found that those in the positive emotion condition ($Wald=5.65, p=.017$) listed significantly more emotion descriptors than those in the neutral condition; participants in the negative emotion condition listed moderately more ($Wald=2.87, p=.090$). Additionally, we a replication of study 1B involving purchasing a book for another person (study WA1), rather than the self, provided evidence against an alternative account that affect regulation rather than affect priming drives this effect of emotion on descriptor use.

We next assess how this choice of descriptors impacts consumers' responses to search results, specifically paid search advertisements. As an initial assessment, in study 3A we extracted a random sample of search queries generated on a search engine platform that contained emotion descriptors of products and compared the CTR's of those queries with matched queries from the same time frame for the same product but without the emotion descriptor. Across 3,277 pairs of search queries, the observed CTR was higher for queries containing emotion descriptors ($CTR=.09$) than those without ($CTR=.05; t=10.15, p<.001$), giving initial evidence for the effect of emotion descriptor use on paid search ad click behavior. We examined this same effect experimentally in study 3B, replicating the search process using a 2 (emotion: positive vs. negative) x 2 (descriptor: emotion vs. non-emotion) between-subjects design. Emotion condition did not influence ad clicks ($(1)=.054, p=.817$) and thus results were collapsed across emotion. In line with our hypothesis, participants using an emotion descriptor (21.6%) were more likely to click on the ad than those using a non-emotion descriptor (15.7%; $(1)=4.67, p=.031$). Using a similar design while also measuring perceived uniqueness of one's search and ad relevance (Study 4) found these two variables produced a significant serial mediation model ($b=.03, SE=.01, CI_{95} [.011, .050]$).

Lastly, study 5 tested the validity of this search engine customer journey by inducing 604 Prolific participants into an emotion state (positive vs. neutral), having them engage in a descriptor choice task (analogous to studies 1A-1B) and then click on links from a set of search results (analogous to studies 3B-4). A causal pathway test the z-score process for 3 categorical variables (Iacobucci 2012). Our analysis confirming that emotion descriptor choice underlies the connection between emotion state and paid search ad clicks (significant $Z_{mediation}$ score of 3.35).

Overall, our findings provide a consumer-focused perspective on the journey of engaging in online search via a search engine.

The Design Communication Assessment Scale (DCAS): Assessing and Adjusting the Effectiveness of Product Design Communications

Dr. Kevin L. Sample, University of Rhode Island, USA

Dr. John Hulland, University of Georgia, USA

Prof. Julio Sevilla, University of Georgia, USA

Dr. Lauren I. Labrecque, University of Rhode Island, USA

EXTENDED ABSTRACT

We integrate design theory and well-established scale development procedures to develop a reliable and valid instrument that measures consumer evaluations of design communication (i.e., the product, packaging, or advertisements). We demonstrate increased intentions and even actual sales on Amazon by using our scale to gauge consumer evaluations of design communications.

Be it the actual product, packaging, or advertisements, all communicate information regarding product design. Yet, marketers can often be left wondering if their communicative efforts are left unheard. That is, do consumers truly understand what a product design does and the benefits it provides? To address this issue, our research integrates marketing literature, design theory, interviews with world-renowned designers, and well-established scale development procedures to develop a reliable and valid instrument that measures consumer evaluations of design communication.

Traditional design methods provide substantial aid in the development of product designs, yet new products still fail at high rates. Whereas the reasons for failure are numerous, one of the primary causes is an inability to effectively communicate product design information to consumers. If a consumer does not understand what a product does or how it may provide benefits, then that product will most likely not even enter a consumer's consideration set.

Whereas prior product design scale papers have been developed to help understand the potential success of product designs, the information provided by prior scales does not allow a designer to appropriately respond to any deficiencies. That is, these prior instruments do not use design theory or common design terms, thus leaving designers with little guidance. Further, product design success or failure is contingent on more than just the product design itself. Every aspect of communication surrounding a product design (i.e., the information communicated via the product design itself, the packaging, and advertisements) needs to be considered when optimizing product design success. Thus, to better address this gap, we utilize a designer lens to develop a scale that measures consumer evaluations of design communications (i.e., the various elements that convey information about product designs), establishing an enhanced ability to predict important outcomes

We propose a new Design Communication Assessment Scale (DCAS) anchored in centuries-old design theories that provides more actionable insights than current alternatives so that marketers might appropriately engage with designers to increase effectiveness. Further, the utilization of these theories expands the nomological network that prior work associates with design to a network that more accurately captures how designs are understood by designers – those that will be adjusting design communications. In a crowded market, where marketers are utilizing and consumers are increasingly relying on visuals, it is imperative that marketers can assess and adjust the effectiveness of their design communications. Our multi-dimensional scale allows for this.

Empirically, we engage in traditional scale development procedures via three different stages. The purpose of stage 1 is to develop a reliable and valid scale that reflects the seven dimensions embedded in our conceptual model regarding design communication evaluations. This stage encompasses item generation, followed by assessments of convergent validity, predictive validity, and face validity. Stage 2 establishes the scale's discriminant validity, temporal stability, nomological validity, further predictive validity, and experimental validity. Finally, in stage 3, we demonstrate the generalizability and applicability of DCAS

across two laboratory-controlled studies and establish the real-world validity of this instrument via a field study where increased traffic, orders, and sales were realized for two different products solely sold on Amazon. Consequently, the contributions of our work are both theoretical and practical.

Theoretically, we develop an enriched framework utilizing marketing insights to reconcile and categorize two long-standing design theories. We demonstrate that designs are evaluated via two primary dimensions: the intrinsic (form and function) and the extrinsic (solidity, usefulness, style, eco-consciousness, and uniqueness). The intrinsic dimensions encompass the inherent aspects of a design utilized to determine what a product does, whereas the extrinsic dimensions are utilized to evaluate the benefits that a product could provide to a consumer. For example, the manifestation and ability (i.e., form and function) of a blender are utilized by consumers to determine what it is (i.e., the intrinsic), whereas the appeal as compared to other blenders is utilized by consumers to determine the greater desirability compared to alternatives. Collectively, consumer evaluations of designs can be accurately measured if there is an understanding of both the intrinsic and extrinsic dimensions. To pinpoint what constitutes these extrinsic and intrinsic dimensions of design, we investigated the roots of design theorizing. This endeavor revealed consistent usage of two centuries-old design theories (form follows function and the Vitruvian Triad) that have helped inform current design theorists, but until now these two theories have never been united into a cohesive framework. Further, we demonstrate how two new dimensions, eco-consciousness and uniqueness, have emerged as important aspects for consumers since the development of those long-standing design theories. These actions, enabled through the integration of designer input and marketing theory, provide novel theoretical insights into consumers' evaluations of design communications.

Practically, our work offers an actionable tool for marketers that can improve design communications. By utilizing DCAS, a firm can pinpoint the dimensions of a design that are (or are not) being effectively communicated to consumers, a crucial contribution as designs are more likely to succeed when marketers can promptly respond to consumer insights and experiences. Additionally, our tool uses a common language that designers understand, thereby allowing them the ability to better adjust designs. Consequently, DCAS represents an evaluative bridge that can help marketers engage with designers, gauge latent consumer desires, and respond accordingly in the creation or adjustment of design communications, regardless of product category.

The theoretical underpinnings and face validity engaged in the development of DCAS progresses the field's understanding as to what constitutes the evaluative dimensions of design. We produce a scale that can assess consumer evaluations of product design communications by integrating long-standing design theories with marketing insights. Through the course of our work, we demonstrate the reliability and validity of our scale, along with its higher effectiveness over alternatives. We provide substantial theoretical and practical contributions to the marketing discipline and provide real-world evidence of how our instrument can be effectively utilized to help avoid failure and increase the likelihood of success. We hope that the introduction of DCAS can facilitate a more accurate and comprehensive understanding of design communications hitherto unavailable.

Disentangling Product Comparisons with the Attribute-Hedonic Model

Dr. Zac Arens, Oklahoma State University, USA

EXTENDED ABSTRACT

This research shows that when consumers compare products the context effects for hedonic judgments and attribute judgments operate differently. Whereas attribute judgments contrast with a standard, hedonic judgments assimilate. Because the two judgments are interrelated, it often creates the misleading appearance of a hedonic contrast effect.

Disentangling Product Comparisons with the Attribute-Hedonic Model

Marketers often try to influence how consumers compare products. For instance, many realtors show homes to buyers in a particular order; scheduling the undesirable homes first to make subsequent homes look better (Cialdini 2007). Similarly, Prego spaghetti sauce ran a successful advertising campaign in the early 1990s, comparing its own product with their competitor, Ragu (Pollack 1996). In one commercial, Ragu's sauce appears thin and unappetizing as it seeps into a bowl of pasta, in contrast making Prego's chunkier sauce appear "thicker, more delicious." The widely accepted explanation for these types of situations is a negative effect between expected enjoyment, known as the hedonic contrast hypothesis (Novemsky and Ratner 2003). Substantial evidence appears to support the hedonic contrast hypothesis. Vacation destinations seem more enjoyable compared to unpleasant destinations than pleasant ones (Raghunathan and Irwin 2001). Beverages taste worse when compared to a delicious one (Zellner et al. 2003). Yet, substantial also evidence suggests the opposite. Sometimes beverages taste better when compared to a delicious one (Ghoshal et al. 2014). Faces appear more attractive when compared to attractive than unattractive houses (Carragher et al. 2019). And consumers spend more on products associated with a favorable celebrity than an unfavorable celebrity (Hasford, Hardesty and Kidwell 2015).

Therefore, it's not entirely clear what is driving these effects. Judgments of a product's enjoyment reflect judgments about its attributes, like size and weight, and it's not clear which is creating the appearance of a hedonic contrast effect. In other words, is Prego more desirable because of a contrast along the enjoyment dimension or the attribute dimension (sauce thickness)? The present research proposes the attribute-hedonic model which says that product comparisons occur simultaneously along both attribute and hedonic dimensions, but in opposite directions: attribute judgments tend to show strong contrast effects, while hedonic judgments show weak assimilation effects. Because the attribute contrast effect tends to overshadow the hedonic assimilation effect, it can create the appearance of hedonic contrast effects. In practice, these effects are confounded, so the studies here use various methods to disentangle them.

One study disentangled attribute and hedonic effects by asking participants to evaluate a series of product pairs, a target and a low (vs. high) competitor. In one scenario participants rated two TVs: a target with a 50-inch screen and a competitor with either a 40-inch screen (low) or a 60-inch screen (high). They rated how much they would enjoy each TV (hedonic) and how big each is (attribute). The target TV seemed more enjoyable when compared to the low (vs. high) competitor. On the surface this appears to show hedonic contrast, but a parallel mediation suggests otherwise. The relationship between hedonic judgments was positive, indicating assimilation, which significantly mediated the overall effect. On the other hand, the mediation through the target's attribute judgments showed an in-

direct contrast effect. In other words, the 40-inch TV made the target seem both more and less enjoyable. The same pattern was found for the other scenarios: music subscription services, tablet computers, and internet service providers.

A second study disentangles attribute and hedonic effects using investment scenarios. Because a large amount is more enjoyable than a small amount for gains, but the opposite for losses, investment scenarios allow the hedonic factor to be manipulated separately from the attributes. Participants rated a target (an investment that gained \$1,000) and a competitor, an investment that gained (vs. lost) \$100 (vs. \$10,000). As predicted, the target seemed more enjoyable compared to a small than a large amount, reflecting an attribute contrast: \$1,000 seemed like more money (and therefore more enjoyable) compared to \$100 than \$10,000. Moreover, the target seemed less enjoyable when compared to a loss than a gain, consistent with hedonic assimilation but contradicting the hedonic contrast hypothesis. Moreover, the interaction effect was not significant, inconsistent with hedonic contrast predictions. Moderated parallel mediation analysis fully supported the attribute-hedonic model.

This research disentangles distinct attribute and hedonic effects in product comparisons and shows a clear pattern of hedonic assimilation. Thus the appearance of hedonic contrast is largely due to attributes. Although this research does not rule out the possibility of hedonic contrast, it does raise questions about it, and calls for reconciliation with prior work (Ghoshal et al. 2014; Raghunathan and Irwin 2001; Zellner et al. 2003). The hedonic contrast hypothesis has been studied for over a century. Perhaps one of the reasons for the abiding interest in this topic is that it intuitively rings true. However, this may be a case where we have been misled by our intuition. Hopefully the model presented here can help provide some clarity to improve future decisions.

Consumers' Reaction to Taste-based Product Modification

Ms. Elisa Solinas, University of Southern California, USA

Prof. Francesca Valsesia, University of Washington, USA

Prof. Joseph C. Nunes, University of Southern California, USA

EXTENDED ABSTRACT

Consumers react favorably to quality-based modifications (e.g., more powerful blender). But how do they react to taste-based modifications (e.g., new color for a cereal)? We document taste-based modifications are perceived to alter the product's essence, and are received negatively when applied to products for which the creative process is important.

Companies frequently change their products. It seems intuitive consumers like the new version of a product if a quality-based element is improved (better performing water filter). Quality describes a vertically differentiated product space in which consumers agree over the best mix of characteristics (Tirole 1988).

In contrast, whether consumers like the new version of a product when the modification involves a taste-based element (new food recipe) is less clear. Taste describes a horizontally differentiated product space, where the optimal choice depends on the particular consumer (Tirole 1988).

While prior work focused on quality-based product modifications, we document when and why consumers are reluctant to accept taste-based modifications. We show applying taste-based modifications is perceived as altering the essence of the product (how the product was intended to be). Given that the notion of essence is especially important for creative products (Kalemen & Carey 2006), we find altering the perceived essence is aversive for those products for which the creative process is particularly relevant. While for creative products the creative process is inherently more relevant, companies can emphasize it for almost any product, for example by connecting it to a creative individual (eponymous brands; e.g., Stella McCartney).

This work extends our understanding of how consumers react to product modifications by delineating one type of modifications that typically is aversive to consumers. Further, our proposed process connects this work to the literature on essentialism.

Six pre-registered studies support our theorizing. In Study 1 (N=402) a tomato sauce was modified. In the quality-based condition, the change impacted the shelf life. In the taste-based one, it impacted the flavor. Respondents exhibited a greater preference for the unmodified version of the sauce in the taste-based condition than in the quality-based one ($p < .001$).

In Study 2a (N=200) we pre-tested 8 products for which the creative process was more (novel, song, print, BBQ sauce) or less relevant (reading glasses, pan, bottle opener, detergent). For each, we asked respondents to imagine the company modified some taste-based element (e.g., shape, color). Participants preferred the unmodified version when the creative process is more relevant, and the modified version when the creative process is less relevant (all p -values $< .007$).

In Study 2b (N=292) we set up a booth on campus and asked passerby to complete a short study in exchange for a piece of chocolate. Our DV of interest was their choice of chocolate. They could pick either the original recipe or the modified one. We manipulated the relevance of the creative process by stating the brand was either named after the creator or not. More people picked the original recipe (74%) when relevance of the creative process was high compared to low (60%, $p = .011$).

Study 3 (N=600) takes a moderation approach. We reason if a modification took place in early stages of product development, it should result in smaller alterations of the product's essence and thus be

received more positively by consumers. This is because a product's essence is established during a product's ideation phase, before commercialization (Hick 2008). In the No Modification condition, the design of a sweater was always the same. In both Modification conditions, the designer modified the design. Further, in the Modification/Early condition, the new design was imagined when ideating the sweater. In the Modification/Late condition, the new design was only recently developed. Participants perceived the essence as more intact in the No Modification condition ($M = 5.43$), followed by Modification/Early ($M = 4.93$), and Modification/Late ($M = 4.10$). Participants had a more positive attitude toward the sweater in the No Modification condition ($M = 5.18$) than in the Modification/Late condition ($M = 4.66$, $p < .001$). There was no significant difference between the No Modification and Modification/Early ($M = 5.00$) conditions.

In study 4 (N=601) we manipulated the relevance of the creative process condition by either having an eponymous brand or not. We also manipulated whether the design of a sweater stayed the same or was changed at some point. Respondents had a more positive attitude toward the unmodified product ($M = 5.30$) than the modified one ($M = 4.93$, $p < .001$). We also found a significant interaction ($p = .005$). When the brand was eponymous, participants had a more positive attitude toward the unmodified product ($M = 5.47$) than the modified one ($M = 4.84$, $p < .001$). When it was not, there was no difference. Respondents believed the essence of the product was more intact when the product was unmodified ($M = 5.89$) than when it was modified ($M = 4.68$, $p < .001$). There was no significant interaction on the essence measure. Thus, taste-based modifications are perceived to alter the essence of the product, and this alteration is aversive when applied to those products for which the creative process is deemed relevant.

Study 5 (N=19,392) is a Facebook field study. We collaborated with a restaurant and created two ads for one of their menu items. Between ads, we either emphasized the recipe has changed or that it was always the same. More participants clicked on the ad emphasizing the same recipe (5% vs. 4%, $p = .046$).

À Vous, but not For You: Multiple Languages on Product Labels Reduce Purchase Intentions

Dr. Eugene Chan, Ryerson University, Canada
Ms. Vanessa Hunter, Griffith University, Australia
Dr. Gavin Northey, Griffith University, Australia
Dr. Patrick Van Esch, Kennesaw State University, USA

EXTENDED ABSTRACT

This research examines how product labels containing multiple languages inhibit purchase intentions in mono-lingual consumers. Across three experiments, results show multiple languages on labels influence perceived personalization, which acts as the causal mechanism.

This research extends theory from marketing and communications and proposes labels are a form of recipient design.

À Vous, but not For You: Multiple Languages on Product Labels Reduce Purchase Intentions

This research examines how product labels containing multiple languages inhibit purchase intentions in mono-lingual consumers. Across three experiments, results show multiple languages on labels influence perceived personalization, which acts as the causal mechanism.

This research extends theory from marketing and communications and proposes labels are a form of recipient design.

INTRODUCTION

In many parts of the world, product labels come in multiple languages. For example, in parts of the United States, consumers find product packages in English as well as Spanish. In Canada, both English and French can be found on products. Labeling products in more than one language may or may not be required by law, depending on a country, but may also be adopted to appeal to the linguistic diversity of consumers.

In the current research, we explore if product labels that come in multiple languages influence purchase intentions. Specifically, we focus on how ‘monolingual’ consumers (those who speak only one language) respond to labels containing multiple languages. We predict that, for monolingual individuals, product labels that come in their native language as well as others (e.g., English and French for an English-speaking consumer) decrease their purchase intentions. Although some research has examined the effect of product label language on consumer behavior (Ho et al., 2019) or marketing communications (Hornikx & van Meurs, 2017), none have studied the impact of multiple languages present. Also, our focus on monolingual consumers actually covers nearly 75% of the American population (Palmer, 2013); this is despite foreign languages being a requirement in both secondary and tertiary educational institutions.

While it may seem unlikely the number of languages a consumer speaks is a basis of segmentation, monolingual consumers may psychologically interpret such products as being less tailored for them, given the labelling is also explicitly communicating to a group that speaks a different language. Personalization, in turn, affects attitudes and behaviors as products (and advertising) are in a sense perceived as “speaking directly” to the consumer or message recipient (Bleier & Eisenbeiss, 2015; Kreuter et al., 1999; Webb et al., 2005; Wogalter, 1994). Thus, we predict a product that has a label containing multiple languages will result in reduced purchase intentions, because monolingual consumers will view the product as less personal.

METHODOLOGY

Study 1

Study 1 tested if consumers who speak mainly English are less likely to buy a product with the label in both English and French or in both English and Korean, relative to one printed in only English. The findings provide evidence that monolingual consumers who only speak English express lower purchase intentions for a product printed in English and another language that they do not understand (French or Korean).

Study 2

Study 2 examined if monolingual consumers consider a product with labels in multiple languages as less personalized, translating into lower purchase intentions. The findings, coming from monolingual French-speaking consumers, replicate those from Study 1 where participants were monolingual English-speaking consumers. Presenting a label in consumers’ primary language produces greater purchase intentions than a product label with multiple languages present. We further find that perceived personalization, or lack thereof rather, explains the lower purchase intentions. This offers support for our proposed mechanism for why presenting product labels in multiple languages reduces consumers’ intent to buy said product(s).

Study 3

Study 3 manipulated the presumed mediator (perceived personalization) in order to determine if doing so would moderate the effect of multiple-language product labels on consumers’ purchase intentions. The findings offer further evidence that the perceived personalization stemming from a product label in consumers’ native language (rather than multiple languages) can explicate their higher purchase intentions. Effectively, a product label in multiple languages lowers such perceptions, reducing purchase intentions.

GENERAL DISCUSSION

The current research examined whether product labels that include multiple languages can reduce purchase intention among monolingual consumers. The results from three experiments show monolingual consumers (vs. multi-lingual consumers) experience less purchase intention when product labels include additional languages other than their native language. To the best of our knowledge, this is the first research to show the presence of multiple languages on product labels can reduce purchase intentions as consumers perceive the product as less personalized. Second, our findings demonstrate by highlighting how the product is “meant for” a specific group of consumers (e.g., monolingual consumers), this can potentially counteract the effect. Third, our findings demonstrate product labels that include multiple languages are also considered a cue for the degree of personalization. Our focus is on product labels, but our findings may also apply to advertising or website design.

Windfall Moments: Framing Tax Refunds to Increase Credit Card Debt Repayments among Indebted Consumers

Prof. Simon Blanchard, Georgetown University, USA

Prof. Beatriz Pereira, Iowa State University, USA

Dr. Remi Trudel, Questrom School of Business, Boston University, USA

EXTENDED ABSTRACT

Considering tax returns as ordinary (vs. windfall) income can promote healthy financial habits. However, in one field and two online experiments, we show that windfall frames are more motivating for debt repayment among highly indebted consumers. Windfall income makes indebted consumers think they made more progress in paying their debt.

INTRODUCTION

Previous research has consistently found that, on average, income that is framed as windfall (vs. ordinary) is spent more easily, justifiable and frivolously. This research aims to test whether the opposite holds for indebted consumers with low financial self-efficacy, in the context of framing tax returns. Prior research supports financial advisors' guidance that consumers should think of a tax refund as ordinary income (earned money being returned) rather than windfall income (unearned money being given) if the goal is to discourage spending of the refunded money and promote healthy financial habits. In this research, we show that the contrary holds for a financially vulnerable population – individuals who carry credit card debt and lack self-efficacy.

METHODS AND RESULTS

Study 1 is a field experiment conducted in partnership with Debitize, an app that helps indebted consumers set aside enough funds to pay credit card debt. We first identified users ($N = 200$) who had a tax return direct deposit from the IRS. We sent an email suggesting they use their return money (windfall vs. ordinary frame) to reduce their credit card debt. We expected that the effectiveness of the frame in increasing the odds of making an additional debt repayment would depend on outstanding debt level. A logistic regression confirmed our hypothesis (interaction: $B = .69$, $Z = 2.08$, $p = .04$). For participants with high debt (20.7% of the sample), the windfall frame increased debt repayment, while it decreased debt repayment for those with low debt (35.3% of the sample).

The field experiment provides a high degree of external validity, but we assumed participants had the goal to pay off debt and low financial self-efficacy due to self-selecting in the platform. Study 2 tests our main hypotheses in the lab, by asking participants to imagine they received a tax return of \$1,500 (framed as windfall vs. ordinary). We also manipulated whether they prioritized debt repayment (via current money management stress: high vs. low) and measured their financial self-efficacy. We analyzed the percentage of the refund going to debt repayment via a Tobit model, and found evidence of a three-way interaction as hypothesized ($B = -208.88$, $t(444) = -2.25$, $p = .03$). When financial self-efficacy is high (49.78% of the sample), there is neither an effect of windfall frame, current money management stress, nor an interaction between them (all $ps > .05$). But as hypothesized, as financial self-efficacy decreases (50.22% of the sample), the windfall income frame increases debt repayment only in the absence of current money management stress (i.e., when credit card debt repayment is prioritized; Johnson-Neyman region of significance: $B = -181.95$, $t(444) = -1.97$, $p = .05$).

In Study 3 we prescreened indebted consumers who lack financial self-efficacy, and found that following advice that frames tax

return as a windfall and encourages debt repayment leads to greater perceptions of progress on debt repayment ($M = 6.82$, $SD = 1.69$) than advice that frames the return as ordinary income ($M = 6.45$, $SD = 1.93$; $t(408) = 2.04$, $p = .04$, $d = .20$).

In Study 4, we asked participants (prescreened to expect a tax return and have credit card debt, which was measured) to recall their past year percent tax return allocations into spending, debt, and saving. Consumers' memory is affected by their current goals and vice-versa (see Epley et al. 2006), since the reconstructive process of memory operates similarly to the construction of preferences during decision-making. Importantly, our windfall (vs. ordinary) framing manipulation only told participants that tax returns are a great opportunity "to make consequential financial decisions." Without specifically directing them to repay debt, low self-efficacy individuals with moderate levels of debt (sample mean = \$5,505) allocated more money away from spending (recalled past savings and windfall frame interaction: $B = .37$, $t(199) = 3.14$, $p < .01$). For the average participant, the windfall frame increased allocations for those who recalled allocating at least 58% of their part tax return to savings or debt payment (i.e., away from spending; high goal commitment), while the windfall frame decreased the allocation for those who recalled allocating less than 15% away from spending (low goal commitment). As expected, income frames had no influence in allocations away from spending for those with low level of debt, and the framing effects were stronger for those with higher levels of debt. This study shows that for the windfall frame to be effective in increasing debt repayment, consumers need to have the goal to reduce debt and receive advice that specifically direct them to use the tax refund for debt repayment.

CONCLUSION

We use a combination of lab and field experiments to provide compelling evidence that framing tax returns as windfalls is more effective to help vulnerable consumers to repay debt. This finding is unique and highlights the need to consider consumer heterogeneity in behavioral science. Our findings are relevant to help policymakers, financial institutions, and consumer advocacy groups.

Adoption of New Technology Vaccines

Dr. Laura Zimmermann, IE Business School, Spain

Dr. Jeeva Somasundaram, IE Business School, Spain

Ms. Barsha Saha, Indian Institute of Management, Shillong, India

EXTENDED ABSTRACT

Many consumers are hesitant to get a life-saving vaccination. But are consumers more hesitant towards certain vaccines than others? In four experiments we show that consumers are unduly averse towards ‘new technology’ vaccines. We explore the underlying reasons for this and propose a strategy to overcome this hesitancy.

INTRODUCTION

We explore aversion towards new technology and ways to overcome this aversion with a simple nudge in the context of vaccine decision making. A plethora of research has shown that consumers are hesitant to receive a potentially life-saving vaccination (e.g., Blaisdell et al. 2016). But are consumers more hesitant towards certain vaccines (i.e., those that are based on a new technology such as mRNA) even if they are more effective? We present four experiments ($N_{\text{total}} = 478$) which test the propositions of a formal model that incorporates ambiguity and other people’s choices into the decision to vaccinate. We show that consumers are unduly averse towards new technology vaccines compared to traditional technology vaccines due to higher perceived uncertainty of side effects. We test a simple nudge based on herd behavior (Banerjee, 1992) to overcome this new technology aversion. By communicating increasing population vaccination rates, we effectively increase uptake of new technology vaccines at a higher rate than uptake of traditional vaccines. Rather than being driven by social conformity or social learning, information about herd behavior seems to alleviate perceived uncertainty (or ambiguity) by narrowing the confidence interval of risk estimates. We do not find evidence of free-riding due to herd immunity.

Methodology and Results

We present four experiments which test the propositions derived from a formal mathematical model. We conceptualize vaccine ambiguity by means of the technology from which a vaccine is derived: new mRNA versus traditional viral vector vaccine technology.

In **study 1a** ($N=80$, recruited via prolific.co, 48% female, $M_{\text{age}}=34$, $SD=10.7$), we show that consumers perceive higher levels of uncertainty stemming from concerns about side effects (and not efficacy) of a new technology vaccine compared to a traditional technology vaccine, despite being told that there are no safety concerns for either vaccine. Participants perceived side effects of a new technology vaccine to be more uncertain than those of a traditional technology vaccine ($M_{\text{new}}=4.20$, $M_{\text{traditional}}=3.20$, $t(78)=2.77$, $p=.006$, $d=.620$).

In **study 1b** ($N=120$, recruited via prolific.co, 69% female, $M_{\text{age}}=37$, $SD=13.5$), we show that consumers are more hesitant to vaccinate with a new technology vaccine even if it is less effective in preventing a disease. We quantify this aversion in the form of an efficacy premium which consumers demand for a new technology vaccine. The average efficacy premium was 19.11 ($SD=14.62$) which was significantly higher than zero ($t(114)=14.01$, $p<.001$). In other words, participants were willing to trade-off 19.11 percentage points in efficacy for receiving the traditional vaccine. Stronger concern about side effects of the new vs. traditional vaccine was positively related to the efficacy premium, controlling for demographics (gender, age, ethnicity), frontline worker status and regular flu vaccination.

Study 2 ($N=149$, recruited via prolific.co, 70% female, $M_{\text{age}}=35$, $SD=11.1$) investigates how aversion towards new technology vaccines can be reduced with a simple herd behavior nudge: communicating increasing population vaccination rates. We employed a 2 (vaccine type: traditional technology vs. new technology) x 6 (population immunization: 1%, 25%, 50%, 65%, 80%, 95%) mixed design, with vaccine type as between-subjects factor. A 2 x 6 mixed design ANOVA yielded a marginally significant interaction effect between the population immunization rate and type of vaccine ($F(5, 732)=1.93$, $p=.087$, $\eta^2=.013$).

For the new technology vaccine, increasing the population immunization rate had a positive effect on willingness to vaccinate for all immunization levels compared to the baseline. For the traditional vaccine, increasing the population immunization rate had a positive effect on willingness to vaccinate for immunization levels higher than 65% but not for lower immunization levels.

Study 3 generalizes the findings beyond the COVID-19 context, exogenously manipulates ambiguity and uncovers the process mechanism. We show that, beyond social conformity and social learning, information about herd behavior reduces uncertainty about side effects of a new technology vaccine and thereby increases its uptake more compared to a traditional technology vaccine.

Discussion

This research shows that consumers prefer certain types of vaccines over others, even if they are less effective in preventing a disease. Vaccines described as using a new technology seem to be ‘second choice’ when compared to traditional vaccine technology.

Interventions based on messages that describe the pro-social benefits of getting vaccinated (Hershey et al., 1994; Trueblood et al., 2021) or promote the autonomy of the decision-maker (Moon et al., 2021) can be effective to encourage vaccine uptake in certain populations. However, new technology vaccines might require a different (or additional) approach. We suggest that interventions and policy campaigns should focus on alleviating the ambiguity surrounding new technology (Zhang et al., 2021).

We conclude that all vaccines are not perceived equal in the eyes of the public. Consumers perceive vaccines that are based on a new technology less favorable and are more hesitant towards them. This could lead to delays in vaccination schedules, missed appointments and a refusal to be vaccinated with a certain vaccine in the hope of receiving an alternative vaccine later. Policy makers and health marketers must take this into consideration when designing vaccination campaigns and take steps to alleviate ambiguity surrounding side effects.

Visual Storytelling: How Images Transport Us into the Narrative World

Ms. Olesia Nikulina, Maastricht University, Russian Federation

Prof. Allard Van Riel, UHasselt, Belgium

Prof. Jos Lemmink, Maastricht University, Netherlands

Prof. Martin Wetzels, EDHEC Business School, France

EXTENDED ABSTRACT

The research systematically reviews existing articles in the visual narrative transportation domain. It suggests nine groups of image features that can transport consumers into a visual story, moderating effects, and outcomes of such transportation. Building on the identified research gaps, the authors also list promising research directions for visual-driven studies.

INTRODUCTION

People get absorbed by well-crafted stories. They dive into a movie plot, empathize with book characters, and forget about time while listening to friends' news. The feeling of being lost in a story, or narrative transportation (Green & Brock, 2000), indicates storytelling power and impact. While much research on text-based storytelling exists, little remains known about storytelling through visuals. The current systematic literature bridges this gap. It identifies nine groups of visual features (with 26 subgroups) that facilitate visual narrative transportation, describes transported viewers' responses, and proposes future research avenues for visual-driven studies.

BACKGROUND

Compared to factual pieces, stories lead to belief change (Van Laer et al., 2014) and ultimately affect narrative consumers' attitudes and behaviors (Escalas, 2004). Existing studies on narrative transportation well-document text features transporting readers into the narrative (Green & Brock, 2000; Van Laer et al., 2014). However, little remains known about how images can lead to such transportation. Since visual and textual processing follow different neural paths (Li et al., 2020), failure to account for the type of media leads to fragmented and conflicting scholarly conclusions in the visual narrative transportation studies (e.g., findings of Farace et al. (2020) and Lim and Childs (2020)).

As an emerging construct, visual narrative transportation lacks actionable and clear conceptualization. To bridge this gap, we systematically review articles from marketing and adjacent fields focusing on visual narrative transportation.

METHODOLOGY

The systematic review followed a three-staged approach. First, we used the search strings to find relevant articles in the citation database Web of Science and scanned their titles and abstracts. Since we aimed to extend the well-established theory of narrative transportation to the visual domain, our search words related to narrative transportation either directly or indirectly, through its antecedents. Then, we sourced additional papers using forward and backward snowballing. Finally, we ran an additional search in the most frequently cited journals from the previous steps. After reading the full texts of 312 papers and applying the inclusion criteria, we were left with 68 relevant articles to review systematically.

FINDINGS

Based on a synthesis of the 68 articles selected during screening, we identified nine groups (with 26 subgroups) of visual features that impact the strengths of visual narrative transportation: people, visual, taboo, objects, background, color, composition, verisimilitude, and dynamism. Characteristics of the advertisement, consumer,

and brand moderate these relationships. Transported viewers elicit emotional (emotions), cognitive (appeal, attitude, comprehension/elaboration, perception, recall, recognition, self-brand connection, experience), and behavioral (choice, consideration, intentions, preferences, price premium, sales) responses.

FURTHER RESEARCH SUGGESTIONS

We propose five clear research avenues for future studies. These are divided into three groups based on their place in the developed conceptual model.

Antecedents

First, reviewed studies mainly focus on high-level visual features as antecedents of visual narrative transportation. High-level visual features are semantically meaningful but difficult to extract and analyze using computational methods. Advanced research methods are repeatedly called for as marketing research priorities (e.g., Grewal et al., 2021), so the gradual transition to automatic analysis of low-level visual features appears a fruitful avenue.

Secondly, scholars tend to explore the effect of a single (vs. several) visual feature at a time. This approach may overlook the effects caused by their interaction. Because human perceptions of some visual features can drastically change in the presence of others (Hagtvedt & Brasel, 2017), we strongly advise conducting comprehensive research that considers the interaction effects among visual features.

Thirdly, the present systematic review focuses solely on one image and omits the effects of external factors. Other images, lighting, haptics, and distraction levels might impact image perception and, thus, transportation into the visual narrative. We invite researchers to study the external environment of visual narrative transportation.

Moderators

We identify moderators of the relationship between visual features and visual narrative transportation in the literature. Yet, other significant moderating effects, for example, cultural aspects, may be explored. Culture-induced associations with visual features may affect perceptions and, thus, the responses of a consumer to a visual narrative.

Consequences

Articles included in the systematic review have predominantly analyzed the effect of visual narrative transportation on behavioral intentions (vs. behaviors). As intentions indicate a willingness to perform a particular behavior, the latter is not guaranteed to occur. We encourage researchers to track actual behaviors occurring due to visual narrative transportation and establish whether and under which circumstances behavioral intentions translate into actual behaviors.

CONCLUSION

Our systematic review of visual-driven studies conceptualizes visual narrative transportation. It identifies nine groups of visual features (with 26 subgroups) that impact visual narrative transportation strengths and lists possible moderators and consequences of such transportation. We also set future research agenda for visual-driven studies by highlighting the existing research gaps and suggesting ways to address them.

Cryptic Signalling: Hidden Markers of Inclusivity in Service Environments

Dr. Kelly Choong, Edith Cowan University, Australia

Dr. Gavin Northey, Griffith, University, Australia

Ms. Vanessa Hunter Griffith, University, Australia

Dr. Rory Mulcahy, University Of The Sunshine Coast, Australia

Dr. Patrick Van Esch, Kennesaw State University, USA

Dr. Eugene Chan, Ryerson University, Canada

EXTENDED ABSTRACT

This study examines the use of implicit badges as a way for service providers to show 'cryptic' support for LGBTQ+ community that is recognised by LGBTQ+ members but not the broader population. Results from three experiments show implicit badges provide cryptic support without alienating other segments of the customer base.

To demonstrate inclusivity and support for LGBTQ+ issues, some firms embrace events such as Pride month, like Starbucks with their large rainbow flag that sits atop their Seattle headquarters. Others, like Amazon, adorn their online portals with rainbow flags, and create special PRIDE stores selling rainbow-striped K-Swiss sneakers. By contrast, some organisations encourage staff, including frontline service delivery personnel, to wear uniform badges (like the rainbow flag pin) that represent a cause.

Badges are one of the ingredients that create a 'symbolic servicescape' (Rosenbaum, 2005), where objects and artefacts evoke similar meanings across the customer base. However, not all badges are created equal. This is because some badges, like the ubiquitous rainbow flag, are 'explicit' representations that are well known across the broader population. In contrast, other 'implicit' badges, such as the pink triangle that today represents support for LGBTQ+ people, are less well known across the broader population but are highly significant to members of the sub-culture. While the use of symbolic badges by staff may represent support and inclusivity, it has the potential to alienate certain customers (Bond and Farrell, 2020). One such group is those who identify as politically conservative.

Prior research (Northey, Dolan, Etheridge, Septianto, & Van Esch, 2020) has shown conservatives experience more negative emotions (such as disgust) than liberals when seeing representations of gender or sexuality in advertisements. As a result, we hypothesise (H1) explicit (vs. implicit) badges will elicit anger in politically conservative individuals. We also hypothesise (H2) when conservatives (vs. liberals) view explicit (vs. implicit) badges, their lower levels of trust and increased levels of anger will have a negative influence on expected service quality.

METHOD AND RESULTS

We test our predictions across a pre-test and three experimental studies. For all experiments, data was collected through a research agency in the United States.

FOCUS GROUPS: Prior to running the pre-test, four online focus groups were conducted to establish which badges were appropriate for the studies. From the focus groups, the traditional 'six-striped' rainbow flag was recognised by all participants as an explicit symbol of LGBTQ+ people and Pride. In terms of an implicit badge, it was found the 'pink triangle' badge was known by most of the LGBTQ+ members but was mostly unknown by the heterosexual participants.

PRETEST: The pretest (n=579) was an exploratory study, using a single factor, one level (badges: implicit/explicit) between subjects design to test the badges as either implicit (pink triangle) or explicit (rainbow flag) representations of LGBTQ+ concepts. Results show the rainbow badge (vs pink triangle) is identified as an explicit (vs. implicit) representation of LGBTQ+ concepts (chi-square = 148.23, df=1, p<.001).

STUDY 1a (n=343) was a one factor, two level (badges/no badges) between subjects design to test whether badges (vs no badges) trigger an emotional response (anger) and identify political ideology as a moderating factor. Results (PROCESS model 1; Hayes, 2018) show when viewing explicit (vs. implicit) badges, political conservatives are significantly more likely to feel anger ($B = -1.85$ t (343) = -4.32, $p = .000$) than politically liberal individuals.

STUDY 1b (n=261) was a 2(badge:implicit/explicit) x 2(service provider gender:male/female) between subjects design to determine which badge (explicit or implicit) triggers an emotional response (anger) within an airline service scenario. Results (PROCESS model 1; Hayes, 2018) specifically show that conservatives (vs. liberals) are more likely to experience anger ($B = .94$, $p = .000$) when viewing an explicit (vs. implicit or 'cryptic') badge. The results provide support (H1) for the hypothesised effects.

STUDY 2 (n=274) was a 2(badge:implicit/explicit) x 2(service provider gender:male/female) between subjects design in a hotel service scenario to increase generalisability and confirm the moderated serial mediation model. Results (PROCESS model 85; Hayes, 2018) show moderated serial mediation was significant (index = -.06; CI -.014 - .001), with conservatives experiencing less trust and increased anger when viewing service personnel wearing explicit (vs. implicit or 'cryptic') badges. In turn, this resulted in lower expected service quality ($B = .94$, $p = .000$) for conservatives (vs. liberals), providing support for H2.

DISCUSSION

This research offers several contributions to theory and practice. First, it builds on prior research involving 'cryptic signalling' (Choong, Drennan, Weeks, & Weber, 2021) by showing cause-related uniform badges that are not widely recognised by the broader population provide a form of 'cryptic' or implicit support for members of the relevant sub-culture. The findings also extend our understanding of political ideology in a marketing context. Our results provide evidence conservatives do not need to view the members of any outgroup to experience negative responses. Instead, conservatives experience the same psychosocial, emotional responses simply by being exposed to badges or artefacts that represent the outgroup.

Effects of Personalization and Ad Algorithm Disclosure on Perceived Creepiness

Mr. Kevin Krause, Saarland University, Germany
Prof. Andrea Groeppel-Klein, Saarland University, Germany
Ms. Sophie Nike Friderich, Saarland University, Germany
Ms. Melanie Schmitz, Saarland University, Germany

EXTENDED ABSTRACT

Online marketing techniques experienced as creepy repeatedly come into crosshairs of consumer behavior research. In three studies we manipulated levels of personalization and ad algorithm disclosure. Results show that consumers feel unsettled, even creeped out, by over-personalization and disclosure of ad algorithms, which negatively affects attitudes and behavioral intentions.

Online marketing techniques experienced as creepy repeatedly come into crosshairs of consumer behavior research. Specific tracking algorithms enable personalized advertising e.g. by automatically investigating consumers' online "lived behavior" (Grassegger and Krogerus 2017). But do consumers perceive personalized advertising as enriching or do they feel spied on, as current research (e.g. Bermes, Hartmann, and Danckwerts 2020) suggests? Furthermore, we are interested in examining ad algorithm disclosure (AAID) whose effects on consumers' responses are still unclear.

Conducting three studies, we manipulated levels of personalization and AAID. We then tested if the effects replicate when attitude toward a well-known retailer is controlled for (study 2) and when the category of the advertised product changes (study 3). Results show that consumers feel unsettled, even creeped out, by over-personalization and AAID, both negatively affecting attitudes and behavioral intentions.

Langer and König (2018, 3) define creepiness as "a potentially negative and uncomfortable emotional response paired with perceptions of ambiguity toward a person, technology or even during a situation." Creepiness in online behavioral advertising is mostly elicited by activities such as social listening or data-driven marketing or occurs when causal ambiguity is present (Torkamaan, Barbu, and Ziegler 2019). This may be enabled by watermarking technologies which refer to triggering advertisements on mobile devices due to detected sound signals, also due to content spoken out loudly (Segijn and van Ooijen 2021).

Past research (e.g. Farman, Comello, and Edwards 2020) has shown the presence (vs. the absence) of personalization in advertisements to violate consumers' privacy, evoking creepiness and negatively influencing brand attitudes and purchase intentions. However, consumers are rather exposed to a continuum of personalization in online settings. We assumed that [H1] the higher the level of personalization (low vs. medium vs. high), the lower the behavioral intention towards the marketer and this effect to be serially mediated by perceived creepiness (M1) and in turn more negative attitude towards the ad (M2).

For AAID, effects are rather unclear as they may increase ad effectiveness (Kim, Barasz, and John 2019) or consumers responding with creepiness to transparency explanations (whether vague or precise, Eslami et al. 2018). We supported the latter view and assumed that [H2] if information regarding ad algorithms is disclosed (vs. not disclosed), the behavioral intention towards the marketer is lowered and that this effect is serially mediated by perceived creepiness (M1) and in turn a more negative attitude towards the ad (M2) as well as the serial indirect effect of H1 to be reinforced when ad algorithm information is disclosed (vs. not) [H3].

In a pretest ($N=56$) we designed causal ambiguity vignettes varying in perceived personalization and participants were randomly assigned to one of three experimental groups (personalization: low vs. medium vs. high). Participants were instructed to imagine themselves meeting a friend in a coffee shop and discussing their forthcoming move. The subject shows photos on a cell phone of the new flat to his/her friend and

subsequently places the phone somewhere visible. It was indicated that no online mobile search had yet taken place. While conversing, the subject mentions – as well as keeping current furniture – a wish to purchase a new furniture item which varied between the three groups: a red leather sofa vs. a gray armchair vs. a white desk. The mover goes home, checks his/her social media apps and receives an ad from an online furniture store advertising a red leather sofa from a fictitious online brand for all three groups. For the red leather sofa group, the ad exactly depicts the item from the previous conversation, representing high personalization. The gray armchair group reflects medium personalization, because the same product category (living room furniture) is promoted. The white desk group refers to low personalization because a different product category is promoted. However, as mentioned earlier, no previous online search took place, suggesting the coffee-shop conversation may have been spied upon. The three groups differed significantly in perceived personalization and this manipulation (iv personalization) was thus also used for study 1 and 2 which our participants were randomly exposed to (between-subjects design) in our online studies (snowball system). For study 3 (3x2-between-subjects-design), we used the same scenario but changed the product category to kitchen equipment (grill with oven function=high_pers, microwave=medium_pers, dishwasher=low_pers). Manipulation checks confirmed successful experimental manipulations in all studies ($N_{Study_1}=252$, $N_{Study_2}=218$, $N_{Study_3}=312$). AAID was manipulated in only study 3 which participants were either exposed to (in-fographic educating about watermarking) or not.

Results of study 1 (multicategorical serial mediation analysis, sequential coding for iv personalization, Hayes 2018), indicated medium (vs. low personalization) and high (vs. medium personalization) leading to more perceived creepiness, deteriorating attitude and ultimately resulting in less behavioral intention for a fictitious retailer. These serial mediation effects could principally be replicated for a well-known brand (study 2) and for a further advertised product category kitchen equipment (study 3), showing support for H1.

Results of study 3 (PROCESS, model 6), showed AAID (vs. no AAID) leading to more perceived creepiness, deteriorating attitude and ultimately resulting in less behavioral intention (confirming H3) but not attenuating the indirect serial mediation effects of H1 (thus rejecting H3, though only present for participants exposed to AAID when comparing medium to high personalization).

Our research is among the first to manipulate personalization levels and to use a causal ambiguity scenario, showing highly personalized advertising leading to perceived creepiness and thus deteriorating ad attitudes. For AAID, we detected similar negative effects implicating a need for more nuanced and differentiated consumer education approaches. As we covered a rather specific form of personalization, further research will test if the effects generalize to different scenarios (e.g. spying experiences during online searches).

From a theoretical standpoint, our research contributes to the relevance of "creepiness research" and from a consumer protection standpoint we argue that perceived creepiness may serve as a potential warning system of consumers' personal information eventually being tapped.

Considering implications, future research will cover a more equal gender balance (mostly females participated) and findings of scenario technique results must be tested in a field study to enhance external validity.

How artificial intelligence influences trust and customer orientation in the banking sector

Dr. Gavin Northey, Griffith University, Australia
Ms. Vanessa Hunter, Griffith University, Australia
Dr. Rory Mulcahy, University Of The Sunshine Coast, Australia
Dr. Patrick Van Esch, Kennesaw State University, USA
Dr. Eugene Chan, Ryerson University, Canada

EXTENDED ABSTRACT

This research examines how financial advice received from an artificial intelligence system (vs. human) influences investment intentions in a retail banking context. Furthermore, it identifies trust and perceived 'customer orientation' as causal mechanisms influencing investment intention, with high involvement as a key boundary condition moderating the effects on investment intention.

Purpose

The global banking sector is huge. In 2021, despite the effects of COVID-19, annual revenue from the global banking system came in above US\$5.5 trillion. Nonetheless, global banking revenues are under intense pressure and the global pandemic has made many banks rethink their strategy and tactics. As a result, there is a digital revolution occurring in the banking sector that is likely to reshape the industry considerably. Specifically, one area where banks have started investing heavily is in the use of artificial intelligence (AI) and automation.

Artificial intelligence has been defined as a system's ability to interpret and learn from external data and use that learning to flexibly adapt to a situation in order to achieve specific goals (Kaplan & Haenlein, 2019). In a banking context, AI allows for robotic process automation that is a quick and simple way for banks to automate a wide range of processes and speed up the processing of big data (Perez-Vega et al., 2021). Till recently though, the use of AI in banking and finance has primarily centred around areas such as asset management, algorithmic trading, credit underwriting and blockchain-based finance as a way to drive cost reductions and productivity enhancements (OECD, 2021). However, recent years have seen a number of fintech companies leading a wave of disruption in the financial services industry (Rosenbaum, 2022). Central to this disruption has been the growth in Robo-advisors, which are digital platforms that provide automated, algorithm-driven financial advice with little or no human supervision (Frankenfield, 2022). In the US alone, it is projected Robo-advisors will soon be managing over \$1 trillion of Americans' wealth (Iacurci, 2022). Part of this growth may be attributed to the fact the ease and usefulness of Robo-advisors has a positive influence on attitudes towards and adoption of the technology (Belanche et al., 2019). However, recent research (Zhang et al., 2021) has suggested consumers prefer human advisers with high expertise over Robo-advisors. That said, there is currently limited understanding why this might be the case.

In summary, this research examines how financial advice received from an artificial intelligence system (vs. human) influences investment intentions in a retail banking context. Furthermore, it identifies trust and perceived 'customer orientation' as causal mechanisms influencing investment intention, with high involvement as a key boundary condition moderating the effects on investment intention.

As such, we propose the following hypotheses:

Hypothesis 1: In a finance context, human (vs. AI) investment advice will have a positive (negative) influence on intention to invest when involvement is high.

Hypothesis 2: In a finance context, human (vs. AI) investment advice will have a positive (negative) influence on trust when involvement is high, which results in higher (lower) investment intention via customers' perceived customer orientation.

To answer these questions, the current research set out to examine how financial advice provided by a human advisor (vs. AI-driven Robo-advisor) influences investment intentions in a retail banking context.

METHODOLOGY AND ANALYSIS

We test our predictions across two experimental studies.

Study 1 was a 2(Financial Advice: Human/Robo-advisor) x 2(Involvement: high/low) between-subjects experiment. Participants (n=165) were recruited through a research agency in the United States (mean age=37yrs; 63.6% male). Two fictitious scenarios were created by the authors for the experiment, based upon the fictitious financial planning service provider "Moneymaker". The AI vs Human (B= 1.67, p<.007) and Investment Involvement manipulations (B= 1.55, p<.012) had significant direct effects on intention to invest.

Study 2 replicated S1, designed as a 2(Financial Advice: Human/Robo-advisor) x 2(Involvement: high/low) between-subjects experiment. The results demonstrate the type of financial advisor (B= .90, SE=.36, p=.013) and level of Involvement (B= .99, SE=.36, p=.006) had a significant negative direct effect on belief in financial advice. Further, as predicted the two-way interaction between financial advisor (Human vs Robo-advisor) and level of involvement (high vs low) was significant (B= -.54, SE=.23, p=.019), providing initial support for H2.

GENERAL DISCUSSION

The current research examined how the source of financial information received by an investor influences their investment decisions. The results from two experiments provide strong evidence that when consumers receive investment advice from an AI-enabled system (rather than from a human), it reduces their intention to invest.

Rational Addiction in Mobile Consumption

Dr. Jeeva Somasundaram, IE Business School, Spain

Dr. Laura Zimmermann, IE Business School, Spain

Mr. Duc Pham, IE Business School, Spain

EXTENDED ABSTRACT

In two pre-registered RCTs, we investigate how (forward-looking or myopic) consumers respond to monetary incentives offered to reduce smartphone usage. Our results provide support for the theory of rational addiction (forward-looking habit formation) and show that pre-announcing future targets and incentives can be a cost-effective intervention to kickstart behavioral change.

Understanding how to incentivize consumers to change a behavior depending on the nature of inter-temporal consumption is important for marketers. We develop a model that examines how a (forward-looking or myopic) consumer responds to temporary monetary incentives offered to reduce the consumption of a good depending on the nature of inter-temporal consumption (habit forming or satiating). We empirically test our predictions in the domain of mobile usage since many consumers would like to reduce their smartphone usage but fail to do so.

Excessive smartphone usage has become a growing concern across the world. The average consumer now spends around four hours every day looking at their smartphone. Cross-sectional and longitudinal studies have shown negative associations between screen time and academic performance (Giunchiglia et al., 2018), performance at work (Liu, Ji, & Dust, 2020) as well as wellbeing (Twenge & Campbell, 2019) and sleep (Hisler, Twenge, & Krizan, 2020).

Based on theory of rational addiction (Becker & Murphy, 1988), we empirically test if pre-announcing targets and incentives for future screen time reduction can reduce current usage even when subjects are not yet incentivized. Rational addiction implies that people are forward-looking and rational when forming a habit (i.e., maximizing lifetime utility by taking into consideration future consumption; (Becker & Murphy, 1988). This implies that incentives paid in the future to encourage behavior change could lead consumers to anticipate and change their behavior even prior to receiving incentives. Thus, one could cost-effectively instigate behavioral change in the present by incentivizing behavior in the future.

METHODOLOGY

We conducted a pre-registered RCT ($N = 110$; 74 females; $Age = 21.1$, $SD = 2.25$) at a international university with the aim to reduce the mobile screen time of our subjects by 25% from baseline usage, by providing monetary incentives and targets. After a baseline period of seven days, we randomized subjects into three conditions: 1) Control (C) condition, 2) Full Incentives (FI) treatment, 3) Anticipated Incentives (AI) treatment. Subjects in the C condition ($N = 33$) had no targets or monetary incentives. Subjects in the FI treatment ($N = 39$) were paid 2€, for each day during period 1 and 2 (nineteen days) whenever their screen time was at least 25% lower than their baseline. Conversely, subjects in the AI condition ($N = 38$) were paid 2€ for each day only during period 2 (ten days) whenever their screen time was at least 25% lower than their baseline usage. Importantly, subjects in the AI condition were informed about their period 2 incentives and targets at the beginning of period 1 itself, nine days prior to period 2. In the post-treatment period, we removed the targets and incentives. We collected individual-level panel data on daily mobile screen time over the entire course of the study. A

follow-up study was also conducted focusing only on AI and C condition to replicate the results of the first study.

RESULTS

We find that when future targets and incentives are pre-announced, subjects behave in a forward-looking (rather than myopic) manner and reduce their mobile usage as predicted by habit formation models even before they are actually incentivized to do so (rather than increase consumption as predicted by satiation models). Using difference-in-difference OLS regressions, we find that subjects in the FI condition not only reduced their screen time during the incentive periods but also sustained a lower usage than the control condition during the post-treatment period. Importantly, subjects in the AI condition anticipated and pre-emptively reduced their smartphone usage (compared to the C condition) in period 1, even prior to the incentivized period 2. This anticipatory reduction was primarily driven by heavy users of smartphones (i.e., those with higher baseline usage). Consistent with predictions of habit formation, we show that the reduction in post-treatment usage is driven mainly by subjects who have lower usage during the treatment periods. The results of a follow-up RCT replicate and supplement the findings of RCT 1.

DISCUSSION

Our RCTs provide an empirical demonstration of rational addiction. We identify the subject group that responds to future incentives (in our case heavy mobile users). In addition, we precisely estimate the effect of anticipated vis-à-vis actual incentives in inculcating and sustaining a behavioral change. For marketers, this is important because anticipation treatments could effectively support the most vulnerable (heavy) users at a lower cost.

Spending the most on those who need it the least: Gift-givers buy more expensive gifts for affluent recipients

Dr. Farnoush Reshadi, Worcester Polytechnic Institute, USA

Dr. Julian Givi, West Virginia University, USA

EXTENDED ABSTRACT

Gift-giving is a widespread prosocial behavior. Typically, in prosocial activities, consumers favor helping those in need. However, we show that when giving gifts, consumers spend more on relatively wealthy (vs. unwealthy) recipients. We also shed light on the psychological processes that lead gift-givers to act this way.

Gift-giving is a widespread prosocial behavior. Typically, in prosocial activities, consumers favor helping those in need. However, we posit that when giving gifts, consumers spend more on gifts for wealthy (vs. unwealthy) recipients.

When buying gifts, givers are influenced by various motives, which can be categorized as other-oriented (i.e., altruistic) or self-oriented (i.e., egoistic; Austin & Huang, 2012). During a gift-giving decision, a giver may be influenced by both types of motives simultaneously (Sherry, 1983). Typically, the two sets of motivations work in opposite directions (e.g., Givi & Galak, 2020). However, we show that, in the current setting, an other-oriented and a self-oriented motive work in tandem to produce the same outcome: givers spending more on relatively wealthy (vs. unwealthy) recipients (**H1**).

First, we propose that givers purchase more expensive gifts for wealthy (vs. unwealthy) recipients due to an other-oriented motive—a desire to select a well-liked gift. It is well-established that consumers' preferences are influenced by their financial status (e.g., Dubios & Duquesne, 1993). Anticipating this correlation, when deciding between expensive and less expensive gifts, givers should be more likely to purchase the former when the recipient is wealthy (vs. unwealthy), because they should see wealthy (vs. unwealthy) recipients as having stronger preferences for expensive gifts (**H2**).

Second, we suggest that givers purchase more expensive gifts for wealthy (vs. unwealthy) recipients due to a self-oriented motive—a desire to signal financial status. Consumers have an innate desire to signal being of high status (e.g., high financial status; Argyle 1994). Individuals sometimes use gift-giving as a means to signal high financial status; specifically, they give flashy and expensive gifts (van de Ven, 2002). The desire to signal high financial status can be influenced by the consideration of the recipient's feelings (Arnett & Sidanius, 2018). While sending a signal of high financial status to a wealthy person likely has only a minimal effect on how the other person feels about themselves, conveying this type of signal to someone who is unwealthy makes them feel quite bad because it highlights their low financial status. Thus, givers should be less (vs. more) likely to choose an expensive gift when the recipient is unwealthy (vs. wealthy), because they are less (vs. more) motivated to signal being of high financial status (**H3**).

Across three studies, we tested our hypotheses. All experiments employed one between-subjects factor (Recipient: *Wealthy* vs. *Unwealthy*). In Study 1, participants imagined they were purchasing a gift for their friend, Jordan, and learned information about Jordan, including Jordan's salary (\$25,000 vs. \$250,000) and filler material. Then, participants read a vignette in which they were buying an Amazon gift card for Jordan's birthday and were asked to 1) indicate what priced Amazon gift card they would purchase for Jordan (open-ended), and 2) choose which of three Amazon gift cards (\$20, \$40, or \$60) they would buy for Jordan. Analysis of the open-ended dependent measure indicated that participants spent 29% more when the recipient was wealthy versus unwealthy ($M_{Wealthy} = 59.38$, $SD_{Wealthy}$

$= 34.15$ vs. $M_{Unwealthy} = 46.17$, $SD_{Unwealthy} = 28.58$; $F(1, 179) = 7.91$, $p = .005$). In the *Wealthy* condition, 51.6% of participants chose the \$60 card, 29.0% chose the \$40, and 19.4% chose the \$20 gift card, whereas in the *Unwealthy* condition, 33.0% of participants chose the \$60, 36.3% chose the \$40, and 30.7% chose the \$20 gift card (Wald $\chi^2(1, N = 181) = 6.51$, $p = .011$). Participant income had no effect in any of the three studies and is not further discussed.

In Study 2, participants read Jordan's salary (\$35,000 vs. \$280,000) and filler information, and chose between a \$25 and a \$50 Amazon gift card for Jordan's birthday. Participants then indicated how much Jordan would like each of the two gift cards (1-7 scale). We created a "liking difference" measure by subtracting participants' liking ratings for the \$25 card from the \$50 card. Participants also indicated how motivated they were to appear wealthy to Jordan when buying the gift (1-7 scale). On average, participants spent roughly 57% more when the recipient was wealthy versus unwealthy ($M_{Wealthy} = 63.81$, $SD_{Wealthy} = 39.87$ vs. $M_{Unwealthy} = 40.53$, $SD_{Unwealthy} = 20.81$; $F(1, 292) = 39.98$, $p < .001$). Additionally, 79.0% of participants in the *Wealthy* condition chose the \$50 card compared to only 54.3% in the *Unwealthy* condition (Wald $\chi^2(1, N = 294) = 19.32$, $p < .001$). Bootstrapped mediation revealed that, both "liking difference" (95% CI = [.01, .64]) and signaling (95% CI = [.04, .45]) mediated the discrepancy in choices across the two conditions.

In Study 3, participants read filler information as well as Jordan's salary (\$40,000 vs. \$300,000), chose between a \$10 and a \$50 bottle of wine as Jordan's winter holiday gift, and completed mediator measures like the ones from Study 2. 81.6% of participants in the *Wealthy* condition chose the \$50 bottle of wine compared to 57.6% in the *Unwealthy* condition (Wald $\chi^2(1, N = 273) = 17.86$, $p < .001$). Bootstrapped mediation revealed that both the "liking difference" (95% CI = [.01, .64]) and signaling (95% CI = [.42, 1.51]) mediated the discrepancy in choices across the two conditions.

The Numerical Processing Likelihood Model

Dr. Daniel Villanova, University of Arkansas, USA

Dr. Mario Pandelaere, Virginia Tech, USA

EXTENDED ABSTRACT

The authors reconcile conflicting findings on how numeracy relates to numerical biases by proposing the numerical processing likelihood model. More numerate individuals emphasize relative representations of information when tasks call for it, but absolute representations to a greater degree on other tasks, leading to predictably less or more bias.

A key numerical information processing bias is the unit effect, in which a difference that is represented with a larger number is perceived as greater than the same difference represented with a smaller number (Pandelaere et al. 2011).

Because the unit effect stems from absolute processing of the numbers by neglecting the units in which information is expressed, many researchers hypothesize that the unit effect should be weaker for those who are more numerate, who possess a greater “ability to process basic probability and numerical concepts” (Burson et al. 2009; Cadario, Parguel, and Benoit-Moreau 2016; Peters et al. 2006; Tangari, Burton, and Davis 2014). However, while Tangari et al. (2014) found a weaker unit effect among the more numerate, Cadario et al. (2016) found a *stronger* unit effect. Prior theory cannot account for this reversal.

The unit effect stems from over-relying on the absolute difference between numbers. However, a substantial amount of prior marketing research highlights the emphasis consumers place not on absolute differences but on relative differences (Hsee, Yu, Zhang, and Zhang 2003; Kwong and Wong 2006; Wong and Kwong 2005). A new theory of numerical cognition ought to offer insights on variation in both the unit effect and proportional sensitivity.

We propose that differences in the way the more (vs. less) numerate process numerical comparisons lead to either a larger or smaller unit effect and proportional sensitivity. The Numerical Processing Likelihood Model is a motivation-ability model – the motivation and ability to process numerical information in particular ways conjointly determine how that numerical information affects perceptions. Specifically, the weights applied to the absolute and relative difference representations depend on an individual’s motivation and ability to focus on either representation. Some tasks motivate a greater comparative focus on the absolute difference, while other tasks motivate a greater comparative focus on the relative difference. Some individuals have a greater ability to discriminate between these task types than others. The Numerical Processing Likelihood Model predicts an interaction between motivation and ability such that more capable people should prioritize the appropriate difference representation. This leads to smaller or larger unit effects for the numerate (compared to the less numerate), depending on the motivation to rely on relative vs. absolute differences, respectively. Our theory also brings proportional sensitivity under the same umbrella, suggesting that sometimes the more numerate will exhibit stronger proportional sensitivity, while at other times they will not. We test this new theory of numerical cognition in five studies (two preregistered).

In Study 1 (N=200), participants were assigned to a 2 condition (scale: contracted, expanded) between-subjects design, which used the same scenario as Pandelaere et al. (2011, Study 5). We expected individuals to view this as a relative task. Afterward, participants responded to the objective numeracy scale (Weller et al. 2013; $\alpha=.84$). A multilevel regression model of ln-WTP revealed that the more numerate were more sensitive to the proportional difference (interaction, $b=.57$, $p<.001$) and exhibited an attenuated unit effect (interaction, $b=-.29$, $p=.002$).

Study 2 (N=200) was preregistered (<https://aspredicted.org/blind.php?x=wj7pj6>); participants were assigned to a 3 comparison type (low single [e.g., 1 vs. 2], high hundred [e.g., 100 vs. 200], high single [e.g., 101 vs. 102]) within-subjects design. The low single vs. high hundred contrast tests the unit effect, while the low single vs. high single contrast tests proportional sensitivity. Participants were told they would be comparing two machines on the basis of how quickly they can produce units, which was expected to induce an interest in relative improvement. They reported their perceived difference and completed the numeracy scale ($\alpha=.69$). We modeled the effects of comparison type, (mean-centered) numeracy, and their interaction as fixed, with a random intercept per participant. The unit effect was significantly weaker for the more numerate (DID [difference-in-differences]= -22.06 , $p<.001$). Proportional sensitivity was significantly stronger for the more numerate ($DID=-29.12$, $p<.001$).

Study 3 (N=196) was also preregistered (<https://aspredicted.org/blind.php?x=pi2ew6>) and followed the same format as Study 2, except participants compared two telephone queues on the basis of wait times, which was expected to induce an interest in the absolute difference (numeracy $\alpha=.69$). The unit effect was significantly stronger for the more numerate ($DID=6.85$, $p=.007$). Proportional sensitivity did not significantly differ across numeracy levels ($DID=-2.53$, $p=.315$).

Study 4 (N=152) tested whether this discrimination in weighting across task types was intentional. Participants were assigned to a 2 task type (more absolute, more relative) within-subjects design. Within each task type, participants saw two situations and rated the extent to which the absolute or relative difference was more important for each and numeracy ($\alpha = .72$). There was a task type x numeracy interaction ($p < .001$). More numerate (+1SD) individuals were more discriminating across task types ($M_{\text{absolute}}=2.17$ vs. $M_{\text{relative}}=4.28$, $p<.001$) than less numerate (-1SD) individuals ($M_{\text{absolute}}=2.84$ vs. $M_{\text{relative}}=3.80$, $p<.001$).

Study 5 (N=603) examined how discriminating about the tasks affects the response patterns depending on participants’ numeracy by manipulating task type within the design. We used a 3 comparison type (low single, high hundred, high single) between-subjects design, and participants were presented with both task types – an absolute sports situation and relative transmission situation – and tasked with evaluating the difference between these numbers. They also reported absolute-relative perception and numeracy ($\alpha=.72$).

We again found the hypothesized task type x numeracy interaction on absolute-relative perception ($p<.001$). For perceived differences, the attenuation of the unit effect for relative (vs. absolute) tasks was greater among the more numerate, consistent with our theorizing that they would discriminate across task types to a greater degree (DDD [difference-in-difference-in-differences]= -11.82 , $p=.005$). Likewise, the accentuation of proportional sensitivity for relative (vs. absolute) tasks was greater among the more numerate ($DDD=8.50$, $p=.053$).

We contribute to the literature on numerical cognition by presenting the Numerical Processing Likelihood Model and showing that individuals are selective of their processing approach when making evaluations, depending on the task involved and their level of numeracy. As a result, the more numerate can be less or *more* biased than the less numerate, depending on the type of processing that is required for a task.

Understanding What Cringe Is and Why We Want to Talk About It

Dr. Brianna Escoe, Vanderbilt University, USA

Mr. Nathanael S. Martin, University of Cincinnati, USA

Dr. Anthony Salerno, Vanderbilt University, USA

EXTENDED ABSTRACT

While many consumers can relate to “cringeworthy” experiences, no research has examined its causes and consequences. We find that cringe occurs when a consumer observes an actor who inappropriately attempts to curry social favor. We also show that consumers want to share cringeworthy experiences with others via word-of-mouth.

What makes an action cringeworthy? Although research on cringe as an emotion is scant, it is an experience that resonates with many people. Drawing from work investigating vicarious embarrassment (e.g., Paulus et al. 2018), we define cringe as a novel form of vicarious embarrassment in which an observer is in a state of emotional discomfort due to an external entity (e.g., a person or brand) miscalculating the appropriate way to curry social favor that—instead of gaining social favor—acts in a way negatively violating established social norms.

This conceptualization of cringe shares characteristics of both vicarious and “traditional” embarrassment (Krishna et al. 2019), including feelings of social discomfort and negative emotional valence. However, the present research hypothesizes two appraisal dimensions (Smith and Ellsworth 1985) through which cringe differs from vicarious and traditional embarrassment. The first appraisal dimension is the source of the social transgression (self vs. other) while the second is whether the entity miscalculated the appropriate way to gain social favor (no vs. yes). The first appraisal dimension distinguishes vicarious embarrassment and cringe from traditional embarrassment, while the second dimension distinguishes cringe from vicarious embarrassment.

When appraising that one miscalculates the proper way to curry social favor, we hypothesize that the observer should feel an elevated sense of social savviness due to perceiving themselves as more socially savvy than the transgressor. Additionally, while vicarious embarrassment is associated with feelings of empathy (Krach et al. 2011), we predict the observer will have a negative attitude towards the offending entity when observing cringe. Therefore, both an elevated sense of social savviness and a negative attitude towards the transgressor are unique to cringe, distinguishing it from vicarious and traditional embarrassment.

If cringe momentarily enhances one’s sense of social savviness, it may also lead consumers to share cringeworthy experiences as a form of self-enhancement. That is, consumers will share the cringeworthy actions of another entity in order to bolster their own social standing via downward social comparisons (Gibbons and Buunk 1999; Hogg 2000). Indeed, discussing cringeworthy behavior reinforces their own social status while highlighting their understanding of the appropriate way to gain social favor.

Study 1 tests the similarities and distinctions between cringe, embarrassment, and vicarious embarrassment. Participants were assigned to a single factor (emotion: neutral, embarrassment, vicarious embarrassment, cringe) between-subjects design. They read a scenario about a coffee shop, wherein they witnessed another customer behave in a way eliciting one of the target emotions. As predicted, results revealed cringe was elicited when (1) one observed an actor committing a social transgression and (2) one appraised the actor miscalculated the proper way to gain social favor. Observing cringe

also heightened senses of social awareness and increased negative attitudes towards the actor (all p 's < .001).

Study 2 tests the effect of cringe on word-of-mouth behavior in an advertising context and the mechanism of boosted social savviness. This study used a single-factor (ad type: neutral, cringe) between-subjects design. Participants were asked how likely they would be to share the ad and how socially aware they felt compared to others. Participants reported a greater likelihood to share the cringeworthy ad ($M = 3.14$ vs. $M = 2.38$; $t(195) = -2.74$, $p = .007$) and elevated social savviness after viewing the cringeworthy ad ($M = 3.87$ vs. $M = 2.46$; $t(195) = -5.03$, $p < .001$). Hayes’ (2018) PROCESS Model 4 revealed that our elevated social savviness mediated the effect on sharing ($B = .59$, 95% CI: .32, .95).

Study 3 tested a potential moderating factor of social comparisons: if consumers share cringe to highlight their own social standing, then the tendency to share should be amplified for consumers who naturally engage in more social comparisons. Thus, participants reported their natural tendency to engage in social comparisons (Gibbons and Buunk 1999) before completing a similar task as study 2. Specifically, participants saw one of two ads (type: bad, cringe) and completed the same measures as study 2. Results revealed a significant interaction between advertisement type and social comparison tendency ($B = .98$, $t = 3.23$, $p = .001$). Participants with a lower tendency for social comparisons more likely to share the cringeworthy ad ($M = 3.12$) than the bad ad ($M = 1.60$; $B = 1.52$, $t = 6.45$, $p < .001$). Participants with high social comparisons were even more likely to share the cringeworthy ad ($M = 4.01$) than the bad ad ($M = 1.41$; $B = 2.60$, $t = 11.01$, $p < .001$).

Study 4 examined consumers’ tendency to share cringe depending on whether the cringeworthy act originated from one’s in-group or out-group. Using self-brand connections (Escalas and Bettman 2003), participants were asked how closely they associated with several brands, including Tesla. Participants were then assigned to one of two conditions (article: neutral, cringe) to read a news article about Tesla CEO Elon Musk. We predicted that sharing cringeworthy experiences would be amplified for those with low self-brand connections to Tesla since the article bolsters one’s social standing without self-indictment, but lower sharing for those high in self-brand connection. Results revealed participants with a lower self-brand connection were more likely to share the cringeworthy article ($M = 3.26$) than the neutral ($M = 2.46$; $B = .79$, $t(334) = 3.29$, $p = .001$), whereas participants highly identified with Tesla (+1 SD) showed no difference in their likelihood of sharing the articles ($p = .73$). Furthermore, the cringeworthy article elevated participants feelings of social savviness ($B = 1.21$, 95% CI: .87, 1.54) in all cases, but increased social savviness resulted in elevated sharing of the cringeworthy article at low levels of connection to the brand ($B = .43$, 95% CI: .28, .57) but not at high levels (95% CI: -.04, .28).

This research establishes what cringe is and how it motivates word-of-mouth behavior through an elevated sense of social savviness. Our work contributes to the emotions literature by conceptualizing the emotion cringe and delineating it from other forms of embarrassment, while also showing that cringe increases word-of-mouth sharing.

Experience for Me, Material for You: Consumers Underestimate the Experiential Advantage for Others (vs. Self)

Dr. Sarah Lim, University of Illinois at Urbana Champaign, USA

Dr. Joe Goodman, The Ohio State University, USA

EXTENDED ABSTRACT

Despite evidence suggesting the hedonic benefits of experiential purchases over material purchases (Weingarten and Goodman 2021), consumers continue to buy material goods for others. For instance, consumers predominantly choose to give material gifts, despite the social and hedonic benefits of giving experiential gifts (Chan and Mogilner 2017; Goodman and Lim 2018; Yang, Koo, and Hwang 2022). Why are consumers not making more experiential purchases for others? Do they fail to predict the experiential advantage for others (vs. themselves)?

We examine these questions and propose an asymmetry in how consumers perceive others' materialism compared to themselves, which results in consumers' underestimation of the experiential advantage for others (vs. themselves). Our research builds on the better-than-average effect, which demonstrates that people are motivated to evaluate themselves more favorably relative to others (Alicke and Govoron 2005; Brown, 2012). Materialism is often viewed as an unfavorable personality trait (Van Boven, Campbell, and Gilovich 2010); thus, we expect people to view themselves as less materialistic than others. Based on this process, we propose that consumers believe that others will enjoy experiences (vs. material goods) less than themselves (studies 1 and 2) and that this belief is due to the biased perception that others are more materialistic than themselves (study 3 and 4).

Study 1 was designed to provide an initial test of whether gift givers and recipients have a different view of happiness from experiential (vs. material) gifts. The study manipulated perspective (giver vs. recipient) across participants and measured gift type (1=material to 7=experiential). We asked participants to write down a specific gift that they recently either gave or received, depending on condition. Then, participants assessed the happiness from the gift (Nicolaio, Irwin, and Goodman, 2009), such that recipients rated their own happiness and gift givers estimated the happiness of the recipients. Then, participants indicated whether they perceived the gift as more experiential or more material. We found a significant interaction between perspective and gift type ($B = .066, t = 2.22, p = .027$). For gift recipients, experiential gifts were associated with greater happiness than material gifts ($B = .10, t = 2.35, p = .02$). Gift givers, however, did not predict that more experiential gifts would lead to more happiness than material gifts ($B = -.03, p = .43$).

Study 2 extends this finding beyond gift giving and examines whether people believe they are more likely to make an experiential (vs. material) purchase in the pursuit of happiness compared to others. After reading the definition of material and experiential purchases, participants answered two questions, one for the others and one for the self (order counterbalanced): They rated (1) which purchase (9 = material, 1 = experiential) others would be most likely to make to increase their happiness and (2) which purchase they would be most likely to make to increase their happiness. As expected, participants thought that other people would be more likely to make a material (vs. experiential) purchase to increase their happiness ($M_{\text{other}} = 5.27$) compared to themselves ($M_{\text{self}} = 4.30; F(1,288) = 30.14, p < .001$).

Studies 3 and 4 examined the better-than-average process underlying this self-other asymmetry of experiential consumption. We proposed that consumers would view themselves as less materialistic

than others due to the self-serving bias. If this is the case, the self-other asymmetry should be mitigated for (1) consumers who do not perceive materialism as negative (i.e., consumers high on material values; study 3), and (2) consumers who do not perceive others as more materialistic than themselves (study 4).

To test our theory, study 3 examined moderation by consumers' material values. We randomly assigned participants to one of two perspective conditions (self vs. other, between-subjects) and measured material values. Depending on condition, participants indicated which purchase either they or most other people would be more likely to make to increase their happiness. Lastly, participants completed the Material Values Scale (MVS; Richins 2004). We found a marginal interaction between perspective material values ($B = .42, t = 1.90, p = .06$). For less materialistic people (-1 SD), we replicated our previous findings: participants thought that other people were less likely to make an experiential (vs. material) purchase to increase their happiness compared to themselves ($B = -.60, t = 3.02, p = .003$). For more materialistic people (+1 SD), however, this self-other difference was eliminated ($B = -.07, t = .34, p = .74$).

Study 4 further examines self-other asymmetry in perceived materialism by measuring not only participants' material values, but also participants' perception of others' material values. The study design was similar to study 3, but with added questions measuring material values for "most other people." First, we examined whether participants viewed themselves as 'better-than-average' in terms of their materialism by examining the MVD score (materialism of others -materialism of the self). Consistent with the better-than-average effect, we found that a MVD score was significantly greater than zero ($M = .81; t(314) = 20.24, p < .001$), suggesting that participants rated others as higher in material values compared to themselves. Second, we examined whether this self-other misperception in material values moderates the self-other asymmetry in the experiential advantage. As predicted, we found a significant interaction between perspective and MVD ($B = -.75, t(311) = 6.97, p < .001$). Specifically, participants predicted that others would prefer an experiential (vs. material) purchase less compared to themselves as they perceived other people as more materialistic than themselves.

In sum, the current research identifies a self-other bias towards materialism perceptions, whereby consumers feel that others are more materialistic than themselves. This effect leads consumers to mistakenly underestimate the experiential advantages for others relative to the self, leading consumers to choose more material purchases for others. The results provide important practical and theoretical implications for gift giving, perceptions of materialism of others, and experiential consumption.

Luxury Tiers: The Curvilinear Effect of Luxury Consumption on Perceived Competence

Dr. Christopher Cannon, University of Hawaii, USA

Dr. Perrine Desmichel, IESEG School of Management, France

Dr. Derek Rucker, Northwestern University, USA

EXTENDED ABSTRACT

Prior research suggests consumers' perceived competence increases with luxury consumption. By contrast, we demonstrate an 'inverted-U' relationship whereby consumers' perceived competence is greatest when consuming moderate (vs. low, high) luxury goods. This result arises from attributions tethered to intrinsic motivation and has implications for both marketers and consumers.

Luxury consumption produces positive social evaluations beyond personal value to the consumer. For example, observers gave more preferential treatment (e.g., higher salaries, compliance, donations) toward individuals when they wore luxury brands because they perceived the individual to have higher status (Lee, Ko, and Megehee 2015; Nelissen and Meijers 2011; Sundie et al. 2011; Wang and Griskevicius 2014). This prior research implicitly suggests that luxury consumption would also offer a positive and linear relationship with one's competence since both are agentic traits that appear to move in parallel in social evaluations (Bellezza, Gino, and Keinan 2014; Fiske et al. 2002).

However, although both status and competence are agentic traits, we argue they are not inherently interchangeable. Status is concerned with one's position within society, whereas competence is concerned with one's skills and abilities (Abele et al. 2016; Carrier et al. 2014; Fiske et al. 2007). However, luxury consumption has largely ignored understanding the differential impact of these two constructs. We submit that, in some cases, this distinction would be less important because status and competence do covary. This might be particularly true when researchers look at simple comparisons between binary categories (i.e., non-luxury versus luxury goods) which only allow for testing and predicting linear relationships. Yet, in practice, it is not as straightforward as brands being either categorically non-luxury or luxury; brands or products can fall within various luxury tiers (Chung and Kim 2020). For example, within the backpack category, JanSport, Samsonite, and Prada represent lower (or non-luxury), more moderate luxury, and higher luxury, respectively.

We propose the concept of "luxury tiers" allows for novel predictions about the relationship between luxury consumption and perceived competence (vs. status). Whereas luxury consumption should positively and linearly affect status perceptions due to associated financial costs, we predict that luxury consumption will exert a curvilinear or 'inverted-U' relationship on perceived competence. Consumers should be perceived as more competent when wearing or using moderate-luxury brands, compared with both low- and high-luxury brands. We hypothesize and explain that this curvilinear relationship is a result of inferred intrinsic motivation (Sun, Bellezza, and Paharia 2021; Wang 2022). Perceived competence is a well-established function of intrinsic motivation (Bandura 1982; Deci 1975). We predict moderate-luxury consumers should be perceived as the most competent because moderate-luxury goods strike a balance between having high product quality (i.e., an intrinsic reason for consumption) but not an excessive amount of brand status (i.e., an extrinsic reason for consumption that undermines one's intrinsic motivation).

We test our theorizing across three experiments using various product categories (e.g., clothing, wine) and different luxury cues (e.g., price, brand name).

In experiment 1, participants ($N = 300$ MTurk) saw a backpack for a fictitious brand "Oasis" and were asked to evaluate the person who owns the product. We manipulated luxury via the price of the product: low (i.e., \$9.99), moderate (i.e., \$39.99), and high (i.e., \$299.99). Participants rated their perception of the consumer's competence ($\alpha = .95$; Brambilla et al. 2011) and status ($\alpha = .98$; Cannon and Rucker 2019). In line with prior work (Nelissen and Meijers 2011), a oneway ANOVA revealed a significant linear effect of luxury consumption on perceived status ($M_{\text{low}} = 2.56$, $M_{\text{moderate}} = 3.30$, $M_{\text{high}} = 5.29$; $F(2, 297) = 99.72$, $p < .001$). Importantly, a oneway ANOVA also revealed a significant curvilinear effect of luxury consumption on perceived competence ($F(2, 297) = 3.23$, $p = .041$). The consumer was perceived as more competent in the moderate-luxury condition ($M = 4.95$) than in both the low-luxury ($M = 4.56$; $t(196) = 2.47$, $p = .014$) and high-luxury conditions ($M = 4.62$; $t(196) = 1.99$, $p = .048$).

In experiment 2, participants ($N = 501$ Prolific) were asked to evaluate the host of a dinner party serving wine. Participants were randomly assigned to one of nine luxury tiers operationalized via the price of the wine (e.g., \$6.99, \$26.99, \$96.99). Participants rated their perception of the consumer's competence ($\alpha = .94$) and status ($\alpha = .97$) using the same items as in the previous study. In line with prior work, there was only a positive linear effect of luxury consumption on perceived status ($\beta = 0.39$, $t = 3.51$, $p < .001$). In contrast, there was a curvilinear effect of luxury consumption on perceived competence ($\beta = -0.02$, $t = -2.14$, $p = .03$).

Experiment 3 provides evidence of the psychological process and operationalizes luxury using real brand names. Participants ($N = 300$ MTurk) were randomly assigned to view and imagine the owner of one of three backpacks: low or non-luxury (i.e., JanSport), moderate (i.e., Samsonite), and high (i.e., Prada). Participants rated the perceived competence of the backpack owner ($\alpha = .93$). Then, participants indicated their perceptions the consumer purchased the backpack for intrinsic reasons ($\alpha = .90$; e.g., quality, enjoy its features) and extrinsic reasons ($\alpha = .96$; e.g., to impress others, prestige). A oneway ANOVA revealed a significant effect of luxury consumption on perceived competence ($F(2, 297) = 10.99$, $p < .001$). The consumer was perceived as more competent in the moderate-luxury condition ($M = 5.34$) than in the low-luxury ($M = 5.05$; $t(198) = 2.11$, $p = .036$) and high-luxury conditions ($M = 4.68$; $t(198) = 4.77$, $p < .001$). To provide evidence of the psychological process, we ran a sequential contrast coded multicategorical mediation using the PROCESS macro for SPSS. Intrinsic motivation mediated the effect of luxury consumption on perceived competence (moderate vs. low luxury: $\beta = 0.18$, bootstrapped 95% CI = [0.03, 0.34]; high vs. moderate luxury: $\beta = -0.63$, bootstrapped 95% CI = [-0.84, -0.45]). Extrinsic motivation did not significantly mediate the effects.

In conclusion, studying luxury tiers can reveal the occurrence of curvilinear relationships. In this research, consuming moderate-luxury goods provides a stronger signal of competence than both low- and high-luxury goods. We also provide evidence for the psychological mechanism: inferred intrinsic motivation. Our research demonstrates the importance of moving from studying luxury in a binary fashion (i.e., non-luxury vs. luxury) to studying luxury tiers.

Economic Inequality Shapes Consumers' Engagement in the Sharing Economy

Ms. Jinyan Xiang, Virginia Tech, USA
Dr. Mario Pandelaere, Virginia Tech, USA

EXTENDED ABSTRACT

Four mixed-method studies ($N=83,626$) find that economic inequality lowers user-provider interpersonal trust, thus discouraging consumers from using and contributing to the sharing economy. Our results suggest that rising or statically high economic inequality could hinder the long-term development of the sharing economy by hurting demands and supplies.

The sharing economy has boomed in the past decade. The literature has identified extrinsic and intrinsic motives for using the sharing economy, as well as, how they interact with other antecedents such as demographic segments, types of shared assets, and characters of platforms (e.g., high vs. low con-sociality) (e.g., Benoit et al. 2017; Milanova and Mass 2017; Perren and Kozinets 2018). In this research, we aim to identify a fundamental socioeconomic antecedent (vs. individual or platform-level antecedents) and examine how it affects consumers' engagement, which incorporates *usage*—the focus of prior research and *contribution*—an understudied aspect yet critical to the success of the sharing economy.

We propose that economic inequality in a region (e.g., state, country) discourages consumers from engaging in the sharing economy in the region because it undermines their interpersonal trust in providers or users from the region, which is a crucial driver of the sharing economy. We conducted four mixed-method studies ($N=83,626$) in multiple contexts of the sharing economy (e.g., p2p lending, lodge-sharing, and ridesharing), and adopted various operationalizations of economic inequality and measures of consumers' engagement.

In study 1, we constructed and analyzed an archival dataset ($N=83,115$). The primary data source is the Prosper listing data. Each listing includes the "borrower's state" information, providing a suitable empirical context to explore the relationship between economic inequality and consumers' engagement in the sharing economy. Then, we added *Gini* indices retrieved from Census Bureau based on the borrower's state and the listing year, and the year-state-level *Gini* served as a quantified measure of economic inequality (i.e., focal IV). We also calculated the *average lending amount (ALA)* for each listing (=original loan amount/the number of lenders) and treated it as the proxy of engagement (i.e., DV). Next, we included *median household incomes* retrieved from Census Bureau as a year-state-level covariate, as well as three listing-level covariates: 1) *Prosper score*—an integrated metric of borrower's credibility, as well as the 2) *estimated return* and 3) *duration* of the listing. Moreover, we created a product term to capture the interaction between *Gini* and *Prosper score* because both are expected to affect interpersonal trust, the antecedent of *ALA*. Finally, we added fixed state and month effects to control unobservable state and time shocks.

Since *ALA* is left-skewed with a few extreme outliers, we took logarithm transformation of it and used robust linear regression for estimation to address the heteroscedasticity and outlier issues. As predicted, *Gini* negatively correlates with the *ALA* ($B=-2.89$, $95CI=[-4.90, -.88]$), suggesting that as *Gini* increases by 0.1, lenders would lend 28.89% less on average for a listing. In addition, there was a significant interaction between *Gini* and *Prosper score* that the negative effect of *Gini* diminishes as the *Prosper score* increases. Study 1 provides field evidence for our propositions; however, the results are essentially correlational (vs. causal). The rest experimental studies address this major limitation.

In study 2 ($N=121$), we told participants they would invest in an international p2p lending platform. Then, they read a mock listing that showed the borrower's location (i.e., a foreign country). Next, partici-

pants read the country's income distribution, which had a high (vs. low) variance, serving as the manipulation (adapted from Payne, Brown-Iannuzzi, and Hannay 2017). Further, participants indicated their interpersonal trust, lending amount, and willingness to choose this borrower over other borrowers. As predicted, participants in the *high (vs. low) inequality* condition were less willing to choose borrower ($p=.003$, $\eta^2=.073$) and intended to lend less ($p=.007$, $\eta^2=.060$), which were mediated by interpersonal trust ($a*b_{willingness}=-.58$, $95\%CI=[-.92, -.28]$; $a*b_{lending}=-185.65$, $95\%CI=[-376.06, -37.10]$). Study 1 and 2 document the negative effect of economic inequality on consumers' engagement in terms of contribution, as well as interpersonal trust as the mechanism. Study 3 and 4 switch to the aspect of usage and retest these propositions in other contexts, using different manipulations.

In study 3 ($N=202$), we told participants they would work in a foreign country for three months. Then, they read a mock Google webpage that described the country as one of the world's most unequal (vs. equal) countries (e.g., Gini index of 0.6 vs. 0.2 and the 5th vs. 160th (out of 164) ranking in the global inequality database), serving as the manipulation (validated by a pretest). Next, participants indicated their willingness to choose a lodge-sharing service over a comparable hotel for accommodation. As predicted, participants in the *high (vs. low) inequality* condition were more likely to choose the lodge-sharing service ($p=.019$, $\eta^2=.027$).

Study 4 used the cover story of study 3 but administered a more implicit manipulation. Specifically, participants were presented with street-view pictures with high-inequality (vs. neutral) cues (adapted from Waldfogel et al. 2021). Next, participants indicated their interpersonal trust and willingness to choose a ridesharing service over other available transportations when arriving at the airport. As predicted, participants in the *high inequality (vs. control)* condition were more likely to choose the ridesharing service ($p=.049$, $\eta^2=.024$), which again was mediated by interpersonal trust ($a*b=-.33$, $95\%CI=[-.59, -.11]$).

Four studies convergently support our propositions. These consumer-level findings suggest that rising economic inequality could hinder the long-term development of the sharing economy by hurting demands and supplies.

Simple or Complex Logos? The Impact of Logo Complexity on the Brand Perception

Ms. Qing Tang, Nanyang Technological University, Singapore

Prof. Xun (Irene) Huang, Nanyang Technological University, Singapore

Prof. Kuangjie Zhang, Nanyang Technological University, Singapore

EXTENDED ABSTRACT

In this article, we show that logo complexity (simplicity) can impact consumers' perceptions of the brand: complex logos can activate a prestigious brand image while simple logos can activate an approachable brand image. Employing mixed methods (field surveys, IAT, and experiments), we provide converging support for this proposition.

Despite the prevalence of logo redesign, existing research remains silent on how logo complexity versus simplicity might influence brand perceptions. The current research addresses this important question. Specifically, we show that logo complexity (simplicity) enhances the perceived prestige (approachability) of a brand.

Logo complexity is defined as the amount of detail in a logo (Snodgrass and Vanderwart 1980). In other words, a complex logo tends to have more visual elements (Henderson and Cote 1998), which can make consumers infer that the brand has a more intricate product design. As prestigious brands (e.g., luxury brands) are known for refined details (Fionda and Moore 2009), a brand with an intricate product design should be perceived as more prestigious. We hypothesize that logo complexity can increase the perceived prestige of a brand and this effect is mediated by the perceived intricacy of the brand's product design.

By contrast, logo simplicity boosts brand approachability because a simple (vs. complex) logo is relatively easier to process. Prior research suggests that a sense of fluency usually reduces psychological distance (Alter and Oppenheimer 2008). Following the same logic, people should perceive a brand with a simple logo to be psychologically more approachable. We hypothesize that logo simplicity can increase the perceived approachability of a brand and this effect is mediated by the processing fluency of the logo.

In Study 1a, we compared the logo complexity of the top 30 luxury brands and top 30 fast-fashion brands listed on Ranker.com. Two hundred US participants from MTurk rated the logo complexity ("To what extent do you feel this logo is complex"; 1 = very simple, 9 = very complex). We found that logos of luxury brands were rated more complex ($M = 4.42$) than those of fast-fashion brands ($M = 3.57$, $F(1,58) = 5.96$, $p = .02$).

In Study 1b, we identified a secondary dataset on brand personality perceptions (Lovett, Peres, and Shachar 2014) and selected the top 100 brands in 2010 from Interbrand.com (only 69 brands' information was available in the secondary dataset). We selected three brand personality traits related to prestige (upper class, prestigious, glamorous) and three related to approachability (down-to-earth, unapproachable [reverse-coded], and friendly). We averaged them to form a prestige index and an approachability index. We recruited 150 US participants from MTurk to rate the logo complexity. A correlational analysis yielded a significant positive correlation between logo complexity and brand prestige ($r = .41$, $p < .001$), and a significant negative correlation between logo complexity and brand approachability ($r = -.24$, $p < .05$).

In Study 2, 70 US participants from MTurk completed the IAT in which they sorted visual patterns (simple vs. complex) or brand names (e.g., Gucci, H&M) into one of the two disjunctive categories ("Complex or Luxury Brand" and "Simple or Mass-Market Brand" vs. "Complex or Mass-Market Brand" and "Simple or Luxury Brand"). If participants mentally associate complexity (simplicity)

with prestige (approachability), their reaction time would be shorter in the compatible block. Following Greenwald, Nosek, & Banaji (2003), we computed an IAT D-score, which was significantly greater than zero ($D = .53$, $t(69) = 10.61$, $p < .001$). This indicates that people have a positive association between complexity (simplicity) and brand prestige (approachability).

In Study 3, we manipulated the complexity of two logos. One hundred eighty-eight US participants from Prolific read a news article about the logo revamp of a fictitious brand Y.L.M.A. In the complex (simple) condition, participants were told that the new design has more details (eliminates extra details) and reflects elaborateness (minimalism). They were shown the two logos with an arrow in between to illustrate the direction of the logo change. Participants rated brand prestige (upper class/sophisticated/prestigious; 1 = not at all, 9 = very much) and brand approachability (down-to-earth, approachable, unpretentious; 1 = not at all, 9 = very much). The brand having a more complex new logo ($M = 6.36$) was perceived as more prestigious than the brand having a simpler new logo ($M = 5.68$; $F(1, 196) = 5.76$, $p = .02$). The brand having a simpler new logo ($M = 5.77$) was perceived as more approachable than the brand having a more complex new logo ($M = 3.83$; $F(1, 196) = 57.88$, $p < .001$).

In Study 4, 200 US participants from Prolific evaluated a logo of a luggage brand and saw either a complex or a simple logo. Participants rated brand prestige and brand approachability as in Study 3. Participants also rated the intricacy of product design ("I feel the product design of this brand shows great intricacy," "I feel the products of this brand are made with fine details;"; 1 = not at all, 9 = very much) and the processing fluency of the logo (1 = not at all fluent/difficult to process, 9 = very fluent/easy to process, adapted from Luffarelli, Mukesh, and Mahmood 2019). We replicated the effect of logo complexity (simplicity) on brand prestige (approachability) as in Study 3. Mediation analyses with perceived intricacy of product design and processing fluency as paralleled mediators showed that only perceived intricacy of product design significantly mediated the effect of logo complexity on perceived brand prestige (indirect effect = 1.34, 95% CI = [.90, .181]). Only processing fluency significantly mediated the effect of logo complexity on perceived brand approachability (indirect effect = -.42, 95% CI = [-.73, -.18]).

In Study 5, 200 US participants from Prolific imagined they were going to attend a social gathering and choosing a T-shirt to wear at the gathering. They were primed with a goal to look either upper class or approachable. Participants in the prestige-signaling condition were more likely to choose the T-shirt with a complex logo (66.00%) than those in the approachability-signaling condition (37.00%; $\chi^2 = 16.84$, $p < .001$).

The current research adds to the existing research on understanding the antecedents of brand prestige and brand approachability by identifying a novel visual element of brands: logo complexity. This research also bears important implications for marketing practitioners.

Easy Calculation or Easy Result: The Paradoxical Effects of Decimal Numbers

Dr. Yi Li, Macquarie University, Australia

EXTENDED ABSTRACT

This research investigates under which condition consumers prefer to exert more mental effort in simple calculations involving decimal numbers. We find that when the calculation outcome is made salient, consumers prefer to calculate two decimal numbers to reach a rounder outcome. This calculation process triggers a positive affect, roundup/round-down pleasure.

Decimal numbers are ubiquitous in the marketplace. They exist in the form of retail prices, tips, and sales taxes. Consumers often need to perform simple arithmetic calculations involving decimal numbers. Decision theory has established that consumers prefer to minimize their mental effort to preserve the limited cognitive resources (Simon 1955; Bettman, Luce, and Payne 1998). Relatedly, research in numeric cognition supports that people have a strong preference for easier-to-process round numbers (e.g., 5.00, 10.00) over precise numbers (e.g., 4.92, 10.37) (Kettle and Häubl 2010; Thomas, Simon, and Kadiyali 2010). These findings together present a paradoxical effect of decimal numbers in mental calculations: while adding/subtracting a *round number* (e.g., 2.00) to/from a decimal number (e.g., 4.92) eases the calculation process, it produces decimal results (e.g., 6.92/2.92); adding/subtracting a *decimal number* (e.g., 2.08/2.92) to/from a decimal number (e.g., 4.92) increases the calculation complexity but leads to easier-to-process round results (e.g., 7.00/2.00). Will consumers prefer easy calculations or easy results?

Although the easy calculation is the by-default preference given that consumers are cognitive misers, this research posits that when *the calculation result is salient*, the goal of reaching round number results gets activated. This prediction is consistent with the findings that people exert extra effort to achieve a round number goal even when a precise number goal is provided (Pope and Simonsohn 2011). When cognitive effort is interpreted as means to achieve a goal, people view effort more positively and are more willing to exert mental effort (Briñol, Petty, and Tormala 2006; Labroo and Kim 2009). Thus, when the round results goal is activated, consumers are more willing to engage in effortful calculations involving decimal numbers.

Goal achievement triggers positive affect, which intensifies towards and after goal attainment (Higgins 1997; McCrea and Vann 2018). We posit that consumers also experience positive affect when reaching the round results, which is specific to the feelings of completion, accomplishment, and comfort of rounding up and down the numbers. We term it the “round up/down pleasure”. This affect plays two roles: it explains why consumers will engage in effortful calculations (i.e., mediator) to reach round results, and it also predicts who is more likely to do so depending on their levels of commitment to round number goal (i.e., moderator; (Kruglanski et al. 2018).

Studies 1a and 1b tested that the preference for easy results can influence consumers’ purchase decisions. Participants were imagining that they were shopping for groceries online and they saw the basket total (a decimal number). They had to choose one final product to add to their basket. In study 2a [2b], participants chose the quantity [brand] of the product. The result salience was manipulated between-subjects: half of the participants had to track their spending by entering the basket total after making the choice. The other half did not do so. Both studies found that when the calculation result was salient, participants significantly increased their choices of roundup options.

Study 2 tested the preference for easy results in the sales promotion context. We asked participants to evaluate a sales promotion by first calculating the sales price by subtracting the discount from

the original price (a decimal number). We manipulated the discount such that in the easy result [easy calculation] condition, the discount rounded down the original price [was a round number]. After, participants rated their purchase intentions and round-down pleasure. Participants reported greater purchase intentions and greater round-down pleasure in the easy result condition. A mediation test confirmed that round-down pleasure mediated the effect of discount type on purchase intention.

Study 3 tested the preference for easy results in the tipping context. The bill total was manipulated between-subjects (\$42.00 vs. \$41.40 vs. \$41.48). Participants were asked to choose from three tipping options: \$8.00, \$8.60, and \$8.52 and enter the bill total. The roundup pleasure was measured as the moderator. A chi-square test showed that participants in each bill total condition had the highest probability of choosing the roundup tip option. Further, a floodlight analysis confirmed the moderating effect of roundup pleasure: for consumers who were committed to round results, they would pick the roundup tip regardless of the bill total, which varied the calculation difficulty. Consumers who were less committed to this goal would do so only if the calculation was easier (i.e., when the bill total was \$42.00).

Taken together, this research demonstrates that when the calculation result is made salient, consumers prefer round numbers more as the calculation result rather than the calculation input. This preference influences a range of consumer decisions such as product choices, promotion evaluations, and tipping.

The Effect of Recycled Packaging on Perceived Product Naturalness

Ms. Joyce De Temmerman, Ghent University, Belgium
Prof. Nico Heuvinck, Ieseg School Of Management, France
Prof. Hendrik Slabbinck, Ghent University, Belgium
Prof. Iris Vermeir, Ghent University, Belgium

EXTENDED ABSTRACT

Across five studies, we demonstrate that consumers perceive products in recycled (vs. regular) plastic packaging as more natural due to higher CSR beliefs, whereas this effect does not hold for recycled versus non-recycled cardboard packaging. Moreover, higher perceived naturalness of products packaged in recycled plastic leads to increased purchase intention.

Manufacturers can offer solutions to address climate change by reducing packaging waste through, among other things, recycling of packaging (Adekomaya & Majozi, 2020; Hopewell et al., 2009; Humphrey, 2009; Nordin & Selke, 2010). Yet, packaging design and materials also impact product perceptions and consumption (Becker et al., 2011; Magnier et al., 2016; Silayo & Speece, 2007).

Package design can create halo effects in which the presence of package design elements can cause consumers to make inferences about the product itself (Bui, Tangari, and Haws 2017; Chandon 2013; Koo and Suk 2016). Previous research on packaging materials focused on comparing the effect of different packaging materials such as cardboard or glass versus plastic (Bhardwaj, 2019; Magnier et al., 2016) on product naturalness perceptions. Yet, the current research focuses on differences in naturalness perceptions inferred from the same packaging material (recycled vs. regular plastic and cardboard). Whether a package is recycled or not might be a diagnostic cue for consumers to assess products' naturalness.

Using recycled packaging implies that companies are invested in protecting the environment. Favourable information that conveys a company's good deeds for the environment such as recycling can make consumers think that the company attaches importance to CSR. When firms signal concern for their stakeholders through corporate-level CSR actions they should also be invested in providing their customers with products containing healthier ingredients and few preservatives (Peloza et al., 2015) and thus higher product naturalness perceptions could occur.

We further argue that the effect of recycled packaging on perceived product naturalness will only be present for unsustainable materials such as plastic and not another type of sustainable material such as cardboard because this is regarded as natural and less harmful for the environment in itself (Bhardwaj, 2019; Lindh et al., 2016; Otto et al., 2021; Peters, 2016).

We tested the following hypotheses in five studies:

- Hypothesis 1: Products in recycled plastic packaging are perceived as more natural than products in regular plastic packaging.*
- Hypothesis 2: A recycled packaging material results in higher naturalness perceptions than a non-recycled regular packaging material for plastic packaging but not for cardboard packaging.*
- Hypothesis 3: CSR beliefs mediate the relationship between recycled plastic packaging and perceived product naturalness.*

The results of Study 1A and 1B denote that products in recycled plastic are perceived as more natural than products in regular plastic packaging.

Study 2 showed that regardless of which product type, products in recycled plastic are perceived as more natural than products in regular plastic packaging. Moreover, a mediation analysis revealed that recycled (vs. regular) plastic packaging increased perceived product naturalness, which, in turn, increased purchase intentions.

Study 3 showed that products in recycled plastic are perceived as more natural than products in regular plastic packaging. There was no such difference for cardboard packaging.

Study 4 showed that both food and non-food products in recycled plastic are perceived as more natural than food and non-food in regular plastic packaging. Moreover, a serial mediation analysis revealed that recycled (vs. regular) plastic packaging increased CSR beliefs of the company, which in turn increased perceived product naturalness, which subsequently increased purchase intentions.

Our research makes several contributions. First, we extend research on structural packaging and naturalness by providing evidence that consumers perceive products in recycled (vs. regular) plastic as more natural, which positively affects purchase intentions. Second, we extend literature on sustainable packaging by revealing the influence of whether packaging is recycled or not. Unlike previous research which focused on comparing different packaging materials (e.g., cardboard vs. plastic, glass vs. plastic) (Bhardwaj, 2019; Magnier et al., 2016), the current research focuses on differences within the same packaging material (recycled vs. regular plastic and cardboard). Moreover, previous research compared sustainable versus non-sustainable packaging that explicitly differed in visual appearance (e.g., color, glossiness) (Magnier et al., 2016), which could be an important confound. In our research we keep these variables constant. Third, we make a theoretical contribution by demonstrating why recycled plastic packaging triggers naturalness perceptions. By addressing that CSR beliefs explain the effect, we show that recycled packaging can have an effect on beliefs about corporate-level information, which in turn can have an effect on product-level attributes such as naturalness (Peloza et al., 2015). By looking at a subtler CSR cue as well as extending it to non-food products, we answer Peloza et al.'s (2015) call for more research on the information location of CSR activities as well as product category extension beyond food products.

This research has many implications, among others for public policy makers, as recycled packaging seems to be a double-edged sword. On the one hand, public policy makers might continue to encourage or mandate using recycled plastic as a packaging material and use product naturalness perceptions as an advantage to convince manufacturers to address packaging waste and associated climate change. Product manufacturers can also benefit from our insights as using recycled plastic packaging would reinforce companies' CSR beliefs, which positively influences perceived product naturalness and purchase intentions of their products. On the other hand, the results are important for public policy makers to control greenwashing practices. Our research contributes to a better understanding of how greenwashing through packaging can be used to manipulate consumer perceptions. Hence, public policy makers have to see whether the pros (climate) outweigh the cons of recycled packaging (biased product naturalness perceptions).

Effect of Political Ideology on Online Interpersonal and Information Evaluation

Dr. Max Yu, Nanyang Technological University, Singapore
Prof. Donnel Briley, University of Sydney, Australia

EXTENDED ABSTRACT

We examine whether and how conservatives and liberals differ in their reliance on online sources when there is no objective truth. A field study and three experiments show that conservatives in comparison to liberals are less skeptical of online reviewers, and in turn, are find online reviews more useful.

Are conservatives or liberals more susceptible to online information? While much attention is given to examine this question in different scholarly fields, most research is limited to examining how conservatives and liberals differ in susceptibility to claims that are factually wrong. It is unclear if consumers' political beliefs influence their susceptibility to online information that is subjective opinions.

In this research, we examine the influence of consumers' political beliefs on their susceptibility to online reviews. Unlike online information studied in this area of research, online reviews are information about consumers' preferences for products and services that is subjective and does not have an objective truth. Consumers are never right or wrong to believe the idiosyncratic preferences presented in online reviews. Existing literature has two main accounts on how political ideology influences online information susceptibility: (1) ideological motivated reasoning (Washburn and Skitka 2018) and (2) underthinking (Pennycook and Rand 2019). Both accounts address whether conservatives and liberals differ in truth discerning, but they cannot be applied to a context where there is no verifiable fact.

We propose that consumers' political ideologies affect their skepticism toward online reviewers and, in turn, how useful they find the opinions they encounter online. On one hand, foundational research on influence of political ideology suggests people who are more conservative often endeavor to reduce threats and maintain order (Jost, Nosek and Gosling 2008), a pattern suggesting right leaning individuals may be more closed to opinions of anonymous others.

On the other hand, as we argue in this research, conservatives are less skeptical than liberals toward online reviewers in order to satisfy their desire for common beliefs. Conservatives in comparison to liberals have greater desire for common beliefs, which stems from their stronger epistemic and relational desire (Jost et al. 2003; Jost, Ledgerwood and Hardin 2008). Trust is inseparable in the process of creating common beliefs (Echterhoff et al. 2009). When individuals are skeptical of another person, they could not relate to this person and rely on her or his views to help them better understand target topics or things. Hence, when people want to rely on someone's opinion to better understand something, being skeptical of this person does not facilitate the goal of achieving common beliefs. Therefore, conservatives are less skeptical than liberals toward online reviewers.

We first conducted a field study using a publicly available data set published by Yelp. We used the business zip code as a proxy for general political leaning by matching zip codes to counties and states using a database generated from sources including the U.S. Postal Service and U.S. Census Bureau. Negative binomial regression analyses were used to examine effects on the number of review useful votes on Yelp. All three models showed that political ideology has a significant effect on the number of useful review votes (all $p < .001$). County political ideology percentage ($\beta = .061$), state political ideology percentage ($\beta = .119$), and state PVI ($\beta = .097$) all have positive coefficients, suggesting more conservative reviewers give higher number of useful review votes.

In study 1 ($N = 203$), we tested our prediction in an online experiment by showing each participant five online reviews of different products. They rated each review either helpful (coded 1) or unhelpful (coded 0), and their perceived helpfulness is the sum of their ratings. Their preferences for news broadcasting stations ($p = .056$, $M_{\text{Fox}} = 4.615$, $M_{\text{CNN}} = 4.480$, $M_{\text{MSNBC}} = 4.000$), U.S. presidential candidates ($\beta = .130$, $SE = .023$, $p = .064$), and taxation and immigration policies ($\beta = .164$, $SE = .043$, $p = .020$) are predictive of their perceived review helpfulness.

In study 2 ($N = 122$), we tested our underlying mechanism by measuring reviewer skepticism (reliable, honest, trust; Packard, Gershoff, and Wooten 2016). Conservatives compared to liberals rated an online review more helpful, and this effect is mediated by reviewer skepticism ($CI = .008$ to $.195$). Review attribution (product quality vs. reviewer taste) does not mediate the effect.

In study 3 ($N = 303$), we manipulated skepticism by priming participants using news articles. If our conjecture is supported, conservatives and liberals should behave similarly when they are primed with high or low skepticism. Political ideology was measured using donation choices. The results showed a significant interaction effect between political ideology and skepticism manipulation ($p = .043$). Political ideology did not affect review helpfulness in high skepticism ($p = .754$), but conservatives compared to liberals rated the review more helpful in the low skepticism ($b = .254$, $SE = .075$, $p < .001$, $CI: .107$ to $.401$) and control ($b = .288$, $SE = .078$, $p < .001$, $CI: .135$ to $.440$) conditions. The results supported our prediction, but it also showed that it is difficult to get liberals to reduce their skepticism.

What underlies the Nutri-Score effect? A multi-methods approach

Ms. Eva Heeremans, Ghent University, Belgium
Prof. Maggie Geuens, Ghent University, Belgium
Prof. Iris Vermeir, Ghent University, Belgium

EXTENDED ABSTRACT

While the Nutri-Score (=front-of-pack label) has been found to be an effective tool to improve food choices, it remains unclear why and for whom it affects buying behavior. We adopt a multi-methods approach and show that the Nutri-Score works because it activates consumers' health goals, irrespective of their health concern.

To reduce the obesity problem, different front-of-pack labels have been introduced. This paper focuses on the European Nutri-Score nutrition label. While the effectiveness of the Nutri-Score ("Nutri-Score effect") has been shown in several lab and real-life experiments (e.g., Herberg, Touvier and Salas-Salvado 2021; Dubois et al. 2020), evidence on why and for whom the Nutri-Score works is lacking.

The current grocery shopping environment constantly exposes consumers to cues that activate short-term hedonic goals (e.g., tempting foods), at the cost of long-term investment goals (e.g., one's health; Geyskens et al., 2008). To reduce hedonic goal activation, several external cues (e.g., dieting advertisements) have been introduced to activate health goals and encourage healthier purchases ("health goal priming", Papiés, 2016). We propose that the Nutri-Score serves as an external cue that activates health goals, which in turn leads to healthier food choices.

Hypothesis 1: The presence (vs. absence) of a Nutri-Score activates participants' health goals which improves the healthiness of shopping baskets.

Research pointed out that the primed concept (i.e., health) leads to the motivational benefits that support goal pursuit more strongly when a person values the specific concept (Papiés and Aarts, 2016). Therefore, we expect that the more health-concerned consumers are, the more likely it is that exposure to the Nutri-Score activates their health goals.

Hypothesis 2: The effect of the presence (vs. absence) of the Nutri-Score on the healthiness of the shopping baskets is stronger the more health-concerned consumers are.

We adopted a multi-methods approach and set up an **experimental-causal-chain design** (study 1 and study 2) and a **measurement-of-mediation design** (study 3A and study 3B) to investigate whether an activation of health goals underlies the "Nutri-Score effect".

Study 1 investigated the impact of the Nutri-Score (presence vs. absence) on the activation of health goals. We recruited 309 participants ($M_{\text{age}}=30$, $SD=15.26$, 63.4% women) in an online between-subjects experiment. Participants were shown different product packages on which the Nutri-Score was present or absent. Afterwards, we measured health goal activation. An independent samples t-test revealed that health goal activation was (marginally significantly) larger when the Nutri-Score was present (vs. absent; $M_{\text{present}}=4.34$, $SD=.67$; $M_{\text{absent}}=4.19$, $SD=.73$; $t(307)=-1.81$, $p=.071$). The moderation analysis (Process Model 1, Preacher and Hayes, 2004) revealed no significant interaction between the Nutri-Score and health concern ($t(307)=.76$, $p=.446$), indicating that the Nutri-Score activates participants' health goals, irrespective of their health concern.

Study 2 tests the relationship between an activation of health goals and the healthiness of the shopping baskets. We recruited 341 participants (77% women, 40.8%: <30yo, 28.8%: 30-49yo, 30.4%: >50yo) in an online between-subjects experiment (health goal activation: yes vs. no). We manipulated health goal activation by means of a scrambled-sentences task (Geyskens et al., 2007). Afterwards, participants shopped for groceries in a simulated online web store. We calculated the healthiness of participants' shopping baskets based on the Nutri-Score. An independent samples t-test indicated that participants in the health goal activation (vs. no) condition composed significantly healthier shopping baskets ($M_{\text{healthgoal}}=3.36$, $SD_{\text{healthgoal}}=0.34$, $M_{\text{nohealthgoal}}=3.28$, $SD_{\text{nohealthgoal}}=.35$, $t(338)=-2.06$, $p=.040$). Based on the findings of study 1 and study 2, we conclude from this experimental-causal-chain design that the Nutri-Score effect is mediated by an activation of health goals, confirming *H1*.

The purpose of **study 3A** is to provide further evidence for our hypotheses in a measurement-of-mediation design. We recruited 122 participants (69% women, 63.1%: 30yo, 18.9%: 30-49yo, 18%: >50yo) to participate in an online between-subjects experiment (Nutri-Score: presence vs. absence). Participants shopped for groceries in a simulated online web store. Afterwards, we measured health goal activation by means of an existing scale (Henselmans et al., 2011). An independent samples t-test showed that participants' shopping baskets were significantly healthier when the Nutri-Score was present (vs. absent; $M_{\text{present}}=3.33$, $SD=.40$, $M_{\text{absent}}=3.15$, $SD=.44$, $t(120)=-2.35$, $p=.020$). A mediation analysis (Model 4, Preacher and Hayes, 2004) revealed that the Nutri-Score effect is significantly and fully mediated by an activation of health goals ($ab=.08$, 95%CI=[.016;.173]). The Nutri-Score activated participants' health goals (coefficient=.44, $t(120)=2.84$, $p=.005$), which in turn improved the healthiness of shopping baskets (coefficient=.19, $t(120)=4.45$, $p<.001$), providing evidence for *H1*. A moderated mediation analysis (Model 8) revealed no significant interaction between the Nutri-Score (absence vs. presence) and health concern on health goal activation (a path; coefficient=-.01, $t(120)=-.02$, $p=.943$) nor on the healthiness of the shopping baskets (c path; coefficient=.03, $t(120)=.26$, $p=.794$), rejecting *H2* (moderated mediation: coefficient=-.002, 95%CI=[-.062;.079]). Hence, the Nutri-Score activates health goals and improves the healthiness of the shopping baskets, irrespective of participants' health concern.

Study 3B replicates the findings of study 3A but we measured health goal activation with a different scale. We recruited 225 participants (68.2% women, $M_{\text{age}}=28$, $SD=14.06$) in a between-subjects experiment (Nutri-Score: presence vs. absence). Participants shopped for groceries in a simulated online web store. The independent samples t-test pointed out that participants' shopping baskets were significantly healthier when the Nutri-Score was present (vs. absent; $M_{\text{present}}=3.24$, $SD=.52$, $M_{\text{absent}}=3.09$, $SD=.55$, $t(223)=-1.99$, $p=.047$). A mediation analysis (Model 4) indicated that the Nutri-Score indeed activates consumers health goals ($t(223)=4.25$, $p<.001$) which in turn improved the healthiness of participants' shopping baskets ($t(223)=2.48$, $p=.014$). In line with study 3A, a health goal activation fully mediates the Nutri-Score effect ($ab=.05$, 95%CI=[.008;.103]), confirming *H1*. A moderated mediation analysis (Model 8) revealed no significant interaction between the Nutri-Score (absence vs. presence) and health concern on health goal

activation (coefficient=-.03, $t(223)=-.16$, $p=.870$) nor on the healthiness of the shopping baskets (coefficient=.03, $t(223)=.39$, $p=.700$), rejecting $H2$ (moderated mediation: coefficient=-.002, 95%CI=[-.032;.027]). This shows that the Nutri-Score activates participants' health goals, irrespective of their health concern.

In line with existing studies, we show that the Nutri-Score improves the healthiness of participants' food choices in experimental-causal-chain and in a measurement-of-mediation design. Our results reveal that the Nutri-Score works because it activates consumers' health goals, irrespective of how health-concerned they are. Moreover, the Nutri-Score positively affects the healthiness of the shopping baskets of both more and less health-concerned individuals. Our findings are promising for the effectiveness of the Nutri-Score and as such create relevant guidance for public policy makers on whether or not to introduce the Nutri-Score as mandatory element on packages.

Neutrality is Complicit: Effect of Political Ideology on Neutral Brand Preference

Dr. Max Yu, Nanyang Technological University, Singapore

Prof. Sharon Ng, Nanyang Technological University, Singapore

Prof. Thomas Allard, Singapore Management University, Singapore

EXTENDED ABSTRACT

Although recent research examines how consumers react to corporates picking a side in sociopolitical issues as part of their marketing, little is known about remaining neutral. We show that conservatives compared to liberals prefer neutral position brands, because neutrality aligns well with their preferences to justify and uphold existing system.

Brands often take public stances on controversial sociopolitical issues. Corporate sociopolitical activism (CSA) illustrates the increasing overlap between brand positions and ideological identities. While consumer activism provides opportunities for brands, they also risk boycotts. Recent surveys show that 83% of chief marketing officers believe brands should not take a stance on sociopolitical issues, but two-thirds of consumers believe otherwise. Thus, there is a significant disconnect between marketers' beliefs and consumers' expectations.

Brands' neutral position could be communicated explicitly via public announcement or by remaining silent. We argue that a neutral stance is perceived as maintaining the status quo. As the name indicates, CSA is a form of activism. When firms take a stand on sociopolitical issues, they seek to create societal change by influencing the attitudes and behaviors of others (Eilert and Nappier Cherup 2020). Brands with a neutral stance are doing the opposite of advocating societal change and are supporting the current status quo.

We argue that conservatives, compared to liberals, prefer brands with neutral stances. Conservatism is associated with support for the status quo and upholding of tradition, while liberalism is associated with progressive societal change and political movements (see Jost et al., 2009 for a review). Specifically, conservatives compared to liberals score higher in system justification motivation (Jost and Banaji 1994), which explains individuals' motivation to "justify and rationalize the way things are, so that existing social, economic, and political arrangements tend to be perceived as fair and legitimate" (Jost and Hunyady 2005, p. 260). Conservatives' greater desire to justify and legitimize the existing system led them to resist change even when the status quo was not in their favor.

We first conducted a pilot study ($N = 151$) to test our assumption that neutrality is perceived as maintaining the status quo. Participants rated neutrality as maintaining status quo ($M = 5.449$) more than pro-conservative stance ($M = 3.069$) and pro-liberal stance ($M = 3.137$; $p < .001$).

In study 1A ($N = 150$), borrowing from Hydock et al. (2020), participants imagined they were shopping for sneakers, and one of the fictitious brands refused to take a position on immigration. Conservatives compared to liberals rated the neutral position brand more positively ($\beta = .302$, $SE = .080$, $p < .001$). In study 1B ($N = 200$), participants read a news article about ASOS (real apparel brand) wanting to remain neutral in the sex- versus gender-based toilet debate. They were asked to decide how much they wanted to spend their bonus payment (£0.50) to enter a lucky draw to win a £15 ASOS voucher. The amount they spent was proportionate to their chance of winning the lucky draw. Conservatives spent more than liberals ($\beta = .157$, $SE = .010$, $p = .026$).

In study 2 ($N = 200$), we showed participants of a news article that a headphone brand had no comment when journalists asked for comment on gun control (i.e., remain silent). Conservatives

compared to liberals have more positive attitude ($\beta = .368$, $SE = .051$, $p < .001$). Political ideology indirectly affected brand attitude via system justification motivation ($b = .118$, $CI: .061$ to $.179$; Kay and Jost 2003).

In study 3 ($N = 604$), participants were randomly assigned to one of the three brand position conditions (pro-life vs. pro-choice vs. neutral). Indicator coding was used with neutral being the reference condition (D1 = vs. pro-life, D2 = vs. pro-choice). Political ideology had significant interaction with both D1 and D2 on brand attitude (both $p < .001$). Liberals reported more positive brand attitude for pro-choice ($b = -.487$, $SE = .066$, $p < .001$), and conservatives reported more positive brand attitude for pro-life ($b = .574$, $SE = .073$, $p < .001$). Conservatives also reported more positive brand attitude for neutral brand ($b = .424$, $SE = .071$, $p < .001$). While conservatives compared to liberals like pro-conservative and neutral brands more, neutrality is not perceived as pro-conservative.

In study 4, we manipulated status quo alignment, and 202 Texas residents and 200 California residents were recruited. Those from Texas (California) were in the conservatism (liberalism) favored condition, and they read a news article on the abortion laws of Texas (California). This study was conducted before the overturn of Roe vs. Wade in 2022. The article describes how the current abortion laws in that state are pro-life versus pro-choice. In both conditions, the article stated that businesses are taking stances, and a particular sunglasses brand took a neutral stance. The interaction between political ideology and location significantly impacted attitude ($p = .013$). Conservatives have more positive attitude than liberals in both Texas ($b = .373$, $SE = .056$, $p < .001$) and California ($b = .168$, $SE = .060$, $p = .005$) conditions, but the effect is weaker in California than in Texas. This finding is consistent with the system justification literature, whereby conservatives uphold and legitimize the status quo even when it is disadvantageous to them.

Omnichannel Sense of Coherence in Consumer-Brand Encounters

Prof. Jano Jiménez-Barreto, Autonomous University of Madrid, Spain

Prof. Nicholas Lurie, University of Connecticut, USA

Prof. Natalia Rubio, Autonomous University of Madrid, Spain

Prof. Sara Campo, Autonomous University of Madrid, Spain

EXTENDED ABSTRACT

Omnichannel sense of coherence (OSC) is conceptualized as the perceived coherence of encounters with a brand's multiple marketing channels. A scale consisting of three principal dimensions: Coordination, consistency, and convenience is developed. Five studies demonstrate OSC's validity, reliability, and ability to predict shopping efficiency, patronage intentions, and perceived product quality.

Prior research on multichannel, customer journey design, and omnichannel marketing takes a firm perspective to determine whether to offer similar products, services, and information across distribution channels. Missing from these approaches is a way to assess how consumers evaluate the extent to which channels function as a unified entity and what this implies for consumers' downstream attitudes and behavior (Bolton et al. 2022). To address this research gap, we introduce the concept of omnichannel sense of coherence (OSC).

Building on research in psychology and sociology on perceived coherence (Letiche et al. 2011), we suggest that dimensions of OSC are likely to include perceptions that a brand's channels are interconnected, share similar information, and are adaptable to the consumer search buying process. To test these ideas, we conducted five studies.

Studies 1 and 2 took a grounded theory approach to identify the dimensions of OSC. Study 1 consisted of focus-group sessions with university students ($N = 32$) who were asked to describe their definitions of coherence when thinking about shopping in two or more brand-owned channels. In Study 2, participants ($N = 23$ U.S. consumers) were exposed to descriptive information for two retail apparel brands (i.e., a brand that allowed them to interact with channels in a simple and coordinated way), and a brand that did not have these features. Participants then responded to open-ended questions asking which of the two brands they felt was more coherent and why. Based on Studies 1 and 2, we identified three primary dimensions of OSC:

- *Coordination.* Consumers perceive coherence when they can interact with the multiple channels of a brand in a simple, integrated, and coordinated way.
- *Consistency.* Consumers perceive coherence when information and stimuli are similar across brand-owned channels.
- *Convenience.* Consumers perceive a brand as coherent if its channels are accessible whenever needed.

To measure these dimensions of OSC, we developed an initial pool of 40 items that we presented to a group of 14 retail managers who assessed the items' appropriateness for measuring OSC. This led to retaining 12 items.

Study 3 assessed the convergent and discriminant validity of the 12-item OSC scale ($N = 363$ U.S. consumers). A factor analysis showed there were three factors with three items each. For each factor, one item with low communality was eliminated. Factors obtained were in line with our prior qualitative item categorization of coordination, consistency, and convenience as components of OSC. A confirmatory factor analysis indicated a good model fit for the OSC 9-items, three dimensions scale ($\chi^2 = 67.03$; $df = 24$, $CMIN/df = 2.79$; $p < .001$; $CFI = .97$; $TLI = .95$; $RMSEA = .07$).

Study 4 examined whether OSC better predicts consumer perceptions of utilitarian aspects of a brand's channels than a related, but conceptually different, measure—Effective Customer Journey Design (ECJD; Kuehn et al. 2019). While ECJD captures broad consumer perceptions of how brand touchpoints consistently convey brand image, OSC has a narrower focus on the extent to which a retailer's stores work well together, provide consumers with similar information, and are

adapted to the consumer's lifestyle. Given this more concrete focus, OSC should better predict utilitarian aspects than ECJD, such as perceptions that a brand facilitates searching for products and services. We recruited U.S. consumers ($N = 179$) who selected a brand from which they had bought a product or searched for information about using two or more brand-owned channels and evaluated shopping efficiency, ECJD, and OSC. Findings confirm the discriminant validity of OSC from ECJD and shopping efficiency. Hierarchical regression analyses show that OSC dimensions ($r^2_{adj} = .56$) better predict shopping efficiency than ECJD ($r^2_{adj} = .32$; comparison, $F(6, 172) = 39.98$; $p < .001$).

Study 5 assessed whether OSC dimensions can explain why an omnichannel (vs. unichannel) implementation of brand policies may have different outcomes for consumer perceptions and behavioral intentions. Study 5 also examined whether OSC can capture the potential compensatory role of omnichannel implementation of brand policies that limit the consumer's ability to access. Because omnichannel offerings give consumers greater flexibility and fit with their lifestyles, they may compensate for channels that constrain consumers, such as limitations on how long consumers have to return items.

U.S. participants ($N = 549$) were randomly assigned to one condition in a 3 (channel implementation: unichannel online vs. unichannel retail store vs. omnichannel) \times 2 (return policy: extended vs. limited) between-subjects experimental design. Participants were shown information about a new apparel brand. They were then provided with information about brand's return policy. In the omnichannel condition, products could be returned in both online and retail stores. In the unichannel conditions, returns were limited to either the online or retail store. The extended return policy condition allowed products to be returned within one year for a full refund. The limited return policy condition allowed returns only within 14 days of purchase.

MANOVA results revealed significant interactions between channel implementation and policy for patronage intention, product quality, and OSC. To test our proposition that the mediating role of OSC would be moderated such that greater differences would be found for a limited than an extended return policy, we ran a moderated mediation analysis. Results show that omnichannel implementation leads to greater OSC, which enhances patronage intentions and perceived product quality. However, these effects are stronger for limited return policies that are less adapted to consumer lifestyles.

A Comprehensive Computational Comparison of Attentional and Decision Processes in Consumer Choice

Dr. Daniel Wall, University of Pennsylvania, USA
Prof. Sudeep Bhatia, University of Pennsylvania, USA

EXTENDED ABSTRACT

We fit and compare 63 distinct decision rules and a 9-parameter attention model on five eye-tracking datasets involving risky, intertemporal, and effort-allocation decisions. Our tests allow us to quantitatively predict novel behavioral effects and determine the core cognitive mechanisms that determine information sampling and decision-making in consumer choice.

Understanding the cognitive processes underlying attention and choice is key to a complete theory of consumer decision-making. Attentional dynamics affect the external reliability of preferences measured via conjoint; manipulating attention towards an item affects choices; modeling attention is key to understanding web search. While models of attention and choice are widely studied in marketing, psychology, and economics, few attempts have been made to combine and comprehensively compare models of decision and attentional processes across multiple datasets. This paper proposes a general computational framework for jointly modeling attention and choice. We test our framework by developing and fitting a 9-parameter computational attention model and 63 decision models on five eye-tracking datasets. This combined framework allows us to predict which option participants choose, whether they decide to terminate or continue sampling, and if they decide to continue sampling, which piece of information they choose to sample. Further, our framework tests multiple assumptions about the consumer decision-making process—e.g., the relationship between attention and choice. Taken together, our framework provides a nuanced computational account of consumer decision processes.

When faced with a choice between options, a person must search their environment for information about the options and combine that information to decide whether to continue searching or stop searching and choose an option. For instance, when faced with an intertemporal choice between two monetary payouts delivered at different delays, they may start by looking at the top left piece of information (e.g., \$10), then the bottom left (e.g., 0 weeks), then the top right (e.g., \$15), then the bottom right (e.g., 2 weeks), then back at the top right (e.g., \$15), and then making a decision to stop sampling and choosing an option (e.g., \$15 in 2 weeks).

To capture the above process, we use novel technical insights to split the modeling problem. Decision models predict people's decision to continue sampling and, if they decide to terminate sampling, which option they choose; attention models predict which piece of information people will sample.

Decision models have traditionally been broken down into two categories: static models, which predict only choices, and dynamic models, which predict choices and other aspects of decision processes. A standard static model, the Weighted Additive (WAD) model, assumes that people calculate the utility of an option by weighting attributes and adding these weighted values together. There are various ways to simplify this calculation: e.g., assuming both attributes receive equal weight. These simplifications make different predictions about qualitative patterns seen in the data. For instance, the equal weighting model makes different predictions about how attribute differences relate to choice than the WAD model.

Dynamic models assume people accumulate evidence for options, and when the evidence reaches a threshold, people choose an option. In the simplest case, dynamic models assume people accu-

mulate attribute values regardless of where they are looking. However, recent work has shown that making evidence accumulation dependent on attention, e.g., evidence accumulates at a higher rate for the fixated option, can lead to superior fits to the data and make critical qualitative predictions. Dynamic models also generally assume that evidence accumulation begins with the first fixation on a piece of choice information and continues until people choose an option.

Within our framework, we can combine the assumptions of static and dynamic decision models. For instance, our WAD Accumulator model assumes that people accumulate the weighted additive utilities of options. This accumulation begins once people have looked at each unique piece of information. Other models assume that utility accumulation depends on which option is being looked at. Combining these assumptions leads to 63 distinct decision models.

While our decision models relate to attention to choice, they do not predict what information people attend to. Our attention model formalizes this process and prior numeric summaries of attention. For instance, it assumes that people may be more likely to sample within an option, within an attribute, or on a never-before-sampled piece of information. Further, the model formalizes the relationship between option value and attention. Specifically, it allows for attention to be directed towards an option with a high attribute value.

We fit these models to data from previously published eye-tracking datasets on risky, intertemporal, and effort allocation decisions. The traditional dynamic decision models were outperformed by models that combined the assumptions of static and dynamic models. Specifically, WAD models that assumed complete search and attention related to evidence accumulation captured key qualitative patterns and fit best quantitatively. This result suggests that prior dynamic decision models may have underspecified how people combine choice information. Our attentional model results suggest that people's attention is drawn toward options with high attribute values. A critical debate revolves around whether attention to an option increases valuation or whether options with high values receive more attention. Our results suggest that both processes may be at play.

Our framework presents a principled method for understanding decision and attentional processes, which is key to designing consumer-centered choice environments.

Tiered Discounts As Multiple Numeric Reference Points

Dr. Andong Cheng, University of Delaware, USA

Dr. Gretchen Ross, Texas Christian University, USA

EXTENDED ABSTRACT

Tiered discounts introduce multiple dollar thresholds with increasing discount percentages. We find that tiered discounts with smaller increments between thresholds encourage higher consumer spending compared to those with larger increments. This effect is driven by consumers' increased motivation to reach higher thresholds when the increment size between thresholds is smaller.

Retailers often use discounts to incentivize consumers to buy more (Chen et al., 1998; Inman & McAlister, 1993), such as a tiered discount which introduces multiple spending thresholds that correspond to different discounts. When designing a tiered discount, a firm decides what amounts to set as thresholds and the distance, or increment size, between those thresholds. For example, Saks Fifth Avenue advertises tiered discounts on their website (spend \$400 or more, receive 20% off; spend \$1200 or more, receive 30% off) (Stoll, 2018). While industry experts suggest that retailers offer tiered discounts to target different consumer segments that might find different spending thresholds more appealing (Mohamed, 2018), an unexplored research question is how tiered discounts' threshold values (and corresponding increment sizes) might act as reference points that subconsciously *alter* consumers' motivation and thus the amount of money they spend. A threshold (e.g., spend \$100 or more) offers a dollar numeric prompt, which may serve as a reference point for consumers' spending and affect real choices (Della Bitta et al., 1981; Huang, 2016; Palmeira & Srivastava, 2013; Wansink et al., 1998). However, a tiered discount is different from previously studied promotions because this discount presents multiple thresholds concurrently to consumers. In fact, consumers may view tiered discount thresholds (i.e., reference points) as goals to strive for (Heath et al., 1999).

We find that tiered discounts with small increments between thresholds lead to higher consumer spending than those with large increments. This effect occurs because the close spacing of the thresholds lead consumers to feel more motivated to reach higher tier thresholds (i.e., reach a goal). Maximizing moderates this effect; maximizers (vs. satisficers) may feel inclined to reach a higher threshold (Schwartz et al., 2002). This research makes both a theoretical contribution to the literature by exploring the psychological consumer response to tiered discounts and a managerial contribution by informing retailers how to design effective tiered discounts.

Study 1 (pre-registered) explores this effect in the field; this quasi-experiment ran for two consecutive weeks. In the small tier condition, the promotion offered "spend \$10+, save 10%; spend \$20+, save 20%; spend \$30+, save 30%." In the large tier condition, the promotion was "spend \$10+, save 10%; spend \$30+, save 30%." We compared net sales after discounts and found that consumers ($N = 240$) spent more in the small increment condition than in the large increment condition ($M_{\text{small}} = \$16.49$; $M_{\text{large}} = \$13.86$; $F(1, 238) = 5.00, p < .05$).

Study 2 (pre-registered) tests the effect in a within-subjects lab experiment. Students ($N = 226$) saw four different tiered promotions (order randomized): large increment (spend \$100+ receive 10% off, spend \$500+ receive 30% off), small increment – numerous tiers (spend \$100+ receive 10% off, spend \$200+ receive 15% off, spend \$300+ receive 20% off, spend \$400+ receive 25% off, spend \$500+ receive 30% off), small increment – low (spend \$100+ receive 10% off; spend \$200+ receive 15% off), and small incre-

ment – high (spend \$400+ receive 25% off; spend \$500+ receive 30% off). After viewing each tiered discount, participants rated how much they would spend (slider scale: \$0-\$1000). We found a significant effect between conditions ($F(3, 225) = 55.92, p < .001$). Contrasts revealed that participants in the large increment condition were willing to spend significantly less ($M = \$106.88$) than those in the small increment – numerous ($M = \$142.77$; $F(1, 225) = 41.03, p < .001$) and the small increment – high conditions ($M = \$203.00$; $F(1, 225) = 71.76, p < .001$). However, there was no difference between the large increment condition and the small increment – low condition ($M = \$108.64$; $F(1, 225) = .15, p > .10$). We reason that the small increment – low condition was not different from the large condition given that the highest tier was lower than in the other small conditions and supports a goal process theory, tested in the next study.

Study 3 (pre-registered) tests the process: consumers feel more motivated to reach a higher threshold and maximizing moderates. Amazon MTurk workers ($N = 188$) imagined they found the perfect chair (\$150) in a store offering a tiered discount: small increment condition (spend \$100+ get 10% off; spend \$200+ get 15% off; spend \$300+ get 20% off; spend \$400+ get 25% off; spend \$500+ get 30% off) or a large increment condition (spend \$100+ get 10% off; spend \$500+ get 30% off). Participants indicated how motivated they were to spend more to reach a higher tier (not at all = 1, very motivated = 7), WTP (open ended), and maximizing tendency (Schwartz et al., 2002). Participants in the small condition ($M = \$189.96$) were willing to pay significantly more than the large condition ($M = \$159.72$); ($F(1, 186) = 23.15, p < .001$) and were more motivated to reach a higher tier ($M_{\text{small}} = 3.95, M_{\text{large}} = 2.34$; $F(1, 186) = 44.73, p < .001$). Moderated mediation (PROCESS Model 8) revealed a significant interaction between tier increment size and maximizing ($b = 3.91, t(183) = 2.01, p = .05$). Floodlight analysis showed that below 5.61 on the maximizing scale, a discount with a small tier increment size had a nonsignificant effect on spending. However, when consumers scored above 5.61, there was a positive effect on spending (at 5.61: $b = 6.15, t(183) = 1.97, p = .05$). For the mediator motivation, the indirect effect was supported for both high maximizers ($axb = 10.49, SE = 2.64, 95\% CI = [5.77, 16.28]$) and low maximizers ($axb = 8.18, SE = 2.40, 95\% CI = [3.79, 13.31]$).

We find that threshold levels within a tiered discount can guide consumer spending and choices. This effect is driven by motivation to reach a higher goal and moderated by maximizing. This paper begins a conversation on how promotions that present multiple dollar reference points affects spending.

Psychological Contracts in the Sharing Economy: How Consumers Respond to Getting Reviewed

Dr. Laura Schrier Rifkin, Brooklyn College, USA
Dr. Colleen Kirk, New York Institute of Technology, USA
Dr. Canan Corus, Pace University, USA

EXTENDED ABSTRACT

We provide the first empirical investigation of managerially relevant outcomes from consumers being reviewed. Even though reviews emanate strictly from peers, we show that consumers retaliate against the platform by generating negative word of mouth (NWOM) about the platform, across five studies, in multiple contexts (e.g., homestay, car share).

Imagine you rent a vacation home through a platform such as Airbnb. Upon your return, you are surprised to find out that your host has left you a negative review. Do you hold the sharing economy platform accountable even though the review came directly from the host?

This research is the first to examine a turn of the tables in which consumers, rather than products or firms, are being reviewed. We propose and find that when consumers get a negative review, they will engage in negative word of mouth (NWOM) about the platform. Integrating sharing economy (Eckhardt et al. 2019) and psychological contract (Morrison & Robinson 1997) literatures, we propose that consumers form psychological contracts with the platforms, which stipulate that the platform is obligated to ensure they do not receive an unwarranted negative review. Such a psychological contract breach leads to feelings of betrayal by the platform and NWOM.

Across 5 studies, including an actual peer-to-peer platform with real behaviors and three different contexts (multi-product platform, home sharing, and car sharing), we illustrate the impact of review valence on NWOM about the platform (study 1). In support of our conceptualization, by manipulating reciprocal obligation fulfillment we establish that a psychological contract breach accounts for our findings (study 2). We then examine how platform policies may impact perceived harm and injustice from a negative review, thereby moderating the effect of the review valence on betrayal and NWOM (studies 3-5). We demonstrate that the effect is intensified when the platform endorses (does not endorse) a host; does not allow (allows) a response to the review; and makes the review public (keeps it private).

Study 1

Student participants (N=87) joined a pilot program for an ostensibly real peer-to-peer platform called *Students4Students*, in which students borrow and lend a variety of items. Participants were matched with lenders, came to a classroom to pick up their reserved textbook and used the book with a realistic task. After returning the book and later logging into their *Students4Students* accounts, they received either a 5-star or a 2-star review from their lender. We assessed NWOM behaviors using participants' star ratings and review comments posted on a review site, *SharingEconomyStories.com*.

Participants gave *Students4Students* a lower star rating on *SharingEconomyStories.com* when they received a negative review ($M_{Neg} = 4.1$) than when they received a positive review ($M_{Pos} = 4.6$; $F(1, 85) = 7.88$; $p = .006$). Further, participants posted more negative/neutral (vs. positive) comments about the platform when they received a negative (36.4%) than a positive review (16.3%; $\chi^2(1) = 4.51$; $p = .034$).

Study 2

Participants (N=222) imagined they had rented a house from Vacation Connections, a P2P platform. They did (did not) follow all the house rules and received a positive or negative review. We measured NWOM and perceived betrayal by the platform.

We found a significant interaction on NWOM ($F(1, 208) = 42.64$; $p < .001$). When participants received a positive review, NWOM did not differ depending on their perceived obligation fulfillment ($p > .12$). However, when participants received a negative review, they reported greater NWOM when they fulfilled their obligations ($M = 5.28$) than when they did not ($M = 3.14$; $F(1, 208) = 61.14$; $p < .001$; $h^2 = .23$). These effects were mediated by betrayal.

Study 3

Participants (N=360) received a positive or negative review from a Vacation Connections host and were told that their host was (was not) a Premier Partner endorsed (not endorsed) by Vacation Connections. We found a significant interaction on NWOM ($F(1, 337) = 240.7$; $p = .023$). When participants received a positive review, host endorsement had no impact on NWOM ($M_{No} = 2.4$ vs. $M_{Yes} = 2.2$; $F(1, 337) = .39$; $p > .38$). However, when they received a negative review, participants reported increased NWOM when the platform endorsed the host ($M_{No} = 5.2$) than when they did not ($M_{Neg} = 4.6$; $F(1, 337) = 5.73$; $p = .017$). We found a similar pattern on the valence of the posted comments, with effects mediated by betrayal.

Study 4

Participants (N=362) received a positive (negative) review and read that the Vacation Connections response policy allows (does not allow) guests to respond to hosts' reviews. We found a significant interaction on NWOM ($F(1, 348) = 7.064$; $p = .008$). When participants received a positive review, response opportunity had no impact on NWOM ($M_{No} = 1.8$ vs. $M_{Yes} = 1.6$; $F(1, 348) = .86$; $p > .35$). However, in the case of a negative review, participants reported increased NWOM intentions when the platform provided no opportunity ($M_{No} = 5.5$) vs. an opportunity ($M_{Neg} = 4.5$; $F(1, 348) = 23.29$; $p < .001$) to respond to the review. We found a similar pattern of results on the valence of posted comments with effects mediated by betrayal.

Study 5

Participants (N=367) imagined renting from *Car Connections*, a car sharing platform. Participants read that their review from the host would be private (public) and then read either a positive or negative review. We found a significant interaction on NWOM ($F(1, 350) = 7.74$; $p = .006$). When participants received a positive review, NWOM did not differ whether public or private ($M_{Pub} = 1.69$ vs. $M_{Priv} = 1.87$; $p > .40$). However, when participants received a negative review, NWOM was greater when the platform made the review public ($M = 5.24$), than when it was kept private ($M = 4.54$; $F(1, 350) = 9.27$; $p = .003$). A two-way ANOVA on the *SharingEconomyStories.com* star rating revealed a similar pattern of results with effects mediated by betrayal.

When Identity Threat Does Not Lead to Compensatory Consumption: The Role of Implicit Theory

Ms. Yuanyi Xu, Durham University, UK
Dr. Hazel Huang, Durham University, UK
Dr. Zhibin Lin, Durham University, UK

EXTENDED ABSTRACT

Do people engage in compensatory consumption to repair their threatened identity? Across six studies, we find that incremental theorists (but not entity theorists) are likely to do so, and that the underlying mechanism is their perceptions of products' efficacy in identity expression, with pricing and compensation domain as boundary conditions.

Extensive research has shown that consumers purchase identity-signalling products, a behaviour known as compensatory consumption, to offset an identity threat (Mandel et al., 2017), but much less is known about who is (un)likely to cope with an identity threat via compensatory consumption. This issue is important, because compensatory consumption can be effective in identity repair (Rustagi and Shrum 2018). To fill this gap, this research explores how consumers' implicit theory affects their compensatory consumption.

There are two implicit theories: incremental theory, the belief that one's self is malleable and can be developed; and entity theory, the belief that one's self is fixed and cannot be changed (Dweck and Leggett 1988). Incremental (vs. entity) theorists tend to take positive actions in response to adverse situations (Allard and White 2015). We expect that in an adverse situation where an important identity is threatened, incremental theorists will be motivated to bolster their identity through compensatory consumption. As incremental theorists' mindset is malleable and subject to change across different contexts (Hogreve et al. 2021), we further predict that incremental theorists' compensatory consumption is mediated by their heightened perceptions of products' efficacy in expressing their identity in the threat (vs. non-threat) context. In contrast, because entity theorists' mindset is fixed, we predict that when threatened, entity theorists' perceptions of products' identity expression efficacy will not be heightened, and accordingly, they will not be motivated to engage in compensatory consumption.

Compensatory consumption can be categorized into within-domain compensation, where people seek out products that signal achievements in the threatened identity; and across-domain compensation, where people seek out products that signal achievements in an identity disassociated with the threat (Lisjak et al. 2015). We predict that incremental theorists are more likely to adopt within-domain compensation than across-domain compensation. Incremental theorists do not form product attitudes easily. Their attitude formation involves a high level of assessment that requires rich cognitive resources to process information (Kwon and Nayakankuppam 2015). An identity threat may deplete incremental theorists' cognitive resources and impede their attention to external information. Compared with across-domain products, within-domain products provide more relevant information to the identity threat, and thus, require fewer cognitive resources for incremental theorists to process.

Literature also documents that incremental theorists perceive a positive relationship between effort and favourable outcomes (Dweck and Leggett 1988). Pricing of products reflects the monetary effort that consumers need to make (Grewal, Marmorstein, and Sharma 1996). Compared with buying identity-signalling products at full price, buying the products at a discount involves "less effort" because of the reduced price. Accordingly, incremental theorists may view discounts as cues of reduced effort that are unfavourable for identity reconstruction/repair. Therefore, we predict that incremental theorists are likely

to bolster their identity by buying full-priced products, but not products on sale.

We test our predictions in six studies. Study 1a ($n = 370$) initially supports that an impaired identity (low sense of power) motivates incremental (vs. entity) theorists to engage in compensatory consumption. We measured participants' sense of power, implicit theory, and purchase intentions for a power-linked product (designer sunglasses). As predicted, the less power incremental theorists had, the higher their purchase intentions ($\beta = -.33$, $t(360) = -2.51$, $p = .01$), whereas entity theorists did not show the same pattern ($\beta = .15$, $t(360) = 1.19$, $p = .24$). These results were replicated in Study 1b ($n = 299$) and extended to a different power-linked product (designer coat). Study 2 ($n = 232$) examines the observed effect in a 2 (implicit theory: incremental vs. entity) \times 2 (power threat: yes vs. no) between-subjects experiment where implicit theory and power were both manipulated. Supporting our prediction, only incremental theorists increased their desire for power-linked products when experiencing a power threat ($F(1,223) = 4.87$, $p = .03$), but not entity theorists ($F < 1$, $p = .59$). Study 3 ($n = 260$) demonstrates the indirect effect of identity expression efficacy on incremental theorists' compensatory consumption. The research design followed Study 2, while participants' implicit theory was measured, along with their perceptions of products' power expression efficacy and desire for the products. As predicted, for incremental theorists, the indirect effect of perceived power expression efficacy on desire for power-linked products was significant (indirect effect = .45, 95% CI = [.1030, .8308]), whereas for entity theorists, this indirect effect was insignificant (indirect effect = .01, 95% CI = [-.3276, .2946]).

Study 4 ($n = 409$) supports that incremental theorists prefer within-domain (vs. across-domain) compensation, and it increases the generalisability of the effect of implicit theory by extending the identity threat to the intelligence domain. In a 2 (implicit theory: incremental vs. entity) \times 3 (identity threat: non-threat vs. intelligence threat vs. power threat) between-subjects design, all participants indicated their subscription intentions for intelligence-linked magazines (*The Economist* and *National Geographic*). As predicted, incremental theorists reported higher subscription intentions in the intelligence threat condition than non-threat condition ($\beta = .44$, $t(396) = 2.40$, $p = .02$), but insignificant different subscription intentions between the power threat and non-threat condition ($\beta = .16$, $t(396) = .89$, $p = .37$). Entity theorists reported insignificant different subscription intentions across the conditions ($ps > .32$). Study 5 ($n = 323$) supports that incremental theorists compensate with full-priced (vs. sale) products. In a 2 (implicit theory: incremental vs. entity) \times 2 (power threat: yes vs. no) \times 2 (price condition: full-priced vs. on sale) between-subjects design, the procedure followed Study 3. As predicted, threatened incremental theorists reported higher desire for the full-priced products than unthreatened incremental theorists ($\beta = .61$, $t(308) = 1.97$, $p = .049$), but not for the products on sale ($\beta = -.20$, $t(308) = -.71$, $p = .48$).

To conclude, this research extends the literature on compensatory consumption and implicit theory. It shows for the first time that in response to an identity threat, incremental theorists, but not entity theorists, increase their desire for identity-signalling products, with the pricing and compensation domain as the boundary conditions.

Investigating consumers' hesitant adoption of medical artificial intelligence

Dr. Elisa Konya-Baumbach, University of Mannheim, Germany

Dr. Miriam Biller, University of Mannheim, Germany

Prof. Sabine Kuester, University of Mannheim, Germany

EXTENDED ABSTRACT

Three experiments corroborate affective trust as an underlying mechanism explaining consumers' low adoption intention of medical artificial intelligence (AI). Consumers high in digital autonomy, respectively digital health literacy, display higher affective trust in medical AI and are more likely to adopt it.

Unlocking the potential of artificial intelligence (AI) for healthcare is one of the major challenges medical companies and policy makers are currently facing (World Health Organization, 2021). Medical AI has the potential to revolutionize healthcare by improving diagnoses and reducing costs related to medical treatments (Agarwal et al., 2020; Longoni et al., 2019; Yokoi et al., 2021). Medical AI are algorithms that analyze patients' data to provide advice in the context of healthcare such as diagnoses and treatment recommendations (based on Castelo et al., 2019; Longoni et al., 2019). Increasingly, AI begins to outperform human experts in medical tasks (Brinker et al., 2019; Haenssle et al., 2018; Chen et al., 2020). However, consumers tend to be reluctant to use medical AI (Dietvorst et al., 2015; Longoni et al., 2019; Promberger & Baron, 2006) and prefer to interact with a human doctor over a medical AI (Castelo et al., 2019). This preference may arise from trust beliefs, as Promberger and Baron (2006) found that patients tend to trust physicians more than a computer program.

Based on Attachment Theory (Bowlby, 1969), we propose that consumers' *affective* trust in medical AI as the medical caretaker plays a pivotal role for its adoption. Even though the adoption of AI is essential for the exploitation of its full potential (Agarwal et al., 2020), research on the causes of the low adoption of medical AI and potential ways to address it remains scarce (Longoni et al., 2019; Cadario et al., 2021). The present study addresses this lack of research via three online consumer experiments identifying affective trust as an underlying mechanism explaining consumers' low adoption intention of medical AI. Further, this study explores digital autonomy (i.e., consumers' preference for being capable of making their own choices with the help of digital self-service technologies instead of service personnel (based on Kim et al., 2016)) and digital health literacy (i.e., consumers' ability to find and process digital health information (Norman & Skinner, 2006)) as potential levers to increase consumers' affective trust building and, consequently, medical AI adoption.

We employed scenarios in medical contexts involving either a human doctor or medical AI. With chronic diseases being promising use cases for medical AI (U.S. National Health Council, 2014), Study 1 and 2 were set up in the context of an online diabetes risk analysis, Study 3 featured the diagnosis of a chronic headache via a health app. Study 1 tests whether affective trust mediates the relationship between the healthcare provider (AI vs. human) and consumers' adoption intention (H1 and H2). Studies 2 and 3 additionally consider digital autonomy (H3, Study 2) and digital health literacy (H4, Study 3) as potential moderators.

Study 1 followed a 2 (healthcare provider: AI vs. human) x 1 between-subjects design. The results of Study 1 demonstrate that the healthcare provider (AI vs. human) influences consumers' adoption intention. Consumers' adoption intention is higher for the human healthcare provider compared to the medical AI. More importantly, mediation analysis (Model 4, Preacher & Hayes, 2004) reveals that

affective trust fully mediates the relationship between healthcare provider and consumers' adoption intention. Compared to the human healthcare provider, consumers appear to adopt medical AI less due to a lack of affective trust. The results of Study 1 support H1 and H2.

Study 2 again used a 2 (healthcare provider: AI vs. human) x 1 between-subjects design. Study 2 validated the findings of Study 1. This time, we additionally controlled for consumers' disposition to trust (McKnight et al., 2002). Further, the results of Study 2 show that consumers' digital autonomy significantly moderates the effect of the healthcare provider on affective trust. Thus, low digital autonomy strengthens the effect of the healthcare providers on affective trust, whereas high digital autonomy weakens it, providing evidence for H3.

Study 3 used a 2 (healthcare provider: AI vs. human) x 2 (digital health literacy: low vs. high) between-subjects design. First, we introduced the option of a headache diagnosis facilitated by a health app to all participants. Participants in the high digital health literacy condition then saw a short step-by-step guide that introduced the functionality of the health app. Participants in the low digital health literacy condition did not see the step-by-step guide. Again, the indirect effect of the healthcare provider on adoption intention via affective trust was significant. Moreover, Study 3 confirms digital health literacy as a situational factor that significantly attenuates the effect of the healthcare provider (AI vs. human) on affective trust, providing support for H4. Increasing digital health literacy appears to be an effective measure to influence consumers' affective trust building in medical AI and, consequently, adoption intentions. The direct effect of the healthcare provider on adoption intention remains significant even when including affective trust, suggesting a complementary mediation (Zhao et al., 2010). There seems to be an omitted variable additionally mediating the relationship of the healthcare provider on adoption intention.

The contribution of the present study is threefold. First, despite consumers' persistent hesitation to adopt medical AI, the underlying mechanisms of consumers' low adoption of medical AI are rarely explored (Longoni et al., 2019; Promberger & Baron, 2006). Applying insights from interpersonal trust research to AI-human interactions, our research adds to prior literature by proposing affective trust as an underlying mechanism explaining consumers' low adoption intention for medical AI. Second, we contribute to a better understanding of influencing factors that may strengthen consumers' affective trust in medical AI and, consequently, their adoption intention. Specifically, we shed light on the impact of consumers' digital autonomy and digital health literacy as two moderators. Finally, based on our findings, we provide healthcare stakeholders seeking to foster acceptance of medical AI, such as medical companies, physicians, companies marketing medical AI, and policy makers, with practical guidance on how to increase consumers' affective trust in and adoption of medical AI.

Renting as a Coping Strategy: The Effect of Unethical Product Attributes on Choice Between Renting and Buying

Prof. In-Hye Kang, University of North Carolina at Greensboro, USA
Prof. Taehoon Park, Florida Gulf Coast University, USA

EXTENDED ABSTRACT

We demonstrate that consumers choose a renting option over a buying option for a product with an unethical attribute to reduce anticipated guilt. This effect of presence (vs. absence) of unethical product attributes on increasing the choice of the renting option is attenuated when consumers are less guilt-prone.

While owning through buying has traditionally been the most dominant mode of consuming products, renting is becoming more prevalent. Prior work has identified factors that may influence consumers' choice between renting and buying, including economic costs (Bardhi and Eckhardt 2012; Lamberton and Rose 2012), personal characteristics (e.g., consumers' desire for freedom and variety; Durgee and O'Connor 1995), and contextual factors (e.g., salience of global versus local identity, Nie et al. 2022). However, limited research examined how a specific product attribute—other than economic attributes like price—influences such choices. In this research, we show that the presence of unethical product attributes impacts consumers' choice between buying and renting.

We define unethical attributes as attributes associated with violations of well-established moral standards, such as unfair labor practices like child labor and moral transgression of a manufacturer/producer like a movie director harassing an employee. Since consumers have a strong desire to avoid negative emotions such as anticipated guilt, they engage in various coping strategies when encountering unethical attribute information, such as ignoring or forgetting unethical product information (Ehrich and Irwin 2005; Rezek, Irwin, Zane, and Ehrich 2018). Similarly, we argue that consumers would use renting to cope with negative emotions associated with using an unethical product because consumers feel more detached from a rented product than an owned product. Specifically, we propose that the presence (vs. absence) of unethical product attributes increases the choice of the renting option over the buying option (even when both options are priced equally). This is because consumers anticipate feeling less guilt from renting (vs. buying) a product with unethical attributes.

In study 1 (Prolific, $N = 320$), participants read a scenario describing that they found a dress shirt that they liked. Participants in the unethical attribute present condition additionally read that the manufacturer had been confirmed to use child labor. Then, they indicated their choice between the two purchase options: Buy at \$79.00 or rent at \$19.00. As predicted, more participants chose renting in the unethical attribute present (vs. absent) condition (68.1% vs. 41.3%, $p < .001$). Participants felt less anticipated guilt from renting than buying in the unethical attribute present (vs. absent) condition ($M_{\text{present}} = 2.94$ vs. $M_{\text{absent}} = 4.28$, $p < .001$). Anticipated guilt significantly mediated the effect of unethical attribute on the choice (95% CI = [1.25, 2.48]). In study 2 (MTurk, $N = 323$), we replicated the findings of study 1 using an incentive-compatible choice measure. Importantly, we set the same price for the buying and renting options to rule out the alternative explanation that our findings could be due to the difference in price between the buying and renting options.

In study 3, we provided further support for the anticipated guilt mechanism by examining a moderating role of guilt-proneness. Guilt-proneness refers to the "extent to which individuals tend to experience guilt across situations" (Tangney and Dearing 2002, p. 251). Individuals who are high on guilt-proneness tend to experi-

ence higher levels of guilt in response to a guilt-inducing event or behavior (Fleeson 2001). This finding suggests that more guilt-prone consumers would feel stronger anticipated guilt from considering using a product with unethical attributes. Therefore, we predicted that the effect of unethical attribute on increasing the choice probability of renting over buying will be attenuated for less guilt-prone consumers.

We collected data in two waves. In the first wave, we measured the individual difference in guilt-proneness by giving them three scenarios and asking how much guilt they would feel in each of the three scenarios (adopted from GASP scale; Cohen et al. 2011). A few days after the first wave, participants completed the main survey. A total of 446 participants (MTurk) completed both first and second waves. In the main study, all participants read a description of a highly rated movie that a famous director directed. Participants in the unethical attribute present condition additionally read that the movie director sexually harassed a staff while filming the movie. They then indicated the choice between the two purchase options on Youtube: Buy at \$4.99 or Rent at \$4.99. There was a marginally significant interaction between unethical attribute and guilt-proneness in the choice ($p = .08$). As predicted, the Johnson-Neyman analysis revealed that when the guilt-proneness score was equal to or greater than 4.70 on a 7-point scale, the presence (vs. absence) of unethical attribute significantly increased the rental choice (22.4% vs. 13.6%).

So far, in studies 1-3, participants chose between the two options: buying and renting. In study 4 (MTurk, $N = 322$), we examined whether the effect holds when we add the no-choice option to the choice set. After participants read a scenario that was similar to the one used in study 3, they chose among the three options: buy at \$4.99 vs. rent at \$4.99 (for 30 days) vs. no-choice. As expected, a multinomial logistic regression revealed that the presence (vs. absence) of unethical attribute marginally significantly increased the relative choice probability of the renting option over the buying option ($p = .07$; Renting_{present} = 10.7% vs. Renting_{absent} = 6.7%; Buying_{present} = 61.6% vs. Buying_{absent} = 81.6%). In other words, consumers were more likely to choose a renting option (vs. a buying option) in an unethical attribute present condition even when the no-choice option was available.

In summary, we demonstrated that consumers were more likely to rent than buy when a product featured an unethical attribute to reduce anticipated guilt using both physical (clothing) and digital products (movie). This effect was attenuated for consumers with lower guilt-proneness. Our findings contribute to the growing literature on renting and access-based consumption by identifying non-financial product attributes, specifically unethical product attributes, as a factor that can impact consumers' renting versus buying choices. Consumers use renting as a coping strategy. Our findings also provide managerial implications for brand manager by suggesting that companies can direct their promotional efforts to encourage renting when the negative publicity breaks out.

The Effects of Image Properties on Consumer Sharing: An Examination of Saturation, Brightness, and Perceived Image Naturalness

Dr. Timothy Kaskela, Oregon State University, USA

Dr. Matthew Hall, Oregon State University, USA

Dr. Bin Zhu, Oregon State University, USA

EXTENDED ABSTRACT

This research demonstrates that image saturation and brightness drive consumer sharing of brand-generated content. Specifically, image saturation has a negative U-shaped effect on sharing—an effect differentially driven by arousal and image naturalness. However, the negative effect of high saturation on sharing can be counteracted by decreasing image brightness.

Firms benefit when customers share brand-generated content (BGC) online. One factor that should predict BCG sharing is the saturation of a post's image. Viewing images with higher saturation increases arousal (Valdez & Mehrabian, 1994), which in turn increases information spread (Berger 2011). Research has yet to test the effect of saturation on sharing, likely because transitive linkages suggest the effect should be obvious (thus, perhaps uninteresting). Despite positive linear effects between saturation and arousal, and arousal and sharing, we propose image saturation may elicit other responses that could limit the positive effect of saturation on sharing.

Consumer decisions to share BCG are affected by how their audience will perceive the content (Magsamen-Conrad 2014). Because highly saturated images are often perceived as unnatural (de Ridder 1995), consumers may hesitate to share them. Thus, overly saturated images may increase arousal (positive effect on sharing), but may also be viewed as unnatural (negative effect on sharing). We therefore propose the effect of saturation on sharing will demonstrate an inverted U-shaped relationship. Because this relationship suggests there is an inflection point at which increasing saturation decrease sharing due to image unnaturalness (despite increased arousal), firms might be interested in shifting this inflection point upward to maximize the positive effect of saturation on sharing. Our theory suggests firms might do this by making highly saturated images appear more natural. Because highly saturated images appear brighter (Allan 2020), decreasing image brightness should offset their unnatural properties (Khan et al. 2014). We propose saturation and brightness will interact, such that reducing image brightness will increase the range of the positive effect of saturation on sharing.

In Study 1, we collected Tweets shared by DJIA corporations from 2017-2021 ($n=32,833$). We conducted an OLS regression with retweets as the dependent variable. Using Python, we measured image saturation and brightness at the pixel level (means calculated for each image). Our focal predictor was average saturation. We also squared this value to test our proposed curvilinear effect. Brightness was included as a moderating variable—interaction terms were calculated between brightness and both linear and quadratic saturation terms. The model also included various controls pertaining to properties of the tweet (e.g., hue, sentiment, complexity) and company (e.g., account followers). As predicted, there was a positive linear effect of saturation on sharing ($b=1.36$, $p<0.00001$), and a negative quadratic effect ($b=-1.67$, $p<0.00001$)—the effect of saturation on sharing was positive for saturation below 40.65%, and negative above this point. There was also an interaction between brightness and quadratic saturation ($b=1.74$, $p<0.001$), as the saturation inflection point shifted upward when brightness was lower ($-1SD$; 44.19%), but downward brightness was higher ($+1SD$; 38.32%).

In Study 2, Prolific participants ($n=500$) saw a Tweet featuring a vineyard—the only difference between conditions was aver-

age image saturation (20%, 35%, 50%, 65%, 80%). Participants reported retweet intentions, arousal, and image naturalness (7-point scales). Saturation significantly predicted sharing ($F(1,496)=3.98$, $p=.003$), in an inverted U-shaped pattern. The 65% ($M=2.63$) and 50% ($M=2.51$) conditions reported higher sharing intentions than the 20% ($M=1.93$), 35% ($M=2.05$), and 80% ($M=2.15$) conditions. Saturation also predicted arousal ($F(1,496)=8.43$, $p<.001$), however this effect was more linear. The 80% ($M=4.22$) and 65% ($M=4.22$) conditions reported higher arousal levels than the 20% ($M=3.75$), 35% ($M=3.95$), and 50% ($M=4.15$) conditions. Saturation also predicted image naturalness ($F(1,496)=6.89$, $p<.001$)—this also revealed an inverted U-shaped pattern. The 50% ($M=6.01$) and 65% ($M=5.86$) conditions perceived the image to be more natural than the 20% ($M=5.38$), 35% ($M=5.68$), and 80% ($M=5.35$) conditions. Mediation analyses suggested that as saturation increased from lower levels, arousal and sharing both increased. However, at high saturation levels (80%), arousal remained high, but sharing decreased due to decreased image naturalness.

In Study 3, 309 undergraduates completed a 2(saturation: high/normal) x 2(brightness: normal/low) experiment. Participants viewed a tweet from Starbucks featuring an image with varied saturation and brightness based on condition. Participants reported sharing likelihood, arousal, and image naturalness. A 2x2 ANOVA of sharing revealed a significant interaction ($F(1,305)=7.42$, $p=.007$). Saturation did not affect sharing when brightness was normal ($M_{High}=1.35$; $M_{Normal}=1.28$; $F(1,305)=.01$, $p=.670$), however there was a positive effect of saturation on sharing when brightness was low ($M_{High}=1.88$; $M_{Normal}=1.21$; $F(1,305)=18.04$, $p<.001$). A 2x2 ANOVA of arousal revealed only a main effect of saturation ($F(1,305)=19.27$, $p<.001$), as the high saturation increased arousal when brightness was normal ($M_{High}=4.25$; $M_{Normal}=3.92$; $F(1,305)=5.39$, $p=.021$) and low ($M_{High}=4.38$; $M_{Normal}=3.82$; $F(1,305)=15.09$, $p<.001$). A 2x2 ANOVA of image naturalness revealed an interaction ($F(1,317)=15.28$, $p<.001$). The highly saturated image was perceived as less natural when brightness was normal ($M_{High}=3.97$; $M_{Normal}=5.17$; $F(1,305)=31.35$, $p<.001$), but equally natural when brightness was low ($M_{High}=5.20$; $M_{Normal}=5.22$; $F(1,305)=.004$, $p=.948$). Mediation analyses suggested higher saturation positively affected arousal and sharing in general. However, this effect was mitigated by decreased image naturalness when brightness was normal, yet it persisted when brightness was low, as highly saturated images were seen as more natural.

In sum, this research confirms image saturation leads to emotional arousal, which increases sharing. Notably, the effect of saturation on sharing (via arousal) is not linear. Within lower saturation ranges, increased saturation increases arousal and sharing. However, within higher ranges, the effect of saturation on arousal is overridden by reduced image naturalness.

The Impact of Disadvantage on Self-Efficacy and Locus of Control

Mr. Bryce Pyrah, University of Iowa, USA
Dr. Chelsea Galoni, University of Iowa, USA
Dr. Jing (Alice) Wang, University of Iowa, USA

EXTENDED ABSTRACT

We look at how a sense of disadvantage (feeling worse off than others) impacts consumer locus of control. We find that consumers who feel disadvantaged adopt an external locus of control which impacts associated consumption behaviors (superstitious consumption, reliance on a higher power, etc.), mediated by decreased feelings of self-efficacy.

Inequality is rising at an alarming rate worldwide. In the United States, for example, the top 1% have had incomes increased five times the level as those in the bottom 90% between 1979 and 2015 (Jetten, 2019). While income is an easy to measure metric of inequality, consumers can experience inequality across a number of different domains (race, gender, sexual orientation, etc.), making it a salient occurrence in many consumers' lives.

In the present work, we are particularly interested in studying how inequality impacts those on the disadvantaged (versus the advantaged) end. Specifically, we study how a *sense of disadvantage*, the feeling that one is worse off due to inequalities (Rucker et al., 2018), impacts the decisions that consumers make. Building on the notion that consumers tend to justify current social arrangements and standings (Jost & Banaji, 1994; Pratto et al., 1994), we propose that a sense of disadvantage leads consumers to adopt an external locus of control which impacts their consumption behaviors. Furthermore, we demonstrate that the effect of sense of disadvantage on locus of control is mediated by decreased feelings of self-efficacy. We argue that this is due to "legitimizing myths" that are internalized by individuals with a sense of disadvantage (Jost & van der Toorn, 2012; Pratto et al., 1994), leading them to falsely believe that they are less capable than more advantaged individuals. In response, those who feel disadvantaged divert their efforts to call on external forces (e.g., superstition, fate, religion, etc.) for positive outcomes. See figure 1 for our conceptual model.

We test our hypotheses across 4 studies. In study 1, we use a correlational study to investigate the relationships between disadvantage, self-efficacy, and locus of control. Participants ($N = 302$) responded to scales measuring their own sense of disadvantage, self-efficacy, and locus of control. A sense of disadvantage was significantly associated with an external locus of control ($p < .001$) and decreased feelings of self-efficacy ($p < .001$). Feelings of self-efficacy mediated the relationship ($CI_{95\%} [-.287, -.165]$).

In study 2, we sought to manipulate feelings of disadvantage and measure locus of control via participants' willingness to engage in superstitious consumption (Randall & Desrosiers, 1980; Tobacyk et al., 1988). Participants ($N = 399$) were randomly assigned to a 2 (disadvantage vs. advantage) \times 2 (lucky vs. control) between-subjects design. Participants first imagined that they were a sports fan of a professional team and were at a disadvantage or advantage in an upcoming game. They then read a scenario that manipulated whether they thought their current shirt they normally wear to games was lucky or not. We then measured participants' likelihood to purchase a new shirt to wear to the upcoming game and their performance expectations assuming they did not buy the new shirt, opting to wear their current one. When their current shirt was framed as lucky, participants who felt disadvantaged were less likely to purchase the new one ($p = .008$). Those that felt disadvantaged likewise felt an increase in performance expectations when their current shirt was

framed as lucky ($p < .001$), while there was no difference for those that felt advantaged ($p = .196$).

In study 3, we sought to provide mediational evidence through self-efficacy, and measured external locus of control in a third domain: reliance on a higher power (such as God). Participants ($N = 200$) were randomly assigned to a 2 (disadvantage vs. advantage) \times 2 (pray vs. not pray) between-subjects design. Participants were manipulated to feel that they were either an advantaged or disadvantaged job candidate interviewing for a job. They were told that some people pray for help before an important interview and were then presented with the second manipulation—they either did or did not pray before their interview. We then measured their performance expectations of the interview and feelings of self-efficacy. For those that felt disadvantaged, the act of praying before the interview increased both performance expectations ($p = .020$) and self-efficacy ($p = .005$). However, for those that felt advantaged there was no difference for either performance expectations ($p = .694$) or self-efficacy ($p = .532$). A significant index of moderated mediation indicated that self-efficacy mediated this relationship ($CI_{95\%} [-.34, -.03]$).

In study 4, we sought to provide additional evidence of the mediation process by manipulating the mediator. We do so through a growth mindset intervention because a growth mindset has been linked with increased feelings of self-efficacy (Burnette et al., 2020; Diseth et al., 2014; Taberero & Wood, 1999). Participants ($N = 424$) were randomly assigned to a disadvantage (continuous) \times 2 (mindset: growth vs. fixed) between-subjects design. Participants first answered a scale on how disadvantaged they felt financially. Participants were then presented with the mindset manipulation that manipulated whether they felt that performance and skills could be improved (growth) or not (fixed). We then presented participants with a financial tool app intended to help them improve financial performance and measured their likelihood to purchase the app and their willingness-to-pay. Significant interactions indicated that for the financially vulnerable consumers, a growth mindset reduced the likelihood of purchasing the app ($p = .019$) and their willingness-to-pay ($p = .009$). This demonstrates that those who feel disadvantaged reduce their reliance on external tools when presented with a growth mindset.

Across 4 studies, we demonstrate that feeling disadvantaged leads consumers to adopt an external locus, as evidenced by measuring locus of control, and an increased reliance on superstitious products, a higher power, and external tools. We further show that this relationship is mediated by reduced feelings of self-efficacy, through measuring self-efficacy and manipulating by a mindset intervention.

The Benevolence of Actively Inflicting Misfortune: When and How Schadenfreude Increases Donations

Dr. Yael Zemack-Rugar, University of Central Florida, USA

Dr. Laura Boman, Mercer University, USA

Dr. Thomas Kramer, University of California, Riverside, USA

EXTENDED ABSTRACT

Can schadenfreude occur when the observer actively inflicts misfortune? Three studies examine this question using a common marketing context: donation appeals that involve inflicting misfortune (e.g., pie tosses, dunk tanks). We show that individuals who inflict mild misfortune on a deserving target experience increased schadenfreude, which leads to increased donations.

Schadenfreude, pleasure in another's misfortune, is a positive emotion, characterized by joy and happiness (Sundie et al. 2009). However, rejoicing in others' misfortune can be morally hazardous (Ben-Ze'ev 2014). Three characteristics can reduce this hazard: mild misfortune (Berndsen and Feather 2016), target deservingness (Feather 2008), and the observer's passive role in misfortune (Ben-Ze'ev 2014). The latter is considered critical yet, remains empirically unexamined. We address this gap.

Contrary to prior theorizing, we propose and show that schadenfreude can occur when consumers actively inflict misfortune. While schadenfreude theory suggests actively inflicting misfortune reflects sadism (Ben-Ze'ev 2014), research in law and philosophy suggests bringing measured punishment on deserving targets is socially just (Furby 1986; Keijser et al. 2002). This social justice is in line with schadenfreude's nature, suggesting that schadenfreude can emerge when the observer inflicts misfortune. We test this proposition in an applied marketing context: misfortune-involving donation appeals (e.g., pie toss, dunk tank). We propose that because schadenfreude represents a pleasant, desired state, its activation will increase donations (Ferguson and Bargh 2004). These predictions were tested across three studies. Complete results are in Table 1.

Study 1 used a 2 (target deservingness: high/low) by 2 (activity: passive/active role in misfortune) between-subjects design (undergraduates; $N = 210$, $M_{age} = 21.64$, 68% female). Participants indicated how much they would donate to dunk a high (vs. low) deservingness target or passively watch others dunk the target (\$0-\$10 scale). Participants then completed four schadenfreude measures (Feather and Sherman 2002; Leach et al. 2003; Sundie et al. 2009; van Dijk et al. 2006; averaged: $\alpha = .95$).

We predicted greater schadenfreude and donations when the target was high (vs. low) in deservingness in both active and passive conditions (no interaction). Further, we predicted schadenfreude would mediate donations. An ANOVA using deservingness, activity, and their interaction to predict donations showed the predicted non-significant interaction ($p = .80$) and significant main effect of target deservingness ($p < .0001$), with higher donations in the high (vs. low) deserving condition regardless of passive/active condition ($ps < .003$). Schadenfreude significantly mediated this pattern (Hayes 2017).

In Study 2 we address an alternative explanation of playfulness. Because targets are volunteering, inflicting misfortune may be playful, rather than harmful. However, playfulness should decline when the target did not volunteer (Mollick and Rothbard 2014). In contrast, target volunteering is not a condition for schadenfreude. Hence, we predicted volunteering would have no impact on donations or schadenfreude.

Participants (Prolific; $N = 158$, $M_{age} = 33.03$, 50% female) completed a preregistered between-subjects study (volunteer/not/control). Participants imagined that a fundraiser allowed them to dump a bucket of ice water on the head of a deserving target that had either volunteered or not volunteered to participate. As a control condition, we

included a no-misfortune appeal, a regular donation booth. Participants indicated how much they would donate (\$0 - \$100) and completed the schadenfreude measures from Study 1.

An ANOVA using appeal condition to predict donation amount ($p = .02$), showed that relative to the no-misfortune control condition ($M = \$6.81$), donations significantly increased in both the volunteering ($M = \$18.38$, $p = .008$) and non-volunteering ($M = \$15.62$, $p = .04$) conditions. As further predicted, the difference between the volunteering and non-volunteering conditions was NS ($p = .52$). Schadenfreude significantly mediated donations.

Study 3 examined the role of misfortune severity while also ruling out sadism. Contrary to prior work, our prior studies show that active inflictors of misfortune can enjoy schadenfreude. Thus, we posit that the line between schadenfreude and sadism lies not with one's the passive/active role, but with misfortune severity. Consistent with the role of schadenfreude in studies 1-2, we expect that sadism, will not drive donations when misfortune is mild. However, when misfortune is more severe, we expect it may no longer be perceived as socially just (Gromet et al. 2006). Thus, but when misfortune is more severe, as sadistic tendencies increase—so will donations, because only sadists enjoy severe misfortune (Burris and Leitch 2018).

To test this interaction, we conducted a two factor between-subject study with manipulated misfortune severity (mild/more severe) and measured sadistic tendencies. Participants (Prolific; $N = 267$, $M_{age} = 35.73$, 50% female) imagined attending a fundraiser where they could either dump a bucket of ice water (mild misfortune) or Tase a deserving target for five seconds (more severe misfortune). Participants indicated how much they would donate to participate (\$0 - \$200) and completed the sub-clinical sadism scale (Plouffe et al. 2017).

An ANOVA using misfortune condition, sadistic tendencies, and their interaction to predict donation amount revealed the predicted interaction of severity by sadism ($p = .001$). Planned slope analysis revealed that, as predicted, there was no impact of sadistic tendencies on donations when misfortune was mild ($p = .24$), and a significant impact when misfortune was more severe ($p = .002$). In the severe condition, means showed donations increased as sadistic tendencies increased (starting at .96 SD above the mean; see Figure 1). These findings suggest it may be more useful to distinguish between schadenfreude and sadism using misfortune severity rather than active/passive observer.

Across three studies, we offer key theoretical and applied contributions. First, we broaden the definition of schadenfreude. Whereas prior theorizing suggests it only occurs when the observer plays no role in bringing about misfortune, we find that schadenfreude can occur even when the observer actively inflicts misfortune. Second, we refine the distinction between schadenfreude and sadism, showing it relies not on the passive versus active role of the observer, but on misfortune severity.

Practically, these findings suggest that schadenfreude is more prevalent than previously theorized. Further, prior theorizing suggests that: "Because of our passivity in schadenfreude, it is likely that this emotion is not very important in terms of the choices we make..." (Ben-Ze'ev 2014, p. 84). Yet, since we demonstrate that schadenfreude can emerge in an active context, its behavioral effects may have been underestimated. Future work can continue to explore schadenfreude's behavioral impact, further contributing to our understanding of this complex and interesting emotion.

The Dynamics of Self-Control

Dr. Paul Stillman, Yale University, USA

Dr. James Wilson, University of Pittsburgh, USA

Dr. Melissa Ferguson, Yale University, USA

EXTENDED ABSTRACT

Self-control is a critical determinant of consumer behavior. We quantify how self-control conflicts evolve in real-time, and use it to test competing models (sequential impulse inhibition vs. simultaneous competition). By revealing the diversity of self-control, we approach a more nuanced understanding of what self-control is and how to support it.

Self-control – the ability to elect long-term goals in the face of short-term temptations -- is a critical faculty of human cognition. Despite the importance of self-control, the cognitive processes enabling self-control are not well understood. Most contemporary models center impulse inhibition: effortfully inhibiting prepotent motor responses towards a temptation, yielding a stage-based evolution of choice. Other theories, in contrast, emphasize dynamic competition between goal and temptation, yielding a more integrative evolution of choice. Until now, methodological limitations have made direct assessment of the evolution of self-control decisions impossible. Here, we use mouse-tracking – a dynamic, real-time measure of decision-making in which we measure participants' computer mouse movements as they make intertemporal payoff decisions (e.g., \$5 today vs. \$20 in 3 months). We develop a novel quantitative approach of analyzing these data that captures the rich temporal and spatial evolution of each decision.

METHODS

Participants. A total of 522 (188, 137, 90, and 107 for studies 1-4) undergraduate students participated in exchange for research credit.

Mouse-tracking procedure. Each trial started with a screen that was blank except for a “start” button placed at the bottom-center. Once participants clicked this button, their cursor disappeared and the delay amounts (e.g., “today” and “180 days”) and the amounts (e.g., “\$25” and “\$40”) appeared in the top-left and top-right corners of the screen. Participants then made their choice by navigating the mouse to one of the two response options. In total, participants completed 180 (Study 1), 195 (Studies 2-3), or 210 (Study 4) trials. In studies 1 and 4, participants were incentivized with real money (via a lottery).

Functional data analysis. We then separated the x and y components of the trajectory, such that we had two time-series vectors each of length 101. For each of these, we generate a smoothed trajectory using basis splines, specifying knots at each timepoint, resulting in a 103 basis functions. For each trajectory we estimate the linear combination of these functions using penalized regression such that result curves are penalized proportional to their smoothness. This resulted in 206 coefficients (103 for x and 103 for y) per trajectory.

Hierarchical clustering. We next subjected these 206 coefficients to agglomerative hierarchical clustering. Specifically, we calculated the Euclidean distance between the 206 coefficients of each of the 46,774 trajectories, resulting in a $46,774 \times 46,774$ distance matrix that served as the basis for the hierarchical clustering algorithm. We then conducted agglomerative hierarchical clustering, which begins by treating each trajectory as its own cluster, and then combines the two closest clusters (according to the above distance matrix) into one cluster. The algorithm then repeats this process iteratively, at each step combining the next two most similar clusters, until the two most dissimilar trajectories have been combined. This results in a binary tree, known as a dendrogram, that details when each trajectory was com-

bined. Dendrograms enable the investigation of homogeneous collections (clusters) of trajectories that are the most dissimilar from other clusters in each split. The top cluster of the dendrogram contains all trajectories. The first split divides the data into two clusters, such that the trajectories in each group are more similar to one another than they are to any in the alternative cluster. As one goes further down the tree, these large clusters further subdivide into their subcomponent parts.

RESULTS

When examining the first split of the data, trajectories appear to categorize into two primary classes: (1) a trajectory that appears consistent with impulse inhibition: an initial and immediate deflection towards the smaller-sooner, followed by a correction back towards the larger-later, and (2) a trajectory that appears consistent with dynamic competition: a gradual evolution towards the larger-later. These results are notable for two reasons. First, these results suggest that impulse inhibition and dynamic competition are indeed the two predominant models that best describe the variability in our data. In other words, using this data driven approach, we find that the largest differentiator of choice evolution is whether trajectories appear discrete (i.e., arriving via impulse inhibition) or graded (arriving via dynamic competition), and, notably, we find evidence for both approaches. Second, however, is that the two clusters are not of equal size – in fact, trajectories were more than twice as likely to be clustered as dynamic (31,496 trajectories, 67.34%) as impulse inhibition (15,278 trajectories, 32.66%). This suggests that, while both impulse inhibition and dynamic competition represent real routes to choosing long-term over short-term, dynamic competition appears to be considerably more frequent.

Who Relies on Impulse Inhibition? One critical distinction between models emphasizing effortful impulse inhibition and dynamic competition is what it means to have good self-control – is impulse inhibition characteristic of those with good or poor self-control? We thus test whether more myopic individuals – that is those who are less patient and discount future rewards more – are more likely to demonstrate impulse inhibition. Using mixed effects models with random effects for subject and choice, we find that as (log-transformed) discount rate increases, participants are more likely to rely on impulse inhibition, $b = .23$, $SE = .02$, $Z = 14.18$, $p < .001$. In other words, people who are less patient showed relatively greater reliance on impulse inhibition than those who were relatively more patient. This result held even when controlling for the difference in subjective value of the two choices on that trial, $b = .20$, $SE = .02$, $Z = 11.15$, $p < .001$.

CONCLUSION

There exist multiple competing theories and conceptualizations of self-control. By taking advantage of the rich spatial and temporal data offered by mouse-tracking, it appears that there are multiple routes to successful self-control – stage-based impulse inhibition and integrative dynamic competition. Notably, impulse inhibition appears to be both in the minority, and characteristic of those with poor self-control. By quantifying the diverse ways in which participants elect long-term over short-term, we can begin to build models of self-control that more comprehensively reflect the realities of the decision-making process.

EXTENDED ABSTRACT

Prior research conceptualizes solid (i.e., enduring, ownership-based) and liquid (i.e., ephemeral, adaptable) consumption along a single continuum. By contrast, we propose that solid and liquid consumption are best represented by two orthogonal dimensions. We show that market offerings which land in the ‘golden quadrant’ (high-solid/high-liquid) reap the highest consumer value.

Solid consumption characterizes market offerings that are enduring and ownership-based (Bardhi and Eckhardt 2017). For example, purchasing a book from Amazon or purchasing a Toyota Camry are examples of solid consumption. By contrast, *liquid consumption* characterizes market offerings that are ephemeral and adaptable (Bardhi and Eckhardt 2017; Bardhi, Eckhardt, and Arnould 2012). For example, checking out a book from the library or reserving a rental car through Enterprise are instances of liquid consumption. Thus, solid consumption primarily offers consumers value in the *security* associated with physical ownership, whereas liquid consumption primarily offers *flexibility* associated with having access to an assortment of products to accommodate consumers’ changing preferences (Bardhi and Eckhardt 2017).

Current theories categorize consumption along a single continuum from purely solid to purely liquid, with the midpoint representing a mixture of solid and liquid (Bardhi and Eckhardt 2017). This continuum perspective suggests a tradeoff, such that solid consumption offers high security but low flexibility, whereas liquid consumption offers low security but high flexibility. By contrast, we propose that solid and liquid consumption are better understood as two orthogonal dimensions (H1). We put forth a 2 (high vs. low solid) \times 2 (high vs. low liquid) framework, which suggests market offerings generally fall into one of four quadrants. Our perspective proposes that some offerings can be characterized as both high solid and high liquid consumption. For example, Amazon Alexa provides the benefits of both security (e.g., physical device, personalized account; i.e., solid consumption) and flexibility (e.g., a wide variety of features, digital technology that can be updated as consumer preferences change; i.e., liquid consumption).

In addition to offering a more accurate perspective on market offerings, our framework allows for novel predictions about consumer behavior. We hypothesize that market offerings occupying the perceptual space of high solid and high liquid consumption will reap the highest consumer value (H2), a phenomenon which the continuum perspective cannot explain. We refer to this hypothesized phenomenon as the *golden quadrant of solid and liquid consumption*. Our studies examine value at the market offering level (e.g., product attitudes) and the brand level (e.g., brand growth).

Experiment 1. To test the orthogonality of solid and liquid consumption (H1), 300 MTurk participants were presented with a random subset of the top 100 global brands from Interbrand (e.g., Coca-Cola, Uber; Interbrand 2020). To assess participants’ perceptions of solid and liquid consumption, they rated each brand’s security (i.e., solid) and flexibility (i.e., liquid; 1 = *no security* [*flexibility*], 7 = *a lot of security* [*flexibility*]). In line with prior research (Cannon, Rucker, and Galinsky 2021; Fiske et al. 2002; Fiske and Dupree 2014), a hierarchi-

cal cluster analysis determined that four clusters best categorize the data (Ward 1963). Importantly, a subsequent *k*-means cluster analysis with four groups determined these four clusters mapped onto the four quadrants of the 2 (high vs. low solid) \times 2 (high vs. low liquid) framework. For example, one cluster with 8 brands, including Amazon and Google, was characterized as high solid ($M = 5.42$) and high liquid ($M = 5.64$). The two ‘‘high solid’’ clusters were perceived as more solid than the ‘‘low solid’’ clusters (all $t > 5.32$, $p < .001$), and the two ‘‘high liquid’’ clusters were perceived as more liquid perceptions than the two ‘‘low liquid’’ clusters (all $t > 8.89$, $p < .001$).

Experiment 2. To provide causal evidence for H1, 252 undergraduate students were randomly assigned to conditions that varied solid \times liquid consumption: (a) purchasing a digital book, (b) purchasing a physical book, (c) renting a book, and (d) attending a book reading. Participants listed three benefits afforded by their assigned consumption opportunity, then rated the degree to which each benefit offered security (i.e., solid) and flexibility (i.e., liquid; 1 = *very little*, 7 = *a lot*). In line with our hypotheses, a mixed-effects regression with indicators of condition revealed that digital books ($M = 5.58$) and physical books ($M = 5.65$) were perceived as more solid than renting books ($M = 4.86$) and book readings ($M = 4.54$; $z = 8.05$, $p < .001$). Likewise, digital books ($M = 5.62$) and renting books ($M = 5.74$) were perceived as more liquid than physical books ($M = 4.95$) and book readings ($M = 4.49$; $z = 8.45$, $p < .001$). Therefore, even within the same product category (i.e., books), different market offerings can fall within each of the four quadrants.

Experiment 3. To examine our *golden quadrant* hypothesis (H2), we obtained performance metrics (brand value and growth) from the Interbrand website for the 100 brands from experiment 1 (Interbrand 2020). We predicted brand performance using the solid and liquid ratings from experiment 1 and their interaction. A regression model revealed a positive and significant interaction between solid and liquid perceptions for both brand value ($b = 29,977.90$, $t(96) = 2.72$, $p = .008$) and brand growth ($b = 0.09$, $t(91) = 2.07$, $p = .041$). Overall, brands that land in the high-solid/high-liquid ‘golden quadrant’ enjoyed the highest valuation in the marketplace, compared with brands that were only high on one dimension.

Experiment 4. To provide additional evidence for H2, we had 200 MTurk participants rate their perceptions of the 12 technology brands from the Interbrand top 100 list (e.g., Google, LinkedIn). Participants indicated their brand attitude using three items ($\alpha = .98$). Then, participants indicated their solid and liquid perceptions for each brand as in previous studies (1 = *not at all*, 7 = *very much*). A mixed-effects regression revealed a positive and significant interaction ($b = 0.02$, $z = 1.99$, $p = .046$), consistent with a golden quadrant of solid and liquid consumption. This study thus replicates the findings of experiment 3 using a different metric of consumer value (i.e., attitudes).

In conclusion, solid and liquid consumption are better conceptualized as two orthogonal dimensions, and *the golden quadrant of solid and liquid consumption* elicits the highest valuation in the marketplace. Relative to existing theorizing, this framework provides an alternative perspective on how to view and design market offerings.

Germ and Possessions: Pathogen Concerns Enhance Psychological Ownership

Dr. Sean Hingston, Ted Rogers School of Management, Canada

Dr. Jodie Whelan, School of Administrative Studies, York University, Canada

EXTENDED ABSTRACT

We examine how chronic and situational differences in pathogen concerns affect psychological ownership. Four studies demonstrate that heightened pathogen concerns lead consumers to put a greater importance on the concept of ownership. This subsequently enhances psychological ownership and impacts downstream consumer behaviors (e.g., attitudes, word of mouth).

Consumers often feel as though they own things regardless of whether they are owned in a legal sense. For example, someone who is a die-hard fan of a television series may come to feel that it is *theirs* even though they have no legal claim to it. This is referred to as psychological ownership (Pierce, Kostova and Dirks 2003). While prior research has dominantly focused on the antecedents that lead to the emergence of psychological ownership (Peck and Shu 2009; Stoner, Loken and Stadler Blank 2018), less is known about the factors that enhance consumers' psychological ownership (Thüridl et al. 2020).

Research on the behavioral immune system (BIS) has demonstrated that the perceived threat of pathogens sensitizes people to contamination relevant cues (see Murray and Schaller 2016 for a review). For example, pathogen concerns increase attention to physical abnormalities (Ackerman et al. 2009) and accents (Reid et al. 2012). Presumably, by becoming more aware of and responsive to cues that are heuristically associated with contamination, people minimize the risk of getting and spreading pathogens. The BIS and the concept of ownership are brought together by the premise that ownership can also serve as contamination cue. Indeed, when pathogen concerns are activated, consumers exhibit a reduced preference for second-hand goods (Huang, Ackerman and Sedlovskaya 2017). Furthermore, there is a strong association between physical (and even imagined) touch and feelings of ownership, further highlighting the common belief that ownership and physical contact are intertwined (Peck, Barger and Webb 2013; Peck and Shu 2009). If people believe that ownership implies physical contact, then pathogen concerns should augment the importance of ownership due to the enhanced heuristic value of determining who owns what.

Finally, if pathogen concerns bring ownership to the fore, this concept should then be more likely to be integrated into consumers' subsequent attitudes, feelings, and perceptions (Janiszewski and Wyer Jr. 2014). Unlike legal ownership, which is relatively binary (i.e., you either have legal ownership rights to something or you do not), psychological ownership exists as a matter of degrees; people can vary in the extent to which they feel something is theirs. Indeed, there are numerous ways in which people's feelings of ownership can change from one moment to the next (Peck et al. 2013; Stoner et al. 2018). Given that relevant cognitions and behaviors can enhance psychological ownership, we predict that when consumers feel that it is important to establish who owns what, this will increase their psychological ownership for targets that they have a preexisting affinity for.

In Study 1, we tested the prediction that that pathogen concerns would enhance psychological ownership for liked targets rather than make it emerge for a neutral target. Americans from Mturk (N = 471) were randomly assigned to either enter the name of a clothing brand that they like or a clothing brand that they are familiar with but neither like nor dislike. Participants reported psychological ownership (Peck and Shu 2009), attitude toward the brand (MacKenzie and

Lutz 1989), and germ aversion (Duncan, Schaller and Park 2009). Consistent with our prediction, germ aversion positively predicted psychological ownership for the liked brand, but it did not predict psychological ownership for the neutral brand. Furthermore, the effect of germ aversion on attitudes was mediated by psychological ownership for the liked brand, but not for the neutral brand.

Study 2 was designed to test whether situational (i.e., manipulated) pathogen concerns would similarly enhance psychological ownership. We also wanted to test our proposed mechanism and whether enhanced psychological ownership would positively predict word of mouth as an act of stewardship (Kirk and Rifkin 2021). Americans from Prolific Academic (N = 740) were randomly assigned to either write about the experience of wearing a shirt that was brand new (control) or used (pathogen). Then, we captured the importance of ownership. Lastly, participants typed the name of a TV show that they like, indicated their psychological ownership of it, and whether they would recommend the show (Consiglio, De Angelis and Costabile 2018). As predicted, participants reported greater psychological ownership and importance of ownership in the pathogen condition. Finally, the positive effect of pathogen concerns on word of mouth was serially mediated by importance of ownership and psychological ownership.

Study 3 was designed to test our theorizing that pathogen concerns also enhance inferences of psychological ownership in others. Americans from Prolific Academic (N = 649) were randomly assigned to either write about the experience of wearing a shirt that was used (pathogen) or used but subsequently sterilized (control). Importance of ownership was captured then participants were asked to imagine that a close friend had a new favorite band. We captured inferred psychological ownership (Kirk, Peck and Swain 2018), then participants stated how likely they would be to share an article about the band that their friend had not yet shared. Results revealed that in the pathogen condition, participants inferred marginally greater psychological ownership and significantly greater importance of ownership. Finally, the positive effect of pathogen concerns on word of mouth was serially mediated by the importance of ownership and inferred psychological ownership.

Study 4 was designed to moderate the downstream effect of psychological ownership on attitudes. We recruited Americans from Prolific Academic (N = 549). Germ aversion and the importance of ownership were captured. Participants were asked to type the name of a clothing brand they like and report their psychological ownership of the brand. Then, participants were randomly assigned to imagine that the brand had launched a campaign that asked either existing customers (no infringement) or new customers (infringement) to help name a collection of the brand's clothing. Attitude toward the campaign was then captured. Results revealed that germ aversion positively predicted psychological and importance of ownership. Finally, although there was a positive effect of psychological ownership on attitudes when the promotion targeted existing customers, this relationship was not significant when the campaign invited new customers to name the collection.

Buying to Impress Others or Buying to Please Yourself? Different Motives Underlying Masstige Consumption

Dr. Alex Yao, San Diego State University, USA
Dr. Zhe Zhang, Ivey Business School, Western University, USA
Dr. Zhiyong Yang, Miami University, USA

EXTENDED ABSTRACT

The fast-growing middle class in emerging markets leads luxury brands to adopt a masstige (mass + prestige) approach. Using a multi-method approach, three studies reveal two major motives underlying masstige consumption, showing that socially-oriented (vs. personally-oriented) motives enhance the preference for foreign (vs. domestic) masstige brands.

Masstige luxury (e.g., Coach, Kate Spade) is a type of luxury that the quality, style, and price are higher than everyday products, but are lower than premium luxury goods (Paul 2019). Compared to premium luxury, masstige luxury takes a more inclusive approach by offering premium goods at attainable prices to reach a *mass consumer population* (Kumar and Paul 2018). While this strategy proves to be successful worldwide, especially in emerging markets (e.g., China, India, Brazil), academic research on masstige luxury consumption is behind (Paul 2018). To further complicate the issue, masstige luxury in emerging markets is consisted of not only foreign brands, but also domestic brands for consumers to choose from. While previous research shows that consumers' motives underlying luxury consumption can be broadly categorized into *socially-oriented* motives (e.g., status signaling) and *personally-oriented* motives (e.g., personal enjoyment and gratification) (Patrick and Monga, 2020), little is known about how socially-oriented and personally-oriented motives influence consumer preference of domestic (vs. foreign) masstige brands. The present research aims to fill this gap by examining the interplay of consumption motives and the product's country-of-origin on consumer choice of masstige brands in emerging markets.

We anticipate that when socially-oriented motives are salient, consumers in emerging markets would prefer foreign (vs. domestic) masstige brands, as consumers in emerging markets have a tradition of adopting foreign brands to signal and boost their social status (Batra et al. 2000). Foreign brands can offer symbolic values which may create social distinctions by exhibiting "elite power and privilege" in developing countries (Burke 1996, p. 181). On the contrary, when personally-oriented motives are salient, consumers in emerging markets are anticipated to prefer domestic (vs. foreign) masstige brands. Domestic masstige brands provide superior "value-for-money" and offer more hedonic values (Xu 2019; Zhu 2018), which directly satisfy consumers' needs for personal gratifications and pleasure (Wu and Yang 2018).

Using a multi-method approach, three studies provide consistent evidence to support our hypothesized effects. In Study 1, participants who had purchased masstige luxury in the previous 12 months were recruited in China. They were asked to list the masstige brands they purchased in the previous 12 months (as complete as they could recall). Afterwards, participants were asked to report: "Among your masstige consumptions made in the past year, what's the percentage of your spending made on domestic masstige brands?" (0-100%). We also measured two important masstige consumption motives: personally-oriented motives through three items ($\alpha = .64$) and socially-oriented motives through four items ($\alpha = .93$). A linear regression analysis shows that, as expected, socially-oriented motives lead consumers to consume more foreign brands over domestic brands ($b = -7.512, p < .01$), whereas personally-oriented motives lead

consumers to prefer domestic brands over foreign brands ($b = 3.789, p < .01$).

Study 2 uses a secondary dataset of Chinese consumer jewelry purchase data from six major brands (two foreign brands and four domestic brands). This dataset records consumption related information, including brand choice, price paid, and perceived quality of the six brands, as well as measures of participants' socially-oriented motives ($\alpha = .82$) and personally-oriented motives ($\alpha = .76$), as in Study 1. With a utility maximization modeling framework, we replicated the findings from Study 1.

In Study 3, we sought to establish the causal direction between consumption motives and preference for domestic (vs. foreign) masstige brands. In this experiment study, we randomly assigned participants to either a socially-oriented or personally-oriented purchase condition, and manipulated their purchase goals (i.e., to impress others vs. to please themselves) accordingly. Participants were then asked to make a choice between a foreign masstige brand (originated and made in the USA) and a domestic brand (originated and made in China). Participants also indicated their socially-oriented motives and personally-oriented motives when making the choice. A binary logistic regression showed a significant main effect of purchase condition (Wald $\chi^2(1) = 52.03, \beta = 2.50, SE = .40, \exp(\beta) = 12.22, p < .001$), with more participants in the personally-oriented condition (90.9%) chose the domestic masstige brand, and more participants in the socially-oriented condition (55.0%) chose the foreign masstige brand. Mediation analysis (Hayes model 4) supported the proposed mechanism (3.09; 95% CI = [2.27, 4.55]).

This research extends extant literature on luxury consumption by showing a congruity effect between different types of consumption motives (socially- vs. personally-oriented motives) and the preference of a brand's country-of-origin (domestic vs. foreign). Findings from this research also offer actionable implications. For instance, to promote domestic masstige brands, marketers can use communication appeals or contextual cues to enhance the accessibility of personal motives (e.g., using ad appeals that promote the independence of the self). Conversely, when promoting foreign masstige brands, marketers may find it effective to appeal to the social aspect of the self (e.g., appeals of social harmony).

The Negative Effect of Name: Mentions of Server Name Reduce Online Review Persuasiveness

Dr. Xinlan Li, School of Management, Huazhong University of Science and Technology, China
Dr. Dong Hong Zhu, School of Management, Huazhong University of Science and Technology, China
Prof. Yaping Chang, School of Management, Huazhong University of Science and Technology, China

EXTENDED ABSTRACT

Although consumers do not pay attention to server names during consumption, server names frequently appear in online reviews. Secondary data and three studies show that readers may perceive positive reviews mentioning server names as less persuasive, but this negative effect is mitigated in industries where server expertise is important.

Online reviews largely influence consumer decision-making (Zhu and Zhang 2010). Servers are one of the important objects of reviews (Zhu et al. 2017). When mentioning servers, most consumers are accustomed to directly using “the waiter/waitress” or “the service” as the subject. At the same time, we have also observed that server names appear apparently in the online reviews of some businesses. Our pilot study of 343 Chinese consumers revealed that 28.86% have experienced being asked by waiters to give positive online reviews including their names, and 56.85% have seen the name of waiters in online reviews. Kim and Baker (2017) proffered that disclosing server names to consumers in ethnic restaurants can enhance their perceptions of experience authenticity. Does the frequent disclosure of server names in the online reviews of a company also enhance its potential consumers’ authenticity perception of the reviews? As the factors that influence online review persuasiveness are the focus of businesses and scholars (Reich and Maglio 2020; Rosario et al. 2020), it is important to know whether the name of servers is a factor.

Our research examines the influence of server names on online review persuasiveness. When readers read reviews, they tend to infer the motivation of reviewers (Naylor et al. 2011). Reviewers’ language use serves as a clue since it provides insights for readers into the relationship between the reviewer and the object being commented (Berger et al. 2019). Similarly, a reviewer’s reference to server names affects readers’ perceptions of the reviewer’s relationship with this company and the server. When a reviewer evaluates the service and mentioned the server name, readers may think that the reviewer has a closer relationship with the server and infer that instead of helping potential consumers better understand the company to make consumer choices, the reviewer has other review motives. Therefore, we indicate that when readers perceive a review to be more deceptive, the persuasiveness of the review will decrease.

But in hairdressing, manicure, and pedicure shops, servers provide high skilled services such as hairdressing and nail painting. At this time, reviews mentioning server names tell readers which servers offer better services, and help readers choose servers in the consumption to obtain better experiences, hence reducing readers’ consumption risks (Moe and Trusov 2011), producing no negative effects. We believe the importance of server expertise moderates this effect.

In Study 1a, we collected data from the Chinese largest independent third-party online review platform Dianping.com (Zhu et al. 2019). On January 26, 2021, we scraped 16,470 reviews, 2910 reviews without server names, and 1560 reviews with server names were obtained, the number of “likes” of the review was a dependent variable representing its persuasiveness. Negative binomial regression results suggested the persuasion of the reviews with server

names was lower than reviews without server names ($b = -.4748, z = -15.87, p < .001$).

Study 1b opted for online experiments to verify our main effect and the mediation effect of perceived deception. We recruited 132 subjects to a one-factor, two-level (existence of server names: yes vs. no) between-subjects design. Participants browsed the review interface of restaurant A and saw several reviews. Participants in the (no-) server name group saw five reviews (that praised the waiter but did not mention the name) with server names. They then reported their patronage intentions, and perceived deception of those reviews. ANOVA showed that compared with the no-server name group, subjects in the server name group had lower patronage intentions ($M_{\text{no-name}} = 5.09, M_{\text{name}} = 4.55, p = .022$), higher perceptions of review deception ($M_{\text{no-name}} = 3.8, M_{\text{name}} = 4.23, p = .031$), perceived deception served as a mediator ($IE = .33; CI [.0240, .6651]$).

Study 2 re-examined the main effect and the mediating effect in experience-oriented services scenarios such as hotels. 142 subjects were invited into two groups. Subjects first read that they planned to travel to areas without the COVID-19 epidemic with their friends. To book a hotel, they searched for hotels online. The manipulation of server names was similar to study 1b. After reading four manipulative reviews and one service-irrelevant review, participants reported the same measures as in study 1b. The results were consistent with our hypotheses.

Study 3 investigated the boundary of our effect. We invited 239 subjects to a 2 (existence of server names: yes vs. no) * 2 (importance of server expertise: high vs. low) between-subjects design. Participants read that they and their friends planned to find a pedicure shop with experienced pedicure technicians (vs. fully automatic multi-functional massage barrels) to provide massage services. Afterward, subjects were told that they saw reviews when they searched for this type of pedicure shop on Dianping.com and browsed pedicure shop A. The manipulation of server names was similar to study 1b. After reading three manipulative reviews and one service-irrelevant review, participants reported the same measures as in study 1b. ANOVA showed the interaction between name and expertise ($p = .003, \eta^2 = .039$) influenced participants’ patronage intentions. When server expertise importance was high, participants between the server name group and no-server name group had indifferent patronage intentions ($M_{\text{no name}} = 4.81, M_{\text{name}} = 4.80, p = .97$). When server expertise was low, compared with the no-server name group, subjects in the server name group had lower patronage intentions ($M_{\text{no name}} = 5.12, M_{\text{name}} = 4.03, p < .001$).

This research brings the server name into name-related researchers’ vision and enriches the factors that influence the persuasiveness of reviews. For merchants in industries where the server expertise is less important, we remind them that it is inappropriate to use the number of reviews mentioning server names as a measure of server performance. For industries where server expertise is important, we encourage them to promote service quality and increase the number of positive reviews mentioning server names.

Multi-Product Brand Extensions Evaluations Vary with Consumers' Implicit Theories of Personality

Prof. Shailendra Jain, University of Washington, USA
Prof. Pragya Mathur, City University of New York, USA
Prof. Huifang Mao, Iowa State University, USA
Prof. Durairaj Maheswaran, New York University, USA
Prof. Mathew Isaac, Seattle University, USA

EXTENDED ABSTRACT

Three studies show that incremental theorists (who believe in malleability of personality traits) prefer extensions that are similar to a specific product exemplar of the parent brand. Entity theorists (who believe that personality traits are mostly fixed) prefer extensions that are similar to the prototype of the parent brand.

Multi-Product Brand Extensions Evaluations Vary with Consumers' Implicit Theories of Personality

We investigate the influence of consumers' implicit theories of change (Mathur, Jain, & Maheswaran, 2012) on evaluations of extensions whose parent brand is broad, i.e., has multiple products under the umbrella brand (e.g., Virgin, General Electric). We invoke the type of fit the extension has with the parent brand and its products (Mao and Krishnan, 2006). Prototype fit considers an extension's similarity to the prototypical representation of the parent brand, while exemplar fit assesses the extension's similarity to a product exemplar under the brand. Three studies find that entity theorists, who believe personality traits are fixed, tend to provide more favorable evaluations to prototype fit extensions, whereas incremental theorists, who believe personality traits are malleable, evaluate exemplar fit extensions more favorably.

STUDY 1

178 US undergraduates (85 females, mean age = 20.77 years, $SD = 2.69$) were introduced to a fictional multi-product beauty brand, Yelian. Participants evaluated two Yelian extensions, one with high exemplar fit/low prototype fit with Yelian (bath sponge), and another with high prototype fit/low exemplar fit (face mask) on six, 10-point relative scales ($\alpha = .92$). Participants then completed the 3-item domain general implicit theory scale (Dweck et al., 1995; $\alpha = .84$). A regression of participants' average relative evaluation on their average implicit theory score showed that a greater entity theory orientation predicted stronger preference for the high-prototype brand extension over the high-exemplar brand extension, $b = .33$, $F(1, 176) = 5.04$, $p < 0.03$.

STUDY 2

113 US students participated in a 2 (implicit theory: incremental vs. entity) x 2 (brand extension fit: exemplar [bath sponge] vs. prototype [face mask]) between-subjects study in which implicit theories were manipulated (Plaks et al., 2001). A 2 x 2 between-subjects ANOVA revealed a two-way interaction between type of fit and implicit theory ($F(1, 109) = 5.06$, $p < .05$). Entity theorists evaluated the high prototype fit extension more favorably ($M_{ET-PF} = 5.27$, $SD = 1.19$ vs. $M_{IT-PF} = 4.39$, $SD = 1.23$, $F(1, 109) = 3.23$, $p < .05$), while incremental theorists evaluated the high exemplar fit higher ($M_{ET-EF} = 4.47$, $SD = 1.03$ vs. $M_{IT-EF} = 5.12$, $F(1, 109) = 4.24$, $p < .05$).

STUDY 3

Study 3 examined how a parent brand is impacted by the success/failure of its extension, referred to as "feedback effect" (Milberg, Park, & McCarthy, 1997). 198 US students participated in a

2 (incremental vs. entity theory) x 2 (exemplar vs. prototype fit) x 2 (extension performance: favorable vs. unfavorable) between-subjects study. Implicit theory was manipulated using proverbs (Poon and Koehler, 2006). Participants read a brief description GE and its products and learnt that GE was launching either Laptops (high prototype fit/low exemplar fit) or Detergents (high exemplar fit/low prototype fit). In the favorable (vs. unfavorable) performance review condition, the extension was reviewed more positively (vs. negatively). Participants evaluated the parent brand pre as well as post-exposure and evaluated the extension on the same scales ($\alpha = .98$). Entity theorists evaluated a successful high prototype fit extension more favorably ($M_{ET-PF} = 5.58$ vs. $M_{IT-PF} = 4.58$; $F(1, 186) = 7.15$, $p < .01$), while incremental theorists judged the successful high exemplar fit extension higher ($M_{ET-EF} = 4.47$ vs. $M_{IT-EF} = 5.25$; $F(1, 186) = 9.10$, $p < .01$). Under extension failure, entity theorists' evaluations of the parent brand declined for both, the high exemplar and high prototype fit extensions, but the decline was greater for the latter (exemplar fit: $M_{ET-EF-Pre} = 5.94$ vs. $M_{ET-EF-Post} = 4.97$; $F(1, 186) = 6.64$, $p < .05$; prototype fit: $M_{ET-PF-Pre} = 5.85$ vs. $M_{ET-PF-Post} = 4.23$; $F(1, 186) = 27.02$, $p < .001$). Also, their evaluations of the parent brand in response to the failed prototype fit extension were significantly lower than those for the failed exemplar fit extension ($M_{ET-EF-Post} = 4.97$ vs. $M_{ET-PF-Post} = 4.23$, $F(1, 186) = 4.94$, $p < .05$). In contrast, incremental theorists did not alter their parent brand evaluations in the face of failure ($M_{IT-Pre} = 5.87$ vs. $M_{IT-Post} = 5.55$; $F < 1$).

GENERAL DISCUSSION

We examine extensions of broad parent brands and show evidence of instances when entity beliefs may be altered, namely, when entity theorists encounter preferred but failed extensions. Similarly, we show instances when incremental theorists are likely to leave their initial assessments unchanged. In particular, we provide the first examination of broad brands and the qualitative type of extension fit (prototype/exemplar) with the parent brand and report that poorly performing extensions may be detrimental for the parent brand, especially with the entity theory segment. Future research should investigate whether the effects observed in our studies may be explained by construal level theory (Trope, Liberman, & Wakslak 2007), since prototypes are abstract representations while exemplars are more concrete instances of a category.

Feeling Small but Thinking Big: Awe-induced Positive Self-diminishment Motivates Sustainable Consumption

Dr. Srinwanti H. Chaudhury, University of Queensland, Australia
Dr. Nitika Garg, University of New South Wales, Australia
Dr. Colin Gabler, Ohio University, USA

EXTENDED ABSTRACT

We propose the association of positivity while feeling small, the positive self-diminishment effect can address the significant attitude-behavior gap for sustainable products. The current research examined awe as an antecedent of the positive self-diminishment effect and found that this effect leads to higher willingness to pay (WTP) for sustainable products.

Research on sustainable attitudes and behaviors has documented promoting aspects of self-relevance to drive sustainable behavior. For instance, research suggests that individuals are motivated to preserve or raise self-esteem when making sustainable purchases. This is because individuals' identity or self-image concerns are important triggers of positive consumer behaviors (e.g., White, Simpson, and Argo 2014). However, enhancement of self-image poses an immediate concern of boosting consumers' self-interests rather than a more self-transcendent perception required to motivate consumption for the greater good. In other words, the relatively higher costs associated with sustainable products act as a barrier for consumer adoption of such goods. Although extensive research has examined the influence of psychological antecedents on sustainable actions and behaviors, marketers still struggle to overcome the attitude-behavior gap of consumers in the domain of sustainable products. Thus, a gap remains in understanding potential motivating factors to consume sustainably and especially, boost inclinations to pay for relatively expensive sustainable products.

In this research, we identify a novel aspect of self-relevance – positive self-diminishment – that will help marketers to bridge the gap by increasing willingness to pay (WTP) for sustainable products. We define positive self-diminishment as the perception of feeling psychologically small without adversely affecting associated self-concept perceptions such as self-esteem, status, and sense of power and control. Put differently, positive self-diminishment is devoid of negative self-perceptions even while making the consumer feel psychologically small. Thus, a sense of positive self-diminishment addresses double barreled necessities relevant to motivating sustainable consumption – first, viewing the self as psychologically smaller primes a sensitivity to others' and promotes self-sacrificing behaviors (e.g., Van Vugt, 2009) and second, a positive self-perception enables uptake of opportunities which can affirm self-worth (Baumeister, 1998; Beauregard and Dunning, 1998; Swann, 1997), such as purchase of socio-desirable sustainable products.

Emotional engagement of consumers is a crucial and pervasive component of marketing. For instance, advertisements that use appropriate emotions increase consumer interest and translate to increased sales volumes (Nielsen, 2016). Similarly, in the domain of sustainable consumption, emotions like anticipated guilt encourage sustainable behavior (Peloza et al., 2013) while sadness can increase donations for sustainable causes (Schwartz & Loewenstein, 2017). However, there are significant drawbacks to experiencing negative perceptions since marketers strive to inculcate positive experiences for consumers. Answering recent calls for research to examine positive emotions, we evaluate a range of positive emotions and test the hypothesis that awe-induced positive self-diminishment is a stronger and more efficient motivator of sustainable actions.

Awe is a positive emotion which is primed by elicitors of natural scenic beauty or magnificent artwork or even spiritual episodes (Shiota, Keltner, and Mossman, 2007). In other words, awe incorporates a sense of wonder (Piff et al., 2015) and alters consumers' existing mental structures (Keltner and Haidt 2003). Importantly, awe induces a perception of reduced self-size whereby individuals feel smaller in the presence of awe-inducing stimuli (Piff et al., 2015). A state of self-diminishment however, even when positive, is undesirable and enhances perceptions of social () We argue and demonstrate that the sense of awe-induced self-diminishment enhances motivation to manifest moral identity and spend more on sustainable products. This is an important advantage of positive self-diminishment since prior research outlines that signaling is an integral part of socio-moral behaviors such as sustainable consumption (e.g., Griskevicius, Tybur, & Van den Bergh, 2010). Thi

Among positive emotions, literature has largely emphasized the role of pride in motivating sustainable behaviors (e.g., Antonetti & Maklan, 2014; Bissing-Olson et al., 2016; Onwezen et al., 2013; Onwezen et al., 2014). However, pride is a self-focused emotion (Tracy & Robins, 2004) and may enhance focus on money and status, thus reducing the tendency to pay for sustainable products which are relatively more expensive. Thus, we examined if awe-induced positive diminishment would emerge as a more efficient motivator than self-referential emotions (such as pride) and other-referential emotions (such as gratitude and compassion) in facilitating higher willingness to pay for sustainable products. Using data from an archival dataset of a nationally representative population in the United States ($N = 1519$), a field study ($N = 108$), and three experiments ($N = 641$), our results show that utilizing awe (versus other positive emotions) primes positive self-diminishment and promotes engagement in sustainable goals including greater willingness to pay for sustainable products. Importantly, while prior empirical research has examined only one to two emotions in comparison with each other, we are the first to examine the effects of a range of positive emotions on sustainable consumption.

We employed five studies to examine the concept of positive self-diminishment via awe and how it might be a useful strategy to bridge the attitude-behavior gap in sustainable consumption. Specifically, evoking awe helps individuals feel small without negatively impacting their self-concept and helps to overcome the dilemma of self-other trade-off, thereby increasing spending levels on sustainable products. This research makes several contributions, including exploration of a novel aspect of self-concept, examination of discrete positive emotions from a functional perspective, and contribution to the nascent work on specific aspects of moral identity. Overall, our research adds to our understanding of factors driving sustainable behaviors, while providing a novel perspective to promote sustainable consumption.

Cui Bono? Exploring Consumers' Responses towards Privacy Notices

Ms. Deniz Lefkeli, Koc University, Turkey
Prof. Zeynep Gurhan Canli, Koc University, Turkey

EXTENDED ABSTRACT

Privacy notices make it salient to the consumers that they are being observed. Consumers think that companies benefit more from tracking practices, which decreases customer centricity of the company and consumers' usage intentions. The effect is mitigated when companies signal their willingness to waive the benefits acquired from observing consumers.

In line with GDPR, companies notify consumers regarding their data collection practices. Research showed that consumers are averse to being observed (e.g., Zwebner & Schrift 2020); however, asking for permission to track can have positive outcomes (e.g., Schmidt, Bornschein and Mein 2020). Here we explore how privacy notices influence consumers' inferences about companies.

We propose that privacy notices make consumers aware that they are being observed, which leads people to think about the party that sends this message. Privacy calculus model suggests that while deciding whether to provide information, individuals calculate the costs and benefits of disclosure (Laufer and Wolfe 1977). As being observed makes the observer salient, consumers calculate not only their own benefits, but also companies' benefits. We predict that consumers think of data collection as a zero-sum market exchange and believe that companies benefit more. This, in turn, decreases perceived customer centricity of the companies, although it is one of the primary goals of tracking, which reducing consumers' usage intentions.

A pilot study (N=100) showed consumers' belief that companies benefitted more than consumers ($M_{companies} = 85.52$, $M_{consumers} = 14.48$, $p < .001$) from tracking. To better understand managers' views, we conducted a survey with executives (N=31), asking whether they agreed with the statement suggesting that the main goal of tracking is to put consumers' interest at the center of companies' actions. 84% of them (N= 26/31) agreed with the statement ($\chi^2(2) = 5.135$, $p = .02$). These findings suggest a mismatch between companies' and consumers' understanding of consumer centricity.

In Study 1 (N=177), we randomly selected 40 companies on the Fortune 500 list. Participants read a short description, rated their familiarity, anticipated profitability, expected tracking activities and perceived motive of the company. Controlling for familiarity, anticipated motive, company fixed effects, age, gender and education of the participants, perceived profitability of a company increased participants' anticipation of tracking ($b = .27$, $SE = .03$, $p < .001$).

In Study 2A, we explored the website metrics of the homepage of a European University over a period of 5 years. This university implemented privacy notices on their websites on January 15, 2021 as a part of GDPR regulations. Controlling for the monthly and annual fixed effects, the availability of the privacy notice decreased the number of pageviews ($b = -8540.7$, $SE = 580.5$, $p < .001$). Study 2B (N=191) showed that participants who received a privacy (vs. update) notice were less likely to use a browser ($M_{privacy\ notice} = 3.53$, $M_{control} = 4.94$, $p < .001$).

Study 3A (N=193) tested the underlying mechanism. After receiving a privacy [update] notice, participants reported their willingness to use the application in future and completed the customer centricity scale (Habel et al. 2020). Participants in the Privacy Notice condition were less likely to use the application ($M_{privacy\ notice} = 3.06$, $M_{control} = 4.89$, $p < .001$). Privacy notice reduced the perceived consumer centricity of the company, which decreased con-

sumers' willingness to use the application (Effect = $-.24$, %95 CI: $[-.48, -.05]$). Study 3B clarified the process and ruled out trust as a potential mechanism. Participants received a privacy (vs. welcome) notice and reported their interest in using the platform (adapted from Zwebner and Schrift 2020) and the extent to which they thought that this platform was profit oriented and customer oriented. Finally, they reported how much they trust the platform (adapted from Brough et al 2021). We calculated a difference score using profit and customer orientation questions for identifying the perceived orientation of the platform. Controlling for trust, the perceived company orientation mediated the relationship between the notification type and interest in using the platform (Effect = $-.16$, %95 CI: $[-.30, -.05]$). However, when we controlled for the company orientation, trust did not mediate the effect (Effect = $-.06$, %95 CI: $[-.25, .13]$).

Study 4 (N=671) employed a 2 (Company Type: For-Profit, Non-Profit) x 2 (Privacy Notice: Available, Control) between-subjects design. Participants imagined opening a website of a for-profit (vs. non-profit) organization (adapted from Aaker, Vohs, and Mogilner 2010). Participants in the Privacy Notice condition viewed the privacy notice. All participants reported their purchase intention, completed the perceived customer centricity scale and manipulation check. Participants in the Non-Profit condition who did not receive a privacy notice perceived the organization more non-profit than the ones who received a privacy notice ($M_{non-profit, control} = 5.50$; $M_{non-profit, privacy\ notice} = 5.10$; $p = .02$). When privacy notice was not available, participants reported a higher willingness to purchase from the non-profit company as opposed to a for-profit company ($M_{for-profit, control} = 4.01$; $M_{non-profit, control} = 4.43$; $p = .01$). For the non-profit companies, participants reported a higher willingness to purchase when they did not view a privacy notice compared to when they received a privacy notice ($M_{non-profit, control} = 4.43$; $M_{non-profit, privacy\ notice} = 4.05$; $p = .02$). When privacy notice was available, participants perceived the for-profit company more consumer centric than the non-profit company ($M_{for-profit, privacy\ notice} = 3.98$; $M_{non-profit, privacy\ notice} = 3.65$; $p = .049$). These results indicated that privacy notices changed the perceived profit orientation of the non-profit companies, decreasing consumers' willingness to purchase.

Study 5 explored a boundary condition. We predict that giving an option to decline the cookies could mitigate the negative consequences of privacy notices as it will be considered as a signal sent by the companies that they are willing to waive the benefits they receive. As in Study 1, we collaborated with a European university. Implementing privacy notices on January 15, 2021, the website provided two options to the users, allowing, or changing preferences. On February 24, 2022, privacy notice was changed, and users were provided with an option to decline. We compared the website metrics. Controlling for the month, giving an option to decline increased the number of pageviews ($b = 2380.8$, $SE = 237.23$, $p < .001$).

We demonstrate that consumers calculate the benefits companies will receive when they are observed. The association of tracking with profit is so strong that it can change the perceived profit orientation of non-profits. Giving an option to decline the privacy notice could improve consumers' reactions. Finally, we identify a gap between consumers' and managers' view of customer centricity and show its consumer-related outcomes.

Could you Please Decide for us? Choice of Algorithm versus Human in Joint Consumption Decision-Making

Dr. Aylin Cakanlar, Jönköping University, Sweden
Prof. Gülen Sarial-Abi, Copenhagen Business School, Denmark
Dr. Aulona Ulqinaku, University of Leeds, UK

EXTENDED ABSTRACT

Our work examines consumers' willingness to use algorithms in the joint consumption context. Across three studies in which we recruit dyads and individuals, we show that consumers are more likely to choose algorithms in the joint consumption context compared with the individual decision-making context.

Rapid technological developments in artificial intelligence (AI) are leading to algorithms that can perform tasks once considered unique to humans (Jago and Laurin 2021). As algorithms proliferate in the marketplace, consumers are increasingly exposed to AI in different contexts and devices. Consequently, a considerable amount of research has examined individuals' responses to algorithms in a variety of contexts (e.g., Dietvorst et al. 2015; Srinivasan and Sarial-Abi 2021). On the one hand, the literature shows that consumers can be averse to relying on algorithms to perform tasks typically performed by humans—a phenomenon called algorithm aversion (Dietvorst et al. 2015). On the other hand, an emerging stream of research shows that “algorithm appreciation” in the individual decision-making context (Logg, Minson, and Moore 2019). Specifically, researchers suggest that individuals can choose algorithms over humans, when the “emotionally neutral” nature of an algorithm can benefit them (Jago and Laurin 2022).

While these studies have examined individuals' receptiveness and reactions to algorithms in the individual decision-making context, prior literature overlooks consumers' use of algorithms in the joint consumption context, which has distinctive features compared with the individual decision-making context (Liu et al. 2019). Our research addresses this gap and examines consumers' willingness to use algorithms in the joint consumption context.

Building on the literature that demonstrates the existence of “algorithm appreciation” in certain contexts, we argue that the joint consumption context also leads individuals to prefer algorithms to individuals. We posit that consumers would be more likely to use algorithms when making consumption choices with another person than when making such choices alone (i.e., without incorporating another person in the decision-making process), since individuals tend to perceive algorithms as “emotionally neutral” (Jago and Laurin 2022). Prior literature on joint consumption suggests that individuals become more relationship-oriented and try to balance their own and their partners' consumption preferences in the joint consumption context (Liu et al. 2019). Therefore, they may prefer options perceived as “neutral” to both parties in the joint consumption context. We tested our hypothesis across three studies.

In Study 1, we recruited 100 couples who were willing to participate in the study together with their partners (i.e., the dyad condition) and 100 individuals who were married or in a committed relationship but participated in the study alone (individual decision-makers). Participants in both conditions were informed that they would watch and evaluate a trailer for an upcoming movie. They were asked to choose between two movie trailers: one movie trailer was recommended by a human, and the other was chosen by an algorithm designed to recommend romantic comedy movies. In the dyad condition, participants read that they had to make a joint decision. Individual decision-makers received the same instructions regarding the movie and learned that they needed to choose a movie trailer to watch alone. Results show that participants in the dyad condition were more likely to choose the trailer recommended by AI than those who made the decision alone ($p=.024$).

Study 2 ($n=300$) replicated the results by randomly assigning individuals on Amazon Mechanical Turk to either the dyad or an indi-

vidual decision-maker conditions. Similar to Study 1, participants read that they would choose a movie trailer from two different options: one recommended by a human expert and the other chosen by an algorithm. Participants in the dyad condition connected with another MTurk participant using ChatPlat, an application that allows participants to chat online, and decided together which movie trailer to watch. Participants in the individual decision-maker condition made the decision alone. The results show that participants in the dyad condition were more likely to choose the trailer recommended by AI than those in the individual decision-maker condition ($p=.049$).

Study 3 ($n=556$) replicated our findings by providing preliminary evidence of our mechanism. Given that we argue that consumers are more likely to prefer AI in the joint consumption context because algorithms are perceived as an emotionally neutral agent, our effect should be stronger when consumers decide with a partner who has conflicting views to themselves in the joint consumption context. Consistent with prior literature, we manipulated consumers' perceptions of whether their partner had conflicting views (vs. similar views) to themselves by recruiting Republicans and Democrats to examine this. Prior literature demonstrates that Republicans and Democrats have conflicting views regarding climate change (Campbell and Kay 2014). Participants were randomly assigned to one of the three conditions: dyads with conflicting views, dyads with similar views, and individual decision-makers. In two dyad conditions, participants were told either that they would communicate with a participant who supports a different political party than themselves or that they would communicate with someone who supports the same political party as themselves. Thereafter, participants were asked to choose a news article about climate change solutions to read: a news article written by a human reporter, or a news article written by an AI reporter. Participants in the dyad conditions made the decision with their partner and those in the individual decision-maker condition made the decision alone. Dyads who had similar views to each other were more likely to choose an AI-generated news article (47%) relative to individual decision-makers (31%; $\text{Wald}\chi^2=5.137, p=.02$). The effect (dyad vs. individual decision-maker) was strengthened for dyads with conflicting views (52%; $\text{Wald}\chi^2=8.408, p<.01$).

Our results reveal that consumers' willingness to use algorithms can vary depending on the decision-making context.

I am a Fan of my Team, but I am not a Fan of this Sponsor: Sport, Sponsorship, and Split Identification

Prof. John A. Clithero, University of Oregon, USA
Prof. T. Bettina Cornwell, University of Oregon, USA
Prof. Eric Setten, California State University, Fullerton, USA

EXTENDED ABSTRACT

Identification, the oneness an individual holds with brands and organizations, has been a construct of interest for decades. We examine split identification, where an individual separates worthy from unworthy elements of a target of identification. Across six studies in sport, we consider how corporate sponsors influence team identification and outcomes.

Understanding how individuals identify with brands has become central to constructs such as customer-company identification (Bhattacharya and Sen 2003). Management has introduced the construct of split identification, “a way of relating to an entity that involves cognitively separating elements of a target of identification that are worthy of continued identification, from other elements that demand ‘disidentification’ (defining oneself in opposition to a target)” (Gutierrez, Howard-Grenville, and Scully 2010). Parallel to the interest in organizational identification, researchers in marketing have investigated the role of identity congruence and the ways in which identity motives influence consumer choice (Reed, Forehand, Puntoni, and Warlop 2012).

In terms of theory, we introduce split identification as an identification form and demonstrate empirically its implications for consumer behavior, brand strategy, and strategic relationship development. We develop new scales to measure identification change and show how consumer behavior outcomes important to both the sport property and the brand sponsor are influenced by split identification. Across six studies, we consider how a sport consumer’s identification with a team is changed based on a sponsor partnership decision, one that may be received as favorable or unfavorable. After the first broad study, the remaining studies capitalize on realism by focusing on ongoing National Basketball Association (NBA) jersey patch partnerships.

Study 1A (N=590) was exploratory. US participants interested in sports chose their favorite team (NBA or MLS). After team selection, participants were asked about their team identification, their favorite team’s current jersey patch sponsor, and randomly assigned to a sponsor change condition (favorable vs. unfavorable) involving a betting firm (FanDuel vs. bet365). Questions about the partnership covered familiarity with the sponsoring partner, as well as the favorability of the partner and the partnership. We developed a single-item identification change question to observe increased, decreased, no change in, or split identification. Participants were asked about behavioral intentions: buying a team jersey that includes the partner logo, downloading the app for the partner, and following the team on social media. In identification change, responses differed across the two conditions with participants more likely to report “split” in the bet365 (unfavorable) than the FanDuel (favorable) condition. Across conditions, there were significant differences in willingness to buy a jersey and follow the team because of the partnership. Linear regressions for both buying the jersey with the sponsor logo and likelihood of following the team show differences in the coefficients for those reporting a “decreased” identification from a “split” identification. Individuals experiencing split identification were more likely than those experiencing decreased identification to continue to support the team.

Study 1B (N=228) considered sponsorship for the Portland Trail Blazers. Participants were randomly assigned to a condition with either similar (Patagonia) or dissimilar (ExxonMobil) brand values. A scale on congruence between the sponsor and the team was also collected. As in study 1A, participants reported different answers to the single-item change in identification question. Perceived congruence was significantly different across conditions and there was a negative relationship between perceived congruence and reporting of split identification. There were significant differences in willingness to buy a team jersey with sponsor logo related to identification change.

Study 1C (N=236) utilized an announced patch sponsor for the Milwaukee Bucks, Motorola, which already sponsored two other NBA teams, throwing their loyalty to any one team into question. Participants responded to the same previously used measures, but were presented with the true team jersey sponsor (Motorola’s three team sponsorships) instead of a manipulation between two hypothetical sponsors. We created a new summary variable from the three sponsor preference questions. We constructed regressions as in studies 1A and 1B. Split identification was again associated with changes in behavioral intentions: a disinclination to buy a jersey with the sponsor logo on it and a negative view toward the sponsor’s products.

Study 2 (N=443) considers the Los Angeles Lakers, with Patagonia and ExxonMobil utilized as hypothetical sponsors, using a study design parallel to study 1B. This study develops (and validates) measures for four distinct forms of identification change: increasing, decreasing, neutral, and split. We examine the extent to which both congruence and split identification serve as underlying mediators for the effect of favorability on purchase behavior, as well as moderation of this effect by team identification (moderated serial mediation). There are two moderated indirect paths: one through both congruence and split identification and one through only split identification. The indices of moderated mediation were both negative and significant.

Study 3 (N=265) was designed for the Minnesota Timberwolves with locally headquartered 3M as our favorable brand and Massachusetts-based Raytheon as our unfavorable brand. It serves as a replication of study 2. All other design choices follow study 2. The results, including moderated serial mediation, closely replicate study 2.

Study 4 (N=369) investigates possible mitigation of the negative consequences of an unfavorable sponsor by reassigning the value of the patch sponsorship to a non-profit using a corporate social responsibility (CSR) strategy. Tyson Foods and World Central Kitchen (WCK) were selected as hypothetical partners for the study. In this situation, WCK is presented by Tyson Foods. We tested and replicated our full mechanism as in studies 2 and 3. These findings suggest that a CSR strategy reassigning value to a charity can mitigate split identification and consumer behaviors associated with it.

Sailing close to the edge: figuring resistant ideational edgework through consumption in cruise ship hospitality workers

Dr. Adam Dennett, University of Huddersfield, UK
Prof. Shona Bettany, University of Huddersfield, UK
Dr. Andrew Jenkins, University of Huddersfield, UK

EXTENDED ABSTRACT

In consumer marginalisation, little research considers those so contained by their working life that any consumption-related activities are highly pathologized. This paper examines the enclave lives of luxury cruise liner hospitality employees, exploring their attempts via resistant ideational edgework to enact consumption within the omnitopia of the luxury cruise liner.

Complimentary Competition: The Impact of Positive Competitor Reviews on Review Credibility and Consumer Purchasing Intentions

Dr. Dikla Perez, Bar-Ilan University, Israel

Dr. Inbal Stockheim, The College of Law and Business, Israel

Mr. Guy Baratz, Tel Aviv University, Israel

EXTENDED ABSTRACT

In three studies, we show that consumers perceive positive reviews written by competitors as more credible than similar consumer-generated reviews. Which in turn, elicits greater purchase intentions. These relationships are attributable to consumers' perception that competitors are less likely than consumers to have received compensation for their reviews.

Online reviews have a significant impact on purchasing decisions across a broad range of fields (Chen & Xie, 2008). This, in turn, leads to an extremely large amount of diverse reviews available to consumers (Gottschalk & Mafael, 2017), generating a fertile ground for unethical behavior. Consequently, the consumer faces a large number of online reviews written by genuine or paid reviewers with significant variance in their quality and relevance (Kowatsch et al., 2009). This makes it challenging for consumers to gain an accurate appraisal of the product and judge the credibility of the online content (Robson et al., 2013). Therefore, marketers strive to enhance the perceived credibility of reviews (Jabr, 2021).

This research offers a less intuitive option to enhance credibility perceptions, by relying on identified expert reviewers that are less likely to be suspected of being incentivized by the marketer, namely, competitor reviews. We argue and demonstrate that a competitor might be perceived as an expert in terms of knowledge, expertise, and experience while being less likely to be suspected of getting paid or compensated by the business for writing the review and showing a positive impact on purchase intentions.

In a pre-test, 239 participants were randomly assigned into one of three reviewer-type conditions (consumer vs. expert vs. competitor) in a between-subjects design, read a review about a product and were asked to evaluate the reviewer expertise (Ohanian 1990). Results showed a significant effect of reviewer type on perceived expertise ($F_{(2,236)} = 18.932, p < .001, \eta^2 = .138$). Reviewer's expertise in the competitor condition ($M = 6.03, SD = 1.08$) was significantly higher than in the consumer review condition ($M = 5.10, SD = 1.09; p < .001$) and similar to the expert's review ($M = 5.91, SD = .95; p = .507$).

In Study 1, 157 participants were randomly assigned to one of two reviewer conditions (Consumer vs. Competitor) and read a review about a restaurant. Next, they indicated their purchase intentions, their perception of the reviewer, and demographics.

Results showed that the purchase intention of participants exposed to the competitor review ($M = 5.97, SD = 0.847$) was significantly higher than the purchase intention of participants exposed to the consumer review ($M = 5.67, SD = 1.04; t_{(155)} = 2.036, p = .04$) and also perceived as more credible ($M = 5.80, SD = 0.83$) compared to the consumer review ($M = 5.50, SD = 0.89; t_{(155)} = 2.152, p = .03$). Mediation analysis (Process, Model 4; Hayes, 2017) showed a significant indirect effect of reviewer type on purchase intentions through reviewer credibility ($b = .12, SE = .05, 95\% CI: .0336$ to $.6666$).

In Study 2 we replicated the effect while using a book as the reviewed product.

In Study 3, 139 participants were presented with the same scenario employed in Study 1 while using a book as the reviewed product. Participants were asked to indicate their purchase intention as

well as the likelihood that the writer of the review received any type of compensation for their review and reviewer credibility.

A multiple mediation analysis (Process, Model 6; Hayes, 2017) showed a significant indirect effect of reviewer type on purchase intentions through perceived likelihood of compensation and reviewer credibility ($b = .09, SE = .05, 95\% CI = .0115$ to $.2084$). Moreover, the direct effect of reviewer type on purchase intention was not significant ($b = .44, SE = .24, 95\% CI = -.0488$ to $.9349$), indicating full mediation.

Subtractive Risk Judgments in Health and Medical Care Decisions

Dr. Mehdi Mourali, University of Calgary, Canada

Dr. Zhiyong Yang, Miami University, USA

EXTENDED ABSTRACT

Adding a low-risk item to a high-risk item reduces overall risk perception. People impose categorical distinctions on quantitative risk, and when forming overall assessments, tend to average across categories. This effect disappears when one risk is exceedingly high and when risk is presented graphically, emphasizing the additivity of multiple risks.

To make informed medical decisions, consumers must understand the risks and benefits associated with different options. However, little is known about how they combine multiple risk items when forming overall risk impressions. Consider a medication with one side effect occurring in 30% of the people who take it and a second side effect affecting 1% of the people who take it. It is objectively riskier than a medication with only the first side effect. Nevertheless, we show that consumers consistently perceive the medication with two side effects to be less risky than the medication with only one side effect. Building on fuzzy trace theory (Reyna and Brainerd 1991) and categorical averaging, we posit that adding a low-risk side effect reduces overall risk perception because people tend to impose categorical distinctions on quantitative risk information, and when combining categorical information, they average across categories instead of adding (Brough and Chernev 2011).

We further expect such subtractive risk judgments to be less common when the averaging rule is not used to integrate information about multiple risks. This may happen when one side effect is perceived to be too risky. The presence of an exceedingly risky side effect offers a salient cue for judging an option's overall riskiness. As a result, consumers may not bother integrating risk information about the second side effect. Categorical averaging is also less likely when consumers are encouraged to use an additive integration rule instead. We propose that graphical presentations that visually highlight the additive property of multiple risks will evoke an additive integration rule and reduce the distortion in the perception of multiple risks.

Study 1 (N = 295) tested the prediction that consumers would perceive lower overall risk in the combined (high-low) risk condition than in the single high-risk condition. Participants were randomly assigned to one of three conditions. Those in the single condition learned that a new medication comes with a 30% chance of abdominal cramps. Those in the combined high-low condition learned that in addition to the chance of abdominal cramps, there was a 1% chance of blurry vision. Finally, those in the combined high-high condition read that in addition to the chance of abdominal cramps, there was a 35% chance of blurry vision.

Consumers who read about the combination of one high-risk and one low-risk side effect reported lower overall risk than those who read about a single high-risk side effect. In contrast, consumers who read about the combination of two high-risk side effects perceived greater overall risk than those who read about the single high-risk side effect.

Study 2 (N = 1551) tested the notion that categorical averaging is less likely when the risk of the first side effect is too high. It also explored the robustness and boundaries of categorical averaging across a range of probabilities for the second side effect. Participants were randomly assigned to one of 14 conditions in a 2 (first side effect) × 7 (second side effect) between-subjects design. Those in the single side effect conditions read that a new medication can cause headaches for either 45% (high) or 75% (too high) of the people who

take it. Those in the combined conditions learned that in addition to the chance of headaches, there was either a 1%, 6%, 17%, 22%, 30% or 35% chance of experiencing heartburn.

As expected, when the probability of headaches was set to 75%, overall risk perceptions of consumers who saw a single side effect were high and did not differ from those who saw two side effects, regardless of the second side effect's probability of occurrence. In contrast, when the probability of headaches was set at 45%, those who read about the possibility of experiencing both headaches and heartburn reported lower overall risk than those who read about only the possibility of headaches when the probability of heartburn was either 1%, 6%, or 17%. Overall perceived risk was also lower when the probability of heartburn was 22%, though the difference was not statistically significant. However, when the probability of heartburn was either 30% or 35%, those who read about both side effects reported greater overall risk than those who read about only headaches.

Study 3 (N = 664) tested the effectiveness of presenting risk information in a graphical format. Participants were randomly assigned to one of five conditions (single/numeric vs. single/graph vs. combined/numeric vs. combined/additive-graph vs. combined/non-additive-graph). Those in the numeric conditions responded to the scenario from study 1 with modified risk values (35% for abdominal cramps, and 3% for blurry vision). Those in the graph conditions responded to the same scenario augmented by bar graphs. Stacked bars were used in the additive-graph format, and side-by-side bars were used in the non-additive-graph format.

Consistent with the previous studies, when the risk information was presented numerically, consumers who were exposed to the combination of one high-risk and one low-risk side effect reported lower overall risk than those who were exposed to only the high-risk side. Moreover, visualizing the combined risks using side-by-side bars did not decrease categorical averaging. In contrast, presenting the combined risks using stacked bars resulted in less categorical averaging. Not only did participants in the combined/additive-graph condition not perceive lower overall risk than those in the single/numeric condition, they also reported higher overall risk than those in the combined/numeric condition, and those in the combined/non-additive-graph condition.

Our research identifies categorical averaging of numerical risk as a key mechanism through which consumers assess multiple risks. This research offers practical implications on how to improve consumers' understanding of the risks involved in their health and medical care decisions. Policymakers could require marketers to present multiple risks in an additive format to help consumers make informed decisions.

Show Me Some Effort! The Effect of Likes versus Comments and Their Presentation Format on User-Generated Content

Ms. Yue Wang, Hongkong University of Science and Technology, Hong Kong
Dr. Ying Zhao, Hongkong University of Science and Technology, Hong Kong
Dr. Min Zhao, Boston College, USA

EXTENDED ABSTRACT

Field data from NetEase Cloud Music (NCM) demonstrate that comments are more effective at eliciting subsequent content generation compared with likes on social media. Two experiments further showed that presenting likes in an unpacked (versus packed) format overcomes the disadvantage of likes. Perceived effort is identified as the underlying process.

Previous work on user-generated content (UGC) has demonstrated a positive correlation between number of likes or comments and their respective effect in eliciting subsequent content generation (Burke et al. 2009; Chen et al. 2019; McIntyre et al. 2016). Given that most posts receive more likes than comments, yet comments contain more information than likes, which type of feedback is relatively more impactful? Further, is there a way to present the feedback differently to elicit greater effectiveness, and what could be the underlying mechanism?

Extant work on reciprocity (Cialdini 1993) has highlighted the importance of effort behind reciprocity (e.g., consumers reward firms exerting extra effort; Morales 2005). Because a natural difference between likes and comments is that writing a comment takes more effort than pressing the like button, we predict that comments elicit greater subsequent content generation than likes (H1). More importantly, while the number of likes/comments received is beyond direct control of the UGC platforms, managers can design their platforms to present the submitted likes/comments effectively for optimized effect. Research on unpacking has shown that presenting a task as several sub-tasks increases numerical judgment (e.g., probability; Thaler 1985; Tversky and Koehler 1994) or predicted enjoyment (Tsai and Zhao 2011). Accordingly, we believe that presenting aggregated feedback in an unpacked format as individual feedback would increase the perceived magnitude of the same feedback, evoking more positive responses and greater subsequent content generation (H2). Drawing on the important role of effort behind reciprocity (Cialdini 1993; Morales 2005), we also hypothesize that perceived effort behind the feedback is the underlying mechanism (H3).

We test our predictions with one field dataset and two experiments.

The field data were collected on NetEase Cloud Village (NCV), a major music streaming platform in China. It contains a total of 68,698,187 impression records from the Discovery tab for 2,085,533 viewers that are randomly drawn from the entire viewer pool of NCV for the period of November 1 to 30 in 2019, involving 89,557 creators. A Probit model was used to capture each creator's daily content creation decision based on the number of likes, comments, and shares the creator received respectively in the past three days while controlling for observed creator heterogeneity. The results showed that while all types of feedback have significant and positive impacts on creators' subsequent posting, comments have a greater impact compared with likes and shares ($M_{\text{comments}} = 0.043$, $SD = 0.009$ vs. $M_{\text{likes}} = 0.002$, $SD = 0.0006$ and $M_{\text{shares}} = 0.014$, $SD = 0.004$), despite the fact that creators received more likes than comments (H1). Potential endogeneity problem was addressed and ruled out using the instrumental variables approach.

Experiment 1 used a 2 (feedback type: likes versus comments) \times 2 (presentation format: packed versus unpacked) between-subjects design to further test H1-H3. Participants were asked to imagine posting a picture and receiving different feedback. In the packed conditions, they saw the total number of feedback as 32 likes or 14 comments. In the unpacked conditions, the same feedback was unpacked into 32 individual likes or 14 individual comments. The results showed a significant main effect of feedback type on attitude ($F(1, 270) = 88.81$, $p < .001$), and this positive effect of comments over likes held under both packed and unpacked format (H1). More importantly, we observed a main effect of presentation format ($F(1, 270) = 61.20$, $p < .001$), and the advantage of unpacked over packed presentation also held for both likes and comments (H2). A direct comparison between unpacked likes and packed comments ($M_{\text{likes/unpacked}} = 3.92$, $SD = 1.18$ vs. $M_{\text{comments/packed}} = 4.13$, $SD = 1.14$; ns) showed that once likes are presented in an unpacked format, it is as effective as comments that are packed. Same results were observed for future posting intention and perceived effort, and mediation analyses confirmed the mediating role of perceived effort in the effects above.

Experiment 2 test H2 and H3 with actual content generation in 6 conditions (packed vs. unpacked likes, packed vs. unpacked comments with no content, unpacked comments with high-effort vs. low-effort content). Participants were asked to submit a real piece of advice for their fellow students to enrich after-school life, and were then shown different fictitious responses from 20 students. The responses were either 12 packed or unpacked likes, 9 packed or unpacked comments into IDs only without content, or 9 unpacked comments with content involving higher effort (e.g., "I am a first-year student. This is such a great tip.") or lower effort (e.g., "Great"). Participants reported their overall attitude and were then asked to submit more new advice to their fellow students. Number of sentences participants wrote for new advice is used to capture subsequent content generation, and number of sentences in initial advice was controlled for in all ANCOVAs.

In the two like-conditions, we replicated the effect of unpacked over packed presentation (H2). In the four comment-conditions, which was our key focus, we observed a significant main effect of presentation format on overall attitude ($F(3, 259) = 12.03$, $p < .001$) and subsequent content generation (H2; $F(3, 259) = 2.90$, $p < .05$). Specifically, compared with packed comment, unpacking comment into either high- or low-effort content increased positive attitude (both $ps < .005$). Further, unpacking comments into high-effort (but not low-effort) content increased actual content generation compared with packed comment ($p < .05$). Lastly, compared with unpacking the comments into IDs with no content, providing any content led to greater subsequent content generation ($p < .01$ for higher-effort comments, and $p = .084$ for lower-effort comments). These results provide further support to the critical role of effort (H3).

Our findings contribute to literature on UGC (e.g., Burtch et al. 2018; Huang et al. 2019), reciprocity (Cialdini 1993) along with the important role of effort behind it (Morales 2005), and unpacking (Thaler 1985; Tversky and Koehler 1994). They offer relevant managerial implications to motivate user-generated content by unpacking likes and facilitating submission of comments, while providing precaution against feedback involving low effort (e.g., AI-automated feedback).

What do I think about this sustainable Gucci?

Product- or company-focused sustainability association, impact on environment, and attractiveness of luxury products

Dr. Dikla Perez, Bar-Ilan University, Israel
Prof. Amir Grinstein, Northeastern University, USA
Mrs. Inbar Elia, Bar-Ilan University, Israel
Prof. Neeru Paharia, Georgetown University, USA

EXTENDED ABSTRACT

Four experiments show that, when faced with a marketing communication regarding a sustainable luxury product, consumers respond more favorably in the presence of a company-focused (as opposed to product-focused) sustainability association. The perceived (positive) environmental impact of consumers, serves as the underlying mechanism for this effect.

In recent years, the seemingly disparate domains of sustainability and luxury have increasingly begun to overlap, with luxury brands integrating sustainability principles and features into their manufacturing processes and products. Still, there is considerable uncertainty about how consumers may respond to these efforts. Very few studies have examined sustainability and luxury consumption together, and the few that have done so have produced mixed results regarding consumer evaluations of sustainable luxury products (Achabou & Dekhili, 2013; Perez, Stockheim, Tevet, & Rubin, 2020). These findings point to a need to better understand the factors that shape consumers' evaluations of sustainable luxury products, towards identifying conditions under which consumers might find such products attractive.

We suggest that consumer evaluations of sustainable luxury products may be influenced by the so-called *sustainability association* embedded in the brand's marketing content—defined as an indicator of whether the content refers to sustainable features associated with the product itself (a “product-focused sustainability association”) or to sustainable features associated with the company behind the product (a “company-focused sustainability association”).

We predict and show in four experiments that a company-focused sustainability association (as opposed to a product-focused sustainability association) is likely to trigger a stronger perception of *environmental impact*, as reflected in the consumer's perception that his or her purchase decisions contribute meaningfully to the environment. This perception is likely to enhance the consumer's evaluations of the luxury product attached to the sustainability association.

In study 1, 113 participants were randomly assigned to one of two sustainability association conditions (company vs. product) in a between-subjects design and were with a picture of an omega watch. In the company condition, the product description was “*Omega Corp. is a leading Swiss design house of luxury watches that follows strict sustainability standards, including the use of recycled material in its production processes.*” “While in the product condition, the product description was “*the watch was manufactured by Omega Corp, a leading Swiss design house of luxury watches*”, and that “*the watch was manufactured under strict sustainability standards, including the use of recycled material in its production process.*” (This between-subject two-condition design and manipulation were used throughout the following studies, with the description adapting the company and product names.)

Next, participants were asked whether they would like to receive additional information on the Omega watch (“yes please” or “no thanks”), and to provide demographic details.

In line with our hypotheses, a crosstabs analysis revealed that more participants were interested in receiving additional information in the company condition (20%) than the product condition (7.5%), ($X^2_{(111,1)}=3.590, p=0.058$).

Following the same design as in study 1, in study 2, 130 participants presented a luxury Couch bag. Participants then indicated the likelihood that they will recommend this product to a friend (0-10 scale). A t-test revealed that participants indicated significantly higher willingness to generate WOM in the company condition ($M = 3.92, SD = 3.02$) than the product condition ($M = 2.84, SD = 3.09, t_{(128)} = 2.02, p = .045$).

Following the same design as in study 1, in study 3, 126 participants were presented with a luxury facial cream. Then, participants indicated on a 7-point scale their overall evaluation of the product and the extent to which they found it attractive, ($r_p = .792$), and their perception of environmental impact.

A t-test revealed that participants evaluated the product significantly higher in the company condition ($M = 4.25, SD = 1.69$) than in the product condition ($M = 3.63, SD = 1.65, t_{(124)} = 2.09, p = .039$), and a mediation analysis (PROCSS, Model 4; Hayes 2013) confirmed the significant mediating role of perceived environmental impact ($b = .511, SE = .19; 95\% CI: .1538 \text{ to } .9167$).

Following the same design as in study 1 and with an additional control condition, in study 3, 229 participants were presented with an Omega watch. Participants in the control condition were informed that *this watch was manufactured by Omega Corp, a leading Swiss design house of luxury watches*. Then, participants indicated, on a 7-point scale, their overall evaluations of the product, the extent to which they find the product attractive ($r_p = .769$), and were asked to estimate how much the watch should cost.

A one-way ANOVA showed a significant effect of experimental condition on participants' ratings of luxury product attractiveness ($F(2,227) = 9.165, p < .001$). An LSD post-hoc analysis confirmed that participants in the company-association condition rated the product as significantly more attractive ($M = 5.66, SD = 1.08$) than did participants in either the product-association condition ($M = 5.14, SD = 1.25, p = .009$) or the control condition ($M = 4.83, SD = 1.30, p < .001$). The latter two conditions did not differ significantly in terms of participants' ratings of product attractiveness.

Another one-way ANOVA showed a significant effect of experimental condition on participants' perceptions of the appropriate price for the product ($F(2,227) = 5.578, p = .004$). An LSD post-hoc analysis confirmed that participants in the company-association condition perceived the price of the luxury product as significantly higher ($M = 982.35, SD = 1058.2$) than did participants in the product-association condition ($M = 550.21, SD = 551.64, p = .001$, in line with H1) or in the control condition ($M = 673.36, SD = 774.60, p = .021$). Price perceptions did not differ significantly between the latter two conditions ($p = .358$).

Posting vs. Refraining: Differences in consumers' beliefs about their and others' achievement sharing behavior on social media

Ms. Honghan Qi, University of Leeds, UK
Dr. Shankha Basu, University of Leeds, UK

EXTENDED ABSTRACT

Consumers often share positive self-related information on social media, yet they criticize the wide prevalence of such posts. Six studies show that consumers believe others will engage in social media boasting more frequently than they do. A belief that others are less moral than them underlies this biased consumer judgment.

Consumers often share their accomplishments on social media. They post about getting a promotion, completing an online course, finishing a marathon, or donating to charity. Companies also nudge consumers to make such posts. For instance, Snapchat uses 'streaks,' a form of gamification, to encourage consumers to post multiple days in a row (Hristova et al. 2020). Consumers believe self-promotion can help them gain status or respect (Sezer 2022). Therefore, most consumers selectively share positive information more frequently (Gonzales and Hancock 2011).

Consumers who brag underestimate how annoyed (Scopelliti, Loewenstein, and Vosgerau 2015) or irritated (Radovic et al. 2017) observers feel. Further, research in moral psychology suggests that humility is considered more moral than bragging (Wright et al. 2017). In many cultures bragging is disapproved or condemned (Watling and Banerjee 2007), while modesty is highly valued (Srna, Barasch, and Small 2022). Thus, consumers might believe that sharing achievements on social media frequently would violate this prized moral norm.

Consumers also tend to hold flattering beliefs about themselves (Dunning 2007). Consumers believe they have better qualities in various domains (e.g., intelligence or creativity) than others (Alicke 1985). More importantly, they believe they are more ethical than others (Epley and Dunning 2000). As frequent achievement sharing might be viewed as immoral behavior, we argue that consumers would believe that others prefer to share their achievements more often on social media than they do because they think that others are less moral than they are. We tested these predictions across five studies.

Studies 1a-1b tested our basic proposition using different designs.

In Study 1a (N= 202, Mturkers USA), we asked participants whether they would like to make three separate posts (vs. one post) about three awards that they would be receiving. 27% participants indicated that they would do so while they predicted that $M=45.26\%$ (SD=22.51) of others would do so (one-sample t-test: $t(99)=8.11, p < .001$).

In Study 1b (N= 300, Mturkers USA), in a scenario involving a language app, we asked participants how 'they,' or 'Sam,' or '100 other students' would share their language learning achievements on social media. 40.4% participants indicated that they would post their achievements at the end of each week (vs. at the end of the course). However, 62.38% participants predicted that Sam would do so ($\beta=-.92$, Wald $\chi^2=9.99, p=.002$). For '100 students' condition, participants predicted $M=51.7\%$ (SD=22.39) students would do so (One sample t-test against 40.4%: $t(99)=5.06, p < .001$).

Study 2 used the causal-chain method (Spencer, Zanna, and Fong 2005) to test if the perceived morality underlies the effect observed in Study 1.

In study 2a (N=200, Mturker USA), we found that participants perceived another Mturker (Mturker #156) as less moral ($M=5.72$, SD=1.11) than they were ($M=7.45$, SD=1.05, $t(198)=11.36, p < .001$).

In Study 2b (N=301, Mturker USA), using the same language app scenario, we asked participants how likely they or 'Sam' were to post their achievements. Crucially, we described Sam as either a highly moral person (vs. not). Participants indicated they were less likely to

post at the end of every week ($M=2.86$, SD=2.09) but predicted that Sam was more likely to do so in the 'Sam' conditions ($M_{\text{Sam}}=4.52$, SD=1.72, $t(191)=-6.16, p < .001$). Moreover, participants predicted that Sam would be less likely to post at the end of every week when we described Sam as moral than when we did not ($M_{\text{HighMoralSam}}=3.84$, SD=1.97; $t(195)=2.62, p=.01$).

In Study 3 (Prolific UK), we tested a managerial consequence of our findings. We recruited 99 full-time US employees with managerial experience and asked them to imagine they were the product manager of a camera app and running a social media campaign. App users can donate meals (\$0.8 for each) to people needing food assistance. Managers can program the app to automatically post users' donations on their social media profiles. We asked managers how likely they thought users prefer that (a) the app posts about each donation instead of (b) a single post at the end of the campaign. We also recruited another 100 participants and asked them to imagine they were the app users. We showed them the same donation campaign and asked them how likely they were to prefer option (a) instead of option (b). An independent samples t-test revealed that managers over-predicted consumers' preference for posting about each donation instead of only once at the end of the campaign ($M_{\text{manager}}=4.51$, SD=1.88, $M_{\text{consumer}}=2.94$, SD=2.03, $t(197)=-5.63, p < .001$).

Across five studies, we consistently found that consumers believe that others prefer sharing their achievements on social media more frequently than they do. We further showed that the perceived morality of others underlies this effect. Our research broadens the literature on self-other differences in bragging beliefs. Moreover, our research found that apart from the impression management goals (Back et al. 2010), consumers' moral belief also explains the incorrect belief about others' bragging behavior. Empirically, our research found that marketers often risk overestimating the frequency with which consumers would like to engage with the campaign on social media. Such overprediction may cause managers to frequently nudge consumers to post on social media leading to consumer irritation. Future research can test this finding with a field study involving actual behavior.

Watch Out! How Strikethrough Price Crosses Out Purchase Intention

Mr. Jintao Zhang, Drexel University, USA
Dr. Yuna Choe, University of North Texas, USA
Dr. Allan Chen, University of Kentucky, USA

EXTENDED ABSTRACT

In this research, we examine the novel factor of discount price presentation format, strikethrough, on consumers' deal evaluation. We find that a strikethrough on the original price increases consumers' difficulty to calculate discount, resulting in lower deal evaluations and intentions to purchase the discounted product.

Retailers have frequently used price discounting to stimulate sales and attract customers, and there are different types of presenting price promotions, such as presenting the absolute discount or relative discount to the original price in the form of dollar-off or percentage-off promotions. The current research proposes a novel factor of discount presentation, strikethrough, to explore its impact on consumers' deal evaluation and consequential purchase intentions.

Holding other factors constant, we predict that strikethrough price presentation leads to a less favorable deal evaluation than regular price presentation. Reference price literature suggests that whenever evaluating the sale price of the products, consumers would seek either external reference (Adaval and Monroe 2002; Kopalle and Lindsey-Mullikin 2003; Lichtenstein, Burton, and Karson 1991) or internal reference (Janiszewski and Lichtenstein 1999; Rao and Sieben 1992). When reference price and sale price are both available, consumers would automatically calculate the discount they will get from the purchase (Biswas et al. 2013). Extending this line of work, we propose that putting a strikethrough on the original price creates greater difficulty in calculating discount as consumers find it uneasy to read the original price. As calculating the discount becomes more difficult, consumers will be less favorable toward the discounted products.

Moreover, some retailers prefer to put the original price below the sale price, and past literature suggests that consumers' perceptions of prices would be influenced by price locations, such that consumers would feel more difficulty calculating the discount when the sale price is presented above the original price than when the sale price is presented below the sale price (Feng et al. 2017). Therefore, we propose that presenting the sale price above the original price should further increase the difficulty of discount calculation and decrease consumers' deal evaluations.

For our initial exploration, we conducted study 1; participants ($N = 409$, 43.8% female, $M_{\text{age}} = 39.02$) were randomly assigned in one of 2 (price presentation: strikethrough vs. normal) conditions. To manipulate price presentation, participants in the strikethrough (vs. normal) price condition saw a promotion flyer of an electronic toothbrush, and on the flyer, the original price (\$80) was crossed out (vs. not crossed out), and the sale price (\$29.99) was presented underneath. After reviewing the flyer, participants reported their purchase intentions using three items ($\alpha = .95$, (Grewal et al. 1998)). As expected, participants who were presented with the strikethrough price format indicated lower purchase intentions ($M_{\text{strikethrough}} = 5.18$, $SD = 1.66$) than those with the regular price format ($M_{\text{regular}} = 5.52$, $SD = 1.49$; $F(1,408) = 4.69$, $p = .031$).

Based on the main effect of strikethrough price on purchase intentions, study 2 was designed to explore the process that explains the effect. Participants ($N = 301$, 45.0% female, $M_{\text{age}} = 37.91$) were randomly assigned in one of 2 (price presentation: strikethrough vs. regular) conditions. Similar to study 1, participants in the strikethrough (vs. regular) pricing condition viewed a promotion flyer of

electronic toothbrush bundle, and on the flyer, the original price (\$80.00) was crossed-out (vs. not crossed-out), and the sale price (\$59.99) was listed underneath. Participants again reported their purchase intentions using the same three items in study 1 ($\alpha = .94$) and on the following page, participants indicated their perceived difficulty of calculating discount using two items (looking at the promotion above, how difficult is it for you to calculate the difference between the original price and sale price; looking at the promotion above, how difficult is it for you to calculate how much discount you will get, 1 = "Not at all difficult", 7 = "Extremely difficult", $r = .91$).

A one-way ANOVA revealed a significant effect of strikethrough price format on purchase intentions ($F(1,300) = 4.27$, $p = .04$) and perceived difficulty of calculating discount ($F(1,300) = 92.38$, $p < .000$). Participants reported lower purchase intentions ($M_{\text{strikethrough}} = 4.44$, $SD = 1.80$ vs. $M_{\text{regular}} = 4.85$, $SD = 1.63$) and higher perceived difficulty of calculating discount ($M_{\text{strikethrough}} = 3.40$, $SD = 2.00$ vs. $M_{\text{regular}} = 1.65$, $SD = .97$) when seeing strikethrough price format. The mediation analysis (Hayes 2017; PROCESS model 4 with 5,000 bootstrapped samples) showed that perceived difficulty of calculation mediated the effect of strikethrough price format on purchase intentions ($b = -.14$, $SE = .06$, 95% CI $[-.26, -.03]$). This result shows that putting strikethrough on the original price leads to less favorable deal evaluation due to higher difficulty of calculating discount.

In Study 3, we tested the moderating role of original price location on consumers' deal evaluation. Participants ($N=301$, 48.5% female, $M_{\text{age}} = 38.81$) were randomly assigned to one of four (2: strikethrough vs. normal pricing × 2: original price above, sale price below as control vs. sale price above, original price below) conditions. Participants then reported deal evaluations using three items ($\alpha = .94$). A two-way ANOVA on deal evaluations of the toothbrush revealed a marginal interaction ($F(1,297) = 3.34$, $p = .07$). Specifically, under original price above conditions, participants indicated lower deal evaluations when presented with strikethrough price format ($M_{\text{up*strikethrough}} = 4.53$, $SD = 1.59$ vs. $M_{\text{up*regular}} = 5.14$, $SD = 1.30$; $p = .013$). On the other hand, under original price below conditions, deal evaluations were not statistically different ($M_{\text{down*strikethrough}} = 4.82$, $SD = 1.59$ vs. $M_{\text{down*regular}} = 4.80$, $SD = 1.45$; $p = .94$).

In sum, this research explores one of the prevalent discount price presentation tactics, strikethrough price, on deal evaluation and purchase intentions. While many retailers may overestimate the effect of strikethrough price, our findings show that, counterintuitively, it may backfire as putting strikethrough on the original price hinders consumers from accurately calculating the discount between original price and sale price. Findings in this research contribute to the pricing literature by examining the novel factor, strikethrough price presentation, that influences consumers' deal evaluation, extending the existing research that explores divergent effects of price promotions. Our findings also provide actionable guidelines to marketers and retailers for their pricing strategy, suggesting which discount price presentation to use for effective promotions.

Thinking of Food: The Mental Representation of Healthy Foods as Unprepared Undermines Healthy Choices

Dr. Bradley Turnwald, University of Chicago Booth School of Business, USA
Prof. Ayelet Fishbach, University of Chicago Booth School of Business, USA

EXTENDED ABSTRACT

Six preregistered studies find that consumers mentally represent healthy foods in their purest, least prepared forms but unhealthy foods in their most prepared forms (cooked, mixed, adding toppings). The effect results from the belief that health and taste are conflicting goals and impacts food choice because preparation increases perceived tastiness.

What comes to mind when consumers think of healthy foods? Perhaps colorful produce at the farmer's market or in the grocery aisle. Compare that with what comes to mind for unhealthy foods – perhaps takeout, fried foods, and party appetizers. There is nothing inaccurate about these exemplars. Colorful produce is certainly healthier than fried foods. Yet there is another key variable besides healthiness that differs in these canonical images: preparation. In the first example, healthy foods are in their purest, unprepared forms. Some of these foods are edible in their raw, whole form (e.g., apples, carrots) but many, such as beans or Brussels sprouts, are not palatable to eat in their raw form. In the second example, representations of unhealthy foods tend to be in their final, fully prepared and ready-to-eat form.

In 6 preregistered studies, this research documents systematic differences in how consumers mentally represent healthy and unhealthy foods. Consumers implicitly and explicitly think of healthy food in their less appealing, healthiest form and think of unhealthy foods in their most appealing, tastiest form. This bias results from the lay perception (supported by modern culture) that health and taste are conflicting goals (Dhar and Simonson 1999; Fishbach and Zhang 2008; Mai and Hofmann 2015; Raghunathan, Naylor and Hoyer 2006). In turn, altering these representations of foods, specifically, reminding consumers that healthy foods are prepared too, promotes healthy food choices.

Our main prediction was that participants mentally represent healthy foods (e.g., vegetables, plant-based dishes, lean meats) as less prepared than unhealthy foods. We found support for this prediction in Studies 1A and 1B using explicit measures and photos, and Study 2 using implicit measures and words. Study 1A (N = 217) demonstrated that participants think of healthier versions of foods as less prepared (i.e., chose a photo of food in less prepared vs. more prepared form) when compared with photo choices of unhealthy versions of similarly matched foods (e.g., whole-wheat pasta vs. pasta, cauliflower crust pizza vs. pizza; odds ratio across 9 stimuli = 0.41, 95% CI:[0.33-0.52], $p < .001$). Study 1B (N = 109) generalized these findings to 12 canonical healthy foods (e.g., vegetables) and 12 canonical unhealthy foods (e.g., desserts, processed meats). Participants' odds of choosing the more prepared version of foods was significantly lower for healthy foods than for unhealthy foods ($M_{healthy} = 29.5\%$ of participants choosing more prepared version vs. $M_{unhealthy} = 75.3\%$; OR = 0.08, 95% CI: [0.04, 0.16], $p < .001$). Study 2 found implicit evidence that participants (N = 89) mentally represent healthy and unhealthy foods with different levels of preparation, using words in an Implicit Association Test (Carpenter et al. 2019; Greenwald, Nosek, and Banaji 2003; D-score = 0.40, 95% CI: [0.27, 0.52], $p < .001$). Participants were faster to associate the names of healthy foods with raw words and the names of unhealthy foods with prepared words than vice versa.

Study 3 demonstrated the process for differing mental representations by showing that perceived goal conflict between healthiness and tastiness moderated the effect of food healthiness on preparation level (interaction: $b = 0.29$, $p = .015$). Participants (N = 115) who perceived less taste-health conflict showed a smaller bias in thinking of healthy foods as less prepared than unhealthy foods compared with participants who perceive greater taste-health conflict. What are the consequences of thinking of healthy foods as less prepared? Study 4 showed that foods in more prepared states, controlling for all ingredients, are perceived as tastier. Participants (N = 94) rated photos of both healthy and unhealthy Blue Apron recipes as tastier in the fully prepared form than the fully separated and raw form ($b = 0.91$, 95% CI: [0.80, 1.02], $p < .001$), using 6 different real recipe photos from Blue Apron meal service delivery kits.

This offers a solution for motivating healthy choices in environments in which healthy and unhealthy choices compete: remind people that healthy foods are prepared, mixed, and topped in ways that make them flavorful. In Study 5, we tested whether consumers are more likely to choose healthier foods when additional language is added describing the ways in which they are prepared. We found support for this hypothesis using restaurant menu descriptions from a popular U.S. chain restaurant. Participants (N = 383) who viewed healthy items with a prepared description were more likely to order them ($b = 0.61$, 95% CI:[0.39, 0.83], $p < .001$) than participants who viewed the same healthy items with no description. There was no boost when adding descriptions for unhealthy menu items because participants already thought of them as more prepared, even absent a description.

Together, these findings add to the rich consumer behavior literature on how lay theories between food healthiness and being less tasty (Raghunathan et al. 2006), less filling (Finkelstein and Fishbach 2010; Suher et al. 2016), more expensive (Haws et al. 2017), colder (Yamim, Mai, and Werle 2020) or more aesthetically pleasing (Hagen 2021) impact decisionmaking. This work also builds on the goal conflict literature, specifically the competing goals of health and taste (Dhar and Simonson 1999; Fishbach and Zhang 2008). Our findings show that the very act of preparing healthy foods in ways that make them tastier also makes them less healthy. These findings also have implications for marketing and public policy. Photos of foods in varying degrees of preparation are ubiquitous in consumers' everyday lives, spanning physical spaces, online platforms, advertisements, and media. Our findings suggest that firms can cater to consumers' with health or taste goals by showing foods as more or less prepared, regardless of how prepared the foods actually are. To help make healthy foods more appealing for those who perceive greater taste-health conflict, firms could depict photos of healthy foods as more prepared and describe the ways in which healthy foods are prepared in decision contexts.

When does scarcity decrease (vs. increase) demand?

Dr. Amy Fehl, Georgia Gwinnett College, USA

Prof. Stacey Finkelstein, Stony Brook University, USA

Prof. Beatriz Pereira, Iowa State University, USA

Dr. Gabriela Jiga-Boy, Swansea University, UK

Dr. Marta Caserotti, University of Padova, Italy

EXTENDED ABSTRACT

Does product scarcity always increase demand? Extant literature suggests yes; however, boundary conditions and new variables could qualify the relationship, prompting a decrease in demand under scarcity. Developing a more nuanced understanding of the impact of scarcity on demand has important policy and practical implications and warrants deeper inquiry.

Since the start of the COVID-19 pandemic, scarcity has taken center stage in day-to-day life and policy matters. Empty shelves, unattainable services, hoarding behaviors signal that many goods are scarce, and demand exceeds supply. Understanding the antecedents and consequences of (perceived) scarcity seems even more urgent with the increasing prevalence of isolationist economic policies and Russia's invasion of the Ukraine. Although literature extensively documents how scarcity can increase product demand (see Hamilton et al., 2019), we propose that the dynamic between the two is more complex than currently acknowledged.

Relationship between Scarcity and Demand

Consumers may find marketplace limitations of both product and resource scarcity. Resource scarcity occurs when consumers do not have the means to acquire desired goods or services, while product scarcity refers to "real or perceived lack of goods and services available to the consumer" from increased demand, decreased supply, or both (Hamilton et al. 2019). Hence, when a good is scarce, this affects consumers in general, although some consumers can still acquire the good. Here, we aim to describe (i) how access and beneficiaries of a good and (ii) how individual differences can moderate the impact of scarcity on demand.

Access and Beneficiary

Under many conditions, product scarcity increases demand as predicted by commodity theory. Companies often purposefully use perceived scarcity as a marketing tactic. For example, firms may offer limited edition collections or limit distribution to certain retailers (Roy & Sharma 2015). In this case, the driver of the perceived product scarcity is the company's deliberate distribution strategy. In other cases, product scarcity may be primarily driven by a significant increase in demand, supply constraints, or both.

However, when the beneficiary of the product is the public rather than the individual, perceived scarcity may reduce demand or drive consumers towards substitute products, altering the typical scarcity-drives-higher demand dynamic. We might see this type of scarcity effect for COVID-19 testing or for voting locations, where the individual benefit is minimal. For example, when long lines at local polling places are reported in the news, some individuals may be deterred from voting.

Furthermore, the presence of a gatekeeper versus direct access to the scarce product can alter the relationship between scarcity and demand. In some cases, the existence of a gatekeeper will increase demand in the face of scarcity, because the product appears to be more exclusive. Conversely, the existence of a gatekeeper may reduce demand, such as needing a doctor's prescription for medicine.

We thus must consider the interplay between beneficiary and access, described below.

Private beneficiary, direct access. According to commodity theory, scarce resources are more valued. Therefore, scarcity enhances the desirability of products by increasing our motivation to find positive attributes, a higher quality perception from heuristic cues, or physiological reactance. Perceived scarcity arises from fewer sources for manufacturing and distribution, fewer possessors, greater effort to obtain the product, greater delay in obtaining the object, etc.

Private beneficiary, access via gatekeeper. Under these conditions, scarcity can also increase demand. Facing gatekeepers of private benefits, individuals can perceive scarcity as a signal of quality, as illustrated by the use of low acceptance rates as a key criterion for the rankings of institutions of higher education.

Public beneficiary, direct access. The tragedy of the commons depicts a dilemma: when resources are widely accessible but scarce, they can be depleted by overuse. Even when individuals are objectively worse off by depleting the common resource, scarcity results in overuse if access is not regulated. Therefore, scarcity of commonly available resources increases demand.

Public beneficiary, access via gatekeeper. Scarcity's impact on demand can be attenuated by creating informal or institutionalized access rules or by having gatekeepers regulate consumption (Ostrom, 1990). A system perceived as fair can lead individuals to wait their turn for accessing a scarce resource, limiting demand. The presence of gatekeepers may also reduce demand by decreasing an individual's sense of personal responsibility for getting the scarce product.

Individual Factors

Individual differences may furthermore moderate the relationship between perceived scarcity and demand. Being altruistic or prosocial can change the relationship between perceived product scarcity and demand, especially when the product provides benefits beyond the individual. For example, when COVID-19 vaccines were presented as scarce (vs. not), highly compassionate individuals were more likely to forgo them (Pereira et al., 2021). Further, a collectivist orientation may serve as a bulwark against increased self-interested demand in the face of scarcity, protecting the public and vulnerable segments. In an individualist culture, the perception of scarcity can lead to extreme behavior, as Black Friday sales demonstrate.

Individual preference for risk may influence how people respond to perceived scarcity: the less tolerant are quick to buy unnecessary stocks of toilet paper, while the more risk-tolerant (Thompson et al., 2020) may not be alarmed by images of empty toilet paper shelves.

CONCLUSION

This manuscript is not an exhaustive description of the factors influencing the relationship between scarcity and demand but exposes the relationship between scarcity and demand as more complex than usually assumed in the literature. Future research should further investigate this multifaceted phenomenon to understand how public

284 / *When does scarcity decrease (vs. increase) demand?*

policies can support demand in situations of scarcity where strong demand improves societal outcomes.

When The Unexpected Happens: How People Respond to Unbudgeted Time Savings

Ms. Maria Giulia Trupia, UCLA Anderson School of Management, USA

Dr. Isabelle Engeler, IESE Business School, Spain

EXTENDED ABSTRACT

How happy do people feel when gaining time unexpectedly? Five pre-registered studies show that whereas finishing a task later than planned strongly decreases people's happiness, finishing it earlier does not substantially increase happiness. This numbness to windfalls is specific to time and due to people failing to reinvest it.

Planning is ubiquitous in people's life. People schedule their work tasks, errands, or even social events (Lynch et al. 2010). However, planning is not an easy task. People may *over-* or *underestimate* the time it takes to finish a task, resulting in unexpected time savings or losses. While losing time will likely reduce people's happiness, how do people react to unexpected time savings?

The literature on "planning fallacy" (Buehler, Griffin, and Ross 1994) suggests that time windfalls may make people substantially happy because they tend to underestimate completion times and thus are typically late. The body of literature on "loss aversion" (Tversky and Kahneman 1991) would also predict that gains substantially increase people's happiness, yet to a smaller extent than equivalent losses. While these two bodies of literatures may disagree in the extent of happiness created from time windfalls versus time losses, they both suggest that finishing a task earlier than planned should lead to a substantial increase in happiness.

However, we find that this is not always the case. Five pre-registered studies demonstrate that, while finishing a task later than planned substantially reduces people's happiness ($d=-2.26$ to -1.15), finishing it earlier by the same amount hardly increases people's happiness, if at all ($d=-0.04$ to 0.29). In other words, we find an extreme losses-loom-larger effect for time-driven by people's numbness to time windfalls. This numbness to time windfalls is robust across different samples (Studies 1A and 1B), specific to time (equivalent money windfalls *do* increase happiness, Study 2), replicates when controlling for outcome quality (Study 3) and happens because people fail to make use of time windfalls (Study 4). Critically, people mispredict that time windfalls will significantly improve their happiness (Study 5), which may add to them being unprepared to use them.

Studies 1A ($N=321$ Europe) and 1B ($N=305$ US MTurk) followed a three between-subjects design (as planned vs. less vs. more). Participants read, "Imagine that today you plan to do an activity from 2 p.m. to 4 p.m.". Depending on the condition, participants were informed that they finished this activity either at the time planned, one hour earlier, or one hour later. In all studies we measured happiness using a slider scale anchored with a sad (=0) and a happy smile (=100) and self-efficacy via 3 items ("competent", "capable", "useful"; 1=not at all; 7=very much; Mogilner et al. 2012).

In Study 1A, a one-factorial ANOVA on happiness revealed that compared to finishing on time ($M=87.59$), finishing the activity one hour later strongly decreased people's happiness ($M=48.28$, $p<.001$, $d=-2.26$), whereas finishing the activity one hour earlier did not significantly increase people's happiness ($M=87.00$, $p=.756$, $d=-0.04$). As predicted, the decrease in happiness when finishing later was 67 times larger than the (non-significant) variation in happiness when finishing earlier ($p<.001$, $d=2.13$). These findings replicated in the US sample. In this and all studies the findings replicated on self-efficacy.

Study 2 ($N=602$) was a 2(domain: time vs. money) x 3(spending: as planned vs. less vs. more) between-subjects design. Partic-

ipants were informed that they plan to spend 50 minutes on [\$50 for] some errands. Depending on the condition, participants were informed that they finished these errands using the time [money] planned, 20 minutes [for \$20] less or more than planned.

As predicted, the increase in happiness due to spending less than planned was significant and substantial for money ($M=11.55$, $p<.001$, $d=0.67$) but not for time ($M=2.91$, $p=.271$, $d=0.16$, difference: $p<.001$, $d=.55$). The decrease in happiness due to spending more than planned was not significantly different between money and time ($p=.412$, $d=.12$; $p_{interaction}=.086$); neither was the hedonic reaction to spending as planned ($p=.209$, $d=0.17$).

Study 3 ($N=304$) replicated Study 1's design, controlling for outcome quality. Participants were asked to imagine that they are writing product reviews that will get a score and informed that their review took them exactly the time planned, one hour less, or one hour more. Then, all participants were informed that they received the maximum possible score.

Compared to finishing the review on time ($M=86.37$), finishing the review one hour later significantly decreased happiness ($M=60.59$, $p<.001$, $d=-1.15$), whereas finishing it one hour earlier again did not significantly increase happiness ($M=89.19$, $p=.183$, $d=0.19$)—despite the fact that they received the maximum possible grade for one hour less of work. Again, the decrease in happiness due to unexpected time losses was 9 times larger than the (non-significant) increase in happiness due to unexpected time gains ($p<.001$, $d=1.04$).

Study 4 ($N=402$) aimed to examine the reason behind the numbness-to-time-windfalls effect. Depending on the condition, participants recalled a time in which the task took them less, more, or exactly the time they had planned. Participants in the spending less condition were also asked what they did with their saved time.

Compared to finishing the task on time, finishing it later significantly decreased happiness ($p<.001$, $d=-2.05$), whereas finishing it earlier led to a comparatively small increase in happiness ($p=.027$, $d=0.29$). Again, finishing the task earlier than planned increased happiness to a substantially smaller extent than finishing it later decreased it ($p<.001$, $d=1.76$). Crucially, the 51% of people who report that they reinvested the time they saved in something else were significantly happier than those 36% who let the time windfall pass unused ($p=.008$, $d=.54$)—leading to an extreme asymmetry for "non-reallocators" (losses loomed 127 times larger) but substantially attenuated for "reallocators" (losses loomed 4 times larger).

Finally, Study 5 ($N=406$) shows that "predictors" predicted that they would feel significantly happier when finishing the activity one hour earlier compared to finishing it at the time planned ($p<.001$, $d=.31$), whereas "experiencers" did not feel significantly happier when finishing the activity earlier than planned ($p=.768$, $d=.04$). Importantly, people overestimate how happy they feel when gaining time ($p=.016$, $d=.36$).

In sum, this work uncovers a systematic tendency to underappreciate unexpected time savings. Our findings contribute to the literature on time famine (Whillans et al. 2017) and prospect theory (Tversky and Kahneman 1991) by demonstrating an extreme "loss looms larger" effect for time. We hope that our findings encourage people to make better use of time windfalls to maximize happiness.

Self-Esteem Influences Covid-19 Prevention Behavior and Messaging Efficacy

Dr. Anika Stuppy, Tilburg University, Netherlands

Dr. Robert Smith, Tilburg University, Netherlands

EXTENDED ABSTRACT

We show that low self-esteem decreases people's engagement in COVID-19 prevention behaviors. This occurs because low self-esteem is associated with a reduced motivation to protect one's health. However, low self-esteem people can be persuaded to engage in prevention behavior (e.g., vaccination) if those behaviors are framed around protecting other people.

The coronavirus pandemic has had devastating consequences worldwide. Although laws and recommendations are in place to slow the spread of the virus, there is large heterogeneity in people's willingness to engage in preventive behaviors such as washing one's hands and practicing social distancing. Society clearly needs a better understanding of why some people are reluctant to protect their health during the on-going pandemic. The present investigation sheds light on this issue by examining the possibility that people's willingness to protect themselves from contracting Sars-CoV-2 depends on self-views – their trait self-esteem.

We hypothesize that low self-esteem people are less willing to engage in COVID-19 prevention behaviors such as hand-washing and mask-wearing. This prediction is based on existing research which suggests that people with lower self-esteem are motivated to verify their negative self-views (Swann & Buhrmester, 2012). Because experiences that are harmonious with one's self-views provide important psychological benefits (e.g., a sense of consistency), low self-esteem people tend to welcome negative feedback (Swann & Read, 1981). Based on these findings, we suggest that people with lower self-esteem are less motivated to protect their health and less willing to engage in self-protective behavior because negative health experiences, such as contracting the coronavirus, are aligned with how low self-esteem people see themselves.

In Study 1a, participants first completed the Rosenberg self-esteem scale and then indicated their willingness to engage in nine COVID-19 prevention behaviors (e.g., I avoid physical contact when greeting). Low self-esteem people were less willing to self-protect ($r = .32, p < .001$). Study 1b replicates this finding using a more objective measure of self-protection (e.g., Compared to before the pandemic, do you wash your hands more frequently? 1 = Strongly disagree to 7 = Strongly agree). We again detect a positive association with self-esteem ($r = .14, p = .018$).

Study 2 manipulates state self-esteem. Participants were randomly assigned to list three good breaks or three bad breaks (between-subjects; Callan et al., 2014) and then indicated how likely they were to disinfect their hands, wear a face mask, etc. in specific scenarios. Lowering self-esteem reduced participants' willingness to self-protect ($p = .040, d = .23$).

Study 3 measured participants self-esteem and their willingness to engage in self-focused (e.g., cleaning hands after leaving a public space) and other-focused prevention behavior (e.g., cleaning hands before entering a public space). We find that self-esteem interacts with message framing (manipulated within-subjects; $p = .001$). Self-esteem was correlated with behaviors to protect one's own health ($r = .30, p = .001$) but not with behaviors to protect the health of other people ($r = .11, p = .248$).

Study 4 examined the effect of self-esteem and message framing on consequential choices. After completing the self-esteem scale, unvaccinated participants were randomly assigned to a health message that framed vaccination as way to protect one's own health or

the health of other people. Participants then indicated whether they wanted to watch an informative video about COVID-19 vaccines. Self-esteem interacted with message framing ($p < .002$). People with self-esteem scores lower than 2.96 watched the video more often when exposed to the other-focused (vs. self-focused) message.

Our empirical package consistently finds that the association between self-esteem and COVID-19 prevention behaviors is driven by people with lower self-esteem being less motivated to protect their health. Studies 1b and 2 measure health motivation (e.g., "My health is an absolute priority for me; Champion & Skinner, 2008). We detect an indirect effect of self-esteem on COVID-19 prevention behaviors via health motivation in Study 1b ($b = .15, 95\%CI [.05-.35]$). In Study 2, a serial mediation suggests that the effect of the recall task on prevention behaviors operates through state self-esteem and health motivation ($b = .14, 95\%CI [.06, .25]$). We also measure health motivation in Study 3, both for oneself (e.g., "My health is an absolute priority for me.") and for other people (e.g., "Other people's health is an absolute priority for me."). A moderated mediation model suggests that self- vs. other related health-motivation explains the combined effect of self-esteem and protection target (self- vs. other) on willingness to engage in protection behaviors. We find much less support for alternative processes.

Individual behaviors such as washing one's hands, practicing social distancing and getting vaccinated, have a large impact on controlling pandemics. This research presents three main contributions to our understanding of people's motivation and likelihood to engage in health-protection behavior during the COVID-19 pandemic; (i) low self-esteem decreases people's engagement in behaviors to protect themselves, (ii) this occurs because low self-esteem is associated with less motivation to protect one's own health, and (iii), because low self-esteem is not associated with less motivation to protect other people's health, people with low self-esteem are actually persuaded best by messages that frame prevention behavior, such as vaccination, as a way to protect other people. This research helps to answer the call for more studies on people's compliance with suggested COVID-19 prevention behaviors.

Functional Similarity: How Consumption Goals Improve Brand Imitation Evaluation

Dr. Femke Van Horen, Vrije Universiteit Amsterdam, Netherlands

Prof. Rik Pieters, Tilburg University, Netherlands

EXTENDED ABSTRACT

Four studies demonstrate that seemingly counterproductive brand imitation strategies can become effective when specific consumption goals are activated. When activated goals bring a distant (close) copycat cognitively closer to (further away from) the imitated brand, evaluations and purchase intention of the copycat increase.

Copycats imitate brand features (e.g., name, logo, shape) of a successful original brand to freeride on its equity (Zaichkowsky 2006). Previous research revealed that brand imitation is ineffective when the imitation is too close to the imitated brand (e.g., blatant similarity or positioned too close to the original) or too distant from the imitated brand (e.g., low similarity or positioned too far away from the original; Van Horen and Pieters 2012; 2017). The current set of experiments demonstrate however how specific consumption goals can increase purchase intentions of these seemingly ineffective brand imitations, while keeping product similarity constant.

Based on the accessibility-diagnostics theory (Feldman and Lynch 1988) we propose that consumers will use input information from copycat-original similarity differently depending on 1) accessibility of the input in memory and 2) perceived diagnosticity of that input. First, we propose that, when the copycat is “positioned” far away without direct references to the original, the similarity information is less likely used as input for evaluation, even under high similarity. However, when a goal is activated that brings copycat and original closer together, similarity information will become more accessible and infuse into copycat evaluation, resulting in an evaluative assimilation effect (Warlop and Alba 2004). Second, as diagnosticity refers to the importance and relevance of the information, goals may make the same similarity information more or less diagnostic for subsequent copycat evaluation, even when accessibility of information is high. When goals make similarity more (less) diagnostic, narrower (broader) category processing is activated, due to which a clear (less clear) representation of the original brand is activated, resulting in evaluative contrast (vs. assimilation; Van Horen and Pieters 2017). Four studies test these propositions.

Studies 1 and 2 test whether goals can make similarity information more accessible, increasing copycat evaluation even when positioned far away from the original. Participants ($N = 100$) were randomly assigned to a 2 (goal: no vs. yes) \times 2 (positioning: far away vs. close to original) between-participants design. Participants read in the goal condition that they would have a relaxing evening at home watching a movie for which they wanted to buy ice-cream and beer. In the no-goal condition they just read they needed to buy ice cream and beer. They then indicated their attitude and purchase intention (7-point scales, averaged scale $\alpha = .88$) of “Vecks” (as imitation of the beer brand “Becks”), in either the category beer (close to the original) or the ice-cream category (far away from the original). Results showed a significant interaction between goal and positioning, $F(1, 96) = 8.03, p = .006, \eta_p^2 = .08$; when the copycat was positioned far away, the brand name “Vecks” was evaluated more positively when the goal “watching a movie at home” was activated ($M = 4.28, SD = 1.43$) than when no goal was activated ($M = 3.27, SD = 1.28$), $F(1, 96) = 8.28, p = .005, \eta_p^2 = .08$. When positioned close to the original, copycat evaluation was negative independent of goal activation ($M_{Goal} = 2.58, SD = 1.06; M_{NoGoal} = 2.96, SD = 1.10$), $F(1, 96) = 1.24, p = .27, \eta_p^2 = .01$. Study 2 ($N = 264$) conceptually replicated Study 1, revealing a significant interaction between goal and positioning,

$F(1, 207) = 4.11, p = .04, \eta_p^2 = .02$. When the copycat brand name “Ray Boz” (as an imitation of “Ray Ban”) was positioned far away from the original (in the category flip-flops) it was evaluated more positively when the goal “going to the beach” was activated ($M = 4.90, SD = 1.29$) than when no goal was activated ($M = 4.08, SD = 1.49$), $F(1, 207) = 7.46, p = .007, \eta_p^2 = .04$. When the copycat was positioned close to the original (in the category sunglasses), goal activation did not influence copycat evaluation, ($M_{Goal} = 4.33, SD = 1.85; M_{NoGoal} = 4.39, SD = 1.70$), $F(1, 207) = .42, p = .84, \eta_p^2 = .00$.

Studies 3 and 4 test how goal activation, even when similarity information is already highly accessible, determines the diagnosticity of such information. Participants ($N = 104$) responded to a primary-goal and secondary-goal condition (within subjects, order counterbalanced). In the primary (secondary) goal condition, participants read that after eating a spicy Thai curry they bought an energy drink because they wanted “an energizing drink to help them studying” (“a sweet drink to neutralize the spicy taste”). Participants then indicated their attitude and purchase intention (7-point scales, collapsed, $\alpha = .88$) of the copycat brand name “Red Mull” (as imitation of “Red Bull”). The results showed that the brand name “Red Mull” was evaluated more positively when the secondary goal was activated ($M = 3.19, SD = 1.26$) than when the primary goal was activated ($M = 2.92, SD = 1.23$), $F(1, 102) = 5.39, p = .02, \eta_p^2 = .05$. Study 4 ($N = 171$) conceptually replicated Study 3, using product packages instead of brand names. The results showed that the copycat product “Lecha” (as imitation of “Milka” chocolate) was evaluated more positively after imagining they wanted to use it to bake a cake for a friend (secondary goal; $M = 4.14, SD = 1.41$) than when to have it as a chocolate snack (primary goal; $M = 3.89, SD = 1.40$), $F(1, 167) = 4.22, p = .04, \eta_p^2 = .03$. In addition, in the secondary goal condition, the copycat “Lecha” made participants think more about the category in general ($M = 25.35, SD = 28.23$) than in the primary goal condition ($M = 21.97, SD = 25.54$), $F(1, 167) = 5.62, p = .02, \eta_p^2 = .03$.

These results show that when a goal brings a seemingly distant (close) copycat cognitively closer to (further away from) the imitated brand, evaluations and purchase intention of the copycat improve. Then, goal activation can mitigate or even reverse boomerang effects of high original-imitator similarity, independent of degree of similarity.

Consumers Prefer to Donate Possessions Close to their Heart to Distant Others

Mr. Itai Linzen, Tel-Aviv University, Israel
Prof. Yael Steinhart, Tel-Aviv University, Israel
Prof. Ziv Carmon, INSEAD, Singapore

EXTENDED ABSTRACT

Consumers are reluctant to part with high-attachment possessions they no longer use. We show that consumers—particularly those high in need-for-uniqueness—are more likely to give such items to others at distant (vs. nearby) locations, as distance diminishes the discomfort associated with the potential of encountering strangers using those items.

People find it difficult to dispose of high-attachment possessions, even when those are no longer in use (Dommer and Winterich 2021; Ferraro, Escalas and Bettman 2011; Trudel, Argo and Meng 2016). Holding on to items that no longer serve us clutters homes, denies others the opportunity to benefit from them and hampers the circular economy. In spite of its obvious importance, the question of how to assist consumers in disposing of their possessions is understudied (Winterich, Reczek and Irwin 2017). Our research explores this question in the context of clothing, a product category whose production is particularly harmful to the environment (Mizrachi and Tal 2021).

This research proposes a counterintuitive approach to encouraging consumers to pass on unneeded possessions: High-attachment possessions will more likely be donated if donors can donate them to distant locations. Specifically, we consider Consumers' Need for Uniqueness (CNFU), the desire to establish a distinct identity from others using material possessions (Chan, Berger and van Boven, 2012; Tian, Bearden and Hunter 2001; White and Argo 2011). One manifestation of Need for Uniqueness is avoidance of similarity—a loss of interest in possessions that no longer provide an advantage of distinctiveness. Hence, we hypothesize that when consumers consider giving up a high-attachment possession, they will prefer to reduce the likelihood of encountering it in the hands of someone else.

Results of six studies ($n=1,341$) consistently support our theoretical predictions: Participants prefer to donate high-attachment clothing items to a distant vs. proximal location, for high-but not for low-attachment items. We present an account of this phenomenon that we name the *Other-Me Effect*, the discomfort associated with a potential encounter with another person using the donated high-attachment possession, which mediates the effect. Moreover, we hypothesize that this effect will be stronger among consumers higher (versus lower) in Need for Uniqueness, who may experience a particularly strong preference to avoid seeing others using their former possessions.

STUDIES

Participants in all studies were asked to describe a clothing item in good condition but no longer worn that is highly meaningful to them (high-attachment task) and then read a brief text about the purging of clothing and its benefits.

Study 1a: After completing the high-attachment task, participants ($N=100$) were asked to consider a scenario whereby they needed to clear up space in their closet and sort unused clothing items, including the one they described. They then rated their willingness to donate the meaningful clothing item they had described (1=keep item, to 7=give away the item) in one of two different scenarios: in the event that the item will be given to (1) people living in the same town (proximal destination), or (2) people living in a different town from where they live (remote destination). We found that participants were more willing to give the item away when the item would be given to people living in a different town ($M=2.77$, $SD=2.12$) rather than to people in the same town ($M=2.46$, $SD=1.92$; $t(99)=2.83$, $p=.006$, $d=1.09$).

Study 1b: This study replicated Study 1a, using a different scenario and presenting a direct choice between proximal and remote donation destinations. Participants ($N=302$) were told about an opportunity to collaborate with an NGO that collects clothes for redistribution, whereby donors could decide whether to donate their items to people living (1) in the same town or (2) in a different town. We found that participants preferred giving away the high-attachment clothing item when it would be distributed to people living in a different town (71.85%) than to people living in the same town ($\chi^2=57.69$, $p<.001$, $w=.43$).

Study 2: In this study, we used both high- and low-attachment conditions and tested for mediation by the *Other-Me Effect*. After completing the high (vs. low) attachment task, participants ($N=200$) read the backstory used in Study 1a. Distance was operationalized differently: participants rated their preference regarding the probability of encountering someone else wearing the item. Finally, they completed two items measuring the *Other-Me Effect*. Results showed that participants' preference for encountering someone else wearing the donated item was lower in the high-attachment condition ($M=3.07$, $SD=1.97$) than in the low-attachment condition ($M=3.91$, $SD=1.62$; $t(198)=3.27$, $p<.001$, $d=.8$). A mediation analysis confirmed that the *Other-Me Effect* mediated these preferences ($b=.64$, $SE=.15$, 95%CI: .97 to .35).

Study 3a: Before being assigned to either high- or low-attachment conditions, participants ($N=241$) completed the CNFU scale (Tian et al. 2001). Next, they read the same scenario used in Study 1 and chose their preferred donation destination. Again, more participants in the high-attachment condition preferred to give the clothing item to people in a different town (57.4%) than participants in the low-attachment condition (41.2%; $\chi^2=6.32$, $p=.012$, *Cramer's V*=.16). A moderation analysis revealed that CNFU moderated this effect: Participants high in CNFU ($M>3.03$, $b=.53$, $SE=.27$, $p=.050$) showed a stronger preference to donate high-attachment items to people in the distant location.

Study 3b: In this study, before completing the high-attachment task, participants ($N=200$) were randomly assigned to either high- or low-CNFU conditions (Moldovan et al. 2014). Next, they chose their preferred donation destination. Results showed that participants in the high-CNFU condition showed a stronger preference for donating the clothing item to people in a different town (74.7%) than did participants in the low-CNFU condition (59.8%; $\chi^2=5.08$, $p=.024$, *Cramer's V*=.15).

Study 4: This study replicated Study 1b with an incentive-compatible design. After completing the high-attachment task, participants ($N=298$) were informed about an opportunity to collaborate with an NGO and were asked whether they were willing to donate the high-attachment clothing item they described. Results showed that among the participants who made a commitment to donate that item, a different town was twice as likely to be chosen as the donation destination (66%) than the same town ($\chi^2(1)=10.66$, $p=.001$, *Cramer's V*=.33).

These findings complement the literature on psychological attachment to possessions and expand the research on helping people part with possessions. Our research identifies an easy-to-apply nudge to help people reintroduce their possessions into the circular economy.

Domestic Brand Transgressions: How, When, and Why Home Country Bias Backfires

Dr. Bill Davvetas, University of Leeds, UK
Dr. Aulona Ulqinaku, University of Leeds, UK

EXTENDED ABSTRACT

Drawing from social identity threat theory and across a correlational study with real word data and three experimental studies, we find that domestic brand transgressions are perceived as stronger threats to home country consumers' social identity than transgressions originated by foreign brands and are thus less likely to be forgiven.

Brand transgressions describe brand-originated actions that violate consumer expectations of appropriate brand behavior that harm consumers' relationship with the brand (Aaker, Fournier and Brasel 2004). Research shows that negative beliefs about transgressing brands spillover to the image of the brand's country of origin and ultimately harm consumer attitudes toward other brands originating in the same country (Magnusson, Krishnan, Westjohn and Zdravkovic 2014). The spillover effects of prototype brand transgressions on country image and related brands. However, opposing theoretical predictions exist about how the domestic or foreign origin of the transgressing brand affects consumer responses to brand violations.

One line of reasoning draws from literature on the beneficial effects of individuals' in-group biases and predicts that consumers should forgive more easily transgressions originated by domestic (compared to foreign) brands because such brands represent members of their in- group and are thus treated more leniently (Brewer 1979). The counter argument views domestic brand transgressions as actions of in-group betrayal and predicts that they should be forgiven less than foreign country ones, not in spite of the transgressing brand's domestic origin, but precisely because of it. In line with the second prediction, we argue that, compared to foreign brands, domestic brands are forgiven less by home country consumers when they engage in transgressions. We base this prediction on social identity threat theory (Wann and Grieve 2005) and propose that consumers forgive domestic brand transgressions with more difficulty because they represent stronger threats to their social (i.e. national) identity. We propose two consumer-related variables – consumer ethnocentrism and self-construal – as well as two transgression-related variables – the type of transgression and transgression attribution.

Forgiving transgressions by domestic versus foreign brands

When brands engage in transgressions, this may damage brand equity (Dawar and Pillutla 2000), result in major losses in terms of revenue and market share (Ahluwalia, Burnkrant and Unnava 2000), lead to negative corporate associations and affect the relationship between brands and consumers, resulting in more negative emotions, attitudes, and purchase intentions toward the brand (Ahluwalia et al. 2000; Dawar and Pillutla 2000). Previous research suggests that victims and observers are more punitive toward in-group members (Shinada, Yamagishi and Ohmura 2004), as a means to protect the in-group from the transgressions of offenders that belong to the same "identity group" (Kerr et al. 1995). In essence, punishing wrongdoers is a way to alleviate and dissociate one's self from the transgression (Kerr et al. 1995). Given that domestic (foreign) brands are part of the consumer's in-group (out-group), we predict:

Hypothesis 1: Consumers are willing to forgive transgressions of domestic brands less than transgressions of foreign brands.

The mediating role of social identity threat

When consumers are exposed to social identity threats, they tend to avoid products that are associated with that identity (i.e., identity-reinforcing products) as a mechanism of self-protection (White and Argo 2009). It is thus expected that consumers experiencing social identity threat resulting from a transgression of a brand they share in-group belongingness (i.e. a domestic brand) would exhibit stronger intentions of revenge and lower likelihood of forgiveness in an effort to reestablish their damages status, honor, image, and identity. Given that consumers share a national identity component with domestic brands, social identity threats would be greater if domestic (vs. foreign) brands engage in transgressions and explain why forgiving domestic brand wrongdoings is more difficult than forgiving foreign brand misconduct. Thus:

Hypothesis 2: Social identity threat mediates the effect of domestic (vs. foreign) brand transgressions on consumer brand forgiveness intentions.

Transgression-related moderators of domestic brand transgression forgiveness

Previous research identifies two main types of brand transgressions: performance-related (where the brand is associated with defective products) and value-related (associated to social or ethical crises by failing to deliver the promised symbolic and psychological benefits). (Dawar and Pillutla 2000). When a brand engages in value-related transgressions, it is seen as deliberately violating the values of the group of consumers that have chosen to identify with the brand (Tyler and Boeckmann 1997). When the brand and consumers share a common perceived identity (e.g., domestic brands) the link between value transgressions and social identity threats should become even stronger (Wenzel and Thielmann 2006). Thus:

Hypothesis 3: Value-related (compared to performance-related) transgressions of domestic brands represent greater social identity threats for consumers and are thus forgiven less.

Domestic Brand Transgressions in Independent versus Interdependent Cultures

According to previous research, individuals vested with interdependent culture (e.g., Asians) would be more willing to defend the morality of the actions of a group member, work with them toward solving the problem, improve the group situation, and extol the virtues of the group to individuals outside the group when faced with transgressive acts (Fehr and Gelfand 2010). This may be explained by the fact that individuals from interdependent cultures view themselves as strictly related to others. As such, they are highly engaged in focusing on the quality and performance of the group, rather than the self, and work toward improving every element of the group (i.e., other in-group members' actions; Gefland et al. 2006). Hence, we predict:

Hypothesis 4: Consumers from independent (compared to interdependent) cultures are less likely to forgive domestic brands transgressions.

Upholding Consumer Forgiveness Following a Domestic Brand Transgression: The Role of Post-Transgression Communications and Attribution Framing

Brand transgressions represent typical examples of actions consumers try to understand (and consequently react toward) using attributional inferences (Aaker, Fournier and Brasel 2004). As a result, consumer forgiveness of brand transgressions should depend on whether they attribute the transgression to dispositional factors such as the brand's unethical motives and profit-seeking, or to situational factors such as environmental pressures or need for survival. The proposed strategy would spin the transgression as a response to competitive threats from foreign competitors. Consequently:

Hypothesis 5: Post-transgression communications attributing domestic brand transgressions to foreign (compared to domestic) competitive threats decreases consumers' social identity threat and thus increases willingness to forgive the transgressive brand.

STUDY 1

Study 1 investigates the main effect of domestic (vs. foreign) brand transgressions on brand forgiveness as well as the moderating role of transgression type (value- vs. performance-related) and consumer self-construal (independent vs. interdependent). We collected data by 762 participants on MTurk (Mage = 31.4 years, SD = 8.98; 40.8% female). Respondents were residents and nationals of either India - interdependent culture - or USA - independent culture. We used a 3 (Transgressing brand type: domestic local vs. domestic global vs. foreign global) \times 2 (Transgression type: value vs. performance) between- participants design. We manipulated brand origin through the location of the brand's headquarters, the country of the brand's founding, and the name of the brand's founder.

Brand availability was manipulated through the geographical dispersion of brand's points of sale within home country borders or around the world (Davvetas & Diamantopoulos, 2018). For the transgression type manipulation (Dutta & Pullig, 2011), we claimed that the brand was involved either in child labor exploitation (value transgression) or defective material usage (performance transgression). Next, participants were asked about the extent to which they would forgive the brand (Xie & Peng, 2009) and willingness to purchase the brand (Estes, Brotto, & Busacca, 2018). Next, respondents completed the manipulation check¹ items for all manipulated factors (transgression type, brand origin, brand globalness, etc.).

We conducted a factorial ANOVA with brand forgiveness as a dependent variable and country, brand type, transgression type and all their corresponding interactions as predictors. The results show a significant main effect of domestic (vs. foreign) brand origin on consumer brand forgiveness ($F = 8.01, p < .01$), a significant main effect of country ($F = 52.77, p < .001$), and a marginally significant effect of transgression type ($F = 3.22, p = .073$). Planned contrasts indicate that consumers forgive value transgressions originated by domestic brands less than value transgressions originated by foreign brands ($M_{\text{value-domestic}} = 3.94, SD = 2.08$ vs. $M_{\text{value-foreign}} = 4.48, SD = 1.89; t = 2.47, p < .05$). No similar differences are observed for performance transgressions which are forgiven with statistically the same intensity both for domestic and for foreign brands ($p = .218$). Regarding culture, planned contrasts indicate that, in line with predictions, US respondents (independent culture) forgive domestic brand transgressions less than foreign brand transgressions ($M_{\text{US-domestic}} = 3.62, SD = 1.95, M_{\text{US-foreign}} = 4.03, SD = 1.97;$

$t = 1.99, p < .05$). The same effect is also observed for the Indian respondents (interdependent culture) ($M_{\text{India-domestic}} = 4.68, SD = 1.91$ vs. $M_{\text{India-foreign}} = 5.11, SD = 1.63; t = 2.11, p < .05$). These results suggest that forgiving domestic brands is more difficult than forgiving foreign ones even in interdependent cultures.

STUDY 2

DOMESTIC BRAND TRASGRESSORS: PRODIGAL SONS OR HOME TRAITORS?

In Study 2, we empirically juxtapose the two mechanisms leading to conflicting theoretical predictions regarding the role of brand origin on transgression forgiveness. We narrow down our investigation to a new value-related transgression (i.e., wage discrimination based on employee's gender).

Method

We collected data through an online survey completed by 250 participants of an online consumer panel (Mage = 34.74 years, SD = 12.45; 52.9% female). Two hundred and six participants continued the study after providing the correct answer to the attention check. To ensure that respondents would perceive the used brand as domestic, all respondents were residents and nationals of the United Kingdom. We used the same domestic manipulation as Study 1. After exposure to the brand, participants read that someone in the company was involved in sexual harassment that they had not promptly addressed.

Following, respondents completed measures of the dependent variables (brand forgiveness, willingness to purchase), the measure of the mediator (social identity threat), a measure of in-group protection, and a series of manipulation checks.

Analysis and Results

To test our proposition that the transgressive brand origin (domestic vs. foreign) affects brand forgiveness through social identity threat, and to rule out the role of protection as an alternative mechanism, we ran a parallel mediation model with brand origin (1 = domestic, 0 = foreign) as independent variable and social identity threat and in-group protection as mediators, and brand forgiveness as dependent variable.

We found a significant mediating effect of brand origin on brand forgiveness through social identity threat ($ab = -0.08, SE = 0.04$, confidence interval [CI] 95%: -0.16; -0.01) but not through protection ($ab = 0.06, SE = 0.07, [CI] 95\%: -0.08; 0.21$).

Study 2 replicates the main effect obtained in Study 1. Additionally, it shows that the reason why consumers forgive domestic brands less is an increased social identity threat experienced when the source of transgression comes from the consumer's own country, ruling out the role of in-group protection as an alternative counter-mechanism.

STUDY 3

CAN POST-TRANSGRESSION COMMUNICATIONS LIMIT THE EFFECTS OF TRANSGRESSIVE BRAND ORIGIN ON FORGIVENESS?

In Study 3, we again collected data exclusively from United Kingdom and we focused again on value-related transgression (i.e. wage discrimination based on employee's gender). Our online study was completed by 408 participants on MTurk (Mage = 37.6 years, SD = 13.6; 70.8% female). We used a 2 (Transgressing brand origin: domestic vs. foreign) \times 2 (Transgression attribution: response to foreign vs. domestic threat) between-subjects design. We manipulated

brand origin and value transgression (here: gender discrimination in payments) similarly to Study 1. Following, respondents completed measures on brand forgiveness, willingness to purchase), a measure of the mediator (social identity threat), and a measure of consumer ethnocentrism.

A moderated mediation model (PROCESS Model 9) with transgressing brand origin (0 = foreign, 1 = domestic) as the independent variable, social identity threat as a mediator, brand forgiveness as a dependent variable and the transgression attribution manipulation (0 = domestic threat, 1 = foreign threat) and consumer ethnocentrism as simultaneous moderators was tested. The results demonstrate that domestic brand origin of the transgressing brand has a positive effect on social identity threat ($\beta = 1.18, t = 4.55, p < .001$) and social identity threat has a negative effect of brand forgiveness ($\beta = -.265, t = -7.65, p < .001$), leading to a significant indirect negative effect. Turning to the moderators, the interaction between brand origin and consumer ethnocentrism on social identity threat is negative and significant ($\beta = -.212, t = -1.916, p_{\text{one-tailed}} = .028$), as predicted. Regarding the moderation by transgression attribution, the respective interaction term is also negative and significant ($\beta = -.462; t = -1.696, p_{\text{one-tailed}} = .045$).

STUDY 4

We collected Twitter posts around two brand transgressions: United and Volkswagen in the 3 months before the scandal was released (we will refer to this as before), in the 3 months after the scandal was released (we will refer to this as short-time after), and in the 3 months following the scandal anniversary (we will refer to this as long-time after), using the PULSAR tracking platform. Our data collection resulted in 227,888 tweets.

Measures

Forgiveness. We proxied forgiveness using the ratings of anger of the tweet. Our assumption was that the greater the anger, the lower would be the forgiveness intentions. The variable anger was calculated using IBM Watson ($M = 16.17, SD = 16.18$).

Domestic brand transgression. We created a binary variable which took the value 1 if the user country and the brand country coincided.

Results

The results of the linear regression suggest a significant interaction effect between domestic brand transgression (domestic vs. foreign) and time (before vs. after the transgression), $\beta = -1.16, p < .001$. The results of the planned contrasts suggest a significant increase in anger before and after the scandal for the domestic brand ($M_{\text{before}} = 15.68, SD = 15.06, M_{\text{after}} = 16.60, SD = 17.04, F = 147.36, p < .001$), but no difference for the foreign brand ($p = .233$). These effects replicated when considering both short-term effects after the event (3 months after) and the long-term effect (1 year after). The results persist if we use sadness as dependent variable, and when we control for number of friends and followers.

While we acknowledge the correlational nature of our results, and the limitation in claiming causality from these findings, we believe that these results show a real behavior of consumers when facing domestic or foreign brand transgressions.

DISCUSSION AND CONCLUSIONS

Our research contributes to brand transgressions literature through (1) extending the list of drivers that determine consumer responses to brand misconduct and (2) considering international variables that should be factored in when investigating the phenomenon of brand transgressions in a globalizing marketplace. Additionally, the findings contribute to the discussion on consumers' domestic country bias by identifying the boundaries of its favorable effects and cases where it might backfire. From a managerial standpoint, the findings (1) inform decisions of domestic and foreign firms when faced with brand crises, product recalls, negative reputation, etc., (2) provide a picture of which countries or consumer segments are more sensitive to these events, and (3) illustrate potential ways to deflect the negative consequences of these events by pinning them to foreign competitors.

Status-Seeking Aggression

Mr. Ethan Milne, Ivey Business School, Western University, Canada
Dr. Kirk Kristofferson, Ivey Business School, Western University, Canada
Dr. Miranda Goode, Ivey Business School, Western University, Canada

EXTENDED ABSTRACT

We demonstrate the existence of a novel consumer-brand aggression category absent from prior frameworks: status-seeking. Using real-world data (11.15M tweets from ~90k users) and four studies, we show status motives drive aggression towards brands and manifest in emotions and behaviors that are meaningfully distinct from retributive or reparative aggression.

When brands hurt people, they often become targets of consumer aggression. Aggressive behaviors include boycotts, vandalism, and negative word-of-mouth (WOM); importantly, consumers' motives for aggression are similarly varied. Recent efforts to introduce an aggression schema have uniformly landed on a dichotomy between *retributive* and *reparative* motives (e.g., Grégoire et al. 2019; Kähr et al. 2016; Antonetti 2016). However, such typologies fail to account for status as another important motivation for aggression. Status motivation has been hinted at in past research: Kozinets and Handelman (1998) found that boycotts were used as tools for self-expression, Ward and Ostrom (2006) found consumer protesters desired to portray themselves as "crusaders" for justice, and Anderson and Simester (2014) found that some consumers leave fraudulent negative reviews to look influential. However, these findings were only explored in passing, and no research to date has identified status-seeking as an important causal factor in consumer aggression, explored what situations or traits lend themselves to such behavior, nor identified how status-seeking aggression is conceptually distinct from past accounts of consumer aggression.

We propose that consumers do aggress against brands to garner status, and that this aggression is theoretically distinct from retributive and reparative aggression in both manifestation and underlying motivation. This proposition is informed by past work suggesting aggressive behaviors like expressing moral outrage are more likely to achieve status objectives like going viral on social media, and that individuals can learn to associate aggressive behavior with status (Rathje et al., 2021; Brady et al. 2021). Thus, status-seeking individuals should behave more aggressively towards brands and do so at greater rates when socially rewarded for such behavior.

We conducted four studies to test our theorizing. Study 1 offers real-world evidence for status-motives driving consumer aggression. We examined responses to a viral @BurgerKingUK tweet that read "women belong in the kitchen". We predicted that users who were socially rewarded (via likes) for aggressive tweets expressing moral outrage prior to the Burger King incident (past) would post a higher number of aggressive tweets targeting Burger King (present). We identified and collected all posts that included the text "@BurgerKingUK" in the 48-hour period following Burger King's tweet, yielding 153,046 tweets. From this set, we identified 90,166 unique Twitter users and collected every post from those users for the 7-day period prior to the Burger King tweet (10.98M). Each tweet was classified as containing moral outrage or not, using Brady et al. (2021)'s Digital Outrage Classifier. We then summarized tweet counts and engagement statistics for each user, counting the total number of non-outraged and outraged posts before and after the Burger King tweets, as well as the like counts for each category. Supporting our status-seeking aggression proposition, we found that the effect of likes for past outrage on quantity of present outrage targeting Burger King was significant and positive ($=0.095, p<.001$). These results demonstrate that consumers are sensitive to the status their

aggression garners, and "learn" to behave more aggressively in contexts where aggression is socially desirable.

Study 2 tests the association between status-seeking motives and consumer-brand aggression. Undergraduate participants ($n=136$) were assigned to conditions in a 3 (harm: none vs. low vs. high) x Continuous (Moral Grandstanding Motivations; Grubbs et al., 2019) between-subjects design that tested participants' willingness to engage in marketplace aggression (Grégoire et al. 2010) and unethical aggression (Rotman, et al. 2018). The Moral Grandstanding Motivations (MGM) scale is comprised of two subscales that assess two ways individuals seek status (Cheng et al. 2012): prestige-strivings, and dominance-strivings. We found a main effect of MGM on willingness to engage in marketplace aggression ($=0.46, p<.001$), and unethical aggression ($=0.54, p<.001$). This effect was driven predominately by the MGM-Dominance subscale (aggression: $=0.38, p<.001$; unethical: $=0.37, p<.001$), but not MGM-prestige (aggression: $=0.18, p=.13$; unethical: $=0.08, p=.49$). Importantly, and supporting our framework, this main effect of MGM on aggression persists even when no harm was done by the brand.

Study 3 tests the causal effect of status goals on consumer aggression, while accounting for potential social desirability bias (SDB) in reporting aggressive intentions (Fisher, 1993). Undergraduates ($n=398$) were assigned to conditions in a 2 (Motives: Status vs. Reparative) x 2 (Questioning: Direct vs. Indirect) between-participants design. Participants were presented with the @BurgerKingUK tweet from Study 1, and informed that many consumers were outraged at the sexist message. Participants were asked to answer as themselves or a hypothetical other and given a goal of either gaining status or effecting positive change. Consistent with our theorizing, we found that intention to send aggressive messages was higher for those with status motives compared to those with reparative motives ($F(1,392)=35.34, p<.001; =0.08$). We did not, however, find a significant interaction between indirect questioning and status goals ($F(1,392)=2.77, p=.097; =0.007$), suggesting that status motives for aggression was not subject to SDB.

Study 4 uses a method adapted from Kähr et al. (2016) to demonstrate the conceptual distinctiveness of status-seeking aggression from retributive and reparative aggression. Undergraduates ($n=301$) participated in a 3-factor within-subjects design (aggression type: status-seeking vs. retributive vs. reparative) where they read 2 stories of each aggression type and rated the aggressor on their emotions, cognition, and behaviors. Responses were compared in a series of t-tests, all statistically significant at the $p<.001$ level. Status-seeking aggressors were rated as feeling less angry and less hatred. They also thought less about changing their target's behavior or achieving a fair outcome. Finally, they were rated as being more willing to re-engage in a relationship with the brand and less disappointed if their actions had no impact. In short, status-seeking aggressors lack the negative emotions (anger, hatred) and desire to achieve something with their actions (harm, fairness, impact, change) compared to retributive and reparative aggression. These findings suggest that the emotions and motives previously considered essential characteristics of consumer aggression are not necessary for some consumers.

Taken together, these four studies support our theorizing that status motives play an important role in consumer aggression and demonstrate its conceptual distinction from prior accounts of aggression motives.

Hospitality in Situation: Dimensions and Ideal-types through the Airbnb Case

Mr. Felix Jelen, University of Rouen Normandie, France
Prof. Renaud Garcia-Bardidia, University of Bourgogne, France
Prof. Thomas Stenger, University of Poitiers, France

EXTENDED ABSTRACT

This research studies hospitality related to stays via Airbnb. It is based on interviews, observations and guided introspections collected from consumers (hosts and travelers). The results obtained reveal three typical forms of hospitality according to five dimensions, and the interest for consumer research of examining hospitality in situation.

“Welcome home”: the promise of a positive consumer experience based on hospitality is at the heart of Airbnb’s service offer. This community-based accommodation rental platform, created in 2008, has become the market leader. While the platform operates a first framing that contributes to a standardization of hospitality, a great deal of freedom is also given to hosts. Their conception of hospitality can then take on very distinct forms that deserve to be investigated : this is the research purpose.

The concept of hospitality in marketing is frequently associated with the hotel and catering industry (Brotherton and Wood, 2000 ; Lashley, 2000). It has led to the development of “hospitality management”, which focuses on its commercial and economic relationship (Brotherton and Wood, 2008). A second perspective has focused on hospitality as a social phenomenon (Derrida, 1999; Selwyn, 2000). It is based on its sociological, anthropological or historical aspects. These two approaches rarely dialogue with each other (Lynch et al., 2011). Brotherton’s definition of hospitality (1999) seems quite complete: “a contemporary human exchange, which is voluntarily entered into, and designed to enhance the mutual wellbeing of the parties concerned through the provision of accommodation and food or drink”. Each “hospitality situation” has a spatial dimension, a behavioral dimension, a temporal dimension and a physical dimension (Brotherton, 2006). While hospitality is at the heart of Airbnb’s promise, it clashes with the different conceptions discussed above. Indeed, this platform most often allows hosts to accommodate travelers in their homes in exchange for a financial payment. The proposed accommodations can thus be considered as “commercial homes” (Lynch and MacWhannell 2000). This hospitality is hybrid in several ways, at the crossroads of social, private and commercial domains (Lashley, 2000). But, how hospitality is produced in this specific context is still unknown.

In line with the academic literature, we posit that the hospitality situation (Brotherton, 2006) and the interaction between hosts and guests (King, 1995) must be the focus of analysis. The aim is to identify the practices of hospitality in situation and the way they express specific forms of hospitality. Any consumption situation (Belk, 1975; Goffman, 1964) can be determined by the triptych “participants - spatial and material elements - temporal dimensions (Michaud-Trévinal and Stenger, 2018). This triptych is largely consistent with the dimensions of hospitality described earlier (Brotherton, 2006 in particular). A comparison of these two conceptual frameworks reveals their complementarity. The aim here is to understand how hosts and travelers interact in these hospitality situations and to identify possible ideal-types via Airbnb.

This comprehensive consumer research is based on 43 interviews, 10 participating observations and 4 guided introspections of hosts and travelers, conducted in France in 2020-2021. The results analysis highlights the importance of hospitality in the discourses and practices of users. Their differing conceptions of hospitality are

reflected in the dimensions of hospitality situations. First, the participants differ, for example, some can modify the hospitality situation : “my host tells me that if I come back late, I must not make any noise: in another room, another traveler is sleeping” (observation note, 05/10/2020). The behavior of the hosts thus indicates the hospitality they wish to implement. In particular, they are more or less present. The spatial and physical dimensions of the situation are similarly adapted by the hosts to facilitate the implementation of hospitality. The situation of hospitality can also be seen through its temporal dimension. It varies according to the duration of the rental or its regularity: “the people who systematically come back, I leave them the key. That’s how it works, when you know each other you don’t need to make an appointment”. (Alain, host).

The analysis ultimately reveals three forms of hospitality in situation with Airbnb. The first is “convivial hospitality” which brings together the host and the traveler in a spirit of sharing. The latter is immersed in the intimacy of the host, which leads to numerous interactions (e.g. discussions, shared activities): “I just wanted to welcome people as if they were friends who were coming to spend a week in this accommodation” (Chantal, host). “Organized hospitality” aims at empowering travelers. The exchanges serve to make the stay more fluid by allowing the traveler to appropriate the accommodation as best as possible so that he or she can be independent. The host is at the disposal of his guest but does not wish to invest himself in the relationship too much: “I prefer to stay in the background and if they need me they contact me” (Paula, host). “Hotel hospitality” takes its reference model from hotel standards: the service is similar to that of professionals, even when the provider is not. The traveler is considered as a client who must benefit from an exemplary service and impeccable accommodation: “it must be welcoming and be at their disposal, it must be clean and perfect, like in a hotel” (William, host).

This research highlights a variety of possible ideal-types of hospitality when staying through Airbnb. It contributes to the existing literature by showing the value of recognizing a plurality of hospitalities rather than attempting to oppose contradictory views of it. Clearly, two of these forms (hotel hospitality and convivial hospitality) largely correspond to the two poles of the continuum proposed by Lynch et al. (2011), ranging from commercial to altruistic hospitality. However, our results reveal a third form, the organized hospitality, which undoubtedly reflects a specificity of organized exchanges with this intermediation platform. This contribution is based on the perspective adopted here, which aims to understand hospitality through its situations and dimensions. Our results thus confirm the interest of considering hospitality in situation and more broadly consumer research in situation (Brotherton, 2006; Michaud-Trévinal and Stenger, 2018).

The Consumption Escalation Effect of Over-priced Permission Fees on Consumer Purchase

Ms. Bingjie Li, University of Warwick, UK
Dr. Miaolei Jia, University of Warwick, UK
Prof. Nick Lee, University of Warwick, UK

EXTENDED ABSTRACT

How do people behave in the following consumption when the focal purchase needs an extremely expensive permission fee? Through five studies, the current research reveals a consumption escalation effect of costly permission fees on subsequent purchase decision-making and provides evidence for the underlying explanation of the proposed effect.

Imagine that you are considering owning a car. In your city, the government asks all citizens to first pay a certificate of entitlement (COE) to get the right of car ownership. Will the price of COE influence your car choice? Previous studies on mental budgeting have demonstrated that subsequent spending is negatively related to prior expenditure in the same category (Cheng et al., 2022; Heath & Soll, 1996). However, evidence from Singapore car sales shows the opposite fact that consumers tend to escalate car purchases when a car's COE is exceptionally high (The Independent, 2013). In this research, we investigate how prior additional fees affect consumers' subsequent choices. We reveal a consumption escalation effect of costly permission fees on subsequent purchases through one field data exploratory study and four lab experiments.

Based on sunk cost fallacy (Arkes & Blumer, 1985), we propose that a large amount of a permission fee facilitates consumption escalation on the subsequent purchase. Specifically, if individuals pay a high permission fee, they tend to spend more money on the focal purchase. We suggest the consumption escalation occurs because individuals tend to take action on the subsequent purchase to avoid wasting the pricey permission fee they have to pay.

In Study 1, we analyzed COE premiums of passenger cars and 63 car brands' sales data in Singapore from 2010 to March 2020. We found that COE price was negatively correlated to Economy and Business car sales ($r_{Economy} = -0.507, p < .000$; $r_{Business} = -0.500, p < .000$) but positively correlated to Luxury and Super Luxury car sales ($r_{Luxury} = 0.592, p < .000$; $r_{Super\ Luxury} = 0.392, p < .000$).

To rule out a potential systematic sampling bias in Study 1, we conducted experiments in Study 2-4. Particularly, Study 2 aims to examine the robustness of the main effect by using two different manipulations (Study 2a & Study 2b). In Study 2a, 497 Prolific workers were asked to choose from ten car prices (\$10,000 to \$100,000) after informed COE premium (\$50/\$500/\$5,000/\$50,000). A one-way ANOVA indicated a marginal significance of the proposed effect ($F(3, 493) = 2.28, p = .078, \eta^2 = 0.014$): Participants in the highest (vs. other conditions) COE condition ($M_{\$50000} = 2.48, SD = 2.41$) chose more expensive (vs. cheaper) cars ($M_{\$50} = 2.06, SD = 1.49, p = .070$; $M_{\$500} = 1.98, SD = 1.57, p = .032$; $M_{\$5000} = 1.96, SD = 1.58, p = .020$).

Besides, Study 2b is a two-level design (low COE: £1,000 vs. high COE: £10,000). 90 valid participants were asked to indicate a specific preferred car price by sliding a bar. An independent t -test further supported the main effect ($M_{low} = 3.73, SD = 0.41$; $M_{high} = 3.92, SD = 0.24$; $t = -2.592$; $p = .011$; *Cohen's d* = 0.34).

Study 3 explored the underlying mechanism of the proposed effect. Arkes and Blumer (1985) assert that sunk cost fallacy occurs because people deny admitting the wastefulness of prior investment; as a result, they invest more on the same investment. We propose that consumers consider a permit fee as a sunk cost of the focal purchase.

A costly (vs. cheap) permit fee leads to the upgrading effect on subsequent purchases because they want to avoid wasting and make the great money worthwhile. Study 3 used two items (1 = strongly disagree; 7 = strongly agree) to test the explanation: "I have already spent a lot on COE, so I don't want to succumb to buying a cheap car."; "It is a waste of the COE cost if I buy a cheap car." 196 workers completed a task similar to Study 2a but with two levels (high: £1,000 vs. low: £10,000). The results showed a robustness of the main effect ($M_{low} = 1.71, SD = 1.22$; $M_{high} = 2.05, SD = 1.42$; $t = -1.841$; $p = .067$; *Cohen's d* = 1.320). Meanwhile, a mediation analysis (Hayes, 2017) revealed the mediator role of wastefulness avoidance on the escalation effect ($\beta = .18, 95\% CI = [.0424, .3507]$).

Study 4 generalized the effect to a relatively cheaper scenario, consumption in a casino. 100 workers participated in a two-level study (entry fee: £10 vs. £100) and were asked to indicate how much to spend on casino tokens. Also, participants' income was asked as a covariate. An ANCOVA indicated the escalation effect of entry fee on preferred spending ($F(1,98) = 11.892, p = .001, \eta^2 = .125, M_{£100} = 165.00, SD = 172.55$; $M_{£10} = 68.08, SD = 67.85, p = .003$).

Our contributions are twofold: first, it explored the successive choices in the multipart pricing area rather than a one-off decision in which additional fees are often perceived as marketers' tricks. Second, it revealed a consumption escalation effect of costly permission fees on subsequent purchases, which diverges from a wane-and-wax relationship among the same categorical purchases in mental budgeting literature. By shedding light on the effect, this study helps consumers better understand successive decision-making, enhance their awareness of rational consumption, and make better financial decisions.

Effect of Pay Schedules on Consumer Budgets

Ms. Alicia Johnson, University of Arizona, USA

Dr. Anastasiya Pocheptsova Ghosh, University of Arizona, USA

EXTENDED ABSTRACT

We examine how consumers select budget timeframes and determine budget amounts across paycheck timeframes. Specifically, we examine how consumers incorporate two opposing factors into their budgets: shorter (e.g., weekly and bi-weekly) paycheck timeframes and longer expense timeframes (rent, utilities, that are paid on a monthly basis) when setting budgets.

Three studies show that when setting budgets, consumers focus on a salient timeframe – the time between pay checks - and selectively recruit timeframe congruent expenses into their budget. As a result, consumers who are paid more frequently consider fewer expenses and have lower budget amounts compared to consumers who are paid less frequently. Across secondary data analysis and several experiments, we demonstrate how pay schedules, which are set by employers and thus outside of consumers' control, affect consumers' ability to set well-calibrated budgets that adequately account for all their expenses.

Study 1: Budgeting App Data

Using a large dataset of budgeting application (Hello Wallet) users, we identify consumers' employers and construct pay frequency based on the pay schedules of all consumers who work for the same employer. The dataset consists of 25 million individual transactions from a panel of more than 25,000 clients observed from 2010-2014. The data provides the day one's budget was set, and the number and amount of the expenses included in one's budget. We use a structural equation model with pay frequency as the independent variable, the number of expenses as the mediator, and the dollar amount budgeted as the dependent variable.

Our results suggest that the effect of pay frequency on the number of expenses budgeted is positive and significant. The direct effect of pay frequency on monthly budget amount is insignificant. However, the indirect effect of pay frequency on monthly budget amount mediated through the number of expenses is positive and significant. The indirect effect accounts for 70% of the total effect. The unstandardized coefficient of the indirect effect of pay frequency on the amount budgeted is \$39.63, 95% CI: [\$17.50, \$61.76]). Thus, a change in pay frequency from bi-weekly to monthly (10 business days) would increase the monthly budget amount by \$396.30, 95% CI: [\$175, \$618]).

Study 2: The Effect of Self-Reported Pay Frequency

In Study 2, (https://aspredicted.org/ROT_MRZ), we demonstrate the effect of pay frequency on budget timeframes and amounts using a one cell between-subjects design. Participants (N=476 CloudResearch-approved Mturkers), indicated how often they receive income and provided their income per pay frequency. Next, they indicated the timeframe they typically set their budget for and provided an estimated budget amount for the upcoming budget period.

Budgeted Amount. As hypothesized, participants' monthly budget amounts varied significantly across pay frequencies ($\eta_p^2 = .027$). Relative to those who were paid monthly, those who were paid bi-weekly budgeted lower amounts ($M_{\text{Diff}} = \$276$; $t(472) = 1.69$, $p = .091$), as did those who were paid weekly ($M_{\text{Diff}} = \$590$; $t(472) = 3.37$, $p = .001$). Additionally, those who were paid weekly budgeted lower amounts relative to those who were paid bi-weekly, ($M_{\text{Diff}} = \$313$; $t(472) = 2.57$, $p = .010$).

Budget Timeframe. Participants' budget timeframes were significantly influenced by their self-reported pay frequency ($\eta_p^2 = .078$). Rel-

ative to those who were paid monthly, those who were paid bi-weekly budgeted for a shorter timeframe ($M_{\text{Diff}} = -.40$; $t(472) = 3.75$, $p < .001$). Additionally, those who were paid weekly budgeted for a shorter timeframe than those who were paid monthly ($M_{\text{Diff}} = -.71$; $t(472) = 6.20$, $p < .001$) and bi-weekly ($M_{\text{Diff}} = -.31$; $t(472) = 3.85$, $p < .001$).

Mediation. The effect of self-reported pay frequency on budget amount was serially mediated through budget timeframe ($ab = 89.86$, 95% CI: [49.42, 139.33]).

Study 3: The Effect of Manipulated Pay Frequency

In Study 3, we provide causal evidence. Additionally, we consider the impact of budget timeframe on the frequency of expenses consumers include in their budget, and how this influences budget amount. We hypothesize that consumers who are paid less (vs. more) frequently, budget across less frequent timeframes, include more less frequently occurring expenses, and budget higher amounts.

We used a two cell (New pay frequency: more vs. less frequent) between-subjects design. Participants (N=215 Prolific) indicated how often they receive income, and provided the income amount they receive each income period. Next, participants were randomly assigned to a revised pay frequency schedule one pay period more (less) frequent. If a participant indicated they were paid weekly, participants imagined they would be paid daily (bi-weekly), resulting in a 5-point scale (daily, weekly, bi-weekly, monthly, bi-monthly). Then, participants indicated the timeframe they would set their budget for as well as a budget amount. Lastly, participants indicated the expenses they included in their budget. Two coders, blind to condition and hypotheses, coded the expenses as occurring monthly, weekly, non-recurring, or uncertain (IRR=73%). None of the expenses were identified as non-recurring.

Budget Amount. Participants who imagined a less versus more frequent pay schedule budgeted higher amounts ($M_{\text{Diff}} = \$234$; $\eta_p^2 = .02$).

Budget Timeframe. A regression with budget timeframe as the dependent variable, and manipulated pay frequency (0=more; 1=less frequent), and self-reported pay frequency (1=weekly, 2=bi-weekly, 4=monthly) as predictors revealed that participants' budget timeframes were significantly related to their manipulated pay frequency ($b = .60$, $F(1, 211) = 17.33$, $p < .001$, $\eta_p^2 = .08$) controlling for monthly income ($p = .066$, $\eta_p^2 = .02$). The less frequently participants were paid, the longer the time periods they budgeted for. The effect of self-reported pay frequency was also significant ($b = .32$, $F(1, 211) = 19.33$, $p < .001$, $\eta_p^2 = .08$).

Number of Expenses. Participants who budgeted for a longer time period, included more monthly ($b = .66$, $F(1, 210) = 25.73$, $p < .001$, $\eta_p^2 = .11$) and weekly ($b = .20$, $F(1, 210) = 4.64$, $p = .032$, $\eta_p^2 = .02$) expenses. The number of uncertain expenses was not significantly influenced by budget timeframe or manipulated pay frequency ($ps > .35$).

Mediation. The effect of manipulated pay frequency on budget amount was serially mediated through budget timeframe and the number of monthly expenses ($ab = 136.84$, 95% CI: [54.57, 262.42]). The effect of manipulated pay frequency on budget amount was not serially mediated through budget timeframe and the number of weekly ($ab = 1.67$, 90% CI: [-7.03, 13.27]) or uncertain expenses ($ab = -.15$, 90% CI: [-10.31, 4.32]).

CONCLUSIONS

Across three studies we find that budget timeframes and amounts are influenced by consumer pay frequencies. Understanding whether consumers anchor on paycheck frequency and thus adopt shorter budget timeframes is important since most expenses are incurred monthly, raising a question of how shorter paycheck frequencies affects consumers' ability to create well-calibrated budgets. With more companies switching to more frequent payment schedules (DailyPay 2021; Fang, 2020; Shapiro 2021), our research has important implications for consumer welfare.

Apple from Apple, Coach from Coach: How the Feeling of Coherence Affects Store Choice

Mr. Deepak Sirwani, Cornell University, USA
Prof. Manoj Thomas, Cornell University, USA

EXTENDED ABSTRACT

When and why do shoppers prefer niche direct-to-consumer DTC stores over the more convenient multi-brand stores? Six pre-registered studies (N=2,635) and a field study (N=11,901) show that the feeling of coherence between the product and the store affects store choice, explaining why some DTC stores are more successful than others.

More and more brands are now opening direct-to-consumer or DTC stores, aiming to bypass intermediaries like Amazon and Walmart. The US DTC e-commerce sales are predicted to increase 128%, from \$77B in 2019 to \$175B by 2023 (eMarketer 2021).

However, all DTC stores are not equally successful. For some products, shoppers readily give up the convenience of the multi-brand stores and prefer to purchase from the brand's DTC store. For example, when buying a Coach bag, a shopper might like to purchase it from Coach.com. However, when spending the same amount of money on kitchen utensils, the same shopper might prefer to purchase these items on Amazon.com or Target.com. This research aims to understand when shoppers prefer specialized DTC stores to their regular multi-brand retailers. What factors influence the preference for DTC stores? And what psychological mechanisms underlie this behavioral pattern?

We argue that apart from economic considerations, purely psychological reasons also play a role in shoppers' DTC store preference. Even when the DTC stores do not offer any tangible benefits (i.e., price, quality, and service levels are the same), people might choose them simply because of the psychological fit or the coherence between the DTC store and the product. That is, for a shopper who regularly shops at Amazon.com, although it might be more convenient to buy an Apple laptop or a Coach bag from Amazon.com, it might feel more coherent to purchase an Apple laptop from Apple.com and a Coach bag from Coach.com. We label this phenomenon as the store-product coherence effect.

Specifically, we demonstrate that when consumers' felt involvement—the *phenomenological experience of involvement stemming from the personal relevance of the stimulus or the task*—in the purchase increases, they become more likely to choose the coherent DTC store (Celsi and Olson 1988). Felt involvement increases the relevance of affective inputs in decision-making. Therefore, factors that increase felt involvement, such as personal relevance or perceived value, increase the importance and subsequent reliance on the feeling of coherence in the store choice. We tested the store-product coherence effect using six pre-registered online studies and one study analyzing actual online transactions.

Study 1 (N=450) and study 2 (N=450) aimed to test whether store-product coherence can influence shoppers' preferences for the DTC store. In study 1, participants had to decide whether they would buy a product from an online store, Apple.com or Amazon.com. We used two different products (Apple Watch vs. Logitech Webcam) to manipulate the Apple store-product coherence. Half the participants considered buying an Apple watch, whereas the other half considered buying a Logitech webcam. In study 2, we kept the product and the store identical across the two conditions. We manipulated DTC store-product coherence by merely changing the store name. Participants decided whether they would prefer to buy a Coach bag from Coach's DTC store or Macys.com. Half the participants were told that Coach's DTC store is called Coach.com, whereas the other half

were told that Coach's DTC store is called Tapestry.com, Tapestry being the name of the company that owns the Coach brand.

Note that these two studies used externally valid designs as Logitech webcams are sold on the Apple and Amazon stores, and Tapestry is indeed the company's name that owns the Coach brand. We informed participants that the two stores are identical on all parameters such as price, return policy, quality, etc. in all the studies. We found that participants were more likely to select the DTC store when DTC store-product coherence was high (i.e., study 1-47.89%; study 2-70.09%) compared to when DTC store-product coherence was low (i.e., study 1-19.72%, $p<.0001$; study 2-46.46%, $p<.0001$). We also found that perceived coherence fully explained the effect of DTC store-product coherence on store choice.

Study 3A (N=255) tested whether the store-product coherence effect is stronger in categories where felt involvement is high. Participants saw seven products—vacuum, jeans, chocolate, TV, headphones, bag, and laptop—and indicated whether they wanted to buy each product from the brand's DTC store or Amazon.com. Next, we assessed participants' felt involvement using three dimensions (care, importance, and concern) in each purchase decision. We found that felt involvement significantly increased participants' propensity to choose the DTC store ($B=.71$, $p<.0001$).

Study 3B (N=11,901) analyzed actual purchase data from an online US consumer panel. Each data point corresponded to the purchase of one of the 15 electronic products—from five brands (HP, Apple, Lenovo, Dell, and Samsung) and three product categories (laptops, desktop computers, and tablets). We conducted a separate study to measure shoppers' felt involvement for each of the 15 products ($M_{Apple\ laptop}=.21$, $M_{Lenovo\ laptop}=-.05$). Using store choice (1-DTC, 0-other stores such as Walmart, Amazon, Best Buy, etc.) as the dependent variable; felt involvement as the independent variable; and brand, category, product price, and various shopper characteristics as covariates, we found that felt involvement significantly predicted consumers' propensity to choose the brand's DTC store ($p<.001$).

Study 4 (N=330) used a quasi-experimental consequential design. We posited that New Yorkers (vs. other US state residents) would perceive a New York University (NYU) coffee mug as more personally relevant and hence, would prefer to purchase it from NYU online store (vs. Amazon.com). To test this idea, we recruited half the participants from NY state and the other half from the rest of the US. We showed participants NYU coffee mugs and asked them to indicate their mug and store preferences. We found that NY participants were more likely to choose the DTC store (59.85%) compared to non-NY participants (44.59%, $p<.01$). Seven lucky participants received the NYU mugs based on their responses.

In Study 5 (N=300), we manipulated felt involvement by changing the product's perceived value (i.e., \$30 vs. \$250 Lacoste sneakers). We found that participants were more likely to choose the DTC store when the perceived value of sneakers was high (56.74%) than when it was low (42.36%, $p=.018$). Finally, study 6 (N=850) showed that even when the perceived value of a product is low, individuals who engage in experiential thinking prefer the more coherent DTC store to the more convenient multi-brand store.

On The Hunt: Search Enjoyment Motivates Collecting Behavior

Ms. Elena Bocchi, City, University of London, UK
Dr. Adam Eric Greenberg, Bocconi University, Italy
Prof. Zachary Estes, City, University of London, UK

EXTENDED ABSTRACT

Five pre-registered studies ($N = 1,951$) using real behavioral tasks, incentive-compatible designs, and hypothetical scenarios demonstrate that when people collect, or simply perceive certain items as collectibles, they experience greater search enjoyment, which in turn boosts their valuation for additional items.

Collecting is a unique and yet very popular form of consumption (Evers, Ryan, and Lindenberg 2022) with substantial economic and social impact (MarketDecipher 2021; Murphy 2022). Yet, little is known about this phenomenon. Most academic work on collecting has focused on delineating extreme collectors' distinguishing features (Carey 2008; Baekeland 1994) and motivations to collect (Belk 1994, 1995; Formanek 1994; McIntosh and Schmeichel 2004; Pearce 1994), or possible item-specific triggers of collecting projects (Gao, Huang, and Simonson 2014; Keinan and Kivetz 2010). Yet no prior empirical work has asked whether framing products as part of a collection affects consumers' valuation of those products, and, if so, why. The current research aims to close this gap.

Being collecting a transformative and inherently playful activity (Belk 1995; Danet and Katriel 1989), we posit that when sought goods are framed as part of a collection (i.e., they are labelled as collectibles in consumers' minds), they become intrinsically more desirable generating higher enjoyment during the search and acquisition process. Such heightened enjoyment leads people to increase their valuation for such items.

We demonstrate our account across five pre-registered studies using real behavioral tasks, incentive-compatible choices, and hypothetical scenarios.

Studies 1 and 2 ($N=550$) tested, respectively, whether collecting increases search enjoyment, and valuation in a highly naturalistic setting: eBay. After reflecting on a lay definition of collection, participants self-selected an item that they either collected or did not collect, and then engaged in a search task for two (study 1) or just one (study 2) additional items on eBay. In Study 1, participants rated how much they enjoyed searching for the items, and as predicted ($n = 22$ preregistered exclusions), people enjoyed the search process to a greater extent for collected ($M = 5.30$, $SD = 1.39$) than for non-collected items ($M = 4.30$, $SD = 1.89$; $t(226) = 4.52$, $p < .001$, $d = .60$). In Study 2, participants made an incentive-compatible choice between an eBay gift card valued at the price of their chosen item (proxy of higher valuation), and a 20% lower-priced cash bonus. As predicted ($n = 25$ preregistered exclusions), the eBay gift card was chosen more often (36%) in the collecting than in the non-collecting condition (20%), $B = 0.81$, $SE = .28$, $z = 2.88$, $p = .004$, suggesting higher valuation for collected items. The effect was not due to variations in item prices ($M_{collecting} = 19.32$, $SD = 10.91$ vs. $M_{non-collecting} = 19.00$, $SD = 10.87$; $t(273) = .25$, $p = .805$).

Studies 3A and 3B ($N=601$) tested whether search enjoyment underlies the effect of collecting on valuation through mediation. In Study 3A, participants self-selected a collected (vs. non-collected) item, and expressed their preference between a hypothetically chosen, yet unexpectedly overpriced item (proxy of higher valuation) versus an alternative, more affordable option on a continuous bipolar scale, and rated the expected enjoyment to search for this additional piece. Results shows that ($n = 26$ preregistered exclusions) people preferred the unexpectedly overpriced item ($M_{collecting} = 4.13$,

$SD = 1.88$ vs. $M_{non-collecting} = 3.28$, $SD = 2.01$; $t(273) = 3.57$, $p < .001$, $d = .44$) and stated higher search enjoyment for collected than non-collected items ($M_{collecting} = 5.37$, $SD = 1.26$ vs. $M_{non-collecting} = 4.11$, $SD = 1.81$; $t(273) = 6.56$, $p < .001$; $d = .81$), and search enjoyment successfully mediated the effect, $B = .26$, $SE = .11$, $CI95 = (.06, .49)$. Study 3B had the same set-up, with the exception that the items (coffee mugs) were held constant and their perception as collectibles (vs. not) was experimentally induced. The effects of collecting on valuation ($M_{collecting} = 4.29$, $SD = 1.85$ vs. $M_{non-collecting} = 3.56$, $SD = 1.99$; $t(299) = 3.32$, $p < .001$, $d = .38$), search enjoyment ($M_{collecting} = 4.92$, $SD = 1.45$ vs. $M_{non-collecting} = 3.81$, $SD = 1.65$; $t(299) = 6.22$, $p < .001$, $d = .71$), as well as the predicted indirect effect, $B = .42$, $SE = .11$, $CI95 = (.22, .66)$ replicated.

Study 4 ($N=800$) followed a 2 (collecting: present vs. absent) x 2 (search enjoyment: low vs. control) between-subjects design and tested whether search enjoyment underlies the effect of collecting on item valuation, using moderation. Participants focused on either a collected or non-collected item, and imagined going to either a neutrally-valenced or unpleasant store to search for an additional piece. We predicted the effect would replicate in the neutral search environment scenario (control), but it would attenuate in the unpleasant one as search enjoyment would be low. All participants rated their willingness to buy their chosen, yet unexpectedly overpriced item (proxy of higher valuation). After making the preregistered exclusions ($n=51$), the 2x2 between-subjects ANOVA yielded significant main effects for collecting ($M_{collecting} = 2.71$, $SD = 1.82$ vs. $M_{non-collecting} = 2.28$, $SD = 1.65$; $F(1, 745) = 20.10$, $p < .001$; $d = .25$), and search enjoyment ($M_{neutral} = 3.62$, $SD = 1.67$ vs. $M_{unpleasant} = 1.37$, $SD = .90$; $F(1, 745) = 544.76$, $p < .001$, $d = 1.68$), and the predicted significant interaction ($F(1, 745) = 4.38$, $p = .037$), such that in the neutral search environment, people were more willing to buy the item when collecting than when not collecting ($M_{collecting} = 3.94$, $SD = 1.65$ vs. $M_{non-collecting} = 3.31$, $SD = 1.63$; $F(1, 745) = 21.53$, $p < .001$, $d = .38$), but such effect was attenuated in the unpleasant search environment ($M_{collecting} = 1.49$, $SD = .98$ vs. $M_{non-collecting} = 1.26$, $SD = .80$, $F(1, 745) = 2.87$, $p = .091$, $d = .26$).

Our findings suggest that when people collect (or simply perceive collecting) a certain item type, they experience greater enjoyment during the search process, which in turn boosts their valuation for such items. Our findings are robust with real (studies 1, 2, 3A, 4) and fictitious (study 3B) collectibles, in both naturalistic (eBay) and controlled (online) settings, using self-selected (study 3A, 4) and constant items (study 3B).

Video cures mind: Estimating how the disaster shifts video consumption

Mr. Zizhou Peng, Warwick Business School, UK

Dr. Miaolei Jia, Warwick Business School, UK

Dr. Iman Ahmadi, Warwick Business School, UK

Prof. John Rudd, Warwick Business School, UK

EXTENDED ABSTRACT

Natural disasters are believed to change the way how people use social media platforms and consume online streaming content. This research explores how the pandemic, as a context of a disaster, impacts consumer video consumption behavior. Specifically, it examines how consumers react to positive versus negative videos during a disaster.

Video viewing has gradually become the most popular web-based activity and is predicted to account for around 82% of all IP traffic by 2022 (Cisco, 2021). Such an increase in video's popularity calls for a better understanding of what types of videos become popular among viewers (e.g., received more views, likes, comments, and shares). Although past research highlights the importance of valence on consumer engagement such as viewing, liking, commenting and sharing (Baumeister et al., 2001; Berger & Milkman, 2012), whether consumers engage more with positive content (as opposed to negative content) is still debatable. We argue that a context, for example a disaster, is essential to understand the impact of valence on engagement. Prior research has solely focused on a certain timeframe and fails to consider the context in their conclusions.

Therefore, to fill these gaps, we utilize COVID-19 pandemic as a viable context and investigate how valence of videos on YouTube affects consumer engagement. More specifically, we aim to answer the following questions: (1) What types of videos (positive or negative) do consumers engage more with before and during a natural disaster? (2) What are the underlying motives of such a behavior? (3) How do these motives evolve during the development of the disaster?

METHOD

We compiled two datasets, covering the time periods before and during the COVID-19 pandemic. Both datasets contained the daily YouTube trending videos in the UK. Our first dataset contained 38,916 videos on the trending list from November 14, 2017 to June 14, 2018 (i.e., the pre-COVID-19 time period). The second dataset, which covered the second national COVID-19 lockdown in the UK, composed of 29,597 trending list videos from August 12, 2020 to January 10, 2021. We then applied the propensity score matching technique to account for the self-selection bias.

For the resulting balanced datasets, we used the sentiment of the video title as a proxy to measure video valence. To obtain the sentiment of video titles, we relied on standard automated text mining procedures. We started by pre-processing all video titles, which consist of tokenizing, stemming, and removing unmeaning phrases (see Klostermann et al. (2018) for standard text analytics procedure). After pre-processing, we used three different approaches for sentiment analysis: Two lexicon and rule-based tools and one machine learning classifier.

We applied AFINN lexicon (Nielsen, 2011) for the main analysis, consisting of over 3,000 coded words. Each word in this dictionary is manually assigned with a score ranging from -5 (negative valence) to +5 (positive valence). The overall valence of the title was calculated by summing up the score for each word within the focal title. We then ran regression models for analysis.

The other two sentiment analysis tools including VADER and distilbert-base-uncased-finetuned-sst-2-english (a machine learning classifier) have been applied for robustness checks. We collected comments for each video and applied VADER for an additional robustness check.

RESULTS

In **Study 1**, regression models indicated a significant and consistent effect of video valence on consumer engagement. Comparing the periods before and during the pandemic revealed an opposite effect direction. In specific, videos with negative titles received more views before the pandemic ($\beta = -0.024$, $p < 0.001$), while videos with positive titles received more views during the pandemic ($\beta = 0.074$, $p < 0.001$). We also found a consistent impact of video valence on other consumer engagement metrics including likes, comments, and virality.

In **Study 2**, to get a better insight into the increased consumption of positive videos during the pandemic, we incorporated national-wide personal well-being data from UK Office for National Statistics (2021). We divided the COVID-19 dataset (the one only contains the trending videos during the pandemic) into five phases, based on four key dates: September 14th when the "Rule of six" social distancing policy was executed; October 31st when PM announced a second lockdown; December 2nd when the second lockdown ended; and January 6th when the third lockdown started. We calculated the strengths of effects and average anxiety levels among each time phase. The estimated coefficient of our main effect was highly correlated with the average national-wide anxiety level ($r = 0.75$).

In **Study 3**, we focused on the same time periods as described in Study 1 and collected daily trending videos in the US. Our results confirmed our main conclusion in Study 1: Before the COVID-19 pandemic, consumers engaged more with negative videos. However, such behavior was shifted during the COVID-19 pandemic, where consumers revealed more taste for positive videos.

IMPLICATIONS

Our research revealed that people actively seek for more positive media content after the outbreak of COVID-19. We suggested and demonstrated that consumers became more dependent on positive videos when they felt more anxious during the pandemic, especially when stricter lockdown restrictions were imposed. Stronger negative emotions may intensify consumers' need for mood regulation. Therefore, they showed increasing favour of positive videos and regarded watching positive videos as an active strategy to cope with negative moods. The revealed effect was not unique to the UK. The same pattern for the US suggested that the phenomenon could be universal for other countries in the world.

Brand Activism: What Factors Shape Outcomes for Represented Consumers?

Ms. Hilary Wright, Creighton University, USA

Dr. Stacey Menzel Baker, Creighton University, USA

EXTENDED ABSTRACT

Integrating social identity and consumer vulnerability, this phenomenological study explores how consumers represented in brand activism experience and evaluate brand activism messages. It identifies factors that shape consumers' brand activism experiences with the aim of helping leaders understand how brand activism can be used to effectively improve relationships and society.

Over the last decade, companies have increasingly participated in brand activism, taking a stance on a divisive sociopolitical issue (Moorman, 2020). Although research has examined brand activism's effect on general stakeholder groups (Bhagwat et al., 2020; Mukherjee & Althuizen, 2020; Burbano, 2021), little is known about how brand activism is perceived by those represented in activism messages. Grounded in social identity theory and the consumer vulnerability literature, this study addresses two questions: 1) How do consumers' issue-relevant identities impact brand activism's effect on consumer attitudes and behaviors? 2) What factors influence brand activism evaluations by the consumers who are represented in the activism? Using phenomenological research, the paper explores the lived experiences of consumers advocated in brand activism and offers insights to firms employing brand activism to improve society and build relationships.

Social identity is "part of an individual's self-concept which is derived from his knowledge of his membership of a social group (or groups) together with the value and emotional significance attached to that membership" (Tajfel, 1981, p. 255). Social identity is applied in the marketing literature to examine how consumers' sense of self impacts their perceptions and behaviors in the marketplace (Bhattacharya & Sen, 2003; Reed, 2002). This study posits social identity could explain how consumers experience activism.

Consumer vulnerability refers to "a state of powerlessness that arises from an imbalance in marketplace interactions or from the consumption of marketing messages and products" (Baker et al., 2005, p. 134). The vulnerability literature explores factors leading to consumer vulnerability and how consumers respond to vulnerability, often with the aim of exposing vulnerable experiences to bring about change in the marketplace (Baker et al., 2005). It is unclear whether brand activism empowers and/or disempowers people in represented groups. For consumers experiencing vulnerability, brand activism may prompt different evaluations and outcomes unlike general consumers.

To understand the lived experiences of consumers advocated in brand activism, a phenomenological approach using depth interviews is adopted. Phenomenological research seeks information-rich participants who have knowledge regarding the phenomenon under investigation; therefore, the purposive sample includes two social groups: LGBTQ (Lesbian, Gay, Bisexual, Transgender, and Queer) and BIPOC (Black, Indigenous, and People of Color). These social groups have recently and regularly been represented in brand activism, which means they have rich experiences to share. In addition, each group represents multiple identities, which offers diverse experiences to inform the study. Members of LGBTQ and BIPOC communities may perceive they have experienced vulnerability or trauma in the marketplace, which gives them a unique experience of being advocated for by an institution where they have previously been mistreated. Participants were recruited via personal and professional networks and through a snowballing technique.

Following a semi-structured interview guide, the interviews explored participants' experiences with the phenomenon, including questions about past brand activism experiences, social identities, and brand activism outcomes. Interviews took place via Zoom and were transcribed by two independent workers. In total, the 23 depth interviews produced 29 hours, 30 minutes, and 47 seconds of recorded interview time. The transcripts totaled to 476 pages and 237,950 words.

Using phenomenological data analysis, significant statements were organized into themes or "clusters of meaning" (Creswell and Poth 2018, 79) to understand the phenomenon. The analysis followed Thompson's (1997) three-stage interpretive framework: 1) identifying themes within individual interviews, 2) finding patterns of shared themes across interviews, and 3) determining broader theoretical and managerial implications.

The results demonstrate that social identity plays a complex and nuanced role in shaping represented consumers' brand activism experiences. Synthesizing the data from 23 interviews, 25 themes emerge that influence brand activism evaluations by consumers who are represented in brand activism, including six themes related to social identity. The study reveals that advocative brand activism triggers various cognitive processes resulting in both positive and negative behavioral, affective, and cognitive consumer outcomes. To summarize the findings, the brand activism evaluation framework is proposed to explain consumers' process of brand activism evaluation.

While other studies have focused on general stakeholder experiences (Bhagwat et al. 2020; Mukherjee and Althuizen 2020; Burbano 2021), to the researchers' knowledge, this is the first to focus on the experiences of those advocated in brand activism. This study yields unique insights into consumer behavior not otherwise observable because the unique experiences of minorities, who are often at the center of brand activism messages, are eclipsed in studies that sample a general consumer population. Further, this study takes the novel approach of integrating social identity and consumer vulnerability literatures with brand activism. Together, these findings can help leaders better understand the impacts of brand activism on the communities they desire to support and how to effectively use activism to improve relationships and society.

Feeling threatened by robots? The role of service failure on consumers' service evaluations

Dr. Ada Maria Barone, Goldsmiths, University of London, UK

Dr. Emanuela Stagno, University of Sussex, UK

Dr. Carmela Donato, University of G. D'Annunzio Chieti and Pescara, Italy

EXTENDED ABSTRACT

Across four studies, we show that consumers respond more positively to service failure involving robots than automatic machines. We show that this effect is driven by attributions of agency and reduced threat to human distinctiveness perceived when robots make mistakes (service failure) than when they work as expected (service success).

Understanding how individuals react to artificial intelligence is crucial and increasingly important. In particular, "anthropomorphism" (Epley et al., 2007), that is the extent to which machines are imbued with human-like characteristics, is a key determinant of consumers' response to AI. This is the case of service robots, which as a result are perceived as having more "agency" (Yam et al., 2021), but also as threatening "human distinctiveness" (Mende et al., 2019).

However, while this effect has been shown when robots are working as expected (i.e., service success) (e.g., Mende et al., 2019), prior research has neglected to account for the threat perceived by consumers when robots make mistakes (i.e., service failure). We fill this gap and show that in the case of service failure (vs. service success) the negative effect of the perceived threat on evaluation is mitigated. We argue that this occurs because making mistakes and being wrong is an innate human trait (Schulz, 2011) that dampens consumers' fears of robots threatening human relations, human identity, and humanity in general. We test our prediction in four experimental studies.

Through an Implicit Association Test (IAT; Greenwald et al., 1998), Study 1 (N = 72, 81% female, $M_{age} = 22.09$, $SD_{age} = 0.94$, European sample) shows that participants had the tendency to attribute agency to the robots rather than to the automatic machine ($M_{D-score} = 0.160$, $SD_{D-score} = 0.440$; $t(71) = 3.085$, $p < 0.0020$, 95% CI [0.05667, 0.2638]). In this sense, we show that consumers subconsciously believe that robots are more intelligent and have more agency than traditional machines and that this belief is activated regardless of whether individuals can observe the physical appearance of such robots.

In Study 2a (N = 400, 85% female, 4% non-binary; $M_{age} = 24.17$, $SD_{age} = 6.82$, US sample from Prolific), and Study 2b (N = 400, 76% female, 3% non-binary; $M_{age} = 26.14$, $SD_{age} = 7.87$, US sample from Prolific), we employed a 2 (type of agent: robot vs. self-check-in machine) \times 2 (service outcome: success vs. failure) between-subjects design to test the effect of agent's type and service's outcome on consumers' evaluation of the service. We tested our conceptualization respectively in two different settings: hotel check-in and restaurant order. In both studies, we run a conditional moderated mediation on PROCESS (model 14) with 10,000 bootstrap analyses. Results of Study 2a show that participants attributed more agency to the robot than to the automatic machine ($b = .2954$, $SE = .1134$, 95% CI [.0664, .5124]). Moreover, an increase in perceived agency leads to an increase in hotel evaluation ($b = .2346$, $SE = .0581$, 95% CI [.1203, .3488]). Most importantly, the index of moderated mediation was significant (Index = $-.0720$, $BootSE = .0490$, 95% CI [-.1894, -.0018]). When the service is a failure, participants tend to give higher hotel evaluation when they perform the check-in with the robot instead of the automatic machine (.1055, $BootSE = .0546$, CI 95% [.0218, .2320]). When the service is a success, there is no significant effect of the type of agent on hotel evaluation (.0356,

$BootSE = .0254$, [-.0044, .0940]). The direct effect of type of agent on hotel evaluation was not significant ($b = -.1092$, $SE = .1223$, 95% CI [-.3497, .1312]). Results were replicated in Study 2b.

In Study 3 (N = 400, 77% female, 3% non-binary; $M_{age} = 35.21$, $SD_{age} = 14.47$, US sample from Prolific), we used the same design as Study 2a and 2b but also included a measure of human identity threat (HIT; Mende et al., 2019).

We run model 87 in PROCESS (Hayes, 2018) with perceived agency as first mediator and HIT as second mediator. The results show that participants attributed higher agency to the robot than they did to the automatic machine ($b = .3130$, $SE = .1209$, 95% CI [.0753, .5507]). Moreover, an increase in perceived agency leads to an increase in human identity threat ($b = .2563$, $SE = .0603$, 95% CI [.1379, .3747]). Most importantly, the index of moderated mediation was significant (Index = $-.0265$, $BootSE = .0162$, 95% CI [-.0669, -.0041]). When the service is a success, participants tend to evaluate the service less positively when they interact with a robot rather than an automatic machine ($-.0306$, $BootSE = .0170$, CI 95% [-.0719, -.0057]). When the service is a failure, there is no significant effect of type of agent on evaluation ($-.0041$, $BootSE = .0065$, [-.0196, .0072]). The direct effect of type of agent on evaluation was not significant ($b = -.0387$, $SE = .0568$, 95% CI [-.3026, .2253]).

Overall, our results contribute to a better understanding of consumers' reactions to automatic machines in service contexts. In particular, we show that consumers are more likely to judge a service failure less negatively when the failure involves a robot rather than an automatic machine. We provide evidence that while robots are perceived as having agency and as threatening human identity, the negative effect of threat on consumers' evaluations is mitigated in case of service failure.

The Influence of Caffeine on the Attraction Effect

Mr. Michael Canty, Otto von Guericke University Magdeburg, Germany

Mr. Felix Lang, Chemnitz University of Technology, Germany

Prof. Marcel Lichters, Chemnitz University of Technology, Germany

Prof. Marko Sarstedt, Ludwig-Maximilians-University Munich, Germany

EXTENDED ABSTRACT

Caffeine as the world's most popular stimulant has been widely neglected in consumer research. We manipulated participants' caffeine consumption and assessed its impact on the attraction effect. We find that caffeine increases the attraction effect in consequential choice scenarios and that this increase is mediated by cognitive processing.

Caffeine is the most widely used psychostimulant worldwide. One recently published study shows that caffeine consumption increases spending behavior (Biswas et al. 2022). However, despite caffeine's huge popularity and ubiquitous presence in and around shopping endeavors (Dolbec, Arsel, and Aboelenien 2022), further studies on caffeine's effect on consumer behavior are missing. We investigate whether caffeine increases consumers' propensity for decision anomalies, more specifically, the attraction effect as the most prominent context effect in consumer research literature (AE; Lichters, Sarstedt, and Vogt 2015).

The AE can be observed when an asymmetrically dominated decoy option is added to a binary choice set consisting of a target and competitor product option: Introducing the decoy, which is dominated by the target but not by the competitor, increases consumers' preference for the target (Huber, Payne, and Puto 1982). Several researchers propose that detecting the dominance relationship requires cognitively demanding and deliberate attribute-wise comparisons of choice options (Pettibone 2012), especially with more complex realistic choice stimuli (Lichters et al. 2017).

Caffeine enhances cognitive processing capabilities, such as reasoning (Jarvis 1993) and attention (Heatherley et al. 2005). Given caffeine's enhancing effect on cognitive processing capabilities, we expected caffeine to increase the AE. We assess this expectation in two double-blinded lab experiments masked as a coffee tasting.

Study 1 applied a 2 (caffeine: treatment vs. placebo) \times 2 (choice set: binary vs. trinary) between-subjects design with real products (trail mixes) in a consequential choice setting. Participants received a 200 ml decaffeinated coffee (placebo group), mixed with 200 mg of caffeine in the treatment group. Participants completed five choice tasks composed of identical product options at varying prices. Participants in the binary condition chose between a lower-price and a lower-quality competitor (L) and a higher-price and a higher-quality target (M). Choice sets in the trinary condition consisted of the identical two products and an additional decoy (D), dominated by M in price and quality. Each choice set also included a no-buy option. A sample of 64 participated in study 1 ($n_{\text{treatment}} = 31$, $n_{\text{placebo}} = 33$). We find a significant AE in the treatment group ($p_{\text{directed}} = .006$, OR = 4.31), but not in the placebo group ($p_{\text{directed}} = .359$, OR = 1.63). Hierarchical logistic regression reveals a significant interaction effect ($\beta = 18.13$, $z = 2.28$, $p = .022$), whereas both main effects were not significant, indicating that the AE only emerges in the treatment condition.

Study 2 also applied a 2 (caffeine: treatment vs. placebo) \times 2 (choice set: binary vs. trinary) design with the same caffeine manipulation as in study 1. Participants chose from five choice sets manipulated between-subjects in the product category *spekulatius* (spiced cookies). These between-subjects-manipulated choice sets occurred between each five binary and trinary choice sets as a within-subjects manipulation (product category: chewing gums). We applied a forced-choice setting without a no-buy option. We used the enhanced version of the Cognitive Reflection Task (CRT-L; Primi et al. 2016) to assess caffeine's influence on cognitive capabilities. A sample of 51 partici-

pated in study 2 ($n_{\text{treatment}} = 26$, $n_{\text{placebo}} = 25$). On a within-subjects level, the AE emerges in the treatment group ($p_{\text{directed}} = .002$, OR = 7.00) but not in the placebo group ($p_{\text{directed}} = .813$, OR = 0.67). Switching rates were significantly higher in the treatment ($M = 0.09$, $SD = 0.25$) than in the placebo group ($M = -0.01$, $SD = 0.12$; $t(49) = 1.82$, $p_{\text{directed}} = .037$, Cohen's $d = .51$), confirming a stronger AE after caffeine consumption. Mediation analyses (PROCESS model 4) reveal a significant indirect effect of caffeine on switching rates mediated by cognitive reflection ($b = 0.18$, $SE = 0.09$, 95% CI [.01, .35]). Furthermore, a hierarchical logistic regression reveals a significant interaction effect of caffeine and choice set ($\beta = 36.74$, $z = 6.46$, $p < .001$), thereby also confirming a stronger AE in the treatment group in between-subjects-manipulated choice sets.

This research shows that consumers' purchase decisions depend on psychophysiological state alterations induced by psychostimulants. Specifically, caffeine increases the AE. This increase is mediated by enhanced cognitive processing capabilities. These results provide evidence that caffeine consumption enhances consumers' decision making in line with behavioral anomalies.

Consumer Empiricism: Consumers' quasi-scientific strategies to evaluate consumption routines

Mr. Jan-Hendrik Bucher, Universität St. Gallen, Switzerland
Prof. Johanna Gollnhofer, Universität St. Gallen, Switzerland

EXTENDED ABSTRACT

How do consumers evaluate consumption routines? Using a qualitative research design, we study consumers who quasi-scientifically evaluate consumption routines. We conceptualize consumers' quasi-scientific approach as consumer empiricism. We uncover four empiricist strategies consumers use to evaluate consumption routines and show how an increasing lay-notion of rationality impacts consumption behavior.

How do consumers evaluate consumption routines? Prior research suggests that consumers use feelings (interpretive reasonings) and reasons (rational reasonings) to guide their evaluations (Hsee et al., 2015). While consumers' interpretive reasonings have been extensively studied (suggesting that consumers for instance rely on brands (e.g., Beverland et al., 2020; Holt, 2002) or aesthetics (e.g., Arsel & Bean, 2013; Huff, Humphreys & Wilner, 2021) to evaluate products), research on consumers' rational reasonings remained scant. To study consumers who seek rational reasonings to evaluate consumption routines, we conducted in-depth interviews and netnographic data collection between 2019 and 2022

We find that consumers use one of four types of quasi-scientific at-home experiments to evaluate consumption routines with seemingly objective and rational reasonings: *control group comparisons* (Consumers compare a purchased product or its effect to a control condition that is not exposed to the product.), *pre-post comparisons* (Consumers compare a purchased product or its effect to the past, prior to using the product.), *side-by-side comparisons* (Consumers compare multiple products of the same category simultaneously.), and *sequential comparisons* (Consumers compare multiple products of the same category in chronological order.). With each strategy, consumers aim for objective and lay-rational reasonings to guide their evaluations. We conceptualize consumers' quasi-scientific evaluation strategy as *consumer empiricism*. Empiricists believe that theories and hypotheses must be observed and tested to be accurate (Curd & Psillos, 2013). Primarily, this worldview is found in philosophy, experimental research, and natural sciences. We find it with consumers who seek to evaluate consumption routines.

Our study finds that consumers increasingly seek quasi-objective lay-rational reasonings to guide their evaluations (complementary to interpretive evaluation strategies) for high-involvement consumption practices as they are driven by three interlocking cultural discourses: *institutional mistrust* (Consumers mistrust brands and institutions.), *hyper-individualization* (Consumers believe they are special and statements from others do not apply to them.), and an urge for *optimization* (Consumers seek to continuously optimize themselves and their consumption behavior.).

Our literature review finds numerous studies that allude to the phenomenon of consumer empiricism. Recent research suggests that more and more consumers use empiricist (analytical, evidence-based, and quasi-rational) strategies to guide their evaluations (e.g., Maciel & Wallendorf, 2016). By mapping the instances of consumers' quasi-systematic and quasi-objective strategies evaluation strategies, we show that the phenomenon of consumer empiricism is evident in previous literature but has not yet been identified and studied as such.

Uncovering and conceptualizing the phenomenon of consumer empiricism yields multiple contributions to consumer research and

marketing practice. First, our study helps to disclose how consumers form product evaluations (e.g., Hsee et al., 2015). Specifically, we stress product evaluation as an explicit process, in contrast to research that theorizes implicit evaluation strategies (e.g., Wirtz & Bateson, 1999). Second, this research shows how an increasing lay-notion of rationality impacts consumer behavior. Third, we contribute to understanding how consumers develop and share lay theories (Broniarczyk & Alba, 1994). In contrast to naïve theories (Deval et al., 2012; Faro, McGill, & Hastie, 2010) we show how consumers believe to develop empirically-grounded logical and profound theories. Fourth, we suggest that the phenomenon of consumer empiricism might affect how consumers perceive marketing claims. Our findings and our literature review suggest that consumers with an empiricist mindset do rather not trust marketing claims a priori (in principle and without further evidence). Instead, we find consumers who test marketing claims a posteriori (drawing from empirical evidence). Finally, our study paves research avenues for future quantitative analyses.

Natural wines as subversive art: Exploring expert consumer and producer framings of an unconventional product

Dr. Camilo Peña, The University of British Columbia, Canada
Dr. Annamma Joy, The University of British Columbia, Canada

EXTENDED ABSTRACT

We explore a new way to define natural wines, a largely undefined type of wine, through the lens of art. In particular, we borrow from previous theorizations of wine seen as art and incorporate the specific lens of subversive art to frame natural wines as artifacts that oppose the mainstream.

By analyzing data from wine producers and expert consumers, given their influence in a market-driving industry (Humphreys and Carpenter 2018), this paper addresses the lack of an accepted definition of natural wines, a niche segment of the wine world characterized by an unconventional approach to winemaking that seeks to reduce the number of human interventions in the process of wine production while implementing sustainability oriented initiatives (Legeron 2014).

Most of the current definitions of natural wines are contested in the wine world and have not reached a level of widespread acceptance that other conventional winemaking approaches have (Alonso González and Parga-Dans 2020). Additionally, these definitions miss to incorporate an important aspect of natural wines: the subversive element that opposes the status quo.

In order to incorporate this missing subversive element, this paper evidences an emergent finding of how natural wines can be characterized as subversive art. By doing this, the paper expands the limited number of studies on artification - i.e., the process of making non-art into art (Shapiro 2019) - of wines (e.g., Joy et al. 2021; Tomasi 2012). In particular, it looks at how art can help define and frame a largely undefined type of product (such as natural wines).

We consider subversive art, for the purposes of this paper, as a countercultural expression of disconformity with the status quo (Auther and Lerner 2012; Kan 2001). Particularly, subversive art can be considered different from other forms of art in that it carries a sense of subversion that can sometimes border in the illegal (Daniels 2016). With no universally accepted definition of “subversion”, subversive art is characterized by actions that seek to undermine institutionalized systems, with subversive artists attempting to oppose and transgress current social norms and practices (Topuzovski 2017). For instance, street art can be appreciated for its ideological message, such as its indictment of consumerism and excessive materialism in public space (Visconti et al. 2010).

The main research question explored in this paper is: In what ways can sustainable and unconventional wines be characterized as artworks? First, to examine how natural (and overall sustainable) wines are framed by wine producers and wine expert consumers, interview and participant observation data was collected and analyzed as part of a broader study on sustainability in British Columbia’s Okanagan (and Canadian) wine industry. During the fieldwork, interviews, informal conversations, and participant observations (working in a cellar, a vineyard, and a wine shop, as well as participating in multiple wine events and fairs), it was evidenced how an emergent theme for (natural and sustainable) wine producers and expert consumers (wine critics, writers, educators, and experts) involved the opposition to mainstream winemaking and positioning of sustainable and natural winemaking that closely resembled subversive movements in other contexts.

Interviews lasted between one and two hours each, and in some cases a second set of interviews was conducted. In-depth, semi-

structured interviews were conducted on-site (usually at a winery, vineyard, or at a convenient and quiet enough venue) or via telephone/video calls. Each interview started with questions regarding the participants’ context and background, and then moved into topics regarding the concept of sustainability, the broader wine world, and the wine industry and sustainability in the Okanagan Valley and Canada. 27 interviews were analyzed: 11 with expert consumers (6 women and 5 men) and 16 with winemakers and/or winery employees/owners (6 women and 10 men). Participant observation methods were also implemented as well as informal conversations with various winemakers and wine experts while attending the international annual Raw Wine Fair twice (2017 in Los Angeles, California and 2018 in Montreal, Quebec).

With artification seen as a process constituted of over ten microprocesses that explain how non-art becomes art (Shapiro 2019; Shapiro and Heinich 2012), this paper is based on the description of how wine can become art, detailed by Joy et al. (2021). The following were key microprocesses that were evidenced through the data collection and analysis and that are of relevance for this particular paper in explaining how natural wines become art, given that Shapiro and Heinich’s (2012) conceptualization of artification specifies that the number and relevance of microprocesses depends on the context being studied: (1) a process of institutional and organizational change is evidenced in the creation and expansion of international and regional natural wine fairs and groups and the ongoing discussion around new normative and regulations about what is a natural wine; (2) the individualization of labour evidenced in certain well-known natural wines (also evidenced in some conventional wines); (3) the displacement seen in iconic natural wines that are no longer just wines but coveted products, sometimes endorsed and revered by well-known public figures; (4) and the redefinition of time that differentiate natural wines that are artisanal and manually cared for and made by winemakers that oppose the growing standardization seen in some conventional wines.

Finally, three key characteristics emerged from the study that help characterize natural wines and differentiate them as subversive art in comparison to mainstream wines: (1) the opposition to the mainstream: natural wines oppose current institutionalized forms of winemaking, similar to subversive indie art and indie cinema opposing mainstream media productions that are seen as more interested in revenue than in generating value and uniqueness in the art produced; (2) the reclaiming of spaces: similar to graffiti that offers young artists and writers a way to reclaim the spaces they work in and inhabit, natural winemaking allows this for farmers; and (3) rituals of resistance: natural winemakers engage in practices that fall outside accepted industry standards, as seen in graffiti and street art where creators are not satisfied with current forms of art or do not want to engage with its norms.

This paper provides an additional understanding of natural wines, with insights that could be used by practitioners when approaching this niche wine market segment. It also provides further analysis of the artification of wines (Joy et al. 2021) by exploring a specific and largely undefined type of wine and category of art.

Project funded by SSHRC grant 435-3017-0958.

Brand Faith: How Consumers Develop Faith in Brands

Ms. Kyungin Ryu, University of Massachusetts – Amherst, USA
Prof. Elizabeth Miller, University of Massachusetts - Amherst, USA
Dr. Matthew Godfrey, University of Massachusetts – Amherst, USA

EXTENDED ABSTRACT

Consumers seek existential security, especially during times of personal and societal disruption. They often consider a brand as an object of faith and try to find existential security in the brand. Analyzing interview and online forum data, we identify key characteristics of “brand faith” and outline its developmental process.

Consumers seek existential security to provide a sense of order and meaning in response to uncertainties and disruptions (Phipps and Ozanne 2017). Even in the COVID-19 pandemic, more consumers try to find answers to existential questions to cope with anxiety for the future (Pew Research Center 2021). The process of searching for existential meaning as a fundamental human need is defined as faith (Fowler 1981). Human beings can have diverse levels of faith both inside and outside of organized religion (Fowler 1981). For example, since ancient society, humans have developed faith in material objects by transforming them symbolically through rituals, inheritance, etc. (Belk, Wallendorf and Sherry 1989). This paper focuses on faith developed by consumers toward brands and examines how this phenomenon we call “brand faith” shapes consumer meaning-making and responses to uncertainties about the future.

The concept of faith is part of theories and popular discourse related to consumers’ relationships with brands. For example, consumers often talk about ‘having faith in Apple’ or ‘losing faith in Tesla.’ Consumers who have faith in Apple maintain relatively strong relationships with brands, even in this era of numerous brand choices. Therefore, other brand managers have desired to develop consumers’ faith in their brands (Thompson 2004). However, although previous research examines “tales of faith being rewarded” as one of the major narratives within brand communities (Muñiz and Schau 2005, 739) and processes of sacralizing material objects (Belk et al. 1989), the concept of brand faith has not been explicitly defined and examined. Therefore, we lack an understanding of how spiritual concerns shape consumer experiences beyond participation in brand communities or attachment to special possessions. Our research addresses this gap by defining brand faith and examining how it develops, diminishes, and recovers.

We focus specifically on Apple and Tesla to investigate the definition and the development of brand faith. Several articles identify Apple and Tesla as brands that inspire faith among consumers (Moorman 2018). Differences between the two brands allow us to analyze multiple dimensions of faith across brands with different histories and product categories. We conducted an iterative analysis on in-depth interview data and netnographic data. The in-depth interview data includes 21 transcripts and 21 biographies that summarize impactful events or attitude changes that may affect brand faith. Also, the netnographic data contains 50 randomly selected postings and 20 biographies created by summarizing impactful events or attitude changes of 20 randomly selected users. We randomly selected postings and users of MacRumors and Tesla Motors Club after filtering 254,449 postings with a customized dictionary of brand faith.

Based on the analysis, we define brand faith as an evolving pattern of believing, valuing, and committing to the brand that strengthens existential meaning in a consumer’s life. Also, our analysis identifies five key stages that represent deepening levels of brand faith: intuitive brand faith, associative brand faith, reflective brand faith, conjunctive brand faith, and holistic brand faith. Consumers in the intuitive brand faith stage develop faith in vague and imagined aspects of the brand by observing visible faith from other consumers or finding symbolic values from brand offerings. In the associative brand faith stage, consumers

develop faith in the pragmatic superiority of the brand by seeking out descriptive and experiential knowledge about the brand. In the reflective brand faith stage, consumers encounter contradictions that conflict with their expectations. Therefore, they start to reflect on whether the brand’s superiority is absolute and will lead to a meaningful future, but they still show strong motivation to seek resolutions. In the conjunctive brand faith stage, people settle into the brand by providing benefits of doubts and affirming the absoluteness of the brand value. In the last stage, the holistic brand faith stage, the brand is firmly embedded into their lives as these consumers consider the brand more holistically, like a belief system of living a meaningful life. At this stage, individuals consider the brand as a part of the center of moral values, which decide what is right or wrong.

As brands and individuals are living entities changing over time, sometimes consumers’ brand faith diminishes, regressing to prior stages or dissolving altogether. When consumers who have brand faith confront doubts that dwindle their expected belief or value of the brand, they regress to the previous stage. Three types of doubts diminish brand faith: doubts about pragmatic superiority, doubts about futurity, and doubts about morality. Consumers also can dissolve brand faith followed by a gradual process by which faith is lost, and lost, until the losses outnumber the original benefits from their beliefs and perceived values of the brand.

This research expands studies on consumer experiences of spiritual devotion toward brands. We provide insights into how such devotion develops at an individual level by identifying key characteristics of brand faith. Our research suggests that brands can support consumers’ secular experiences of faith by offering symbolic and material resources that consumers can draw on to find existential meaning in the uncertain future. Brands provide a means to improve consumer wellbeing while at the same time delimiting the meanings, resources, and actions available for consumers to achieve that end.

“More the Merrier? Or Do Too Many Cooks Spoil the Broth?” Effects of Plural Brand Names on Brand Attitude

Dr. Tanvi Gupta, Indian Institute of Management Udaipur, India
Dr. Shirley Chen, Wilfrid Laurier University, Canada
Dr. Smaraki Mohanty, Elon University, USA

EXTENDED ABSTRACT

Using a combination of real-world data and lab experiments, we demonstrate that plural brand names are preferred over singular names. This is driven by the belief that a collective team is more efficient, which increases competence, leading to more favorable attitude. The effect is attenuated when self-expressive motive is salient.

Brand names serve as an important strategic tool for companies to communicate to consumers, and firms invest heavily in naming and maintaining a brand (Heath and Heath 2011). To address this important topic, prior work has suggested that linguistic qualities including phonetic (specific sounds), morphological (word formation) and semantic (connotative meanings) characteristics convey brand information (Vandenbergh, Adler and Oliver 1987). While substantive research has focused on phonetic (Argo, Popa and Smith 2010; Lowrey and Shrum 2007; Pogacar et al. 2021) and semantic (Gunasti and Ross 2010; Keller, Heckler, and Houston 1998) characteristics, few research examines morphological characteristics of brand names. To address this gap, we study how consumers react to the use of the pluralizing morpheme in brand names, i.e., the inclusion of a suffix *-s* at the end of a brand name.

To understand the impact of plural brand names on consumers, we draw from prior work on grammatical number — a linguistic device that expresses quantity by adding affixes to the root word, thereby distinguishing singular from plural entities (Wallis, Robins, and Knott 2014). A singular form of an entity focuses on a single instance of an object. Whereas the plural form of an entity construes a collective composed of a homogenous group of more than one instance of the unit object (Wallis et al. 2014). These homogenous groups can further be interpreted as an assemblage – a group collectively performing as a cohesive entity (collective reading) or as multiple individuals performing separately (distributive reading) (Rossi, Kumar, and Cohen 2005). When plural nouns are marked with partitive phrases (e.g., *each of the cars*), they are processed through distributive reading. However, when plural nouns are unmarked, they are processed through collective reading (e.g., *the cars*) (Kaup, Kelter, and Habel 2002). In the context of brand names, we expect plural names to activate collective reading by default because brand names are not preceded by partitive phrases. Collective reading leads to the perception of the plural entity as a cohesive group, where multiple individuals together represent common intention and collective agency (Gallotti and Frith 2013).

Another form of plural noun, especially when used with proper nouns (i.e., person names or family names) is the associative plural. It is used to refer to a close-knit group of individuals associated with a dominant reference-group identity and strong internal cohesion (Daniel and Moravcsik 2013). For example, family names like *The Joneses* are used to create a reference to social groups. Since brand names are proper nouns, we expect plural brand names to be processed the same as associative plural nouns, i.e., as a cohesive group. We posit that being perceived as a cohesive group is likely to offer advantages to the brand because of an increased perception of synergy.

To test our propositions in a real world setting, we first analyzed an archival dataset containing brand ratings for 618 brands by a representative sample of 17,000 individuals from the U.S. (Lovett,

Peres, and Shachar 2014) and found that the plural named brands were evaluated more favourably than brands with singular names ($M_{\text{singular}} = 2.75$, $SD = .72$; $M_{\text{plural}} = 2.96$, $SD = .69$; $F(1, 527) = 5.05$, $p = .025$). Next, we conducted an online field experiment using Google Ads, where we designed two versions of a display ad for a landing page with the objective to generate traffic to the landing page by maximizing clicks on the ad. We found that the ad with the plural brand name performed better than the ad with the singular brand name (Singular: investment = USD 13.34, clicks = 91, ROI = 6.82%; Plural: investment = USD 12.21, clicks = 132, ROI = 10.81%). Taken together, these two studies in the real-world setting demonstrate initial evidence suggesting a plural brand name advantage. We then used a series of controlled lab experiments to further investigate the basic effect and the underlying psychological mechanism.

While linguistics offers a wide toolkit to analyze language at multiple levels—including phonology (specific sounds), morphology (word formation) and semantics (connotative meanings), research on brand names has predominantly focused on phonemes (e.g., Argo et al. 2010; Lowrey and Shrum 2007; Pogacar et al. 2021). There is little work on understanding the role of morphemes in brand names. We make a theoretical contribution in the field of brand linguistics by examining the effect of a prevalent but understudied grammatical morpheme, the pluralizing suffix *-s*, on brand name evaluation.

The Time-varying Effects of Nutrition Claims on Product Sales and Its Drivers

Ms. Faith Li, McGill University, Canada

Dr. Hajar Fatemi, University of Windsor, Canada

Dr. Yu Ma, McGill University, Canada

Prof. Laurette Dubé, McGill University, Canada

EXTENDED ABSTRACT

This research examines the effect of a nutrition claim and its relationship with associated product marketing efforts. Using sales of yogurt and cereal categories, the authors find a negative effect of market presence, indicating that over-presenting claims in the market leads to decreases in consumer preference.

Consumers worldwide struggle with weight management and face serious health issues due to obesity and other food-related chronic diseases. To encourage a healthy diet, the consumer-packaged goods industry has applied food labeling techniques to address regulatory changes as well as to differentiate their products from the competition. (Food and Drug Administration 2006). One of these labeling techniques is nutrition claims (NCs) which either describe the level of a nutrient in the product using terms such as “free”, “high”, and “low”, or compares the level of a nutrient in a food item to that of another food item, using terms such as “more”, “reduced”, and “lite” (Food Standards 2016). Aiming to aid the interpretation of nutrient tables and health benefits and to avoid misleading information, NCs have been widely adopted by manufacturers across nations and product categories.

Although there has been an ever-increasing consumer demand for a healthier diet (Andrews et al. 2014; Chrysochou and Grunert 2014), the findings on consumers’ response to NCs are mixed. Some studies found NCs to be helpful in simplifying the cognitive process of product evaluation (Williams 2005) and in invoking more attention to the nutrient by alluding to its importance (Garretson and Burton 2000). As a consequence, consumers perceive these products as healthier (Roe, Levy and Derby 1999), have a more favorable attitude (Kozup, Creyer, and Burton 2003), and are willing to pay a premium price (Ballco, Jurado and Gracia 2020). Conversely, a growing body of studies has highlighted the negative impact of nutrition claims. This stream of work has revealed that NCs could lead to decreased perceived tastiness (Civille and Oftedal 2012; Raghunathan, Naylor, and Hoyer 2006), consumer skepticism (Garretson and Burton 2000), negative evaluations, and lower purchase intentions due to confusion and misleading information (Benson et al. 2018; Williams 2005).

While many papers attempt to address these mixed results with factors such as variations of claim type (e.g. André, Chandon and Haws 2019) or consumer characteristics (e.g. Cavaliere, De Marchi and Banterle 2016), the learning and evolution of NC perception over time has been overlooked. For example, longitudinal research conducted by the Canadian Foundation for Dietetic Research (2013) shows that there has been an increasing trend in the frequency of consumers’ food choices based on the amount of a specific nutrient the food contains. However, such dynamics have been understudied in the literature.

We aim to address two important research questions: (1) Whether the increasing market-level presence of products with NCs improve or impair NC effectiveness? (2) To what extent, do marketing-mix changes and the competition among products with NCs and their regular counterparts influence NC effectiveness?

We address these questions by measuring the effectiveness of various NCs over four years with scanner data. The advantage of using scanner data is two-fold. First, there is increasing evidence that

what consumers say about their preference for NC is inconsistent with what they purchase (Ballco et al. 2019). For example, despite an increasing self-reported trend towards a healthy diet and well-being (Block et al. 2011; Chrysochou and Grunert 2014), only 10 to 30% of new nutritious food products survive in the market for over two years (Bimbo et al. 2017). As opposed to survey reports or household panel data, the scanner is free of self-report errors and less vulnerable to sample selection bias (Sriram, Balachander and Kalwani 2007). While some researchers have utilized scanner data to measure actual healthy purchases in a retail environment (e.g., Nikolova and Inman 2015, Ma, Ailawadi and Grewal 2013), we are one of the first to examine NCs’ impact. Second, the point-of-sales data allows us to capture the impacts of retail marketing strategies and marketing presence on NCs’ effectiveness.

Using the scanner data from two widely used packaged food categories in the NC literature – namely, yogurt and breakfast cereal – we estimated a dynamic linear model that captures the time-varying effects of NCs on brand sales. The time-varying parameter measuring NC effectiveness is modeled as a function of the marketing effort of NC products with respect to regular products as well as of the intensity of market presence of the NC within the product category. Our results provide managerial implications for marketers and policymakers by capturing a multilayered dynamic of NC effectiveness, which potentially explains the conflicting findings in the literature and the failure of most new product introductions with nutrition claims in the market.

This research contributes to the food marketing literature in the following ways: first, to our knowledge, this is the first study to account for the changes in the effectiveness of NCs over time. As previously discussed, the controversy over the value of NC has raised multiple concerns for marketers and policymakers. Factors such as taste inference (Civille and Oftedal 2012) or consumer skepticism (Garretson and Burton 2000) may cause backfires for the brand. Second, there has been a call for research to analyze how the use of nutrition information is related to market response because most studies focus on consumer use and understanding of nutrition labels (Cao and Yan 2016). This research fills in the gap by quantifying the actual effect of NC on sales over time.

In addition, we examined the moderation effects of marketing presence and marketing mix. We first confirmed the negative impact of marketing presence on the effectiveness of NC. It suggests that repeated claiming will not provide extra competitive advantages. An NC is more effective when it’s scarce in the market. Marketers should focus on health benefit innovations to appeal to consumers. Policymakers may help mitigate this wear-out effect by imposing stricter and more detailed standards, which reduce the competition in the market. Secondly, the impact of marketing strategies such as price and feature and display promotion has been overlooked in the extant literature. We found that the price difference and feature and display promotion intensity between NC products and regular/no-NC options increase the effectiveness of NC. Our results highlight how the retailer environment could shape consumers’ preference for NC. Policymakers should take such effects into account.

Social Exclusion and Consumers' Decision to Reject Unethical Brands

Dr. Xiaoqi Han, Western Connecticut State University, USA

Dr. Ruomeng Wu, Western Kentucky University, USA

Dr. Frank Kardes, University of Cincinnati, USA

EXTENDED ABSTRACT

This research examines the effects of social exclusion (i.e., being ignored and being rejected) on consumers' reactions to socially irresponsible businesses. We propose that out of an intention to punish unethical behaviors, socially ignored (but not rejected) consumers actively avoid socially irresponsible businesses at the sacrifice of consumption benefits.

Social exclusion is the state of being forced into solitude or denied social contact (Blackhart et al. 2009; Baumeister et al. 2005; Williams 2007). It threatens the fundamental need to belong (Baumeister and Leary 1995), which is a powerful motivational basis for social interaction (Baumeister et al. 2005). In this paper, we attempt to expand the bright side of social exclusion in the marketing domain. We argue that social exclusion may trigger consumers' urge to do something in a morally desirable direction. We argue that with the intention of punishing an unethical brand, excluded consumers may decide to stop purchasing from the brand even if the purchase seems beneficial. Furthermore, we distinguish the effect of being ignored and being rejected. We propose that only the experience of being ignored (but not rejected) triggers the above effects.

THEORETICAL BACKGROUND

Evidence in the consumer domain suggests that people who feel socially excluded may try to re-develop social ties through affiliative consumption (Mead et al. 2011; Loveland, Smeesters, and Mandel 2010). Even though prior research has shed light on the positive effect of social exclusion (e.g., Lee and Shrum 2012), no research has investigated how social exclusion influences consumers' decisions to withdraw consumption in order to punish a company due to concerns about its social responsibility (Garrett 1987). Neither has any prior research distinctively discussed the effects of being ignored and rejected on consumers' ethical decisions.

Research shows that while being rejected leads to deficiency in relational needs, being ignored undermines one's self-efficacy needs (Lee and Shrum 2012). Because ignored consumers face more threats on the self-efficacy needs including power and need to control, they are more likely to engage in attention-gaining behaviors (Lee and Shrum 2012).

Based on prior findings about the motivational and behavioral differences behind the experience of being rejected versus ignored (Lee and Shrum 2012; Molden et al. 2009), we predict that ignored individuals, but not rejected ones, will punish an unethical/socially irresponsible business by deliberately withdrawing purchase from such a business.

OVERVIEW OF THE STUDIES

We ran three pretests and two experimental studies to test our hypotheses. In the three pretests, across three different purchase contexts, we demonstrated that the feeling of being socially excluded (ignored) increases one's likelihood to reject an appealing, yet socially irresponsible/unethical business. In Study 1, we showed that only the feeling of being ignored (but not rejected) reduces the likelihood to visit an unethical business. In addition, we detected the mediating role of the intention to punish the business and ruled out the prosocial intention as an alternative explanation. In Study 2, we replicated the effects of the two types of social exclusions through direct scenario manipulations.

Study 1

In Study 1, we had participants complete two ostensibly different tasks. In task one, we measured how ignored and rejected participants feel in general (Molden et al. 2009; Su et al. 2017). Then in the second task, participants imagined that they would like to visit a nearby restaurant for dinner. The restaurant seemed very favorable as it received plenty of positive reviews recently and the visitors enjoyed the food there. However, it treated its employees unfairly. Following the scenario, on a 7-point scale, participants reported their likelihood to look for other restaurant options. Next, participants reported how much they agreed or disagreed with three items testing their general intentions to punish unethical businesses. Following Baumsteiger and Siegel (2019), prosocial behavioral intentions were measured with four items ($\alpha = .77$).

The analysis confirmed the hypotheses, such that when controlling for rejection which had no impact ($p > .41$), the more neglected one felt in general, the higher likelihood s/he looked for other restaurant options ($B = .27, b = .35, t(172) = 3.17, p = .002$). Consistently, when controlling for rejection which had no impact ($p > .65$), the effect of being ignored strongly shaped the intention to punish ($B = .34, b = .47, t(171) = 4.61, p < .001$). We then used bootstrapping procedures to test whether the intention to punish unethical businesses was the mediator (Model 4, Hayes 2013). The analysis confirmed its mediating role ($b = .17, 95\% \text{ CI: } 05, .33$). Our analysis also ruled out prosocial intentions as an alternative explanation.

Study 2

In Study 2, we aimed replicate the effect of being ignored through direct manipulations of social exclusions. The experiment employed a 3 (social exclusion experience: rejected vs. ignored vs. control) between-subject design. The first task involved a manipulation of being ignored or rejected, which was adapted from prior work (Lee & Shrum, 2012). The second task involved having participants choose to stay in a hotel (i.e., Hotel A) or to keep looking for other hotels located 15 minutes' drive away. Despite positive online reviews, the hotel was involved in a labor dispute over low employee wages and lack of medical benefits. Participants could choose Hotel A or searched for other hotels. Next, on 7-point scales, participants reported their likelihood not to spend money there to punish Hotel A and

Consistently, participants who felt ignored were less likely to book Hotel A than those in the rejected and control conditions ($M_{\text{ignored}} = 2.78, SD = 1.76$ vs. $M_{\text{rejected}} = 3.63, SD = 2.01$ vs. $M_{\text{control}} = 3.67, SD = 1.99, F(2, 209) = 4.69, p = .01$). Further, participants who felt ignored were less likely to book Hotel A than those in the control condition ($t(138) = -2.79, p < .01$). However, we did not observe the same pattern when comparing rejected individuals with those in the control condition ($t(142) = -.13, ns$). Consistent with Study 1, bootstrapping procedures (Model 4, Hayes 2013) revealed significant mediating pathways through the punishment likelihood to both booking intentions ($b = -.19, 95\% \text{ CI: } -.4056, -.0146$) and choice ($b = -.21, 95\% \text{ CI: } -.4945, -.0104$).

GENERAL DISCUSSION

The present research complements our understanding about how social exclusion impacts ethical consumption. This finding suggests that social exclusion, particularly the experience of being ignored, may heighten the instrumentality of money as a means to exert control (Duclos, Wan, and Jiang 2013; Lee and Shrum 2012).

Snimex for Nasal Congestion: Phonaesthetic Brand Name Priming

Dr. Stacey Brennan, University of Sydney, Australia

Dr. Jasmina Ilicic, Monash University, Australia

Prof. Shai Danziger, Tel Aviv University, Israel

Dr. Alicia Kulczynski, University of Newcastle, Australia

EXTENDED ABSTRACT

Many brands adopt pseudo-words as brand names, but how can meaning be delivered via this approach? This research introduces a novel approach to developing brand names—phonesthemes (meaningful letter clusters). Across six experiments, we show that brands can communicate meaning and promote brand preference and choice through utilizing phonesthemes.

A brand name is a fundamental brand element that influences brand image, and creates points of difference and competitive advantage. With 72% of brand names being pseudo words (non-words) or acronyms, it is important to consider how these non-words can be imbued with meaning. Some work has focused on the meaning derived from brand name sound (i.e., *phonology*). However, in this work we introduce a novel approach to developing brand names – *phonesthemes*. Phonesthemes are letter clusters that have a predictable effect on a words meaning. For example, in the Brown Corpus, 60% of words starting with *gl-* have definitions relating to light (e.g., *glow, glisten, gleam, glitter*). Phonesthemes may take the form of a prefix (initial phonestheme; e.g., *Squ-*; soft, compressed; *squish, squeeze, squash*) or a suffix (final phonestheme; e.g., *-imple*; uneven; *dimple, crimple, pimple*). The defining attribute of phonesthemes is that their existence relies on the recurrent pairings of *form* and *semantic* (meaning) properties which allows them to play a role in unconscious language processing. Phonesthemes are prevalent across languages (e.g., English, Indonesian, Japanese). While research has confirmed the existence of phonesthemes in language, their effect on consumer perceptions, preferences, and choice is unknown.

Across six studies this research aims to: (1) provide evidence of phonesthemic brand name priming (perceptions, preference, and choice), (2) eliminate phonology (brand name sound) as an explanation for our phonesthemic brand name priming effect, and (3) demonstrate brand positioning as a boundary condition of the effect.

Study 1 sought to establish the presence of phonesthemic brand name priming. Specifically, we examine whether phonesthemic brand names prime: (1a) product attribute perceptions (n = 170), (1b) preference (n = 240), and (1c) choice (n = 130). Results of Study 1a showed that phonesthemic brand name primes significantly affect participants' perceptions of product texture. Specifically, participants perceived a facial scrub to be rougher in the phonesthemic prime condition (*-imple*) than the control condition. In Study 1b, a large majority of participants chose the phonesthemic brand name *Snimex* (Sn- related to nose, or breathing) over the control brand name *Srimex* (Sr- unrelated to nose, or breathing) for a nasal spray product. Study 1c revealed that significantly more marshmallow packets were taken in the phonesthemic brand name condition (*Squegz*) than in the control condition (*Schegz*).

Study 2 aimed to demonstrate that morpho-semantic priming facilitates the phonesthemic brand name priming effect (n = 190). Participants were shown a fictitious logo for a brand of dishwashing liquid. Participants were asked to list five words that came to mind when seeing the brand logo. Next, participants evaluated the products ability to create luminous dishes. Participants were found to report a greater proportion of words that shared the same morpheme as the prime and were semantically related to the phonestheme in

the phonesthemic brand name prime condition than in the control condition. Next, morpho-semantic lexical representation was found to mediate the relationship between the phonesthemic brand name prime and product perceptions.

Study 3 aimed to eliminate phonological priming (Flurz vs Phlurz) as a process underlying our phonesthemic brand name priming effect (n = 170). Participants were shown a fictitious logo for a brand of chair and were asked to evaluate the chairs movement. Results showed the phonesthemic brand name prime to have a significant effect on participants' perceptions of product movement when compared to the phonological control.

Study 4 aimed to demonstrate brand positioning as a boundary of the phonesthemic brand name priming effect (n = 312). Participants were informed that a new brand of car wax was seeking input from consumers on their brand name. Results show that when product attributes were linked to luminance, the large majority of participants chose the phonesthemic brand name *Glif*, over the control brand name *Blif*.

With the over two-thirds of marketers adopting pseudo (non-word) words and acronyms as brand names, understanding approaches to developing novel, yet meaningful brand names makes a contribution to both marketing theory and practice. Numerous studies in marketing have demonstrated that phonological sound-based devices (such as homophones, pseudohomophones, and phonemes) can have a priming effect, influencing consumer purchase intentions and brand evaluations. Our research provides a novel approach to brand linguistics and contributes to the marketing literature by being the first to demonstrate phonesthemic brand name priming effects. Marketers can use phonesthemes to create distinctive brand names which connote product meaning. The strategic use of phonesthemes in the creation of brand names can therefore assist marketers in communicating important information about products. For example, a brand of hairspray that holds the hair but also allows the hair to move might benefit from a brand name with the sub-morphemic unit *fl-*, for example *F/alek*, to create perceptions of movement. Furthermore, a brand of hammer may create stronger associations that influence perceptions and preference by adopting the brand name *Zash*, as the phonestheme *-ash* means to apply energetic force (e.g., *bash, clash, slash*).

Besides contributing to research on brand name development, this research advances psycholinguistic research in marketing and, in particular, the emerging area of brand linguistics. While research has examined the effect of brand name phonology on brand preferences and recall, this body of work adopts either a phonetic symbolism, or homophonic (same pronunciation but different meaning) perspective. Our research introduces an innovative psycholinguistic device and presents novel findings within an emerging research stream.

Threshold versus Capped Framing: An Equity Theory of Restricted Promotions

Mr. Shangwen Yi, University of British Columbia, Canada

Dr. Thomas Allard, NTU Singapore, Singapore

Dr. David Hardisty, University of British Columbia, Canada

Prof. Dale Griffin, University of British Columbia, Canada

EXTENDED ABSTRACT

We examined how restricted promotions affect consumers' choices. We found consumers were more likely to make a purchase with threshold promotions than with comparable capped promotions when the threshold was low because consumers perceived threshold promotions as higher than expectations and fairer. The reverse happened when the threshold was high.

Marketers regularly send coupons like "\$5 off a purchase of \$10 or more" or "50% off a purchase, max \$5 discount". The former one is a *threshold promotion* where the offer is applicable if the spending amount exceeds a threshold, and the latter one is a *capped promotion*, a percentage-term promotion for which the value is capped. Although capped promotions dominate threshold promotions, we propose that consumers prefer threshold promotions to capped promotions when the threshold is low. The percentage in the capped promotions shapes consumers' expectation while the actual percentage is lower than the expectation. For comparable threshold promotions, consumers' attention is anchored to a spending amount equal to the threshold, and thus their perceived outcome-input ratio is larger than the usually expected ratio. Six pre-registered studies including five on Prolific and a field study tested our hypotheses:

Hypothesis 1: When the threshold is low, consumers are less likely to make a purchase with a capped promotion than a comparable threshold promotion.

Hypothesis 2: When the threshold is low, consumers expect higher promotion value from the capped promotion and perceive it as less fair than the threshold promotion.

Study 1 (N = 403) tested H1. Participants were asked to decide whether to hail a ride and take a bus. Half of the participants read "If you hail a ride, you will spend \$20 on average" and half did not. Participants in the threshold promotion condition read "Enjoy \$5 off a ride. On a ride of \$10 or more"; this read "Enjoy 50% off a ride. \$5 max discount per ride." in the capped promotion condition. Results revealed that people seeing the capped promotion are less likely to use the offer, $p = .017$, and perceive the deal as worse, $p < .001$, than participants seeing the threshold promotion regardless of whether the average spending is mentioned.

Study 2 (N = 127,443) tested H1 in a field experiment. Tiktok users saw either a threshold promotion ("Enjoy \$3 off, on an order of \$5 or more") or a capped promotion ("Enjoy 60% off, \$3 max discount on an order"). We found that the audience were more likely to click on the threshold promotion than the capped promotion, $p = .021$.

Study 3 (N = 403) tested H1 and H2 in charity promotion. Participants were asked to imagine buying groceries in a store. Participants in the threshold promotion condition read "We donate \$5 per purchase (if you purchase \$10 or more)"; this read "We donate 50% of your purchase price (up to \$5 per purchase)" in the capped promotion condition. We found that people seeing the capped promotion are less likely to make a purchase, $p = .039$, perceive lower fairness, $p < .001$, and higher negative expectation discrepancy, $p < .001$. The effect of promotion framing is serially mediated by negative expectation disconfirmation and fairness perception.

Study 4 (N = 600) tested H1 and H2 in food ordering context. We included an unrestricted promotion condition as a reference. Participants were asked to decide whether to order food OR to cook dinner at home. Participants in the threshold promotion condition read "Enjoy \$3 off on an order of \$5 or more"; this read "Enjoy 60% off. \$3 max discount on an order" in the capped promotion condition, and "Enjoy \$3 off" in the unrestricted promotion condition. Results reveal that people are more likely to make a purchase with a threshold promotion than they are with a capped promotion, $p < .001$. Intriguingly, we find that compared with an unrestricted promotion, people are more likely to make a purchase with a threshold promotion ($p < .001$) and less likely to make a purchase with a capped promotion ($p = .008$). Results on fairness perception show same pattern, and fairness mediates the effect of framing.

Study 5 (N = 200) examined people's evaluation between two food-ordering apps side by side, one using threshold promotion and the other capped promotion. We find that consumers prefer the app using threshold promotions (61.5%) to the app using capped promotions (38.5%), $p = .001$, and perceive the threshold promotion as fairer and to have lower negative expectation disconfirmation than the capped promotion. Thus, H1 and H2 are supported even in a joint evaluation mode.

However, when the threshold is high, the threshold promotion ("\$5 off on orders of \$50 or more") would not be applicable and the actual outcome would be zero. Thus, the actual outcome-input ratio of the threshold promotion (0) would be lower than the expected ratio (10%). In contrast, consumers typically can get the expected percentage (10%) in capped promotions ("10% off, max \$5") when the threshold is high.

Hypothesis 3: When the threshold is high, consumers are more likely to make a purchase with a capped promotion than a threshold promotion.

Hypothesis 4: When the threshold is high, consumers expect higher promotion value from the threshold promotion and perceive it as less fair than the capped promotion.

In Study 6 (N = 398), participants in the low-threshold threshold promotion condition read "Enjoy \$5 off (On an order of \$10 or more)"; this read "Enjoy 50% off (\$5 max discount on an order)" in the low-threshold capped promotion condition. Participants in the high-threshold threshold promotion condition read "Enjoy \$5 off (On an order of \$50 or more)"; this read "Enjoy 10% off (\$5 max discount on an order)" in the high-threshold capped promotion condition. In low-threshold conditions, consumers have higher purchase intention with threshold promotion than they do with capped promotion, $p < .001$; however, in high-threshold conditions, consumers have lower purchase intention with threshold promotion than they do with capped promotion, $p < .001$. The mediation effect of promotion framing on purchase intention serially through negative expectation disconfirmation and fairness perception is moderated by threshold level, which supports all hypotheses.

Theoretically, our findings of dominance violation are inconsistent with the standard economic models. We further reveal the cognitive mechanism of evaluating restricted promotions based on equity theory (Adams 1965) and expectation disconfirmation (Oliver and Swan 1989).

Women's Resistance to Artificial Intelligence: The Zero-Sum Game of Thing-People Interests

Dr. Sylvie Borau, TBS Education and Institute for Advanced Study in Toulouse, France

EXTENDED ABSTRACT

Women resist AI because AI (like STEMs) is perceived as thing-oriented, and women are less thing-oriented than men. The perception that AI is incompatible with caring about people extends to consumers who like AI and is rooted in the belief that liking AI and humans is a zero-sum game.

Today, women are underrepresented in the fields of robot's technology and AI. The question is whether this gender imbalance extends to AI consumption: are women more likely to resist adopting AI than men, and if so, why? Academic research on this potential gender gap is scarce, and the evidence is mixed. Nor has prior research addressed the underlying cause of this potential gender gap.

Recent research that details gender-related trends linked to warmth and competence dimensions (Martin & Slepian, 2021) and different motivational drivers of people and thing orientations (Woodcock et al., 2013) offer a relevant framework for investigating why resistance to AI may be stronger among women. Arguably, women's generally stronger communality and people orientation, and weaker thing orientation influence their personal preferences and interests, such as their pursuit of education and jobs in STEM (science, technology, engineering, math) fields. Accordingly, we gather insights from research devoted to understanding this gender gap in STEMs with a novel application to AI consumer solutions.

We posit that women might be more likely to resist AI because, similar to STEMs, AI is thing oriented, not people oriented (Yang & Barth, 2015). In turn, AI is not compatible with a sense of communion or an orientation to interact with and care about other people. Because women are more people-oriented and tend to endorse communal goals, they may be more likely (than men) to resist AI in favor of real relationships that afford them more communion.

We tested our predictions in seven studies.

Study 1 (qualitative study; 2 focus groups and 8 face-to-face interviews) suggests that imaginary others, described as liking AI, are perceived as more likely to be men, thing-oriented, agentic, and competent rather than women, people-oriented, communal, and warm. These initial results also suggest that interest in AI means less interest in people.

Study 2 (between-subject experiment; $N = 315$ respondents, 152 women, $M_{age} = 31$) confirms these preliminary findings: Consumers believe that people who like AI (vs. who don't) are more likely to be men ($p < .01$), to be more thing-oriented ($p < .001$) and less people-oriented ($p < .001$), and to trust people less ($p < .001$).

Studies 3–5 (surveys and within-subject experiment; $N = 895$, 436 women, $M_{age} = 34$) investigate whether these lay beliefs that people hold are true. Study 3 confirms that women are less likely than men to express positive attitudes toward AI ($p = .01$) and to trust AI ($p = .02$). This study also reveals that AI is more associated with a thing (vs. people) orientation, as well as with masculinity, competence, and agency. Studies 4 and 5 provide further evidence that women express less acceptance of AI than men as well as process evidence of a mediating role of thing orientation in acceptance of AI. More specifically, Study 4 reveals that women are more people oriented ($p < .001$) and less thing oriented ($p < .001$), and their thing orientation (or lack thereof) mediates the relationship between gender and attitudes toward AI (CI: $-.576, -.132$). Women's perception of the risks involved in AI also explains their resistance, but adding this variable in the model does not suppress the role of

their low thing orientation in resistance to AI. Study 5 replicates the finding of a gender gap in acceptance of AI: Women are less likely than men to accept ($p < .001$) and trust AI ($p < .001$). However, this study also delineates a boundary condition for resistance toward AI, related to the communal or agentic goal of the AI task. While women resist all types of AI to the same degree, men are less likely than women to resist AI for agentic rather than communal tasks ($p < .001$), and thing orientation only influences acceptance of AI for agentic tasks.

Study 6 (experiment, 286 respondents, 145 women, $M_{age} = 39$) reveals a potential new underlying mechanism of consumers' resistance to AI: the belief that liking AI is a zero-sum game. Participants imagine that people who like AI are more likely to spend time on things ($p = .002$) but less time on people ($p < .001$). They appear to have fewer friends ($p < .001$), to have weaker feelings for their romantic partner ($p < .001$) and trust people less ($p < .001$). Women's higher belief in this zero-sum game operates through their people orientation (CI: $.0197, 2.053$).

Finally, **Study 7** (experiment: 386 women, $M_{age} = 35$) tests three interventions to increase women's attitudes toward AI. The proposed interventions do not directly mitigate women's resistance to AI, though. The intervention highlighting the sexist threat of an AI gender gap even has the opposite expected effect and triggers increased reactance.

Overall, we show a novel effect of thing and people orientations to help explain variability in AI aversion, particularly between men and women. With this new perspective on thing vs. people orientation and AI, we reveal a tension related to the role of AI in people's daily lives. Consumers, and especially women, fear that AI can decrease humanity by dampening human connections and decreasing the time and resources devoted to interpersonal relationships in a zero-sum fashion and in line with sociology research by Turkle (2011). These insights raise ethical quandaries for AI designers and policymakers: Increasing women's thing orientation to increase acceptance of AI could undermine humanity, and interventions emphasizing communal AI could be deceptive.

Reasoning about Robot Abuse

Dr. Sylvie Borau, Tbs Education, France

Dr. Tobias Otterbring, University of Agder, Norway

EXTENDED ABSTRACT

The abuse of social robots in retail is on the rise. Four studies show that exposure to robot abuse and reasoning about this issue increase perception of robots' moral standing, thus expanding consumers' moral circle. This reaction is automatic and intuitive, correlated to moral identity, and immune to cognitive deliberation.

The use of social robots, such as toy bots, nursing bots, sex bots, personal assistant bots, and educational bots, is pervasive. Along with increasing uses of these bots, their abuse by consumers is on the rise. For example, a robot was molested at a tech fair and security robots keep being assaulted in shopping malls. Beyond material costs, robot abuse affects consumers who witness the abuses, as indicated by surprisingly strong public responses. Consequently, several groups call for protecting robots from abuse and granting them rights (e.g., American Society for the Prevention of Cruelty to Robots). In response, companies and policymakers have started a wider conversation about robot rights, but the controversial ethical issues persist, with strong implications for companies, customers, employees, and policymakers.

Prior research has extensively studied the ethics of robot abuse from a philosophical perspective (Coeckelbergh, 2022), sparking a passionate, necessary debate about robot rights, though typically without offering empirical evidence. Here, we (1) examine whether people morally condemn robot abuse and the impact of robot abuse on moral concern for robots; (2) investigate the moral profile of people who condemn robot abuse; and (3) explore the role of reasoning on moral concern for robots to understand the cognitive underpinnings of this phenomenon. Does reasoning decrease moral concern for robots by diminishing the intuitive emotional empathy bias or does reasoning increase moral concern for robots by making the moral issue of robot abuse more salient, thus expanding the circle of moral concern? If the latter is true, this would be a case against reasoning, as moral concern for non-sentient beings appears irrational.

Study 1 (348 participants; 182 women; $M_{age} = 36$) investigates people's emotional reactions and moral attitudes toward robot abuse in a retail context. Participants were randomly assigned to either a robot abuse condition (a 20-second video showing a robot that gets beaten up) or a control condition (a 20-second video showing the same robot in the same setting, but the robot simply interacts with an employee). Following the video exposure, participants indicated the degree to which they thought that facial expressions of six basic emotions matched how they felt while watching the videos, as well as their moral concern for robots. Linear regression analyses on these outcome variables, with video condition (robot abuse vs. control) as the predictor and optimism toward technology, participant gender, and age as covariates, revealed that participants in the robot abuse (vs. control) condition were significantly more likely to experience negative emotions ($p < .001$) and to express moral condemnation ($p < .001$), moral concern ($p < .001$), and moral feelings for robots over humans ($p = .002$).

Study 2 (775 participants; 425 women; $M_{age} = 45$) tested whether moral concern for abused robots reflects our morality and whether reasoning prevents consumers from feeling moral concern for robots. Deliberative reasoning was measured both at the state level (by experimentally manipulating response times and working memory loads and reporting the comparison of participants' intuitive response with a one response control condition - between-subjects;

Bago et al., 2022), and at the trait level (by measuring cognitive fluidity with a six-item version of the CRT). Participants were then presented with three stimuli in a randomized order: a video showing robot abuse, pictures of robot abuse with a text describing the scenes, and a tweet reporting robot abuse at a restaurant. In the following analyses, we computed an average for the three stimuli. After each argument, participants were randomly exposed to a single statement related to moral condemnation, moral concern, or moral feelings. Moral identity was assessed using three positively framed items from the moral identity scale (Aquino and Reed, 2002). Linear regression analyses on the three outcome variables, with moral identity as the predictor and our usual covariates show that participants who score high on morality are more likely to express moral condemnation ($p = .009$), moral concern ($p < .001$), and moral feelings ($p < .001$) for robots. Another series of linear regression analyses with the type of reasoning (deliberate vs. intuitive response) as the predictor and the same covariates show that participants in the System 2 condition (deliberate thinking) are more likely to express moral condemnation ($p < .001$), moral concern ($p = .002$), and moral feelings ($p = .04$) for robots than participants in the System 1 condition (intuitive thinking). Finally, regression analyses run on the same three dependent variables, with the usual three covariates but with CRT as the independent variable show that cognitive fluidity decreases moral condemnation ($p = .009$), concern ($p = .006$) and love for robots ($p = .005$).

Study 3 (survey; 177 participants; 87 women; $M_{age} = 36$) and **Study 4** (IAT; 97 women; $M_{age} = 35$) show that, *outside* of an abusive context, consumers' moral identity does not predict moral concern for robots (S3: $p = .80$) and negatively predicts moral feelings for robots over humans (S3: $p = .002$; S4: $p = .029$).

We offer the first empirical evidence that feeling bad for abused robots is an indicator of one's own moral standards. We also find that motivated reasoning (i.e., deliberation at the state level) does not prevent people from feeling moral concern for abused robots (on the contrary, deliberation seems to increase moral concern and feelings for abused robots); while reasoning at the trait level (cognitive fluidity) decreases these concerns and feelings.

This research highlights the ethical quandary of robot abuse: exposure to robot abuse increases moral concern for non-sentient machines, and even more when people thoroughly think about the issue; yet outside of an abusive context, this concern is not a reflection of humanity. These results suggest that exposure to robot abuse may shift people's moral concern from humans to robots, and thus probably erode, rather than protect, their concern for living entities.

Advertising Diversity is Viewed as Pandering

Mr. Aihui Ding, University of South Florida, USA

Dr. Zhihao Yu, University of Nebraska – Omaha, USA

Dr. Kelly Cowart, University of South Florida, USA

EXTENDED ABSTRACT

Embracing corporate diversity can bring advantageous and detrimental consequences. Across six studies, we document that advertising diversity (vs. not) elicits less favorable ad attitudes because consumers infer that companies are pandering. This work contributes to research on diversity, advertising, ulterior motive, and to marketing practice.

Diversity, Equity, and Inclusion (DEI) has attracted the attention of practitioners and academicians for decades, especially in Western countries (Anand and Winters 2008; Arsel et al. 2022). Embracing diversity brings not only beneficial outcomes to companies (Khan and Kalra, 2021; Van Knippenberg, Van Ginkel, and Homan 2013), but also negative results (Brown and Jacoby-Senghor 2021; Windscheid et al. 2016). In the current research, we hypothesize that advertising diversity (vs. not) in a business ad elicits less favorable attitudes and pinpoint the ulterior motive to pander (McGraw, Lodge, and Jones 2002) as the underlying mechanism.

Our research makes important contributions. First, we contribute to diversity research. We examine the effect of corporate diversity shown in a business ad and find that this type of advertising may not be well received by the public. Second, we contribute to the literature on ulterior motive and pandering. Specifically, we document that corporate pandering is recognized by consumers and it negates marketing initiatives. Lastly, we contribute to the marketing practice by showing that consumers may be more receptive to corporate DEI communication when it is shared unobtrusively rather than through conspicuous advertising.

STUDY 1A AND 1B: MAIN EFFECT

In Study 1a, two-hundred-nine MTurkers were randomly assigned to one of three conditions (diversity advertising: control vs. homogeneity vs. diversity). In the control condition, participants read a detergent advertisement. We added employee homogeneity/diversity information to create the homogeneity and diversity conditions, respectively. Participants then indicated their attitudes to the ad. A one-way ANOVA revealed a significant effect ($F(2, 205) = 28.55, p < .001$). Participants in control condition ($M = 4.81$) indicated more favorable ad attitude than those in diversity condition ($M = 3.20; p < .001$), which generated more favorable attitudes than the homogeneity condition ($M = 2.64; p = .058$).

Study 1b ($n = 136$; Prolific) replicated the negative advertising diversity effect using a more implicit way to manipulate diversity by adding a diversified employee image to the ad (or not).

STUDY 2: MAIN EFFECT

Three hundred fifty-three Prolific participants were randomly assigned to one of five conditions (diversity advertising: control vs. age vs. gender vs. nationality vs. ethnicity). Participants read an ad featuring different types of diversity. A one-way ANOVA revealed a significant effect ($F(4, 348) = 8.36, p < .001$). Participants in control condition ($M = 4.29$) indicated more favorable ad attitude than those in the ethnicity-diversity ($M = 2.86; p < .001$), age-diversity ($M = 3.79; p = .068$), gender-diversity ($M = 3.32; p < .001$), and nationality-diversity ($M = 3.23; p < .001$).

STUDY 3: MEDIATION BY PANDERING MOTIVE

Two-hundred-ten Prolific participants were randomly assigned to one of three conditions (diversity advertising: control vs. irrelevant information vs. diversity). We added the irrelevant-info condition by

replacing the diversity info to “Plants are located in Louisiana.” Participants also indicated their inferences of the company’s pandering motive. A one-way ANOVA revealed a replication of the main effect ($F(2, 207) = 25.93, p < .001$). A one-way ANOVA on pandering motive revealed the similar patterns ($F(2, 207) = 43.91, p < .001, = .30$). Further, we conducted a mediation analysis using Model 4 (Hayes 2013; X_1 : control = 0, irrelevant-information = 1, diversity = 0; X_2 : control = 0, irrelevant-information = 0, diversity = 1). Results showed (1) that the indirect effect of X_1 on ad attitude was not significant (95% CI [-.28, .04]), and (2) that the indirect effect of X_2 on ad attitude was significant ($b = -.69, SE = .17, 95\% CI [-1.05, -.37]$). Thus, pandering motive mediates the negative effect of advertising diversity on ad attitudes. More importantly, the reason why irrelevant-info condition did not decrease ad attitude compared to control condition is that the former does not elicit greater ulterior motive.

STUDY 4: INFERENCE MAKING AS A MODERATOR

Three hundred seventy-five Prolific participants were randomly assigned to one of four conditions that varied on diversity advertising (control vs. diversity) and inference making (absent vs. present). We manipulated inference making by asking participants to infer the motive of this company mentioning the feature(s) in this ad. A two-way ANOVA revealed a significant interaction effect ($F(1, 371) = 3.86, p = .050$). When inference making was absent, participants in diversity condition ($M = 3.20$) indicated less favorable attitude towards the ad than those in control condition ($M = 3.69; F(1, 371) = 5.61, p = .018$), replicating the prior findings. When inference making was present, however, the negative effect was larger ($M = 2.96$ vs. $M = 4.03; F(1, 371) = 25.70, p < .001$).

STUDY 5: REVERSED-EFFECT CONDITION

Six hundred and eleven Prolific participants were randomly assigned to one of three conditions (diversity-disclosure type: control vs. advertised vs. unadvertised). We manipulated “unadvertised diversity” by informing participants that they found the diversity information on the firm’s official website, not in the ad. A one-way ANOVA revealed a significant difference ($F(2, 608) = 40.51, p < .001$). Contrary to the results in prior studies, participants in unadvertised-diversity condition ($M = 4.20$) indicated more favorable ad attitude than those in control condition ($M = 3.82; p = .008$) and those in advertised-diversity condition ($M = 2.95; p < .001$).

GENERAL DISCUSSION

Studies 1a and 1b provide evidence for the negative advertising diversity effect. Study 2 generalizes this effect to various types of diversity: age, gender, nationality, and ethnicity. Study 3 provides evidence for consumers’ inferences of the company’s pandering motive as the underlying mechanism of the effect while excluding the addition of irrelevant information as the alternative account. Study 4 identifies inference making as one theory-driven effect-strengthening moderator. Study 5 documents a reversed-effect condition. Specifically, when diversity is not advertised but disclosed unobtrusively, consumers will appreciate this company by producing the most favorable attitudes.

Consumers prefer products with directionally consistent causal chains

Mr. Soaham Bharti, University of Chicago Booth School of Business, USA
Dr. Abigail Sussman, The University of Chicago Booth School of Business, USA

EXTENDED ABSTRACT

The causal steps involved in the action of common products can evoke some directionality (involving steps that either *increase* or *decrease* intermediate outcomes). We find that consumers prefer products with directionally consistent causal chains. This is because they find directionally consistent causal chains to be simpler and, therefore, more effective.

Products often aim to help consumers achieve a desired end state, such as appearing youthful or maintaining high energy. These products tend to rely on dynamic causal chains to elicit intended effects. Further, steps involved in these causal chains often evoke some directionality:

- A face cream *decreases* the breakdown of collagen to *reduce* wrinkles.

- Energy drinks *decrease* adenosine activity, which *increases* firing of neurons, which *increases* energy.

Across 6 preregistered studies, we find that the structure of these causal chains influences product evaluations: consumers prefer products with directionally consistent (i.e., steps evoke consistent directionality) versus inconsistent (i.e., steps evoking contrasting directionalities) causal chains.

Evidence from adjacent fields of learning (Brehmer, 1973) and reasoning (Evans, 1972) suggests that directional consistency between variables enhances simplicity. Separately, people prefer simpler causal explanations (Lombrozo, 2007; Pacer & Lombrozo, 2017). However, prior work on simplicity typically operationalizes the construct as the number of causes invoked in an explanation. In the present research, we suggest that consistency within the steps involved may also relate to perceived simplicity, with consequences for evaluations of efficacy and choice. Hence, we propose that consumers will prefer products with directionally consistent causal chains because they consider such chains simpler and correspondingly more effective.

In Study 1 (N = 304), participants evaluated two supplements designed to either *increase* alertness (energy aids) or *decrease* alertness (sleep aids). One of these worked via an *increasing* mechanism (amping up the production of a hormone), and the other via a *decreasing* mechanism (winding down the production of another hormone). Participants reported the option with directional consistency between mechanism and effect as more effective; $t(303) = 13.43, p < .001$. Study 2 (N = 398) extended these results to longer causal chains. Participants compared two drugs that achieved an unidentified final effect using mechanisms that spanned two steps: The drugs first resulted in glandular changes, which then resulted in hormonal changes in the body. Participants indicated higher efficacy from directional consistency within these steps; $t(397) = 4.27, p < .001$. These results suggest that consumers continue to prefer directional consistency within the intermediate steps of causal chains, even in the absence of information about the direction of the final effect.

Studies 3a and 3b explored practical applications of these findings. Study 3a (N = 601) examined whether 1) perceived efficacy influenced product choice across 4 categories: hair serums, creams, drinks, anti-anxiety aids, and 2) labels describing the same products using consistent or inconsistent chains would lead to the patterns observed above. We described the effect from these products either in *increase*-coded (e.g., increase hair growth) or *decrease*-coded (e.g.,

decrease hair loss) terms. Participants chose between two fictitious products for each category: that either highlighted an *increase*-coded (amp up blood supply to the scalp) or *decrease*-coded (suppress shrinking of follicles) intermediate step from a shared causal chain. A greater proportion of participants chose the directionally consistent product for each category ($\chi^2s \geq 10.88, ps < .001$).

Similarly, Study 3b (N = 313) assessed whether consumers are more likely to choose a product with directional consistency within the intermediate steps of its mechanism. We modeled our stimuli for this study after a supplement that is purported to work by influencing various chemicals in the body in two phases: 1) *increasing* GABA and/or *decreasing* Glutamate in the initial phase, and 2) *increasing* serotonin and/or *decreasing* cortisol in the later phase. Once again, we asked people to choose between two supplements designed for general wellness. In a between-subjects design, we manipulated whether we described the 2nd step in the mode of action of both the supplements as *increasing* serotonin or *decreasing* cortisol. Participants then chose between two options that differed in terms of the description of the 1st step – which was *increasing* GABA for one option and *decreasing* Glutamate for the other. A chi-squared test revealed that participants were more likely to choose the supplement with directional consistency within the two phases; $\chi^2(1) = 5.12, p = .024$.

Finally, Studies 4 and 5 examined the possibility that perceived simplicity of directionally consistent causal chains underlies perceptions of product efficacy. In Study 4 (N = 213), participants made predictions about the efficacy of two drugs: one with a consistent causal chain (4 intermediate steps, all *increasing* the levels of various enzymes), and another with an inconsistent causal chain (steps alternating between *increasing* and *decreasing* the levels). They first predicted the efficacy of these drugs, and then rated them on their simplicity. Participants predicted higher efficacy from the drug with consistent causal chain; $t(213) = 11.73, p < .001$. Crucially, ratings of simplicity mediated this difference (ACME: 95% CI = [7.09, 15]).

In Study 5 (N = 419), we probed the role of simplicity further by exploring whether reducing the simplicity of the directionally consistent chain attenuates its edge in perceived efficacy. Once again, participants rated the efficacy of products with two causal chains. However, in 2 between-subjects conditions, we manipulated whether the consistent chain had the same number of steps as the inconsistent chain (4 vs. 4) or an extra step (5 vs. 4). A pretest confirmed that adding the extra step to the consistent chain reduced its simplicity to be in line with the inconsistent, shorter chain. We found an interaction between consistency and condition, such that the effect of directional consistency was attenuated when the consistent chain was also longer; $F(1, 417) = 4.77, p = .030$.

These preregistered studies provide evidence that consumers prefer products with directionally consistent causal chains. Theoretically, this project advances research in causal efficacy by 1) proposing consistency between steps in a causal chain as a determinant of simplicity of causal explanations, and 2) highlighting the relationship between simplicity and perceived product efficacy. On the applied front, we provide recommendations on crafting maximally effective product labels.

Why Minimum Purchase Restrictions Work: The Role of Reference Points

Mr. Guanzhong Du, The University of British Columbia, Canada

Dr. David Hardisty, The University of British Columbia, Canada

EXTENDED ABSTRACT

A minimum purchase restriction on a coupon (for example, “\$2 off, on a purchase of \$5 or more”) serves as an external reference point that overrides consumers’ internal reference points, changing the perceived magnitude of the discount. This can create a dominance violation, leading consumers to prefer objectively worse coupons.

Consumers frequently encounter coupons with a minimum purchase requirement (such as, “\$2 off, on a purchase of \$5 or more”). However, prior research on such restrictions has been conflicting regarding the effects on consumer behavior. Some research has suggested that these restrictions generate positive consumer reactions (Inman, Peter and Raghubir 1997), while others have demonstrated the opposite (Cheng and Blank 2019; Gneezy 2004; Wierich and Zielke 2014). We seek to resolve these conflicting findings by investigating the process by which minimum purchase restrictions impact cognitive evaluations.

Prior research has established that consumer evaluations of price discounts are often based on an assessment of the discount value relative to a reference point (Thaler 1985). There are two types of reference points: External ones are observed information (Mayhew and Winer 1992), while internal ones are developed from experience and based on memory. In the absence of an external reference point, people tend to use an internal reference point as a default to evaluate a target; however, people adjust their reference point accordingly if an external reference point is available (Biswas and Blair 1991). Building on these findings, we propose that a minimum purchase can serve as an external reference point that overrides consumers’ internal reference point.

In the context of our study, which is focused on retail coupons, we believe a salient internal reference point is the cost of a typical purchase at the store. In a pretest, we asked 100 Prolific participants how much they typically spend at different types of stores and used the median in each category to estimate consumers’ internal reference points. We posit that when a minimum purchase cutoff is lower than consumers’ internal reference point, the restriction enlarges the perceived discount magnitude and boosts coupon redemption intentions. For example, the typical grocery store purchase is £4. In this context, a “£1 off groceries” coupon feels like “25% off”, but a “£1 off any grocery purchase of £2 or more” feels like “50% off”, and is preferred by consumers, thus creating a dominance violation. In contrast, when the cutoff is higher than consumers’ internal reference point, it produces the opposite effect. Five preregistered studies provide converging evidence for our hypotheses.

Field study 1 demonstrates that a minimum purchase can generate positive consumer reactions. We created two coupon ads for a grocery store on Facebook (restricted vs. unrestricted). The unrestricted coupon ad, which read “\$1 off,” generated a higher CTR (1.14%) than the unrestricted ad (0.88%), which read “\$1 off if you spend \$2 or more” ($p < .001$). This was replicated in the lab in study 1B.

In study 2, we varied the minimum purchase cutoff. Participants ($N=300$) were randomly assigned to one of three between-participants conditions: unrestricted, low cutoff (£2 minimum purchase), or high cutoff (£20 minimum purchase). Participants were asked to imagine having found a £1 coupon for a supermarket near their home, and indicate their coupon redemption likelihood (1=very un-

likely, 7=very likely). Participants in the low cutoff condition were more likely to redeem the coupon ($M=6.03$, $SD=1.17$) compared to those in the unrestricted condition ($M=5.22$, $SD=1.71$), $p=.002$, and high cutoff condition ($M=4.03$, $SD=2.02$), $p < .001$. The perceived magnitude of the discount (1=very small, 7=very big) showed the same pattern.

Study 3 provides further evidence for the underlying process through moderation. If the perceived magnitude of the discount drives the effect, then a minimum purchase should not influence redemption intentions when a discount is presented in a percentage format, which makes the magnitude of the discount explicit. Participants ($N=400$) were randomly assigned to one of four conditions in a 2 (percentage vs. absolute format) \times 2 (restricted vs. unrestricted) between-participants design. Participants were asked to imagine they find either a 10% off any purchase or £2 off any purchase coupon for a department store near where they live. The restricted coupon requires a £3 minimum purchase. A 2 \times 2 ANOVA of redemption intention revealed a significant interaction ($p=.003$). The restriction increased redemption intention only when the discount was presented in an absolute format ($p < .001$) but not in a percentage format ($p=.86$). A 2 \times 2 ANOVA of perceived discount magnitude revealed the same pattern (see Figure 1). Moreover, a moderated mediation analysis showed that the discount format moderated the mediation by perceived discount magnitude (95% $CI=[.94, 1.79]$). Perceived discount magnitude mediated the effect when the discount was presented in an absolute format (95% $CI=[1.22, 1.91]$), but not when the discount was presented in a percentage format (95% $CI=[-.05, .47]$).

Study 4 reveals that a product category restriction can also function as a reference point, although it does not provide a precise reference point. Participants ($N=352$) indicated greater intentions to redeem a “\$1 off fruits and vegetables” coupon ($M=4.73$, $SD=2.15$) than a “\$1 off” coupon ($M=3.55$, $SD=2.08$) in a flyer for a supermarket near where they live, $p < .001$. The perceived magnitude of the discount fully mediated the effect (95% $CI=[.47, 1.18]$).

In sum, the present research resolves conflicting results in the literature, enriches our understanding of reference effects, and demonstrates the conditions necessary for a dominance violation.

Finding Meaning: Loneliness Increases Preference for Art-infused Products

Ms. Saira Raza Khan, University of Auckland, New Zealand

Dr. Yuri Seo, University of Auckland, New Zealand

Dr. Felix Septianto, University of Queensland, Australia

EXTENDED ABSTRACT

The present research posits that the feelings of loneliness increase preference for art-infused products. This occurs because lonely individuals are more actively seeking meaning in life, which subsequently makes them perceive the art-infused products as more meaningful.

Loneliness refers to the unpleasant feelings of social isolation, which occur when social needs are not adequately met (Peplau and Perlman, 1982). It is associated with poor physical, emotional, and mental health, as well as with the perception that one's life lacks meaning (Stillman et al., 2009).

To experience life as meaningful is a fundamental need for humans (Baumeister, 1991). Since the feelings of loneliness lead to the perception that one's life lacks meaning (Stillman et al., 2009), lonely consumers are more likely to recognize the meaning-based concepts within their consumption-related judgments. This is because individuals selectively pay attention to features of the environment depending on their current motivations (Taylor and Fiske, 1978). Thus, on the one hand, with an increased desire to find meaning in life, lonely individuals will be drawn to features of meaningfulness in a product more so than when they are less lonely.

On the other hand, the consumption of art-infused products can be perceived by consumers as a more meaningful activity. Art infusion refers to the use of artworks within advertising, packaging, or design (Hagtvedt and Patrick, 2008). One pertinent feature of artworks is that they can also be perceived as adding meaning to people's lives (Hagtvedt, 2022). Interdisciplinary scholarship suggests that artworks can enhance meaning by encouraging people to draw their own interpretations (Hagtvedt, 2022). Thus, art-infused products could be perceived by consumers as more meaningful than those that are not art-infused. Importantly, however, we argue that such perceptions are likely to become more accessible for lonely consumers who are more motivated to search for meaning in life. The predictions are as follows:

Hypothesis 1a: Lonely (vs. non-lonely) individuals will exhibit increased preference for art-infused products.

Hypothesis 1b: Product meaningfulness mediates the effect of loneliness on preference for art-infused products.

We conducted five studies to test these predictions.

Study 1 examines whether trait loneliness is associated with an increased preference for art-infused products. Participants (131 MTurkers) were first asked to complete the loneliness scale (Wang et al., 2012). They were then asked to choose between two product options, art vs non-art. Finally, they were asked whether their preference was driven by price considerations, quality considerations, or product meaningfulness. Results showed that lonely participants had an increased preference for art-infused products, and this preference was driven by product meaningfulness and not by other considerations.

Study 2a provides causal evidence of the effect of loneliness on preference for art-infused products and that product meaningfulness would mediate this effect. First, participants (221 MTurkers) were randomly assigned to either the lonely or control condition. Participants in the lonely condition were asked to write about an event that made them feel lonely. Participants in the control condition were asked to write about their daily activities. They were then asked to choose from three sets of options: art vs non-art as the focal dependent vari-

able, and art vs art and non-art vs non-art as filler choices. Next, participants were asked how much their choices were driven by product quality, price, and meaningfulness. Results showed that loneliness led to increased preference for art-infused products, and that the loneliness effect was mediated via product meaningfulness (and not other considerations).

Study 2b rules out luxury as an alternative explanation. The first task used similar procedures and materials to those of Study 2a. Then participants (202 MTurkers) were asked to choose between an art-infused and a luxury product. Results reveal that lonely participants exhibited higher preference for art-infused (vs luxury) products.

Study 2c replicates Studies 2a and b by testing a consequential decision-making context as the dependent variable. Participants (126 students) were randomly assigned to either lonely or control condition, similar to study 2a. As a reward for participation, they were presented with a choice between a café located in the art gallery (art) and a usual café (non-art). Results reveal, the proportion of participants who chose the art café was higher in the lonely condition than in the control condition.

Study 3 demonstrates that loneliness increased preference for art-infused products by employing a 2 (feelings: loneliness, control) X 2 (product: art-infusion, control) experimental design. Participants (406 Prolifics) were randomly assigned to either lonely or control condition and were asked to evaluate statements meant to induce the feeling of loneliness or calmness. Next, participants were asked to evaluate either an art-infused or a non-art-infused product and were asked about their likelihood of buying the product. We then measured product perceived meaningfulness and luxuriousness. Results revealed that the preference for art-infused product was greater among lonely (vs. non-lonely) participants, whereas there was no difference in preference for the non-art-infused product between the two feelings conditions. In the same vein, while the art-infused product was perceived more meaningful by lonely (vs. non-lonely) participants, there was no difference in the perceived meaningfulness for the non-art-infused product. We found a main effect of art-infused product on perceived luxuriousness that did not vary across the feelings condition.

In sum, our research establishes that loneliness increases preference for art-infused products due to perceived meaningfulness.

Mind Over Body in Games of Chance

Mr. Amin Shiri, Texas AandM University, USA

Prof. Gerald Häubl, Alberta School of Business, University of Alberta, Canada

Mr. Rory Waisman, Alberta School of Business, University of Alberta, Canada

EXTENDED ABSTRACT

The role that gamblers perform systematically affects their outcome expectations. Gambling roles that focus on thinking (mental roles) activate more favorable outcome representations than roles that focus on doing (physical roles). Mental roles promote greater optimism, are preferred over physical roles, and result in greater financial risk-taking when gambling.

The gambling industry contributes over \$700 billion annually to the global economy (StrategyR 2020) but entails a significant cost to society, with over eight million problem gamblers in the U.S. alone and social costs of \$10 billion every year (NCPG 2020). Development of gambling regulations and effective interventions for problem gambling hinges on an understanding of the psychology of gambling. We advance this understanding by showing that the manner in which gamblers interact with games of chance affects the magnitude of the cognitive biases that influence their behavior.

We theorize that the way in which a gambler interacts with a game systematically influences the focus of their cognitive activity, with implications for optimism about the gambling outcome. The cognitive representations associated with one's anticipated role in a game could focus either on doing (i.e., physical actions) or on thinking (i.e., mental actions). Different roles may facilitate one focus versus the other, leading to differences in the extent to which representations of a favorable outcome are activated. We theorize that roles that focus on thinking (mental roles) are more likely to activate favorable outcome representations than roles that focus on doing (physical roles), and thus promote greater optimism about obtaining a favorable outcome. The increased activation of favorable outcome representations in a mental role manifests in a preference for a mental role over a physical role when people are given a choice between them and in greater willingness to take financial risk when gambling. Our theorizing builds on research on mental simulation (Carroll 1978), activation of implementation goals (Gollwitzer 1989), and counterfactual thinking (Markman et al. 1995).

To test our theorizing, we conducted seven pre-registered studies ($N = 4975$) featuring games of chance that do not require any expertise. In the first three studies (1A, 1B, and 1C), participants were introduced to one of three games of chance (coin toss in 1A; wheel of fortune in 1B; sphere game in 1C), and were shown two versions of the game—one in which they would perform the physical role (flipping a coin, spinning a wheel, or operating an air pump) and another in which they would perform the mental role (calling the winning side, letter, or color)—and then indicated which version they would prefer to play for a chance to win \$10. For Study 1C, we constructed a novel game—the sphere game—to avoid tapping into prior experience or knowledge. In all three studies, the majority of participants preferred the mental role over the physical role—74% in 1A, 60% in 1B, and 70% in 1C (all $ps < .001$).

In Study 2, we ruled out temporal distance to the outcome as an explanation for the preference for a mental role by manipulating the order in which the mental and physical roles were initiated in a coin toss game. The majority of participants chose the mental role when it was first (66%) and when it was second (69%; $ps < .001$). In Study 3, we used the sphere game from Study 1C and manipulated knowledge of the probability of winning by informing participants either that the sphere contains two balls or that the number of balls

is unknown. Again, the majority preferred the mental role regardless of whether the probability of winning was known (72%) or unknown (81%; $ps < .001$).

Study 4 sheds light on the underlying psychological mechanism. Participants rated their optimism about winning in the two versions (physical role vs. mental role) of the sphere game and then chose the version of the game they preferred to play. Participants were more optimistic about winning in the mental role ($p < .001$) and more likely to choose it (63%; $p < .001$). Critically, the difference in optimism scores (Mental – Physical) significantly predicts participants' choices ($p < .001$).

Study 5 tested our theorizing in an economically consequential setting. Participants were randomly assigned to either the physical (operating the air pump) or the mental (calling the winning color) role in the sphere game and they reported their optimism about winning. Next, we endowed them with a bonus payment and offered them the opportunity to use this bonus to pay to play the game for a chance to double their bonus. Participants in the mental role were more likely to pay to play ($p < .01$) and more optimistic about winning ($p < .039$) than those in the physical role. Mediation analysis reveals that the mental (versus physical) role increased the tendency to pay to play via greater optimism about winning the game (indirect effect: $\beta = .09$, $SE = .05$, 95% CI : [.003 to .182]).

Extensive prior research suggests that people are motivated to control their environment—reflecting a need for competence, mastery, superiority, or personal causation. This fundamental desire is often satisfied when one is able to produce a tangible change in their physical environment, which has profound implications for unrealistic optimism in gambling. By its very nature, a mental role in a game cannot produce a tangible change in the physical environment. Nevertheless, as shown in the present research, a mental role actually generates greater optimism about the gambling outcome than a physical role, is preferred over a physical role by gamblers, and promotes greater financial risk-taking when gambling.

Do People Gain Similar Well-Being Benefits from Prosocial Behavior? The Impact of Political Partisanship on Well-Being Benefits Gained from Volunteering versus Donating

Ms. Bonnie Hao, University of Minnesota, USA

Dr. Akshay Rao, University of Minnesota, USA

EXTENDED ABSTRACT

We tested the interaction effect of prosocial behavior and political partisanship on well-being. Two studies demonstrated that Republicans perceived more happiness from volunteering than Democrats. Republicans also perceived more happiness from volunteering than donating. Democrats, in contrast, perceived similar levels of benefits from the two prosocial actions.

INTRODUCTION

In 2020, individuals gave around \$324 billion to charities (Giving USA 2021), and approximately 25 percent of U.S. adults volunteered in 2017 (McKeever 2018). Charitable behaviors enhance consumer well-being (e.g., Dunn, Aknin, and Norton 2008). However, to whom these activities are more beneficial is unclear. Because volunteering and donating differ on many dimensions, individuals who value the dimensions differently ought to display differing preferences and experience different levels of happiness. Drawing from literatures on prosocial behavior and well-being, self-determination theory, and political ideology, we argue that volunteering requires more effort than an economically equivalent donation and that this difference impacts the happiness people gain from prosocial behaviors, depending on their political partisanship.

STUDY 1

Study 1 ($n=199$, 65.3% female, $M_{age}=45.68$ years) examined the interaction effect of prosocial behavior and partisanship on happiness in a 2 (volunteering vs. donating) \times 2 (Republican vs. Democrat) between-subjects design. Prosocial behavior was manipulated, and partisanship was measured.

Prolific workers with 95% or higher approval rate participated in the study. Participants were told that we were interested in their opinion about Make-A-Wish, a non-profit organization that helps children diagnosed with life-threatening medical conditions have their wishes fulfilled. Participants were randomly assigned to volunteering versus donating conditions. Depending on the condition, participants were asked to volunteer 20 minutes of their time (or donate 6 dollars of their money) to Make-A-Wish. After spending two minutes imagining their prosocial behaviors, participants indicated perceived happiness when thinking about their behaviors to Make-A-Wish. Happiness was assessed by subtracting negative affect from positive affect (Weinstein and Ryan 2010). Positive affect items include joyful, happy, pleased, and enjoyment ($\alpha=.980$, Diener and Emmons 1984). Negative affect items include worried, depressed, frustrated, angry, and unhappy ($\alpha=.892$, Diener and Emmons 1984). Responding to a 7-point scale (1=not at all true, 7=very true), participants reported their feelings. Participants filled out demographic and partisanship measures (1=Democrat, 2=Republican, 3=Independent, 4=Libertarian, 5=Other) at the end.

Manipulation check measures indicated that the prosocial behavior manipulations worked as intended. Additionally, aligned with our hypotheses, simple effects analyses showed that Republicans perceived more happiness from volunteering than from donating ($M_{vol} = 4.15$, $M_{don} = 3.09$, $p = .046$). In contrast, Democrats did not differ on perceived happiness between volunteering and donating ($p > .54$). Republicans also perceived more happiness from volunteer-

ing than Democrats ($M_{rep} = 4.15$, $M_{dem} = 3.52$, $p = .148$). Although the difference did not reach statistical significance, the results followed the predicted pattern.

Study 1 provided initial evidence that partisanship impacted happiness people perceived from prosocial behaviors. Study 2 replicated Study 1 results and examined the mediating roles of autonomous motivation and need for autonomy.

STUDY 2

Prolific workers with 95% or higher approval rate participated in the study ($n=394$, 55.8% female, $M_{age}=41.19$ years). Study 2 followed the same design and procedures as Study 1, except that before the manipulation, we measured participants' baseline happiness using two items. On a 5-point scale (1=not at all; 5=extremely), participants responded to "do you feel happy right now?" Participants also responded to the item "In general, I consider myself..." on a 5-point scale (1=not a very happy person; 5=a very happy person). Additionally, after filling out happiness measures, participants indicated their autonomous motivation and need for autonomy. Autonomous motivation was measured using six items ($\alpha=.922$, adopted from Weinstein and Ryan 2010, sample item "I volunteered time/donated money... because I thought it was important to act in this way."). Three items ($\alpha=.79$) were used to assess need for autonomy (adapted from La Guardia et al. 2000, sample item "I felt free to be who I am when deciding whether to volunteer my time for Make-A-Wish."). Participants rated these items on a 7-point scale (1=not at all true; 7=very true). Participants then answered the manipulation check question and provided partisanship and demographic information.

Manipulation check measures indicated that the prosocial behavior manipulations worked as intended. A 2-way ANCOVA was conducted to test our hypotheses. Happiness was calculated by subtracting negative affect ($\alpha=.827$) from positive affect ($\alpha=.966$). Pre-happiness was calculated by averaging participants' responses on the two measures (correlation=.67, $p < .001$). The 2-way ANCOVA indicated a significant effect of pre-happiness ($p < .001$). More importantly, simple effects analyses showed that Republicans perceived more happiness from volunteering than Democrats ($M_{rep} = 3.96$, $M_{dem} = 2.68$, $p < .001$). Republicans also perceived more happiness from volunteering than donating ($M_{vol} = 3.96$, $M_{don} = 3.41$, $p = .034$). However, Democrats perceived the same levels of happiness from two behaviors ($p > .78$).

Additionally, we examined the interaction impact on autonomous motivation and need for autonomy. Simple effects analyses showed that Republicans perceived more autonomous motivation from volunteering than Democrats ($M_{rep} = 5.56$, $M_{dem} = 5.03$, $p = .012$). Republicans had more autonomous motivation from volunteering than from donating ($M_{vol} = 5.56$, $M_{don} = 5.10$, $p = .011$). In contrast, Democrats had similar levels of autonomous motivation from the two behaviors ($p > .280$). Similarly, Republicans perceived more need for autonomy from volunteering than Democrats ($M_{rep} = 5.34$, $M_{dem} = 4.76$, $p = .067$). Republicans had more need for autonomy from volunteering than donating ($M_{vol} = 5.34$, $M_{don} = 4.98$, $p = .030$). However, Democrats had similar levels of need for autonomy from the two behaviors ($p > .98$).

Lastly, using PROCESS model 86 (Hayes 2013), we found evidence of the mediating roles of autonomous motivation and need for autonomy. A bootstrap confidence interval for the indirect effect of prosocial behavior and partisanship (Republican) on happiness via autonomous motivation and need for autonomy indicates support for the serial mediation mechanism ($b = .11$, $SE = .05$. 95% CI [.0241, .2216]).

Study 2 supported our arguments that partisanship moderated well-being benefits from volunteering versus donating and illustrated the mediating effects.

GENERAL DISCUSSION

In summary, our research shows that people with different political preferences benefit differently from prosocial behaviors. Our research, therefore, contributes to relevant literatures. Our results can also help marketers promote prosocial campaigns more effectively.

What Motivates People to Share Commercial Content via Their Social Network? A Cost-Benefit Perspective on Social Promotional Advertising

Dr. Jie Wang, Renmin University of China, China

Dr. Xuejiao Lin, Renmin University of China, China

Dr. Jing Jiang, Renmin University of China, China

EXTENDED ABSTRACT

We introduce a new form influencer marketing strategy that hinges on consumers' social influence on strong ties—social promotional advertising (SPA). We propose an integrated framework that captures the factors that drive and impede consumers' sharing intention in SPA activities.

A common influencer marketing campaign (IMC) involves identifying a set of influential consumers (i.e., bloggers with numerous followers) and then soliciting them to share specific content about products and brands (Libai et al., 2013). Audiences typically have a weak-tie relationship with influencers (i.e., people they do not know well) as opposed to their strong-tie relationships with friends, family members, or other people to whom they are closely tied. Nevertheless, information exchange in strong social ties is more frequent and influential (Aral & Walker, 2014; Haythornthwaite, 2001). In this study, we introduce a new form of influencer marketing that utilizes consumers' strong-tie social networks. We define it as social promotional advertising (SPA), whereby the company first generates digital content and then inspires consumers to share it in their close social circles by offering them various incentives, including, but not limited to, scarce products, price discounts, coupons, and cash rewards.

To shed more light on this marketing practice, our study adopts a cost-benefit perspective to examine consumers' engagement in SPAs. Moreover, based on the level of involvement, we distinguish between informative and interactive SPAs and conduct a multigroup analysis between the two types of SPA activities to compare the differences in what drives consumers to share.

We draw on the literature and the results of the qualitative study to delineate the integrated model that captures the benefit and cost factors that affect consumers' intention to share SPAs on strong-tie social media platforms. Benefit factors—financial reward, reciprocity, sense of self-worth, and socializing—would increase consumers' intention to share SPAs by enhancing perceived value. However, cost factors—time and effort, perceived responsibility, and image concern—would decrease sharing intention by weakening perceived value.

We further contend that the process of consumer engagement differs with different types of SPAs. In informative SPAs, consumers receive a reward if they pass the link to others, and the recipients voluntarily choose to read or watch advertising messages. Conversely, interactive SPAs entail engagement, whereby consumers share messages with their friends and ask them to engage in specific tasks designated by the company. Essentially, these tasks, such as giving a thumbs up, clicking on the link, or visiting the online shop, guide the recipients to view the commercial message. Sharers in interactive SPAs typically invest more effort and time, obtain more financial rewards and increase social interactions with recipients but also bear more risks of being refused and are more likely to feel indebted compared with informative SPAs. It can reasonably be expected that the factors that drive and impede consumer sharing are different in relation to informative and interactive SPAs.

We distributed 600 questionnaires via online and offline channels using convenience sampling. A total of 588 valid questionnaires were obtained for further analysis—294 for informative SPA and

294 for interactive SPA. Participants were randomly assigned to either the informative or the interactive SPA condition. First, they were introduced to the concept and presented with a definition and several examples of each condition. Participants were then asked to report their agreement with the statements measuring all nine variables. Finally, participants responded to two attention-check questions which were followed by demographic questions.

We employed covariance-based structural equation modelling (CB-SEM) for path analyses (Hair et al., 2012). For the informative SPA condition, the results showed that reciprocity ($\beta = 0.196^{**}$), sense of self-worth ($\beta = 0.192^{**}$), and socializing ($\beta = 0.362^{***}$) were drivers of sharing intention. However, time and effort ($\beta = -0.091^*$), perceived responsibility ($\beta = -0.090^*$), and image concern ($\beta = -0.151^{***}$) exerted negative effects on sharing intention. The effect of financial reward on sharing intention was not significant. For the interactive SPA condition, the results showed that financial reward ($\beta = 0.126^{***}$), reciprocity ($\beta = 0.201^{**}$), and socializing ($\beta = 0.342^{***}$) were drivers of sharing intention. However, time and effort ($\beta = -0.124^{**}$) and image concern ($\beta = -0.199^{***}$) exerted negative effects on sharing intention. The effects of sense of self-worth and perceived responsibility on sharing intention were not significant.
