We propose that people seeking advice employ the specificity heuristic because they overweigh the importance of differences among available choice options or courses of action. While expertise allows one to perceive both more similarities and more differences among options, to the person seeking advice the latter ability is more important. This is because individuals seeking advice typically lack the depth of knowledge necessary to discern between available options and actions and identify superior one(s) – to the novice eye, "they all look the same." The more specific the advice that an agent provides, then, the more knowledgeable he is judged to be.

While the use of the specificity heuristic may seem as a reasonable inferential process, specificity per se does not determine the accuracy or validity of a recommendation. A recommendation can be unnecessarily restrictive – for example, the Dukan diet prescribes that the daily dose of protein be taken with "no more than 1.5 tablespoons of oat bran." While this specification is most likely random, consumers may infer that taking their protein with more or less than the prescribed amount would affect the success of their diet. Thus agents aware of the specificity bias can deliberately include random specific restrictions, similar to the manner in which confidence, extremity, or over criticism can be misused to influence impression of expertise.

We report the results of six studies that document the use of the specificity heuristic and identify boundary conditions.

METHOD AND FINDINGS

Studies 1 and 2 demonstrate the use of the specificity heuristic when specificity takes the form of excluding particular options from a choice set. A travel agent advising a customer on places to visit in Brazil, receives more favorable evaluations ($M_{restr.}$ = 4.66 vs. $M_{control}$ = 3.88, $t(81)$ = 2.39, $p < .05$) and is perceived as more knowledgeable ($M_{restr.}$ = 4.51 vs. $M_{control}$ = 3.74, $t(81)$ = 2.32, $p < .05$) when she excludes specific destinations or modes of transport from her recommendation. Similarly, in Study 2, a waiter recommending wine receives higher evaluations ($M_{restr.}$ = 5.68 vs. $M_{control}$ = 4.94, $t(83)$ = 3.06, $p < .005$) and knowledge ratings ($M_{restr.}$ = 5.62 vs. $M_{control}$ = 5.02, $t(83)$ = 2.11, $p < .05$) when he excludes particular wines from a set of recommended wines.

Studies 3 and 4 document the use of the specificity heuristic in the context of medical decision making and demonstrate that it cannot be explained with a negativity bias. In study 3 a doctor who recommends that the patient *include* dairy food while taking the prescribed medication is evaluated just as favorably as one who recommends that the patient *exclude* dairy food from their diet ($F < 1$). In both scenarios, which represent specificity cases, the doctor is evaluated more positively, on average (M = 4.75) than a doctor who prescribes the same medication but states that dairy intake does not impact its effectiveness (M = 4.14, $t(150)$ = 2.40, $p < .05$). In study 4, a doctor who advises a patient to take three dietary supplements is evaluated more favorably ($M_{restriction}$ = 4.90 vs. $M_{control}$ = 4.38; $F(1, 125)$ = 4.42, $p < .05$) and is perceived as more knowledgeable ($M_{restriction}$ = 4.90 vs. $M_{control}$ = 4.33; $F(1, 125)$ = 4.58, $p < .05$) when he recommends that the supplements be taken in a particular order (versus a control condition, in which he states that the order makes no difference).

Studies 5 and 6 demonstrate that the use of the specificity heuristic is moderated by the availability of other diagnostic information. Individuals are less likely to rely on the heuristic when they are familiar with the recommended option (study 5) or when they have access to diagnostic information about the agent's expertise (study 6).

CONTRIBUTION

This research contributes to the literature on advice taking by expanding our understanding about factors which impact the perceived expertise of agents. The research contributes, more broadly, to the literature on information source evaluation, by documenting a heuristic that people use when they have access to little diagnostic information. Such situations represent a significant proportion of real-life decision making, especially given the increased use of online recommendations whose sources are often anonymous.

Regulating Consumer Behavior by Refraining From Action

Anneleen Van Kerckhove, Ghent University, Belgium
Maggie Geuens, Ghent University, Belgium

EXTENDED ABSTRACT

In face of positive stimuli, people generally activate approach motivation, whereas avoidance motivation is activated in face of negative stimuli (Elliot and Thrash 2002). Embodied cognition research has shown that engaging in approach/avoidance-related motor actions also activates the corresponding motivational system, and as such has a profound influence on consumers' judgments and choices (Cacioppo et al. 1993; Friedman and Förster 2000). Performing approach motor actions increases both preference for vices over virtues (Van den Bergh, Schmitt, and Warlop 2011) and attractiveness ratings of generally positively evaluated consumer goods (Förster 2004). Likewise, engaging in avoidance motor actions leads to a devaluation of generally negatively evaluated stimuli (Förster 2004), and is suggested to increase insurance adoption (Van den Bergh et al. 2011).

We propose that refraining from engaging in approach/avoidance motor action may be embodied as well, as people often encounter situations that require them to override impulsive approach/avoidance tendencies (Kühn et al. 2009). For example, a person who passes a stall selling fresh lemonade may experience the urge to buy some, and may yet choose to walk by and avoid consuming the calories. Similarly, medicines often evoke an avoidance reaction because of their bad taste, yet consuming them is indispensable when ill (Hung and Labroo 2011).

Hence, people often benefit from overriding initial approach and avoidance impulses by refraining from executing an impulsive motor action. Therefore, we investigate whether experiencing the retraction of a reflexive approach/avoidance movement leads to decreased activation of approach/avoidance systems. The former should manifest in the devaluation of positively evaluated stimuli and a decreased preference for vices over virtues, as these consumption-related variables have been shown to be influenced by differential activation of approach motivation (Förster 2004; Van den Bergh et al. 2011). The latter should be apparent in a more positive evaluation of negative stimuli, and decreased likelihood to purchase insurance products.

As people's behavioral approach and behavioral inhibition systems may exhibit differential sensitivity (Carver and White 1994), the effect of refraining from an approach (avoidance) motor action should be moderated by BAS (BIS) sensitivity, such that only people with a highly sensitive BAS (BIS) likely experience the influence of exercising restraint in the face of positively (negatively) evaluated stimuli.

Study 1 investigates the consequences of refraining from action on the evaluation of positive and negative stimuli and addresses the moderating role of BIS/BAS sensitivity. 284 students were randomly assigned to one of five conditions; arm positions (flexion vs. extension) and the amount of exercised pressure (slight pressure vs. refraining from exercising pressure) varied between subjects, and a control condition provided no instructions on arm movements. Subjects were presented with consumer goods with either positive and negative valences.

First, the participants completed the Sensitivity to Punishment/ Sensitivity to Reward Questionnaire (Torrubia et al. 2001) as a self-reported index of BIS/BAS functioning (Caseras, Avila, and Torrubia 2003). Next, while adopting the required hand positions, participants indicated how much they liked each consumer good on a 9-point scale by pressing the appropriate number on the keyboard. Most in-

teresting, the results indicate that engaging in and refraining from avoidance motor actions had opposite effects on the evaluation of generally negatively evaluated consumer goods. While the former resulted in a devaluation, the latter increased the evaluation of negative goods (figure 1a). In addition, the more negative evaluation after performing an avoidance movement and the more positive evaluation after refraining from an avoidance movement reached its highest level among participants with a highly sensitive BIS (figure 1b). Evaluations of positive consumer goods improved when participants performed approach behavior and worsened when they refrained from performing approach behavior (figure 2a). This difference in liking reached its highest levels among participants with a highly sensitive BAS (figure 2b).

Figure 1a: Negative Consumer Good Attractiveness Dependent on Hand Position and Exercised Pressure
Figure 1b: Negative Consumer Good Attractiveness for People Engaging in Arm Extension, Dependent on Exercised Pressure and BIS Sensitivity
Figure 2a: Positive Consumer Good Attractiveness Dependent on Hand Position and Exercised Pressure
Figure 2b: Positive Consumer Good Attractiveness for People Engaging in Arm Flexion, Dependent on Exercised Pressure and BAS Sensitivity
These findings suggest that refraining from approach/avoidance behavior likely decreases the activation of an approach/avoidance motivation. If so, refraining from approach/avoidance motor action should also lower preference for vices/decrease preference for insurance. This is tested in Studies 2 and 3 with data gathered from, respectively, 183 and 165 students, and a design similar to study 1. A 2 × 2 between-subjects design, plus a control, manipulating participants' right-hand position and the amount of exerted pressure. While keeping their right hand in place, participants chose between pairs of vice/virtue products (study 2),or indicated their willingness to pay for insurance (study 3) by checking an "include" or "do not include" box for several car insurance options at a certain price.

In both studies the interaction of hand position and exercised pressure appeared significant. Among participants engaged in arm flexion, those who exercised pressure were significantly more likely to select vice products than those instructed not to exercise pressure, but no significant difference emerged for those engaged in arm extension. Among participants engaged in arm extension, those who exercised pressure were significantly more inclined to obtain insurance options than those instructed to refrain from exercising pres-

sure, but no significant difference in insurance adoption emerged for those engaged in arm flexion. Studies 2 and 3 yield further confirmation for the influence of refraining from approach/avoidance motor actions in consumer choices that reflect the activation of the motivational approach/avoidance system.

Overall, this research adds to a body of consumer research on strategies to increase self-control (Hoch and Loewenstein 1991; Mukhopadhyay and Johar 2005). People are often shortsighted and easily tempted by hedonic "sins", such as overbuying, splurging on tasty but unhealthy food, and indulging in luxuries (Baumeister 2002; O'Guinn and Faber 1998). As these impulsive behaviors result from an impulsive approach/avoidance response, they often contradict with long-term goals (Baumeister 2002). From a consumer well-being perspective it is valuable to gain insight in elements underlying increased willpower.

When Lower is Better: The Impact of Activated Magnitude Interpretation Frames on Reactions to Alpha-numeric Brand Names

Anneleen Van Kerckhove, Ghent University, Belgium
Hendrik Slabbinck, Ghent University, Belgium
Mario Pandelaere, Ghent University, Belgium

EXTENDED ABSTRACT

Brand names play a vital role in the construction of a brand image that can affect the consumers' purchase decisions (Kohli and LaBahn, 1997). As brand names frequently comprise numerical components, resulting in alpha-numeric brand names, number liking should be an important consideration of marketers interested in creating effective brand names. Besides associations with specific, often culturally determined, meanings (e.g., the number 7 is lucky) (Battig and Spera 1962), structural characteristics of numbers (e.g., magnitude) may affect their liking. As people exhibit a general tendency to rely on magnitude information in their judgments, even when non-diagnostic (Silvera et al. 2002), this research investigates whether brand name conveyed magnitude information affects alpha-numeric brand preferences.

It is not clear how the magnitude of the numerical part is evaluated. Often when relying on magnitude information people endorse the idea that "bigger is better". People often favor bigger objects (Silvera et al. 2002); Larger assortments are evaluated better (Broniarczyk et al. 1998) and increasing the number of attributes accompanying a brand increases its favorability (Carpenter et al. 1994). Similarly, people also prefer larger numbers and this translates to object preference; colors are perceived as better when labeled with larger versus smaller numbers (Fias and Fischer 2005). Of particular relevance, Gunasti and Ross (2010) show that consumers' preference for alpha-numeric brands increases when the magnitude of the numerical part increases.

Situations in which small objects are highly valued are also prevalent. In today's society it is a challenge to build the smallest microchip, cellular phone or laptop computer. Body weight is typically evaluated more favorably when it is lower (Meier et al. 2008). In addition, lower numbers are better for many health indicators, golf scores, product grades, etc. As such, two opposing magnitude interpretation frames may exist and color people's judgments. Consumers may exhibit a preference for higher versus lower level alpha-numeric brand names dependent on whether they adopt a "bigger-is-better" versus a "smaller-is-better" frame. On which frame consumers rely may be influenced by external cues. Priming research has shown that people's interpretation of information depends on concepts that are currently active. In addition, priming cues may not only activate specific conceptual information, but also information processing procedures (Meyers-Levy 1989).

That both concepts and procedures can be primed suggests interpretation frames (i.e., procedures by which meaning is attached to concepts) can also be primed. As such, contextual information may affect alpha-numeric brand preferences dependent on whether it evokes a "larger is better" or "smaller is better" magnitude interpretation frame. Three studies yield evidence for this proposition.

Studies 1a (n = 122) and 1b (n = 122) rely on attribute specification to cue magnitude interpretation frames. Participants were presented with two printer (Study 1a) or refrigerator (Study 1b) brands and chose one of both. Each choice set varied along 2 dimensions (Tables 1a and 1b). The brands were described by units of expression representing a higher is better or smaller is better logic. In addition, brands were described by neutral terms (Brand A and Brand B) or by alpha-numeric brand names (CR-P-9 and CR-P-91 for printers; DMB-4 and DMB-96 for refrigerators).

Most importantly, when brands are described by a neutral label, changing the logic of the attribute units does not affect brand preferences. However, when brands are described by alpha-numeric brand names, changing the logic of the attribute units flips brand choices. When expression mode represents a "lower is better" ("higher is better") logic brands including a small (large) number are chosen more often compared to when expression mode represents a "higher is better" ("lower is better") logic (Tables 2a and 2b). These results demonstrate the importance of matching the number of an alpha-numeric brand name to the contextually evoked magnitude interpretation frame.

Study 2 (n=122) demonstrates that magnitude interpretation frames may also be evoked by brand slogans and that these frames may also guide absolute evaluations of alpha-numeric brand names including numbers that are generally judged as small (e.g., 1) or large (e.g., 100). In this study, participants inspected an advertisement of a new soda can 'Valens' (see Figure 1 for an example), which varied along two dimensions: the magnitude of the number included in the alpha-numeric brand name (No Number = 'Valens' vs. Small = 'Valens 1' vs. Large = 'Valens 100') and the slogan that was used to promote the product (Lower-is-better interpretation frame = 'Leave everyone behind' vs. Higher-is-better interpretation frame = 'Take it all'). Next, participants rated the attractiveness of the can they had been exposed to on a one-item 101-point scale.

Table 1a: Attribute Scores of the Printer Choice Options in Study 1a

Attribute Expression logic	Attributes	Brand A CR-P-9	Brand B CR-P-91
Higher is Better	Printing Speed # pages per minute	12	19
	Ink Price # pages for 1€	25	17
Lower is Better	Printing Speed # seconds to print 1 page	5	3
	Ink Price # cents to print 1 page	4	6

Table 1b: Attribute Scores of the Refrigerator Choice Options in Study 1b

Attribute Expression logic	Attributes	Brand A DMB-4	Brand B DMB-96
Higher is Better	CO_2 Emission # seconds to emit 100 gr	53	61
	Price Expenditure # minutes for 1€	353	286
Lower is Better	CO_2 Emission # grams per hour	114	98
	Price Expenditure # cents per hour	17	21

Figure 1:Example of a Fictitious Soda Can Used in Study 2

Figure 2: Mean Attractiveness Ratings of Brands Including No Number, aSmall or a Large Number Depending Evoked Magnitude Interpretation Frame

Most importantly, matching number magnitude onto the magnitude interpretation frame generated higher brand attractiveness ratings, whereas mismatching decreased the attractiveness ratings (see Figure 2).
This finding shows that not only relative preferences, but also absolute evaluations of brands may be influenced by activated magnitude interpretation frames. Studies 1 and 2 activated magnitude interpretation frames by changing brand-related information which is important, as these elements are under control of brand managers. Though, study 3 assesses whether contextual information, unrelated to the target brands, also affects alpha-numeric brand preferences, by using a different cue. Participants (n=103) rated the attractiveness of brand promotions, either announcing a price discount or a package premium (see Figure 3 for an example). Next, participants indicated their preferences for three pairs of printers. Each choice option was presented with a picture and an alpha-numeric brand name.

Figure 3: Example of Brand Promotions used in Study 3

The pictures and the left-right presentation of brand names were counterbalanced within pairs across participants. Priming different types of brand promotions significantly influenced participants' brand choices (see Table 3). Evaluating a price promotion (package

Table 2a: Choice Shares of the Printer Choice Options in Study 1a

Attribute Expression logic	Neutral Brand Name		Alpha-Numeric Brand Name	
	Brand A	**Brand B**	**CR-P-9**	**CR-P-91**
Higher is Better	76.3%	23.7%	61.3%	38.7%
Lower is Better	72.4%	27.6%	91.7%	8.3%

Table 2b: Choice Shares of the Refrigerator Choice Options in Study 1b

Attribute Expression logic	Neutral Brand Name		Alpha-Numeric Brand Name	
	Brand A	**Brand B**	**DMB-4**	**DMB-96**
Higher is Better	59.4%	40.6%	27.3%	72.7%
Lower is Better	45.7%	54.3%	72.7%	27.3%

premium) leads participants to prefer a printer comprising the lowest (highest) numerical portion.

The current paper contributes to research investigating how alpha-numeric brand names' numerical part affects their appeal. We focused on the impact of the conveyed magnitude. While Gunasti and Ross (2010) demonstrated alpha-numeric brands to benefit from including a higher number, our research demonstrates that this depends on the activated magnitude interpretation frame.

In or Out of Focus? Subcategories Trigger In-group Heterogeneity and Out-group Homogeneity Effects in Product Assortments

Erica van Herpen, University of Wagening, The Netherlands
Anick Bosmans, Tilburg University, The Netherlands

EXTENDED ABSTRACT

Ever since organic, fair trade, and other 'special' products have entered the conventional supermarket channel, retailers face "a dilemma as to where such products should be shelved" (Dahm, 2005). The retailer can place, for example, a line of organic products separately from conventional products, and devote part of the total shelf space for a product category to these products. Retail managers often believe that this will attract new consumers by drawing their attention to products they might not otherwise have considered (Lazarus, 2010). However, it also entails the risk that consumers ignore these products when they browse the shelf. Alternatively, the retailer may integrate an organic product line into the mainstream shelf. This may increase the chance that consumers will notice the organic products when browsing through the regular products, but also decreases the visibility of the organic product line as a whole.

Whereas previous studies have focused on how assortment organization affects consumers' variety perception of the total assortment (Hoch, Bradlow, & Wansink, 1999; Mogilner, Rudnick, & Iyengar, 2008), little is known about if and how the use a specific subcategory affects the variety perceptions of the products placed inside and outside that subcategory. Whereas the perceived variety of the total assortment might increase as a function of the amount of subcategories available, as suggested by previous studies (Kahn & Wansink, 2004; Mogilner et al. 2008), the perceived variety of the products presented in a specific subcategory may not. We argue that variety perceptions can increase and decrease simultaneously, and that whether consumers perceive less or more variety within a subcategory crucially depends on their intrinsic interest in the subcategory. People have a natural tendency to selectively attend to categories that are important to them, which affects their similarity perceptions (Goldstone 1998). Ample psychological studies have provided evidence for in-group heterogeneity and out-group homogeneity effects in people perception (Boldry & Kasy 1999; Judd, Ryan & Park 1991), and we expect that similar effects are present in product perception. That is, when a subcategory is of interest to consumers, they will focus more on these products and attempt to differentiate between them, while at the same time giving less attention to the products in another subcategory. These other products are perceived as more similar to one another, because they all share a common product attribute. As a result, perceived variety is high for products presented in the category of interest (i.e., in-group heterogeneity) but low for products presented outside this category (i.e., out-group homogeneity).

In two studies we investigate the effects of assortment organization (i.e. product presented in subcategories vs. products presented in a mixed display) and consumers' intrinsic interest (as an externally induced shopping goal in experiment 1 and as a measured individual difference variable in experiment 2) on perceived variety of products presented in the subcategories. In both experiments, organic products (teas and wines, respectively) are presented either mixed with regular products or in a separate subcategory in a computer-based experiment. Choice is recorded, as well as which products are clicked on for closer examination. The proportion of organic product examined is investigated as a mediator to test whether assortment organization allows consumers to better focus on the products they are interested in, which should drive variety perceptions.

Results for both experiments show that assortment organization can indeed trigger in-group versus out-group effects, such that variety perceptions for one subcategory increase and variety perceptions for another subcategory decrease simultaneously. Hence, we show that the presence of subcategories does not uniformly increase variety perceptions, but that it can even decrease variety perceptions for a specific subcategory. As expected, these effects are moderated by consumers' intrinsic interest in the subcategory: consumers pay attention to the subcategory of interest, leading to an increase in perceived variety of the subcategory of interest (i.e., an in-group heterogeneity effect), but ignore the subcategory that is not of interest (i.e., an out-group homogeneity effect). Moderated mediation analyses suggest that these effects are indeed mediated by the attention that consumers allocate to the different subcategories. In addition, our effects carry-over to consumers' product choice.

Our results extend prior research in several ways. In particular, whereas previous studies have shown that the use of subcategories can increase variety perceptions of the total assortment (Hoch et al. 1999; Kahn and Wansink 2008; Mogilner et al. 2008; Morales et al. 2005), we show that subcategories can affect variety perceptions of products presented inside and outside the subcategory of interest differently. These effects cannot be explained by processes proposed in prior research. For instance, whereas prior research has indicated that larger assortments are processed differently from smaller assortments (Iyengar & Lepper 2000; Broniarczyk et al. 1998), this alone cannot explain why two subcategories of equal size receive different variety ratings.

Our results have important implications for retailers who want to promote sustainable (e.g., organic or fair trade) or otherwise 'special' products (e.g., private labels). Whereas the use of a separate display might increase the salience of the attribute (e.g., sustainability), it may not necessarily increase the perception of variety and choice for these products. In fact, when many of the store's customers are not interested in the subcategory, devoting a separate section to these products may decrease sales levels. Contrary to current practices (Dahm 2005), when consumers' initial interest in the product category is low, retailers may be better off to integrate these products in the existing assortment, instead of presenting them in a separate product category.

Together or Alone: How The Social Setting of Experiences Impacts Preferences For Improving Versus Declining Sequences.

Rajesh Bhargave, University of Texas at San Antonio, USA
Nicole Votolato Montgomery, College of William and Mary, USA

EXTENDED ABSTRACT

People experience consumption episodes either in the presence of others or individually. For instance, a consumer may tour a museum as part of a group or only by himself. To date, little is understood about the impact of social context on how an experience unfolds over time or the subsequent effects on experience evaluations. We find that people's preference for improving vs. declining trends depends on whether the experience is consumed together or alone. This effect stems from differences in how consumers process and incorporate early versus later parts of the experience in evaluations.

Past research has demonstrated both direct and indirect social influence during experiences. Consumers communicate their reactions to others verbally (Raghunathan & Korfman 2006) or through subtle signals, such as facial expressions (Ramanathan & McGill 2007). We argue that social influence operates on another subtle dimension: consumers' processing style. Research on culture and self-construal has found that people embedded in social relations process information holistically, whereas those less embedded in these relations process analytically (Nisbett et al. 2001; Monga and John 2007). We predict that these differences will also emerge when comparing social and isolated hedonic experiences.

Processing style has been shown to moderate how people integrate sequences. In a person perception task, Forgas (2011) showed that participants who processed holistically (analytically) exhibited judgments that were more impacted by early (later) presented personality traits, consistent with a primacy effect (recency effect). Under holistic processing the initial information was weighted more in summary judgments and also provided an overarching frame to which later information was assimilated. Conversely, analytical processing suppressed such top-down perception, facilitating recency effects.

Extending Forgas' findings to consumption episodes, we identify a preference reversal that emerges due to differences in the processing style that the social setting promotes. We hypothesize that when people experience episodes alone, they prefer improving (vs. declining) sequences of events (i.e., those beginning with the worst event and ending with the best event), consistent with past research on hedonic experiences (Kahneman et al., 1993; Redelmeier & Kahneman 1996). However, when an experience occurs in the presence of others, the improving trend preference will be attenuated or even reversed, because such social experiences promote holistic processing, As such, we expect evaluations of later parts of the sequence to assimilate to earlier parts of the sequence, leveling the slope of the experienced trend. Moreover, when processing holistically, greater weighting of early events can produce higher evaluations for experiences that begin with the best event (declining sequences) versus the worst event (improving sequence).

Study 1 was a 2 (analytical vs. holistic processing prime) x 2 (improving vs. declining vacation experience trend) between-subjects design. Participants were either asked to find embedded images in a presented scene (analytical prime), or write about what they saw in the scene (holistic prime) (Monga and John 2008). Subsequently, they read about a vacation with events presented in either improving or declining order of pre-tested liking. Finally, participants rated their willingness to pay for the vacation. Consistent with past research (Kahneman et al. 1993), we found a main effect of trend,

showing a preference for the improving sequence (F(1,89) = 3.95, p =.05). Supporting our hypothesis, we also found a processing style X trend interaction (F(1,89) = 4.09, p <.05). Under analytical processing, participants preferred the improving sequence (Mimproving = $1642.86 vs. Mdeclining = $766.67, t(43) = 2.10, p < .05), but there was no trend preference under holistic processing (Mimproving = $722.68 vs. Mdeclining= $715.38, t(46) < 1).

Study 2 utilized the same design, but differed in two important ways. First, we used an actual experience (not simulated) with trend (improving vs. declining) manipulated using a sequence of 15 pre-tested art images. Second, we manipulated processing style using the presence or absence of others during the experience (vs. the processing style prime in study 1). Participants in the isolated condition wrote about themselves prior to viewing the images. Participants in the social condition were asked to introduce themselves to another person and were told that others in the lab would experience the same episode, prior to viewing the images. A pre-test confirmed that participants in the isolated versus the social condition exhibited a less holistic style of thinking (M = 4.45 vs. 4.86, F(1,74) = 5.20, p < .05) (Choi et al. 2007). After viewing the images, participants indicated their willingness to pay for the experience using a scale with different payment levels. Supporting our hypothesis, there was a significant social setting X trend interaction (F(1, 178) = 6.69, p = .01). Participants in the isolated condition exhibited a preference for the improving sequence (Mimproving = 2.95 vs. Mdeclining= 2.04, t(90) = 2.35, p = .02), whereas participants in the social condition directionally preferred the declining sequence (Mimproving = 2.39 vs. Mdeclining= 2.93, t(88) = 1.33, p = .18). Participants also rated each art image. Analyzing the slope of their ratings over the sequence's duration, we found a main effect of manipulated trend condition (F(1, 178) = 201, p < .001) and a social setting X trend interaction (F(1, 178) = 8.65, p < .01). Slopes were steeper in the isolated condition compared to the social condition (see figure 1). These results are consistent with our explanation that people undergoing the social experience anchor on earlier events in the sequence when reacting to later events.

Three unreported studies examine other operationalizations of the social vs. isolated distinction. Combined, this research advances our knowledge of the role of social context on consumption experiences, offering several contributions. Foremost, we demonstrate that social context influences hedonic experiences even without direct social interaction, and we show how these effects emerge over the course of the episode. Second, we reveal how processing style differences emerge due to variations in the social context of experiences, whereas past research on processing style focused on individual differences and cultural factors. Finally, we find an important boundary condition to the common preference for improving trends. These findings have implications for how marketers present experiences under different social situations.

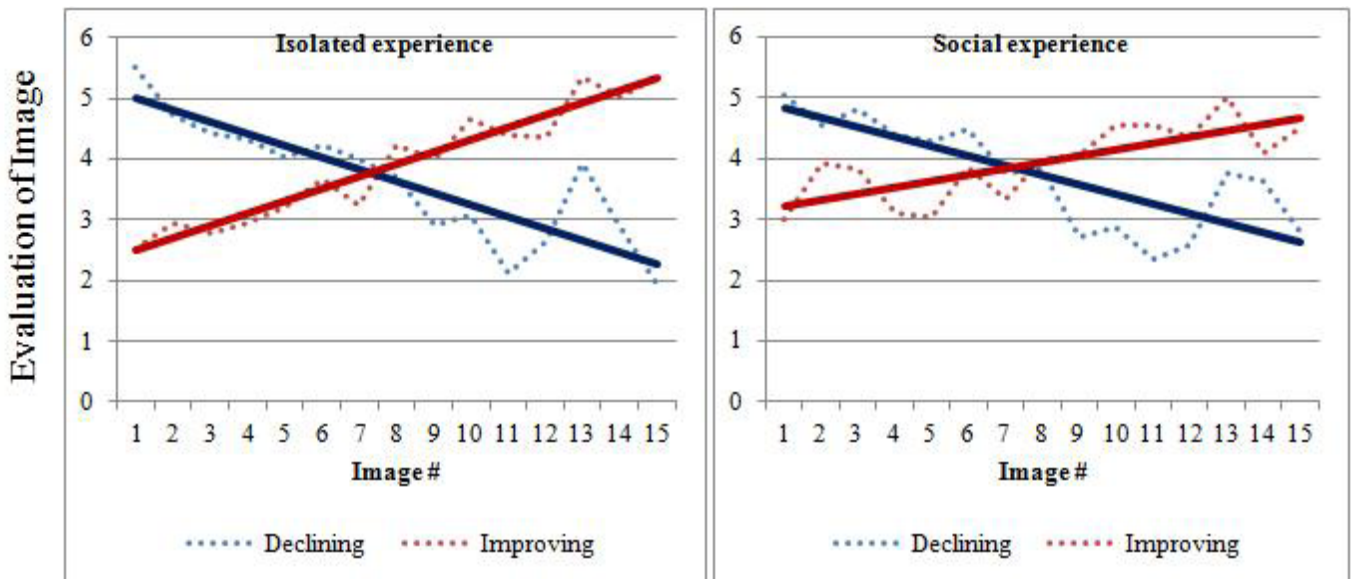
Figure 1: Moment-to-moment evaluations of art images


Mean moment-to-moment evaluations of art images in the second study described in the extended abstract. The left hand panel depicts evaluations for these images in the isolated experience conditions, and the right hand panel depicts these evaluations for the social experience conditions. Ratings for each image were on a 7-point scale of enjoyment, as reflected by the vertical axis in each panel. The sequence consisted of 15 images. The dashed lines indicate mean evaluation for each image in the declining (blue) and improving (red) trend conditions separately. The darker lines depict the trendline for each trend condition.

On Higher Ground: Moral Thinking Leads to Abstract Processing

Eugene Chan, University of Toronto, Canada
Eunice Kim Cho, University of Toronto, Canada

EXTENDED ABSTRACT

We often describe people who do the "right" thing as being "on a moral high ground", or we say that they are "taking the high road". There are also other similar sayings that refer to people behaving morally as "high-minded" or "upstanding" individuals. All of these images suggest a metaphorical connection between the concept of morality and the spatial orientation of vertical height. Specifically, they suggest that people who behave morally hold a position that is higher above ground than those who behave less morally. But are there cognitive consequences of being so high above ground – and thus, so *distant* to the world "down below" – that they would process their world differently?

Recent research on metaphorical thinking adopts an embodied cognition view, suggesting that people use their concrete physical sensations to describe abstract psychological experiences (Bargh 2006; Boroditsky and Ramscar 2002). For example, metaphors involving vertical height often have an embodied basis. In contexts of social power, powerful people are said to be "up high", such that individuals with social authority attend to high spatial locations quicker than low ones (Moeller, Robinson and Zabelina 2008). In many religions, "God is most high", and people perceive others as being more religious when their pictures are displayed at the top of a page rather than the bottom (Chasteen, Burdzy, and Pratt 2009). And people often give "thumbs up" to communicate positive feedback, stemming from the perception that anything "up" is good but "down" is bad (Meier and Robinson 2004). These findings suggest that moral metaphors referring to vertical height or the physical sensation of being high above ground may also have a similar embodied basis.

We posit that a consequence of behaving morally is that the vertical height increases the *distance* to the world down below, affecting how people high above ground would cognitively process their world. According construal level theory, as distance (vs. closeness) increases, so does abstract processing (Trope and Liberman 2003). Consider spectators sitting in the highest rows of a sports stadium, and hence are vertically high from where the main action is located. They describe their experiences as "squinting to see ant-sized players", and only see the broader aspects of the game, not its finer details. Building on these links between metaphorical thinking, embodied cognition, and construal level theory, we thus hypothesize and find in four experiments that people who do the right thing process their world abstractly.

Experiment 1 demonstrated the main effect that moral thinking leads to abstract processing. To prime moral or less moral thinking, we had undergraduate students write about an instance in their lives in which they did the "right" or "wrong" thing, respectively. They then completed the Behavioral Identification Form (BIF; Vallacher and Wegner 1989). As predicted, participants who recalled behaving morally selected more abstract descriptions on the BIF than those who recalled behaving less morally. We also ruled out mood as an alternative explanation for our findings.

Experiments 2 and 3 aimed to explore how moral thinking may influence specific cognitive consequences of abstract thinking. In Experiment 2, we reason that people who process abstractly pay little attention to details, and so they should be worse at analytical reasoning than those who process concretely (Friedman and Förster 2011). To prime moral or less moral thinking, we had undergraduates write stories about themselves using either positively- or negative-

ly-valenced words, such as *kind* or *greedy*, respectively. They then completed the Cognitive Reflection Test (CRT; Frederick 2005). As expected, participants in the moral prime scored lower on the CRT than those in the less moral prime. Mood had no effect. Meanwhile, in Experiment 3, we hypothesized that people who do the right thing are more creative than those who do the wrong thing (Förster, Epstude, and Özelsel 2009). Undergraduates received the same prime as Experiment 1, in addition to a control condition. They then generated as many creative ways of using a brick as possible. Planned contrasts revealed that participants in the moral prime generated more ways to use a brick creatively than those in the control, who generated more than those in the less moral prime.

Finally, Experiment 4 examined how moral thinking may influence consumer preferences. Mechanical Turk participants received the same moral or less prime as Experiment 1. They then saw an ad for the "Simply Orange" brand of orange juice that emphasized either the brand's abstract, future benefits or its concrete, immediate benefits. Participants who recalled behaving morally had more favourable attitudes toward Simply Orange when the ad was in an abstract than a concrete frame. Conversely, participants who recalled behaving less morally had more favourable attitudes toward the ad in a concrete than an abstract frame.

Across four experiments, this research demonstrates that metaphors like "on a high ground" and "taking the high road" are linked to embodied cognitions. More specifically, this link can cause people doing the right thing to subsequently process their world abstractly. Our findings may also offer another explanation for other consequences of moral thinking, such as licensing. Furthermore, our present findings encourage future research to understand morality not in isolation, but in terms of physically-grounded concepts.

Table 1
Experiment 2: Correct responses on the CRT.

	Ball/Bat	**Widgets**	**Lily Pads**	**Total**
Moral Thinking (*N* = 100)	42.7%	39.2%	36.8%	.81
Less Moral Thinking (*N* = 112)	58.3%	60.8%	63.2%	1.14
p-level	.241	.059	.008	.027

The Role of Gender Congruity for Anthropomorphized Product Perception

Ellis van den Hende, University of Amsterdam, The Netherlands
Ruth Mugge, Delft University of Technology, The Netherlands

EXTENDED ABSTRACT

Anthropomorphism refers to the tendency to attribute human-like characteristics, intentions, and behavior to non-human artifacts, such as products (Epley, Waytz, and Cacioppo 2007). When consumers anthropomorphize products, this will enhance their evaluation and reduce their willingness to replace these products (Aggarwal and McGill 2007; Chandler and Schwarz 2010).

Prior research has used product-schema congruity to explain consumers' evaluation of anthropomorphized products (Aggarwal and McGill 2007). They suggested that only if there is congruity between the activated human schema and the product's features (e.g., two same-sized bottles with a primed twin schema), consumers are able to humanize the product, and anthropomorphism will increase product evaluation. Such product-schema congruity is thus considered to be crucial for anthropomorphism to be effective. However, for many products the opportunities to add schema-congruent product features are limited (Delbaere et al. 2011). Accordingly, the present research seeks to broaden our understanding of anthropomorphism by investigating when and why priming a human schema will encourage consumers to perceive the product as human, thereby positively affecting product evaluations, even when there is no product-schema congruity. Extending the anthropomorphism literature on twins and salespersons that are generally self-incongruent, this research uses self-congruity theory (Sirgy 1982) to explain the effects of humanizing a product through self-congruent gender primes (i.e., describing the product as male/female) on product evaluations.

This research focuses on gender because gender is a central part of consumers' self-concept (Cross and Markus 1993), As a consequence, consumers prefer products that are associated with their own gender and avoid those associated with the other (White and Dahl 2006, 2007; Worth, Smith, and Mackie 1992). We propose that because of the importance of gender to the self-concept, consumers can readily see the human analogy suggested by the marketer if the human gender schema that is primed, is congruent to their own gender, regardless of the presence/absence of schema-congruent product features. Furthermore, the human gender schema that is primed contributes to the product's symbolic image and will affect consumers' product evaluations. We thus hypothesize a gender-schema congruity effect: when primed with a human gender schema that is congruent (vs. incongruent) to consumers' own gender, consumers show more preferential evaluations (H1). In contrast, when a human gender schema is primed that is incongruent to a person's own gender, (s)he may not readily see the analogy. Then, schema-congruent features of the product will help consumers to anthropomorphize the product successfully. Consequently, we hypothesize that product-schema congruity moderates the effect of gender anthropomorphism on product evaluations (H2). Finally, we hypothesize that the extent to which consumers perceive the product as human mediates the effects of gender-schema congruity and product-schema congruity on consumers' product evaluations (H3).

Two experimental studies tested the hypotheses. Study 1 tested our basic premise that consumers' evaluation of anthropomorphized products are more positive when the human gender schema that is primed is congruent to their own gender. The study used a 2(human gender schema: male vs. female schema) × 2(participants' gender: men vs. women) between-subjects design. To prime the human gender schemas, we created product descriptions of a bottle perfume with either a male or female focus (e.g., "This little guy/girl is the decidedly young scent […] He/She has a family of 30ml, 50ml, and 100ml bottles"). This resulted in conditions of either low or high gender-schema congruity, depending on the gender of the participant. Participants read the product description, and subsequently, completed a multi-item product evaluation measure. The results revealed only a significant human gender schema by participant's gender interaction. Comparing contrasts showed that male participants evaluated the product more positively when a male schema was primed, that is congruent to their own gender, than when an incongruent, female schema was primed. This gender-schema congruity effect on product evaluation was also identified for female participants. Specifically, female participants evaluated the product more positively when a congruent, female schema (vs. incongruent, male schema) was primed, supporting hypothesis 1.

In study 2, we extended these findings by investigating the gender-schema congruity effect alongside the effect of product-schema congruity. Furthermore, Study 2 provided insights in the underlying process of the gender-schema congruity effect by investigating perceived anthropomorphism as a mediator. The study used a 2(human gender schema) × 2(product features: black/blue vs. yellow/purple) × 2(product replicate: camera, car) mixed design and used male subjects. Product replicate was a within-subjects variable. Different colors were pretested to select products with masculine (black/blue color) and feminine (yellow/purple color) features (Grossman and Wisenblit 1999), resulting in products with features that were either congruent or incongruent to the activated human gender schema. Participants read the product description, in which a human gender schema was primed, together with a product picture, and subsequently, completed multi-item product evaluation and perceived anthropomorphism measures. Results revealed a main effect for human gender schema, providing additional support for the hypothesized gender-schema congruity effect (H1). Furthermore, a significant two-way interaction was found. Comparing contrasts showed that when primed with a human gender schema that is congruent to the participant's gender (i.e., male schema), the presence of product-schema (in)congruent features in the product did not affect product evaluations or perceived anthropomorphism. However, when primed with a human gender schema that is incongruent (i.e., female schema), participants evaluated the product more positively and were more likely to perceive it as human when the product is endowed with a feature that is congruent with that human gender schema, than when it is endowed with a feature that is incongruent. Finally, regression analyses and Sobel tests showed that perceived anthropomorphism mediated the effects of gender-schema congruity and product-schema congruity on product evaluations. Together, these results support our hypotheses.

Our research contributes to the literature by demonstrating that product-schema congruity can only partly explain consumer response towards anthropomorphized products. Specifically, we demonstrate that products do not necessarily need to be endowed with schema-congruent features for product anthropomorphism to be effective. If a human gender schema is primed that is congruent to consumers' gender, gender-schema congruity will positively influence product evaluations, even when there is no product-schema congruity.

Disclosure in Word-of-Mouth Marketing: The Role of Prior Agent Experience

Lisa J. Abendroth, University of St. Thomas, USA

EXTENDED ABSTRACT

Recent research on marketer-incented word-of-mouth (WOM) finds that disclosing an agent-brand relationship can make the recommendation more effective (Carl 2008; Tuk, Verlegh, Smidts, and Wigboldus 2009). Abendroth and Heyman (2012) further found that disclosure increased product attitudes and feeling informed, which mediated the effect of disclosure on purchase consideration. The present research looks deeper into why this positive effect occurs. Further, as the growing prevalence of incented WOM increases the likelihood that a WOM recipient has experience as an agent, this research also examines how past experience affects perceptions of the technique and its effectiveness.

Abendroth and Heyman (2012) argue that voluntary disclosure, which goes against relationship norms (Tuk et al. 2009), makes the agent seem more credible, in turn allowing the recipient to feel more informed. If this is true, then adding a disclaimer that disclosure is federally mandated (per the Federal Trade Commission) should eliminate the effect. An alternative explanation is that recipients feel a closer connection to the brand when the agent discloses a relationship with the brand. This should occur regardless of any legal disclaimer and is consistent with feeling more informed. An additional consideration is whether the message recipient has been an agent in another campaign, in which case their reaction to disclosure may be different. They know how receiving incentives affected the nature of their own WOM, and in turn may respond to other incented recommendations less positively.

First, a survey (N=102) was conducted to understand how current undergraduates perceive incented WOM. After explaining the difference between incented and organic WOM, 65% of respondents thought marketers use incented WOM "quite often" or "very often" on college campuses. If asked to be an agent, only 56% indicated they were likely to disclose receiving incentives, despite being informed of the FTC disclosure guidelines. Although concerning, these results are consistent with Ahuja, Michels, Walker, and Weissbuch (2007). When asked who is at fault if the relationship is not disclosed, 26% indicated the company is more at fault and 39% indicated the recommender is more at fault. Finally, looking at the impact of disclosure, 43% thought it would help and 29% thought it would hurt product attitudes, while 28% thought it would help and 24% thought it would hurt attitudes toward the recommender. The remainder expected no impact from disclosure. While 28% of those surveyed had experience as a WOM agent, this did not significantly alter their responses.

Second, an experiment (N=148) was conducted that manipulated WOM (disclosure, disclosure plus legal disclaimer, organic/ no disclosure) between-subjects and measured agent status (agent, non-agent). The manipulation was embedded into a scenario about a friend recommending a winter jacket. Participants responded to several 7-point semantic differential scales that measured purchase consideration (6 items, e.g. I would consider purchasing this brand), product attitude (3 items, e.g. good/bad), agent credibility (5 items, e.g. credible/not credible), feeling informed (3 items, e.g. I feel knowledgeable) and brand connection (3 items, e.g. I can relate to this brand). All cronbach's alphas were greater than 0.88. Lastly, they were asked whether "a company had previously given (them) products, cash, or other incentives to talk about their products with other people," to which 26% answered yes.

An interaction between agent status and WOM type was found for purchase consideration ($F(2,142) = 4.3$, $p<.05$), product attitude ($F(2,142) = 3.6$, $p<.05$), and feeling informed ($F(2,142) = 3.7$, $p<.05$), along with a marginal interaction for brand connection ($F(2,142) = 2.6$, $p<.08$). Meanwhile, agent credibility only showed a main effect of WOM type ($F(2,142) = 7.9$, $p<.01$) with greater credibility in the organic condition versus both the disclosure ($F(1,142) = 11.2$, $p<.01$) and disclosure plus disclaimer ($F(1,142) = 11.9$, $p<.01$) conditions. Interestingly, adding a legal disclaimer to the disclosure had no effect ($F<1$) on the agent's credibility.

Next we look more closely at the effect of WOM type by agent status, beginning with non-agents. Compared to organic WOM, when the agent discloses their relationship to the brand along with a legal disclaimer, purchase consideration increased ($F(1,142) = 4.1$, $p<.05$) as did feeling informed ($F(1,142) = 4.9$, $p<.05$) and feeling connected to the brand ($F(1,142) = 4.0$, $p<.05$), while attitude toward the product remained unchanged ($F=0$). Comparing the two disclosure conditions, adding a disclaimer made the message recipient feel more informed ($F(1,142) = 4.5$, $p<.05$) and feel marginally more connected to the brand ($F(1,142) = 2.7$, $p<.10$), but had no effect on product attitudes ($F<1.1$) or purchase intentions ($F<1.3$).

In contrast, agents had the opposite response to disclosure. Compared to organic WOM, disclosing a brand relationship decreased purchase consideration ($F(1,142) = 7.3$, $p<.01$), product attitudes ($F(1,142) = 12.7$, $p<.01$) and brand connections ($F(1,142) = 4.6$, $p<.05$), along with a marginal decrease in feeling informed ($F(1,142) = 3.3$, $p<.07$). Adding a legal disclaimer led to mean results between disclosure and no disclosure, but lacked the power necessary to find significance for all variables.

This research makes several contributions to the WOM literature. First, the survey indicates that undergraduates are aware of the prevalence of incented WOM on college campuses with over a

Table 1: Means for Experiment

	Non-Agent			Agent		
	Organic	Disclose + Disclaimer	Disclose	Organic	Disclose + Disclaimer	Disclose
Purchase Consideration	4.3	4.9	4.6	5.2	4.7	3.9
Attitude toward Product	5.7	5.7	5.4	6.0	5.2	4.5
Feeling Informed	4.5	5.0	4.6	5.4	4.7	4.6
Brand Connection	3.9	4.6	4.1	4.8	4.4	3.6
Agent Credibility	5.4	4.8	4.8	5.6	4.6	4.5

quarter of respondents in both the survey and the experiment having acted as an incented WOM agent. Second, despite knowledge of FTC disclosure guidelines, the issue of non-disclosure of the agent-brand relationship remains, and both agent and brand carry blame for this non-disclosure. Third and more interesting, most undergraduates cannot accurately predict the impact disclosure has on WOM effectiveness. Fourth, while agent status had no effect on WOM perceptions, experimental results suggest that it does impact WOM effectiveness; organic WOW was more effective for past agents, while knowledge of an agent-brand relationship was more effective for non-agents. Fifth, feeling connected to the brand is introduced as a new factor that is impacted by disclosure. Results surrounding the addition of a legal disclaimer as the reason for disclosure were less conclusive.

Exploring the Mythology of Viral Videos and the Epic Fail:
Why Video Communications Capture the Market's Imagination

Dante M. Pirouz, Ivey Business School, Western University, Canada
Allison Johnson, Ivey Business School, Western University, Canada
Raymond Pirouz, Ivey Business School, Western University, Canada
Matthew Thomson, Ivey Business School, Western University, Canada

EXTENDED ABSTRACT

There are few rewards more exhilarating to marketers than the exponential increase in reach, awareness, and word-of-mouth from communications gone 'viral'. Marketers strive for the viral success of communications across a number of channels, but recent developments in online video (i.e., YouTube's emergence in 2005) offer a means of tracking audience responses in a manner not previously possible. Video also affords a tremendous opportunity for people to engage others with emotion and information. We focus on online video and examine content and audience response features that predict the video going viral.

It might be assumed that any interesting content that generates a strong emotional response is enough to achieve viral status. Indeed, research (Berger 2011; Berger and Milkman 2011) has identified emotional arousal intensity as the motivation for news content sharing, with higher arousal emotions more strongly linked to sharing (Berger 2011). Berger and Milkman (2011) also find that the emotional responses of positivity, awe, anger, sadness, and anxiety all predict sharing.

Logically preceding this strong emotional response, we predict that video content features will also explain viral success. Based on the Incongruity-Resolution theory of humor (Mulder and Nijholt 2002), videos with *elements of incongruity* should be more successful. This incongruity might take the form of juxtaposition (i.e., unexpected combinations) or exaggeration (i.e., hyperbole of basic facts). Though the implication of humor might seem to suggest that such videos would be perceived positively, we also investigate the role of negative reactions, such as sadness and anger because Benign Violation theory (McGraw and Warren 2010) suggests that negative reactions may also lend explanatory power.

We compiled a dataset of over six-hundred English-language videos hosted by YouTube across 15 categories (e.g., Auto, Comedy, Education). Four research assistants blind to the hypotheses coded the videos. One was exclusively tasked with collecting data on the outcomes while the remaining were responsible for coding all the videos according to a scheme we provided. The inter-rater reliability (PRL) scores for each coded variable exceed .80.

Predictors: Many videos contain highly exaggerated content, such as those that make hyperbolic claims or show extravagant or over-the-top behavior. We code this variable (*exaggeration*) on a three point scale ('none', 'modest exaggeration', to 'extensive exaggeration'). Second, we code to what extent videos put together two or more elements whose joining seemed incongruous (*juxtaposition*) also on a three point scale ('none', 'moderately incongruous' to 'highly incongruous'). The correlation between the two predictors was weak ($r = .10$, $p < .01$).

Mediators: Each content coder also included ratings on a 5-point scale ('none/very weak' to 'very strong') of how a 'typical viewer' would respond emotionally to the video in terms of 6 basic emotions: joy, love, sadness, fear, anger, and surprise (Shaver et al. 1987).

Outcomes: All five outcomes measures are based on statistics provided by YouTube: Under each video, viewers are able to press one of two buttons: '*like*' and '*dislike*', a likely indicator of positive and negative attitudes; the number of '*comments*' made by viewers and the number of times a viewer added the video to a personal page ('*favorites*');

and '*video views*', the number of times a video has been seen overall. The five variables are positively correlated ($r = .51-.77$, $p < .01$).

We conducted our analysis using Structural Equation Modeling and a series of covariates (e.g. dummies to reflect the category from which we harvested the video, length of video, interactive component, presence of a call to action). Our first model (without mediators) suggests that Exaggeration predicts Comments ($\gamma = .08$, $p < .05$), Dislikes ($\gamma = .15$, $p < .01$), Favorites ($\gamma = .07$, $p < .05$) and Likes ($\gamma = .10$, $p < .01$) while Juxtaposition predicts Comments ($\gamma = .08$, $p < .05$), Favorites ($\gamma = .08$, $p < .05$) and Video Views ($\gamma = .08$, $p < .05$).

Model 2, including only significant emotional mediators (all were initially included but only significant paths are retained), shows that Exaggeration influences Anger ($\gamma = .16$, $p < .01$), which in turn impacts both the number of Dislikes ($\gamma = .07$, $p < .05$) and Favorites ($\gamma = -.07$, $p < .05$). Also, Juxtaposition predicts Surprise ($\gamma = .45$, $p < .01$), which in turn leads to increased Comments ($\gamma = .11$, $p < .01$) and Video Views ($\gamma = .10$, $p < .01$). With the mediators included, the direct path between Exaggeration and each of Comments ($\gamma = .09$, $p < .05$), Dislikes ($\gamma = .14$, $p < .01$), Favorites ($\gamma = .08$, $p < .05$) and Likes ($\gamma = .10$, $p < .01$) remain significant while the impact of Juxtaposition on Comments ($\gamma = .03$, $p > .10$) and Video Views ($\gamma = .04$, $p > .10$) disappears. We also assessed each emotional mediator one at a time in order to guard against the possibility that two or more mediators were accounting for the same variance in the outcomes, but this revealed that none of Joy, Love, Sadness or Fear individually predicted any of the outcomes regardless of the method of analysis. Based on our data, only Anger and Surprise offered explanatory power.

The findings of this research show that indeed there are two strategic ways that video content goes viral: Exaggerated content has a direct positive effect of the number of favorites, likes, and dislikes but at the cost of inspiring anger. Juxtaposed content has a direct positive effect on the number of comments and video views, an effect that is fully mediated by surprise. These findings open the door to additional exploration and theorizing as well, such as what is the role of specific video features (e.g. use of humor versus disgust versus sexual imagery) in driving virality by virtue of differentially impacting juxtaposition, exaggeration, anger and surprise?

When Excuses Backfire: The Ironic Effect of Excuses on Consumer Perceptions

Elise Chandon Ince, Virginia Tech, USA
Nora Moran, Virginia Tech, USA
Rajesh Bagchi, Virginia Tech, USA

EXTENDED ABSTRACT

He who excuses himself, accuses himself.
Gabriel Meurier

In any service setting, failures are likely to happen, and fallout is often significant. Consequently there is considerable literature assessing how providers can recover from failures. We study the role of one noncontroversial strategy: we investigate whether providing an excuse (vs. not) can have a detrimental effect on consumer service perceptions, specifically looking at minor versus major failures.

Service providers believe that after any failure, proper recovery is essential for maintaining customer satisfaction (Hart, Heskett, and Sasser 2000). Likewise, after failures, consumers appreciate communications from firms (Tax, Brown, and Chandrashekaran 1998), and personnel feel compelled to provide information to alleviate guilt, manage impressions, and distance themselves from failure (Bies and Shapiro 1987; Snyder and Higgins 1988; Schlenker 1982; Schlenker and Weigold 1992).Although extensive, past literature has not addressed how failure severity affects inferences—in particular, how consumers evaluate minor failures, which are more common and require prompt responses from personnel.

First, we argue that expectations regarding responses from firms depend on failure severity (H1). While those experiencing a major failure might expect a reason for the transgression, those experiencing a minor failure may not —consumers may not wonder about the reason for the minor failure unless it is made explicit. However, once an excuse is offered, recipients elaborate and focus more on the failure, even when an excuse is considered valid. Specifically, we predict that customers' critical evaluations of a minor failure increase when an excuse is provided (H2), thus decreasing customer satisfaction (H3). We then identify a boundary condition, level of suspicion, and show that individuals primed with suspicion of negative ulterior motives are less satisfied after a minor failure when given no excuse (H4), as priming suspicion prompts individuals to seek out causes for failures (Fein, 1996; Fein, Hilton, and Miller, 1990).

We test these predictions in three studies, using different failure contexts and excuses. In study 1, we used a 2 failure (major/minor) x 2 excuse (yes/no) between subjects design. The scenario indicated that participants were getting their car's battery replaced. We manipulated failure by varying the actual price for the replacement from its prior estimate ($120): $125 for minor, and $170 for major failure. In the excuse condition, the mechanic offered an apology and excuse ("We did not have the right kind of battery for your car and had to order it and that is why your price is higher"), whereas in the no-excuse condition, the mechanic only apologized for the price increase. In addition to main effects, we obtained the predicted significant failure x excuse interaction. In the minor failure condition, providing an excuse elicited lower satisfaction ratings relative to when an excuse was not provided. No difference emerged in the major failure condition.

In study 2, we investigated the process in detail. We used a 2 failure (major/minor) x 2 excuse (yes/no) between subjects design. The scenario was identical to that of study 1, except we manipulated delivery delay. At pickup, either the mechanic showed up after a 5 minute-delay (minor failure) or a 30 minute-delay (major failure). In the excuse condition, the mechanic apologized for the delay and of-

fered an excuse ("We did not have the right kind of battery for your car"), but only offered the apology in the no-excuse condition. In addition to main effects, a significant failure by excuse interaction also emerged. When failure was minor, satisfaction was lower with an excuse (vs. no-excuse). In the major failure condition, no differences emerged as a function of excuse presence. A marginal two-way failure x excuse interaction also emerged for critical evaluations; in the minor failure condition, participants were more critical when an excuse was offered relative to when it was not. No differences emerged in the major failure condition. Furthermore, critical evaluations mediated the effect of excuses on satisfaction.

In study 3, we manipulated suspicion by asking participants to either read an article on the potential for unethical behavior among employees (suspicion condition) or a neutral article (control condition) before completing the mechanic scenario from study one. We only considered the minor failure condition. As expected, the suspicion x excuse interaction was significant for satisfaction. In the control group, participants were less satisfied when an excuse was offered relative to when it was not. However, when primed with suspicion, participants were more satisfied when an excuse was offered relative to when it was not.

While prior research suggests that valid excuses lead to positive evaluations (Hill, Baer, and Morgan 2000), we find that provider-relevant valid excuses can be problematic (we conducted several pretests to ensure that excuses were considered valid). Our findings also suggest different processes for evaluating minor versus major failures. By studying service failures from the consumer perspective, our findings provide a fuller understanding of consumers' immediate reactions to service failures, and enriches both services and excuse-making literature in new ways.

While past research has focused extensively on what wrong-doers can say and do to recover from failures, our results suggest that doing nothing can be advantageous. Thus, there appears to be a significant asymmetry between what both researchers and firms think increases satisfaction and what actually occurs, particularly after minor failures. At a time when the ethos of service is to go above and beyond the call of duty to keep consumers happy, we suggest that omission of information can do more to improve satisfaction and firm perceptions. Our findings thus are consistent with a quote attributed to Gabriel Meurier that "He who excuses himself, accuses himself."

When Losing Hurts Less:
How Spending Time versus Money Affects Outcome Happiness

Subimal Chatterjee, Binghamton University, USA
Chien-Wei (Wilson) Lin, Binghamton University, USA

EXTENDED ABSTRACT

When consumers engage in an activity, they are likely to invest both time and money in that activity to ensure a desirable outcome. However, research recognizes that thinking about spending time or spending money on an activity evokes distinctly different consumer mindsets (Liu and Aaker 2007). Thinking about spending time evokes real and imagined experiences that are invariably tagged with deep feelings and emotions (Schwarz and Clore 1996), whereas thinking about spending money triggers less emotional and more concrete thoughts about the rewards that consumers can expect in return (Vohs, Mead, and Goode 2006). The current paper builds upon these existing theories to suggest that spending time on an activity may reduce the sting of an ultimate loss, relative to spending a commensurate amount of money on the same activity.

When individuals spend money (relative to time) on an activity, they are more likely to regard the spent money as an investment that should give them a tangible benefit or a return (Soman 2001; Okada and Hoch 2004; Vohs, Mead, and Goode 2006). A subsequent loss, then, is likely to trigger thoughts that the money has gone to waste. However, when individuals spend time on the same activity, the time spent strengthens their personal connections to the activity, and focuses them more on the activity experience (Mogilner and Aaker 2009; Schwarz and Clore 1996; Van Boven and Gilovich 2003). A subsequent loss, then, may not sting as much, as the thoughts that are triggered may focus more on how the time spent helped the individuals to develop (gain) their potential (Ryan and Deci 2000).

Study 1 tests the above proposition in a 2 (spending time/spending money) by 2 (win/lose) between subjects scenario-based study. One hundred and twenty undergraduates (52 females) imagine that they are preparing in different ways to win a tennis tournament. For the time/money manipulations, we calibrated the exchange rate between the two currencies in a pretest ($n = 30$) and found that the tradeoff rate to be \$12.50 per hour (see Okada and Hoch, 2004, for similar results). Accordingly, half of the participants imagined that they had spent 40 hours (practicing with friends) and \$25 (buying equipment) preparing for the tournament, whereas the other half of the participants imagined that they had spent \$500 and 2 hours, doing the same. The win/lose manipulation had half of the sample imagine that they ultimately won the tournament, and the other half imagine that they lost.

We measured outcome happiness on a 7-point scale (unhappy/happy scale; see Van Boven and Gilovich 2003), and the extent to which our participants felt pressured for time (Andrews and Smith 1996) and pressured for money (Mittal 1994) in their lives. In all analyses, we treated the latter two variables as statistical covariates. Figure 1 shows the means of outcome happiness across all four experimental conditions. As expected, in the loss condition, participants were less unhappy, if they had spent more time, relative to spending more money ($F(1, 55) = 4.9$, $p < .05$). The time/money manipulation did not affect outcome happiness in the win condition ($F(1, 57) = 1.45$, $p > .10$).

Figure 1
Study 1: Results
In Study 2, we made two changes relative to Study 1. First, we use a different scenario (an investments competition); the change in context was promoted by a pretest ($n = 23$), which showed that while participants are more predisposed towards spending time to prepare for a tennis tournament, they are more inclined to spend money to prepare to win an investments competition. Second, Study 2 tests for a potential mediator of the time/money effect on outcome happiness. Specifically, we argue that spending time on an activity makes a person focus more on the experience of personal striving and social connection (Mogilner and Aaker 2009; Mogilner 2010). This experience allows individual to get closer to attaining his/her potential, thereby enhancing that person's feelings of psychological well-being (Ryan and Deci 2000), and buffering the sting of the ultimate failure. Spending money on an activity, however, makes a person focus on external rewards that fail to satisfy needs for self-actualization (Van Boven and Gilovich 2003). An ultimate loss, then, only highlights that the reward was not obtained and the money spent was wasted.

One hundred and forty-eight undergraduates (61 females) participated in Study 2, and were randomly assigned to one of four conditions in a 2 (time/money: spending \$500, spending 40 hours) by 2 (outcome: winning, losing) between subjects experiment. In addition to outcome happiness, and the tendencies to feel pressured for time and money (see Study 1), we measured psychological well-being by tapping into the three main elements of that construct: autonomy, competence, and relatedness (Deci et al. 2001; La Guardia et al. 2000, $\alpha = .81$). The Appendix reports the scales, as adapted to the study context.

Figure 2 shows the means of outcome happiness across all four experimental conditions. As expected, in the loss condition, participants were less unhappy, if they had spent more time, relative to spending more money ($F(1, 70) = 3.69$, $p = .06$). The time/money manipulation did not affect outcome happiness in the win condition ($F(1, 70) < 1$). Preacher and Hayes's (2008) SAS macro with 5,000 bootstrapped samples revealed indirect-only mediation (Zhao, Lynch, and Chen 2010), in which psychological well-being mediates the effect of spending on outcome happiness (95% confidence interval between 0.03, and 1.18; Figure 3).

        *** = significant at the .01 level;
        NS = not significant

Our research shows that spending time (as opposed to a commensurate amount of money) on an activity reduces the sting of an ultimate loss as consumers may think of the time spent as enhancing their psychological well-being in their goal pursuit. Future research may wish to investigate how such enhanced psychological well-being could engage consumers to continue pursue their goals when substantial effort has already been invested (Fishbach, Dhar, and Zhang 2006) and/or prevent them from disengaging from goal pursuit after encountering some initial failure (Fishbach and Dhar 2005). A second direction would be to investigate, how enhanced feelings of well-being could potentially elevate the desirability of the ultimate goal (Zhang et al. 2011) and assist in goal pursuit.

APPENDIX
MEASURE FOR PSYCHOLOGICAL WELL-BEING*

1. I feel that I have become a better investor (*competence*)
2. I feel that I have been able to learn new investing skills (*competence*)
3. I do not regret, for one moment, the amount of time (money) that I put into preparing for the competition (*autonomy*)
4. I do not care what other people think about the amount of time (money) that I put into the competition (*autonomy*)
5. I feel more connected to the bank (*relatedness*)
6. I feel more close to the other interns/professionals in the bank (*relatedness*)

    * All measures on a 1 = *Not agree at all* to 9 = *Very strongly agree* scale

Matching The Words to the Features in Persuasive Advertising:
A Construal-Matching Hypothesis

Karthik Easwar, Ohio State University, USA
Lifeng Yang, University of Mississippi, USA

EXTENDED ABSTRACT

Recently, a number of journal articles have examined the effects of construal on consumer behavior. Construal level has been shown to influence voting, self-control, saving, social influence, conservation and perceptions of complementarity or promotion value (Cheema & Patrick, 2008; Ülkümen & Cheema, 2011). Our research finds evidence that matching the construal level of advertising copy to that of the focal product can improve product attitudes by facilitating processing fluency, a finding that has significant implications for attitude and advertising research.

Construal level theory (CLT), has found evidence that, as abstraction increases, psychological distance increases and as psychological distance increases processing of abstract events is facilitated (Liberman and Trope 1998). This research has shown that desirability is more abstract than feasibility, idealistic values (respect, honesty, etc.) are more abstract than pragmatic and functional concerns (uses, extrinsic benefits) and hedonic products (music, chocolate) are also more abstract than utilitarian products (glue stick, ball point pen). CLT has also discovered that psychological distance can be affected by temporal, geographical and social distance in such a way that objects that are farther away on these dimensions are construed more abstractly. In other words, a computer that comes out in a year, or was made in Europe, or is owned by an out-group member is construed at a higher level than one that is coming out next week, made in the US or owned by a close friend.

While social psychology has found differences in attitudes, perceptions, and behavior depending on the level of construal, psycholinguists have also studied the idea of abstract vs. concrete. Research on linguistic categories finds that words with the same semantic definitions can be grouped into different levels of abstractness. The Linguistic Category Model developed by Semin and Fiedler (1988) provides 5 categories of words that have different degrees of cognitive functions in interpersonal communications and vary in their level of abstraction. It is found that adjectives are generally governed by abstract, semantic relations rather than be governed by the contingencies of contextual factors; verbs, in contrast, are generally governed by concrete relations.

We apply these speech classifications to marketing messages in print ads and propose a construal-matching effect. We hypothesize that an effective match facilitates a fluency that results in increased persuasiveness of the matched messages. Using verbs (concrete) to advertise utilitarian (concrete) products (e.g. glue stick), due to matching, will make the message more effective. In the same vein, using adjectives (abstract) to advertise hedonic (abstract) products (e.g. music) will create positivity.

Study 1 examines the matching hypothesis by examining two different products with either matched or unmatched messages. Study 2 examines the matching hypothesis by priming the same product to be either hedonic or utilitarian. Finally, in study 3, to provide more evidence of the construal-matching hypothesis, we alter the release date of the iced coffee to be distal or proximal, manipulating a different dimension of psychological distance and still see the positive effects of construal-matching.

A pretest revealed a glue stick to be primarily utilitarian and an mp3 to be primarily hedonic. Therefore, these were taken as the two focal products in study 1. Two versions of ads for each of the two products were developed for the experiment and pretested to be semantically equivalent. One version of the ads use concrete verb words, the other version of the ads use abstract adjective words. After reading the ads, subjects reported their brand attitude, message believability and desirability, cognitive involvement when reading the ad, and cognitive responses.

The results of study 1 support the construal-matching hypotheses. Ads framed in concrete words were perceived to be more believable and persuasive when they were used to describe the utilitarian product. In contrasts, ads framed with abstract words were perceived to be more convincing and more effective when used to describe the hedonic product.

The initial pretest also revealed that iced coffee was considered to be a hybrid product consisting of hedonic and utilitarian attributes. Therefore, this product was used in study 2. In study 2, subjects were primed to either view iced coffee as hedonic or utilitarian. Consistent with traditional methods of priming, subjects were given a word search in which they were either asked to find words that related to utility (function, aim, objective, function, etc.) or to hedonicity (love, enjoy, fun, pleasure, etc). They were then shown an ad promoting a new iced coffee drink at a university café. This ad either used verbs to promote the product and café or adjective (e.g. tastes great vs. tasty).

Results from this study also support our construal-matching hypothesis. Those who viewed ads that matched their primed mindset had more positive attitudes towards the iced coffee, the café, and the advertisement itself.

Finally, to test the generalizability of our matching hypothesis, in a third study, we change the dimension of psychological distance that influences construal of our focal product. In study 3, we use the same iced coffee, but alter the opening day of the café to be either this coming fall or one year from now. Again, even using a different manipulation, we see the same construal-matching. Over all three studies, we see that using adjectives (verbs) to advertise abstract (concrete) products is the most effective.

This research adds to the steam of research examining the positive effects of matching. Work in frame matching (Cheema and Patrick, 2008; Yan and Sengupta 2011) demonstrates that when message frames match an individual's mindset, consumers are more likely to develop positive attitudes. Consistent with these positive matching effects, this research finds matching the construal level of advertisement language to product features creates positivity. Using adjectives (verbs) to advertise abstract (concrete) products leads to the most positive product attitudes.

The Influence of Discrete Emotions on Strategic Goal-Setting

Karthik Easwar, Ohio State University, USA
Patricia M. West, Ohio State University, USA

EXTENDED ABSTRACT

People regulate affect when they choose options and behaviors specifically for their affect-related consequences (Cohen et al. 2008). Generally, people prefer to experience positive affect, a desire that manifests itself in two different affect regulation motivations; protection and lifting (Zillman 1988). When mood protecting, people attempt to remain in a positive affective state by avoiding tasks that may produce negative outcomes (Andrade and Cohen 2007; Isen and Means 1983). When mood-lifting, people approach various tasks in hopes of an affective boost.

People in a positive affective state tend to exhibit a mood protection motivation. They engage in more enjoyable behaviors, avoid painful experiences, take fewer risks, and help less, in order to maintain their positivity (Andrade 2005; Andrade and Cohen 2007; Forest et al. 1979; Isen and Geva 1987; Isen and Means 1983).

Those in a negative affective state worry less about the affective consequences of their choices, seek more variety and are more helpful than those experiencing positive affect (Cialdini and Fultz 1990; Cohen et al. 2008; Drolet and Luce 2004; Wegener and Petty 1994). However, when experiencing negative affect people's focus on mood-lifting differed depending on their beliefs about the transience and controllability of their affective state (Labroo and Muhkopadhyay 2009; Shen and Wyer 2008; Tice, Bratslavsky, and Baumeister 2001). Norem and Cantor (1986) argue for two regulation strategies: defensive pessimism, in which people prepare for the worst, and optimism in which they hope for the best. However, they provide little insight into what underlying process leads to the selection of a strategy.

Our research identifies regulatory focus as the process by which affective states influence affect regulation motivation. Regulatory focus theory argues that there are two separate and independent self-regulatory orientations: prevention and promotion (Higgins, 1997). A prevention focus emphasizes safety, responsibility, and security needs, is concerned with losses, and is especially sensitive to failure. A promotion focus emphasizes hopes, accomplishments, and advancement needs, is concerned with gains, and is especially sensitive to attainment. Thus, someone who is either chronically, or situationally, prevention-focused generally prefers a "vigilant strategy", and someone who is either chronically, or situationally, promotion-focused generally prefers an "eager strategy" (Crowe and Higgins, 1997; Higgins et al., 2001).

We hypothesize that one's current affective state will directly impact their motivational state, which in turn will affect goal-setting, but that this impact will depend on one's regulatory focus. We also expect that the affect regulation motivation of an individual will drive their goal-setting strategy; a protection motivation will lead to low goal-setting while a lift motivation will lead to higher goal-setting. In other words, participants who are protection motivated will set goals lower than those who are lift motivated, regardless of their affective state.

Study 1 utilized a 3 × 3 between subjects, factorial design where affective state (positive, neutral or negative) was induced using previously tested videos (Cohen and Andrade 2004) and regulatory focus was manipulated by having participants write about their hopes and aspirations (promotion focus) or their duties and obligations (prevention focus) or daily routine (Freitas and Higgins 2002).

The dependent variable was the goal set in an anagram task. After setting a goal, participants evaluated their level of agreement with two key statements intended to capture their affect regulation motivation ("I chose this goal because I wanted to improve my state of mind" and "I chose this goal because I wanted to keep the same state of mind"; Cohen and Andrade 2004). Using these two items, we created a Motivation Score to capture the degree of one's affect regulation motivation. This index ranged from -6 to 6, where -6 indicates a strong protection motivation and 6 indicates a strong lift motivation.

Results from study 1 (see table 1) indicate that participants in a positive affective state who were promotion focused, displayed a greater lift motivation than either those who were prevention focused or had no induced regulatory focus. In a negative affective state, participants who were prevention focused were the most protection oriented when compared to those who were promotion focused or had no induced regulatory focus. These results demonstrate that regulatory focus is moderating the effect of affective state on affect regulation motivation for people experiencing negative affect.

We expect that one's affective regulation motivation will mediate the relationship between the current affective state by regulatory focus interaction and the goal-set. We support this hypothesis using Preacher and Hayes (2008) bootstrapping procedure to test for mediation (see figure 1). This mediation analysis shows that, regardless of their affective state, protection motivated participants set lower goals than participants that are lift motivated.

Table 1
Study 1: Affect Regulation Motivation and Goal-Setting by Affective State and Regulatory Focus

Regulatory Focus	Affective State		
	Positive	**Neutral**	**Negative**
	Motivation Score		
Promotion	-.19	-.08	-1.07
Prevention	1.70	-.13	1.15
No Focus	1.35	.31	-.09
	Goal-Setting		
Promotion	30.0	31.4	34.6
Prevention	23.5	31.1	25.5
No Focus	25.6	30.5	31.2

Figure 1
Study 1: Affect Regulation Serving as Mediator of Goal
In a second study, we extend the literature on affect regulation by studying the role of specific emotions in strategic goal-setting. Previous research has indicated that while happiness and calm are both positive affective states, they have very different regulatory focuses. Specifically, calmness is associated with a prevention focus, while happiness is associated with a promotion focus. Similarly, anxiety is associated with a prevention focus, while sadness is associated with a promotion focus. Based on the results from study 1, we expect that regardless of affective state, those who are prevention focused will set lower goals than those who are promotion focused. Supporting this general hypothesis, we find that those who were in an anxious mood (prevention focused) set lower goals than those who were sad (promotion focused). While not as strong an effect, those who were calm (prevention focused) also set lower goals than those who were happy (promotion focused).

Our research expands the affect regulation literature in three key ways. First, we extend this work by demonstrating that goal-setting – because it divides the outcome space into success and failure (Heath, Larrick, and Wu 1999) – is a tailor-made way to strategically regulate affect. Second, we identify the role of regulatory focus in affect regulation, in the process, explaining some of the contradictory results previously seen in the literature. Finally, we use regulatory focus to identify how different emotions, not general affect, influence affect regulation motivation and strategic goal-setting.

When the Message "Feels Right": When and How does Source Similarity Enhance Message Persuasiveness?

Ali Faraji-Rad, Columbia University, USA
Luk Warlop, KU Leuven, Belgium and BI Norwegian Business School, Norway
Bendik M. Samuelsen, BI Norwegian Business School, Norway

EXTENDED ABSTRACT:

We study how momentary subjective experiences (feelings) caused by a characteristic of a message source contribute to message persuasiveness. Specifically, we focus on message recipients' perceived similarity with the message source and argue that similarity enables higher self/other merging (Aron et al. 1991), which is turn yields to a "feels right" experience driven from receiving and processing that message. This feeling is then incorporated, as information (Schwarz & Clore 1983), into judgment about the target of the message – increasing message persuasiveness.

We used a similar paradigm in all our studies. In all studies we asked participants to read a scenario describing them trying to book a hotel online and to read a reviews of an unknown hotel and then evaluate the hotel based on the review. Similarity was manipulated through reviewer profiles. Other than the review(s), we gave no information regarding the hotel to the participants. In studies 1A-B we tested our basic assumption that feelings are responsible for a similar source's higher persuasiveness. We manipulated our participants' reliance on feelings versus logic by either instructing (1A) or priming (1B) them to use either their feelings or logic while evaluating the hotel. Specifically, in study 1A we adopted the instructions from Pham and colleagues (2001) and in study 1B, under the disguise of an open-ended study about different decision-making strategies, we told the participants to write down why they think using emotion (logic) in decision making is more beneficial than using logic (emotions). Then, in both studies we asked participants, to read the scenario and evaluate the hotel based on a negative review from an MBA student. Then participants reported their perceived similarity to the reviewer. In both studies we hypothesized that similarity enhances message persuasiveness only when participants are induced to rely on their feelings while evaluating the hotel, and not when they are made to use their logic. Results from both studies supported our hypothesis.

In studies 2 and 3, we built on research that shows that compared to experiential motives, if people have functional motives they will make less use of their feelings (Pham 1998; Adaval 2001). In both studies, we hypothesized and showed that similarity enhances message persuasiveness only when the motive of booking a hotel is experiential (vacation), and not when it is functional (work). Study 2 was different from studies 1A-B in that we manipulated similarity instead of measuring it. In this study we used a sample of student participants and ask them to imagine planning a trip for experiential or functional purposes. However, one group saw a profile of a reviewer who was an MBA student and the other group saw a profile of a researcher in a major chemical company. As expected, results showed that similarity influenced message persuasiveness only when motive was experiential, and not when it was functional. In study 3 we used scenarios similar to study 2. However, we ran the study on a sample similar to studies 1A-B and we measured (instead of manipulating) similarity. We also used two different profiles similar to study 2 in this study, with the goal of showing that the profiles per se do not have any effect on persuasiveness. Replicating results of study 2 we showed that higher message persuasiveness was associated with higher perceived similarity, but only when participants had experiential motives. Our effects held for both reviewer profiles, generalizing our findings.

In study 4, we built on research suggesting that the affective system is a decision-making system of the present (Chang & Pham 2012) to show that similarity increases message persuasiveness more if people are making a judgment about the near future, versus distant future. Here all participants had to first read a scenario that asked them to imagine that they would go on the trip in a week (near-future), or a year from now (distant-future) and then complete the procedure similar to study 3, except that they only saw the profile of an MBA student. The results supported our hypothesis. We based study 5 on the notion that people use feeling more for more reachable and immediate decisions (Mischel & Shoda 1995). Here the scenarios either told participants that they are participating in a lottery to win the trip and chances of winning are either 1-in-5 (high-probability) or 1-in-5000 (low probability). As predicted, the association between perceived similarity and message persuasiveness was higher if participants had higher probability of winning the hotel (compared to lower probability).

In study 6, we built on the literature that shows that assessment of relevance of feelings requires substantial cognitive resources (Avnet, Pham, & Stephen 2012) and showed that even when people have functional motives, a similar source is more persuasive if participants have only limited cognitive resources. Here, as in study 2 we manipulated similarity instead of measuring it. Student participants had to first memorize a two-digit (low-cognitive-load group) or a seven-digit (high-cognitive-load group) number. Then they all read the functional scenario identical the one used in study 2. We manipulated similarity same as study 2. As expected, similarity enhanced message persuasiveness if participants did not have cognitive resources, but not when they had cognitive resources available. In all our studies, controlling for reviewer expertise, credibility, and trustworthiness did not affect the results. Also, in studies 3, 4, and 5, we measured participants' self-reported "feels right" sensation towards the message. Mediated moderation analysis in all studies supported the notion that similarity makes the message "feel right" but people do not use this feeling when they do not see feelings relevant, thus lack of persuasiveness of a similar source in conditions where we expect less use of feelings.

Using Construal-Level Theory to Deter Social Desirability Responding

Scott Wright, Providence College, USA

EXTENDED ABSTRACT

Social desirability responding (SDR) is the tendency of respondents to adjust their responses or behavior in such a way as to present themselves in socially acceptable terms (Maccoby and Maccoby 1954). The systematic bias introduced by SDR threatens the legitimacy of empirical research by confounding a phenomenon of interest with impression management behavior, thus obscuring research results and potentially triggering false conclusions (see Fisher 1993; Ganster, Hennessey, and Luthans 1983). When SDR is a concern (e.g., when asking socially sensitive, embarrassing, or private questions), researchers commonly use techniques such as indirect questioning to avoid the bias introduced by SDR. By asking respondents how *most* or the *typical* person would respond (i.e, referring to a third party target) the respondent transcends from an egocentric focus on his or her own unflattering attitudes or behavior onto that of an ambiguous target. Given the target's indistinctness, respondents project their own feelings, attitudes, behaviors, or beliefs when responding while remaining psychologically distanced from the true, yet socially undesirable response (Calder and Burnkrant 1977; Grubb and Stern 1971; Haire 1950).

According to construal-level theory (CLT) this process of "*transcendence*" is made possible because individuals are able to form abstract mental construals (Liberman and Trope 1998; Trope and Liberman 2003; Trope and Liberman 2010). This mental construal process is essential to recalling the past, empathizing with others, imagining what could have been, and visualizing future events. As mental construals increase, individuals refocus from detailed, incidental features to central, fundamental characteristics (Trope and Liberman 2010). Consequently, we propose that indirect questioning prompts respondents to deemphasize the contextual demand to engage in impression management behavior through an increase in construal-levels.

In our project, we apply CLT to develop and explain novel techniques deterring SDR. To test the effectiveness of our techniques, we chose two contexts known to exhibit SDR (consumer surveys and consumer choices). In study 1 we demonstrate that increasing construal-levels through psychological distances decreases SDR within a survey context. To gain deeper insights into the cognitive mechanism, we directly manipulated construal-levels in study 2, and found that increasing construal-levels directly decreased SDR on a subsequent choice task. In study 3, we examined a mediational model establishing relationships between psychological distance, impression management, and choice.

STUDY 1

To investigate whether increasing construal-levels through psychological distances might attenuate SDR within a survey we had 453 participants complete seven marketing scales shown or suspect to elicit SDR: Materialism (Richins 2004), Impulsive Buying Tendency (Martin, Weun, and Beatty 1994), CSR (Sen and Bhattacharya 2001), Green Orientation (Dunlop and Van Liere 1978), Frequency of Healthy Preventative Behaviors (Jayanti and Burns 1998), Television Viewing Frequency, and Regulation of Alcohol Consumption, while manipulating the questioning format according to the dimensions of psychological distance (i.e., temporal, spatial, or social distance). Participants also completed a measure of SDR using Paulhus' (1991) BIRD scale.

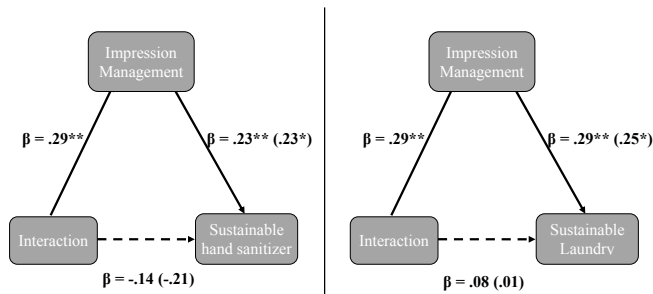
To detect the presence of SDR, we implemented Steenkamp et al.'s (2010) substance versus style approach and regressed the two dimensions of SDR onto each marketing scale. In support of our hypotheses, when using direct questioning, five of the seven constructs exhibited a non-negligible relationship with one of SDRs two factors. We hypothesized that indirect questioning increasing social or spatial distance would attenuate SDR, while temporal distance would enhance SDR given research on the future optimism effect (see Regan, Snyder, and Kassin 1995; Weinstein 1980). Results indicate that whereas indirect questioning increasing social or spatial distance reduced the number of scales demonstrating a non-negligible relationship with SDR (compared to direct measures), indirect questioning increasing temporal distance increased this number, thus lending preliminary support to our hypotheses.

STUDY 2

Previous research demonstrates a bidirectional relationship between the psychological distance dimensions and construal-level, such that as construal-levels increase, inferred psychological distances increase, and vice versa (Trope and Liberman 2010). In study 2 we explored the mediational role of construal-levels and extended our findings to a consumer choice context. Consumers construe sustainable actions, products, and attitudes as pro-social in nature (i.e., beneficial to society), as a result, there exists a social pressure to display behaviors endorsing sustainability (see Luchs et al. 2010). Consistent with our hypothesis that increasing construal-levels will decrease SDR we found that when we increased contrual-levels through an obstensably unrelated mind-set task (Freitas, Gollwitzer, and Trope 2004), the share of choice for a non-sustainable (vs. sustainable) laundry detergent increased from 10% to 27% in a subsequent choice task ($\chi^2(1,97) = 4.48$, $p < .05$).

STUDY 3

To provide additional clarity into the underlying mechanism, in study 3, we manipulated self-presentation demand and the psychological distance of the choice task while incorporating a measure of SDR (N=406). Self-presentation demand was manipulated by asking participants to present themselves as favorably as possible during the experiment (see Paulhus 2002). To test the generalizability of our results we incorporated two choice tasks each between a sustainable and non-sustainable option. The results provide evidence of an indirect-only moderated mediation model (see figure 1). When the demand to engage in impression management behavior was high, increasing the psychological distance of the choice task successfully deterred respondents from engaging in deliberate SDR. We also report a significant relationship between the impression management dimension of SDR and choice, whereby the impression management tendency increased the likelihood of selecting the sustainable (vs. non-sustainable) laundry detergent ($\beta = .37$, Wald $\chi^2 = 8.63$, $p < .004$) and hand sanitizer ($\beta = .34$, Wald $\chi^2 = 5.67$, $p < .02$). A significant indirect effect between our interaction term and choice through impression management provided evidence of the mediational process and identified the distortion as deliberate for both laundry detergents ($\beta = .18$, $p < .05$) and hand sanitizers ($\beta = .16$, $p < .05$).

Figure 1
Study 3: Indirect-Only Mediated Moderation Model For Choice


Note: Betas outside parenthesis represent standardized regression coefficients for the direct relationships between the variables; betas inside parentheses represent regression coefficients for the strength of relationships between to variables after statistically adjusting for the other variable in the model. Asterisks indicate level of significance (* *p* < .05, ** *p* <.01).

The results support our hypothesis that increasing construal-levels directly or through psychological distances deters SDR by deemphasizing contextual demands to engage in impression management behavior, thus, encouraging respondents to report accurate responses. This research has important methodological and substantive implications for marketers, researchers, and consumer psychologists.

Conservative When Crowded: How Social Crowding Leads to Safety-Oriented Choices

Ahreum Maeng, University of Wisconsin - Madison, USA
Dilip Soman, University of Toronto, Canada
Robin Tanner, University of Wisconsin - Madison, USA

EXTENDED ABSTRACT:

While extant research on crowding in retail contexts indicates that it can reduce shopper satisfaction and precipitate an earlier departure from the store (Eroglu et al., 2005; Hui and Bateson 1991), relatively little research has examined whether being crowded might influence the actual choices consumers make. Thus, despite the fact that many socially crowded locations (e.g., stores or offices) are actually places where highly consequential decisions are made, our understanding of the potential effects of crowding on decision making is rather incomplete (e.g., Epstein and Karlin, 1975).

The most germane concept in developing our theoretical framework is the notion of personal space, as violations of personal space are particularly likely to occur in crowded public settings. Personal space is defined as a moveable boundary around the human body, primarily functioning as a buffer protecting individuals from potential threats (Graziano and Cooke, 2006). Research shows that violations of this personal space lead individuals to experience feelings of anxiety and psychological unease (Hall, 1966). Further, recent neurological research has shown that personal proximity activates the amygdala, the structure known to be involved in social approach and avoidance response (Kennedy et al., 2009). Indeed, crowding leads to physiological outcomes such as increased skin conductance, high arousal, and low experienced pleasure (Worchel and Teddlie, 1976). From an approach-avoidance motivation perspective, all these findings are consistent with social crowding leading to the avoidance motivation system being activated as part of a broader self-protection mechanism (Lang and Bradley, 2008).

Substantial empirical evidence demonstrates that an avoidance motivation is associated with prevention goals (Forster, Higgins, and Idson, 1998). Consequently, we propose that if social crowding leads to the activation of the avoidance system, then a greater prevention focus is likely to result. Therefore, we propose crowded individuals are more likely to seek objects with connotations of personal safety as these objects are instrumental in achieving the activated prevention goal (Markman and Brendl, 2000). Similarly, from a regulatory fit perspective, individuals experience regulatory fit when they choose objects with safety implications because those alternatives align with their goal orientation (i.e., a prevention goal). As such, individuals may more readily choose these options because it feels appropriate to them to choose an option that fits their regulatory focus (Higgins, 2000; Lee and Aaker, 2004). Three studies explore the relationship between social crowdedness and risk oriented choice.

Study 1 (N=49) was an initial investigation as to whether being socially crowded increases the accessibility of safety oriented constructs. Social crowdedness was manipulated directly by having participants complete the task in a laboratory room that was either crowded (24 participants per session) or uncrowded (3-4 participants per session). Participants were presented with a word search grid and were given 3 minutes to write down as many words as they could find. The grid contained 10 neutral words (e.g., speaker, coffee) and 10 safety related words (e.g., insurance, helmet). While participants found a similar number of words in each condition, participants in the crowded room uncovered a greater number of safety-related words than those in the less crowded room (F(1, 47) = 9.23, p=0.004).

Study 2 (N=75) was designed to build on Study 1 by exploring if this apparent crowding driven increase in safety-orientation would influence product decisions, and whether this effect would be mediated by a greater prevention focus. To generalize the results from Study 1, social crowdedness was manipulated via picture priming. Specifically, participants were exposed to one of three images: a crowded scene, an uncrowded scene, or a no picture control. Next, participants completed two preference tasks designed to explore their preference toward making choices with prevention orientated benefits. These were presented as scenarios requiring participants to indicate their relative preference between two places to visit while their flight was delayed (pharmacy vs. convenience store) and between two free gifts at a local store (first aid products vs. a box of cookies). Finally, we administered a questionnaire designed to measure participants' incidental regulatory focus. This questionnaire followed Higgins and colleagues (1994) approach and required participants to rate the importance to them of 14 different issues on a nine-point scale anchored from 1 ("extremely important") to 9 ("extremely unimportant"). Half of the items reflected a promotion focus (e.g., "doing well in work") and half a prevention focus (e.g., "avoiding unsafe sexual practices"). The summed importance scores for the promotion items were subtracted from the equivalent summed prevention item scores to create a measure of net prevention focus (see Lockwood, Jordan, and Kunda 2002).

Results showed that, participants in the crowded condition illustrated a dramatically stronger net prevention focus than did those in the uncrowded and control conditions (F(2,72) = 11.9, p<.001). Similarly, both rating tasks also indicated a stronger preference for the safety oriented options (i.e., pharmacy and first-aid kit) in the crowded conditions. More importantly, mediation analysis using 5,000 bootstrap samples revealed that these safety-oriented preferences were mediated by the net-prevention focus scores. For a detailed description of these results.

Study 3 (N=114) aimed to further generalize our findings by examining if the crowdedness of the environment would enhance receptivity towards persuasive messages presented with a prevention-oriented frame. After completing the same picture priming task from Study 2 (control vs. crowded vs. uncrowded conditions), participants were presented with an oral-hygiene message presented with either a prevention or promotion focus and were asked to rate the importance of the message in various ways. Results revealed the expected Crowding X Message framing interaction on the message importance rating (F(2, 108) = 11.9, p < .001) with participants primed with crowdedness rating the prevention oriented message as (a) more convincing (p = .013), (b) more appealing (p = .03), and (c) as saying something important to them (p < .01). For detailed analysis.

In sum, our research provides the first demonstration of the important finding that the crowdedness of the choice environment can significantly influence the choices we make in that environment.

APPENDIX

A) How You Can Prevent Gingivitis

Gingivitis is a serious and very common dental condition, but it is 100 per cent preventable and easily treated if you have it diagnosed early. So if you begin to notice the signs of gingivitis, then you need to pay a visit to you dentist for a recommended treatment plan.

The condition is caused by an overgrowth of bacteria inside the mouth that converts into plaque and leads to bad breath, bleeding gums and often sore or swollen gums. If you leave the condition for too long, it can cause more serious conditions such as tooth loss, periodontal disease and even heart disease.

You can easily prevent the condition from occurring by combining good home dental practices with regular dentist visits. By brushing, flossing and rinsing twice a day at home using the correct technique and then having a professional clean twice a year at your dentist, the instance of gingivitis is drastically reduced.

Before you brush, you should floss your teeth and get all the bacteria and food particles that get trapped between the teeth out. Brushing with then help to get rid of the bacteria on the tooth surface and get rid of plaque. Using a natural toothpaste that is based on mint oil is the best choice as it is both effective and gentle on your body. Mint oil is a naturally powerful antibacterial agent and also has antifungal properties. In contrast commercial toothpastes contain detergents, which can act as allergens for many people.

Mouthwash is another essential part of a good dental routine. It is able to kill bacteria left over in the mouth, particularly the bacteria that gets stuck around the gum line. Additionally, scraping your tongue can also get rid of a lot of bacteria that can lead to gingivitis. You can buy tongue scrapers, or alternatively, use your regular tooth brush.

Protecting your dental health from the onslaught of gingivitis is relatively easy, but the key is consistency. You have to ensure that you are brushing, flossing and rinsing twice a day to prevent the buildup of harmful bacteria in the mouth. When you visit your dentist you should discuss how you can best prevent gingivitis and other dental conditions and ask them to show you how to most effectively brush your teeth as many people do not use the right technique.

B) How You Can Get Brighter Smiles

Everyone loves a bright white smile. Fortunately there are a variety of procedures and products available today that can improve the look of yours. When exploring these options it's wise to know the difference between "teeth whitening" and "teeth bleaching" and familiarize yourself with cosmetic dentistry and its terminology. With so many companies offering their magical teeth whitening treatments, it's easy to feel overwhelmed. To counteract the influx of these potentially bogus programs, several websites have recently popped up with accurate and easy to digest information regarding your teeth.

Whitening one's teeth is the process of restoring teeth to their natural color. This is done by removing the build-up and dirt collected on the tooth's surface. You can achieve these results with toothpastes that boast a whitening agent. Having your teeth cleaned regularly is an excellent way to keep your teeth free of debris.

Bleaching one's teeth actually whitens teeth beyond their natural state to produce its desired result. The use of a bleach-containing agent will draw out the stain and color leaving them clean and whiter than before. There are two types of bleach used in this process. Hydrogen peroxide is used by your dentist in a controlled environment and contains a high level of peroxide. Take-home kits use carbamide peroxide which has a lower percentage of peroxide and is therefore safer to use on your own.

Over-The-Counter teeth bleaching products can be purchased at your local drugstore for the most affordable prices. A good choice would be one that uses a tray (as a dentist would) that covers the teeth and holds the peroxide-based gel in place over your teeth. Other options include strips and "paintable" teeth whitening gel. Many toothpaste brands incorporate peroxide as a way to bleach teeth while brushing.

Professional take-home teeth bleaching kits are slightly more expensive but are dentist-approved and therefore more reliable. They utilize the tray process and are custom fitted for your teeth. This makes them more effective than over-the-counter brands. Custom molded trays may take several weeks to receive so plan accordingly.

The long and the short of it is that teeth whitening works. Virtually everyone who opts for this cosmetic treatment will see moderate to substantial improvement in the brightness and whiteness of their smile. However, teeth whitening is not a permanent solution and requires maintenance or "touch-ups" for a prolonged effect.

When the Accessible Global Identity Leads to Unfavorable Evaluations of Global Products? The Roles of Consumers' Lay Theory on Global and Local Cultures

Yinlong Zhang, University of Texas at San Antonio, USA
Ying-Yi Hong, Nanyang Technological University, Singapore

EXTENDED ABSTRACT

In today's increasingly globalized world, many consumers tend to have both global and local identities (Arnett 2002; Benet-Martinez et al. 2002; Zhang and Khare 2009). A global identity refers to mental representations in which consumers are interested in global cultures and identifying with people around the world. A local identity refers to consumers' mental associations of their faith in and respect for one's local traditions and cultures as well as identifying with people in one's local community (Arnett 2002; Zhang and Khare 2009).

How will consumers respond to marketing efforts targeted at their global and local identities? Recent research (Benet-Martinez et al., 2002; Hong et al., 2009) suggests that this may be dependent on consumers' view of their two cultural identities; specifically their subjective perceptions of their two identities as compatible with or oppositional to each other. Consumers who believe that their two cultural identities are compatible with each other tend to show assimilative responses to the identity prime, while those who believe that their two cultural identities are opposite each other tend to show the contrastive response. Based on Hong and her colleagues (2009), this happens because consumers who believe that their two identities are compatible with each other tend to hold separate knowledge about these two identities, and activation of one identity via prime will not activate the other identity. Since consumers tend to rely only on the accessible identity to form their evaluations, they provide identity consistent evaluations (i.e., assimilative identity effect). Consumers who believe that their two identities are oppositional to each other will experience activation of both identities in response to a prime. These two identities are conceptually opposite each other and as a result, consumers provide identity inconsistent evaluations (i.e., contrastive identity effect).

Earlier studies have shown that consumers' view on global and local cultures determines their global and local identities (Arnett 2002). As a result, their lay theory of the relationship between global and local cultures can have similar effects as their lay theory of the global and local identities on product evaluations. Applying this framework to the global-local context, the bi-cultural identity lay theory predicts that the global-local identity will lead to an assimilative identity effect for consumers who believe that global and local cultures are compatible with each other. For consumers who believe that the two cultures are oppositional to each other, a contrastive identity effect will be observed. We ran three studies to test this hypothesis as well as the underlying process.

Study 1 was an identity primed (local vs. global) x lay theory (compatible vs. oppositional) x product version (local vs. global) mixed design, in which we measured consumers' lay theory on global and local cultures. A total of 134 undergraduate students from a large southwestern U.S. university took part in this study for extra course credit. In this study, we found that the identity prime lead to an assimilative identity effect when participants believed that global and local cultures could be compatible with each other, and that the identity prime lead to a contrastive identity effect when participants believed that global and local cultures were opposite each other.

Study 2 was a lay theory prime (compatible vs. oppositional) x identity measured (local vs. global) x product version (local vs. global) mixed design, in which consumers' lay theory of global and local cultures was manipulated. A total of 164 undergraduate students

from a large southwestern U.S. university took part in this study for extra course credit. In this study, through directly manipulating the lay theory, we showed that the measured global-local identity lead to an assimilative identity effect when participants believed that global and local cultures could be compatible with each other. Further, the measured global-local identity lead to a contrastive identity effect when participants believed that global and local cultures were oppositional or conflicting each other.

Study 3 was run to further test the possible process underlying this effect. A total of 152 undergraduate students from a large southwestern U.S. university took part in this globalization prime (positive vs. negative) x oppositional lay theory measured x product version (local vs. global) mixed design study for extra course credit. This study provided a test of the counter-arguing mindset, the explanation for the contrast effect observed in the first two studies. Because the oppositional lay theory prime tends to make people believe that the two cultures are conflicting, they seem to engage in a counter-arguing mindset when they process the global-local stimuli, and as a result they have the exact opposite associations in response to the stimuli.

Our results have several important theoretical implications. First, we provide boundary conditions for the identity accessibility effect in the context of global-local products. While earlier studies (Arnett 2002; Zhang and Khare 2009) tended to focus on the assimilative accessibility effect, we found that when the global or local identity is made accessible it does not always lead to the assimilative identity effect.

Second, our results have important implications for understanding the assimilation vs. contrast debate in the literature (Förster & Liberman 2007; Reed 2004). While the earlier debate tended to focus on the diagnosticity of the accessible identity to determine if the evaluation is assimilative or contrastive (Zhang & Khare 2009), our results showed that the consumers' view about the relationship between global and local cultures is another key to understanding the exact nature of product evaluation.

Third, we provide a theoretical explanation for the contrasting findings about differential preference for local and global products. While earlier studies (Arnett 2002; Zhang and Khare 2009) showed that it is important to specify consumers' accessible global or local identity, we replicated the identity accessibility effect but also showed that it will happen only when consumers view their two identities as compatible with each other. Thus, our study provides a more comprehensive theoretical explanation for reconciling earlier reported divergent preference patterns for local and global products.

Moving On and Away: Closure Increases Psychological Distance Through Emotion

Jae-Eun Namkoong, University of Texas at Austin, USA
Andrew Gershoff, University of Texas at Austin, USA

EXTENDED ABSTRACT

Psychological closure is the feeling of completeness of an experience, providing a feeling of *pastness* or distance between an experience and the current time (Beike, Adams et al. 2007). A same event can feel like it happened yesterday or like ancient history (Van Boven, Kane et al. 2010), and the notion of closure is important to consumer researchers because it may influence evaluations of the time since a product or service failure, or the likelihood that similar negative events will reoccur. In turn, this could affect the likelihood of consumers retaliating against a brand, likelihood of re-trying or reconsidering a brand, as well as decisions about insurance to protect from similar outcomes.

In this research, we examine how closure influences evaluations of psychological distance from negative product experiences. We propose and test the role of emotional intensity as a mediating mechanism. Prior research has shown that closure alleviates negative emotion (Beike and Wirth-Beaumont 2005; Li, Wei et al. 2010) and that emotional intensity and psychological distance have a negative relationship (Van Boven, Kane et al. 2010). In the present research we link these constructs to demonstrate that psychological closure is a significant determinant of psychological distance, both perceived temporal distance in Studies 1 and 2, and perceived probabilistic distance in Studies 3 and 4. Further, we explore the role of emotional intensity as both mediator (Study 1 to 4) and moderator (Study 3 & 4) of this process.

Our findings show that, when people experience closure on a negative event, they feel as if the event happened a longer time ago and that a similar problem is less likely to reoccur. This perception was reflected in perceived product quality, purchase intention, and willingness to purchase insurance.

Study 1 was conducted in a university with a top ranked football team. The negative consumer experience was the team's previous football season, which was one of the worst in the school's history. All participants first read a short news clip reminding them of the overall abysmal performance of the team during the season. Next, depending on condition, participants were instructed to provide reasons why they would consider the prior year's football season as "closed" or "not closed." This manipulation task has been successfully used in previous literature (Beike, Adams et al. 2007; Beike, Adams et al. 2010) and was used in all 4 studies of this research. After the closure manipulation, participants reported on 11-point scales their felt emotions (i.e. frustrated, upset) when thinking about the football season. Finally, using measures from previous research (Van Boven, Kane et al. 2010), participants provided perceived temporal distance from the previous football season (0 = *Feels like yesterday*, 10 = *Feels far away*; 0 = *Feels very close*, 10 = *Feels very distant*). As predicted, participants in the high (vs. low) closure condition reported greater temporal distance ($M = 7.2$ *vs.* 5.4; $p = .003$), which was mediated by a significant reduction in emotional intensity (n boots = 5,000; 95% CI(.095, .822)). Study 2 further examined the mechanism by manipulating both closure and emotionality of the experience, and by looking at embarrassment rather than a loss as the negative experience (Dahl, Manchanda et al. 2001). Participants first recalled an embarrassing moment from the past and described it in either an emotional or emotionless manner depending on condition. Next, participants completed the closure manipulation as in study 1. As predicted, there was a significant interaction between closure and description emotionality. Those in the emotional description condition reported significantly higher perceived temporal distance in the high (vs. low) closure condition ($M = 6.78$ *vs.* 5.19; $p = .004$) while there was no significant effect of closure in the low emotion condition. The moderated mediation was also significant. In the emotional description conditions, emotional intensity significantly mediated the effect of closure on perceived temporal distance (n boots = 5,000; 95% CI(.234, .75)), but no effect or mediation was found in the low emotion description condition.

Study 3 and 4 further expanded these results by examining closure on probabilistic distance. In study 3 participants read a negative product review and were instructed to write about why the experience could be thought of as closed or not closed, depending on condition. Participants in the high (vs. low) closure condition thought the likelihood of the problem reoccurring was lower which was also reflected in their evaluations of product quality and purchase intention ($M = 3.85$ *vs.* 3.37; $p = .032$). This was mediated by significant changes in emotional intensity (n boots = 5,000; 95% CI(.015, .213)).

Study 4, like study 2, manipulated both closure and emotionality on participants' own negative product experiences, by manipulating whether participants wrote about it in either an emotional or pallid style, and by whether or not the experience could be considered closed or not. The predicted interaction revealed that, when participants described the event in an emotional manner, high (vs. low) closure led to a lower willingness to purchase insurance that would protect them from that problem in the future ($M = 3.86$ *vs.* 5.81; $p = .001$). The same moderated mediation pattern as Study 2 emerged. In the emotional description conditions, emotional intensity significantly mediated the effect of closure on probabilistic distance (n boots = 5,000; 95% CI(-.486, -.003)), but no effect or mediation was found in the emotionless description condition.

To summarize, our results demonstrate how closure increases psychological distance as mediated though emotional intensity. With closure participants feel events happened longer ago (Study 1 & 2) and were less likely to reoccur (Study 3 & 4). Manipulation of emotionality and mediation analysis shows how emotional intensity underlies this effect. The findings contribute to the literature on psychological closure and psychological distance by finding it a new consequence and determinant, respectively.

Powerlessness-induced Compensatory Consumption:
The Preference for Experiential vs. Material Luxury Products

Ayalla Ruvio, Temple University, USA
David Dubois, INSEAD, France

EXTENDED ABSTRACT

Despite the lasting financial crisis, the commerce of luxury goods and services has enjoyed a continuous growth, reaching $276 billion in sales in 2011 worldwide (Bain 2011). To better understand the reasons of this success, recent work has started to examine more specifically the motives underlying individuals' motivation to consume luxury products. In particular, recent work suggested that states of powerlessness can increase consumers' preference for status products, because these products help them to alleviate the aversive feelings associated with powerlessness (Rucker and Galinsky 2008).

The present work builds on a key distinction between two types of luxury offerings: experiences (e.g., a luxurious vacation or dining in a high-end restaurant) and products (e.g., a status car or designer piece of furniture). Interestingly, while some offerings might be uniquely categorized as experiences or products, a luxury brand might choose to frame its offering (e.g., a car) either as an experience (by emphasizing driving the car) or a material product (by emphasizing its features). As a first step, we investigate how one pervasive factor – consumers' sense of power – will affect consumers' preferences for experiential vs. material luxury. By power, we refer to people's perceived or actual asymmetric control over valued resources in social relations (Rucker, Galinsky and Dubois 2012). Past work showing that powerless consumers are more willing to spend on a luxury product than powerful and power-neutral consumers (Rucker and Galinsky 2008) might predict that states of powerlessness equally foster preferences for material and experiential products, but little is known about whether the powerless' preference might vary based on whether luxury is experiential or material. Yet, recent research argued that experiences can be more rewarding than products (Carter and Gilovich 2010; Van Boven and Gilovich 2003). Thus, we make the novel proposition that states of powerlessness would foster greater preference for experiential luxury than for material luxury. In support for this proposition, the powerless' sensitivity to their environment might increase the value derived from experiential products (Galinsky et al 2008).

We conducted two experiments to test these hypotheses. Results were analyzed using ANOVAs, regressions and t-tests, as appropriate.

EXPERIMENT 1

The Powerless' Preference for Experiential vs. Material Luxury. One hundred and sixty four undergraduates filled out an online survey in exchange for extra course credit. They were randomly assigned to conditions in a 3 (power: low, high, control) × 2 (status: low, high) × 2 (product type: experience, possession) mixed design with status and object serving as a within-participants factor. Participants were asked to recall a time they had or lacked power (Galinsky et al. 2003). Subsequently, participants were told they would participate to the evaluation of different consumer products. More specifically, participants were shown four different products associated with high and low levels of status, two of which were experiences (high-status: a luxury vacation; low-status: a massage; Van Boven and Gilovich 2003) and two of which were material objects (high-status: luxury car; low-status: a fabric sofa; Rucker and Galinsky 2008). Participants were asked to indicate how much they would be willing to pay for each of the products. Consistent with past research, results re-

vealed a main effect for power, status and type of product, replicating both Rucker and Galinsky's (2009) and Van Boven and Gilovich's (2003) findings. Participants were willing to pay significantly more for a product under the low power (p< .05), for high status products (p < .001), and for experiential products (p < .001). Of key importance, there was he significant interaction of power × status × product type (p < .05). Low-power participants indicated a higher willingness to pay for experiential luxury than for material luxury, p <.01. Overall, these results support both Rucker and Galinsky (2008) and Van Boven and Gilovich (2003) assertions. Under the aversive state of powerless, consumer will pay more for high status material products, but will pay even more for high status experiential products.

EXPERIMENT 2

Framing Luxury as Experience or Material. One hundred and twenty eight undergraduates filled out an online survey in exchange for extra course credit. They were randomly assigned to conditions in a 2 (power: low, high) × 2 (status: low, high) × 2 (product characteristics: experiential, material) between-participants design. Power was manipulated through the recall task as in experiment 1. Next, participants took part to a consumer product experience. Participants were exposed to a high-status (Ferrari car) or low-status (Mini-van) framed as experiential ("the perfect driving experience") or material luxury ("the perfect car to own"). Our dependent variable was participants' willingness to pay for the product, in percent of the retail price. Results revealed significant main effects for status and for product type, similar to experiment 1 (p < .05). Of most importance, there was a significant power × status × product interaction (p < .01). That is, our participants were willing to pay the most under a low power condition and for the high status car when highlighting its experiential attribute than when highlighting its material attribute (p <.01).

Thus, overall consumers will be willing to pay more for material products when they are thinking of the in experiential terms. Nevertheless, once again, state of low power forester greater attractiveness to high status experiential purchases in the form of willingness to pay for them.

CONCLUSION AND CONTRIBUTIONS

Overall, our results successfully both replicated and integrated classic findings from the power literature (Rucker and Galinsky 2008; 2009) and the literature on experiential purchases (Carter and Gilovich 2010; Van Boven and Gilovich 2003) assertions, and supported our novel proposition: powerless consumers paid more for high status luxury products overall, and indicated a higher preference for experiential purchases over material ones. These results suggest that experiential purchases have a greater compensatory power than material ones, and multiply the possibilities for future research. Implications for power, and luxury marketing practices are discussed.

Can Brands Move In from the Outside:
How Moral Identity Enhances Out-group Brand Evaluations

Woo Jin Choi, Texas A&M University, USA
Karen Page Winterich, Pennsylvania State University, USA

EXTENDED ABSTRACT:

Consumers tend to evaluate out-group brands less favorably than in-group brands. Though in-group favoritism and out-group hostility are well-established in the literature, little is known about how out-group brand evaluations can be improved. However, as the number of niche brands with small customer segments expand (Aaker 1991; Erdem and Sun 2002), brands that are perceived as the outgroup or are seeking to increase their customer base by appealing to more customer segments will need to overcome the less than favorable attitudes toward their brands. As such, marketers need to understand how consumers' out-group brand evaluations can be improved. To address this issue, we theorize that moral identity (hereafter, MI) will aid marketers of out-group brands in overcoming out-group hostility by enhancing brand evaluations.

MI is a self-regulating construct that fosters one's moral actions (Aquino and Reed 2002). Prior research on MI suggests that individuals with high self-importance of MI have more expansive group boundaries (Reed and Aquino 2003). However, this expansive effect of MI has focused on prosocial and moral behavior toward outgroups (Hardy et al. 2010; Reed and Aquino 2003) without considering whether these psychological characteristics of MI may extend to brands. Recognizing the role that morality may play in personal relationships (Hart et al. 1998; Reed and Aquino 2003) and the relationships that consumers have with brands (Aaker 1997) suggests that MI can be extended beyond moral behavior. Specifically, MI may influence consumers' responses to brands, which hold important social and reference group associations for consumers.

We theorize that MI will act as a conduit that reduces the perceived distance between a consumer and his or her out-group brands, thereby enhancing out-group brand evaluations. More specifically, consumers with high MI will more favorably evaluate their out-group brands compared to those with low MI such that MI moderates the effect of group membership on brand evaluations. Given the existing tendency to favor in-group brands (Escalas and Bettman 2005; White and Dahl 2007), we propose that MI will not influence in-group brand evaluations. Furthermore, we theorize that this effect will be mediated by the psychological distance, the "subjective" perception regarding how close or far an object is from the self (Trope and Liberman 2010), between consumers and their out-group brands.

We conducted four studies to test our theorizing. Study 1 examined the moderating effect of MI on brand evaluations by measuring the chronic self-importance of MI. First, participants self-identified one ingroup and one outgroup and then listed a brand associated with each group, which followed Escalas and Bettman's (2005) procedure. After a 20 minute unrelated task, participants evaluated (using 4 items; e.g., unfavorable/favorable on a 7-point scale) the two brands that they identified earlier among several other filler brands and completed the Self-Importance of Moral Identity Scale (Aquino and Reed 2002). As theorized, the results revealed that consumers' MI enhanced attitudes toward out-group brands but did not affect attitudes for in-group brands.

To assess whether this effect occurred due to MI rather than related constructs, study 2 replicated these results using temporarily salient MI (Aquino et al., 2009). We primed participants with either MI or a student identity (SI, hereafter). Those primed with MI should temporarily have MI salient and those primed with SI should tem-porarily have their SI salient, and thus temporarily low salience for MI, such that those in the MI condition would evaluate out-group brands more favorably than those in the SI condition, but identity prime would have no effect on in-group brand evaluations. Results were consistent with this theorizing.

Studies 3 and 4 investigated the underlying process by examining the mediating role of the psychological distance between the consumer and the brand. To measure the psychological distance between a consumer and a brand, we utilized the Inclusion of Others in Self scale (IOS; Aron et al. 1992). In study 3, a 2 (brand group membership: in-group vs. out-group) within-subjects design was used with MI measured continuously. All participants evaluated the pre-designated in-group (i.e., Nike, Polo) and out-group (i.e., TOMS, Old Navy) brands, which were pretested and presented in random order. The findings of Study 3 replicated the results of the first two studies, demonstrating the positive influence of consumers' MI on out-group brand evaluations but no effect of MI on in-group brand evaluations. More importantly, the effect of MI was mediated by the psychological distance such that consumers with high MI were more likely to expand their boundaries to outgroups than where those with low MI.

Study 4 sought to demonstrate the practical implications of these findings for out-group brands seeking to improve their brand evaluations. Thus, we primed MI versus business identity (BI) in an advertisement for a hypothetical brand. Though previous studies on MI (e.g., Reed et al. 2007) manipulated participants' MI through priming tasks, to the best of our knowledge, this study is the first attempt to show that MI can be temporarily primed through an advertisement. A 2 (brand group membership: in-group vs. out-group) X 2 (primed identity: BI vs. MI) between-subjects design was used. The results replicated the moderating effect of MI on brand group membership on brand evaluations as well as the mediating role of psychological distance such that brand evaluations of a hypothetical out-group brand were more favorable when participants were exposed to the brand with an advertisement eliciting temporarily accessible MI.

This research extends both the marketing and MI literature by addressing the role of MI in consumers' brand evaluations. First, we identify the role of MI in everyday consumer judgments that do not regard moral decision-making. Though it may be obvious that MI would influence prosocial behavior and brand evaluations for brands engaging in CSR or other moral behaviors, we demonstrate that the effects of MI extend beyond prosocial behavior to marketplace judgments such as brand evaluations irrespective of the moral behaviors of the firm. Furthermore, brand managers seeking to overcome the less favorable perceptions associated with out-group brands may benefit from drawing upon consumers' MI in their marketing communications.

The Influences of Social Power on Social and Physical Distance

Yanli Jia, Chinese University of Hong Kong, China
Robert S. Wyer, Chinese University of Hong Kong, China
Hao Hu, Chinese University of Hong Kong, China

EXTENDED ABSTRACT

Social power refers to the ability to control others' resources and outcomes (e.g., Fiske, 1993). However, there is a metaphorical relationship between social power and social distance. This relation is often conveyed symbolically. When a picture of a company hierarchy is drawn, for example, the CEO is at the top, with less powerful individuals at increasing distances away. This relationship may extend to physical distance as well. Construal level theory (e.g., Liberman, Trope and Wakslak, 2007) suggests that activating concepts of distance along one dimension can potentially influence judgments and overt behavior along other dimensions of distance to which these concepts are metaphorically related. The present research examined implications of this possibility.

The notion that "power equals distance" pervades many societies. Socially powerful individuals typically possess substantial material/social resources and do not need to depend on others for survival. Therefore, they may be disposed to see themselves as separate and distinctive. By the same token, individuals with little power are more likely to depend on others to survive. Consequently, they are more likely to be motivated to maintain social closeness to others. These differences in social distance could generalize to physical distances.

This relation may not hold for the particular individuals involved in a power relationship. Powerful people might be motivated to be close to their powerless counterparts in order to successfully exert their influence, whereas low-power individuals might resist being influenced against their will and find others' imposition on them to be aversive. To this extent, they may be motivated to keep distance from those who have power over them. This, therefore, leads to our main hypothesis:

Hypothesis 1   *People who perceive themselves to have high power in a particular relationship will judge themselves to be closer to the other person involved in this relationship, but more distant from people in general, than people who perceive themselves to have low power.*

Three studies examined the possibility. In one study, participants wrote about a personal experience in which they either had power over another or another had power over them. Then, they indicated both how close they felt to the other person in the situation they recalled and to other college students in general (adopted from Aron, Aron and Smollan, 1992). Participants perceived their distance from the person they wrote about to be less, but their distance from people in general to be greater, when they had written about a powerful experience than when they had described a powerless one.

A second study showed that individuals' perception of themselves as socially distant from people in general affected the *physical* distance from others at which they feel comfortable. After performing the same recall task we used in Study 1 to manipulate power status, participants were told that "because other persons are going to use this room, you will have to complete the second part of the experiment in a different room" and on this pretext, participants moved to a different room for completing a questionnaire that assessed their conformity (adopted from Shen, Wan and Wyer, 2011). Seven chairs were lined up in the middle of this room, and a schoolbag had been left on the chair next to the extreme right, suggesting the presence of another person (Snyder and Endelman, 1979). Participants chose to sit further away from the chair occupied by unknown other if they had previously described a powerful experience than if they described a powerless experience. Furthermore, they showed less willingness to conform to others' product preferences in the former condition than in the latter.

Finally, people's perceptions of their social distance from others may affect their subsequent behavior. We examined this possibility under a gift-exchange situation. Gift-giving has been interpreted as a confirmation of the giver's desire to establish a connection to the recipient (Sherry, 1983). When accepting a gift, however, people may take reciprocity norms into consideration and feel indebted if they accept a gift from someone they feel close to (Shen, Wan and Wyer, 2011). Therefore, we hypothesized that people who perceived themselves to be close to another would be more willing to give than to accept a gift, whereas people who perceived themselves to be distant from others might show the reverse pattern.

In a third study, participants first completed the same power-manipulation task employed in other studies. Then, they were asked to imagine a situation in which they shared a taxi with either (a) the person they recalled interacting with in the power-manipulation task or (b) a casual acquaintance. Finally, some participants indicated the likelihood that they would accept the other's offer to pay the fare for both of them, whereas others estimated the likelihood that they would personally offer to pay the fare for both of them. As expected, participants were more willing to offer to pay the fare for the person they had written about, but were less willing to accept the other's offer to pay, if they had had power over this person than if the person had had power over them. However, priming feelings of power slightly *decreased* their willingness to pay for a casual acquaintance, but increased their willingness to accept an offer from this person, than priming feelings of low power.

To conclude, although individuals who feel powerful are motivated to be close to the specific individuals over whom they have power, they prefer to be distant from people in general. Moreover, this tendency generalizes to actual behavior, leading them to sit further away from others, decreasing their tendency to conform to others' preferences in a product choice situation, and affecting their tendency to give and accept gifts.

The Effect of Package Shape on Consumer's Calorie Estimation

Jieun Koo, Korea University, Korea
Kwanho Suk, Korea University, Korea

EXTENDED ABSTRACT

People are becoming more conscious about health and weight control and as a consequence, calorie intake is an important concern for many consumers. However, people's calorie estimation is shown to be vulnerable to various biases associated with the influence of nutrition labels (e.g., low fat) and package sizes (Chandon and Wansink 2007; Scott et al. 2008). This research investigates another source of bias in calorie estimation, namely, the shape of the package containing food.

According to the well-known elongation bias, container shape affects perception of spatial volume. People perceive the volume of a taller container as larger than that of a shorter and wider container (Raghubir and Krishna 1999). Extant research has also shown that the shape of the container affects perceived consumption and product choice (Chandon and Ordabayeva 2009; Folkes and Matta 2004; Krishna 2006; Raghubir and Krishna 1999; Wansink and Van Ittersum 2003). However, little attention has been directed to the influence of container shape on calorie estimation, which may be partially caused by the common belief that calorie is a direct function of volume. This lay belief would suggest that when the two containers are equal in their actual volume, foods will be estimated to have more calories when they are contained in a taller container than a wider container due to the elongation bias.

We propose the idea contradictory to this belief. Specifically, we hypothesize that food is perceived to have *lesser* calories when it is contained in a taller than in a wider container. This counterintuitive effect is assumed to arise from different psychological processes underlying the estimation of spatial volume and that of calories. Volume estimation is based on perceptual judgment and a taller container is perceived to be more voluminous because human perception emphasizes height as the most salient dimension (visual prominence effect) (Krider, Raghubir, and Krishna 2001). In contrast, calorie estimation is conceptually driven. Because calorie is ambiguous and intangible, calorie judgment relies on inferences based on cognitive associations. This is reason why consumer's calorie estimation has been shown to be influenced by situationally activated concepts (Chandon and Wansink 2007; Chernev 2010; Scott et al. 2008; Kardes, Posavac, and Cronley 2004, Wansink and Chandon 2006).

We hypothesize that package shape affects calorie estimation due to different conceptual associations activated by different shape. We propose that taller and thinner packages activate the concepts relating to slimness and lightness, whereas shorter and wider packages activate concepts relating to fatness and heaviness. Further, consumers use concepts brought to their mind to infer calories, resulting in biases in judgment. The slimness and lightness activated by an elongated container will lead to underestimation of calories. By contrast, fatness and heaviness associated with a shorter and wider container will lead to overestimation of calories.

Hypothesis 1:   *Food will be perceived to have lower calories when it is contained in a taller container than when it is contained in a wider container even though the actual volume is made constant.*

In Study 1, 40 participants estimated the calories of milk placed in a tall or a wide glass. The two glasses had equal volumes. The estimated calorie of milk in the wider glass was higher than that in the taller glass ($M_{taller} = 140.0$ vs. $M_{wider} = 163.3$; $F(1, 38) = 20.75$, $p < .001$). The results were consistent with our hypothesis.

Study 2 demonstrates the opposite effect of package shape on volume estimation and calorie estimation. We expect a taller container to be perceived to have more volume but lesser calories than a wider glass. Participants were presented with orange juice placed in a tall or wide glass. The participants estimated either the calories or the volume of the contained orange juice. Consistent with the elongation bias, the juice in the taller glass was perceived to be greater in volume than that in the wider glass ($M_{taller} = 947.9$ vs. $M_{wider} = 917.6$; $F(1, 143) = 5.42$, $p = .021$). However, the juice in the taller glass was judged to have lower calories than that in the wider glass ($M_{taller} = 461.3$ vs. $M_{wider} = 485.6$; $F(1, 144) = 7.92$).

Study 3 extends our findings to the package display orientation. In this study, the same rectangular-shaped package is displayed either vertically or horizontally. Vertical display would make the product look slimmer and lighter, whereas horizontal display would make the product look fatter and heavier. Accordingly, perceived calorie would be lower when the same package is presented vertically instead of horizontally. In the study, participants were presented with five food products, each of which is contained in a rectangular-shaped package. The packages were then presented either vertically (i.e., height is greater than width) or horizontally (i.e., width is greater than height). A 2 (package display: vertical vs. horizontal) × 5 (products) ANOVA on estimated calories showed the significant main effect of package display, indicating that participants estimated lower calories when the packages were presented vertically, rather than horizontally ($M_{vertical} = 334.7$ vs. $M_{horizontal} = 475.2$; $F(1, 53) = 11.27$, $p = .001$). Separate test for each product category showed the significant effect of display direction for all five products (all $t(53) > 2.12$, all p's $< .046$).

In conclusion, the results of the current research demonstrate the relationship between shape of product package and consumer's calorie estimation. Contradicting to the belief that calorie estimation is a positive function of volume estimation, our findings from three studies show that a taller package perceived to have more volume was judged to contain lesser calories. We believe our research contributes to the existing literature on consumer calorie estimation and spatial perception by separating the psychological mechanisms underlying these two seemingly related judgments.

Anti-Consumption Lifestyles and Personal Debt

Marcelo Nepomuceno, ESCP Europe, France
Michel Laroche, Concordia University, Canada

EXTENDED ABSTRACT

This study examines if the scores on anti-consumption lifestyles correlate with account balance and balance due. In a sample of Brazilians customers, it was found that voluntary simplicity, but not frugality and tightwadism, correlate negatively with balance due. In addition, none of the lifestyles correlates significantly with account balance.

The adoption of anti-consumption lifestyles results in the voluntary reduction of consumption by individuals. This study investigates the impact of adopting such lifestyles on the banking behavior of Brazilian customers. Arguably, an individual who reduces consumption will naturally spend less money, and have more resources. Therefore, we test if frugal consumers (Lastovicka et al. 1999), tightwad consumers (Rick, Cryder, and Loewenstein 2008), and voluntary simplifiers (Iwata 1999; Zavestoski 2002) are less susceptible to debt.

Testing this susceptibility to credit is important for two reasons. First, financial institutions should be particularly interested about customers who adopt such lifestyles. Banks that attract such customers are able to use their credit to provide loans to other customers. Second, policy makers concerned with reducing the rate of personal indebtedness in a given population might promote anti-consumption lifestyles that correlate with lower debt levels.

This study looks at other factors that might affect one's personal debt. Antecedents included in the model are income, self-control, long-term orientation and materialism. Additionally, the interactions between these antecedents are also considered in the model.

A partnership between a Brazilian financial institution and the authors made the study possible. In this agreement, the financial institution supported the data collection by recruiting their customers for the study. The sample includes 502 customers with bank accounts in Cuiaba, in one of the major rural areas of Brazil. A special effort was dedicated to recruit participants with a wide range of income levels. To increase customer participation, the financial institution created a raffle with an Ipad2. The participants answered an online survey composed of several scales, presented in random order. To measure frugality, we used Lastovicka's et al. (1999) frugality scale, as translated by Castilhos and Petersen-Wagner (2009). To measure materialism, we used Garcia's (2009) adapted version of Richins' (2004) materialism scale. Tightwadism was measured with a back translated version of the tightwad-spendthrift scale (Rick, Cryder, and Loewenstein 2008). Voluntary simplicity was measured with a back translated version of the adapted Iwata's (1999) scale. Self-control was measured with a back translated version of the self-control scale (Tangney, Baumeister, and Boone 2004). Long-term orientation was measured with a back translated version of the long-term orientation measure (Bearden, Money and Nevins 2006). In addition, we used a translated version of an instructional manipulation check (Oppenheimer, Meyvis, and Davichenko 2009) to identify and remove inattentive participants. This resulted in the exclusion of 45 participants (or roughly 9%), and a final sample of 457 customers.

The financial institution provided information on the income, account balances and balance due for each of the 457 participants. Income, participants' scores on these scales and the interaction terms were considered as independent variables in two different analyses. First, a linear regression was performed using account balances as the dependent variable. It was found that account balances do not correlate significantly with income, anti-consumption lifestyles, materialism, self-control or long-term orientation. Therefore, the adoption of an anti-consumption lifestyle does not affect one's account balance. This occurs probably because the money saved through the adoption of an anti-consumption lifestyle is directed to savings accounts. However, the interaction between the materialism dimensions with income, self-control and long-term orientation significantly affects the scores on account balances. Most notably, it was found that a person who believes that acquisition is a central goal in life will have larger account balances to deal with the temptation of consuming. In addition, low-income individuals have larger account balances when they think that possessions are a source of happiness.

In the second analysis, a regression was run only with the 172 participants who had balances due. Financial institutions in Brazil offer pre-approved credit to its customers, without the need to sign a loan. However, a high-income is a necessary condition to have access to this service. Therefore, low-income individuals are considerably less likely to have balances due, as financial institutions do not offer them this service. To deal with this bias, the variable balances due was transformed into a new variable, which considers participants' incomes. This new variable, named "weighted balances due", is the mathematical result of the division of balances due by income. When analyzing the impact of the independent variables on weighted balances due, it was found that voluntary simplifiers own less debt (β=-.283, p=.006), whereas frugality and tightwadism do not shield one from having larger balances due. Also interestingly, high-income individuals who score high on self-control have large balances due, probably because they are fooling themselves into believing that they are more self-controlled that they actually are. Finally, we found a negative correlation between the success dimension of materialism and "weighted balances due" (β=-.214, p=.05), indicating that individuals who use possessions to signal success are more prone to own larger debt. On the other hand, the centrality and happiness dimensions of materialism do not correlate significantly with balances due.

The current results show that not all anti-consumption lifestyles reduce one's balances due. The adoption of a simple lifestyle is the best shield that one has against owning larger debts. Furthermore, the belief that possessions signal success also leads one to have larger balances due. Therefore, at least in Brazil, policy makers concerned with the citizens' debt level should promote anti-materialistic values and a simple lifestyle, particularly to groups of individuals with high indebtedness. Finally, future studies should evaluate participants' saving accounts to test which anti-consumption lifestyles lead to more saving behavior. The current study showed that none of the lifestyles correlates with account balances significantly. However, this result might be particular to Brazil, where individuals are significantly motivated to invest any outstanding money. That is because, Brazil is a country with high inflation, and a place where investing in financial institutions is highly profitable.

Rebels Without a Clue:
Nonconscious Motivation for Autonomy Preservation Moderates Social Decision Biases

Randy Stein, University of California-Riverside, USA
Joshua Ackerman, Massachusetts Institute of Technology, USA
John A. Bargh, Yale University, USA

EXTENDED ABSTRACT

Consumer judgment and decision making is often shaped in unwanted ways by unconscious and uncontrollable processing, a phenomenon known as mental contamination (Wilson & Brekke, 1994). However, when consumers believe that contaminating influences threaten their judgments, they engage several resistance strategies. For instance, several lines of research converge on the idea that consumers prefer to make judgments that are self-generated and free from the influence of others, thus satisfying a basic need for autonomy (Ryan & Deci, 2006). When consumers perceive that communications threaten their freedom of belief, they become resistant to those communications and endorse their original positions more (Brehm 1966). Consumers also generally consider themselves better decision makers than others and devalue the thoughts and feelings others use to make decisions (Pronin et al., 2007; Pronin, 2008; Pronin & Kugler, 2007).

This line of thinking suggests that (at least from a lay perspective), when active, a motive to protect judgments from exogenous social influence might be an effective means of decreasing mental contamination. But is this accurate? Here, we confront the veracity of this idea by examining whether nonconscious autonomy preservation motivation reduces or, perhaps counterproductively, amplifies several decision biases that may result from contaminating social information.

Many decision biases might occur because individuals fail to properly regulate how social information is used. For example, incidentally heightened accessibility of another person can influence self-directed judgments via an automatic comparison process (e.g., Dijksterhuis et al., 1998). Here, an exogenous agent (the exemplar) taints views of the self because individuals fail to reject irrelevant social information. Since mental contamination is often caused by processing outside of conscious awareness, we reasoned that corrective processes need to be operating nonconsciously as well.

Thus, here we examine the effects of nonconsciously priming autonomy preservation (using a scrambled sentence test) across a wide range of decision biases. The current research adds to our understanding of mental contamination by addressing the broad sense in which the social environment contributes to biases, by showing how social perception processes can both increase and decrease bias (contrary to the lay belief that exogenous social influence is generally bad), and by examining how biases can be reduced without conscious awareness (previously thought to be impossible; Wilson & Brekke, 1994).

In Study 1, we demonstrated how autonomy preservation priming attenuates the usual effects of exemplar priming. Indeed, consistent with prior research (Dijksterhuis et al., 1998), in a neutral scrambled sentence prime condition, participants primed with Einstein considered themselves less intelligent than those primed with Britney Spears. However, in line with our hypothesis, when initially primed with autonomy preservation, this tendency actually reversed, $[F(3,27) = 7.87, p = .01]$.

In Study 2 we demonstrated that resistance priming also attenuates exemplar priming effects that usually cause assimilation. Following Gollwitzer et al. (2011) we utilized the exemplar prime of Mother Teresa and assessed its influence on judgments of prosocial values. In a control condition, participants tended to assimilate to the Mother Teresa prime; however, this tendency was reversed when initially primed with autonomy preservation $[F(3, 71) = 8.26, p = .005]$.

In Study 3 we tested whether autonomy preservation priming attenuates the halo effect, the robust tendency to evaluate attractive people more positively than unattractive people on a number of dimensions unrelated to attractiveness (Nisbett & Wilson, 1977). This effect is due at least in part to perceived similarity between attractive others and the self (Horton, 2003). Based on our earlier findings, we hypothesized that resistance priming should reduce the expression of this bias. We had participants rate two women (one relatively more attractive, one less attractive) on several interpersonal attributes. We found that resistance priming attenuated the tendency to evaluate the more attractive woman more positively, $[F(1, 113) = 6.76, p = .04]$.

The initial studies spotlight decision biases that result from a failure to reject social influence. However, it is also possible that some biases result from a too great an emphasis on autonomy preservation. For example, egocentric biases can occur when people fail to properly discount their own knowledge and take into account another person's knowledge and beliefs (e.g., Keysar, Ginzel, & Bazerman, 1995). Here, outside influence (i.e., other people's knowledge and beliefs) would help to mitigate such biases, but resisting influence would theoretically aggravate such biases.

In Study 4, we hypothesized that resistance priming would increase the "curse of knowledge" error (Keysar, Ginzel, & Bazerman, 1995). Participants completed Converse et al's (2008) adaption of the Birch & Bloom (2007) false belief task. In this task, participants make probability estimates about the likelihood that person A will look for an object (a violin) in a specific container when person B has either moved the object to a new container without person A's knowledge (privileged knowledge condition) or not (no privileged knowledge condition). We found that autonomy preservation-primed participants were more likely to use privileged knowledge (and hence, make a curse of knowledge error) when it was available, $[F(3, 96) = 4.15, p = .044]$.

In study 5 we examine how autonomy preservation priming increases the correspondence bias, an egocentric bias because of a failure to properly consider why someone might make a judgment that is disposition-inconsistent. Following Jones and Harris's (1967) classic paradigm participants were given an essay about the legalization of marijuana, with instructions indicating that the author's position was assigned by the experimenter. Participants estimated the author's actual attitude towards marijuana. Autonomy preservation-primed participants made stronger dispositional attributions than control participants $[t=2.18, p = .03]$.

These five studies highlight how autonomy preservation motivation reduces decision biases involving over-reliance on social information but increases biases involving under-reliance on social information, all without conscious awareness. These results highlight the broad influence of the social environment on mental contamination by strengthening while also alleviating specific biases. Thus, due to the nonconscious and autonomous operation of social resistance goals, consumers' presumption that resisting social influence will improve decision quality is not always accurate.

The Difference Novelty Makes:
Incidental Exposure to Unfamiliar Stimuli Primes Exploratory Behavior

Gerri Spassova, Monash Unviversity, Australia
Alice M. Isen, Cornell University, Ithaca, USA

EXTENDED ABSTRACT

Understanding what makes consumers more likely to explore new products is of crucial importance to marketers. Prior research on consumer innovativeness has focused on identifying stable individual characteristics that determine the propensity of consumers to try new offerings. The present research takes a different perspective by investigating the role of contextual factors on consumer innovativeness. We propose that situational exposure to novelty primes exploratory behavior that carries over to subsequent unrelated choice tasks. Three studies demonstrate these effects and investigate their consequences.

THEORETICAL BACKGROUND

At the individual consumer level, innovativeness has been operationalized primarily as a stable trait, a "predisposition to buy new and different brands rather than remain with pervious choices" (Steenkamp, ter Hofstede, and Wedel 1999) and has been measured using various personality scales (Mehrabian 1978; Raju 1980; Zuckerman 1978).

There is some evidence, however, that innovativeness may be a malleable construct. For example, innovativeness is influenced by socio-behavioral variables, such as age, education, and income (Steenkamp and Gielens 2003), and by prior knowledge (Moreau, Lehmann, and Markman 2001). The amount of change in a person's life can also affect consumers' likelihood of trying less familiar products (Wood 2009) and contextual factors, such as positive mood, can enhance consumers' propensity to adopt brand extensions (Barone, Miniard, and Romeo 2000) or try less familiar products (Kahn and Isen 1993; Menon and Kahn 1999). In this research, we investigate the possibility that exposure to contextual novelty also promotes innovativeness, by priming exploratory behavior.

Context can have powerful effects on behavior (Bargh, Chen, and Burrows 1996; Bargh et al. 2001; Fitzsimons, Chartrand, and Fitzsimons 2008). Subtle environmental cues can activate mental constructs related to traits or goals that subsequently prompt construct-consistent behavior. Behavior can be automatically guided by the presentation of semantic associates (e.g., Bargh et al. 2001; Chartrand and Bargh 1996; Chartrand, Huber, Shiv and Tanner 2008), by the presence of other people (Bargh et al. 1996; Shah 2003), or by situations or objects associated with the behavior (e.g., Aarts and Dijksterhuis 2003; Chen, Lee-Chai, and Bargh 2001; Kay and Ross 2003). Even stimuli that have no prior associations but from which people extract meaning, such as visual arrays, can be a source of non-conscious construct activation (Maimaran and Wheeler 2008).

In this research we argue that behavior can also be influenced by stimuli that carry different semantic meanings but share a common property, such as being novel. We propose that this common property prompts property-consistent behavior, which carries over to unrelated situations. Specifically, we argue that exposure to novel stimuli primes subsequent exploratory behavior. It has been established that novel stimuli attract attention and promote exploration (Berlyne 1960; Fiske and Maddi 1961; Hirshman 1980; Venkatesan 1973). We build on this research and propose that exposure to novel stimuli prompts exploration in an unrelated subsequent situation, similar to the way in which exposure to a cue activating a semantic concept primes behavior consistent with this concept. We investigate the implications of the proposed effect for consumer behavior by testing the hypothesis that presentation of novel contextual stimuli prompts consumers to choose less familiar and more diverse products in a subsequent choice task.

METHOD AND FINDINGS

Study 1 shows that people who have been exposed to novelty choose a broader range of products in an unrelated subsequent choice task, but only when the available options are relatively unfamiliar. Novelty is operationalized as exposure to either new or familiarized neutral images. The subsequent consumer task involves choice of snacks from a set containing either very familiar options or less familiar options. A 2 x 2 ANOVA reveals a significant interaction between novelty prime and choice set familiarity ($F(1, 97) = 6.43$; $p < .05$). Novelty-primed participants choose a broader range of options than controls, indicating a greater propensity to explore, but only when the available options are relatively unfamiliar ($M_{novelty} = 4.97$ vs. $M_{control} = 4.35$, $t(58) = 2.39$, $p = .01$). When choosing from the more familiar set, novelty participants do not differ from controls ($M_{novelty} = 4.44$ vs. $M_{control} = 4.92$, $t(41) = 1.32$, $p = .10$).

Studies 2a and 2b test the effect of novelty on exploration in the context of choice of jam, using presentation of unfamiliar (vs. familiar) words as a manipulation of novelty. In Study 2a, where participants can choose as many options as they want from an assortment of 45 jams, novelty participants select a broader range of jams than controls ($M_{novelty} = 7.11$ vs. $M_{control} = 4.61$; $F(1, 35) = 5.21$, $p < .05$) and also choose a higher number of unusual flavors ($M_{novelty} = 4.08$ vs. $M_{control} = 1.89$, $F(1, 35) = 8.51$, $p = .006$). In study 2b, where participants can choose one out of a set of 30 jams, novelty-primed participants again choose more unusual and unfamiliar flavors ($N_{novelty} = .54$ vs. $M_{conrol} = .15$; $F(1, 47) = 10.91$, $p = .002$).

Study 3 replicates the previously observed effects in the context of real product choice. Novelty participants choose more unusual and unfamiliar jams, relative to controls ($M_{novelty} = .61$ vs. $M_{contorl} = .31$; $F(1, 38) = 4.13$, $p = .05$). After sampling their chosen jam, however, novelty participants report lower satisfaction with the chosen option ($M_{novelty} = 4.83$ vs. $M_{control} = 5.86$; $F(1, 38) = 4.65$, $p < .05$). Mediation analysis reveals that the effect of novelty exposure on post-sampling satisfaction is mediated by the unusualness of their choice.

CONTRIBUTION

This research contributes to the literature on consumer innovativeness by studying the ability of novelty exposure – a contextual factor that to some extent is controllable by retailers and manufacturers – to enhance exploratory behavior. We also contribute to the priming literature by showing that behavior can be influenced by exposure to stimuli that reference different semantic concepts but share a common property. This property primes related behavior that can carries over to unrelated tasks. Finally, we build on the literature on novelty by documenting downstream effects of novelty exposure that have not been shown before.

Guilt Appeals as a Blessing or a Curse?
Influences of Sponsorship Identity and Sponsor-Issue Fit on Guilt Appeals in Charity-Related Advertising

Chun-Tuan Chang, National Sun Yat-sen University, Taiwan
Ya-Ting Yu, National Sun Yat-sen University, Taiwan
You Lin, National Sun Yat-sen University, Taiwan

EXTENDED ABSTRACT

Nowadays as companies experience increasing competition, social cause efforts become a prominent role in the profit-seeking efforts of the corporation domain. Two types of societal marketing programs are common: (1) social sponsorship through explicit donation to a cause and (2) cause-related marketing (CRM) through consumer purchases. Because advertising determines the success of societal marketing programs (e.g., Chang, 2008), many advertising persuasion techniques are adopted. Emotional appeals are widely used to "cut through the clutter" in crowded media environment. Among them, guilt appeals are identified as popular to arouse persuasive communication, especially in prosocial and charitable contexts (e.g., Basil, Ridgway, and Basil, 2006 and 2008; Hibbert et al., 2007). Chang (2011) suggested the importance of exploring potential moderating variables in explaining the effects of guilt appeals.

Although societal marketing programs with charitable causes become popular among corporations, consumers may respond differently to corporate-sponsored social messages than they do to the similar ads sponsored by a non-profit. A corporate sponsor in association with a social message is likely to make ulterior motives accessible, which lead consumers to question the reasons behind sponsorship (Szykman, Bloom, and Blazing, 2004). People possess stereotypes of organizations merely based on the knowledge that a firm is a for-profit or non-profit (Aaker, Vohs, and Mogilner, 2010). Therefore, we predict that sponsorship identity will matter in consumer information processing and moderate the effects of guilt appeals.

Selecting the "right" cause by a company is a key to a successful societal marketing program. Nevertheless, the results of previous studies are inconsistent and contradictory regarding the influences of fit on advertising persuasion, e.g. whether high fit can be an asset or liability. A good fit between prior expectations, knowledge, and competencies of a firm and a promoted social cause can be more easily integrated into the consumers' existing cognitive structure and lead to favorable evaluation of the company (Becker-Olsen, Cudmore, and Hill, 2006; Menon and Kahn, 2003; Pracejus and Olsen, 2004; Rifon et al,. 2004; Sen and Bhattacharya, 2001; Simmons and Becker-Olsen, 2006). However, highly fitting relationships may raise consumer skepticism about company motives and lead consumers to respond more positively to non-fitting relationship (Barone, Norman, and Miyazaki, 2007; Bloom et al., 2006). The intriguing questions of whether and how different sponsorship contexts (who the ad sponsor is and what the sponsorship fit is) may enhance or disrupt consumer guilt perceptions and evaluation are addressed in this paper.

An experiment with 3 (sponsorship identity: corporate social sponsorship vs. CRM vs. non-profit) X 2 (sponsor-issue fit: high fit vs. low fit) X 2 (ad appeal: guilt vs. non-guilt appeals) factorial design was conducted. Prior to the experiment, the treatment booklets were randomized. Administration of the experiment was performed via a shopping mall intercept method. 429 participants were recruited over a 2-week period during mall operating hours. After successful manipulation checks, a series of analysis of variance were conducted to examine proposed hypotheses. Analyses on maladaptive responses were further conducted to test the mediator of maladaptive responses on the effect of guilt appeal on purchase intention for the condition of corporate social advertising and CRM. Univariate results with dependent measures of attitudes toward the ad, attitudes toward the sponsor, and behavioral intentions are summarized in Table 1. Table 2 presents related descriptives across experimental conditions. Three main findings are noteworthy.

First, guilt appeals are found more effective than non-guilt appeals when the ad sponsor is a non-profit. The findings are consistent with previous studies (anti-alcohol: Becheur et al., 2008; bone marrow donation: Lindsey, 2005; charity donation: Basil et al., 2006 and 2008; Hibbert et al., 2007; condom promotion: Alden and Crowley, 1995; mammogram promotion: Turner et al., 2009). Social responsibility guilt has been identified as one of the major forms of consumer guilt (Burnett and Lunsford, 1994). The findings also echoes the charity donation literature that the guilt may be viewed as an awareness of the difference in well-being between oneself and others (Ruth and Faber, 1988) and guilt feelings can be used as a method of gaining compliance (Lindsey, Yun, & Hill, 2007).

Second, guilt appeals backfire when the sponsors-issue fit in a corporate social ad (i.e., explicit donation) is high. Maladaptive responses to charity appeals occur when an individual feels he or she is being manipulated, causing the individual to respond in a negative manner (Coulter and Pinto, 1995). Such responses make sense in that they seek to protect a consumer's balanced (homeostatic) state. In ads using guilt appeals, consumers may evaluate the degree to which the advertiser is attempting to manipulate their attitudes. Consumers will resist the message when they perceive the message as manipulative (Wood and Eagly, 1981). When guilt appeals are used to promote a corporate social ad, consumers are likely to interpret the ad as an explicit placement and view the advertising message as manipulative. Promotion with a high-fit social cause may be viewed as opportunistic and the sponsored company as merely seeking commercial gain for itself. Consumers thus counterargue the message and discount the sponsor to protect themselves from the persuasion attempt.

Third, guilt appeals have boomerang effects when the sponsor-issue fit in a CRM ad is low. When consumers could not find the link between the brand and the cause, they might not understand why they should give away a small fraction of the price they pay to a social cause. Consumers may also feel skeptical why the company "sells" such a low-fit cause to them. Due to people's fiscal associations with the for-profit's motive, the suspicion may negatively influence guilt appeals on sponsor evaluation.

The main goal of the present study was to extended earlier work on guilt appeals by identifying boundary conditions associated with the role of guilt appeals in consumer perceptions and attitudes. Findings from this investigation are informative both theoretically and pragmatically, and underscore the importance for marketers to learn more about when guilt appeals work, and in turn describe how practitioners can avoid negatively toward guilt appeals.

Brand-Related Background Music and Consumer Choice

Arnd Florack, University of Vienna, Austria
Claudiu Dimofte, San Diego State University, USA
Karin Rössler, University of Vienna, Austria
Susanne Leder, Zeppelin University, Germany

EXTENDED ABSTRACT

Previous studies have shown that background music associated with a product category can have positive effects on related sales in a retail environment (North et al. 1999). However, the mechanism by which this effect occurs has not been clearly explained, nor has the effect been shown at lower categorical levels of representation (e.g., the brand). The fact that many marketers select particular songs for use in brand advertising in order to strengthen their brand image raises the question of whether exposure to such brand-related auditory cues affects consumer behavior toward the brand.

In this research, we propose that consumer exposure to a brand-related song enhances the accessibility of the brand attitude in memory and consequently the reliance on that brand attitude. Hence, we expect positive effects of exposure to brand-related music on the choice of brand products when consumers' brand attitudes are positive and when the specific product evaluated (and not others in the brand's portfolio) is associated with the music.

In 3 studies, the impact of the incidental presentation of a brand-related song on product choice is examined in both field and laboratory settings. Study 1 shows that a song used in prior advertising for a brand influences brand sales when played within background music, but only for the brand product directly associated with the music. Study 2 demonstrates that exposure to a brand-related song increases the reliance on the brand attitude and examines fluency perceptions as the underlying mechanism resulting from the exposure to brand-related music. Finally, study 3 looks at possible negative effects of the exposure to brand-related music for brand products that are not directly associated with the respective music.

STUDY 1

The study was conducted in a grocery store in Germany and aimed to assess whether the inclusion of a brand associated song (*Beck's Pils* beer advertising tune) within the background music leads to an increase of sales for the product. It was expected that the presence of this song would lead to an activation of the associated product, making its choice more likely. We found that Beck's Pils sales increased significantly, but we also observed a marginally significant reduction of sales in other beers in the Beck's line. Thus, the brand song had a clear effect on consumers who favored Becks' brands, but induced them to switch from other Beck's products back to the traditional, leading product (Pils) in the brand portfolio.

STUDY 2

The results above suggest that exposure to brand-related music is most likely to increase brand choice for consumers who already favor the brand. We assume that the exposure to a brand-related song increases the accessibility of the associated brand attitude, rendering consumers more likely to rely on their brand attitude when exposed to a brand-related song. Hence, one objective of study 2 was to examine whether the exposure to brand-related music (*Merci* chocolate song) increases the correlation between brand attitudes and brand choice. However, we hold more specified assumptions about how attitude accessibility shapes choice. We expect that enhanced accessibility leads to higher perceived fluency that is attributed to the attitude's "rightness." To test this hypothesis, we included a misattri-

bution manipulation in study 2. In one condition, participants could attribute their perceived fluency to an alternative, exogenous source (a merely perceivable smell of chocolate in the room). Hence, we applied a 2x2 design with the music manipulation (brand-related song played/not played) and the misattribution manipulation (misattribution source mentioned/not mentioned). In order to provide incidental processing of music similar to a shopping context, we applied the guise of a memory test: participants were told that background music was being played to distract them during the memory test. In the experimental condition, the background music included short pieces of the brand-related song. In the control condition, alternative songs were played. The brand attitude was measured outside of the lab with an online-questionnaire.

The results support our hypotheses. We found significantly higher correlations of the brand attitude with brand choice and faster choice latencies when participants were exposed to the brand-related music than when they were not. Importantly, the difference in correlations and the effect on choice latencies disappeared when participants could attribute the felt fluency to an exogenous source. Thus, the perceived fluency resulting from exposure to the brand-related song seems to be critical for effects on choice to occur. In line with study 1, the results imply that positive effects of exposure to brand-related music are less likely for target groups with negative brand attitudes.

STUDY 3

The aim of this experiment was to build on study 1 and assess the effects of a song related to a particular brand product line on the evaluation of other product lines sold under the same brand. We hypothesized that the positive effect of brand-related background music on choice for specific product lines results in negative effects for other product lines in the same brand portfolio. Participants completed a memory task while music was played. In the treatment condition, the music included the famous Oscar Mayer wiener jingle, associated with Oscar Meyer hot dogs. Afterwards, participants were exposed to five ads that included either an ad for Oscar Meyer hot dogs (matching ad) or an ad for another product of the Oscar Meyer line (bologna; non-matching ad). The results provided support for the formulated hypotheses. Exposure to the Oscar Mayer wiener jingle had a positive effect on the evaluation of the matching ad, but negative effects on the evaluation of the non-matching ad. Process measures revealed that the wiener song enhanced (inhibited) responses toward Oscar Mayer hot dogs (bologna).

CONCLUSIONS

The present research supports the assumption that brand-related music used in the background has direct effects on consumer attitudes and choices, despite being limited to incidental processing that is not explicitly acknowledged by consumers. However, negative effects of brand-related music can be expected when negative attitudes are activated and when alternative products in the brand portfolio (not directly associated with the music) are evaluated.

Using Consumption in Everyday Resistance Practices to Contest Negative Stereotypes: The Case of Teenage Mothers

Emma N. Banister, University of Manchester, United Kingdom
Margaret K. Hogg, Lancaster University, United Kingdom
Mandy Dixon, Lancaster University, United Kingdom

EXTENDED ABSTRACT

Media representations of younger mothers often allude to their inexperience and lack of preparedness for motherhood, and in particular, target young working class mothers for derision (Tyler 2008).

We pose three questions: firstly what do young mothers *do* with this stereotype of the teenage mother (and its associated discourses); secondly what role do the everyday practices of consumption play in young mothers' attempts to distance themselves from the negative aspects of this stereotype and contest these discourses; and thirdly how do they manage an inconsistency between two aspects of their identity (age versus parental status) and what role does the marketplace play?

DISCOURSES AND MOTHERHOOD

Expectations of motherhood are socially embedded, emphasized via prevailing discourses (Miller 2007) and include a variety of publicly and privately-generated messages regarding good mothering and its reverse, bad mothering. The main culturally pervasive discourse that affects women's identity projects as new mothers relates to self-management (Fischer et al 2007:433) and taking on the responsibilities of parenthood. Planned parenthood is one of the markers of 'responsible parenting' generated by societal and life-framing discourses. Motherhood when entered into at the 'correct' time is positioned as "women's supreme achievement" (Phoenix et al. 1991:9) but young mothers are contradictorily positioned because they reach the same landmark which then becomes devalued because of their age. Children and adults are seen as separate categories, so instead of an achievement, motherhood is seen by many as a challenge to morality and the role of the family (Hunt et al. 2005).

CONSUMPTION, RESISTANCE AND MOTHERHOOD

We focus on individual (Penaloza and Price 1993), everyday (Reissman 2000) acts of resistance, rather than the political and collective action that has provided the focus for many consumer research studies (e.g. Kozinets and Handelman (2004). Resistance can be identity-based, focused on the resister's "expected or attributed identity" (Hollander and Einwohner 2004:537). In this context, the expected and attributed identity reflects the expectations of teenage motherhood, informed by societal and life-framing discourses, what it means to be a good mother. We examine the ways in which young mothers use consumption as a tool with which to resist the life-framing negative discourses surrounding the negative imagery associated with the teenage motherhood stereotype, and explore the ways in which young women use consumption to help provide alternative positive mothering identities.

METHOD

We use empirical data collected from a sample of teenage mothers to explore how resistance is deployed via consumption to contest negative stereotypes, and to achieve splitting i.e. separation of *teenage* [age status, negative imagery] from mother [parental status, positive imagery] in the identity frame. Qualitative data was collected via two phased interviews (prior and post birth) with seventeen new mothers who became pregnant between the ages of 17 and 19. We recruited participants via a National Health Service (NHS) antenatal service for younger women. Interviews were analyzed by the three authors: emergent themes were coded and then compared, along with the exchange of detailed notes and memos. An agreed interpretation of the data was written up.

FINDINGS

Our findings support recent research that suggests that early motherhood can help some women from relatively disadvantaged backgrounds to develop a stronger and more mature identity (Duncan 2007; Wilson and Huntingdon 2005). In their attempts to be seen as a 'good mum' or 'just a mum' our informants abandon many of their previous notions of what it means to be young and use consumption as a means to demonstrate a 'responsible' approach to parenting. Participants produce a counter position, a positive young mothering identity that incorporates positive aspects of younger mothering. Participants were aware of the communicative properties of goods, particularly clothing, and sought to manage their identity via the consumption process. This concern with appearance also extends to participants' babies. A recurring theme was the importance of *not* dressing the baby in particular fashions that participants saw as associated with stereotyped out-groups (White and Dahl 2007). Through their marketplace knowledge, women sought to differentiate themselves from the kind of person who would dress their baby in particular ways (Tyler 2008).

Participants turn to the market as a means to prepare for motherhood (Davies et al. 2010) and to demonstrate that they are good mothers and understand the important ingredients of good, 'responsible', mothering (being careful planners; systematic allocation of resources; thoughtful care of their new babies). A clear theme was the challenge of providing and preparing for motherhood on a limited budget, often through second hand items and hand me downs, which were interpreted in two ways. Some mothers positioned second hand items as an inexpensive means to prepare appropriately for the arrival of a baby within financially limited circumstances. For these young women, second hand items reinforced a positive image of prepared motherhood and thus reflected an adult approach to managing the allocation of limited resources. Second-hand goods were sometimes repositioned as 'gifts for the baby'. For other participants accepting second hand goods was seen as an admission of failure; an acknowledgement of truth in the discourses surrounding young motherhood about a lack of responsibility in either planning to have the baby, or how to cope once the baby is born. Our mothers also made important associations between being a 'good mother' and consuming certain branded products (e.g. diapers).

DISCUSSION

This research contributes to understandings of the role of consumption in identity formation (Arnould and Thompson 2005). Consumption played an important role in our participants' contestation of undesired identities as they turned to the market for assistance in resisting negative associations with being a young mother. However, in resisting the teenage mother stereotype, participants risked upholding a dominant discourse (that there is an appropriate time at which women should have children) or at least recognising its existence. Our study demonstrates that every day practices of resistance to the

stereotypical negative images associated with an undesired self (i.e. teen mother = bad mother) are important components in the creation, appropriation and maintenance of identity projects as our informants embrace the positive imagery of motherhood and distance themselves from their teenage status.

Should I Get in Shape or Get Closer to "Mr. Health"?
The Effects of Goal Anthropomorphization on Goal Pursuit

Frank May, University of South Carolina, USA

EXTENDED ABSTRACT

Extant research on anthropomorphism has exclusively focused on the anthropomorphization of either physical objects (Aggarwal and McGill 2007) or the representation of physical objects (i.e., brands; Aggarwal and McGill 2012). Given that anthropomorphism entails endowing non-human agents with human-like qualities (Epley et al. 2007), it makes sense to extend the notion of anthropomorphism to the abstract concept of goals—goals can be thought of as agentic forces in the lives of the people who possess them (Patrick and Hagtvedt 2012). This research explores the consequences of goal anthropomorphization.

First, goal anthropomorphization must be defined—goal anthropomorphization occurs whenever humanlike qualities are assigned to a goal. For example, a student may possess the goal of graduating with honors. If the student were to anthropomorphize her goal as "Mrs. Academics", the goal representation would take on human characteristics. If this occurs, as the student closes in on her goal, instead of approaching the goal representation of "graduating with honors," which lacks human qualities, she will instead be approaching the anthropomorphized entity "Mrs. Academics".

Do people actually anthropomorphize goals? Two preliminary studies were conducted to explore this notion. A prudent first step in the study of goal anthropomorphization would be to determine if established antecedents of physical entity-based anthropomorphism apply to goals as well. Research has shown that need for control positively predicts the tendency to anthropomorphize physical entities (Epley et al. 2008), and the first pretest tested whether this relationship holds for goals. Indeed, need for control (Burger and Cooper 1979) positively predicted the anthropomorphization of a financial goal (as measured by an anthropomorphism scale adapted for financial goals; Waytz et al. 2010). That is, individuals who have the tendency to anthropomorphize physical entities also direct this natural tendency to imbue goals with human-like attributes. The second pretest involved measuring the natural tendency to anthropomorphize goals (Waytz et al. 2010) and eight other items (e.g., dogs, cars, brands, insects, robots, computers, mountains, and phones) using an established scale that measures the tendency to anthropomorphize in general and adapting it for all of the items. The results revealed that the average goal anthropomorphism score was significantly lower than those of the two living items, but it was higher than those of all other items. These results suggest that, when left to their own devices without external stimuli provided by researchers or prodding from marketers, individuals anthropomorphize goals to a greater degree than they do entities that are more traditionally considered able to be anthropomorphized

The results from these two initial studies provide encouraging evidence that goals can be anthropomorphized and that an investigation into the consequences of goal anthropomorphization is warranted. Given that a goal is a desired end state (Bagozzi and Dholakia 1999) that one approaches or makes progress toward (Fishbach et al. 2005), conceptualizing a goal as possessing human qualities should have differential effects depending on the degree to which the person setting the goal desires the company of others. People who are high (low) in sociability regularly approach (avoid) people in their everyday lives (McAdams 1988). Therefore, it is hypothesized that goal anthropomorphization will help (hurt) individuals who are high (low) in sociability when the goal is anthropomorphized as a person

to be approached (study 1, 2 and 3), but this relationship will reverse when the goal is anthropomorphized as a person to be avoided (studies 2 and 3). Furthermore, perceptions of goal fit will mediate this interaction (study 2).

Study one tested the notion that goal anthropomorphization would help (hurt) those who are high (low) in sociability using a 2 (anthropomorphism: high vs. low) X 2 (sociability: high vs. low) between subjects design. Participants first described their health goals. Next, they indicated how motivated they were to achieve their health goals. Afterward, the goal anthropomorphism scale used in the second preliminary study was completed. Finally, participants completed a sociability scale (Cheek and Buss 1981). For participants high (low) in sociability, as the tendency to anthropomorphize goals increased (decreased), so did goal motivation. Additionally, it was shown that sociability and the tendency to anthropomorphize goals were not related.

While the first study demonstrated the effects of natural goal anthropomorphization, study two demonstrates the effects of completely active goal anthropomorphization. A 3 (Goal conceptualization: Anthropomorphized goal-inconsistent outcome, Non-anthropomorphized goal, Anthropomorphized goal) x 2 (sociability: high vs. low) between subjects design was utilized. In the non-anthropomorphized goal condition, participants merely described their health goals. In the anthropomorphized goal (anthropomorphized goal-inconsistent outcome) condition, participants described their goals as personified by a third person character named Mr./Mrs. Health (Mr./Mrs. Anti-Health). Sociability was measured as it was in study one. For people who were high (low) in sociability, motivation was higher in the goal anthropomorphization (goal-inconsistent outcome anthropomorphization) condition than in the non-anthropomorphized goal condition. Additionally, for people who were high (low) in sociability, motivation was lower in the goal-inconsistent outcome anthropomorphization (goal anthropomorphization) than it was in the non-anthropomorphized goal condition. A similar pattern emerged for purchase intentions toward a goal related item (i.e., a book on healthy living). Finally, goal fit mediated the interactive effects of anthropomorphization and sociability.

In the third study, it is demonstrated that the effects of goal anthropomorphization extend to actual goal-related behavior. A 2 (Anthropomorphism: absent vs. present) x 2 (goal framing: goal vs. goal-inconsistent outcome) x 2 (sociability: high vs. low) design was utilized. In this study, participants were asked to solve anagrams. Before solving the anagrams, the participants were asked to either describe the goal of solving puzzles, or the exact opposite of the goal of solving puzzles, in an anthropomorphized or non-anthropomorphized manner (as was done in study two). Afterward, the participants were directed to a screen that contained 80 anagrams and were told that they could exit the anagram solving task at any time. However, they were automatically exited from the task after 5 minutes. Sociability was measured as it was in previous studies. In the goal condition, people high (low) in sociability persisted longer on the puzzle task in the anthropomorphized (non-anthropomorphized) condition. In the goal-inconsistent outcome condition, people low (high) in sociability persisted longer on the puzzle task in the anthropomorphized (non-anthropomorphized) condition.

Happiness from Actions versus Inactions

Priyali Rajagopal, Southern Methodist University, USA
Sekar Raju, Iowa State University, USA
Rao Unnava, Ohio State University, USA

EXTENDED ABSTRACT

Happiness is an important goal for consumers, and an understanding of how happiness can be enhanced may therefore be beneficial. In this article, we focus on a subtle but important distinction between experiencing happiness by doing something (actions) versus not doing something (inactions). We find that actions are attributed internally whereas inactions are attributed externally and therefore actions elicit greater happiness than inactions. Thus, people believe that greater happiness is associated with actions because they perceive actions as more intentional than inactions, even though not acting may be a volitional decision.

Research finds that attributing positive outcomes to one's own effort yields greater happiness than attributing such outcomes to external sources (Nurmi 1991). Similarly, literature in subjective well-being shows that willful actions yield greater wellbeing than non-autonomous actions (Deci & Ryan 2000). We extend these findings and suggest that actions evoke greater dispositional attributions than inactions, and elicit greater happiness than inactions.

In Study 1 (N = 34), we provided an example of happiness elicited by actions versus inactions and asked respondents to choose whether they experienced greater happiness from their actions or inactions over the course of their lifetime. Subsequently, we asked respondents to rate the extent to which they experienced happiness from their actions and inactions.

A majority of the respondents (85%) reported experiencing greater happiness from their actions than their inactions ($\chi2 = 16.9$, $p < 0.01$). Further, respondents reported experiencing greater happiness from their actions (5.64) as compared to their inactions (3.88, t (33) = -4.85, $p < 0.01$).

In Study 2 (N = 15), we used a free response measure for happiness. Respondents were asked to recall and write down events that elicited happiness over the course of their lifetime. A significantly larger number of actions (4.4) than inactions (0.27, t (14) = 7.75, $p < 0.01$) were recalled. Further, a chi-square analysis revealed that a majority of respondents (87%) listed an action as the first item on their list ($\chi2 = 8.06$, $p < 0.01$) suggesting that actions are more accessible in memory than inactions.

In Study 3 (N = 47), we randomly assigned respondents into either an action or inaction condition. Respondents in the action condition were asked whether they agreed or disagreed with the statement "I am happy about things that I have done in my life" while respondents in the inaction condition were shown the statement "I am happy about things that I have not done (my inactions) in my life"). We found that respondents were faster at agreeing with the action statement (4.1s) than the inaction statement (7.57s, F (1, 43) = 14.86, $p < 0.05$), suggesting greater accessibility for actions. Further, a chi-square analysis of the agreement with the statements revealed that a more respondents (77%) in the action condition agreed with the statement than respondents in the inaction condition (48%, $\chi2 = 4.24$, $p < 0.05$,).

One potential explanation for the results of studies 1-3 is that actions are more impactful than inactions, i.e. they have greater consequences, which leads to greater accessibility and happiness and not the action- inaction distinction per se. To test this explanation, we used scenarios with identical consequences in study 4 (N = 55).

Respondents were shown two scenarios adapted from previous research (Gilovich & Medvec 1994) that contained two protagonists, one who acted to obtain a positive outcome (e.g. switched schools) and the second who did not act (e.g. did not switch schools) but also obtained the same positive outcome. Respondents were asked to choose which of the two characters would experience greater happiness. A majority of respondents expected the person who acted to experience greater happiness than the one who decided not to act in the first (76% vs. 24%, $\chi2 = 15.29$, $p < 0.01$) and second scenarios (62% vs. 38%, $\chi2 = 3.07$, $p = 0.08$). Thus, even when the outcomes of actions and inactions were held equal, respondents associated greater happiness with actions than inactions.

We tested our attribution explanation in study 5, i.e. people believe that they will experience greater happiness from their actions than inactions because actions are more amenable to internal attribution (dispositional attributions) than inactions.

Fifty-five respondents were asked to recall either actions or inactions that had given them happiness during the course of their entire life and then asked to rate how much happiness they experienced. They were then asked to rate the frequency with which they thought of their actions/inactions and the impact of their actions/inactions on their life. Two different measures were used to measure the impact of actions and inactions. The first measure required respondents to list all the consequences of their actions/inactions. The second measure required respondents to select all the areas of their life (from a set of 13 categories) that had been impacted by their actions/inactions (Rajagopal et al 2006). We also included a four item, 7-point scale (Dube, Jodoin, and Kairouz 1998) to measure respondents' attributions of their decisions.

As expected (Table 1), we found a larger number of actions listed as compared to inactions (F (1, 44) = 6.7, $p < 0.05$). Actions were also reported to elicit greater intensity of happiness (F (1, 44) = 4.86, $p < 0.05$), and greater frequency of thought than inactions (F (1, 44) = 6.09, $p < 0.05$). There were no differences in either of the two impact measures (F's < 1). Thus, neither the number of consequences nor the areas of life affected were different for actions as compared to inactions. These results suggest that actions are not perceived to have greater impact or consequences than inactions (similar to the results from study 4), but are nonetheless thought about more than inactions. In line with our expectations, actions evoked greater internal attributions than inactions (F (1, 44) = 5.02, $p < 0.05$).

Table 1
Results Of Study 5

Variable	Actions	Inactions
Mean number	7.08 (4.06)	4.55 (2.24)
Mean happiness intensity	6.33 (.64)	5.68 (1.28)
Mean frequency of thought	5.13 (1.59)	3.95 (1.62)
Net internal attributions	5.84 (.50)	5.37 (.88)
Mean number of consequences	4.56 (2.51)	3.94 (2.98)
Mean number of areas of life impacted	7.39 (2.13)	6.93 (3.23)
N	24	22

Note: Numbers in parentheses indicate standard deviations

Across 5 studies we find that actions elicit greater happiness than inactions because they are attributed internally and thought

about more frequently. We did not find support for a larger network of consequences for actions versus inactions. Thus, the impact of actions and inactions appears to be no different, but the motivation to take credit for actions and hence, think about them more frequently appears to underlie the perceived differences in happiness.

Bonding Through Service Friendliness: A Potential Double-Edged Sword

Elison Ai Ching Lim, Nanyang Technological University, Singapore
Yih Hwai Lee, National University of Singapore, Singapore
Maw-Der Foo, University of Colorado, Boulder, USA

EXTENDED ABSTRACT

Amidst growing interest in the engineering of positive emotions in commercial interactions (e.g., Tan, Foo, and Kwek, 2004), research underscores the need to consider both employee and customer characteristics when it comes to the appreciation for nonverbally- expressed emotion (Rafaeli and Sutton 1990). We posit that strong employee-customer bonds are formed when the affective style (i.e., expressiveness) of employees aligns closely with the customer's preference for nonverbally- expressed emotions. Support comes from research suggesting that rapport (i.e., quality interpersonal interactions characterized by a connection among the interactants) can be established using nonverbal cues (Harrigan, Oxman, and Rosenthal 1985).

Given that the quality of consumers' interaction with the service provider predicts customer (dis)satisfaction (Mohr and Bitner 1995), we expect a more rapportful employee-customer interaction to enhance consumers' satisfaction. Paradoxically, we predict that a dissatisfying event will appear more negative to consumers from high-rapport conditions, as it poses as a greater contrast to the initial enjoyable interaction. We further examine how low-/high-rapport employee-customer interactions affect the way in which customers vocalize felt (dis)satisfaction. Besides positive (e.g., compliments) and negative (e.g., complaints) voice, we further differentiate between customer voice that is directed inward (to the organization) and outward (to the public). Despite key differences between inward and outward voice, no research has yet examined consumers' relative tendency to use them. We predict that when there is a rapportful exchange due to affective match (i.e., low expressiveness-low receptivity, high expressiveness-high receptivity), consumers will behave in a way that enhances or protects the well-being of the service employee. This is expressed either by a higher tendency to direct positive voice inward (vs. outward) after a positive encounter, or a lower likelihood to voice negatively inward (vs. outward) after a negative encounter.

OVERVIEW OF STUDIES 1 AND 2

Two experiments (featuring a satisfying or dissatisfying service context respectively) were conducted to test our predictions. Both studies used a 2 (emotional expressiveness: low vs. high) x 2 (emotional receptivity: low vs. high) factorial design whereby emotional expressiveness was manipulated and emotional receptivity was measured. Data collection was completed over two sessions. In the first session, participants' emotional receptivity (Lee and Lim 2010) was assessed. A week later, they watched a video showing an employee-customer exchange in a holiday resort. The employee was actually a confederate actor who was trained to deliver low-, or high-, expressiveness by varying the use of smiling, voice intonations, and hand gestures hand gestures[1]. The dependent variables were rapport, customer satisfaction, and participants' proclivity to use inward and outward positive voice (see Appendix).

---

1 Across both studies, manipulation checks indicate that the actor displayed appropriately lower (higher) levels of expressiveness in the low- (high-) expressiveness conditions respectively.

Key findings from Studies 1 and 2

In Study 1, we found that less emotionally receptive participants reported less rapport with a more (vs. less) expressive employee, whereas high receptivity respondents perceived higher rapport with the more (vs. less) expressive employee. In terms of satisfaction, the more expressive employee condition produced lower satisfaction for low receptivity levels. For high emotional receptivity, conversely, participants were more satisfied with high (vs. low) expressiveness. Further, low receptivity participants in the less (vs. more) expressive employee condition indicated a higher relative tendency to voice inward than outward. At high receptivity levels, a higher relative tendency to voice inward than outward was observed in the more (vs. less) expressive employee condition.

In Study 2, we observed that low receptivity participants indicated less rapport with a more expressive (vs. a less expressive) employee, whereas high receptivity respondents reported higher rapport with the more (vs. less) expressive employee. While the less receptive participants were more dissatisfied in the less (vs. more) expressive condition, high receptivity participants felt more dissatisfied in the high (vs. low) expressive employee condition. In terms of customers' voice intentions, for low receptivity, participants in the less (vs. more) expressive employee condition indicated a lower relative tendency to voice inward than outward. At high emotional receptivity level with high (vs. low) expressiveness, the relative inward-to-outward voice tendency was lower.

Discussion

Our work supports the common belief that strong relationships with customers can be beneficial (e.g., Ganesan, Brown, Mariadoss, and Ho 2010), but cautions that they can backfire in service failures. Theoretically, this research expands the voice literature by delineating positive and negative customer voice, as well as its direction (inward vs. outward). Since rapport can be formed even in service encounters (as we show in this research), firms should coach service employees about how to leverage the use of nonverbal cues to enhance customers' overall service experience.

Moving forward, we conjecture that the amplification effects due to strong employee-customer bonds may diminish for senior employees (e.g., the general manager) as they are seen to be more representative of the organization. Future research may investigate if the strength of employee-organization affiliation, as communicated via overt or subtle cues (e.g., employee's uniforms or corporate artifacts; Rafaeli and Pratt 1993), moderates the observed in this current research.

APPENDIX
Dependent Measures Used In Studies 1 and 2

STUDY 1

Emotional receptivity
(1 = strongly disagree, 7 = strongly agree; Lee and Lim 2010)
1. The use of hands and other body movements is very helpful in facilitating communication
2. It is not necessary to show too much facial expressions (reverse-coded item).
3. People should show a lot of facial expressions when talking.
4. When communicating, a person should use a lot of variation in his/her voice tone, pitch, and loudness.

Rapport
(1=strongly disagree, 7=strongly agree; Gremler and Gwinner 2000)
1. In thinking about my relationship with the service employee.
2. I would enjoy interacting with this employee.

3. I would look forward to seeing the service employee when I visit this resort again.
4. The service employee relates well to me.
5. I care for the service employee.
6. I am comfortable interacting with the service employee.
7. The service employee has my personal interest in mind.

Satisfaction
(1=strongly disagree, 7=strongly agree; adapted from Maxham and Netemeyer 2002)
1. I am satisfied with my overall experience with the resort.
2. As a whole, I am happy with the resort.
3. Overall, I am pleased with the service experience at the resort so far.

Positive Voice
(1 = not at all, 7 = very likely; adapted from Maxham and Netemeyer 2002).
Inward voice. How likely are you to send your compliments to the resort manager?
Outward voice. How likely are you to recommend this resort to my friends if there were looking for a vacation in the same area as (name of resort)?

STUDY 2
The items used to measure emotional receptivity and rapport are identical to those used for Study 1.

Dissatisfaction
(1=strongly disagree, 7=strongly agree; adapted from Maxham and Netemeyer 2002)
1. I am dissatisfied with my overall experience with the resort so far.
2. As a whole, I am not happy with the resort.
3. Overall, I am displeased with the service experience at the resort.

Negative Voice
(1 = not at all, 7 = very likely; items adapted from Maxham and Netemeyer 2002).
Inward voice. How likely are you to complain to the resort manager?
Outward voice. How likely are you to discourage your friends from the resort if there were looking for a vacation in the same area as (name of resort)?

Over and Over Again: Negative Emotions, Consumer Rumination and Post-Service Failure Outcomes

Yuliya Strizhakova, Rutgers University, USA
Julie A. Ruth, Rutgers University, USA

EXTENDED ABSTRACT

With social networking, youtubing, and twittering, consumers are gaining power to express publicly their discontent with products and services (Grégoire, Tripp and Legoux 2009). Yet, consumer research has largely ignored internal processes that prompt or hinder consumers' public display of thoughts and emotions toward companies at fault in service failures. We investigate consumer rumination as a psychological process through which consumers' negative emotions influence three service failure outcomes: complaining, negative word-of-mouth, and repatronage intentions. Rumination is defined as recurrent thoughts instigated by a discrepancy between one's current position versus a goal (Martin and Tesser 1996; Porath, MacInnis and Folkes 2010). Although extensively studied in psychology, rumination has received sparse attention in the consumer domain. By conceptualizing and testing rumination as a mediator within the consumer's experience of a service failure, we contribute to knowledge of consumer emotions and show that rumination has important implications for service providers.

CONCEPTUAL MODEL AND HYPOTHESES

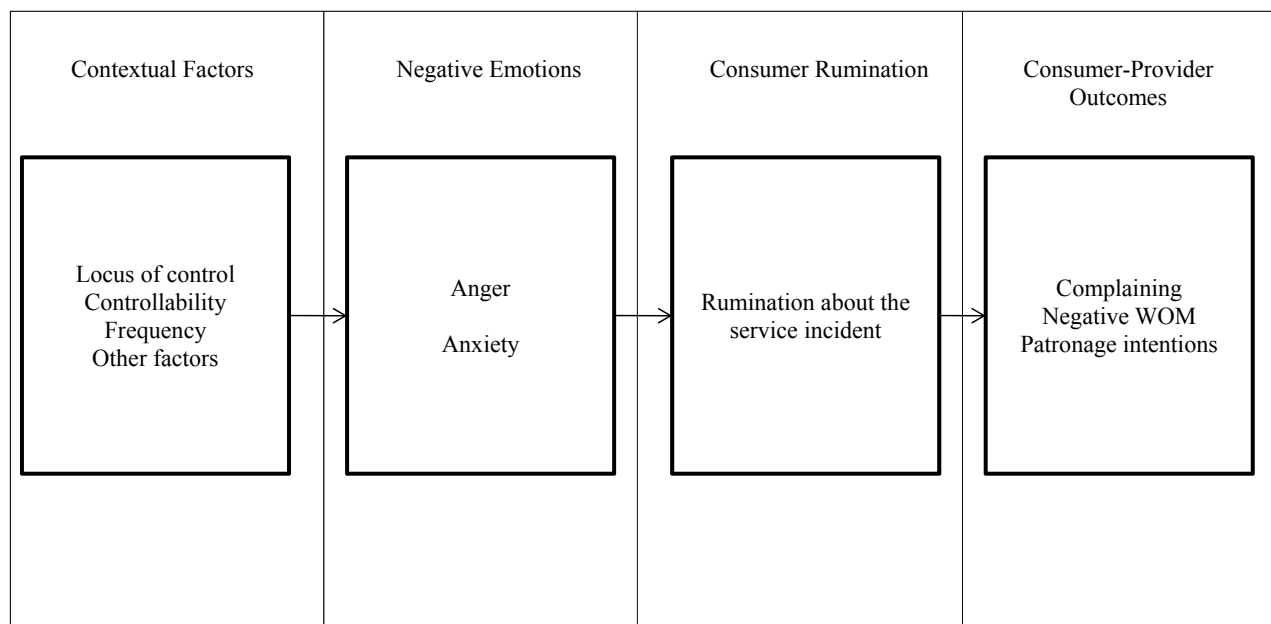
Building upon emotion (Bagozzi, Baumgartner and Pieters 1998; Lazarus and Folkman 1984) and attribution theories (Weiner 1986), we posit that in service failures, contextual factors shape consumers' negative emotions that contribute to rumination and service failure outcomes (see Figure 1). Specifically, contextual factors – locus of control (internal/external), extent of controllability (under someone's /beyond anyone's control), failure severity, and outcome certainty – are systemically linked to negative emotions such as anger and anxiety (Smith and Ellsworth 1985; Roseman, Wiest, and Swartz 1994). Rumination is believed to be an involuntary response elicited in response to such emotion-provoking situations (Salovey et al. 2002; Martin and Tesser 1996). Research in non-business contexts shows that, when activated, rumination facilitates negative and hinders positive behaviors toward transgressors. Accordingly, because service failures provoke negative emotions such as anger and anxiety (e.g., Bougie et al. 2003; Gelbrich 2010), we hypothesize rumination as an involuntary response mediating the relationship between negative emotions and service failure outcomes such as complaining, negative word-of-mouth and repatronage intentions.

METHODS AND ANALYSIS APPROACH

Three experiments were conducted. In each study, adult participants were presented with an experimentally manipulated scenario regarding a service failure. Participants then responded to measures of emotions, rumination, complaining, negative word-of-mouth (WOM), and patronage intentions. Conceptual mediation models were analyzed via SEM with bootstrapping bias-corrected procedure. Measurement and hypothesized models achieved satisfactory model fits (Bagozzi and Yi 2012); detailed results are available from authors.

Study 1 manipulated three contextual factors: locus of control (external/internal), controllability (high/low), and frequency (high/low). Results show that anger and anxiety have significant positive direct effects on rumination. Rumination has significant positive direct effects on complaining and negative WOM intentions as well as a significant negative direct effect on patronage intentions. Consumer rumination about the service failure fully mediates effects of anger on complaining and negative WOM and partially mediates effects of anger on patronage; rumination fully mediates effects of anxiety on the three outcomes. Anger and anxiety only partially mediate effects of controllability on rumination, but they fully mediate effects of external locus of control and frequency on rumination. The results sug-

Figure 1
Conceptual Framework

Contextual Factors	Negative Emotions	Consumer Rumination	Consumer-Provider Outcomes
Locus of control Controllability Frequency Other factors	Anger Anxiety	Rumination about the service incident	Complaining Negative WOM Patronage intentions


gest that effects of consumer anger and anxiety on outcomes may be underestimated if the internal process of consumer rumination about the service failure incident is not taken into consideration. Studies 2 and 3 examine the effects of other contextual factors. Results are available from the authors.

DISCUSSION

Our research expands understanding of an internal process – consumer rumination – that mediates effects of anger and anxiety on outward manifestations of service failures: consumer complaining, negative word-of-mouth and repatronage intentions. We adapted a measure of rumination to the service failure context, demonstrating its validity and reliability across studies. Our research contributes to emotion theory by showing that rumination is an important mediator, adding explanatory power across contextual conditions that elicit anger and anxiety. Our research also contributes by showing that rumination not only has damaging effects when providers are at fault, consumer rumination decreases patronage intentions and increases negative WOM when consumers are responsible for the failure. Given that only a small percentage of dissatisfied customers actually complain, consumer rumination may provide an explanation for the loss of customers and greater negative publicity that accompany service failures.

Seeking the Coherent Moral Self: A Process of Alignment

Michal J. Carrington, La Trobe University, Australia
Benjamin A. Neville, University of Melbourne, Australia
Robin Canniford, University of Melbourne, Australia

EXTENDED ABSTRACT

Can a manageable sense of self-coherency co-exist with identity multiplicity and internal fragmentation? Through immersive/interpretive research, we discover multiplicity extending to life projects and themes; ideological fragmentation resulting in a sense of incoherent moral self; and a compelling meta-life project directed towards a coherent moral self.

Prior CCT research conceptualizes the 'self' as an integration of many aspects, including multiple identities, relationships, possessions and other various symbols that enable the individual to construct themselves in ongoing processes (Bardhi, Eckhardt, and Arnould 2012; Schouten 1991). In this state of identity multiplicity, the consumer is constantly assessing (consciously or subconsciously) which identity should be activated in a given situation to guide their behavior (Brewer 2001; Schouten 1991). The multiple identities coalescent in the construction of self, however, are not always in alignment, and this divergence results in a self that is fragmented (Ahuvia 2005; Bahl and Milne 2010; Firat and Venkatesh 1995; Tian and Belk 2005). Fragments of self that are in conflict are expressed in contradictory consumption choices when influenced by competing identities that are momentarily clashing in the marketplace (Ahuvia 2005; Bahl and Milne 2010; Ustuner and Holt 2007).

In prior research, we discover two dominant framings of identity multiplicity: liberated multiplicity and manageable multiplicity. One perspective, liberated multiplicity, takes an optimistic view of the fragmented self (Goulding, Shankar and Elliott, 2002), arguing that consumers are "content to live with the paradoxes" (Firat and Venkatesh 1995) arising from multiplicity (Firat, Dholakia, and Venkatesh 1995; Firat and Venkatesh 1995). Indeed, that postmodern consumers have been liberated from the constraints of a unified sense of self, and are free to weave multiple identities into the complex tapestry of their life's narratives (Firat and Dholakia 2006; Schau, Gilly, and Wolfinbarger 2009). This optimistic view, however, is not the only lens through which multiplicity and fragmentation are viewed (Goulding, Shankar, and Elliott 2002). A second perspective acknowledges the tension created by conflicting identities and takes the view that fragmented consumers manage this tension by deploying coping strategies such as compartmentalizing the discordant fragments of self (Ahuvia 2005; Goulding et al. 2002) or engaging in dialogue between competing identities (Bhal and Milne, 2010).

We note, however, that these consumer studies are predominantly contextualized within the domains of the *aesthetic* and *hedonic* – such as high-end automobile purchases (Luedicke et al. 2010; Bahl and Milne, 2010), weekend rave parties (Goulding et al. 2002; Goulding et al. 2009), cherished possessions (Ahuvia, 2005), and global elites (Bardhi et al. 2012). Moreover, though many studies of consumer identity projects and communal consumption contexts recognize the ideologically charged nature of consumers' life worlds (Canniford and Shankar 2012; Kozinets 2002; Luedicke, Thompson, and Giesler 2010), fewer explore the personal, internal, tensions that consumers experience from contradictions when the ideological frameworks guiding their consumption experiences clash. Thus, we argue that existing theory has stopped short of exploring the identity conflict that is played out in *ideologically* charged consumption arenas.

Our primary research question, therefore, asks whether consumers are less willing to tolerate discordant multiplicity when the resulting conflict is waged on ideologically charged consumption stages in which contradictory choices impinge on their moral frameworks. In this sense, moral values are inherently ideological, informing the consumer's worldview and filtering their perceptions of acceptable choice (Luedicke et al. 2010; Monroe 2009). Second, to what layers or levels of abstract self does multiplicity and conflict extend? Consumer research has tended to present a disjointed account of multiplicity (e.g. Belk 1988; Gould 2010). Third, what processes of transformation enable consumers to dynamically re-align their multiple identities with their integrated moral beliefs and transition to an ideologically coherent self? The context specificity of current consumer multiplicity research limits our understanding of the contingencies of liberated fragmentation and related consumer struggles.

The contradictory consumption of ethically-minded consumers is a well documented site of *ideologically* charged consumption (e.g. Chatzidakis, Hibbert and Smith, 2007; Carrington, Neville and Whitwell, 2010), presenting a potent context from which to develop theory about the multiplicity of identity and discordant selves in transition. Taking an ethnographic approach, we immersed in the daily lives of 13 ethical consumers over a nine month study to explore the construction of the ethical-self in the midst of everyday consumption practices (Newholm and Shaw 2007). We employed multiple methods including semi-structured interviews, photographic and written diaries, video interviews, projective interviews, and extended participant observation in a range of personal and social activities.

TABLE 1
Data Summary

Activity/Data Format	Details/Volume
Duration of Study	Nine Months
Transcribed Material	445 pages
Photographic Material	34 images
Video Footage	63 minutes
Field Notes	49 pages
Coded Observations	2605

Aligned with the aims of the study, the data were analyzed using an interpretive, grounded approach (Corbin and Strauss 2008). To enhance trustworthiness of the study, we strategically combined triangulation of methods, sources and data; member checks; persistent immersion; and regular researcher debriefing sessions (Wallendorf and Belk 1989).

In contrast to previous researchers' suggestions that identity multiplicity may be liberating (Firat and Venkatesh 1995) or manageable (Bahl and Milne 2010), our data analysis reveals that multiplicity becomes an unmanageable problem for some consumers when the conflict is ideological. We discover that the presence of a *dominant moral life theme* compels these consumers to seek coherent moral selves. We also discover that multiplicity and conflict extend beyond identity to the clashing of life themes reflected in conflicting life projects. Finally, we reveal a dynamic and purposive overarching consumer transition to a more coherent ideological self, a process of alignment that we call a *meta life project*. Meta life projects are guided by a single dominant moral life theme that act as a pathway

to moral coherence. We show that through meta life project work, fragmented life projects and identities, discordant extended selves and inconsistent consumption choices are progressively aligned with informants' sense of moral self. Our study integrates and develops multiple threads of extant consumer research – multiplicity (Belk 1988; Goulding et al. 2002; Luna, Torsten, and Peracchio 2008; Schau and Gilly 2003; Thompson 1996), fragmentation (Bahl and Milne 2010; Firat and Venkatesh 1995; Goulding et al. 2002), moral conflicts (Luedicke et al. 2010), and identity conflict resolution (Ahuvia 2005; Bahl and Milne 2010; Murray 2002). – to offer an alternative lens through which to view the consumption contradictions and purposive life transitions of fragmented selves in the ideological domain.

Family Quality Time and the Techno-Culture Food Environment

Pepukayi Chitakunye, University of KwaZulu-Natal, South Africa
Amandeep Takhar, University of Bedfordshire, United Kingdom

EXTENDED ABSTRACT

More than ever, new technologies are demonstrating their potential for transforming society. Although we know much about consumption of technology (Vandewater and Lee 2009; Kozinets 2008; Sorenson 2006), interplay between technology and family quality time still needs further investigation. Within the social sciences, attention to family time has been more attuned to differences across men and women in terms of time spent at work (Fiese, Foley and Spagnola 2006), lack of family time driven by consumption desires (Mestdag and Vandeweyer 2005), how mothers and fathers balance work and home responsibilities (DeVault 2000; Hochschild 1997), and the role of homemade food in the construction of family identity (Moisio, Arnould and Price, 2004). Despite the noteworthy contributions of these studies, we have virtually no understanding of how family quality time is changed and altered in form particularly when media devices such as iphones, ipads, and cell phones encroach on the mealtime context.

Whilst prior research explores the role of technology in consumer lives (Kozintets 2008; Ventantesh 2006; Jackson 2002; Mick and Fournier 1998), there is silence on how technology impacts on parent-child mealtime interactions, and family routines. What we need to understand is whether the purpose and meanings of quality time changes when new technologies become an inseparable part of family mealtimes. Gutierrez, Price and Arnould (2008: 189) observe that time spent over family dinner, is positively correlated with benefits such as reduced childhood obesity, aiding literacy development and reduced speech impairments, language socialization, lower levels of behavioral problems, higher academic achievement and reduced drug and alcohol use among teens. And yet, media devices such as iPods, iPads, smart phones, encroach on daily family life and transform the meanings of time spent over family dinner. Further, technology, in the form of TV programs and their characters can become an obsession with which viewers constantly interact and around which they model their lives (Chitakunye and Maclaran 2012; Russell, Norman and Heckler 2004; Russell and Puto 1999; O'Guinn and Shrun 1997). Although these new technologies continue to mediate family relationships and are progressively more embedded in everyday practices, our knowledge is still limited as to how these are changing the form and meaning of family quality time.

Given this background, the purpose of this study is to explore how the techno culture environment is transforming family quality time in the domestic context of food consumption. In particular, we are interested in children's naturalistic practices when they come into contact with media devices at mealtimes. Unlike previous research, this study takes everyday mealtime practices as the unit of investigation.

This study uses an interpretive research strategy. Informants were children aged between 13 and 17 who provided insights through visual diaries that generated 360 photographs, and 13 in-depth interviews, which was supplemented by immersing ourselves in four families on five different occasions. These constant repetitive visits to the families, over a period of two years, were vital in deepening our experience of action, conversations and the mealtime context. Prior to, during, and subsequent to our immersion into mealtimes, we kept detailed written fieldnotes.

Consistent with previous research, we find that technology transforms family relations in different ways (Venkatesh, Stolzkoff, Shih, and Mazumdar 2001; Mick and Fournier 1998). In line with previous research, our findings also show how, in some families, the essence of quality time has been reorganised around specific television programmes. For example, the *X-factor*, *East Enders*, and *Coronation Street*, were popular programmes around which families communed. However, this presented a paradox that resulted to assimilation and isolation effects (Mick and Fournier 1998), particularly in families with conflicting viewing interests.

Prevalent across the families visited, we observed an array of multitasking practices at mealtimes, not only with the television, but with other with media devices such as iPods, iPads, smart phones, cellphones, and laptops. Similarly, photographs generated by the children reveal the continued presence of these media devices at the dinner table, indicating a willingness to use them whilst eating. Although it is becoming increasingly rare that families eat together, at times, family members stay connected through interplay with technology. For example, in Hayley's household (female, 16), the father worked away from home, and through media devices, he stayed connected to family members at different times, including mealtimes. In this sense, mediated communications during family dinner are sometimes with family members who are not present, and not just friends, and other non-family members. Within this context, we argue that interplay with technology contribute to the construction of both family and individual identity.

In some families, children felt that media devices were intertwined with family interactional processes. On the contrary, some parents saw these media devices as disruptive to family togetherness. However, examples from our study include some parents using these media devices at the dinner table. For example, during one mealtime observation, a mother could be seen using the cordless phone more frequently than the children. In another family, the father always took the cordless phone to the dinner table. Agreeing with Mick and Fournier (1998), we found that technology presents a paradox that leads to both assimilation and isolation effects. Within this context, we align assimilation effects with the construction of a collective family identity, and isolation effects with the construction of individual identity. For example, when the children were connected to the outside world, parents felt more isolated, and vice versa. Here, it emerged that different communication technologies are preferred by family members. In one family, the children preferred to use their smartphones whilst the parents preferred to use the cordless phone. When the cell phone or cordless phones were answered, at times, the family members would leave the table, and continued talking whilst in another part of the house. This behaviour reduced family quality time.

One contribution of this study is that it shifts the focus of the interplay between family quality time and technology from the television and its contents (Chitakunye and Maclaran 2012; Russell et al 2004; Schau and Muniz 2004; O'Guinn and Shrun 1997) and instead considers the construction of collective and individual identities within a mix of mealtime multitasking practices, in particular, in relation to media devices that encroach on the mealtime context. These devices include iphones, ipads, cordless phones, laptops; cell phones and other related devices. Within this context, we argue that, family quality time is changed and altered in form, but not ultimately abandoned.

The Best and the Bizarre:
Prototype and Exemplar-based Retrospective Evaluations of Experiences

Robert Latimer, New York University, USA
Priya Raghubir, New York University, USA

EXTENDED ABSTRACT

Consumers evaluate past experiences based on overall impressions (prototypes) and specific remembered components (exemplars). The prototype-based memory system converts experience components into an "abstracted representation" (Shreiber and Kahneman, 2000) or "gestalt" (Ariely and Carmon, 2003), which leads to retrospective evaluations based on a limited number of key components, such as trend, peak, and end. The prototype system draws from prototype theories in the categorization literature (e.g. Rosch and Mervis, 1975). Prototypes influence evaluations immediately after an experience and are robust to delay. Distinctive experience components – components that share few features with their surroundings – should have little influence on the prototype.

The exemplar-based memory system represents experience components individually, which leads to retrospective evaluations based on the most contextually accessible components (Montgomery and Unava, 2009). The exemplar system draws from the memory literature which suggests that distinctive information (Hunt, 1995, Hunt and Worthen, 2006) and experiences (Berntsen, 1996, 1998) are more accessible than typical information and experiences. Critically, the privileged accessibility of distinctive components increases with delay.

Four studies test a framework integrating prototype and exemplar models, focusing on the ability of retrieved exemplars (Studies 1 and 2) and the presence of a distinctive peak (Studies 3 and 4) to predict participants' overall retrospective evaluations, immediately after the experience and after a delay. We predict and find that when exemplars are contextually accessible, their ratings flow through to the overall evaluation that remains the same after a delay. However, when the peak component (the most pleasant component of a pleasant experience) is a distinctive one, this particular component does not change the prototype, but becomes an accessible exemplar, which is used to form an overall evaluation. Further, as this distinctive peak is even more easily recalled after a delay, its weight in evaluations increases over time, leading to improved overall evaluations after a delay. These predictions are tested by examining the weight (ß) and overall predictive power (R^2) of models including the ratings of prototypical and distinctive components of the experience on overall evaluations of the experience.

STUDIES 1 AND 2

Study 1 demonstrates in a field setting that distinctive experience components are more likely to be spontaneously recalled and used as inputs to overall evaluations, especially if they are made contextually accessible. Attendees of a large theatre festival (n = 46) completed a short survey while waiting in line for a show. They indicated the overall quality of the festival either before or after listing and rating six shows that they had seen. Finally, participants rated the distinctiveness of the first and last shows on their list on a three item 7-point scale (afirst = 0.83, alast = 0.88) and reported the total number of shows they had seen. Ratings of the six listed shows better predicted the overall evaluation when participants listed the shows before evaluating the festival overall. Festival attendees were more likely to base their overall evaluations on retrieved exemplars (listed shows) when those exemplars were contextually accessible.

Study 2 (n = 98) replicates the results of Study 1 for evaluations of films released in 2011 using a different manipulation for exemplar accessibility: cognitive load. Specific films recalled under load were worse predictors of participants' overall ratings for films released during 2011 when they were recalled under load, as compared to when there was no load.

Studies 3 and 4 go on to examine the role of delay in increasing the accessibility of distinctive peaks that become inputs to overall retrospective evaluations.

STUDIES 3 AND 4

Study 3 examined the role of a distinctive peak before and after a delay. Fifty-five participants viewed fifteen pieces from the Museum of Modern Art's collection and rated their enjoyment of each. Participants viewed either three paintings and twelve sculptures (paintings distinctive) or twelve paintings and three sculptures (sculptures distinctive). Participants then rated their overall enjoyment of the set of pieces, both immediately and after a delay of three to six weeks. A linear regression model tested the predictive power of components extracted from individual ratings: the peak, end, mean of non-distinctive pieces, mean of distinctive pieces, and whether or not the peak was one of the distinctive pieces.

Without a delay, only the mean of non-distinctive components) and peak ratings were significant predictors of the overall liking of the set. After the delay, the mean non-distinctive rating failed to predict retrospective liking of the set, but the peak remained important. Critical to my hypothesis, the presence of a distinctive peak increased overall evaluations, but only after the delay. Study 3 confirms the importance of the peak-dominated prototype, even after a delay, but suggests that distinctive exemplars may amplify the peak effect through a separate, exemplary-based memory system.

Study 4 replicates (4a, n = 82) and reverses (4b, n = 85) the results of Study 3 for experiences with music and jelly beans respectively. A pretest revealed that music was well suited to retrieval of specific exemplars, while jelly beans tended to be thought of in generic, prototypical terms. In both 4a and 4b, we manipulated the presence or absence of a distinctive component in a five part experience. In Study 4a, a distinctive peak increased overall evaluations after a two week delay, supporting the exemplar system. In Study 4b, a distinctive peak decreased overall evaluations immediately after the experience, supporting the prototype system.

SUMMARY

People rely on exemplars when they are contextually accessible (Studies 1 and 2), leading to a disproportionate influence for distinctive peaks on overall evaluations after a delay (Studies 3 and 4a). Non-distinctive peaks remain important with and without delay however (Studies 3 and 4a), and may produce increased overall evaluations in contexts well suited to prototype formation (Study 4b). These findings are of interest to researchers concerned with how consumers represent experiences and construct evaluations, or managers who wish to design experiences that consumers will remember as enjoyable.

Social Context as Price Information:
Social Density, Status Inferences, and Object Valuations

Ahreum Maeng, University of Wisconsin - Madison, USA
Thomas O'Guinn, University of Wisconsin - Madison, USA
Robin Tanner, University of Wisconsin - Madison, USA

EXTENDED ABSTRACT:

It has been widely demonstrated that the context in which an object appears influences its evaluation. One way in which such context effects have been shown to occur is by automatically altering the internal comparative standards consumer use when evaluating products (Mazumdar, Raj, and Sinha, 2005). To date, the majority of the research on context effects has examined them in terms of product attributes (e.g. Adaval and Monroe, 2002; Simonson, 1989). However, in this research we explore an example of how the broader social context of the choice environment may provide a meaningful context. In particular, we propose that the crowdedness of a retail store can spontaneously evoke a set of stored representations such as the social status or disposable income of the people frequenting the store. Furthermore, these representations of social class can lead to distortions in perceptions of price and willingness to spend. For example, we propose that a highly crowded store environment activates lower class representations (e.g., that shoppers have lower disposable income) which in turn alters consumers' expectations about the prices of products in the store. Three studies explore this hypothesis.

In a pilot study, we wanted to demonstrate that different levels of social density have historically been associated with different expectations about social class. Thus we performed Google image searches for the terms "upper class Americans" and "working class Americans". For the first 100 images retrieved in each search we counted the number of people portrayed in each image. This analysis revealed that working class images contained a higher number of people (M= 5.4) than did images associated with the upper class (M = 1.6; t(198) = -5.80, p <0.001). Thus, as far as historical imagery is concerned, there does appear to be a clear visual relationship between class and social density.

Study 1 (N=75) was designed to test whether this apparent relationship between class expectations and social density could actually influence the class inferences individuals make from social density cues. All participants were shown a picture which they were told was a stylistic representation of an actual social scene, and which consisted of human stick figures on a white background. The scene was either crowded (36 stick figures) or uncrowded (2 stick figures). Stick figures were used to ensure no inferences could be drawn from specific social cues such as clothing. Participants were asked to estimate both the average social class of the individuals in the scene (1=upper class to 5=lower class) and their average annual income. Results revealed that participants rated the figures in the low-density context as being from a higher class (Msparse = 2.1) than those in the high-density condition (Mdense = 3.7; F(1,73) = 64.9, p < 0.001). Furthermore, figures in the low-density context were also rated as having a higher annual income (Msparse = $114K) than those in the high-density condition (Mdense = $49K; F(1,73) = 51.6, p < 0.001).

Study 2 (N=84) was designed to explore if a similar social density manipulation would influence inferences of price of products in a store. To do this, we created three images of a clothing store, which contained 35 to 4 human silhouettes depending on the level of crowdedness. Participants, who were once again told the image was adapted from a real picture, were asked to make an inference for the price of a typical pair of shoes in the store. Ratings of the expected income of a typical customer were collected in the same manner as Study 1. Results showed that participants estimated shoe price highest at the low-density store (M= $207), lowest at the high-density store (M= $131; F(2, 81) = 3.62, p=0.03), and in-between at the medium-density store (M = $171). Furthermore, the expected income findings from Study 1 replicated and mediated the effect of social density on expected price of the given product. Thus, perceived value of products in the store, seemed to be determined by their beliefs about other shoppers incomes, which were themselves driven by how crowded the store was.

By examining if the mere crowdedness of a store could influence how products are subsequently recalled, Study 3 (N=180) was provides differential evidence that the social density of a store can influence how consumers codify the relative prices of products in the store. Study 3 built on prior research demonstrating that consumer's abstract recollections of the expensiveness of a particular product presented in a specific context are influenced by the prices of the other products viewed in that context. Specifically, consumers subsequently remember products as being relatively more expensive/(cheap) if they were originally presented in the context of other products which were themselves relatively lower/(higher) in price. Thus we predicted that individuals who considered a product in an uncrowded/(crowded) store context should subsequently remember the product to be relatively more cheap/(expensive).

The study was carried out in two stages: First, participants were asked to choose between two similar pairs of dress shoes at a pictured store which was uncrowded, moderately crowded, or crowded. While we were ultimately interested in memories of the expensiveness of the product chosen, not the choice itself, we had participants make a choice between two similar products to ensure they considered them in as naturalistic a way as possible. 24 to 36 hours later participants were asked to rate the expensiveness of the shoes they had previously chosen on an 11-point scale anchored from very inexpensive to very expensive. As predicted, results showed that participants recalled the chosen product to be less expensive when previously presented in an uncrowded context (Msparse= 6.05), versus the crowded context (Mdense= 6.57) with the moderate density context in-between the other two (M = 6.14; F(2, 177) = 2.98, p=0.05).

Taken together, these data provide the first evidence of the important finding that the social density of the choice environment can act as a context effect and influences how consumers process price information in the store.

An Examination of Social Collective Decision-Making

Julie Tinson, University of Stirling, UK
Pete Nuttall, University of Bath, UK

EXTENDED ABSTRACT

Decision-making by a social entity is a universal experience yet virtually overlooked in consumer research (Ward and Reingen, 1990). A recent call for research to consider affiliation and separation in a social group decision-making setting supports the assertion that this area is under-researched (see Tinson and Nuttall, 2011). Exploring group as opposed to individual decision-making is of particular interest as it provides an opportunity to understand both the social context and social interaction that occurs when making consumption decisions. Although there are a plethora of studies examining the phenomena of family decision-making (e.g. Beatty and Talpade, 1994; Palan and Wilkes, 1997; Lee and Collins, 2000; Chaplin and John, 2010), exploring group consumption and consumer behaviour in an alternate social environment (e.g. amongst colleagues or peers) will generate insight and provide marketing implications for social collective decision-making. Collective decisions made by social groups can be for low or high involvement products and may include, for example, friends deciding which film to see at the cinema, which night club or restaurant to go to, or which holiday to choose. The purpose of this paper, employing a qualitative approach, is to explore the decision-making of an adolescent collective, their social interactions (including conflict and conflict resolution) and to propose an original model based on influencing strategies for social collective decisions.

As such, the objectives of the study are as follows:

- To explore the experience of adolescent social collective decision-making and to establish how adolescents influence one another in a group to make decisions with consequences for the collective
- To understand how social collective decision-making is influenced by the social environment as well as the group dynamics
- To propose an original model based on influencing strategies for social collective decisions

RESEARCH DESIGN

A two stage qualitative approach, employing a longitudinal single embedded case study (Yin, 2009) followed by in-depth interviews, was designed to meet the proposed objectives of this investigation. This involved conducting four focus groups with the committee throughout the year and four individual interviews with the 'Services Captain' with overall responsibility for the high-school prom. She was an "embedded unit of analysis" (Yin, 2009: 46). That is, discussions with the Services Captain would allow a more holistic understanding of the way in which social collective decision-making was shaped. There were six members of the committee. Permission to meet with the members of the high-school prom organising committee was given by the school and on-going consent was provided by the pupils (see Tinson, 2009).

Following analysis of the case study material 12 in-depth interviews were arranged with young adults (18-20 years of age) who were members of a high-school prom organising committee within the last three years (see **Table 1**). All the interviewees attended school in Scotland and each respondent contributed to social collective decisions about the high-school prom e.g. venue, menus, photographer, band etc. The respondents were recruited via email through the use of university class lists to send invites. A semi-structured interview guide was developed for this phase of data collection. Questions ranged from an initially broad approach with questions such as 'tell me about your prom organising committee' with later questions addressing the specific aspects of social collection decision-making such as negotiation within the group and how was any conflict resolved to did decisions change over time.

DATA ANALYSIS

An interpretive analytic stance was adopted that drew on the transcriptions (see Bryman and Burgess, 1994) and the constant comparative method described by Glaser and Strauss (1967) was employed. Emerging insights and prior assumptions allowed interpretations to develop (Spiggle, 1994). The data was examined by considering social collective decision-making behaviour and changes to decisions and the associated negotiations and context.

FINDINGS

The findings established that adolescents influence one another in a group using a variety of influencing techniques (e.g. coalition formation, reasoning, bargaining and playing on emotion) and that the group is subject to conflict and conflict resolution (e.g. yielding, dominating, compromising and avoiding). Coalition formation (see

Lee and Collins, 2000) was not only evident within the group but externally between teachers and/or venue liaisons. This allowed for an exploration of the inter-relationship between the macro and micro environment (see Bamaca and Umana-Taylor, 2006). These external coalitions were significant not only because they were recognised as being credible but as a consequence of how the perceptions of these coalitions changed over time. Over the period of event preparation (typically nine months) the external coalitions became more important and were able to appreciably impact on the dynamics and related decision-making of the social collective. Intra coalitions were more likely to use bargaining or emotional appeals (e.g. guilt) to influence decisions whilst inter coalitions and their subsequent position/s on issues were often used as leverage within the social decision-making collective. Dominant roles adopted by intra coalitions typically materialised in (potential) conflict. Noticeably, those who appeared most dominant within the social group either disassociated from decisions made within the collective that they did not agree with or exited the group 'on principal' to preserve their perceived integrity (and more effectively manage their individual goals and identity ambitions).

CONCLUSIONS

This paper responds to the need for greater consideration of separation and affiliation in a social group context. This research has not only identified influencing strategies employed to influence choice but has also established how these strategies are used variably over time. The inter-relationship between the macro and the micro environment has also been explored within the context of social collective decision-making and has furthered our knowledge of adolescent social interaction e.g. inclusion and exclusion. A novel theory has been produced here and can be tested in other contexts.

The Dead People Bias in Disaster Aid

Ioannis Evangelidis, Erasmus University Rotterdam, The Netherlands
Bram Van den Bergh, Erasmus University Rotterdam, The Netherlands

EXTENDED ABSTRACT

"In Peru, the rainy weather and flooding have caused 15 deaths across the country, and affected another 30,000 residents".

Natural disasters often result in severe death tolls and economic damage. In an effort to help those who require immediate assistance, fund-raising activities often follow such catastrophes. In this paper we investigate how numerical information (i.e., the number of dead and the number of affected people) influences decision-making about disaster aid.

When the United Nations compile a Humanitarian Action Plan to support victims of a disaster, they estimate the appropriate amount of donation by multiplying the number of affected with a minimum amount. Indeed, the ideal size of donation depends on the number of people affected, and not on the number of dead people, since the affected people represent the beneficiaries of disaster aid.

Nevertheless, past work on prosocial behavior has documented numerous biases in decision-making, such as the identifiable victim effect (Kogut and Ritov 2005; Small and Loewenstein 2003), psychophysical numbing (Friedrich et al. 1999; Slovic 2007), and scope insensitivity (Desvousges et al. 1993). This evidence suggests that decision-making is subjected to inherent limitations in the way we process information (Kahneman 2003). As a consequence, donors may not always react in the way the United Nations hopes. Indeed, donors may use the number of dead, rather than the number of affected people, to determine the extent to which financial aid must be provided.

In our first study, we analyzed real disaster relief data about 381 natural disasters using a two-stage model. We find that the number of dead, and not the number of people affected in a disaster, is a significant predictor of the probability to grant financial aid (Heckman z = 3.54, p < .001), as well as of the size of the financial aid (Heckman z = 13.25, p < .001). Donors are both more likely to donate and more likely to donate more money to a natural disaster as the number of dead people increases, whereas they are insensitive to the number of affected.

Because correlational studies are not always reliable and do not allow causal inferences, we experimentally manipulated the number of affected (Study 2A) and the number of dead (Study 2B). Using an imaginary earthquake in Asia, we found that people donate more money when the number of dead people increases [t(47) = -2.45, p = .018], but remain insensitive to the number of people affected in a disaster [t(35) = -.38, NS].

We place the dead people bias in the category of one-reason heuristic decision-making (Gigerenzer and Gaissmaier 2011) in which a single cue (e.g., number of affected people, number of dead people) drives decisions. The validity rule asserts that the use of a cue is based on its validity, that is, the relative frequency with which the cue allows for correct inferences (Gigerenzer and Goldstein 1996). Other work highlights the importance of a cue's reliability. This account suggests that individuals are more likely to rely on a cue when they perceive its values as reliable regardless of cue validity (York et al. 1987). We argue that although the number of affected is a more "valid" driver of financial donations, the number of dead is more "reliable". Further studies provide evidence that individuals do not consider cue validity, but use a cue as long as it is seen as reliable.

In a third experiment, we test whether people's sensitivity to the number of dead is attenuated when they are primed to think in terms of validity. In addition to manipulating the number of dead and the number of affected, we also manipulated validity (control vs. primed). In the primed validity condition, respondents were instructed to "think about who will receive the donation" prior to deciding on how much should be donated. We found a significant two-way interaction between the number of dead and validity [F(1, 228) = 4.32, p < .04]. At the control level of validity, we replicate the dead people bias: People donated more to a fictitious earthquake in Asia when the number of dead people is high rather than low [F(1, 228) = 4.01, p < .05]. However, this bias is eliminated when validity is primed [F(1, 228) = .77, NS]. This study provides evidence for the use of a discrimination rule in responses to disasters and that priming validity of cues eliminates the dead people bias.

The final study consisted of two parts. In the first part, we manipulate the number of dead and affected people between-subjects and replicate the dead people bias: People feel that more money should be donated when the number of dead people due to a tropical cyclone in the Caribbean was high rather than low (Heckman z = 2.87, p = .004), but not when the number of affected is high rather than low (p > .16). In the second part, we manipulated the number of dead and affected people within-subjects and asked participants to rank-order four disasters in terms of appropriate size of donation. We predicted that when people are forced to use one cue at the expense of the other, such as when rank-ordering, cue usage would be based on validity rather than discrimination ability. Confirming our predictions, we found that the majority of the participants used a validity rule, thus ranking a disaster with a high number of affected higher than a disaster with a high number of dead (Friedman's χ^2 = 200.42, p < .001).

Our research contributes to theory on heuristic decision-making by showing how cue selection critically depends on the decision context. In addition, we examined event severity, and attribute evaluability as potential alternative explanations, but none of these mechanisms seemed to drive donation decisions. The potential implications of the present research are broad and important as we provide novel insights on how communications of fund raising agencies, journalists or humanitarian organizations should be optimally designed. Our ultimate goal is to improve aid towards future disaster victims.

Ayalla Ruvio, Temple University, USA

EXTENDED ABSTRACT:

Children love getting presents. In fact, children today are deemed the most materialistic and brand conscious generation (Schor 2005). Research on materialism, which has been conducted with adult samples, has found a link between materialism and less happiness (Carter and Gilovich 2010). If we simply apply adult findings to children, this would mean that children are the least happy. Yet, studies have shown that there are no significant differences in happiness by age (see Myers and Diener 1995). Thus, the findings from the adult literature cannot simply be applied to children. In fact, children might find more happiness in objects than experiences. If so, a related question emerges – when might children begin to resemble adults in favoring experiences over objects?

We propose that young children (3-5 years old) appreciate and prefer objects over experiences. Because young children notice and give their attention to concrete features of their world more so than abstract features, they are likely going to connect with concrete aspects of their world (e.g., objects) more so than abstract aspects (e.g., experiences). By late childhood (6-12 years old), children are beginning to think more abstractly, opening up the possibility of defining themselves in more complex and abstract terms (e.g., I like spending time with my family doing yard work), and therefore, intangible experiences may begin to gain recognition as useful devices for characterizing the self more for older children compared to their younger counterparts. However, the intangible abstract nature of experiences will still likely make it too hard for even older children to appreciate experiences over objects. By late adolescence (16-17 years old), we expect a reversal of this relative preference, in that older adolescents will prefer experiences over objects. Thus, we propose that relative preferences will change over time (age) for all children and adolescents, such that objects are preferred the most in the earliest years (ages 3-5), that this relative preference will decline for older children (ages 6-12), and reverse for older adolescents (16-17).

Figure 1
Happiness Collage: Developmental Changes in Children's Preference for Objects vs. Experiences
We also propose that age moderates the effect of memory and theory of mind on children's preferences for objects over experi-

ences. Specifically, young children simply do not have sufficiently developed knowledge structures to think about details of prior experiences (Justice 1985). Moreover, young children have not collected enough memorable experiences. In other words, to appreciate experiences, one must first collect memorable experiences, or develop what Keinan and Kivetz (2010; p.937) call an "experiential check list or experiential CV." Clearly this experiential CV is underdeveloped during early childhood and develops with age.

An underdeveloped theory of mind is also likely to contribute to children's preferences for objects over experiences. Without the ability to understand theirs' or others' emotions/feelings that result from an experience [dining out together] or to be able to predict others' behaviors or feelings based on an experience, it will be difficult for children to fully appreciate the value of experiences in building successful social relationships, which is one reason why adults prefer experiences over objects (Diener and Seligman 2004). We suspect that as children grow older and develop into more socially aware individuals (Piaget 1932; Turiel 2006), develop better memories for experiences, and begin to make more disadvantageous comparisons between objects, that experiential purchases will begin to make them happier than objects. But, until all of the above-mentioned develops, we would expect children to look more to objects to make them happy.

We test these predictions in three studies. In Study 1, we used unstructured interviews to ensure that children do indeed think of objects and experiences when they think about what makes them happy. Providing participants with an unstructured, open-ended task, as opposed to asking them to tailor their responses to narrowly focus on experiences and objects, allowed us to let children reveal what specific experiences and objects are meaningful to them. Results from Study 1 were used to develop age and gender appropriate stimuli for Studies 2a, 2b, and 3. In Study 2a, children ages 3-12 were asked to construct collages using pictures of objects (e.g., toys, clothes) and experiences (e.g., birthday parties, playing sports) to answer the question, "What makes you happy?" . In Study 2b, we examined further age differences by sampling 16-17 year olds. In Study 3, we used a reaction time experiment with the full age range of children and adolescents, ages 3-17, to determine whether objects or experiences were most accessible to children and adolescents.

Our research provides evidence that the preference for objects over experiences is quite strong from early to middle childhood (ages 3-9). Although the preference for objects over experiences exists throughout childhood (ages 3-12), by late childhood (ages 10-12), the preference is significantly weaker. By late adolescence, the preference reverses and adolescents find more happiness in experiences than objects, resembling findings in the adult literature. Finally, we offer a process explanation (memory and theory of mind), for the developmental change observed—moving from preference for objects in childhood to preference for experiences by adolescence.

In conclusion, happiness emanates from many sources. People derive happiness from objects (a luxury handbag, a large house, a nice car) and from experiences (an exotic vacation, an exquisite dinner). However, research suggests that objects and experiences are not valued equally. People tend to derive more happiness from experiences than from objects. Our research confirms these findings,

but with a very important caveat. A preference for experiences over objects is not an innate characteristic, but a child developmental process that unfolds over time. The thrill of objects during childhood is a phase that all children go through. When they have acquired a sufficient "experiential CV" and their memory and theory of mind have matured, the stage will be set for them to appreciate the intangible benefits of experiences— they will indeed prefer experiences over objects similar to adults.

My Heart Longs for More: The Role of Emotions in Assortment Size Preferences

Aylin Aydinli, London Business School, UK
Yangjie Gu, London Business School, UK
Michel Tuan Pham, Columbia University, USA

EXTENDED ABSTRACT

Past research has documented the factors that influence consumer choice among assortments, such as the decision flexibility (McAlister and Pessemier 1982), the probability of a match between consumers' preferences and the available alternatives (Lancaster 1990), availability of ideal point (Chernev 2003), the anticipated cognitive effort in making a choice (Huffman and Kahn 1998) and the nature of decision process (Chernev 2006). This research has mainly focused on the cognitive processes used in the construction of assortment size preferences.

In this paper, we investigate the role of emotions in influencing consumers' assortment size preferences. In particular, we investigate how feeling-based (compared with reason-based) decisions may influence preferences for assortment size. Prior research has shown that emotional system is holistic (Epstein 1994). Accordingly, while evaluating the assortment, people who engage in such holistic processing may focus more on judging the global features of the choice set. Research suggests that people who search at a global (vs. local) level tend to have larger consideration sets (Pham and Chang 2010). In addition, it has been shown that global evaluations favour varied sequences (Ratner, Kahn and Kahneman 1997). Therefore, people who perform global evaluations might desire for more variety and compared to small assortments, large assortments provide greater fit to the desire for more variety. Hence, we posit that people who make feeling-based choices would be more satisfied with a large assortment than a small assortment. In contrast, people who rely on their feelings less may experience less fit from the large assortment. As a consequence, the difference in preferences for large and smaller assortments is mitigated. The predicted effect of feeing-based decision on preferences for large assortments versus smaller assortments was tested in four studies.

The first three studies aimed to test the predicted effect by using different approaches to manipulate how much participants relied on their feelings. Study 1 was a 2 (assortment size: small vs. large) x 2 (product type: hedonic vs. functional) between-subjects design. Participants were asked to imagine going to a supermarket to purchase either detergent (functional) or jam (hedonic) from a selection of either 12 (small-set) or 36 options (large-set). Research shows that hedonic products elicit greater affective response in consumers than functional ones (Okada 2005). We measured participants' satisfaction with the selection. Results showed that participants evaluating the jam selection were more satisfied with the large assortment than the small assortment. However, this difference was mitigated when they evaluate the detergent selection.

Study 2 employed a 2 (assortment size: small vs. large) x 2 (trust in feelings (TF): high vs. low) between-subjects design. Participants, either in high-TF or low-TF conditions, were asked to imagine purchasing a coffee from a menu that either provided a selection of 12 (small-set) or 36 coffees (large-set). Before the choice task, supposedly in an unrelated study, we manipulated participants' momentary trust in their feelings and thus their reliance on feelings using a procedure called the *trust-in-feelings manipulation* (Avnet, Pham, and Stephen 2012). Participants were asked to describe either two (high-TF) or 10 (low-TF) situations where they trusted their feelings to make a decision and it turned out to be the right decision. It has been shown that recalling two (vs. 10) instances of successful reliance on feelings induce higher (vs. lower) reliance on feelings. Results showed that in the high-TF condition, satisfaction with the large assortment was higher than the small assortment. However, this difference was not significant in the low-TF condition.

Study 3 was a 2 (assortment size: small vs. large) x 2 (cognitive load: high vs. low) between-subjects design. Participants were asked to imagine selecting a coffee from a selection of 12 (small-set) or 36 options (large-set). ROF was operationalized through a cognitive load manipulation (Shiv and Fedorikhin 1999), where participants were asked to memorize either a 2-digit code (low-load) or a 10-digit code (high-load) and to reproduce the code at the end of the study. Prior research has demonstrated that choice under cognitive load limits cognitive capacity, thus generating a greater degree of reliance on feelings than choice under low cognitive load (Lieberman et al. 2002). Accordingly, we expected participants who memorized 10-digit (vs. 2-digit) code to rely more on their feelings while making decisions. Results showed that participants in the high-load condition were more satisfied with the large (vs. small) assortment. However, this difference was not significant for low-load participants.

Study 4 aimed to test the process driving the observed effect. Study 4 employed a 2 (assortment size: small vs. large) x 2 (cognitive load: high vs. low) between-subjects design. The procedure of study 4 was similar to study 3, except that this time participants were asked to imagine considering purchasing a snack from a vending machine that contained a selection of 12 (small-set) or 36 snacks (large-set). To test the process, we measured whether participants would like to have had greater variety in the selection they were given. Results showed that in the high-load condition, the desire for more variety was less for participants who were confronted with the large assortment than for those who were faced with the small assortment. Therefore, in the high-load condition, participants liked the large assortment more than the small assortment, because the former provided a better "fit" to their need for variety. However, in the low-load condition, the difference in desire for greater variety was not significant. Consequently, there was no difference in satisfaction with large and small assortments. Mediation analysis further supported that desire for greater variety mediated the observed effect only in the large-set condition.

To summarize, four studies documented the impact of reliance on feelings on consumers' assortment size preferences. We found that greater reliance on feelings boosts individuals' preference for larger assortments as opposed to smaller assortments. First three studies have demonstrated the effect of reliance on feelings on satisfaction with the assortment. Study 4 has provided the process evidence: A large assortment provides a better "fit" to the desire for variety that is triggered by the feeling-based process.

Me, Myself, and Ikea: Qualifying the Role of Implicit Egotism in Brand Judgment

Jacob H. Wiebenga, University of Groningen, the Netherlands
Bob M. Fennis, University of Groningen, the Netherlands, and Norwegian Business School BI, Norway

EXTENDED ABSTRACT

We frequently like occupations, partners, cities, streets, birthdays, and a host of other objects, events and entities because, essentially, we like ourselves (Pelham et al. 2005). This intriguing phenomenon is known as 'implicit egotism' – the unconscious attraction to things that are linked to the self (Pelham et al. 2002). Although abundant research in numerous contexts has shown its pervasive existence (Jones et al. 2004; Pelham et al. 2002), research in the consumer sphere is surprisingly scarce (but see Brendl et al. 2005). This is all the more surprising given that recent trends indicate that the use of personal pronouns in branding such as 'I' and 'my' (e.g., iTunes and MySpace) shows a marked surge in recent years (BOIP 2012). The present research extends previous findings and examines whether and when such self-referencing brand names affect brand judgment, and under which conditions the self-referencing effect might turn from positive into negative.

To understand the possible impact of pronouns in brand names, we draw from work on the disproportionate liking of people for things that are associated with the self (Greenwald and Banaji 1995). Most notably in this regard is the finding that people even like their own names to such an extent that they like the letters that comprise it over other letters in the alphabet (Nuttin 1985). Recent research has found that this so-called 'name letter effect' extends to the liking of people, places, and products with similar name letters (Brendl et al. 2005; Pelham et al. 2005). The underlying rationale is that name letters produce a link between the self and the target which subsequently leads to a transfer of self-evaluations to the self-associated target (Gawronski et al. 2007).

It is striking to note that most studies have limited themselves to examining the effects of implicit egotism by assessing name letters as proxies for self-referencing. We, however, posit that self-associations can also be created by more generic self-referencing stimuli. More in particular, we propose that also first person pronouns like 'I' and 'my' may function as persuasion cues in eliciting a bias toward the self-associated target. Hence, we expect that brands featuring self-referencing pronouns in their name will be liked better than brand names without such pronouns.

Implicit egotism is thought to be a self-enhancement mechanism which enables people to preserve their positive self-view (Pelham et al. 2002). Research on self-enhancement has shown that people often respond to self-threat in ways to reaffirm their sense of self-worth (Tesser 2000). One way in which people compensate for this threat is by enhancing the value of external targets that are associated with the self (Jones et al. 2002). We posit that if pronouns in brand names create a self-target association, these brands might also function as a source for self-affirmation. More specifically, we propose that the positive effect of self-referencing brands on brand name liking will be more pronounced under conditions of self-threat, i.e., when the need for self-affirmation is high.

To date, research on implicit egotism has found that the bias resulting from the self-target association is generally positive because the 'default' evaluation of the self is mildly positive (Greenwald and Banaji 1995; Yamaguchi et al. 2007). Hence, self-referencing stimuli are assumed to enhance the favorability of practically anything even when the self-associated target itself is undesirable (Nelson and Simmons 2007). But what if people's self-evaluations are not positive but negative? If the self-referencing effect hinges on the valence of people's self-evaluations, and if the positive bias is the result of a transfer of positive self-evaluations to the target, then, by implication, also negative self-evaluations can spill over to the target resulting in a negative bias. It follows that attraction can turn into avoidance or at least an unfavorably valenced brand judgment when consumers' self-evaluations are negative. We tested these notions in three studies.

Study 1 showed that, while controlling for brand familiarity, existing brand names with a generic self-referencing pronoun (e.g., iPhone, iDeal) were evaluated more positive than non-self-referencing brand names (e.g., X-Box, X-Travel) or brand names without any prefix (e.g., Blackberry, Paradigit). Interestingly, this study also showed that references to the self that are less specific than 'I' (i.e., brand names starting with 'you' or 'u') did not yield the implicit egotism effect.

Study 2 ruled out the alternative account that the previous effects were driven by other, existing brand name associations than with the self. More in particular, in Study 2 we used fictitious instead of existing brand names and were able to replicate the effects found in Study 1 while using 'I' and 'my' as self-referencing stimuli. Moreover, we tested whether the self-referencing effect was more pronounced when the self-concept was threatened. As hypothesized, we found that the preference for generic self-referencing (vs. non-self-referencing) brand names only increased after self-threat but not when the self was affirmed.

Study 3 sought to provide converging evidence for our notions, and to directly test the role of negative self-evaluations in implicit egotism while using a consumer sample representative of the population. That is, Study 3 tested the hypothesis that under conditions of negative self-evaluations the attraction effect turns into an avoidance effect. As expected, results showed reduced (instead of increased) liking of generic self-referencing brand names when consumers' self-evaluations were negative. In contrast, we found that positive self-evaluations led to increased liking of brands that referred to the self.

The present findings extend previous research on implicit egotism by taking into account the valence of the consumer's self-evaluations. Moreover, the present work showed that implicit egotism is not limited to such incidental instances where (brand) names and name letters match, but extends to more generic references to the self, and particularly when the consumer is in need of self-affirmation. Simply referring to the consumer's self by using personal pronouns in brand names may therefore influence a host of consumption decisions and hence account for the stunning marketing success of such brands as Ipod, Ikea and MySpace.

Trading off Health for Thrift in a Supersized World

Kelly L. Haws, Texas A&M University, USA
Karen Page Winterich, Pennsylvania State University, USA

EXTENDED ABSTRACT

Have you ever found yourself holding a larger dish of ice cream or mega-size latte because though you only intended to get the small, you couldn't seem to pass up the value as getting nearly twice as much for only a few cents more? Such behavior corresponds to the classic effect of nonlinear pricing in the form of increasing purchase quantity in the presence of quantity discounts (Dolan 1987; Gu and Yang 2010). However, in this case, the increased quantity is consumed immediately by one person rather than in multiple servings over time, potentially negatively impacting health. In such situations, consumers may experience conflict between their desire to obtain a good value (Grewal, Monroe, and Krishnan 1998) and their desire to consume food in moderation (Wansink, Payne, and Chandon 2007). We examine conflict and goal tradeoff processes as well as whether the supersized effect holds when a health goal is salient (e.g., encountering messages about healthy behaviors) to provide insight into the consumer processes that lead to the effects of nonlinear pricing. Such understanding may be particularly important given the prevalence of such pricing strategies for unhealthy fast foods and snacks coupled with America's obesity epidemic.

Consumers tend to focus on achieving one goal at a time, often at the expense of other goals (Baumeister, Heatherton, and Tice 1994). Generally, whichever goal is made more salient by the environment will take priority over conflicting goals (Shah and Kruglanski 2003). However, most research focuses on tradeoffs between goals within the same general domain of consumption (Dhar and Simonson 1999; Soman and Zhao 2011) whereas we examine inter-domain goal conflict and the tradeoff of health goals for thrift goals in the presence of supersized pricing. In doing so, we demonstrate that supersized pricing engenders a thrift goal as consumers experience pleasure from the discount offered by supersized pricing.

Moreover, immediate financial consequences are likely to be far more concrete than are potential health consequences. That is, while consumers, even those with numerical illiteracy, may realize that getting 24-ounces for $3.00 versus 12-ounces for $2.00 is a better deal consumers are likely unable to grasp the consequences of the extra (often unknown quantity of) calories or the financial costs of obesity (Close and Schoeller 2006). Thus, consumers may focus on the thrift goal due to the clear and immediate gratification of saving and the corresponding discounting of ambiguous, delayed health benefits (Frederick, Loewenstein, and O'Donoghue 2002).

Our studies focus on products consumed immediately following purchase (e.g., candy bars, movie popcorn, milkshakes, and snack chips). We show supersized pricing leads to larger size choice and greater consumption and demonstrate the intervention of health goal salience to retain focus on health goals and overcome the effects of supersized pricing.

In study 1, participants in an online study were randomly assigned to one of four conditions in a 2 (consumption: immediate vs. delayed) x 2 (price: linear vs. nonlinear) between-subjects design. Participants were asked to imagine choosing between two sizes of their favorite candy bar. Results from a logistic regression showed that nonlinear pricing increases purchase size relative to linear unit pricing. Additionally, the increase in size choice is significantly larger for immediately consumed purchases rather than those consumed over a period of time. More importantly, we show that size choice is influenced by more importance on thrift (vs. health) goals for im-

mediately consumed goods offered at nonlinear pricing, which is accompanied by greater conflict.

In study 2, participants in a behavioral lab study were offered the opportunity to purchase popcorn and were either given supersized or linear pricing options for 3 sizes of popcorn. Again, the presence of supersized pricing led consumers to choose larger sizes as compared to linear pricing for immediately consumed goods. Process evidence showed that an increased emphasis on the importance of thrift relative to health drove the differences in size choice. This study replicated the main findings of study 1 for real choice and consumption.

Study 3 examines a potential intervention as a moderator: increasing health goal salience. A 2 (price: linear vs. supersized) x 2 (goal salience: health vs. control) between-subjects design revealed an interaction between the factors such that salient health goals attenuate the effect of supersized pricing on purchase quantity. Process evidence shows that the shifts in the salience of health importance in the purchase environment impacts responses to supersized pricing.

Studies 4 and 5 provide further evidence of health goal salience interventions. In a field study (study 4) examining purchase size for 1 and 2 ounce bags of potato chips offered with supersized pricing, we find that the presence (vs. absence) of a nutrition poster as a health cue overrides the effects of supersized pricing on purchase size. Similar to study 2, study 5 was conducted in a lab examining effects for real food and real money. Results reveal that a health salience prime again reduces the effect of supersized pricing. In addition, consumption quantity is found to be closely related to size choice, such that once a larger size is purchased, consumption quantity increases.

In conclusion, we demonstrate that supersized pricing leads to an increase in the quantity of food purchased and consumed. This occurs because supersized prices cause thrift to become a more focal goal than health, particularly for immediately consumed goods, unless a health goal is made salient. This focus on thrift when supersized pricing is offered may give the struggling consumer justification to achieve their thrift goal while inadvertently increasing their waistline. Substantial practical implications, including the consequences of increased consumption quantity, relate to both individual consumers and society at large.

Would You Purchase From A Seller in Alaska?
Preference for Differently Located Sellers in Online Marketplaces

Sae Rom Lee, Pennsylvania State University, USA
Margaret G. Meloy, Pennsylvania State University, USA

EXTENDED ABSTRACT

With the advent of new technology, especially the Internet and the Web, consumers today can purchase what they need from multiple sellers around the world. As a result, many have argued that the issue of the sellers' physical distance is "dead" (Cairncross, 2001). However, we argue that distance should not be dismissed as a factor affecting consumers' preferences for sellers. Based on real transaction data from two large online stores, eBay and MercadoLibre.com, Hortaçsu et al. (2009) found that distance is still an important deterrent to transactions between geographically distant buyers and sellers. The locations of sellers can be an important factor influencing consumers' purchase decisions. Understanding what drives perceptions of distance is thus an important issue given that sellers are competing to attract consumers' attention in the online marketplace.

We propose that consumers will prefer a near seller over a distant seller despite holding the costs associated with distance constant. We also propose that preference for a distant seller can be increased if the psychological distance of that distant seller is reduced. To establish a baseline for consumer preference for near over far sellers, we conducted a pilot study. When both near and far sellers provided an identical computer monitor at the exactly same price, free insured shipping, and same delivery time, participants preferred the near seller over the far seller, regardless of whether the difference in distance was large or small between the locations. We attribute this finding to not only physical distance but psychological distance as well.

Psychological distance is a "subjective experience that something is close or far away from the self, here and now (Trope and Liberman 2010, p.440)." We suggest that greater psychological distance, normally associated with greater physical distance, will negatively influence the preference for the far seller. This greater distance will lead to an abstract mental representation of the product and uncertainty in online shopping. Thus we predict that if the psychological distance of the near seller is not shorter than the far seller, preference for the near seller will be attenuated. We test this prediction in study 1.

In study 1, participants located in Pennsylvania were asked to imagine that they were spending their summer in Arizona and were purchasing a new backpack online. In the two cell design, two differently located sellers were selling the exact same backpack, all else equal. The far seller was always located in Pennsylvania, physically far from Arizona but socially near to participants. In one condition, the near seller was located in Arizona, a location both socially and physically nearer. In the second condition, the near seller was located in Colorado, physically closer to Arizona but not socially closer to the participants than Pennsylvania. The results revealed that participants clearly preferred the near seller over the far seller when the near seller was both socially and physically closer to them. However, when the seller was physically closer to the participants but not socially closer to them, participants preferred the physically distant seller in Pennsylvania (Figure 1). Mediation analysis revealed that the difference in preference for the far seller relative to the near seller was mediated by psychological distance.

What can far sellers do to reduce psychological distance in online marketplaces? We propose that sellers can overcome the disadvantages associated with physical distance by changing the perception of psychological distance through their product presentations.

Figure 1. Study1. Choice of Near Seller versus Far Seller
Note. Error bars represent confidence intervals.

Past research suggested that information processing fluency increases liking of an object (Alter and Oppenheimer, 2008). In particular, information with distance-congruent levels of construal increases fluent evaluations of objects (Trope et al. 2007; Nussbaum et al. 2006). As such, to enhance fluency, the far seller should present their product information with descriptions in abstract terms denoting far distance while the near seller should present their product information with descriptions in concrete terms, denoting near distance. In contrast, we propose that using descriptions denoting near distance that help consumers to envision the product more concretely will always increase preference for a product in an online marketplace. When people easily and vividly envision a product experience, purchase intentions increase (Elder and Krishna 2011; Petrova and Cialdini 2005; Schlosser 2003). Thus, we propose that to increase preference for far sellers, these sellers should present their product information with distance-incongruent descriptions (i.e. far sellers should provide concrete product descriptions denoting near distance).

We tested this prediction in study 2. We created product advertisements using a product picture and words denoting different levels of distance (Bar-Anan et al. 2007) (Figure 2). Participants were assigned to one of the four conditions in a 2 (near seller: proximal vs. distal product descriptions) by 2 (far seller: proximal vs. distal product descriptions) between-subjects design. Participants were asked to select which of two sellers (near vs. far) they wished to purchase a new computer monitor from. The study revealed that the interaction between the description of near seller and far seller was significant. When the near seller's product was described in proximal terms, the near seller was always preferred relative to the far seller, regardless of whether the far seller's product was described proximally or distally. However, when the near seller's product was described distally, the choice of the far seller increased significantly, especially when the far seller's product was described proximally rather than distally. Mediation analysis revealed that psychological distance underlies the interaction effect.

Figure 2. Study 2. Proximal and Distal Product Information

Proximal Presentation

This LCD monitor surely is perfect for you if you are looking for a monitor with high quality. It is a must-have for you who love watching movies on your computers. Its fast response time also ensures you great gaming experience everyday from today.

Distal Presentation

This LCD monitor may be perfect for people if they are looking for a monitor with high quality. It would be a want-to-have for people who love watching movies on their computers. Its fast response time may also provide people great gaming experience for years to come.

    This research contributes to our understanding of how the distance between consumers and sellers influences consumer choice in online marketplaces. Consumers prefer near sellers to distant sellers, even when the costs associated with physical distance are held constant. When the seller was nearer physically but not socially closer, preference for that near seller diminished. The far seller who was socially closer became more attractive due to the reduced psychological distance. Presentation of product information denoting near distance could also reduce psychological distance associated with physical distance and increase preference for the far seller. The managerial implications of the research will be discussed.

The Thrifty Meal: Re-creating Value in the Kitchen

Benedetta Cappellini, Royal Holloway, University of London, UK
Elizabeth Parsons, Keele University, UK

EXTENDED ABSTRACT

This paper looks at the localised control of value within the household and the intersection of practices of thrift and accommodation with familial relations in the household. Its focus on food leftovers is significant in that it foregrounds the varying creative practices through which food is re-ordered, transformed and reused, and the resulting travels and circularities of food. Leftovers are theorised as 'thrifty meals' using Miller's (1998) work on thrift and sacrifice. As such they might be viewed as a form of saving by spending. However what is saved in relation to leftovers is not only money, but also importantly time and effort in the kitchen. Using up leftovers saves not only financial resources (ingredients) but also time and effort in preparing the food. These resources can then be invested elsewhere.

Instead of viewing food leftovers as the negative or non-present end point of production this paper explores possibilities of their return, renewal and reuse. Taking inspiration from theorists who have explored the ways in which we classify, manage and value household durables through practices of storing and sorting (Cwerner and Metcalfe, 2003; Daniels, 2009) hoarding (Maycroft, 2009; Cherrier & Ponnor, 2010) and accommodating (Gregson, 2007), this paper shows an intimate relation between decisions to rid, the channels and conduits chosen for disposal and relationships indicated or made present by these practices. These practices have received scant attention in domestic food consumption contexts (although see Evans, 2011).

This paper emerges from an interpretive study looking at discourses and practices surrounding the everyday meal in the Midlands (UK). Fieldwork consisted of observations of meal times of 20 households and semi-structured interviews of the person in the family responsible for the food provision. Data were analysed following the general guides of qualitative research and a thematic analysis was conducted following common practices in interpretive consumer research (Silverman, 2006).

Despite having different routines and standards of judging a meal as quick, easy or cheap just about all of the participants' selection of their everyday meal was driven by saving resources. For example, in a manner similar to Miller's (1998) mothers, Margaret plans her meal in order to save her scarce resources which are time, effort and money. She customises her 'spag bol' in such a way that it becomes a dish in which leftovers can be reused. Margaret and the other participants' focus on thrift does not necessarily mean that they save resources, but rather that they are motivated by saving resources in order to spend them elsewhere. It is here that leftovers become significant for our participants, considered a strategic means of saving resources in the kitchen.

A second finding was the degree of skill and knowledge employed in using up leftovers. For example David who keeps parts of his Sunday roast chicken to make a salad for lunch on Monday. He prepares a stock with the bones which he freezes along with any leftover vegetables in order to make a risotto during the week. David applies a significant amount of knowledge to his meal leftovers he breaks it down into its constituent parts each with different characteristics and thinks creatively about how each part might be reused and re-valued in the context of a new meal. This process of revaluation also has a geography attached to it. In describing his conduits of disposal of the meal, David divides the leftovers into various parts and moves them into different places (such as the bin, the fridge,

the freezer and the lunchbox). Here David's differing placings of the food shows how disposal is not simply a matter of moving things away but rather moving things along (Gregson et al. 2007) according to their possible re-use.

People spent a considerable amount of time changing the look of their leftovers. In some cases they become a completely new dish, like the Thursday night chicken and pea risotto that Tim prepared from what was left from his Sunday roast dinner. Tim deliberately cooks an over generous portion of risotto giving him enough to feed his family and leaving enough for his own lunch on Friday. On such occasions meals might be composed of the leftovers of leftovers. As such food might travel through a range of conduits before it is finally fully disposed of. In the case of Tim the chain goes from Sunday roast dinner to his Friday lunch box, from the bone china serving plates in his dining room with his family to the more modest plastic container which will be opened at lunch time on his office desk.

To conclude we see value in theorising the consumption of leftovers as thrifty meals. These thrifty meals contribute to the control of the flow of value within the home just as much as thrifty practices of shopping. Drawing on Miller's (1998) concept of thrift we observe that it is likely that the resources saved in thrifty meals are then spent in more extravagant meals in the longer term. Preparing and eating Sunday dinner everyday simply would not be possible or practical given the resources of time and effort required. Thus we see a longer run cycle of spending to save and saving to spend in mealtime practices.

However these meals are not only a means of saving resources they are also a means of value creation, food is literally revived and re-valued once more as 'meal'. This process takes both skill in planning meals with re-use in mind, but also knowledge of the material elements of food ingredients (i.e. the length of their reusable lifetime and the likely contexts of their reuse). Value is therefore created through creative acts of transforming and re-framing food. The framing or placing of food is important here in understanding its value considering the bone china plate in the dining room against the plastic lunchbox in the office. Therefore food provision and in this case the consumption of leftovers in order to make sense must be located within everyday household routines wherein the social context of (re)valuation is vital.

Virtually Unhappy:
How Probability Neglect in Social Comparison Biases Judgments of Satisfaction with Life

Mudra Mukesh, IE University, Spain
Dilney Goncalves, IE University, Spain

EXTENDED ABSTRACT

Our perception of how great (or not!) our lives are is often based on comparisons with others' lives (Corcoran, Crusius, and Mussweiler 2011; Festinger 1954). With the proliferation of social networking sites, our ability to get a glimpse of others' lives is magnified, with vast information available at our fingertips. However, the representativeness of this information is contentious since people have a tendency to selectively share information that is self-enhancing (Manago et al. 2008) while observers tend to underestimate the prevalence of misery among others (Jordan et al. 2011). When individuals read the information provided by friends online, they may compare facets of their life to the vivid content posted, to assess how well they are doing (Wood 1996; Wood, Taylor, and Lichtman 1985).

Whilst the dominant paradigm used in social comparison literature acknowledges that cues used to make social comparisons are subjective, it doesn't remedy the fact that people don't have perfect information about others (Prentice and Miller 1993). When judging life satisfaction, people need to make inferences about the others' life satisfaction based on sampled pieces of information, however these inferences are likely to be subject to cognitive biases. Probability neglect—ignoring actual probability of events (Rottenstreich and Hsee 2001; Sunstein 2002) is one such bias. On social networking sites, people with large number of friends would be likely to encounter a larger sample of ostentatious information each time they visit the site. Probability neglect would thus result in people not accounting for probability of observing ostentatious information and, consequently assuming that the *amount* of ostentatious information viewed on a social networking site reflects *how good* the lives of their connections are. Thus, people would rely on the *number* of informational cues ignoring the probability of observing such cues given the number of friends. So even if research (Ellison, Steinfield, and Lampe 2007; Helliwel and Putnam 2004) and popular wisdom might favor having more friends for a better life, we hypothesize that reading others' posts on social networking sites will have a negative (positive) impact on life satisfaction for people with a large (small) number of friends. Furthermore, probability neglect in this domain could be a result of accessibility bias since information that is implicit is often ignored or underweighted by people (Tversky and Koehler 1994). Thus, we hypothesize that making the relationship between number of friends and ostentatious posts accessible will reduce the bias.

We conducted two studies to test our hypotheses. In the first study (N = 158), the participants, recruited online, were randomly assigned to one of the two conditions: *Updates* or *Control*. In the *Updates* condition the participants viewed the first five updates on their homepage on Facebook. They then categorized the updates and indicated the number of updates in each category. Subsequently, participants completed the Satisfaction with Life Scale (SWLS; Diener et al. 1985) and the Social Comparison Orientation (CO) scale (Gibbons & Buunk 1999). The *Control* group only responded to the scales. Information relating to number of Facebook friends and demographics was collected.

We found a significant positive correlation between the number of ostentatious updates (operationalized as sum of purchase, travel related and professional achievements updates) and the number of Facebook friends. More importantly, we found a significant interaction of number of Facebook friends with *Updates* Condition (t(152) = -2.59; p < .05) where CO was included as a control variable. A spotlight analysis compared the effect of reading updates (vs. control) on participants' life satisfaction at large and small (one SD above and below mean) number of Facebook friends. When the number of friends was small, viewing updates increased life satisfaction (B = 0.554; t(152) = 2.089; p < .05). However, when the number of friends was large, viewing updates decreased life satisfaction (B = -0.554; t(152) = -2.103; p <.05). Thus the results provided support for our hypothesis.

The second study was undertaken to examine if individuals can correct their judgments when provided information about the correlation between number of Facebook friends and the number of ostentatious updates. Moreover we wanted to test the hypothesis that the bias occurs because of low accessibility of the aforementioned correlation (Accessibility Hypothesis) at the time of assessing life satisfaction. To rule out alternate explanations we also test if the bias occurs because people have no knowledge about the phenomenon (Knowledge Hypothesis). Participants (N = 204) were recruited online and assigned to one of the three conditions: *debias-before-update*, *debias-after-updates* or *no-debias*. In the *debias-before-update* condition, the debiasing information that related the correlation between number of friends and number of ostentatious information was presented before the participants read updates. In the *debias-after-update* condition the debiasing information was presented after the participants read updates but just before the SWLS. No information regarding the correlation was presented in the *no-debias* condition. In the end, all participants completed the SWLS.

Planned contrasts showed that the difference between *no-debias* and the two *debias* conditions was not statistically significant (F(1, 201) = 0.530; p = .468). Thus, we found no support for the knowledge hypothesis. Supporting the accessibility hypothesis, the difference between *debias-before-updates* and *no-debias* conditions to the *debias-after-updates* condition was statistically significant (F(1, 201) = 5.115; p = .025).

The contribution of this article is twofold. Firstly, we show how ignoring the probability of available information used to make social comparisons can impact the outcome of those comparisons. Thus, this research represents one of the first studies to focus on the nature of informational cues people use to make social comparisons. By introducing the concept of probability neglect in the domain of social comparisons, this research paves the way for seamless integration of social comparison literature with decision-making literature. Secondly, we demonstrate, within the powerful context of Facebook, that a large friend network on social networking sites may be detrimental to the well-being of users. With more than 845 million users and 50% of them logging on to Facebook everyday (Facebook 2012), this research has resounding practical implications for the life satisfaction of millions.

Slow Sinkers Are the Real Stinkers:
Why a Plummeting Stock Price Can Be Better for Investors Than a Gradual Decline

Neil Brigden, University of Alberta, Canada
Gerald Häubl, University of Alberta, Canada

EXTENDED ABSTRACT

Choosing to sell a poorly performing financial asset can be difficult. Indeed, prior research has shown that investors tend to hold flagging assets for too long (Odean 1998; Shefrin and Statman 1985; Weber and Camerer 1998). This is in line with prospect theory (Tversky and Kahneman 1979) in that an asset that has lost value relative to a reference price is coded as a loss. Decision makers are risk seeking for losses, and therefore hold losing assets hoping they will recover.

However, investors do not hold sinking assets indefinitely. In particular, they do tend to respond to large price changes (Andreassen 1988). We hypothesize that an asset that declines rapidly can actually be better for the investor than one that declines slowly or stagnates. This occurs because the investor holding a rapidly declining asset is more likely to sell it quickly, while the investor holding a slowly declining or stagnating asset is more likely to continue to hold that poor asset. Compounding the effect, investors may become less likely to sell a poor asset the longer they hold it because of inaction inertia (Tykocinski, Israel, and Pittman 2004; Tykocinski, Pittman, and Tuttle 1995).

Inaction inertia refers to the decreased likelihood of taking an attractive course of action when a similar and superior course of action has been previously foregone (Tykocinski and Pittman 1998; Tykocinski et al. 1995). If investors do not sell a poorly performing asset initially, they are less likely to sell it in the future, because they compare the opportunity to sell with previous, superior opportunities.

We hypothesize that "slowly sinking" assets can be more costly to investors than assets that decline rapidly. However, the risk of sinking slowly can be reduced by preventing investors from maintaining their asset allocations via mere inaction – using an "forced-selling" intervention, whereby investors must actively choose how to invest their capital afresh each period.

To test these hypotheses, we conducted an experiment in which 152 participants played a consequential investment game. Participants were initially endowed with an investment portfolio worth $40,000 to invest over the course of the game. Upon completion of the experiment, all participants were paid 0.0005% of the final value of their portfolio.

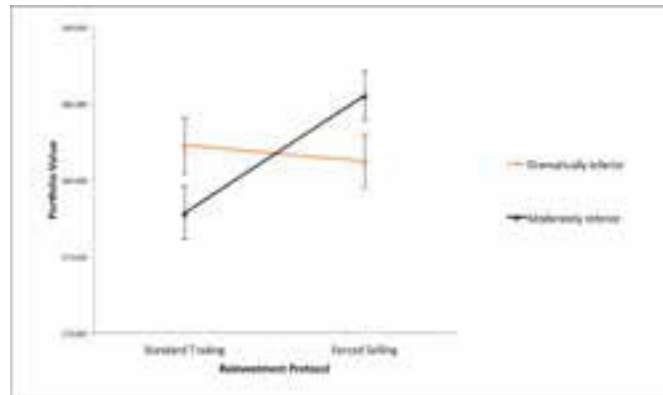
The portfolio was initially divided evenly among four assets. In each of 20 periods, participants saw updated price information and could then reallocate the value of their investments across the four assets. Participants could not keep money out of the market as cash, nor could they borrow additional funds to invest.

All participants had one asset in their portfolio that was inferior to the other three in performance. The severity of the inferior asset's poor performance was manipulated as either dramatically inferior (averaging -6% per period) or moderately inferior (averaging 0% per period). The other three assets were common to all participants and averaged returns of 1%, 3%, and 5% per period. All prices were determined individually for each participant and subject to random variations of plus or minus 3% per period.

In the standard-trading condition, participants continued to hold the same number of shares of each investment by default, unless they chose to sell. By contrast, in the forced-selling condition, all shares

were sold at the end of each period, and participants had to allocate their entire capital across assets afresh.

As predicted, there was a significant two-way interaction between asset performance and condition $F(3, 148) = 8.346$, $p < .01$ (see figure 1). In the standard-trading condition, participants earned less money when their portfolio initially included the moderately inferior asset $(M=\$77,834)$ than if it included the dramatically inferior asset $(M=\$82,264)$, $t(75)=2.05$, $p<.05$. By contrast, in the forced-selling condition, participants earned more when their portfolio initially contained the moderately inferior asset $(M=\$85,514)$ than if it included the dramatically inferior asset $(M=\$81,209)$, $t(73)=2.04$, $p<.05$.

Figure 1: Final Portfolio Value (After 20 Periods) by Experimental Condition


We predicted that these effects would be driven by how investors respond to the inferior asset. When that asset declines rapidly, investors respond quickly, regardless of the selling manipulation, and sell those shares. By contrast, when the lowest performing asset has zero growth, investors' responses depend on the selling manipulation. Under standard trading conditions, investors are slow to sell. The lack of growth does not attract much attention, and several periods may pass before investors realize that the asset is dragging their portfolio down. By that point, they have already missed several, more attractive, opportunities to sell the asset. Therefore, although selling now is still the normative action, it may appear relatively unattractive because it is being compared to superior, previously foregone opportunities.

Forced selling overcomes this inaction inertia trap because it requires investors to make an active asset allocation decision each period. Rather than deciding whether to retain an asset that has not increased in value, investors must decide whether to buy this poorly performing asset instead of an asset that has increased in value. Although these decisions are economically equivalent, they are very different psychologically and, as a result, they lead to different wealth states.

Figure 2 shows the number of inferior asset shares investors hold across all 20 periods. For both dramatically inferior conditions, and the moderately inferior, automatic selling condition, the pattern of results is almost identical. Participants sold most of their shares in the lowest performing asset within the first three periods. By con-

trast, in the moderately inferior, standard-trading condition, participants still had most of their shares in the inferior asset at the end of the fifth period. Over time, compounding growth amplifies the importance of these early decisions.

Figure 2: Units of the Inferior Asset Held
The present research identifies a previously unidentified threat to investors – "slow sinkers" that perform moderately poorly, don't attract attention, and tend to be held for too long, dragging down the value of consumers' investment portfolios. The results of the forced-selling intervention pinpoint inaction inertia as the key psychological mechanism leading investors to hold "slow sinkers" for too long, and also identify an intervention that enhances consumer welfare by expediting the sale of investments that perform poorly without being spectacular losers.

Shape Matters: How does Logo Shape Inference Shape Consumer Judgments

Yuwei Jiang, Hong Kong Polytechnic University, Hong Kong
Gerald J. Gorn, University of Hong Kong, Hong Kong
Maria Galli, HKUST, Hong Kong
Amitava Chattopadhyay, INSEAD, Singapore

EXTENDED ABSTRACT

Brand logos, are important components of any company's identity. Previous empirical research on brand logos (e.g. Henderson and Cote 1998; Henderson et al. 2003; Janiszewski and Meyvis 2001) has primarily focused on measures related to its aesthetic appeal (e.g., how beautiful a particular logo is) and on ease of recognition. How different logo shapes influence consumers' perceptions of the company and its products is still largely unknown. This is the focus of our research.

Broadly speaking, logo designs can be classified as angular, circular, or a combination of the two. Angular shapes are those consisting of straight lines and sharp corners (e.g. a rectangle); whereas circular shapes are curved and without sharp angles (e.g. an oval). According to Berlyne (1976), angular shapes induce confrontational associations such as energy, toughness, and strength. In contrast, circular shapes induce compromise associations such as approachableness and friendliness (e.g. Liu and Kennedy 1994). We expect that the associations that a person has with an angular vs. round shape, will transfer to consumers' perceptions of objects with that shape. Regarding brand logos, we expect the associations to transfer to the brand associated with the logo. Specifically, we predict that circular brand logos have a symbolic meaning of "soft", and angular brand logos have a symbolic meaning of "hard" and hence that the symbolic meaning of "soft" and "hard" will influence consumers' perceptions of the brand and its product characteristics. We test this hypothesis in four experiments.

In experiment 1, participants were asked to give us their initial reactions towards a company and its products after viewing either a circular logo or an angular logo. As expected, participants judged the brand using a circular logo to: 1) be less tough/hard than the brand using an angular logo, and 2) more likely to be in an industry associated with softness (e.g. *Daycare Center* or *Pet Shop*) than the brand using an angular logo; the brand using an angular logo was perceived to be more likely in an industry associated with toughness (e.g. *Construction Company* or *Law Firm*) than the brand using a circular logo.

Several important product attributes are closely connected with the concept of "soft" vs. "hard/tough". Products made of soft materials are usually perceived to be more comfortable to use, for example. In contrast, products made of hard materials are usually perceived to be capable of lasting longer. Thus the second experiment examined whether different logo shapes can influence consumers' beliefs about a product's comfortableness and durability. We also tested whether the observed logo inference effect occurs through a process of misattribution, akin to the HDIF heuristic (Schwarz and Clore 1988). After seeing a shoe ad with either a circular or an angular logo, participants were either asked to explicitly report their logo-shape inferences (e.g. "The logo gave me the impression that the shoe is very comfortable/durable") before they reported their beliefs of the comfortableness/durability of the shoe, or report the shape inferences after reporting their product beliefs. We found that participants believed the product is more comfortable when the brand had a circular logo, and believed that the product is more durable when the brand has an angular logo. Moreover, consistent with the misattribution hypothesis, the effect of logo shape on product beliefs disappeared when participants were explicitly asked about their logo inferences before measuring their product beliefs.

Experiment 3 built on the first two studies by exploring the relationship between explicit verbal claims and the logo. We examine whether the consistency between the inference drawn from logo and the verbal claims leads to more favorable outcomes than when the logo shape and verbal claims are not matched. Participants were shown a shoe ad with either a circular or an angular brand logo. Also the verbal information contained in the shoe ad focused either on the comfortableness of the shoe or its durability. Consistent with expectations, the results showed a matching effect. Consumers liked the shoe more and were willing to pay more for the shoe if the logo shape inferences were consistent with the verbal information in the advertisement.

Experiment 4 attempted to expand the generalizability of our findings by showing that brand logo shapes not only influence consumer inferences about specific product attributes, but also inferences about general brand characteristics, including the behavior of company employees. Extending the idea that circular logos lead to inferences of softness to the notion that soft also implies caring, we examined whether consumers expected companies with circular logos to be more responsive to consumer needs. Participants were shown a consumption scenario– a passenger has an over-weight luggage when trying to board an airplane operated by an airline company with either a circular logo or an angular logo—and asked how likely the passenger was to be allowed to board without some penalty. As expected, participants predicted that the airline company would be more likely to allow the passenger to bring their bag on board without penalty if the company has a circular brand logo. Participants also thought that the airline company was more willing to respond to consumer needs/demands, and cared more about its customers if the brand used a circular logo.

Summarizing, we find that brand logo shapes impact both specific product attribute judgments and overall product evaluations. We show that this impact is due to a misattribution of the inference elicited by the logo shape and that it is stronger when the explicit claims are in line with the inference elicited by the logo, inferences which seem to be outside the consumers' awareness. These findings are novel and contribute to our theoretical understanding of how brand logos can influence consumers' responses to a brand. Our research has practical implications, in suggesting that companies should choose logos that have aesthetic properties that reinforce the desired image of the brand.

Predicting Consumer Preference:
Prediction Strategy and Data Presentation

Jaewoo Joo, Kookmin University, Korea

EXTENDED ABSTRACT

When designers predict consumer preference using market information, they often base their predictions on consumer preferences for similar products. This categorization-based strategy, however, can result in biased predictions because similar products are not liked equally by an individual consumer. We propose that designers should use a sequential learning strategy – making a sequence of predictions and receiving feedback after each prediction – and, for further improvement in prediction accuracy, they should make predictions with multiple data sets rather than with a single data set.

Psychologists have long argued that categorization shapes the way people use cross-category information and make predictions (Medin et al. 1993; Osherson et al. 1990). However, marketing studies suggest that these categorization-based strategies can introduce prediction bias (Shocker et al. 1990). Following a significant body of research on Multiple Cue Probability Learning (MCPL), we propose that designers make predictions more accurately when employing a sequential learning strategy (Klayman 1984; West et al. 1996). This strategy will be of particular benefit to designers when their implicit rule of categorization is incongruent with the target rule of data (West 1996).

Hypothesis 1: *Prediction accuracy is greater when designers employ sequential learning strategy than when employ categorization-based strategy.*

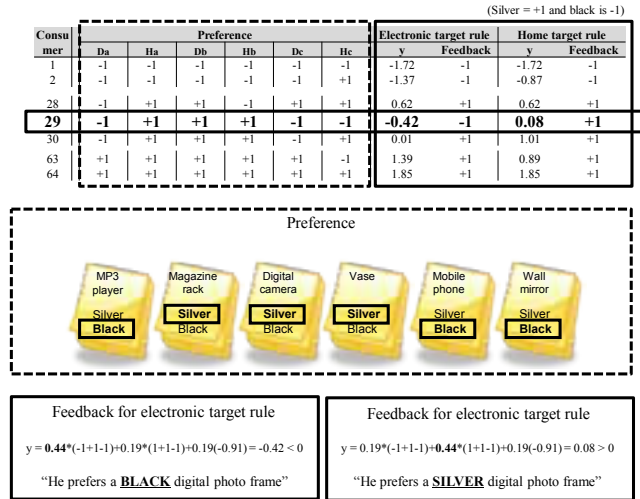
Psychologists also claim that data presentation affects learning. Research shows that when classifying randomly provided items, people often fail to form coherent abstract categories, whereas they succeed in doing so when inferring the rules that govern pre-classified items. This is because inference learners are more likely to understand the fundamental similarities among items than are classification learners (Markman and Ross 2003; Rehder and Ross 2001).

Hypothesis 2: *Prediction accuracy of sequential learning strategy is greater when data are presented in multiple sets than when presented in a single set.*

We applied a typical Multiple Cue Probability Learning experiment to a designer's preference learning task and conducted two studies to test whether prediction accuracy is the function of prediction strategy and data presentation.

STUDY 1

We created 69 preference profiles by simulating the preferences of 64 hypothetical consumers. In particular, we randomly distributed two colors, silver and black, to the six products to create 64 preference profiles ($2^6 = 64$), randomized their order, and repeated the initial five preference profiles after the end of the preference profiles, creating a set of 69 preference profiles (Figure 1).

Figure 1. An Example of Preference Profile


Subjects were instructed to select the color for a target product by predicting consumers' color preferences. They went through 69 iterations of prediction trials. They (1) were provided with one preference profile; (2) predicted which color the target consumer would prefer for a digital photo frame; and (3) were provided with feedback whether their prediction was correct.

This study consisted of a 2 (category of the target product: electronic vs. home) x 2 (target rule of data: electronic vs. home) between-subjects design. First, we manipulated the category of the digital photo frame by emphasizing its different attributes. Subjects in the electronic category condition read about the electronic attributes of a digital photo frame (e.g., supporting JPEG and BMP photo formats). Subjects in the home category condition read about its home accessory attributes (e.g., placed on a table top or hung on a wall). Next, we manipulated the target rule of data by developing two

Table 1. Prediction Accuracy Between Seqeutnial Learning Strategy and Categorization-Based Strategy (Study 1)

	When Two rules are congruent		When two rules are incongruent	
Categorization	*DIGITAL*	*HOME*	*DIGITAL*	*HOME*
Target rule	*DIGITAL*	*HOME*	*HOME*	*DIGITAL*
64 trials	80.25 (90.63)	81.35 (90.63)	80.92 (59.38)	79.58 (59.38)

* Scores in the parentheses are the simulated prediction accuracies of the categorization-based strategies

different data sets. We placed greater weight on the preference of the electronic products than of the home accessories for the electronic target rule, and a greater weight was assigned to the home accessories than to the electronic products for the home target rule.

We found that the sequential learning strategy is better than the categorization-based strategy (Table 1). When the two rules were congruent, the sequential learning strategy performed slightly poorly compared to the categorization-based strategy (electronic category + electronic target rule: sequential learning = 78.57% vs. categorization-based = 87.50%, $t(13) = 2.69$, $p < .05$; home category + home target rule: sequential learning = 74.17% vs. categorization-based = 75.00%, $t(14) = 0.29$, $p > .05$). However, it dominated the categorization-based strategy when the two rules were incongruent (electronic category + home target rule: sequential learning = 74.11% vs. categorization-based = 50.00%, $t(13) = 6.74$, $p < .01$; home category + electronic target rule: sequential learning = 79.17% vs. categorization-based = 37.50%, $t(14) = 12.34$, $p < .01$). Since designers are unable to predict whether the two rules are congruent or not, we conclude that prediction accuracy increases by 14% on average when employing the sequential learning strategy instead of the categorization-based strategy.

STUDY 2

We employed the same stimuli and the same procedures in study 1. This study consisted of a 2 (rule congruency: congruent vs. incongruent) x 2 (data presentation: single vs. multiple) between-subjects design. We manipulated rule congruency in the same way as Study 1. We manipulated data presentation by providing the identical data in different formats. Subjects in the single data set condition were asked to complete 32 prediction trials without break. In the multiple data set condition, subjects were provided with four sets of the 32 preference profiles and asked to take a break every eight prediction trials.

We found that predictions were more accurate when data were presented in multiple sets (69%) than when in a single set (59%, $F(1,154) = 20.12$, $p < .01$). This suggests that breaking down a single data set into multiple sets benefits the sequential learning strategy.

CONTRIBUTIONS

Our research contributes to the existing body of knowledge on market research and MCPL. First, previous work on market research pays significant attention to data collection without discussing data analysis (Urban and Hauser 2004; Zaltman 1997). Our work addresses this issue by demonstrating and correcting designers' mis-takes when analyzing data. Secondly, a significant body of research on MCPL has found that the performance of the sequential learning strategies may depend on contextual variables (Karelaia and Hogarth 2008; Klayman 1984, 1988). We add data presentation to the list of the contextual variables.

Should Birds of a Feather Flock Together? Navigating Self-Control Decisions in Dyads

Hristina Dzhogleva, University of Pittsburgh, USA
Cait Poynor Lamberton, University of Pittsburgh, USA

EXTENDED ABSTRACT

While the bulk of research in consumer behavior focuses on self-control tasks undertaken independently, our tendency to exercise self-control is often socially-determined. For example, a pair of friends may decide together whether to study or go to a movie. Similarly, a couple may go grocery shopping or create a household budget together. Moreover, individuals in work environments may have little choice about the self-control levels of the people with whom they need to make decisions. How will different types of dyads make these decisions together, and how can these patterns be altered?

To answer this question, we examine how different dyad types, formed on the basis of different combinations of partners' self-control levels, perform on joint self-control tasks. We examine the following dyad types: dyads containing two low self-control individuals (homogeneous low self-control), dyads composed of one low self-control and one high self-control individual (mixed self-control), and dyads of two high self-control partners (homogeneous high self-control). Our objective is to determine which dyads would lead to better self-control and what can be done to improve self-control outcomes for non-optimally-constructed dyads.

We predict that homogeneous high self-control dyads will perform better on joint self-control tasks than both homogeneous low self-control and mixed dyads. However, we propose that there will be no difference in the self-control performance of the latter two dyad types. The rationale for this proposition is based on past research that conceptualizes working with other people on a shared task as an activity that requires self-regulatory resources since it involves sacrificing individual to group interests (Baumeister and Exline 2000; Glance and Huberman 1994). Since forgoing individual for collective interests demands self-control, high self-control individuals will be more likely to do this than will low self-control individuals, for whom this would be too demanding. Therefore, within a mixed dyad, the low self-control individual will play a more determining role in the dyad's decisions, which would cause the dyad's self-control performance to be comparable to that of a homogeneous low self-control pair. However, if primed to maintain their independent mindset, we would expect high self-control individuals to decrease their likelihood to capitulate to the low self-control individuals' preference. In such cases, mixed dyads should perform like homogeneous high self-control pairs rather than homogeneous low self-control pairs.

In Experiment 1, couples (married for 1-60 years) completed a brief questionnaire. The outcome of interest was the extent to which the couple was successful at meeting long-term goals. We also asked both spouses to respond individually to the Tangney et al. self-control scale. Based on the partners' self-control levels, we categorized the couples into three types: homogeneous low self-control, mixed, and homogeneous high self-control couples. Results demonstrated that homogeneous high self-control couples were more successful at achieving long-term goals than both homogeneous low self-control and mixed couples (p=.03; p=.02). However, there was no difference between the long-term goal performance of the latter two dyad types (p=.98), which reveals that one high-self-control spouse might not be enough to ensure a couple's long-term success.

Experiment 2 replicated these findings using artificially-created dyads working on a self-control task in the lab. In this study, individuals first completed the Tangney et al. self-control scale and several filler tasks. Then the experimenter paired participants to create the three dyad types. All dyads worked on a menu selection task. The self-control measures were the amount of calories and fat in each pair's menu. Results revealed that homogeneous high self-control dyads chose menus that contained fewer calories and fewer grams of fat than did both homogeneous low self-control (p=.03; p=.02) and mixed self-control dyads (p=.06; p<.05). Nevertheless, there was no difference in the amount of calories and fat in the menus of homogeneous low self-control and mixed dyads (p =.74; p=.76). Both pairs chose equally unhealthy menus and exhibited poorer self-control than did homogeneous high self-control pairs.

Experiment 3 tested the proposed mechanism. Participants were paired based on their responses to the Tangney et al. self-control scale, included in a prescreening questionnaire. On arriving at the lab, participants were primed with independence using a sentence unscrambling task. Then, working in pairs, participants planned together their time for the upcoming week, by allocating 84 hours to time for studying, fun, and errands. The percentages of hours allocated to fun and studying were our DVs. Results showed that priming independence switched the pattern of effects observed in our first two studies, such that mixed dyads now exhibited self-control comparable to that of homogeneous high self-control pairs (p's>.70 for the two DVs). Specifically, both mixed and homogeneous high self-control dyads allocated less time for fun than homogeneous low self-control pairs (p=.01; p=.02). Similarly, these two dyad types allotted more time to studying than did homogeneous low self-control dyads (p=.02; p=.03). This experiment provides support for our proposed mechanism by showing that making high self-control individuals more individualistic led them to be the driving person of the mixed dyad's decision-making and elevated the mixed pairs' self-control performance to that of homogeneous high self-control dyads.

The present work contributes to our understanding of both dyad decision-making and self-regulation. Theoretically, we build on findings by Rick, Small and Finkel (2011), who suggest that a tendency toward mixed tightwad/spendthrift combinations in marriage leads to conflict and marital unhappiness. While our first study similarly focuses on married couples, we generalize this investigation beyond financial outcomes. Moreover, we demonstrate that mixed dyads also show general self-control lapses when created artificially and in the short-term. Finally, we illustrate the mechanism underlying these effects and how they can be reversed. These findings are also of practical importance. Many individuals who struggle with self-control place themselves in groups or "accountability pairs" in an effort to improve their behaviors. For example, Weight Watchers encourages individuals to sign up in a "buddy system," and Alcoholics Anonymous pairs recovering individuals with those who have already completed treatment. These strategies, however, may only work in certain circumstances, with appropriate reminders to maintain one's independent goals, or given a certain combination of partners' self-control levels in the dyad.

How do Adolescents Define Consumer Vulnerability? Toward A Youth-Centric Approach

Wided Batat, University of Lyon 2, France

EXTENDED ABSTRACT

Young consumer vulnerability is today regarded as an important social issue to analyze in marketing and consumer behavior literature. Researchers have focused on this topic by studying the behaviors and the main features of vulnerable groups such as homeless consumers (Hill and Stamey 1990), poor consumers (Lee et al. 1999), older consumers (Moschis 1992), disabled consumers (Adkins and Ozanne 2005), immigrant (Baker et al. 2001), low-literacy consumers (Peñaloza 1995) and younger consumers (Martin and Gentry 1997; Pechmann et al. 2005; Pechmann et al. 2011). Baker et al. (2005) have defined consumer vulnerability as "*a state of powerlessness that arises from an imbalance in marketplace interactions*". In their consumer vulnerability conceptual framework, they distinguish between actual and perceived vulnerability. However, the concept of consumer vulnerability has not been studied widely and the field lacks studies on who experiences vulnerability and what is the consumer perception of his vulnerability within the consumption context. In this perspective, today's adolescents represent an important at-risk group to focus on by consumer researchers and public policy (Pechmann et al. 2011). Because adolescents' perception of their own risks is larger than adult's reality, they do not always behave in ways that serve their own interest. Thus, they may experience vulnerability as they face difficult situations where they loose control. In other cases, adolescents underestimate the risks and engage in risky behaviors because of their perception of invulnerability. Therefore, it is important for researchers to focus more on teenage consumers who underestimate the consequences of their risky behavior. Following this logic, Transformative Consumer Researchers (TCR) suggested that future research should explore the "dark-side" of adolescent behavior by focusing on his limitation related to his inaccurate perception of invulnerability. Despite this attention, few consumer researchers have explicitly defined consumer vulnerability from the youth perspective. This has allowed the term of vulnerability to be used in different ways according to the adult perception and with a direct inadequate application to the youth subculture. The purpose of this paper is to understand on the "dark-side" of adolescent's definition of consumer vulnerability.

RESEARCH QUESTIONS

Using a youth-centric approach to consumer vulnerability in this research leads us to understand deeply through a bottom-up strategy the domains and the dimensions of consumer vulnerability as defined by adolescents aged 11-15. A comprehensive approach of the perception of vulnerability within today's adolescent subculture seems to be an urgent issue to be taken into consideration. In this study, consumer vulnerability will be studied from the adolescent's perspective through an immersion within the youth subculture. To accomplish this purpose, the objective of this research is to define the dimensions related to young consumer perception of vulnerability within the consumer society. This definition might enable Transformative Consumer Researchers and public policy to address the "dark-side" of adolescent's vulnerability via a bottom-up approach based on youth subculture rather than adult's perception.

METHOD

To investigate these aspects of youth vulnerability within the consumption context, we conducted a longitudinal ethnographic research (Wolcott 1994) for six months with a group of 20 adolescents. This ethnographic approach allowed us to delve deeply into vulnerability's meanings emerging within youth consumption subculture. Methods included participant and non-participant observations, document reviews, photographs, drawings, informal conversations and formal interviews. A grounded theory method (Strauss and Corbin 1990; Glaser and Strauss 1967) was used to explore and analyze data collected from in-depth interviews with the 20 teenagers aged 11-15 both male and female, followed by Wolcott's (1994) ethnographic conventions to interpret the data emerging from specifics transcripts, artefacts and observations of teenage subculture and youth social environment. The first approach based on grounded theory led the researcher to define themes, concepts and behaviors that were indicative of young consumer vulnerability. The second analysis method with respect to analysis and interpretation as defined by Wolcott's framework allowed us to developed patterned regularities in the data on adolescents' perceptions of consumer vulnerability and the behaviors associated with the risky behaviors.

FINDINGS

The key findings illustrate the domains and the behaviors related to teenage consumer vulnerability in a youth subculture. The results revealed six categories related to young consumer's perception of vulnerability within their youth subculture: 1) impulsivity and self-conscious, 2) incapacity of making independent and confident decisions, 3) incapacity to resist peer group pressure, 4) lack of knowledge and consumption experiences, 5) the paradox of the digital society, and 6) using risky online communities as a confident source of information. Furthermore, adolescents can experience a vulnerable situation on the basis of their consumption experiences and the way others view them in social or community settings. The teenage consumer vulnerability concept appears to be more reflexive and irrational than adult consumer vulnerability. Thus, the experience of consumer vulnerability with the youth subculture might be a deliberate as well as an imposed experience. In the first posture "deliberate vulnerability" determined by experiencing vulnerability through a risky behavior such as surfing porn websites is a desired behavior. Indeed, the main purpose of such a practice for adolescents is to transgress the rules established by adults by showing their independence and their resistance to adults' rules and policy makers. In the second case "imposed vulnerability" characterized by experiencing consumer vulnerability within the youth subculture such as purchasing brands that they can't afford is a stage within the young consumer socialization process. Consumption items are then considered as facilitator objects because they might help the adolescent to belong to a peer group by wearing the same brand. In this case, the young consumers are vulnerable because they can't control or resist the peer group pressure and consequently they involve their parents in debt problems.

CONTRIBUTIONS

This research contributes to the comprehension of explicit "imposed" and implicit "desired" dimensions of youth vulnerability within the consumption context. These ideas might change the way researchers are studying at-risk groups such as young consumers (Pechmann et al. 2011) and have several implications for both public policy and marketers targeting young consumers. Therefore, understanding the peer group influence (positive/negative) within youth consumption culture can help public policy makers to adapt

their policy to the youth target by using the peer group as a communication medium and as a tool to empower young consumers through a bottom-up approach based on youth subculture.

Focusing Attention on the Hedonic Experience of Eating and the Changing Course of Hunger and Pleasure

Jordan LeBel, Concordia University, Canada
Ji Lu, Dalhousie University, Canada
Laurette Dubé, McGill University, Canada

EXTENDED ABSTRACT

With a comparison of low- versus high-external eaters, this research examines the influence of attention focus to hedonic experience (compared to a distraction) on the change in hunger feeling and hedonic experience, as two important motivational forces, over the course of a food consumption episode.

LITERATURE REVIEW

For consumers in current sensation-rich marketing environment, various food-related, hedonic cues often override hunger and other homeostatic signals and motivate overconsumption (Loewenstein 1996; Paquet et al. 2010). Furthermore, the pleasure brought by food consumption can be enhanced/weakened by external factors, which direct/distract the attention toward/away-from the hedonic experience (Nowlis and Shiv 2005; Shiv and Nowlis 2004; Tal 2008), such as the cognitive information about food (Lee, Frederick, and Ariely 2006; Siegrist and Cousin 2009), the package image (Mizutani et al. 2010), and expectation on taste (Wansink et al. 2000). Also, the subjective experience of hunger, although is closely tied to the homeostatic signals, does not necessarily reflect the diminishing need for food during eating (de Castro and Elmore 1988). Being exposed to food-related cues, be it visual, taste or smell, can turn one's attention to the hedonic experience of consumption (Stroebe, Papies, and Aarts 2008), and can increase the hunger feeling (Nederkoorn, Smulders, and Jansen 2000).

An individual propensity that eating is easily triggered by hedonic rather than homeostatic cues is identified as external eating (Rodin and Slochower 1976), and was found to be associated with food overconsumption and obesity (Burton, Smit, and Lightowler 2007). The vulnerability to hedonic cues and the maladaptive eating behaviors demonstrated among external eaters certainly showcase the importance of "uncontaminated" hunger signals in keeping healthy eating pattern.

HYPOTHESES

Statically, enhancing one's hedonic experience can increase the hunger feeling; therefore we hypothesize that an attention focus on hedonic experience during an eating episode will translate in sustained feeling of hunger, compared to the decline expected under a distraction condition. Moreover, we expect that external eaters intrinsically tune themselves into a hedonic experience focus states during the course of food consumption. Hence, the externally imposed hunger-sustaining effects of hedonic focus should not be particularly salient for them. By the same token, we expect that a cognitive distraction compared to a hedonic focus can at least initially suppress the pleasure rating, but the pleasure suppression effect of cognitive distraction is relatively smaller for external eaters than others. We also predict that external eaters are less sensitive to hunger feeling for the motivation to continue eating, compared to low-external eaters.

METHOD

Two studies were conducted to examine the hypotheses. The procedure for these two studies is similar, except in field study (n=52), each participant received a 100 grams of chocolate bar, and they were invited to eat as much or as little of the chocolate at home within a 20 minutes period; while in laboratory study (n=85), participants were informed that they had to eat one 5-gram-square chocolate at regular intervals (for a total intake of 30g) in our laboratory. In both studies, Participants were randomly assigned to one of two attention focus conditions; one is distraction condition, and the other is hedonic-focus condition. In both conditions, participants worked on a word puzzle while eating the stimulus. In the hedonic-focus condition, participants were prompted to "set the puzzle aside momentarily. Eat the chocolate and focus exclusively on the sensations and feelings it produces in your mouth." In the distraction condition, participants were asked to keep working on the word while eating.

Before the chocolate-eating begins, participants rated their current feeling of hunger. Analyses revealed no differences on pre-consumption hunger between two conditions. Participants rated their pleasure right after the first bite of chocolate and completed the same measure again after the last bite. When they were done eating, participants rated their hunger once again. Participants also reported how much they would like to eat (desire) another piece of chocolate after their last bite. Participants were identified as high- or low-external eaters based on the median split on their external eating score, which was obtained from their responses to the Dutch Eating Behavior Questionnaire (van Strien et al. 1986).

FINDINGS

Both studies revealed that the hedonic-focus manipulation slowed down the decreasing speed of hunger feeling, compared to the condition that participants were distracted by cognitive task (interactions: ps<.03). Furthermore, results show that such hunger-sustaining effect of hedonic-focus was only salient for low-external eaters, whose homeostatic signals are less "contaminated." Also, low-external eaters' desire to continue eating was significantly predicted by self-reported hunger and pleasure (ps<.01), while high-external eaters' desire was only associated with pleasure (p<.01).

The laboratory study, which strictly controlled the consumption environment, volume, and speed, clearly demonstrated that the "immunity" to attention focus manipulation demonstrated on high-external eaters' self-reported hunger may be largely due to high-external eaters' predisposition of hedonic experience focus, which imposed a similar influence as sensory-focus experimental condition. As shown in figure 1; first, the initial impact of attention focus on pleasure was significant for low-external eating group (p<.001), whereas hedonic-focus/distraction manipulation did not impact high-external eaters first-bite pleasure. This implies that high-external eaters' predisposition effectively directs their attention to the hedonic signals therefore insensitive to the externally imposed attention focus. Second, in terms of the changing course of pleasure, high-external eaters did not experience pleasure decrease as low-external eaters did (p<.001). This suggests that the hedonic-experience focus predisposition makes high-external eaters enjoyed more hedonic experience during the food consumption than low-external eaters did.

Figure 1: First- and Last Bite Pleasure Ratings by Attention Condition and External Eating Group - Lab Study

Panel A: Low-external Eating Participants
Panel B: High-external Eating Participants
CONTRIBUTIONS

To our knowledge, this research is the first analyses on the impact of conditions that direct attention to or distract from hedonic experience on changes in hunger feeling over the course of a consumption episode. The results highlight the individual difference in the responsiveness on attention focus; external eaters tend to be more sensitive to hedonic signals rather than other internal and external signals. This pattern reveals that distracting people from hedonic experience of food, as a strategy to decrease the motivation to eat unhealthy (often palatable) food, does not necessarily work for all.

The Distributed Spirit of Consumerism:
How Consumers Inform and Defend Themselves in a Fragmented World

Dominique Roux, Université Paris-Sud, France
Corinne Chevalier, Université Paris-Sud, France
Lydiane Nabec, Université Paris-Sud, France

EXTENDED ABSTRACT

Research groups such as Macromarketing, Marketing Ethics, Consumer Economics, Public Policy and Marketing, Social Marketing, and more recently Transformative Consumer Research (Wilkie and Moore, 2012) frequently address issues related to consumer protection. However, though consumer education and rights constitute hot topics and common concerns, the way consumers inform and defend themselves in a more complex multi-actors environment remains understudied. Thus, we aim at exploring how mainstream consumers proceed, what representations they hold and types of relationships they maintain with non-profit consumer organizations (NCOs) and other competing new market actors who now contribute to the "consumerism industry" (Smith and Bloom 1984, 369). We also seek to investigate the links between individual and collective actions when addressing consumers' demands of legal remedy. This objectives take place in a context where NCOs are experiencing a decline in their influence, while social media offer new opportunities for consumer empowerment and social change (Josefsson and Ranerup 2003; Kozinets, Belz, and McDonagh 2011; Rezabakhsh et al. 2006; Umit Kucuk and Krishnamurthy 2007).

LITERATURE REVIEW

The many regulations in terms of consumer protection policy and lobbying by activist groups have led to major advances in consumer protection (Aaker and Day 1972; Barksdale and Darden 1972; Brobeck, Mayer, and Herrmann 1997; Buskirk and Rothe 1970; Day and Aaker 1970; Herrmann 1970; Rao 1998; Smith and Bloom 1984). However, the outcomes of excessive consumption as well as the recent threats of failure of the financial system have exposed the frailty of consumers faced with the corporate power of big businesses. In this gloomy context, the desired or implemented responses of the public authorities accompany growing questioning as to the state of consumerism and consumer well-being (Cohen 2010; Mick et al. 2011; Rotfeld 2010). At the same time, literature on online communities and social media (Kozinets et al. 2011), consumer resistance and empowerment (Kozinets 2002) opens more optimistic avenues as to the ability for individuals to share problems and educate one another.

METHOD

Two sets of data were used. First, in-depth interviews were conducted with 29 consumers to analyze the way they orient themselves among various informational channels and how they deal with post-purchase dissatisfaction. Informants were selected through a snowballing technique, with age, gender, socio-professional standing, and prior experience with NCOs taken into account (Lincoln and Guba 1985). The interviews focused on four themes: the types of actors and pre-purchased sources consulted; reactions to problems encountered with a company and types of actions undertaken; knowledge and representations of NCOs as well as other consumerist actors; and overall expectations in terms of information and defence. A second set of data then sought to provide a broader view of collective actions. Though class action is not legally valid in France, we conducted interviews with the main protagonists of four 'collective actions' against big firms. By 'collective actions', we mean groups of similarly situated individuals represented by the same lawyer, simultaneously bringing their case to court and sharing litigation costs. The three authors jointly developed a coding scheme for analyzing informants' discourses. This inductive process helped illuminate the various strategies consumers deploy, with whom and how.

FINDINGS

The consumers' individual discourses shed light on two main themes. The first shows the erosion of the preventive role of NCOs in a situation of informational excess and consumers' ability to orient themselves alone. Regarding NCOs, several informants question their independence, largely ignoring their way of operating. Major contradictions also emerge around possible ways of correcting NCOs image deficit. Their need to communicate to make themselves more visible implies the use of marketing techniques but comes up against the idea of the possible confusion with market actors. Regarding difficulties encountered in marketplace relationships, the findings also stress the ability of mainstream consumers to deal with companies by their own. Again, informants do not rely upon NCOs to solve their problems but, instead, try to find direct arrangements with merchants. Turning to NCOs thus appears to be a "last resort" solution when the "seriousness" of problems requires seeking help to restore equity.

The second theme finally highlights the dominant idealized view of NCOs' problem-solving capacity, ex post facto, for collective defence and prevention of abuses. Their perceived residual role consists of regulating the balance of power and defending an ideal of justice against big market actors. However, this federative role in protecting "little people" is mainly accounted by informants who never faced severe situations or who accepted to cope with poor performances of products and services. Conversely, those who decided to sue defaulting companies where not so prone to idealize NCOs' power. The second set of data illustrates how mainstream consumers become entrepreneurs of consumerism by deploying new skills to defend themselves and others.

Findings pertaining to collective actions show that hard core members of these transient defence communities first problematize the unfair situation and generate interest from other "victims". They then provide the arguments, moral support, skills and material devices to build support-based networks through communal websites (Kozinets et al. 2011). The second stage illuminates how they subsequently succeed in enrolling additional agents such as media, lawyers, private or institutional ombudsmen, political leaders, and NCOs. It shows that larger networks prove to be more successful in spreading influence far beyond the online community.

CONTRIBUTIONS

Our research challenges the more or less pessimistic predictions as to the survival of consumerism (Cohen 2010; Rotfeld 2010) in showing that it spirit and practices are distributed on multiple actors and enacted by new means that bring empowerment to isolated individuals. In line with Kozinets et al. (2011), the findings bring evidence of the emergence of support-based online communities that organize collective defence and actively struggle against unbalanced marketplace power. But they extend previous research in showing that these communities overstep their own limits by enrolling new actors and building powerful though ephemeral networks.

The Red Sneakers Effect: Inferring Status from Signals of Nonconformity

Silvia Bellezza, Harvard Business School, USA
Francesca Gino, Harvard Business School, USA
Anat Keinan, Harvard Business School, USA

EXTENDED ABSTRACT

We examine the inferences observers make based on individuals' nonconforming behaviors (e.g., not complying with a certain dress code). Research in social psychology, sociology, and consumer behavior demonstrates the benefits of conforming to group norms and expectations (Dittes and Kelley 1956; Phillips and Zuckerman 2001; Wang et al. 2012)2 different norms were developed: one concerning a social value judgment; the other, a simple perceptual judgment. The Ss were experimentally made to feel different degrees of being accepted by the other members and were then given opportunities and incentives to deviate from the norms. Subsequent conformity, participation, and attitudes toward the group were studied in relation to the different conditions of acceptance. The results point to 2 contrasting patterns of conformity evolved by different conditions of acceptance. The first appears to consist of a high degree of genuine adherence to the norms\u2026 . The second pattern is marked by high conformity only under public conditions.\"", "author" : [{ "family" : "Dittes", "given" : "James E." }, { "family" : "Kelley", "given" : "Harold H." }], "container-title" : "The Journal of Abnormal and Social Psychology", "id" : "ITEM-3", "issue" : "1", "issued" : { "date-parts" : [["1956"]] }, "page" : "100-107", "title" : "Effects of different conditions of acceptance upon conformity to group norms", "type" : "article-journal", "volume" : "53" }, "uris" : ["http://www.mendeley.com/documents/?uuid=459ecb6e-f9ef-4f2d-b1b7-bc23eb26531a"] }], "mendeley" : { "previouslyFormattedCitation" : "(Dittes and Kelley 1956; Phillips and Zuckerman 2001; Wang et al. 2012. In this research we argue that under certain conditions, nonconforming behaviors, such as entering a luxury boutique wearing gym clothes rather than an elegant outfit, or wearing red sneakers in a professional setting, can be beneficial and signal a higher status.

High-status individuals generally feel confident about their social acceptance. Unlike lower status individuals, high-status people are more likely to deviate from conventional behavior and common expectations about appropriate responses other people might have (Hollander 1958). For instance, CEOs of major corporations, such as Bill Gates (Microsoft) or Mark Zuckerberg (Facebook), often appear without ties or wear sweatshirts at interviews or formal gatherings like the World Economic Forum. In this research, we focus on the perspective of external observers and investigate when nonconforming behaviors may lead to inferences of higher status.

We propose that inferences of status demand that the observer is aware of the norms of appropriate behavior in the group to which the individual belongs and that the context is prestigious. Our investigation of underlying mechanisms reveals that the inference of status from signals of nonconformity is mediated by perceived intentionality and moderated by individual differences in need for uniqueness (Snyder and Fromkin 1977).

A series of lab and field studies explore responses to a variety of nonconforming behaviors in different settings. In an effort to ensure high external validity of our findings, all our studies are preceded by interviews and pilots to explore the expected behavioral norms in specific environments and to confirm that higher status individuals in these contexts tend to deviate from such norms.

Study 1 examines responses to descriptions of potential prospects by shop assistants in luxury boutiques in downtown Milan. As was confirmed in interviews with store managers of luxury boutiques in Italy, the accepted norm for shoppers at these high-end stores is an elegant outfit that fits the store's atmosphere. In this study, we manipulated between-subjects the descriptions of a client (non-conforming vs. conforming) entering the store, and compared reactions of shop assistants to those women not familiar with the norm who were recruited in Milan's central station. Shop assistants in luxury boutiques have an economic incentive to learn how to interpret the unconventional behavior of their prospects. Thus, we predict they will infer higher status from signals of nonconformity.

In particular, in study 1a the prospect entering the store was described as wearing gym clothes and a jacket (non-conforming), or wearing an elegant dress and a fur (conforming). We find that shop assistants of luxury boutiques perceive a client as wealthier and more likely to buy when she is wearing gym clothes, rather than elegant dresses. Respondents indicated that these poorly dressed shoppers are often "playing a role and doing it on purpose." They mentioned that "wealthy people sometimes dress very badly to demonstrate superiority", and that "if you dare enter these boutiques so underdressed, you are definitely going to buy something". In contrast, women recruited in Milan's central station perceived the shopper with the elegant outfit as a higher-status individual.

In study 1b we operationalize nonconformity through usage of well-known brand names. The prospect entering the store was described as wearing flip-flops and a Swatch watch on her wrist (nonconforming), or elegant sandals with heels and a Rolex (conforming). Again, we find that boutique assistants attribute higher status to the nonconforming individual, whereas people not acquainted with these boutique shoppers attribute higher status to the conforming individual.

In studies 2 and 3, we examine the effect of non-conforming on another dimension and test students' responses to the nonconforming dress-style of their professors. In these studies, we recruited students who could ensure that our sample is familiar with the experimental stimuli manipulated (i.e. descriptions of professors). In a pre-test with students we confirmed that participants perceive the majority of their professors to dress more formally (i.e. professional / business attire), rather than informally (i.e. wear t-shirts). Furthermore, in a pilot study conducted at the ACR conference in 2011, we provided evidence that in this environment high status individuals tend to deviate from the norm. We find a significant negative correlation between formality in clothing style and the number of publications in top journals. Individuals who are well-published were more likely to wear an informal or unusual outfit or clothing item (e.g., wearing jeans, red sneakers, or t-shirts) rather than a professional / business attire (e.g., a button-down shirt).

In study 2 we demonstrate that undergraduate students perceive a male professor who wears a t-shirt and is not shaven as having higher status than a professor who wears a tie and is shaven, but only when the professor teaches at a top school, i.e. the context is prestigious. These inferences of status are mediated by participants' perceived intentionality of the individual's nonconforming behavior. Participants who judged the professor to have higher status when his behavior was nonconforming rather than conforming also believed that the nonconforming professor was purposely deviating from the accepted norm of appropriate behavior in an attempt to distinguish himself.

In study 3, we find that when a specific nonconforming behavior becomes the norm, then the inference of higher status disappears. Participants did not infer higher status when they were told that wearing a t-shirt to school was the accepted norm in the professor's department.

Finally, in study 4 we examine nonconformity in the presentation style of participants in an entrepreneurship competition. We show that inferences of status are moderated by need for uniqueness (Snyder and Fromkin 1977).

Taken together, these results identify a counterintuitive strategy for gaining status in the eyes of others: rather than dressing up and adhering to norms, one may instead need to adopt nonconforming behaviors.

Growing with Love:
Priming Attachment Security Enhances Exploratory Consumer Behaviors

Yuan-Yuan Li, KU Leuven, Belgium
Sabrina Bruyneel, KU Leuven, Belgium
Luk Warlop, KU Leuven, Belgium

EXTENDED ABSTRACT

Love is one among very few topics that have fascinated people across all times and cultures. Marketers often use reminders of love to decorate their stores, to package products, and to organize promotion campaigns. We know very little, however, about how cueing loving relationships might affect consumer behavior. In this paper we explore the impact of a specific consequence of love primes, namely feelings of attachment security, on exploratory consumer behavior.

Attachment is the innate tendency to form strong emotional bonds with particular individuals and to seek proximity to these individuals when distressed (Feeney and Van Vleet 2010). Attachment security is developed early in life, through initial interactions with significant others who are available and supportive in times of need (Bowlby 1973). It guarantees that offspring will maintain proximity to caring attachment figures in times of need, and thus enhances chances of survival, reproduction, and parenting (Bowly 1982). Feelings of attachment security become internalized in a working model of attachment, and generalize to other important relationships that come into existence later in life (Bowlby 1973).

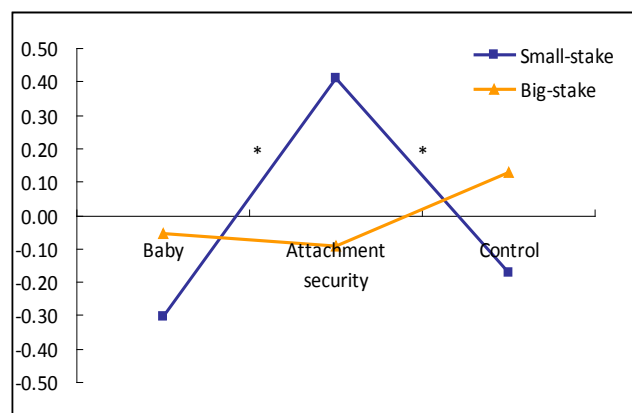
Attachment and exploration are believed to be tightly intertwined (Bowlby 1988), but empirical evidence has been lacking (Shaver and Mikulincer 2010). Exploration is the urge to go out in the world to work, play, discover, and create (Feeney and Van Vleet 2010). It has been argued that being securely attached gives individuals the confidence and courage to explore the environment, accept challenges, and take risks (Bowlby 1988; Feeney and Van Vleet 2010). As risk taking and variety seeking are two prominent manifestations of exploratory tendencies in consumer behavior (Raju 1980; Steenkamp and Baumgartner 1992), the present paper aims to explore whether priming consumers with attachment security enhances financial risk taking and variety seeking.

In Study 1, we demonstrated that attachment security enhanced variety seeking. 43 participants (Mage=18.42, SDage=.59; 22 males) were randomly assigned to one of two story writing conditions, and were instructed to imagine and describe an interaction with "someone who takes good care of you and who is there for you whenever necessary" (attachment security condition) or "a mere acquaintance" (control condition). Then they chose four scoops of ice-cream out of five flavors. Choosing more flavors indicates more variety seeking. Attachment security indeed increased variety seeking (F(1, 38)=4.75, p<.05).

In Study 2, we replicated the effect of attachment security on another exploratory consumer behavior, namely risk taking. Participants (N=54; Mage=21.76, SDage=2.03; 17 males) were randomly assigned to one of two story writing conditions, and were instructed to imagine and briefly describe a walk with someone they felt attached to (attachment security condition) or alone (control condition). Afterwards, all participants completed two sets of seven monetary risk preference questions, one small-stake and one large-stake set (Hsee and Weber 1999). For example, they indicated their preference between "receiving €30 for sure" and "flipping a coin; receiving €100 if Heads or €0 if Tails". The risk preference index for each participant ranged from 1 (extremely risk-aversive) to 8 (extremely risk-taking). We found a significant interaction between attachment security priming and stake size on financial risk taking (F(1, 51)=6.24, p=.02).

Specifically, when stakes were small, risk taking was higher in the attachment security (MRP=4.04, SDRP=.28) compared to the control condition (MRP=3.26, SDRP=.29; see Figure 1).

Figure 1: Study 2
In Study 3, we replicated the effect of attachment security on financial risk taking for small financial gains, but not for large gains or losses. Participants (N=115; Mage=21.38, SDage=2.33; 49 males) were randomly assigned to one of three picture evaluation conditions. They evaluated ten pictures of mothers holding babies (attachment security condition), babies (baby condition), or landscapes (control condition). Afterwards, they provided certainty equivalents for various uncertain gambles (50% chance of gaining [losing] €4 [€2000] or 50% chance of gaining [losing] €0) (Abdellaoui, Bleichrodt et al. 2008). In the gain domain, the interaction between stake size and attachment security was replicated (F(2, 56)=2.92, p=.06). When the risk was small, participants primed with attachment security stated larger certainty equivalents than those in the baby priming (p=.03) and control condition (p=.05), meaning they were more risk taking. However, when the risk became larger, the effect disappeared (ps>.48)(See Figure 2). We found no significant effects in the loss domain.

Figure 2: Study 3


It has been shown that decision-makers prefer options with 100% of winning $W over uncertain options with P% of winning a higher prize $J and (1-P)% of winning $0, even if these two options have the same expected utility (U=W=P*J) (Tversky and Kahneman 1992). Both feelings of security (captured by the size of $W) and optimism (captured by the probability to win) may drive risk taking behavior. In Study 4, we employed two decision tasks to explore the underlying mechanism. Participants (N=44; Mage=21.82, SDage=5.69; 22 males) were randomly assigned to either the same attachment security or control treatments as in Study 2. Then they engaged in two decision tasks (p-game & w-game) in a random order (Demaree, Dedonno, Burns, and Everhart 2008). In the p-game, the wager was fixed, and the probability to win was changeable to participants (0-100%). The lower probability to win was accompanied by a higher prize. In the w-game, the probability was fixed, and participants could decide on the wager (0-50€). A higher wager was accompanied by a higher prize. Both small and large risks were included. We found a significant interaction between stake size and attachment security in both w-game (F(1, 42)=3.59, p=.065) and p-game (F(1, 42)=5.09, p=.03) (See Figure 3). When stakes were of a moderate size, attachment security enhanced risk taking in both p-game (p=.001) and w-game (p=.06). However, we found no effect when stakes were extremely small.

Figure 3: Study 4
In conclusion, we demonstrate that attachment security enhances exploratory consumer behaviors in the form of variety seeking and risk taking for financial gains at acceptable levels of risk. Preliminary evidence suggests that both optimism towards the environment and feelings of security drive this effect.

Low Batteries Make You Greedy: The Effect of Product States on Human Behavior

Zoey Chen, Georgia Institute of Technology, USA
Nicholas H. Lurie, University of Connecticut, USA

EXTENDED ABSTRACT

Humans depend on resources to survive and reproduce. Historically, those who successfully competed for resources thrived while those who failed languished. Although most residents of developed economies no longer struggle for basic resources, such as food and shelter, they are increasingly reliant on technological products such as cell phones and laptop computers for work and maintaining social relationships. An important characteristic of these products is that they take on different transitory states as they are used. For example, a cell phone will be in a full state after charging overnight but will lose its charge after usage.

We propose that product states act as resources that affect human behavior. Specifically, we predict that exposure to a low product state (i.e., a low battery) leads to behavior consistent with resource scarcity. Building on research showing that scarcity in one resource domain increases resource seeking behavior in other domains (Briers et al. 2006; Nelson and Morrison 2005), we theorize that exposure to a low product state will increase acquisition of other, more basic, resources such as money and food. In addition, since resource scarcity precipitates coping behaviors to boost self-concept (Hobfoll 1989), we predict that exposure to a low product state will also increase performance on cognitive tasks since this boosts self-concept (e.g., I did well, therefore I'm smart, Skaalvik and Hagtvet 1990). However, when a low product state is actively being restored (i.e., by plugging the product in) thereby removing the threat to resources, the effect of a low product state on enhancing cognitive performance should diminish.

STUDY 1: MONEY HOARDING

In Study 1, we exposed people to low versus full product states and measured money hoarding behavior using the dictator game (Bolton, Katok, and Zwick 1998; Fehr and Camerer 2007).

Participants from an online forum completed the study for pay. They were told the study was about attitudes towards cell phones. Participants were asked to imagine they owned an iPhone and were presented with two images of "their iPhone." The first image showed either a fully charged (i.e., full product state) or nearly drained (i.e., low product state) iPhone battery and the second image showed an iPhone home screen displaying different iPhone applications (see Figure 1). Consistent with the cover story, participants were asked questions about the iPhone's design (e.g., design, readability, etc.). Then, participants were told that there was a fixed bonus to be split with another participant, and were asked to indicate how much of the bonus they would keep for themselves. Participants were then debriefed and paid both the fixed fee and the bonus they requested.

Confirming our predictions, participants exposed to a low product state took more of the bonus money for themselves than those exposed to a full product state.

STUDY 2: FOOD HOARDING

Study 2 examines whether a product's state also affects food hoarding. Participants from an online forum completed the study for pay. The first half of the study was identical to Study 1, in which participants viewed screenshots of an iPhone (that was either in a full or low product state) and rated the iPhone on design. Participants were then asked to imagine a shopping scenario in which they were offered chocolate biscuit samples. They were then asked how many samples they would take.

Consistent with Study 1, those exposed to a low product state took more biscuit samples than those exposed to a full product state.

Figure 1
Product State Manipulation in Studies 1 and 2

Full Product State

Low Product State

STUDY 3: COGNITIVE PERFORMANCE

In Studies 3 and 4, we test the idea that exposure to low product state will increase cognitive performance, since resource scarcity increases the desire for positive self-view (Hobfoll 1989) which—in turn—can be enhanced through superior performance on cognitive tasks (Newman 1984).

Undergraduate students completed the study for course credit. In the first part of the study, participants played a game on iPod Touches where we manipulated product state by placing a translucent image of a battery icon into the background of the game. The battery icon either stayed full or started off full and then slowly drained throughout the game, ending in a low product state. Then, iPods were taken up by the experimenter and participants participated in a

seemingly unrelated study that involved solving anagram puzzles on desktop computers.

Supporting our predictions, those who interacted with an iPod in a low product state showed higher cognitive performance (i.e., solved more anagrams) than those who interacted with an iPod in a full product state.

STUDY 4: RESTORING PRODUCT STATES

Restoring a product that's in a low product state (i.e., plugging in a low battery product) should reduce the need to compensate for low resources by enhancing self-concept (Hobfoll 1989). This should, in turn, lower cognitive performance relative to being unable to restore a low-state product.

Undergraduate students completed the study for course credit. As in Study 3, participants first played a game on the iPod Touch. Since the manipulation of product state in Study 3 may be perceived by some as too heavy handed, in Study 4 we relied on the iPod's default battery display. All iPod Touches were in a low product state condition (i.e., charged to 1/3 full) and half of the participants were asked to charge their iPods during the game. After playing the game, participants completed an ostensibly unrelated proofreading task. Cognitive performance was measured as the number of errors correctly identified.

Supporting our prediction, those who were not able to charge their iPods showed significantly better performance on the proofreading task than their charging counterparts. In addition, there was no significant difference in the false detection rates or mood for the two groups, suggesting that difference in performance was not driven by differences in the criteria participants used to identify errors.

GENERAL DISCUSSION

To our knowledge, this is the first study that looks at how dynamically changing product characteristics affect consumer behavior. Our research suggests a broader definition and interaction of resources relevant to human behavior.

Measuring Arousal in Consumer Research: A New EDA Signal Processing Method

Mathieu Lajante, University of Rennes 1, and Center for Research in Economics and Management, France
Olivier Droulers, University of Rennes 1, and Center for Research in Economics and Management

EXTENDED ABSTRACT

A careful reading of the literature has identified several processing methods of the EDA signal in consumer research. Recommendations are proposed and illustrated in an empirical study which shows that the application of new EDA signal processing techniques improves the valuation of work in consumer research.

For thirty years now, research in consumer behavior has included the measurement of skin conductance response (SCR) in the evaluation of « activation » component of an emotional episode (arousal) (Kroeber-Riel 1979). This electrophysiological index is commonly used in marketing (Micu and Plummer 2010; Ohme et al. 2009 ; Peacock, Purvis, and Hazlett 2011) since its recording technique is reachable, provided you follow some basic rules and have the proper equipment. Furthermore, electrodermal activity (EDA) is an electrophysiological signal like EEG or EMG which requires a rigorous processing before any data interpretation. However, if the interest of marketing researchers in EDA seems certain, what about the processing and interpretation of the signal?

The review of marketing literature identifies three methods for SCR measurement, which is understood as the physiological index of arousal. The first method is based on comparing the overall level of EDA according to experimental conditions (Peacock et al. 2011). This approach is unsatisfactory because it ignores the signal properties of the EDA, which are composed of a tonic activity (baseline) and a phasic activity (SCR). Indeed, measuring the overall level of EDA does not distinguish the tonic activity from the phasic activity, nor identify significant SCR following the occurrence of a stimulus. The second method is based on comparing the average level of EDA before stimulus presentation (baseline) and the average level of EDA during the stimulus presentation (Lang et al. 1999). This approach is problematic because it ignores the SCR time course, thereby causing confusion with the tonic activity and the phasic activity, depleting the information by removing the number of SCR appeared during stimulus presentation, and most importantly removing the spatial (amplitude) and temporal (duration) information of SCR. The third method is based on comparing of the EDA baseline with the sum of the SCR peak amplitudes (Groeppel-Klein 2005). This approach is questionable because it focuses solely on the spatial dimension of SCR and ignores its temporal dimension. However, two of the same SCR amplitude may have different time values.

Moreover, the main focus should be placed on the inherent limitation on the temporal properties of SCR. These properties are characterized by a deflection (1/3sec), followed by a steep slope to a peak (1/3sec) which thereafter slowly declines in the recovery phase (Boucsein 2012). Due to the fact that the rise time of SCR is always shorter than the recovery time, the appearance of several SCR in restricted time interval generates an overlapping phenomenon. Furthermore, this overlapping phenomenon results in an underestimation of the latency and amplitude of subsequent SCR, thus biasing the interpretation of results. To our knowledge, the marketing literature to date has ignored this phenomenon.

However, recent authors in psychophysiology have presented several significant methodological advances in the field of EDA signal processing. For example, the toolbox Ledalab (www.ledalab.de) developed by Benedek and Kaernbach (2010a, 2010b) is based on a signal deconvolution that responds to enacted issues. This method treats the waning asymmetric SCR, fixes the overlapping phenomenon and optimizes the accuracy of SCR time markers calculation (start/end). Several indices of EDA property can be calculated; most importantly the integral of SCR (ISCR). This index should be emphasized because many authors consider that the calculation of the integral as an optimal solution for evaluating the arousal. With that said, it integrates both the spatial and temporal dimensions of SCR (Benedek and Kaernbach 2010a, 2010b).

Therefore, we created a study to assess arousal caused by exposure to seven national brand television commercials (Coca-Cola, McDonald, Nikon, Spa, Pantoloc, Philadelphia, Bose; t=30sec) using the toolbox Ledalab for the first time in marketing. 30 right-handed subjects (22 women) participated in the study in exchange for a fee (15 euros). Each subject had two 10mm Ag-AgCl electrodes prepared with an isotonic paste, which were placed on the medial phalanges of digits II and III of the non-dominant hand. Electrodes were connected to a wireless preamplifier which then forwarded the signal to an amplifier coupled to data acquisition software (MP150, Biopac System, Inc., Goleta, CA). The signal downsampled offline at 10Hz was analyzed with Ledalab V3.2.3 (Benedek and Kaernbach 2010a, 2010b).

We observed a significant variability of results based on the evaluation index of arousal. With our observations, we realized that the first index (mean EDA) does not distinguish a significantly different level of arousal of a commercial to another. The second index (SCR amplitude) distinguishes a significantly different level of arousal between the commercials "Spa" versus "Nikon" (p=.01) and "Spa" versus "Bose" (p=.03). Finally, the third index (ISCR) can distinguish a significantly different level of arousal between the commercials "Spa" versus "Nikon" (p<.01), "Spa" versus "Bose" (p=.002), "Spa" versus "Philadelphia" (p=.01) and "Spa" versus "Pantoloc" (p=.02).

In conclusion, we show that the choice of the evaluation index of arousal leads to different results. Most importantly, our study highlights the importance of the signal processing phase to reach major academic conclusions, as well as robust managerial recommendations in marketing research which mobilizes the EDA recording. Based on our observations, we advocated more transparency in the methodological choices made in terms of EDA signal processing. Additionally, it seems essential to communicate the three indices – mean, amplitude, ISCR – and justify the choice of index used for data interpretation. Overall, beyond identifying the methodological limitations inherent of EDA signal processing, our results demonstrates the usefulness of both the signal deconvolution method by Benedek and Kaernbach (2010a, 2010b), and the ISCR as a robust index for evaluating arousal.

When Making it Easy Leads to Working Harder:
The Effects of Popularity Cues on Consumer Decision Making

Erin Younhee Ha, University of Illinois at Urbana-Champaign, USA
Tiffany Barnett White, University of Illinois at Urbana–Champaign, USA
Robert S. Wyer, Chinese University of Hong Kong, Hong Kong

EXTENDED ABSTRACT

Consumers are often assumed to use consensus cues (e.g., cues indicating a product's popularity) as a heuristic to reach conclusions about products' desirability without carefully considering specific information about a product's attributes (Burnkrant and Alain 1975; Salganik et al. 2006; Shugan 1980; West and Broniarczyk 1998). Moreover, decision complexity is typically assumed to increase the use of consensus information and, correspondingly, to decrease attention to product attribute information (Gino and Moore 2007; Johnson et al. 1988; Shugan 1980).

In fact, however, these assumptions may not always hold. We investigated the circumstances under which product popularity *increases* the tendency to process product attribute information and consequently leads to more confident decisions and a higher likelihood of purchasing unpopular as well as popular items. We propose that product popularity can increase consumers' consideration of attribute information when they perceive a gap between what they know about the product category in general and what others seem to know about the specific product being promoted. This gap in their knowledge increases the consumers' epistemic curiosity (Loewenstein 1994) and consequently increases their attention to attribute information and the influence of this information on judgments.

We further show that consumers' epistemic curiosity (and thus their attention to attribute information) is greater when a large number of unfamiliar options are presented with popularity cues, and thus the gap in their knowledge is more apparent. It also depends on consumers' perceptions of their expertise in the product domain in question. If consumers consider themselves to be novices in this domain, they may use popularity cues to reduce their uncertainty about their decision, leading to greater conformity and less attention to the available attribute information. When people believe that they are knowledgeable about a product, however, they tend to be sensitive to the gap between their general knowledge and others' knowledge about the particular product. Consequently, they are curious about the reasons for the others' judgments when consensus cues are provided, and are more motivated to process attribute information in this condition, leading the information to have greater influence on their judgments than it would in the absence of consensus cues.

EXPERIMENT 1

Experiment 1 used a 2 (assortment size: large vs. small) × 2 (presence of cue: no-cued vs. popularity-cued) between-subjects design. Relatively unfamiliar cheesecakes were used to construct two sizes of assortment (6 vs. 24 options). The names and descriptions of each cake were provided in all conditions. In *popularity-cue* conditions, however, half of the items in each assortment size condition were cued with three people-shaped icons. After viewing the product list, participants chose the option they would be most likely to buy and reported their intention to purchase it, the extent to which they had considered the descriptions, their choice confidence, and choice difficulty.

As we expected, the effect of popularity cues depended on the assortment size. When the size of the assortment was large, participants were significantly more willing to purchase the item they had chosen when popularity cues had been provided than when they had

not (6.20 vs. 5.48, respectively). In addition, they reported giving relatively more consideration to product descriptions (6.40 vs. 5.70) although their decision difficulty and level of confidence did not differ. When the assortment size was small, however, no effects of popularity information were evident.

EXPERIMENT 2

The design and procedure used in Experiments 2 and 3 were similar to those in Experiment 1, but the focal product category was wine in Experiment 2 and beer in Experiment 3. Experiment 2 focused on the effect of popularity cues on participants' level of deliberation. Consistent with Experiment 1, participants who were confronted with a large assortment reported greater intentions to purchase the product they had chosen when popularity cues were provided than when they were not (4.78 vs. 4.48, respectively) and were more confident of their choice in the former condition (7.54 vs.6.56, respectively). More important, however, they reported deliberating over the wine descriptions to a significantly greater extent when popularity cues were provided than when they were not (6.57 vs. 5.56, respectively) and spent more time making choices in the former condition (102.45 vs. 81.65, respectively). None of these differences were evident when the assortment size was small.

EXPERIMENT 3

Experiment 3 provided more direct evidence of the mediating influence of curiosity and also the moderating role of perceived product knowledge. Participants were classified as having high or low perceived knowledge about beer based on their self-reports (5.21 vs. 1.80, respectively). As expected, knowledgeable participants who had been exposed to a large assortment reported being more curious when popularity cues were provided than when they were not (3.07 vs. 2.65, respectively). Moreover, they reported considering attribute information to a significantly greater extent (8.64 vs. 7.33, respectively) and wanted additional product descriptions (7.64 vs. 6.92). When the assortment size was small, however, the opposite was true: these participants felt *less* curious when popularity cues were provided than when they were not (2.65 vs. 3.35, respectively), were less likely to consider attribute information (7.92 vs. 8.46, respectively) and were less likely to want more product information (5.46 vs. 7.38, respectively).

In contrast, less knowledgeable participants who received a large assortment showed *less* curiosity when popularity cues were provided than when they were not (2.06 vs. 2.70, respectively) and considered less attribute information in the former condition than in the latter (6.89 vs. 9.90).

Taken together, the results confirm that when participants are knowledgeable about the product domain, popularity cues lead to deliberative processing of attribute information. That is, popularity cues lead to heuristic processing only when participants have little knowledge about the type of products they are considering (word count: 936).

How does Power Affect the Evaluations of Luxury Brand Extensions?

Youngseon Kim, Central Connecticut State University, USA
Yinlong Zhang, University of Texas at San Antonio, USA

EXTENDED ABSTRACT

Existing research on brand extensions indicates that luxury brands have a greater extendibility than non-luxury brands (Monga and John 2010; Park, Milberg, and Lawson 1991). For example, luxury brands such as Rolex can be more successfully extended into dissimilar categories than non-luxury, functional brands such as Timex (Park et al. 1991). Little research has been devoted to explaining the differential extendibility across luxury brands. For instance, luxury brands such as Louis Vuitton have been successful in the market through brand extensions, whereas luxury brands such as Pierre Cardin have failed after brand extension efforts. How can we explain this variation of brand extendibility within luxury brands? The current research aims to provide an answer to this question.

Past brand extension researchers have investigated the role of a variety of brand-related factors that affect an extension success (e.g., perceived fit with the parent brand, Ahluwalia 2008; Keller 2002); however, the role of consumers' power states has never been explored. Given the central role that power states play in determining consumer attitudes toward luxury products (Rucker and Galinsky 2008, 2009), we argue that power states will affect consumer evaluations of luxury brands' extensions. Following Rucker and Galinsky (2008, 258), we define power as "the capacity to control resources and outcomes, both one's own and that of others." We define broad extensions as a large range of extended products, that is, brand extensions into different categories from a parent brand regardless of the level of fit. We define narrow extensions as a small range of extended products, that is, brand extensions into similar categories from a parent brand. A pretest indicated that broad versus narrow extensions are independent from vertical versus horizontal extensions.

Powerful consumers have a desire to communicate their relatively exclusive association with status symbols (Berger and Ward 2010; Han, Nunes, and Drèze 2010). Because luxury brands with narrow (vs. broad) extensions are perceived as relatively scarce and exclusive (Kirmani, Sood, and Bridges 1999), we propose that:

Hypothesis 1: *Powerful consumers (vs. powerless consumers) will show a stronger preference for luxury brands with narrow (vs. broad) extensions.*

If the effect of power on luxury brand extension preference is due to powerful consumers' desire to show their exclusive association with scarce resources as a status symbol, this effect will be stronger when consumers are in a competitive (vs. non-competitive) mindset. This tendency occurs because a competitive mindset induces a desire for a higher status (Kawada et al. 2004). In other words, people try to maximize position gains and compete for a higher status when social competition goals are activated (Griskevicius et al. 2009; Ordabayeva and Chandon 2011). Therefore, powerful consumers' desire to communicate their exclusive social position tends to be stronger. Formally:

Hypothesis 2: *The impact of power on luxury brand extension preference will be significant only when consumers are in a competitive (vs. non-competitive) mindset.*

To further test the underlying process, we investigated the role of public vs. private consumption. Public (vs. private) consumption induces a strong desire for self-presentation (Goffman 1959). Consumers are more likely to engage in variety seeking behavior to show other consumers that they are interesting to be with when their consumption is public (vs. private) (Ratner and Kahn 2002). In addition, individuals with fashion knowledge show a stronger preference for subtle signals in public consumption than in private consumption (Berger and Ward 2010). Accordingly, we propose that the two-way interaction between power and a competitive mindset will be stronger under public (vs. private) consumption because one's status should be noticed by others. More specifically:

Hypothesis 3: *Public (vs. private) consumption will make the interactive effect of power and a competitive mindset stronger.*

Experiment 1 was a one factor between-subjects design in which we manipulated power by asking participants to recall a past event in which they were powerful or powerless (Galinsky, Gruenfeld, and Magee 2003). After reading a description of luxury brands with narrow, vs. broad, extensions, participants indicated their attitudes toward two different brand extensions. The results showed that powerful participants preferred brands with narrow (vs. broad) extensions more than powerless participants ($p < .05$). A meditational analysis indicated that the power effect was driven by the association between high status and narrow luxury brand extensions.

Experiment 2 was a 2 (powerful vs. powerless) x 2 (competitive vs. non-competitive mindset) between-subjects design. The power manipulation was the same as experiment 1. Following the power manipulation, we manipulated a competitive or a non-competitive mindset (Griskevicius et al. 2009). After that, participants were asked to report their attitude toward luxury brands with narrow, vs. broad, extensions. We found that powerful participants liked the narrow (vs. broad) extensions more than powerless participants only when they were in a competitive (vs. non-competitive) mindset ($p < .05$); however, a difference was not found in the non-competitive mindset condition ($p = .27$).

Experiment 3 was a 2 (powerful vs. powerless) x 2 (competitive vs. cooperative mindset) x 2 (public vs. private consumption) between-subjects design. The manipulations of power and competitive mindset were the same as those in experiment 2, but the manipulation of non-competitive mindset was replaced with cooperative mindset for a cleaner contrast. The public vs. private consumption was based on Berger and Ward (2010). We found a significant three-way interaction: the two-way interaction between power and competitive mindset was significant for the public consumption ($p < .05$), but not for the private consumption ($p = .42$). The two-way interaction of power and competitive mindset was of the same nature as that in experiment 2: powerful participants preferred luxury brands with narrow extensions more than powerless participants; this effect was significant for the competitive mindset but not for the cooperative mindset.

Our results provide a possible theoretical explanation for the inconsistent results of brand extensions of luxury brands: Consumers' power states influence the range of extensions that luxury brands can achieve.

Modelling Everyday Consumer Behavior: The Case of Restricted Consumption

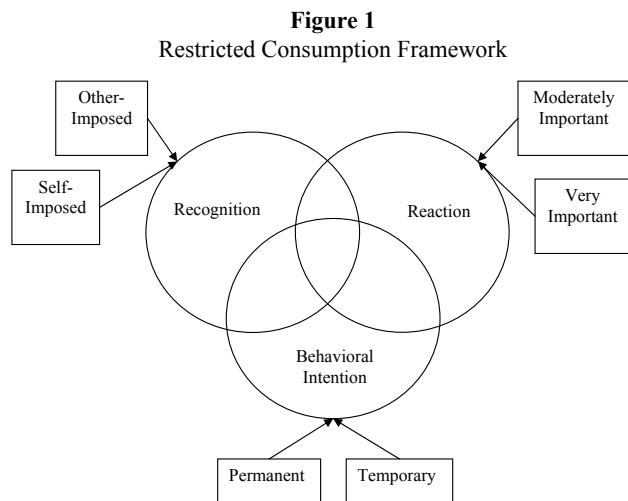
Justine Rapp, University of San Diego, USA
Ronald Paul Hill, Villanova University, USA
Donald Lehmann, Columbia University, USA

EXTENDED ABSTRACT

Despite our needs and desires, many consumers face a number of restrictions to acquisition and consumption of marketed commodities. While a majority of the restriction literature highlights subsistence populations (see Andreasen 1975; 1993; Hill 2002; Hill and Gaines 2007), marketplace restrictions also arise from nonfinancial sources, such as illiteracy and physical impairment (see Baker et al. 2005; Viswanathan, Rosa, and Harris 2005). Yet, little has been done to understand everyday consumer behavior based on the premise of restricted consumption as part of our material landscape. Thus, we seek to comprehend how consumers recognize restrictions, their subsequent affective reactions, and any behavioral aftermath, emphasizing support for theory development on our everyday decision making and consideration of the larger sociopolitical context.

RESTRICTED CONSUMPTION

Our model of restricted consumption (Figure 1) is composed of three parts in a sequential and interrelated order – recognition, reaction, and behavioral intentions. First, recognition of restriction is evaluated as either self- or other-imposed. A dichotomy exists in extant literature between self-imposed restriction (e.g., vegetarianism) and other-imposed restrictions (e.g., product discontinuation). As self-imposed restrictions place a strong focus on individual autonomy, we expect that such restrictions remain either unnoticed or recognized as beneficial. Contrarily, other-imposed constraints generate a more dynamic array of outcomes – from frustration and inconvenience to malice and personal harm (Hill and Gaines 2007), thus posing roadblocks to successful navigation of the marketplace and increasing negative emotional states.

Figure 1
Restricted Consumption Framework


Secondly, we observe cognitive and affective reactions, understood through the subjective importance (moderate versus very) of the restricted object at hand. Defined as "the extent to which a consumer links a product to salient enduring or situation-specific goals" (Bloch and Richins 1983, 71), we surmise that product importance is the primary determinant of consumer reactions to restrictions, and limitations in access to very important products may produce greater emotional reactions due to stronger product-consumer connections (Laurent and Kapferer 1985). Such reactions range from active defiance (e.g., fighting restriction) to positive sense of autonomy.

The third facet of our argument explores behavior of restricted consumers through time (permanent versus temporary). As some consumers revolt against typical consumption behaviors by refusing ownership, curtailing product use, and giving possessions away (Mick 2008), we expect converse reactions in subsistence populations. Potentially positive effects may occur, however, through development of business frameworks termed microenterprises (Viswanathan, Rosa, and Ruth 2010) that allow the poor to become change agents in their consumptive lives.

METHOD

Our empirical work entails both qualitative and quantitative measurement using a sample of 145 participants. Each participant was asked to reflect on a time they were faced with a restrictive situation based on a combination of the following: (1) the source of restriction (i.e., self- or other-imposed), (2) time length of restriction (i.e., temporary or permanent), and (3) importance of the restricted object (i.e., very or moderately). The qualitative component required identification of restricted items, while the quantitative portion developed composite scores for individual feelings towards the restriction, as well as measurement of resultant behavioral reactions based on seven dependent measures.

FINDINGS

As seen in Table 1, three themes emerged through this qualitative assessment, allowing for a richer perspective. Our first quantitative assessment finds that consumers felt better about restrictions when based on their volition. Further, an interaction showed respondents in the moderately (very) important product condition expressed more positive feelings about restriction when the constraint was permanent (temporary) (F(1,117) = 4.221, p < .05).

Next, we evaluate how our three independent variables contribute to the restricted consumption model. Addressing consumer recognition, our participants more easily accepted restriction and were more willing to find a substitute when caused by one's volition. Counter intuitively, participants were more willing to fight and attempt to get around restrictions when products were moderately important to them. Further, individuals believed they were unable to get products they wanted/needed when restricted from an item of only moderate importance. Finally, we found that permanent restrictions led to higher substitution rates and feelings of greater ability to acquire goods and services. An interaction occurs between importance and time in relation to participant's perceived ability to obtain goods (F(1,117) = 4.43, p < .05), as respondents in the moderately (very) important product condition expressed greater inability to obtain products when restriction is permanent (temporary).

Exploring multidimensionality, factor analysis performed on the seven dependent variables revealed two distinct behavioral patterns: (1) lack of acceptance (comprised of fighting, not accepting, trying to get around the restriction, and believing the restriction to be negative), and (2) autonomy (comprised of finding a substitute, feeling in control of one's own destiny, and feeling able to obtain needed/wanted products). We found individuals experiencing restriction of moderately im-

portant products were less accepting of the restriction ($F(1,116) = 6.76$, $p < .05$), while individuals felt greater sense of autonomy if restriction is permanent ($F(1,118) = 4.48$, $p < .05$) or self-imposed ($F(1,118) = 14.61$, $p < .001$).

DISCUSSION

The findings presented set the stage for deeper discovery into restricted consumption domains. It is clear that self-imposed restrictions produce greater behavioral nuances, through more positive attitudes and greater autonomy. Presence of autonomy among consumers highlights potential inherent motivations within their reactions to unexpected changes in the marketplace. Greater autonomy suggests one's likelihood to seek alternative product options and maintain a more positive outlook, which more accurately supports the presented hypotheses. Accordingly, action is based on empowerment rather than dissatisfaction or frustration. This finding encourages additional research to understand subjective valuation processes consumers use with goods and services.

We also find both confirmatory market reactions, as well as intriguing results for future analysis. More detailed and prescriptive methodological designs are need, perhaps utilizing directed restriction situations to systematically eliminate subjective valuation. Such knowledge may allow for greater ease predicting consumer response patterns, thus enabling increased customer support processes and/or product search tools. Further, the two-factor solution among our original seven dependent variables helps strengthen theoretical contribution to marketing scholarship enabling progress towards a more holistic interpretation of consumer decision making within restrictive situations.

Consuming the Dead: Symbolic Exchange in Thai 'Hungry Ghost' Festivals

Chris Hackley, Royal Holloway University of London, UK

EXTENDED ABSTRACT

This study contributes to the theoretical and conceptual understanding of death and consumption in two main ways. Firstly, it describes and interprets a ritual context that has not previously been the subject of published consumer research: 'hungry ghost' festivals in the Thai Theravāda Buddhist tradition. Previous consumer research studies have touched upon the hungry ghost cosmology, but within the rather different Tibetan Mahāyāna Buddhist tradition (e.g. Gould, 1991; 1992) and without the focus on the dead as the nexus of relational consumption. Secondly, we use this cultural context to move towards a dyadic conceptualisation of ritual death consumption, expanding the focus on the management of death *by* the living to embrace the symbolic exchange *between* living and dead. We follow Bonsu and Belk's (2003) ethnographic work on death ritual in Ghana, Africa, in seeking to move from the predominant Western assumption of death as end point for consumption and identity toward a relational perspective on death, using the interactions between living and the ghosts at the festival. This perspective is facilitated by the belief in this tradition that ghosts are literally present in, and interact with, corporeal life. These interactions are engaged with in ritual form in various aspects of hungry ghost festivals.

LITERATURE

Ritual and death remain two relatively neglected topics in consumer research. Since Rook (1985) first introduced ritual into the field, various commentators (e.g. Arnould, 2001) have remarked on the relatively small number of follow-up studies that elaborate on the importance of ritual to consumption, and of consumption to ritual. Death, similarly, has been neglected, partly perhaps it is assumed to be beyond the scope of corporeal consumer researchers since, in Western philosophy and the Judaeo-Christian-Islamic eschatology, death is assumed to mark the end of earthly identity, and of consumption (Bauman, 1998; Giddens, 1991; Riley, 1983). For the living, material possessions have symbolic meanings (Belk et al., 1989; Gentry et al., 1995) but there are instances where possessions and their meanings invoke the dead, for example where items symbolise the relationship with the deceased. The closeness of life to death has been commented upon by some Western philosophers (Baudrillard, 1993; Hegel, 1977) but the consumption issues surrounding death remain relatively under explored. Exceptions include some social scientific studies that explore the links between consumption and death (Turley, 1998; Metcalf and Huntington, 1991; Davies, 1997). Within consumer research, the link between secular immortality and consumer affluence has been explored (Hirschman, 1990) as have the ways in which the living dispose of the possessions of the dead (Kates, 2001; Price et al., 2001). More recently, consumer researchers have explored the interplay of death with identity (Bonsu and DeBerry-Spence, 2008; Bonsu and Belk, 2003; O'Donohoe and Turley, 2005; Wattanasuwan, 2005; Langer, 2007). Three consumer culture studies in particular look into death rituals and death consumption in a non-Western context: Bonsu and Belk (2003) (and a subsequent work by Bonsu and DeBerry-Spence in 2008); Zhao and Belk's (2008) study of Chinese death ritual consumption; and Wattanasuwan's (2005) research on the paper burning ritual in Thailand. Our study draws on and extends this line of work into a previously uncharted cultural context, developing a dyadic conceptualisation of death consumption and informing understanding of how death is produced and consumed in different cultural contexts.

METHOD

We use a multi-method approach to interpret the cultural meanings of this festival, bearing in mind the complexity, depth and variability of the Thai Theravāda Buddhist tradition and the consequent impossibility of achieving a single definitive reading. We employ a cultural semiotic analysis (Buckingham, 2009; Pink, 2006) focusing mainly on the centre piece of the 'Pee Ta Khon' festival, in which the living re-enact the mythical journey back from exile in the forest, of the tenth and last incarnation of the Buddha, Prince Mahavejsandon. According to legend, the Buddha was escorted on this journey by hungry ghosts. The hungry ghost figure varies in different traditions of Buddhist mythology but a common feature is that the ghosts are dead relatives seeking to move to the next stage in the wheel of life. The ghosts are perpetually hungry because they yearn for earthly gratifications, and in their liminal state they need the intercession of the living to transition to become ancestors. In the festival procession, the bizarrely costumed ghost figures indulge in ribald humour, giving the proceedings a carnivalesque air, in contrast to the more pious and solemn parts of the ritual. We set this within a local cultural context by drawing on the first author's cultural knowledge as a Thai national, on informal conversations with Thais supplemented by other internet and literary sources of information, and through interviews, conducted in Thai and translated, with festival organisers. In addition, we also draw for our frame of understanding on our first hand ethnographic investigations of other Theravāda Buddhist death rituals in Thailand. We choose to focus this study on the world famous 'Pee Ta Khon' festival (also known under different Anglicised spellings) because of its unique mythology and the visual flamboyance which makes tangible the presence of ghosts in Thai cultural life.

FINDINGS/DATA

The findings offer an ethnographically-informed description of the hungry ghost phenomenon in Thailand. Observation and analysis of the ritual underlines the immanence of ghosts in Thai religious life and the centrality of consumption to this death ritual. We focus on 'Pee Ta Khon' as one of the most important and visually striking merit-making 'hungry ghost' festivals in the highly spirit-infused Thai Theravāda Buddhist tradition (McDaniel, 2006). Originally known as 'Pee Tam Khon', which is literally translated as 'ghosts follow the living', Pee Ta Khon also doubles as a fertility ritual, and has, in recent years, evolved into an important tourist attraction for the Dansai district of Loei province in North-Eastern Thailand. It has major economic implications for the region, both in terms of the cash it generates from visiting tourists and from the success it may bring to the growth of crops if the spirits are suitably placated. A striking feature of the festival is the combination of evil, represented by the grotesque and fearsome masks, and the joyous irreverence of the hungry ghost figures as they poke fun at the crowds with their huge phalluses during the procession. Profanity is highly unusual in Thai public life and especially so in religious ritual, yet the ghosts of Pee Ta Khon revel in their ribaldry. In return for giving the hungry ghosts assistance, in the form of prayers, food or other ritual forms of respect and holy celebration, the living will receive blessings

which can increase their spiritual and material wellbeing in this life, through the benevolent intercession of the duly placated ancestors. It is the manifest reality of ghosts in this tradition as liminal beings capable of great evil a well as good which bring into relief the tangibility of symbolic exchanges between living and dead in hungry ghost rituals. In Pee Ta Khon and other hungry ghosts festivals, the living, in a sense, symbolically consume the dead in ways that have implications for the identities of the living, as well as for the dead.

The Crossmodal Effect of Attention on Preferences

Hao Shen, Chinese University of Hong Kong, Hong Kong
Jaideep Sengupta, Hong Kong University of Science and Technology, Hong Kong

EXTENDED ABSTRACT

Consumers often have to decide between two products located adjacent to each other – as for example, on a supermarket shelf. How are such decisions, which are based on visually processing the two products, influenced by unrelated, non-visual stimuli that may emanate from either lateral direction? Suppose, for example, that you are standing in a supermarket aisle, trying to decide between two packets of cookies, one placed nearer your right side and the other nearer your left. While you are trying to decide, you hear an in-store announcement, on your left, store closing hours. Will this unrelated announcement influence your cookie decision?

This research seeks to answer such questions by demonstrating what we believe is a novel phenomenon: namely, an enhancement in product evaluations that are based on visual processing, as a result of a spatial match between the product's location along a lateral dimension and the location of an external, non-visual stimulus. Thus, in the example above, the store announcement from the left (an auditory stimulus) should increase the preference for the cookie packet on the left.

According to our theorizing, such phenomena are driven by crossmodal links in spatial attention (see Driver and Spence 1998a, 1998b for a review). Because of such links, when attention in one sensory mode is drawn in a particular direction, people find it easier to direct attention in another sensory modality towards that direction. Thus, an auditory stimulus from a particular direction makes it relatively easier for consumers to process products that are more aligned with that general direction. The consequent fluency of processing, we argue, should directly influence product evaluations and choice.

In study 1, participants were asked to listen to a news broadcast while simultaneously being exposed to pictures of two hotel rooms that either appear on the left or right side of a computer screen. The key manipulation involved the location of the loudspeaker from which the news was broadcast. This speaker was placed either towards the left or right corner of the room. We found that participants paid more visual attention to the hotel room on the left (right) of their screen if the auditory signal came from their left (right), and that this attention bias was reflected in fluency of processing as well as actual preference for the room on the corresponding side.

Study 2 aimed to illustrate the applied implications of our findings by documenting them in a field setting. The study was conducted in the context of choosing a product from one of two adjacent vending machines, both selling soft drinks. A research assistant placed a speaker on the top of each vending machine and linked the speakers to a notebook computer that was broadcasting a local news bulletin. The assistant also adjusted the speaker's volume control to ensure that at any moment in time, only one of the speakers (either the one on the right or on the left) was playing at normal volume, while the other was muted. We found that consumers were more likely to purchase a drink from the machine placed on the right when the broadcasting speaker was placed on top of that machine, than when it was placed on the one on the left.

We assumed that consumers might either passively attend to any voice or actively choose which voice to attend to. Study 3 aimed to investigate whether the latter possibility is true by manipulating the valence of voice. Participants either listened to positive or annoying music while making an impression of two pictures of restaurants on a computer screen. The music, which lasted for 1.5 minutes, either came from their left or right side. In positive music condition, we replicated the findings of study 1. In annoying music condition, however, participants paid more visual attention to the restaurant on the opposite side to the music and prefer that restaurant to more extent than the restaurant on the same side of the music. These results suggested that participants had avoided listening to annoying music and that this shift in audio attention had affected their visual attention accordingly.

We assumed that even when participants listen to annoying music, they might initially attend to it passively and then consciously avoid it in order to cope with their negative feelings elicited by the music. If this is the case, their visual attention should also first be shifted toward and then away from the music. Study 4 sought to examine this process. Participants listened to annoying music that either came from their left or right side. At the same time, they sequentially examined product options of two categories on a computer screen. In each category, they examined two options, one on the left and the other on the right side of the screen. Participants examined options of the first category while listening to music for 20 seconds. Then the music stopped, and participants reported their preference and relative attention toward each option. After that, the experimenter continued to play music, Participants examined options of the second category while listening to music for another 20 seconds. Consistent with our assumption that participants would first attend to annoying music and then avoid it, we found that participants paid more attention to the option of the first category on the same side of music but to the option of the second category on the opposite side to the music. Their actual preference for option was affected accordingly.

This research represents the first investigation of how attention shifts in one sensory mode can influence preferences in another. In doing so, not only does this research add to the literature on attention, but also to the small but growing body of work illuminating the vital role of the senses in shaping product preferences (Elder and Krishna, 2010; Krishna and Morrin, 2008).

Insights into Decisions from Neuroscience and Choice Experiments:
The Effect of Eye Movements on Choice

EXTENDED ABSTRACT

Discrete Choice Experiment (DCE) research has predominately been used to observe choice outcomes. However a better understanding of the underlying choice process can help improve our ability to predict choices. Prior work examining choice processes has traditionally used methods such as concurrent or retrospective reporting (verbal protocols), information boards, mouse-tracing methods, or eye-tracking and click stream analysis in computer-based environments. However, these methods face issues of internal and external validity. For example, concurrent reporting consumes mental resources and forces serial processing, limiting external validity. Moreover, many of these measures are unable to capture emotional or automated processes, base state (engagement), or conviction, resulting in compromised internal validity. Thus, there is a need for a better process measurement system for experimental decision making environments that offers both externally and internally valid data.

We proffer that the combination of eye-tracking measures and discrete choice experiments fulfills that need. Eye-tracking has been used to study decision processes in various tasks including probabilistic inference, risky decisions, and advertisements. Indeed, if visual attention and eye movements are coupled, attentional shifts should be related to changes and patterns of eye movements (Hoffman 1998; Rayner 1998). However, eye-tracking observes only information acquisition behavior and not internal cognitive processes. Instead, one must infer underlying cognitive strategies from eye-tracking data. Alternatively, process may be inferred through the experimental design by maximizing the resultant statistical information on cognitive factors influencing choice. For example, choice experiments (Louviere and Woodworth 1983) using full factorial designs allow one to infer certain types of decision rules (Anderson 1971). In this paper we use eye-tracking measures in discrete choice experiments to exploit the benefits these methods offer in understanding preference and choice processing. The broad purpose of our research is to identify empirical generalizations that can be integrated with neuroscience and other literatures.

RESEARCH HYPOTHESES

Consistent with research suggesting individuals are selective in information search (e.g., Bettman, Johnson, and Payne 1991), we hypothesize that individuals quickly look for features and/or feature levels of choice options that best help them discriminate and they focus fixations in areas of a scene that most likely contain information to shorten search length (Rayner and Castelhano 2008).

Hypothesis 1: *The time to first fixate on important features is shorter than that for less important features.*

Hypothesis 2: *Fewer fixations should occur before an individual looks at an important feature compared with the number occurring before looking at an unimportant feature.*

In familiar choice contexts, individuals have the ability to isolate that which is most important and task relevant (Alba and Hutchinson 1987). Thus, individuals may focus their visual attention more on choice options or features that require deliberation or a second look than choice options or features that individuals have quickly identified as important.

Hypothesis 3: *Individuals spend more time looking at less discriminating features than more discriminating features.*

Hypothesis 4: *We expect fewer fixations or unique visits for chosen options than for unchosen options. Similarly, we expect fewer fixations or unique visits to attractive, more discriminating features/levels than for less attractive, less discriminating features/levels.*

STUDY 1: VISUAL ATTENTION AND CHOICE

In study 1 we a) design, implement and execute a choice experiment that incorporates eye-tracking, b) obtain meaningful eye-tracking measures and c) relate eye-tracking measures to choices.

Method

We used a Tobii X60 eye tracker. The experiment focused on choices of cracker options described by combinations of three features: shape (circle, square, triangle), flavor (wheat, dark rye, plain) and topping (salt, poppy, no topping). We selected nine cracker descriptions from the 3^3 factorial using a main effects design. Following Louviere et al. (2008) we used a balanced incomplete block design to assign the crackers to 12 choice sets, each containing three crackers. The 12 sets of crackers were displayed one set at a time, and 14 participants chose their most and least preferred cracker for a party they would host.

Results

Table 1 gives the results from stacking all the participants' choices (Horsky and Rao 1984) and estimating an aggregate conditional logit model (McFadden 1974) including the effects of eye-tracking measures as covariates. Although preliminary, the results are promising, suggesting the visual attention measures are systematically associated with choices.

Specifically, 'time to first fixation' was significant ($B_{time\ to\ first\ fixation}$ = -.3190, $p < .05$), implying the longer to fixate on a choice option, the less likely it is chosen. 'First fixation duration' also was significant ($B_{first\ fixation\ duration}$ = 2.100, $p < .001$), implying the longer one initially fixates on a choice option the more likely it is chosen. The latter result supports the notion that individuals quickly look for features/feature levels of choice options that help discriminate choice options. Finally, 'visit count' was significant ($B_{visit\ count}$ = -.408, $p < .05$), implying fewer unique visits to more attractive than less attractive choice options. Thus, the results suggest eye movements play a non-trivial role in choice.

STUDY 2: GREATER NUMBER OF CHOICE SETS AND VISUAL ATTENTION

Study 2 builds on study 1 by using a greater number of choice sets to insure participants evaluate each cracker relative to all 27 possible crackers.

Method

The stimuli, design and procedure was identical to study 1, except for 18 participants evaluated 57 choice sets. Observing most and least preferred choices in each set provides a complete preference ranking of the three, and allows extrapolation to non-tested choice sets. This method ensures participant-level estimation of the conditional logit choice model (Louviere et al. 2008) required to test hypotheses 1-4. For brevity, individual-level model results are not reported.

Results

Consistent with study 1, both 'time to first fixation' and 'visit count' were significant ($B_{time\ to\ first\ fixation}$ = -.953, $p < .001$; $B_{visit\ count}$ = -.552, $p < .001$) and offer the same implications as study 1. There also are fewer unique visits to more attractive cracker features than less attractive features.

CONCLUSION

This research provides an innovative manner for examining the processing behind choice without the pitfalls of limited external and internal validity implicit in other methods. Moreover, our findings offer strong support that there is, in fact, a strong relationship between eye movements and choice.

Uncertainty Increases People's Reliance on Their Feelings

Ali Faraji-Rad, Columbia University, USA
Michel Tuan Pham, Columbia University, USA

EXTENDED ABSTRACT

Imagine sitting in your office in a normal day, trying to make an important decision. Suddenly, a colleague of yours passes by your office door and says "congratulations!" and quickly vanishes. You have not received any good news recently so you do not know why the colleague congratulated you. This creates a momentary (positive in this case) feeling of uncertainty. How is this feeling of uncertainty likely to influence your subsequent, and unrelated decision? People usually think of uncertainty as a state of lack of information about the actual decision at hand, yet, uncertainty can be due to a feeling of not knowing, or activation of the concept of uncertainty in the mind. This feeling could be related or unrelated to the decision at hand (Bar-Anan, Wilson, and Gilbert 2009). In this paper we propose that a general feeling of uncertainty increases people's propensity to rely on their feelings.

This proposition has not been tested before, yet, prior research in psychology is suggestive of such an effect. For example, using fMRI, Berns et al (2001) showed that the response of human reward region to rewarding stimuli (i.e., juice) was greatest when the stimuli were unpredictable. Also, Grupe and Nitzchke (2011) showed that people's aversion towards negative stimuli is heightened with cues related to uncertainty. Research in experimental psychology too has documented that uncertainty elevates people's responses to both positive and negative stimuli (Bar-Anan et al 2009; Lee and Qiu 2009; Wilson et al 2005). But could these findings, at least partly, be due to a general reliance on feelings in face of uncertainty? We report 4 studies that are designed to test this question.

In study 1, we first asked participants to recall and write down the thoughts and feelings they experienced in a situation where they felt uncertain (uncertain condition), certain (certain condition), or went shopping (control condition). Then as a "second" task, we asked them to make a choice between an apartment that was superior on logical dimensions (e.g., more spacious closet space) and an apartment that was superior on affective dimensions (e.g., better view). In support of our hypothesis, compared to participants in the certain condition (42.5%), or the control condition (50%), participants in the uncertain condition (68%) chose the affectively superior apartment more than the cognitively superior apartment ($?2 = 6.28$, $p < .05$).

In studies 2A-B, we replicated the results of study 1, with a different, and novel, manipulation of uncertainty. In both of these studies, first, under the disguise of a study on the effects of length of measurement-scales on people's reporting of their emotions, we asked participants to answer a question ("How do you feel right now?") 5 times. The end-point of the scales where used to manipulate uncertainty, or certainty. Specifically, in the uncertain condition the end-points where "somewhat uncertain" and "totally uncertain", and in the certain condition, the end-points were "somewhat certain" and "totally certain". Participants had to answer the question five times using 5, 9, 11, 15, and 19-point scales. The logic behind this manipulation was that the use of half of the range of the scale (i.e., scales starting with "somewhat uncertain", instead of "not uncertain") would create a momentary feeling of uncertainty/certainty in the participants. After completing this task, participants went on to participate in an ostensibly separate task, which in study 2A was to

make a choice between apartments similar to study 1, and in study 2B was to make a choice between 2 laptops. One of the laptops used in study 2 was superior on the cognitive dimensions (e.g., performance), and the other was superior on the affective dimensions (e.g., aesthetics). As predicted, in both studies, compared to participants in the certain conditions (38% in 2A and 51% in 2B), participants in the uncertain conditions (61% in 2A and 68% in 2B) chose the affectively superior options more than the cognitively superior options.

In study 3 we tried to rule out the alternative explanation that a feeling of uncertainty, compared to certainty, creates a negative mood and thus encourages people to regulate their mood by opting for more affective (i.e., hedonic) options. Here, we first asked participants to recall and write down a situation where they were certain in a positive way (positive certain condition), certain in a negative way (negative certain condition), uncertain in a positive way (positive certain condition), or uncertain in a negative way (negative uncertain condition). Then under the disguise to a second task, participants had to choose between the two apartments as in study 1. Results revealed a main effect of uncertainty such that compared to certain participants, uncertain participants chose the affectively superior apartment more than the cognitively superior apartment ($B=0.361$, Wald $?2=3.88$, $p<.05$). Also a main effect of valence was found such that compared to the positive condition, those in the negative condition chose the affectively superior apartment more than the cognitively superior one ($B=-.367$, Wald $?2=4.02$, $p<.05$). But importantly, we observed no interaction between uncertainty and valence (Wald $?2=.373$, $p>.89$), suggesting that the effect of uncertainty works independent from the effect of mood.

Collectively these results are suggestive of the fact that a feeling of uncertainty increases people's reliance on their feelings. A shortcoming of our research is that in all studies only one paradigm was used to test people's reliance on their feelings (i.e., people opting for more affective options, compared to more cognitive ones). Using other paradigms, such as testing a higher effect of people's incidental mood states on their evaluations in uncertain situations (compared to certain situations), are possibilities for further research.

"Seeing" the Consumer-Brand Relationship:
How Relative Physical Position Influences Relationship Perceptions

Irene Xun Huang, The Chinese University of Hong Kong, Hong Kong
Xiuping Li, National University of Singapore, Singapore
Meng Zhang, The Chinese University of Hong Kong, Hong Kong

EXTENDED ABSTRACT

Consumers can form various relationships with brands similar to those that they form with other human beings (Aggarwal, 2004; Fournier, 1998). Despite the relevance and rich implications of brand relationship research, few studies to date have investigated the antecedent factors associated with different types of brand relationships. In this paper, we examine the possibility that the physical positioning of brands in relation to the customer influences brand relationship perception and brand evaluation. Specifically, we start this line of investigation by focusing on two kinds of relationships (brands as leaders, or as friends), and examining the effects of relative physical location (horizontal vs. vertical) and distance (close vs. distal) between a brand and its customer in print ads. We draw on the following two lines of research on metaphors to propose our theory.

Horizontal distance and social distance perception. Spatial distance has a direct influence on judgments of interpersonal connectedness and emotional attachment (Williams & Bargh, 2008; Zhang & Wang, 2009). This line of research suggests that there is a positive correlation between horizontal closeness and social closeness. The closer the horizontal distance between two individuals the stronger the intimacy felt between them. Indeed, in our daily languages, we tend to use "closest friend" to describe a person who cares about us the most, or with whom we have a mutually strong and enduring relationship.

Vertical positions and power perception. Studies from a different stream of research, however, show that vertical location is associated with power perception (Meier & Dionne, 2009; Schubert, 2005). For instance, Schubert (2005) finds that people tend to judge an animal (e.g., a wolf) as being more powerful if its picture is physically positioned in a higher place versus a lower place. In addition, there is a negative correlation between vertical closeness and power perception: the closer the vertical distance between a leader and his followers, the less the power inferred on the leader (Giessner & Schubert, 2007). Looking again at linguistic cues, we "look up" to a leader, and admire or are inspired by someone "above" ourselves.

Our proposition. Based on research on location metaphors, we make three predictions. First, we posit that consumers are more likely to represent relationships involving power differences (i.e., brand-as-a-leader; e.g., The Times "When the Times speaks, the World listens") in a vertical manner, and those involving no power differences (i.e., brand-as-a-friend; e.g., Hyundai "Always there for you") in a horizontal manner. Second, we hypothesize that for friend-like brands, physical closeness could lead to social closeness and intimacy, strengthening the relationship (Aaker, Fournier, & Brasel, 2004; Fournier, 1998). However, this dynamic might be reversed for leader-like brands. Finally, we predict that location metaphors will influence consumers' evaluations of brands. When promoting a new brand, if the promoted relationship matches its physical position (i.e., location and distance) relative to its customers, consumers will evaluate the brand more favorably, than when the promoted relationship mismatched physical position.

We tested our predictions in two experiments. In Experiment 1 (N=54), we collected 40 real ads: half of them had brand image and consumer image horizontally to each other, whereas the other half had the brand image being located "up" to the consumer image. Participants viewed both groups of ads with the order of the group counterbalanced. They were asked to infer the kind of relationship that the brand has with its customers (i.e., as a leader or a friend). Their familiarity and attitudes towards each brand were included as covariates. As predicted, controlling for familiarity and prior attitudes, leader-like relationship was more frequently inferred by participants in the "up" group ($M = 8.89$) than in the "horizontal" group ($M = 7.44$; $F(1, 50) = 4.84$, $p < .05$); On the contrary, friend-like relationship was more frequently inferred in the "horizontal" group ($M = 11.11$) than in the "up" group ($M = 12.56$; $F(1, 50) = 4.84$, $p < .05$).

Experiment 2 (N=323) used a fictitious new watch brand, and had a 2(promoted relationship: leader, friend) × 2(position: up, right) × 2(distance: close, distant) between subject design. Participants were asked to view the ad carefully. The ad had a tagline, an image of customer in the center, and an image of a watch, either to the up, or to the right of the customer image. We manipulated the promoted relationship by different taglines of the ad (leader: "A leader always inspires you"; friend: "A friend you can trust". After viewing the ad, participants reported their evaluations of the brand. As expected, consumers evaluated the brand more favorably in the matched conditions. For leader-like brand, participants had the highest evaluation of it in the *up-distant* condition ($M = 5.43$), as compared to other conditions ($M_{\text{up-close}} = 4.70$; $M_{\text{right-close}} = 4.60$; $M_{\text{right-distant}} = 4.53$; $F(1, 315) = 8.45$, $p < .01$). For friend-like brand, participants expressed the most favorable attitudes toward it in the *right-close* condition ($M = 5.41$), as compared to all the other conditions of mismatch conditions ($M_{\text{up-close}} = 4.79$; $M_{\text{up-distant}} = 4.55$; $M_{\text{right-distant}} = 4.64$; $F(1, 315) = 8.22$, $p < .01$).

Taken together, results from our research provide new insights as to bring physical positioning metaphors – both relative location and relative distance – into the literature of consumer-brand relationships.

Mere-Alignability of Alphanumeric Brand Names:
How Exposure To Mercedes C350 Affects The Choice Between BMW 335I and BMW 330I

Kunter Gunasti, University of Connecticut, USA
Berna Devezer, Michigan State University, USA

EXTENDED ABSTRACT

The use of numbers along with letters in brands—in other words, alphanumeric brand names (ABs) —became pervasive in many product categories (Boyd 1985). In a retail setting, consumers often encounter numbers not only as a part of attribute values (e.g., 10 vs. 14 megapixel resolution) but also as a part of brand names (e.g., Canon SD3500 and SD4500 cameras). While research on ABs has examined different types of associations between brands and attributes, the possibility that ABs themselves can function as independent attributes and get traded off has not been explored. Current research aims to address this gap, proposing three major contributions.

First, drawing on the numerology literature, we develop a *mere-alignability* hypothesis to explain how ABs can function as regular attributes—even when they do not convey meaningful product information—and get traded off against objectively diagnostic attributes. For instance, a choice between Canon SD3500 with14MP vs. Canon SD4500 with 10MP potentially involves brand-attribute tradeoffs. Second, we show that even mere exposure to merely aligned competitor ABs can affect the choices of focal ABs (e.g., exposure to Nikon S6000 affecting the choice between Canon SD4500 and SD3500). Lastly, we identify competitive categorization as a boundary condition for the mere-alignability effect such that only the ABs that are viewed as competitors affect the focal choices.

The processing of numbers requires a different type of knowledge compared to the processing of nonnumeric information. Dehaene (2001) refers to this as "number sense" and defines it as a combination of biologically, socially, and culturally developed knowledge that enables us to understand numbers. As a result, individuals can process numbers and compare their magnitudes almost effortlessly. ABs are semi-quantitative in nature and have a tendency to form trends; as a result, they can trigger consumers' number sense. We introduce the term *mere-alignability*, to refer to the conception that when exposed to multiple ABs that include easily comparable numbers (e.g., XC100, XK200), consumers engage in comparisons and tradeoffs among ABs as well as other numerical information.

If ABs function as regular product attributes due to their mere-alignability, well known context effects (e.g., compromise and attraction effects) should arise, leading consumers to give up higher attribute values in favor of ABs with higher numbers. These preference shifts occur when making a choice among options within the same brand as well as across competitor ABs, even when the options introduced in the context are not available for choice.

Categorization theories (e.g., Schwarz and Bless 1992) suggest that at least some type of similarity between two exemplars is needed in a decision making to group them together. Accordingly, we propose that consumers will engage in comparisons of ABs only if they are perceived as competitors. We tested our hypotheses with three empirical studies.

Study 1 examined how the mere-alignability of ABs leads attribute-brand tradeoffs resulting in preference shifts. The study involved a two-way between-subjects design where participants were presented with a choice task involving either a binary or a trinary choice set of e-readers of the same brand (i.e., Nook). Control conditions were given the same binary set which involved a tradeoff between the AB and the screen size (Table 1). Treatment conditions received a trinary set, which included an extreme third option. E-

reader B had a smaller screen than e-reader A and was the inferior option. Participants' choice for e-reader B doubled when it became a compromise option.

Table 1*
Study 1 - Compromise Effect – Choice Stimulus

	A	B	C
Attributes			
Brand	Nook NB-3400 *by Barnes & Noble*	Nook NB-5600 *by Barnes & Noble*	Nook NB-7800 *by Barnes & Noble*
Screen Size	8.1" screen	7.2" screen	6.3" screen

Study 2 – Competitor Brand Name Stimulus

	A	B	C
Attributes			
Brand	Nook NB-3400 *by Barnes & Noble*	Nook NB-5600 *by Barnes & Noble*	iLiad TR-7800 *by iRex*
Screen Size	8.1" screen	7.2" screen	6.3" screen

* Various filler attributes including*: Micro-USB 2.0 cable**, AC adapter, Rechargeable battery**, 15 books* Storage capacity, Wi-Fi (802.11 b/g)…etc. were also presented. Since these did not differ among the options, they are not shown in the above table.*

The letter labels are only presented in this table for ease of representation. In the actual experiments the options were presented in random order with no letter labels. The binary set consisted of options A and B depicted above and trinary sets also included options C or D.

Study 2 closely resembled study 1 with the exception that the third option in the treatment condition belonged to a competitor brand, iLiad (Table 1). We replicated the findings of study 1 within this across-brand context, where participants' preference for the inferior Nook option doubled when it became a compromise option.

Study 3 tested competitive categorization as the boundary condition for the mere-alignability effect. We used a one-way design with four conditions where participants were introduced to a used luxury sedan purchase scenario. The control condition consisted of a binary choice set of two Mercedes brands with different mileage (Table 2). In all three treatment conditions, a third, phantom AB was added to the choice set. This third option was a BMW 350i in the

competitor brand condition, a Ford Explorer 350 in the non-competitor brand condition, and a Mercedes M350 in the non-competitor product condition (all established with pretests). In the competitor brand condition, exposure to BMW 350i significantly increased the choice of C340. On the other hand, in the non-competitive brand and non-competitor product conditions, the presence of the phantom option did not affect the choice of C340.

Table 2
Study 3 – Competitor and Non-Competitor Choice Sets

Focal Choices In The Binary Set – Control Condition

Brand-Model	Mercedes C340	Mercedes C330
Year	2008	2008
Transmission	Auto	Auto
Upholstery	Leather	Leather
Mileage	14,300 miles	12,900 miles
Options	Heated Seats	Heated Seats

Third Brand Options Included In Trinary Sets*

Competitor Brand	Non-Competitor Product by Same Brand	Non-Competitor Product by Different Brand
BMW 350i	Mercedes M350	Ford Explorer 350
OUT OF STOCK	*OUT OF STOCK*	*OUT OF STOCK*

* In each treatment condition one of these third options was added to the binary choice set. No Attribute information was shown for any of the third options - only the "OUT OF STOCK" label

Overall, these three studies show how and when ABs can be traded off against objective attribute values. In Study 1, we demonstrated that consumer preferences can be shifted easily through introducing new ABs in the choice context. Although the numbers had no diagnostic value, consumers treated them as regular attributes and engaged in AB–attribute tradeoffs that prompted normative violations. Second, Study 2 extended the mere-alignability effect to different competitor ABs by showing that consumers' mere exposure to competitor ABs affects their focal choices. Third, Study 4 revealed that preference shifts disappear when the nonfocal brand appears incomparable with the focal options, whether it represents a noncompetitive brand or a different product category, establishing competitive categorization as a boundary condition.

Two-sided Messages for Health Risk Prevention:
The Role of Argument Type, Refutation and Issue Ambivalence

Erlinde Cornelis, Ghent University, Belgium
Veroline Cauberghe, Ghent University, Belgium
Patrick De Pelsmacker, University of Antwerp, Belgium

EXTENDED ABSTRACT

A variety of studies suggests that commercial advertising can include some negative information along with the positive product information, and still be more effective than when only positive information is provided (Crowley and Hoyer 1994; Pechmann 1992). For instance, when selling a product, it might pay off to also mention a few shortcomings (Eisend 2006). Such two-sided messages are found to generate attitudinal resistance to counter-persuasion (Kamins and Assael 1987).

However, the two-sided message strategy has not been tested in a reversed way (e.g., to prevent unhealthy behavior) (Eisend 2006). What if health prevention campaigns not only emphasize the negative aspects of, for instance, binge drinking, but also mention the perceived benefits of that behavior? Two experimental studies were set up to address this research gap. The effectiveness of two-sided anti binge drinking and anti marijuana messages was investigated in relation to argument type, refutation, and issue ambivalence.

Study 1 serves as a baseline study in which the principle of message sidedness (one- versus two-sided) is tested in combination with argument type (rational versus affective). Previous message sidedness literature mainly focused on rational arguments (Eisend 2007), neglecting the role of affective arguments, despite the importance of affect in consumer persuasion processes (Ray and Batra 1983; Pham 1998). Affective arguments are especially relevant for health issues, as affect plays a crucial role in health-related decisions (Agrawal, Menon, and Aaker 2007). The results of study 1 show that two-sided messages have superior effects on attitude toward the ad over one-sided messages, but only when the argument is affective (see figure 1). The reason is that affective arguments are more issue-relevant for consummatory motivated behavior (such as binge drinking) than rational arguments (Pham 1998; Ricciardelli, Williams, and Finemore 2001).

Figure 1: The Interaction Effect Between Message Sidedness and Argument Type on Attitude Toward the Message
Study 2 therefore builds on the results of the first study by focusing solely on affective two-sided messages. In order to investigate two-sided messages more profoundly, a distinction is made between two different subtypes of two-sided messages: a refutational versus a non-refutational two-sided message. In a non-refutational two-sided message, advertisers simply present positive and negative information. In a refutational two-sided (commercial) message, advertisers subsequently refute or discount the negative information in an attempt to 'inoculate' the audience against possible counterclaims by competitors afterwards (Eisend 2007). In our study of binge drinking prevention, a two-sided refutational message would refute the positive argument (instead of the negative one), in order to bolster teenagers' attitudes when they are subsequently exposed to peer pressure. After receiving one of the two stimuli (a refutational or a non-refutational two-sided message), the participants were exposed to peer pressure. Peer pressure was conceptualized as a printed online chat conversation between two peers who explicitly promoted binge drinking.

Using a physiological analogy, inoculation theory (McGuire 1961) states that offering mild counterarguments in a message and afterwards refuting them enhances attitudes in the preferred direction (Eisend 2007). In immunology, to build resistance to a disease, people are often injected with a solution that contains a mild form of the disease itself (Etgar and Goodwin 1982). One of the main tenets of inoculation theory is the need for including a refutation of the counterargument(s) within the message (Crowley and Hoyer 1994). However, many researchers also found beneficial effects for two-sided advertising without refutation (Crowley and Hoyer 1994; Golden and Alpert 1987; Kamins and Assael 1987). These mixed findings indicate that refutation is not always necessary, but rather depends on certain moderating variables.

Study 2 explains the inconsistent findings of previous literature concerning the effectiveness of refutational versus non-refutational two-sided messages by including a moderating variable: issue ambivalence. The reason why some previous studies report no different effect for a refutational versus non-refutational two-sided message, could be due to the nature of the issue itself. For instance, the issue we used in study 1 (i.e., binge drinking) is not a very ambivalent issue in that most people would consider it as undesirable behavior. Binge drinking is characterized by strong contra-arguments and (relatively) weak pro-arguments, making it easy for individuals to mentally refute the pro-argument themselves. So, in the case of a unambivalent issue, refutation of the (weak) pro-argument within the message would offer little added value, as refutation can easily be done by the consumers themselves. Conversely, for a more ambivalent issue, characterized by relatively stronger pro-arguments besides the contra-arguments, it might be more difficult for consumers to mentally refute the pro-argument themselves. Consumers in an ambivalent condition need a stronger direction in the message (e.g., a refutational statement) in order to resolve the ambivalence (Zemborain and Johar 2007). Hence, in this case, refutation of the pro-argument within the message might be more necessary. We therefore expected to find a positive persuasive effect of refutational over the non-refutational two-sided message only when the topic is more ambivalent. Based on the results of a pretest, in which seventeen differ-

ent issues were questioned within-subjects among 20 respondents, we selected marijuana use as an ambivalent issue and binge drinking as a unambivalent issue.

The results of study 2 reveal that for the ambivalent issue (marijuana use), refutation of the positive argument within the two-sided message is more effective than when the argument is not refuted. In other words, for an ambivalent issue, teenagers' attitudes toward the issue are significantly more negative when they were inoculated by a two-sided refutational message prior to exposure to peer pressure, than when they had received a two-sided non-refutational message before. In the case of the unambivalent issue (binge drinking), however, the results show that refutation is not necessary, hence, no different effect between the refutational and the non-refutational two-sided message was found for a unambivalent issue (see figure 2).

Figure 2: The Interaction Effect Between Refutation and Issue Ambivalence on Attitude Toward the Issue After Exposure to Peer Pressure
The theoretical added value of this research is threefold. First, it extends message sidedness literature to a health prevention context. Second, our study addresses not only rational, but also affective two-sided messages. Third, our research explains a gap in message sidedness literature by addressing the effect of a crucial moderator, namely issue ambivalence, on the impact of refutational versus non-refutational two-sided messages.

Decrease or Enhance?
Assessment of the Effect of Shanzhai on the Original Products

Liangyan Wang, Shanghai Jiao Tong University, Shanghai
Cornelia Pechmann, University of California, USA
Yitong Wang, Tsinghua University, Beijing

EXTENDED ABSTRACT

As a term connoting copycat manufacturing, "Shanzhai" has become a significant market phenomenon in many economies. Shanzhai has grown into a major industry segment in China. The number of people involved in the Shanzhai industry is estimated to be up to one million, and the annual total capital flow can reach as much as 100 billion yuan (Zhu and Shi 2010).

Shanzhai products are indeed based on imitation, which is an infringement of copyright to some extent. However, putting legal issues aside, the ubiquity of Shanzhai products in the market deserves attention. Investigating the effect of Shanzhai products on the original products from a consumers' perspective will benefit both marketers and manufacturers. The expected effect of Shanzhai on incumbent business players in mature industries is almost one-sided: companies with famous brands worry that imitators will eat up their market share and cause huge losses in profits. This issue is frequently discussed in the media, but surprisingly, there is scant academic research on it especially from the perspective of consumer behavior. The existing research examines this phenomenon either from a sociological or from an anthropological point of view, and the results are mostly qualitative. There has been a lack of research on the role that Shanzhai products play in consumers' perceptions and evaluations of leading brands.

Attempting to fill the gap from consumers' perspective, our study aims to examine the effect of Shanzhai on original products in China. Specifically, by applying and extending the General Evaluability Theory (Hsee 1996; Hsee and Leclerc 1998; Nowlis and Simonson 1997; Hsee and Zhang 2010) and the Expectancy Disconfirmation Model of Satisfaction (Wirtz and Bateson 1999; Spreng, MacKenzie and Olshavsky 1996), we address the following questions using both laboratory and field experiments: Do Shanzhai products have a positive or negative effect on the original products? Are there variables moderating this effect? Finally, what underlying mechanism accounts for this effect?

The General Evaluability Theory predicts that, apart from noticing the categorical differences (i.e., Shanzhai vs. Original, in our case), people will be more sensitive to the incremental differences (i.e., low-quality vs. high-quality differences, in our case) in the joint evaluation mode. Therefore, the juxtaposition of a low-quality Shanzhai product and the original product should make the quality difference more salient, thus increasing the evaluation of and the intent to purchase the original products, and indicating a contrast effect. The Expectancy Disconfirmation Model of Satisfaction focuses on the process of evaluation and emphasizes the comparison between attribute-based expectations and perceived performance, which is also called expectations congruency (Wirtz and Bateson 1999; Spreng, MacKenzie and Olshavsky 1996). Thus when Shanzhai and the original products are juxtaposed, the quality of Shanzhai product matters and serves as a baseline or starting point for people to form their expected performance of the original product. Viewing and evaluating high-quality Shanzhai may unintentionally lead consumers to expect the performance of the original product to be above the actual level of performance. Subsequently, the original product performs at the actual level but falls short of their inflated expectations. Thus, consumers would likely be less satisfied with their overall experience with the original product than if they had not been shown and allowed to view and evaluate the high-quality Shanzhai (i.e., single evaluation mode). Accordingly, we propose that the quality level of Shanzhai may moderate the effect of Shanzhai products on the original products, and the expectations congruency toward the original may mediate the effects of Shanzhai quality level on the original products.

In Experiment 1, we found that compared with the single evaluation of the original, the joint presence of low-quality Shanzhai and the original enhanced consumers' evaluation of and intent to purchase the original. In Experiment 2, which was conducted among real consumers, we replicated the findings in Experiment 1 with low-quality Shanzhai (Experiment 2a) and found that the pattern observed earlier reversed with the comparison of the high-quality Shanzhai (Experiment 2b). In Experiment 3, we found that the effects of Shanzhai on satisfaction and evaluation of the original were mediated by participants' expectations congruency of the original when it was juxtaposed with Shanzhai with differing quality levels.

We have sought to make several substantive contributions through this research. First, we quantitatively studied the effect of Shanzhai on the original in terms of consumer preference and explored its underlying mechanism. Second, the results suggest that if there is no contrasting quality and performance discrepancy between Shanzhai and the original products, Shanzhai has a detrimental effect on the original because it decreases consumers' evaluation of and intent to purchase the original products. Third, the results of our study indirectly help explain why Chinese consumers have more enthusiasm for leading brand and luxury products compared with consumers from western countries where Shanzhai or counterfeits are not available, aside from the existing explanation of status signaling (Han, Nunes and Drèze 2010) and social motivations (Wilcox et al. 2009).

Actors Conform, Observers Counteract:
The Effects of Interpersonal Synchrony on Conformity

Xianchi Dai, The Chinese University of Hong Kong, Hong Kong
Ping Dong, University of Toronto, Canada
Robert S. Wyer Jr., The Chinese University of Hong Kong, Hong Kong

EXTENDED ABSTRACT

Synchrony is an integral part of our daily life: chorus, dancing, and marching are just a few examples that we experience or see every day. Given the ubiquity of these behaviors, it is surprising that little is known about how synchrony may affect consumers' judgments and decisions. Our research shows that not only engaging in this behavior but also observing it can influence people's later judgments in quite unrelated choice domains. Moreover, the effects of actual and observed behavior can often be diametrically opposite.

Our conceptualization of these effects distinguishes between (a) the cognitions that govern behavior and (b) the motivation that is elicited as a result of performing or observing it. Performing goal-directed behavior can activate concepts that, once accessible in memory, elicit conceptually similar behavior in a later situation (Wyer, Xu, and Shen 2012). Prior research has documented that interpersonal synchrony can give rise to a sense of group cohesiveness (Ehrenreich 2006; see also Haidt 2007; Haidt, Seder, and Kasebir 2008), stronger cooperation and greater social attachment in later situations even at the expense of monetary rewards (Hove and Risen 2009; Wiltermuth and Heath 2009). To this extent, actively engaging in synchronous behavior may activate more general concepts associated with behaving like others and that these concepts might influence the likelihood of conforming to others' behavior in a later situation.

At the same time, however, individuals who are consciously aware of the requirement to copy others' actions might often feel that their freedom of behavior is restricted and experience psychological reactance (Brehm 1966). Thus, they may attempt to assert their freedom by making judgments and decisions that deviate from others' and confirm their uniqueness and individuality. For instance, Andreoli, Worchel and Folger (1974) showed that after seeing another person's freedom being restricted, participants' ratings of the desirability of normatively popular stimuli declined. This was true regardless of whether the observers expected to interact with the person who imposed the threat, the person who was threatened, or neither. We therefore expected that in the conditions we investigated, observers of interpersonal synchrony would experience threat to their freedom and that the reactance induced by this threat would decrease their disposition to conform to others' preferences in a product choice task.

These cognitive and motivational factors could both exert an influence and their effects on conformity could partially offset one another. However, the relative impact of these factors may differ. This difference is suggested in part by research on actor-observer differences in attributions and judgment (Jones and Nisbett 1971; for a review, see Fiske and Taylor 1991). Moreover, the differences in actor and observer perspectives could influence other things, including the intensity of emotions (Hung and Mukhopadhyay 2011), the reliance on concrete versus abstract information (Yan and Sengupta 2011) and expectations for a service encounter (Cowley 2005). In the present context, actors who engage in synchronous behavior are likely to focus their attention primarily on the goal toward which their behavior is directed (i.e., matching the actions of others). To this extent, general concepts associated with this goal may become salient and influence later behavior for reasons suggested by Wyer et al. (2012). In contrast, observers' attention may be directed primarily to the actors' behavior per se (Nisbett and Wilson 1977). Conse-

quently, observers may be relatively more sensitive to the restrictions on freedom exemplified by this behavior than to the goal to which the behavior is directed and may be more likely to experience reactance.

We conducted four studies to examine these predictions and the underlying mechanisms. In Study 1, participants either first engaged in, or first saw others engage in synchronous or non-synchronous exercise, and then were asked to make brand choice for several product categories. Consistent with our prediction, participants were more likely to conform to others' preferences in a product choice task after engaging in synchronous behavior than after behaving non-synchronously, whereas observers of this behavior were less likely to conform to others' product choices when the behavior they observed was synchronous than when it was not. In Study 2, actors in some conditions were given a free choice over whether to perform the behavior or not, and this choice was made salient to observers. As expected, giving actors freedom to choose whether to engage in synchronous behavior increased both actors' and observers' conformity relative to conditions in which actors were required to perform the behavior. Also, we found that situational reactance mediated the effect of choice freedom on conformity.

Studies 3 and 4 evaluated further implications of our conceptualization. In Study 3, actors were told that they would compete with other groups for a reward to be given to the group that was most successful in behaving synchronously. Moreover, in some conditions, observers were told that they would share the reward with the actors, thus tying their own outcomes to the actors' success. In other conditions, observers believed that their reward would be independent of the actors' success. Results in this study showed that stimulating observers to imagine that the persons they observed were in-group members, which increased their sensitivity to the restrictions imposed on their behavior, decreased their likelihood of donating to unique charity organizations in a subsequent unrelated donation task. Study 4 showed that stimulating actors to anticipate engaging in synchronous behavior rather than actually doing so, thus inducing them to imagine the behavior from the perspective of an observer, decreased their conformity relative to conditions in which they actually performed the behavior. In combination, the four studies provided converging evidence for the dual effects of interpersonal synchrony that we proposed.

This research, to our best knowledge, is the first to test the implications of engaging and observing synchronous behavior on individuals' disposition to subscribe to popular courses of actions in the context of consumer choice. In addition, our paper shows that cognitive processes, such as mindset, can interact with motivational processes (e.g., reactance) to jointly affect subsequent unrelated behaviors. These results suggest the importance of considering the relative impact of cognition and motivation in studying consumer behavior.

Intertwined Destinies: How Subsistence Entrepreneurs and Consumers Harness Social Capital to Overcome Constraints and Uncertainties

Srinivas Venugopal, University of Illinois at Urbana-Champaign, USA
Madhu Viswanathan, University of Illinois at Urbana-Champaign, USA
Raj Echambadi, University of Illinois at Urbana-Champaign, USA
Srinivas Sridharan, Monash University, Australia

EXTENDED ABSTRACT

Consumer research has significant potential for contributing unique insights into the human experience of poverty and mechanisms for poverty alleviation (Chakravarthi, 2006). Reaching this potential, however, will require CB research to explore some of the distinct and unique consumption experiences that occur in the lives of the poor. One such phenomenon is the duality of consuming and engaging in entrepreneurial activity, both with the goal of survival. The consumption-entrepreneurship interface is inadequately explored in the consumer literature, especially in contexts of poverty. Entrepreneurship involves the detailed study of the sources and exploitation of entrepreneurial opportunities and the set of individuals who discover, evaluate, and exploit them (Shane and Venkataraman, 2000). Despite the burgeoning body of research in entrepreneurship, the study of entrepreneurial action in poverty contexts has received limited attention. Consequently, little is known theoretically regarding the entrepreneurial process in these contexts (Webb et al., 2009). In this article, we attempt to fill this gap by focusing on subsistence entrepreneurs, also referred to as subsistence consumer-merchants, who operate within the informal economy (Viswanathan et al., 2010). Subsistence entrepreneurs are those who a) live in poverty themselves, b) are embedded within the social milieu of their customers and c) engage in entrepreneurial action with the goal of economic survival (Viswanathan et al., 2010). Past literature brings to light the duality of roles of subsistence entrepreneurs. Viswanathan and colleagues (2010) maintain that, in subsistence contexts, the consumer and entrepreneur roles are two sides of the same coin. Further, the subsistence entrepreneur is seen as being a hub of an interdependent and self-sustaining system of relationships with vendors, consumers and family members (Viswanathan et al., 2010). We draw from this systemic view of the subsistence entrepreneur's relational ecosystem and focus specifically on the entrepreneur-consumer dyad. We employ a nuanced view of social capital, namely, structural, relational and cognitive social capital as a theoretical lens. We use this theoretical lens to explain the mechanisms thorough which the subsistence entrepreneur-consumer dyad harnesses different dimensions of social capital to overcome constraints and uncertainty and co-create unique value in contexts of poverty.

Figure 1: Model

Our field research was conducted in Chennai, South India. We conducted 11 in-depth interviews, beginning with informant's life circumstances and then focusing on consumer and entrepreneurial activities (see Moustakas, 1994). Interviews were analyzed in accordance with guidelines for constructing grounded theory (Goulding, 1998).

Life in poverty is marked by constraints and uncertainty at multiple levels. As reviewed, individual-level constraints include low literacy and low income. Community level constraints include such factors as limits to interactions and opportunities across gender lines or social hierarchies, the lack of recourse in the face of exploitation by more powerful community members. Further, subsistence individuals face larger environmental-level constraints relating to physical infrastructure, institutional mechanisms, and labor and capital markets (Khanna and Palepu, 2005). Constraints at multiple levels contribute to a mix of uncertainties that leave individuals vulnerable. In the face of poverty and limited survival prospects, entrepreneurial action is seen as the primary source of earning income, thereby managing uncertainty and ensuring immediate survival.

Despite extreme constraints, subsistence entrepreneurs survive and overcome daunting challenges and possess both strengths and vulnerabilities to navigate these trying environments. Entrepreneurs are "experts" at survival but, at the same time, they are also constrained at individual and marketplace levels. Learning about the marketplace stems from face-to-face interactions between buyers and sellers. Sharing adversity and empathizing with each other leads to greater understanding of the two roles. Interestingly, these relationships with consumers help entrepreneurs learn about and navigate the marketplace. In the following section, we highlight how the entrepreneur-consumer dyad harnesses cognitive, relational and structural social capital to co-create mutual value.

The cognitive dimension, i.e. shared life circumstances and common life goals, forms the platform for the development of social capital. Both the entrepreneurs and their customers live in poverty and hence the level of empathy for one another's life circumstances is inordinately high (Viswanathan et al., 2009). Subsistence entrepreneurs share adversity with their customers and they tend to identify with each other being members of the same group, as noted in literature in other contexts (Tajfel, 1982). They tend to possess a shared narrative of living and subsisting in poverty which enables them to comprehend, process, and exchange rich sets of deeper meanings that literature in other contexts has highlighted (Nisbet, 1969). Both entrepreneurs and their customers perceive themselves to be part of a larger community and hence are both bound by community-level expectations, norms, and obligations to help each other in times of need.

Owing to the nature of, and the frequency, of interactions between the entrepreneurs and the customers, trust is developed which, in turn, leads to commitment to each other (Morgan and Hunt, 1992) and enduring relationships. Trust becomes the mechanism by which entrepreneurs and their customers become open and willing to share information, co-operate, and invest in each other. Trust is a by-product of the interactional environment that has been characterized as having enduring relationships and being empathetic (Viswanathan et

al., 2011). Relational social capital emphasizes the primary purpose of subsistence entrepreneurship, i.e. to survive at a basic human level and to help "similar" others. Over time, the history of repeated fruitful interactions begets more trust and renewed commitment thereby leading to enhanced levels of social capital.

Subsistence entrepreneurs live in close proximity with their customers and their lives are interdependent. Interdependence marks social ties between entrepreneurs and their customers and reflects structural social capital referred to as the "impersonal configuration of linkages between people" (Nahapiet and Ghoshal, 1998; p244). As physical proximity is positively related to greater interpersonal communications (Ganesan et al., 2005), by virtue of being in the same community, subsistence entrepreneurs and their customers can engage in frequent face-to-face communications. Information benefits occur to these subsistence entrepreneurs in all three forms of access, timing, and referrals (Burt, 1992). Apart from the access and timing benefits that arise of these embedded social connections, these rich relationships also provide referral opportunities to other customers within the same community.

The Product-agnosia Effect: How Increased Visual Scrutiny Reduces Distinctiveness

Jayson Jia, Stanford University, USA
Sanjay Rao, Stanford University, USA
Baba Shiv, Stanford University, USA

EXTENDED ABSTRACT

A picture is said to be worth a thousand words. But does that mean two pictures are worth two thousand words? And what about seven pictures? Situations abound where consumer decisions are based on visual appeal, whether we are looking at cars, shoes, or birthday cakes. When comparing objects visually, our intuition suggests that more visual scrutiny should aid information processing. However, this simple intuition does not consider the possibility that acquiring more visual information may alter the structure and style of visual information processing – with potentially detrimental effects. Thus, looking more can end up yielding less if it changes *how* we look.

Specifically, increased viewing of choice objects leads to more local-level processing and less global-level processing. Since products are often distinguished through global-level features such as style and brand, increased focus on a product's local-level features can result in a relative decline in uniqueness and attractiveness. Conceptually, such a shift in perceptual focus is akin to comparing brush strokes in a painting rather than the overall picture, or contrasting individual trees instead of entire forests. Across four studies, we explored how more visual exposures can generate product-agnosia (the loss of ability to distinguish between products) through shifts in perceptual focus.

STUDY 1

To demonstrate the basic effect, participants (n=105) in Study 1 were randomly assigned to one of three conditions to evaluate two pairs of shoes. In the single picture condition, subjects were exposed to one picture of each shoe. In the multiple-repeated picture condition, subjects were exposed to seven of the same picture of each shoe. In the multiple-unique picture condition, subjects were exposed to seven unique pictures of each shoe (see Figure 1). To simulate a real purchasing context, the pictures were obtained from a leading online retailer (zappos.com), which like many other retail websites has the option of viewing more pictures of products from "additional views".

We found that similarity ratings of the shoes were higher in the multiple-unique picture condition than in the single and multiple-repeated picture conditions ($p < .05$). There was no significant difference between the single and multiple-repeated picture conditions. In other words, the products became relatively less distinct after multiple visual scrutiny to new visual images.

STUDY 2

Study 2 expanded the findings of Study 1 to another product category (duffel bags) and contained a thought listing task to explore the mechanism driving product-agnosia. Participants (n=102) were randomly assigned to the single-picture or multiple-picture condition using the same experimental paradigm as Study 1. At the end of the survey, participants were also asked to list their thoughts about the products presented. The thoughts were coded for perceptual focus (local vs. global-level) by two independent coders (alpha = .98).

Consistent with Study 1, we found that perceptions of product uniqueness ($p < .05$) and predicted liking ($p < .1$) was lower in the multiple picture condition. The thought listing task showed a higher proportion of local-level thoughts ($p < .05$) in the multiple exposure condition, and no difference in total number of thoughts between the

two conditions ($p = .39$). Thus, in addition to providing a further demonstration of the main effect, Study 2 yielded evidence that increased visual exposure can lead to a shift to more local and less global –level processing

STUDY 3

In Study 3, we demonstrated the causal link between local and global –level processing and the product-agnosia effect by directly manipulating perceptual scope using a 2 (global, local processing) X 2 (single, multiple visual exposures) ANOVA design. In Part 1, we induced global versus local processing using a procedure similar to Friedman et al (2003). Participants (n = 124) were shown seven maps of different American states sequentially, each on a different page. In the global condition, subjects were asked to look at the overall features of each state map, whereas in the local condition, subjects were asked to focus their attention on a marker that pointed to a city near the center of the map. In Part 2, we used the same single versus multiple exposures experimental paradigm as in Study 1 (as well as the same products and images).

We found significant interactions for perceptions of uniqueness (Figure 2), attention-grabbing, predicted liking, and choice strategy (p's < .05). Under induced- local processing, increased visual exposures resulted in an analogous pattern of results as Study 1, where the shoes became less distinct, attention-grabbing, and attractive, and participants were less likely to engage in a global-level choice strategy ('focus on style'). But under induced global processing, we found the opposite trend, and that increased visual exposures resulted in the shoes being rated as more distinct, attention-grabbing, and attractive, and a global-level choice strategy was more prevalent.

STUDY 4

In Study 4 (n = 84), we found an analogous reversal of the product-agnosia effect under different memory conditions. The intuition for such an effect is that when evaluating from memory, we recall gestalt (global) features more than details (local). Under stimulus-evaluations (not memory based), we find that the multiple picture condition induces product-agnosia (less distinctiveness, lower willingness to pay, p's < .05). However, under recall-evaluation (memory based), we find that the multiple picture condition increases perceived distinctiveness and willingness to pay (Figure 3, Figure 4, p's < .05).

Overall, the persistence of the effect after inducing local processing but its reversal after inducing global processing provides evidence that the product-agnosia effect is driven by perceptual scope. When one's perceptual scope is local and focused on narrow details, new information through multiple observations were disadvantageous for ratings of distinctiveness and predicted liking. However, when one takes a metaphorical step back under global processing, increased visual exposures begin to have benefits for a product's perceived distinctiveness and predicted liking. These effects have numerous implications for marketing strategy, product positioning, and optimal consideration set construction: For example, generic or entry brands may seek to induce product-agnosia to better compete with premium brands, while brands that desire to maintain unique positioning would do best to carefully manage the perceptual scope of their own advertising.

Exploding Turkeys and Shattered Reporters:
Comparative Ads and Their Unintended Affective Consequences

Ozge Yucel-Aybat, Pennsylvania State University at Harrisburg, USA
Thomas Kramer, University of South Carolina, USA

EXTENDED ABSTRACT

Comparative ads, in which marketers "identify their competitors directly or by clear implication," are becoming more popular in media (Roggeveen, Grewal and Gotlieb 2006). Frequently, when marketers compare their brands to others, they show comical situations in which misfortunes befall those consumers who are using competitors' brands instead of theirs. For instance, in AT&T's "Exploding Turkey" commercial, we see a house destroyed by an exploding deep-fried turkey since the owner who did not have AT&T service could not be reached on time to be notified of the danger. In another commercial, misfortunes befall reporters, who do not have AT&T service and could not be warned that they were standing in a blast zone. We propose that when marketers show unfortunate events happening because of using the wrong or a competitor's product, they may incidentally invoke "schadenfreude," defined as a malicious pleasure at the misfortunes of others, which in turn will impact consumers' purchase intentions and attitudes.

Comparative (vs. noncomparative) ads have been shown to generate positive consumer responses (Grewal et al. 1997). Moderators, such as comparative valence of framing (Jain et al. 2007) and consumer-related variables such as need for cognition (Polyorat and Alden 2005) have been identified. Surprisingly, research to date has examined the impact of comparative ad appeals without taking consumers' affective reactions into account. However, persuasive messages used in advertisements have been shown to elicit affective reactions that may mediate consumers' attitudes and behaviors (Holbrook and Batra 1987). Schadenfreude appears particularly relevant in comparative advertisements because these ads often depict the unfortunate failures of competitors' brands. Thus, in the current research, we examine schadenfreude as an incidental emotional response elicited by comparative ads and investigate its impact on attitudes and purchase likelihood. Further, we suggest that the effects of schadenfreude may not be uniform for everyone and an individual's competitiveness is an important antecedent of incidental schadenfreude.

In study 1, participants were presented with the storyboard of a digital camera (XYZ) and their competitiveness level was measured. In the comparative ad condition, brand XYZ compared itself to a cheaper brand by showing the competitor brand fail; in the noncomparative ad condition no competitor was mentioned. Results revealed a significant two-way interaction between ad type and competitiveness on schadenfreude (β = .500, t = 2.335, p < .05). More competitive individuals were likely to feel greater levels of incidental schadenfreude when exposed to comparative versus noncomparative ads ($M_{comparative}$ = 3.67, $M_{noncomparative}$ = 2.87, t = 2.128, p < .05). Also, more (vs. less) competitive participants experienced greater levels of schadenfreude in the comparative ad condition ($M_{more\_competitive}$ = 3.67, $M_{less\_competitive}$ = 2.77, t = 2.287, p < .05). Moreover, ad type did not have any significant effect on schadenfreude for less competitive participants.

Study 2 introduced a boundary condition by investigating the impact of brand status and shows that higher- (vs. lower-) status brands invoke greater levels of incidental schadenfreude in their comparative (vs. noncomparative) ads. Brand status was manipulated by portraying Mercedes (vs. Kia) as the advertiser in the higher-status (vs. lower status) brand condition. Results showed that more

competitive participants felt more schadenfreude when they saw the comparative (vs. noncomparative) ad of the higher-status brand ($M_{comparative}$ = 4.44, $M_{noncomparative}$ = 1.73, t = 4.358, p < .01). However, level of schadenfreude of less competitive participants did not significantly differ according to ad type. Consistent with study 1, more (vs. less) competitive participants felt more schadenfreude in the higher-status brand condition ($M_{more\_competitive}$ = 4.44, $M_{less\_competitive}$ = 3.43, t = 1.7564, p = .08). There were no significant results in the lower-status brand condition (β = 0.281, t = 0.674, p > .50).

In study 3, we explored the effect of incidental schadenfreude on the downstream implications of attitudes and purchase likelihood. Participants in the comparative ad condition were presented with the storyboard for a deodorant in which a higher-status (vs. lower-status) brand compared itself to another brand by showing the misfortunes happening to the person who bought the competitor brand. No comparisons were used in the noncomparative ad condition. The analysis revealed a significant three-way interaction on purchase likelihood (β = 1.510, t = 3.396, p = .001). Consistent with the results of study 2, more competitive individuals experienced greater schadenfreude when exposed to the comparative ad of the higher-status brand. As a result, they were more likely to buy the advertised product ($M_{comparative}$ = 4.93, $M_{noncomparative}$ = 3.76, t = 2.63, p < .01). However, purchase likelihood of less competitive individuals did not significantly differ according to ad type. A moderated mediation analysis demonstrated that schadenfreude was the mediator on purchase likelihood for the higher-status brand. Moreover, the mediating effect was valid for more competitive but not for less competitive participants. Incidental schadenfreude also mediated brand and ad evaluations such that more competitive individuals had more positive attitudes towards the brand and the ad when exposed to the comparative ad of the higher-status brand.

Study 4 manipulated level of competitiveness and investigated a way to persuade less competitive consumers to buy the advertised product in a comparative ads. Research has indicated that schadenfreude may heighten individuals' anticipation of misfortunes happening to them (Kramer, Yucel-Aybat and Lau-Gesk 2011). Therefore, in this study, we reassure participants that the misfortunes shown in the ad will not happen to them if they buy the advertised brand, and thus encourage them to feel higher levels of schadenfreude. An ANOVA on purchase likelihood revealed a three-way interaction among the predictor variables (F(1, 126) = 7.222, p < .01). As expected, reassurance encouraged less competitive participants to buy more in the higher-status brand condition ($M_{reassurance}$ = 4.56, $M_{no\_reassurance}$ = 3.50, F(1, 126) = 9.393, p < .01). However, the purchase likelihood of more competitive participants did not significantly differ whether reassurance was present or absent. Moreover, schadenfreude mediated purchase likelihood for less competitive participants and not for more competitive participants when reassurance was present.

What Did You Do To My Brand?
Consumer Responses to Changes in Brands Towards Which They are Nostalgic

Alison B. Shields, Kent State University, USA
Jennifer Wiggins Johnson, Kent State University, USA

EXTENDED ABSTRACT

Marketers often make changes to brands to make the brand seem current or exciting. Some updates are successful while others are spectacular failures. This research establishes a connection between consumer acceptance or rejection of updated brands and the consumer's reported nostalgia towards the brand. We develop and measure a new construct, Nostalgia Towards the Brand, defined as "an individual's positive affect towards a brand due to the brand's associations with the individual's lived past." We show that consumers' affective and attitudinal responses to changes in a brand are moderated by Nostalgia Towards the Brand.

Nostalgia has been defined as "a positively toned evocation of a lived past" (Davis 1979), and "a fondness for possessions and activities associated with days of yore" (Holbrook 1993). Consumers have been observed to engage in nostalgic behaviors, from re-watching favorite old movies (Holbrook, 1993) to reminiscing about favorite cars from their youth (Brown, Kozinets and Sherry 2003) to consuming specific foods as a way to reconnect with the past (Loveland, Smeesters and Mandel, 2010). Consumers have also reported nostalgic feelings for particular brands or items (Holbrook and Schindler 2003).

When individuals recall nostalgic memories, they recall affect and brand information stored in their schema for the target brand (Collins and Loftus 1975). Nostalgia is "not a true recreation of the past but rather a combination of many different memories, all integrated together and in the process, all negative emotions filtered out" (Hirsch 1992). Thus, the individual's memory trace will be biased, leading the individual to recall the brand as being better than it actually was. Once the individual experiences the updated brand, he will compare the new experience to his biased memory and attempt to assimilate the new stimuli into his existing schema. The individual's ability to assimilate the new experience into their schema built on the biased memory will depend on the degree of change to the brand as well as the individual's level of nostalgia towards the brand.

Therefore, we predict that when the change to the brand is small, individuals will be able to assimilate the change regardless of their nostalgia toward the brand because the update will fit smoothly into their existing schema without significant cognitive effort. Individuals' affective response and attitudes toward the changed brand are expected to reflect their feelings towards the original brand, leading higher nostalgia individuals to exhibit more positive attitudes toward the changed brand than lower nostalgia individuals. However, as the degree of change to the brand increases, individuals who are more nostalgic towards the brand will engage in higher levels of cognitive effort when making assimilation/contrast judgments because of their increased schema complexity and resulting attribute-based processing. This increase in cognitive effort will lead to a smaller latitude of acceptance, causing nostalgic individuals to reject the change more readily than individuals who are not nostalgic towards the brand.

Hypothesis 1:   When the change to the brand is small, individuals with higher nostalgia towards the brand will exhibit more positive affective response and attitudes toward the brand than individuals with lower nostalgia toward the brand.

Hypothesis 2:   As the change to the brand becomes larger, individuals with higher nostalgia towards the brand will exhibit more negative affective responses and attitudes toward the brand, while individuals with lower nostalgia towards the brand will not exhibit a change in affect and attitudes.

The hypothesized effects were tested in two experiments, one using two distinct brands with perceived small and large degrees of change (based on pretests) and the second using a single brand with two levels of manipulated changes. Subjects were assigned to low, moderate, and high nostalgia clusters based on their response to the Nostalgia to the Brand scale and their affective responses, attitudes toward the original and changed brand, and purchase intentions toward the changed brand were measured.

Across both studies, attitudes towards the original brand were more positive when nostalgia towards the brand was greater. Consistent with the proposed positive memory bias, highly nostalgic participants in the small change condition also reported more positive affective and attitudinal responses to the updated brand than did low or moderately nostalgic participants, supporting Hypothesis 1. In the large change condition, highly nostalgic individuals rejected the change and showed a significantly greater magnitude in the drop of their affective and attitudinal responses than did individuals in the moderate nostalgia cluster. In the low nostalgia cluster, conversely, individuals reported similar levels of attitude and affect in both the high and low change conditions, suggesting more attitude based processing and wider latitudes of acceptance, supporting Hypothesis 2. Interestingly, moderately nostalgic individuals exhibited a negative change in affect and attitudes in Study 1, but not in Study 2, suggesting that there is a threshold level of nostalgia before these changes are observed.

These findings suggest that when confronted with changes to a brand, consumer responses will be influenced by nostalgia towards the brand. Brands with nostalgic consumers should be wary of making changes to their brands and risking negative consumer responses.

The Mere Presence of Money Motivates Goal Achievement

Gülen Sarial-Abi, Koç University, Turkey
Kathleen D. Vohs, University of Minnesota, USA

People's relationship with money is inherently tied to goal pursuit. When people use money, they do so as an act that serves to reach a desired end-point (Baumeister, 1998; Carver & Scheier, 1990). Likewise, people also obtain money for performing jobs and tasks that meet a standard, which also links the idea of money to goal pursuit. Consider the act of going to dinner at a restaurant. The diner who is hungry and wants to be full (i.e., this is the goal) pays money to the restaurateur as compensation for providing the means to achieve the goal. Hence, money enables the means by which people reach myriad commonplace goals. The current work tested whether people reminded of money become particularly attuned to the presence of a goal in that they show enhanced motivation in the presence of goals.

We do not posit that reminders of money enhance motivation without the presence of a goal. The concept of money has many connotations, including greed, fair trade, free markets, and so on. In other words, the construct of money does not wholly overlap with goal pursuit, but is proposed to have such deep motivational connections that the construct of money will potentiate the psychological system to be ready for goal pursuit. Hence we predicted that in the presence of goal pursuit cues, reminders of the concept of money would stimulate motivation, relative to non-money reminders. In contrast, when goal pursuit cues were absent, we predicted that reminders of the concept of money would not change motivation relative to non-money reminders. We tested these hypotheses in 5 experiments. Using contexts ranging from financial, health, performance, and fun goals, we saw robust support for our predictions.

In study 1 (N = 108), we tested whether participants reminded of money, relative to others, would report lower purchase intentions if they had been given a goal of curbing their spending. An ANOVA with money prime and goal condition factors as predictors of spending intentions revealed the predicted interaction effect, $F(1, 104) = 5.21, p < 0.05$. Planned comparisons showed that participants in the money condition who were given an explicit goal (versus no goal) reported lower spending intentions, $F(1, 104) = 7.17, p < .05$. Participants in the no money condition, however, did not differ in their spending intentions as a function of goal condition, $F < 1$.

In study 2 (N = 90), we studied goal pursuit in the domain of limiting caloric intake. An ANOVA with money prime and goal condition as predictors of healthy attitude scores revealed the predicted interaction effect, $F(1, 86) = 4.68, p < .05$. Planned comparisons revealed that participants in the money condition who were presented with a goal to restrain their eating had more favorable attitudes toward the healthy words than did participants who were not reminded of money, $F(1, 86) = 13.81, p < .001$. Furthermore, in the absence of being given a goal, whether participants earlier had been reminded of money did not affect their attitudes toward the healthy words, $F < 1$.

In study 3 (N= 108), participants were once again reminded of money or not. They were given a lengthy set of mathematical prob-

lems to solve by hand. Some of them were told that their goal was to solve as many as possible, whereas others were not given a goal. Time spent on the problems was our dependent measures of motivation. An ANOVA with money prime and goal condition as predictors revealed the predicted significant interaction effect, $F(1,104) = 18.85, p < .001$. When given a goal, participants who had been primed with money, relative to their non-money primed counterparts, spent more time trying to solve the math problems (39.69 min vs. 29.64, $F(1,104) = 17.20, p < .001$). Without being given a goal, though, duration was equivalent among participants primed with money or fish (25.86 vs. 30.76, $F(1,104) = 3.98, p > .05$).

Study 4 (N = 113) adopted a new context in which to study the effects of money cues and goals. Because people's exposure to money is largely utilitarian, it could be that reminding people of the concept of money simply activates hard work but not goal pursuit per se. We tested this alternative explanation in a study in which participants' goal was to have fun and enjoy themselves. An ANOVA on intentions to do fun things revealed a significant money (vs. no money) and goal (vs. no goal) interaction, $F(1, 109) = 4.25, p < .05$. Specifically, when participants in the money (vs. no money) condition had a goal, they were more likely to have intentions to do fun things (6.47 vs. 5.56, $F(1,109) = 6.09, p < .05$). Furthermore, when participants in the money (vs. no money) condition did not have a goal, intentions to do fun things did not differ significantly (5.61 vs. 5.76, $F(1,109) = .19, p > .67$).

Finally, results of Study 5 (N = 96) showed that duration spent to solve the puzzles revealed a significant money (vs. no money) and task framed as fun (vs. no fun) interaction, $F(1, 92) = 6.29, p < .05$. Specifically, when participants in the money (vs. no money) condition had a task framed as fun, they spent more time on solving the puzzles (50.14 vs. 41.31, $F(1,92) = 8.02, p < .05$). Furthermore, when participants in the money (vs. no money) condition had a task that is not framed as fun, time spent on solving the puzzles did not differ significantly (37.35 vs. 39.56, $F(1,92) = .51, p > .48$).

The findings of this research contribute to the literature in several ways. First, we demonstrate money as a tool for goal-achievement. Second, we integrate the literature in psychology of money and self-regulation to highlight the underlying mechanism under the influence of money on goal-achievement. In sum, our data, for the first time, shows that money can be used as a facilitator for goal-achievement.

Power Distance Belief, Status, and Charity Giving

DaHee Han, Indiana University, USA
Ashok K. Lalwani, Indiana University, USA
Adam Duhachek, Indiana University, USA

EXTENDED ABSTRACT

Power distance belief-the tendency to accept and expect inequalities in society- is a central construct in cross-cultural research (Hofstede 2001). Although limited research has examined the effects of PDB on consumer behavior, there is growing recognition that PDB is an important construct with significant implications on varied facets of consumer behavior (Winterich and Zhang 2011; Zhang et al. 2010). The current research is concerned with the effects on PDB and charitable giving. Some research shows that people in high PDB contexts are less likely to donate to maintain the status quo (Winterich and Zhang 2011).

Although this finding provides initial evidence that individual beliefs about inequalities in power affect charitable giving, we argue that charitable giving depends not only on individual beliefs toward power disparity but also on their own perceived power within the system. Prior research suggests that power held by individuals affects prosocial behaviors (e.g., Goetz et al. 2010; Piff et al. 2010). Therefore, we propose that the extent of charitable giving across PDB contexts depends on the power (i.e.,"perceived asymmetric control over valued resources [Keltner, Gruenfeld, and Anderson 2003; Rucker, Galinsky, and Dubois, 2011, p.8]").

In particular, we propose that among high PDB consumers, high power people will be more likely to donate to charity than low power people because in high PDB contexts low power people owe high power people respect and obedience whereas high power people in turn owe low power people protection, help, and support (i.e., the reciprocity principle; Carl et al. 2004). In contrast, we argue that in low PDB contexts, high power people will be less likely to donate to charity than low power people because low PDB consumers believe that it takes a lot of effort, persistence, and energy to become a member of the high power group as the government and society have rules to protect equality in society. Given the difficulties involved, high power people in low PDB contexts tend to be careful with money at best and miserly at worst (Stanley and Danko 1998).

We further posit that the mechanism underlying these effects relates to differences in empathy, defined as "an other-oriented emotional response congruent with the perceived welfare of another" (Batson 1990, p.399) felt by high and low power people in the two types of systems. Specifically, we hypothesize that in high PDB contexts, high (vs. low) power people will feel greater empathy toward people in need because of the reciprocity principle outlined earlier (de Waal 2008; Fisher et al. 2008), thus leading to greater charitable giving. Conversely, in low PDB contexts, low (vs. high) power people will feel greater empathy toward people in need because low power people in low PDB contexts have been found to pay more attention to others' needs (van Kleef et al. 2008) and behave in ways that enhance social engagement and connection with others (Piff et al. 2010), thus leading them to be more prosocial (i.e., greater charitable giving).

Study 1. We manipulated participants' perception of their power using the role playing scenario (Anderson and Berdahl 2002) and power distance belief by following the procedure of Zhang et al. (2010). Next, we showed the brief description of charities and then measured the amount of money participants would donate to charities. Results revealed a significant power by PDB interaction (p<.003) such that in the high PDB condition, participants with high

power donated more than those with low power (p<.033) whereas among participants in the low PDB condition, those with high power donated less than those with low power (p<.042), supporting our hypotheses.

Study 2. PDB was manipulated by asking participants to complete a scrambled sentences task (see Zhang et al. 2010). We manipulated power by asking participants to recall the incident that they felt powerful or powerless (Rucker and Galinsky 2008). Donation intention and empathy were measured (Stürmer et al. 2006). A 2-way interaction results (p<.001) revealed that in the high PDB condition, those with high power reported greater intentions to donate money to the charity than those with low power (p<.001) whereas within the low PDB condition, those with low power reported greater intentions to donate money to the charity than those with high power (p<.001). In addition, a 2-way interaction results (p<.001) indicated that in the high (low) PDB condition, those with high (low) power reported greater empathy than those with low (high) power (ps<.03). Finally, we performed mediation analyses (Muller et al. 2005) and found that empathy mediated the proposed relationship (Sobel test:z=3.01,p<.002).

Study 3. We experimentally manipulated empathy to provide further evidence of the process underlying our effects. We manipulated empathy (Batson et al. 1997, study 1) and power as in study 2 and measured PDB using the scale developed by Zhang et al (2010). We also used a different charity and measured donation intention. We measured perceived similarity to rule out the alternative explanation. Results indicated that the three-way interaction was significant for donation intention (p<.001). In the high empathy condition, the results replicated such that for participants high in PDB, power was positively associated with charitable giving (ß=3.44,p<.001), whereas for participants low in PDB, power was negatively associated with charitable giving (ß=-2.86,p<.001). These relationships were not observed in the low empathy condition. The three-way interaction for perceived similarity was not significant (p>.79), ruling out the alternative explanation.

Our research makes a number of contributions. First, it shows that charitable giving depends on not only individual beliefs about inequalities in society, but also on their own power within the system. Second, prior research suggests that empathy based charitable donations stem from perceived similarity between the donor and the recipient. In sharp contrast to this perspective, our framework highlights the role of differences based on inequalities within the system. Hence, empathy does not always result from perceived similarity, but strong differences in power and inequality can promote empathy and lead to charitable giving.

When Does Personalization Really Pay Off?

Isabelle Kes, TU Braunschweig, Germany
David M. Woisetschläger, TU Braunschweig, Germany

EXTENDED ABSTRACT

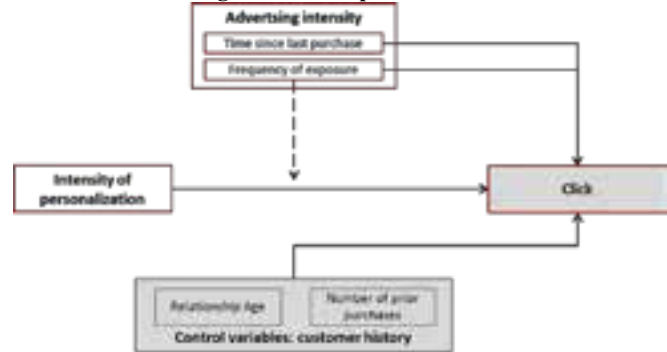
Personalized advertising is seen as THE mean to increase advertisement effectiveness and efficiency by selecting ad content being relevant to the customer and by answering the need for convenience of customers at the same time (Milne and Bahl, 2010). Especially regarding the depreciative opinion of many users on personalized advertisement it is important to know whether personalized advertisement is really worth the effort and costs it bears. Although in practice it seems to be common sense that personalization is more effective than standardization, little knowledge exists about circumstances that affect its performance outcomes. Therefore, this study questions the effectiveness of personalization in different conditions and attempts to identify success factors of personalized advertising. In particular we test the effect of personalization intensity, frequency of exposure, and the time since a customer's last action on the probability of a click. Additionally we control for differences in customer history.

CONCEPTUAL BACKGROUND

Several studies report that personalization in general is more effective than standardized mass communication (e.g., Lambrecht and Tucker, 2011). Beneath this, other studies focus on negative impacts of personalization, especially on customer reactions regarding the use of personal information (e.g., Pavlou and Stewart, 2000). As to the authors best knowledge no research exists that analyzes different intensities of personalization and its effectiveness and, surprisingly, no elaborate research stream exists that concentrates on circumstances under which different levels of personalization are effective. Our study tries to fill this gap by analyzing various intensities of personalization as well as the influence of the advertising strategy on its effectiveness.

Personalized banners use information about a customer to choose banner content the customer is highly involved with and that fit his interests. Thus, banners showing complementary products to a formerly bought one are seen as highly personalized, while those banners referring to a category of formerly visited products are slightly personalized. So, generally personalized banners are expected to be clicked more often than standardized ones, that show randomly chosen products unrelated to the customer. Moreover, higher personalization goes along with higher likelihood of a click (H1a/b).

After the consideration of this general coherency we focus on the different circumstances that determine varying potential for personalization. Our conceptual model includes hypothesis (H2-H5) regarding advertising strategy and its interactions with personalization intensity: While it is without controversy that frequency of exposure is a crucial determinant of banner success, no consensus exists about the optimal number of ad impressions (e.g., Manchanda et al., 2006). A high frequency goes along with the fear of oversaturation but it is also a mean to avoid banner blindness (Chatterjee, 2005). But even more critical is whether the effect on click likelihood is really linear: there are two opposing psychological processes operating simultaneously in the case of banner exposures (Lee and Cho, 2010): "Positive habits" lead to increasing effects with diminishing returns of each additional exposure, while "tedium" starts as result of repetitive exposure and decreases the effects gradually (Berlyne 1970). Referring to this discordance whether frequency has a linear or non-linear effect, we formulate rivaling hypothesis (H2a1-H2b). Moreover, time since the customer's last observed action is supposed to negatively influence click behavior. Structuration Theory sees interactions as recurring events that are embedded in a structure (Giddens, 1984). Hence past transactions influence future ones and are responsible for a decision to click (H3).

Figure 1: Conceptual Model


Furthermore, interactions between frequency of exposure and personalization are anticipated. As highly personalized advertising, using high involvement of a customer with banner content, is recognized faster, we expect that customers need to be contacted less often, to increase the likelihood of a click. (H4)

DATA AND METHOD

To answer our research questions, we used a real experimental design, that contained 1,939,939 adimpressions showed to 98.984 customers of whom 7,450 customers clicked on a banner. Five types of banners were sent out, including a standardized (click-through-rate .1%), two slightly personalized (.3%) and two highly personalized banners (.2%).

We take a binary logistic regression approach for testing our conceptual model. An often overlooked characteristic of logistic regression is that in case of an imbalanced sample it produces biased logit coefficients that underestimate rare events (King and Zeng, 2001). To take this as well as the huge amount of data into account we used bootstrapping. Thus, 1000 control samples are taken to control for the stability of the estimates. To adress the class imbalance between clicks and non-clicks within the data a stratified sampling is used to ensure a balanced sample of clicks and non-clicks (Nigam and Rao, 1996).

RESULTS

The analysis is separated in two steps: firstly the general advantageousness of personalization is tested, followed by a more detailed look on the differently personalized ads.

Personalized advertisement is clicked more often than standardized banners, confirming H1a. Surprisingly, with increasing levels of personalization the likelihood of clicking is reduced. Banners based on the product category of visited products had a stronger positive effect as those that contain products complementary to formerly bought ones. Hypothesis H2 and 3 could not be confirmed. Contrary to H4, sending out less personalized banners more frequently affects the probability of a click just slightly positive. But a slight increase of frequency for strongly personalized advertisement results in a con-

siderably higher click probability. Besides, controlling among others for number of prior purchases shows that with more past purchases more information about a customer can be collected and the more efficient is the advertising.

CONCLUSION AND IMPLICATIONS

First and foremost, companies need to realize that personalization is no universal remedy. Personalized banners are more effective than standardized while using high involvement content is not always the most effective personalization. Furthermore, weaker personalization is easier to realize and can be used with new customers that only visited a shop once. Regarding the frequency of exposure an increase is only effective in case of highly personalized banners. Although highly personalized banners seem to be inferior when considered isolated, in combination with a high frequency of exposure the probability of a click increases considerably.

Two Paths from Boredom to Consumption

Soo Kim, Northwestern University, USA
C. Miguel Brendl, Northwestern University, USA

EXTENDED ABSTRACT

Boredom is prevalent in today's society. Naturally in this era, one of the behaviors oriented towards escaping boredom is consumption (Spacks 1995). Indeed, it is not difficult to imagine our bored selves mindlessly reaching for the bowl of jellybeans or perhaps the long-neglected Dostoevsky on the table. However, what is yet unknown is when bored individuals would reach out for either the jellybeans or the Dostoevsky and why one over the other.

Although scarce, past literature has suggested that it is possible for individuals to attribute their experience of boredom either to the situation (Mikulas and Vodanovich 1993) or to the self (Svendsen 2005). Given these viewpoints, we propose that differences in to which source the experience of boredom is attributed would lead to a different consumption means for escape.

Specifically, we propose that when consumers attribute their boredom to the situation they would be drawn to vices, because vices (e.g., snacks) offer sensory pleasures that can reconcile the inadequately stimulating nature of the situation (Wertenbroch 1998). On the other hand, we propose that when consumers attribute their boredom to the self they may be looking for something that can help them restore the sense of meaningfulness (cf., van Tilburg and Igou 2011), known to be achievable by investing one's resources into attaining higher-order goals (King et al. 2006). In consumption context, one means to perceive that one is investing to achieve a higher-order goal (e.g., becoming a healthy person) would be to consume virtues (Khan et al. 2004), because, by consuming virtues (e.g., healthy foods) consumers can restore the sense of meaningfulness that they are engaging in purposeful actions ("I am investing to be healthy.").

Hence, we propose and test in three experiments that, whereas consumers under the influence of situation-attributed boredom would display a vice-preference, those under the influence of self-attributed boredom would display the opposite pattern: a virtue-preference.

EXPERIMENT 1

Experiment 1 tested whether consumers under situation-attributed boredom would increase evaluation of a vice whereas those attributing their experience of boredom to the self would increase evaluation of a virtue.

Participants were randomly assigned in a 3 (boredom-attribution: situation vs. self vs. baseline) x 2 (product: vice vs. virtue). Participants in the situation-attributed boredom condition read the description of boredom that drew their attention to the environment as the source whereas participants in the self-attributed boredom condition read the description of boredom that drew their attention to the self as the source. They also elaborated on how it felt/would feel to experience the respectively described boredom. Then, they indicated willingness-to-pay for either a vice (sundae) or a virtue (asparagus salad) on a $0-$10 scale. Baseline participants only completed the product evaluation.

Experiment 1 found that participants who attributed boredom to the situation increased evaluation of a vice whereas those who attributed boredom to the self increased evaluation of a virtue, compared to those in the other two conditions.

EXPERIMENT 2

Experiment 2 tested whether consumers under situation- or self-attributed boredom would still exhibit a preference for either a vice or a virtue, even when both options are available.

Participants were randomly assigned in a 3 (boredom-attribution: situation vs. self vs. baseline) and were instructed to write about their personal experience of boredom. Additionally, those in the situation-attributed boredom condition were asked to describe which aspect of the environment caused boredom whereas those in the self-attributed boredom condition were asked to describe which aspect of their character caused boredom. Baseline participants wrote about their rooms. Then, participants in the two boredom conditions waited 90 seconds on a blank screen for the "second" study to load. Baseline participants moved on without waiting. Then, all participants indicated willingness-to-pay ($0-$10) for both a vice (cake) and a virtue (salad). Participants' vice- versus virtue-preference was computed by subtracting their willingness-to-pay for a virtue from that for a vice.

Experiment 2 demonstrated that even when participants were provided with both a vice and a virtue, those under situation-attributed boredom paid more for a vice than a virtue (vice-preference). On the other hand, participants under self-attributed boredom paid more for a virtue than a vice (virtue-preference), even when both options were available.

EXPERIMENT 3

Experiment 3 tested whether the virtue-preference of consumers under self-attributed boredom was driven by their need to restore meaningfulness rather than by their need to boost their self-worth after attributing boredom to the self.

Participants were randomly assigned in a 2 (boredom-attribution: situation vs. self) x 3 (buffer: life-meaning, self-worth, no-buffer). As in experiment 2, participants first either wrote about their situation-attributed or self-attributed boredom. They then waited 90-seconds for a "second" task, where they had to write about their important possession (Dalton 2008) that either reflected their meaningful purpose in life (life-meaning buffer) or makes them feel good about themselves (self-worth buffer). Participants in the no-buffer conditions did not buffer via writing. Then, participants indicated willingness-to-pay ($0-$10) for both a vice (cookies) and a virtue (asparagus salad). Again, participants' vice- versus virtue-preference was computed by subtracting their willingness-to-pay for a virtue from that for a vice.

Experiment 3 found that participants who attributed boredom to the self but restored the sense of meaningfulness via a life-meaning buffer no longer exhibited a virtue-preference. However, the virtue-preference persisted for participants under self-attributed boredom who restored their self-worth (self-worth buffer) or those who did not buffer the self. Additionally, the vice-preference of participants under situation-attributed boredom persisted regardless of whether they buffered and what type of buffering they engaged in, indicating that it is the external environment, rather than aspects of the self, that must change for one to resolve situation-attributed boredom.

CONCLUSION

In sum, this work provides empirical evidence that bored individuals' consumption patterns differ depending on whether they attribute boredom to the situation or to the self. Also, by demonstrat-

ing that individuals under situation-attributed boredom prefer vices to virtues and vice versa for those under self-attributed boredom, we extend the field's understanding of why consumers experiencing boredom might be more drawn to one type of product over another.

Consumers' Search Intentions in Response to Conditional Promotions

Atul Kulkarni, University of Missouri, USA
Hong Yuan, University of Illinois, USA

EXTENDED ABSTRACT

Online retailers often offer conditional promotions such as a cash reward or free shipping, which shoppers can avail when their order sizes reach a threshold dollar value, e.g., $100. In this research, we examine consumers' search behavior in response to the conditional promotions.

Presumably, sellers' objective of offering a conditional promotion is to encourage shoppers to increase their basket sizes (Zhou, Katehakis, and Zhao 2009). If so, it would be useful to understand the effects that a free shipping promotion may have on consumer response, as compared to a cash reward promotion. We hypothesized that consumers perceive cash reward promotions as gains to be obtained, whereas free shipping promotions as losses to be avoided. Therefore, in accordance with the psychological value function (Kahneman and Tversky 1979; Thaler 1985) that is steeper in loss domain than in gain domain, we expected consumers to value free shipping promotion more than cash reward promotion. Study 1 tested this hypothesis.

Study 1. A 2-factorial (promotion type: free shipping versus cash reward) between-subjects design was used. In response to a hypothetical shopping scenario, participants were asked to imagine that they had to visit an online store to purchase a gift item for their niece's birthday. Further, they were asked to imagine that they found the gift item for $75, and proceeded to the checkout. At the time of checkout, the store reminded them of the promotion -free shipping or a cash reward- if their total basket size exceeds $100. They were also informed that the shipping charges (or, the cash reward) were flat $10. After reading this scenario, the participants were asked to report the likelihood that they will search for additional items in order to increase the basket size to be over $100. In line with our expectations, the search likelihood was significantly higher (F(1, 59) = 5.44, p<.023) when the promotion was free shipping (M_{sh} = 4.45) as compared to cash reward (M_{cr} = 3.42). Therefore, study 1 results support the conjecture that consumers encode different promotion types differently such that free shipping (cash reward) incentive is perceived as a loss (gain) to be avoided (obtained).

In study 2, we tested whether conditional promotions act as goals for consumers. If conditional promotions serve as shopping goals (e.g., Lee and Ariely 2006), then in accordance with the goal gradient hypothesis, consumers are more likely to search when they are relatively near to (vs. farther from) the goal (e.g., Hull 1932). Further, previous research has suggested that goal framing may interact with perceived distance to goal such that people may value positively (negatively) framed goals more when they perceive to be relatively far from (close to) the goal (e.g., Mogilner, Aaker, and Pennington 2008). Therefore, we hypothesized an interaction between promotion type (i.e., goal framing) and the relative distance to threshold basket sizes.

Study 2. A 2 (promotion type: free shipping vs cash reward) X 2 (original basket size: $25 vs $75) between-subjects design was used. A scenario similar to the study 1 was presented, and participants' search likelihood reports were obtained. As expected, the interaction between promotion type and original basket size was significant (F(1, 55) = 29.70, p<.001). In response to the threshold order size of $100 and the original basket size of $25, participants reported higher search likelihood for cash reward promotion (M_{cr} = 2.54) than for free shipping promotion (M_{sh} = 1.39). When the original basket

size was $75, participants reported higher search likelihood for free shipping promotion (M_{sh} = 5.03) than for cash reward (M_{cr} = 3.27). Further, as expected the effect of original basket size on search likelihood was also significant (F(1, 55) = 66.71, p<.000) with participants in the $75 ($M_{75}$ = 4.15) condition reporting higher search likelihood as compared to $25 ($M_{25}$ = 1.96). Thus, study 2 results support the conjecture that conditional promotions serve as shopping goals, and that promotion type interacts with relative distance to the threshold order size to influence search intentions.

In study 3, we examined whether consumers' search behavior is influenced specifically by their relative distance to a threshold order size or by a general sense of psychological distance experienced due to incidental objects/events. Previous research has implied that a sense of distance caused by an object or event (stimulus A) may influence individuals' subsequent evaluations, judgments, and behaviors toward another object or event (stimulus B) even when stimulus B may be unrelated to stimulus A (e.g., Brown and Levinson 1987). Trope and Liberman (2010) have argued that people access a common meaning underlying the different dimensions of psychological distance even when it is not directly related to their current goals.

Study 3. A 2 (promotion type: free shipping vs cash reward) X 2 (psychological distance: far vs close) between-subjects design was used with the experimental scenario similar to studies 1 and 2. The objective difference between the original basket size ($50 for all) and the threshold order size ($100) was kept the same for all participants. Following Liberman, Trope, and Stephan's (2007) postulation that psychological distance can be represented in terms of subjective perception of spatial distance, we manipulated spatial distance to prime participants with psychological proximity/remoteness. After reading the conditional promotions scenario, participants were asked to read a scenario about the city of Sydney (Chicago) for priming psychological remoteness (proximity), and then were asked report their search likelihood in response to the conditional promotions scenario. The interaction effect of psychological distance and promotion type on search likelihood was significant (F(1, 50) = 35.11, p<.006). When primed with psychological remoteness (proximity), participants reported higher search likelihood for cash reward (M_{cr} = 4.63) (free shipping (M_{sh} = 4.86)) promotion than for free shipping (M_{sh} = 2.59) (cash reward (M_{cr} = 3.58)). Thus, study 3 results suggest that not only perceived distance from the threshold order size, but completely irrelevant cues priming a sense of psychological distance can also interact with promotion type to influence consumers' search behavior in response to conditional promotions.

When White Obscures Evaluations: The Influence of Automatic Color Preferences on Product, Race and Spokesperson Evaluations

Ioannis Kareklas, Washington State University, USA
Frédéric F. Brunel, Boston University, USA
Robin A. Coulter, University of Connecticut, USA

EXTENDED ABSTRACT

Visual characteristics contribute greatly to the formation of initial evaluations of products and people (Bloch 1995). In this research, we focus on one visual element, color, and investigate how automatic color preference is linked to automatic product and spokespeople preferences. Building on color theory research, we argue that an automatic preference for the color white impacts consumers' automatic evaluations of products and people and may explain the lack of automatic in-group favoritism previously reported for African-Americans.

Research suggests that preference for white over black (1) can be traced to ancient tribal fears for darkness, the night and the unknown, versus the fondness for light, fire and the sun (Mead and Baldwin 1971), and (2) is acquired during early childhood and culturally reinforced through the learning of color symbolism (Duckitt, Wall, and Pokroy 1999). For example, in religion, literature and the media white often symbolizes "goodness," whereas black connotes "badness" (Williams, Tucker, and Dunham 1971). Because of this deeply rooted preference, and based on cross-cultural findings of an explicit white color preference across socio-cultural and ethnic backgrounds (Adams and Osgood 1973), we expect that Caucasian and African-Americans will automatically prefer the color white (vs. black) (**H1**) and white products over otherwise identical black products (**H2**).

The potential impact of automatic color preference becomes more complex as we consider evaluations of advertising spokespeople. Although skin color is a readily noticeable visual characteristic, its impact on automatic preferences is multifaceted. On one hand, building on an automatic preference for white and research showing a positive relationship between color and racial preferences (Neto and Williams 1997), one would expect that everyone would prefer light skinned (i.e., white) people and advertisements featuring light-skinned spokespeople (**H3**). On the other hand, because skin color can serve as a basis for in-group identification (Spira and Whittler 2004), and people evaluate members of their own group more favorably than people from other groups (in-group favoritism; Tajfel, Billig, Bundy, and Flament 1971), we would expect that both Caucasian and African-Americans would prefer in-group spokespeople (**H4**). However, H3 and H4 would lead to conflicting predictions for African-Americans.

These conflicting theoretical predictions for systematic color-based versus in-group-based preferences are echoed in previous studies. Although past findings support that consumers favor spokespeople from their in-group, the effects are mixed when race is the salient basis for identification. Research using explicit (i.e., self-report) measures has demonstrated that African and Caucasian-Americans respond more favorably to messages by spokespeople from their racial in-group (Schlinger and Plummer 1972; Whittler 1989). Yet, studies utilizing implicit measures have found that while Caucasian-Americans exhibit automatic in-group preferences, African-Americans do not exhibit automatic in-group preferences (Brunel, Tietje, and Greenwald 2004; Nosek, Banaji, and Greenwald 2002).

System justification theory provides an explanation for the lack of automatic in-group preference among African-Americans (Jost and Banaji 1994). It posits that a long history of discrimination can

lead individuals to internalize negative attitudes toward their own group as a means of justifying the status quo (Rudman, Feinberg, and Fairchild 2002). Notwithstanding, we propose that a universal automatic white color preference is an even more fundamental explanation for these contradictory results. We expect that automatic preference for white will strengthen (weaken) automatic in-group favoritism for Caucasian-Americans (African-Americans). In other words, observed automatic in-group preference is the combined cumulative effect of an automatic color preference plus a "unique" in-group effect. In particular, we argue that ignoring the effect of an automatic white color preference might have prevented previous studies from showing that African-Americans favor their in-group. Therefore, by removing the color effect, one can disentangle the two underlying effects and uncover a unique in-group preference for both African and Caucasian-Americans (**H5**).

METHOD

We administered a series of Implicit Association Tests (IAT; Greenwald, McGhee, and Schwartz 1998) to explore African and Caucasian-Americans' implicit color preferences (ICP, studies 1&2), implicit product preferences (IPP, study 1), implicit racial preferences (IRP, study 2), and implicit attitudes toward advertisements featuring African and Caucasian-American spokespeople (IAad, study 2). See Appendix for stimuli examples.

FINDINGS

In study 1 (see figure 1), we support H1 and H2 and show that African-American (N = 96) and Caucasian-American (N = 123) adults exhibit automatic pro-white color (ICP_Mean$D$ = .23 and .68 respectively) and pro-white product preferences (IPP_Mean$D$ = .17 and .48 respectively). Additionally, ICP significantly predicted IPP ($F(1,217)$ = 59.67, β = .46, $p < .001$).

Figure 1
Mean D Scores for IAT Measures in Study 1

* D measure > 0, p<0.001
In study 2 (see figure 2), we provide additional support for H1 by showing that African-Americans (N = 81) and Caucasian-Americans (N = 245) exhibit an automatic pro-white color preference (ICP_Mean$D$ = .36 and .58). We also show that Caucasian-Americans exhibit racial (IRP_Mean$D$ = .46) and advertising preferences (IAad_Me-

an$D$ = .40) consistent with a color or in-group preference explanation (H3 and H4). But, African-Americans do not exhibit significant racial (IRP_Mean$D$ = -.02) or advertising preferences (IAad_Mean d = -.03) (no support for H3 or H4). In addition, we show that across groups, ICP is linked to IRP (F(1,324) = 52.56, β = .37, p < .001), and IAad (F(1,324) = 31.41, β = .30, p < .001), and that IRP mediates the effect of ICP on IAad.

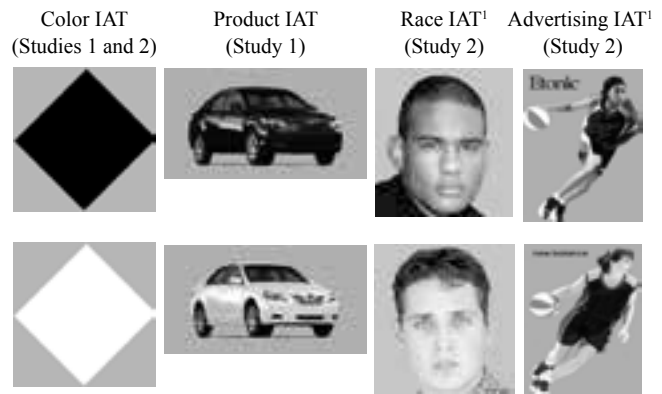
Figure 2
Mean *D* Scores for IAT Measures in Study 2

* *D* measure > 0, p<0.001
† *D* measure < 0, p<0.001
We then regressed IRP (IAad) on ICP and saved the unstandardized residuals which represent the portion of IRP (IAad) that is not explained by ICP. Once this is done, both racial groups exhibit in-group racial and advertising preferences. Specifically, African-Americans exhibit both a Unique Implicit Racial Preference (UIRP_Mean$D$ = -.21) and a Unique Implicit Attitude toward the Ad (UIAad_Mean$D$ = -.19) in favor of their in-group.

CONTRIBUTION

Our research extends color theory into the consumer behavior area. In particular, it shows that there are automatic and predictable underlying color associations that impact automatic product, racial, and advertising preferences. Also, our findings suggest the need to take into account the potential effect of automatic color preference in order to avoid overestimating (underestimating) automatic in-group preferences of Caucasian-Americans (African-Americans). Accounting for automatic color preference allows us to show that Africans-Americans have underlying automatic pro-in-group attitudes, thereby providing an alternative viewpoint to system justification theory. Instead of offering a socio-historical explanation for a "lack of in-group preference" among African-Americans, we show that a more fundamental explanation based on automatic color preference may explain past results.

APPENDIX
Examples of IAT Stimuli used in Studies 1 And 2

Color IAT (Studies 1 and 2) Product IAT (Study 1) Race IAT[1] (Study 2) Advertising IAT[1] (Study 2)


Note: All stimuli were presented at a resolution of approximately 250 x 250 pixels, and the background color was gray (RGB color code 127 127 127).

[1]An equal number of women and men from each racial group photographed in similar poses were depicted in both the race and advertising IATs.

Sticking to Plan: How Concrete Mindsets Increase Reliance on Mental Budget

Sonja Prokopec, ESSEC Business School, France
Francine Espinoza, ESMT, Germany
Vanessa M. Patrick, University of Houston, USA

EXTENDED ABSTRACT

Our research aims to contribute to the extant literature on mental budgets as self control devices by demonstrating: 1) that mental budgets are temporally unstable in that consumers do not rely on them for future consumption decisions, and 2) that concrete mindsets can enhance reliance on mental budgets over time. We present a set of three studies to investigate these notions.

Making the decision to exert self-control is not enough. Monitoring or keeping track of relevant behavior is an important aspect of the self-regulatory process (Baumeister 2002). Little research, however, has investigated the factors that impact the *efficacy* of the monitoring devices and control strategies that consumers rely upon to monitor goal-directed behavior *after* the decision to exert self-control has been made. This is the impetus for the current research.

Mental budgets have been shown to be effective self-control devices because they allow consumers to monitor their behavior around an active self-control goal (Krishnamurthy and Prokopec 2010). We conceptualize mental budgets as concrete plans of action or specific intentions framed in terms of explicit quotas that an individual uses to execute and monitor a particular behavior (e.g., "I can drink two small glasses of wine per day"). The extant research has found that mental budgets are effective, but have only investigated them in the short-run. The assumption is that mental budgets will be similarly effective self-regulatory tools *in the long run*. The current research invalidates this assumption to illustrate that while mental budgets are effective for implementing a self-control goal when decisions are made for present consumption, their efficacy decreases for future consumption decisions.

The question then becomes, how can we increase the efficacy of mental budgets in making future consumption decisions? We argue that mindsets determine whether consumers align their consumption with the mental budget. Our argument draws on the role of construal in the execution or implementation of the goal (Bayuk, Janiszewski, and Leboeuf 2010). We argue that mindsets moderate the efficacy of mental budgets. Specifically, a concrete mindset facilitates the execution of the self-control goal, increasing the reliance on the mental budget while an abstract mindset permits competing information to be accessible, decreasing this reliance. In sum, this research aims to contribute to the extant literature on mental budgets as self control devices by demonstrating: 1) that mental budgets are temporally unstable in that consumers do not rely on them for future consumption decisions, and 2) that concrete mindsets can enhance reliance on mental budgets over time. We present a set of three studies to investigate these notions.

Study 1 employed a 2 (Mental budget: Yes/No) x 2 (Decision: Present/Future) between-subjects design (N = 179). The design of this experiment was adapted from previous work on the relationship between mental budgeting and self-regulation (Krishnamurthy and Prokopec, 2010). A pre-test revealed that European students struggle with over-consumption of alcohol. To manipulate mental budget, participants in the mental budget condition were asked to type in the number of small wine glasses that they planned to consume during the wine tasting event (part of the cover story); after this, participants saw pictures of 10 different wines and indicated the number of small glasses of wine they would like to drink immediately (present deci-sion condition) or a week later (future decision condition). Results revealed a significant interaction between mental budget and decision time frame (F (1,175) = 6.16, $p < .02$). Planned contrasts suggest that participants drank less wine when they had set a mental budget for the present ($M_{no\ mb} = 6.77$, $M_{mb} = 5.12$, F (1,175) = 3.79, $p < .05$), than for the future ($M_{no\ mb} = 5.88$, $M_{mb} = 7.26$, F (1,175) = 2.46, $p = .11$).

Study 2 employed a 2 (Mental budget: Yes/No) x 2 (Decision: Present/Future) x 2 (Mindset: Concrete/Abstract) mixed design (scenario as Study 1), where mental budget and decision time frame were between-subjects and mindset was measured using the behavioral identification form (Vallacher and Wegner 1989) (N = 296). Results revealed a main effect of mental budget (F (1, 284) = 25.41, $p < .001$) and a tree-way interaction between mental budget, decision time frame, and mindset (F (1, 284) = 3.98, $p < .05$). When mindset was concrete, a main effect of mental budget (F (1, 284) = 14.07, $p < .05$) suggests that presence of mental budget reduces consumption for both present ($M_{no\ mb} = 7.55$, $M_{mb} = 4.10$, F (1, 284) = 3.51, $p < .06$) and future decisions ($M_{no\ mb} = 9.07$, $M_{mb} = 4.54$, F (1, 284) = 9.94, $p < .01$). When mindset was abstract, a main effect of mental budget (F (1, 284) = 11.41, $p < .01$) that was qualified by a 2-way interaction (F (1, 284) = 4.35, $p < .05$) suggests that mental budget reduces consumption for present decisions ($M_{no\ mb} = 9.09$, $M_{mb} = 3.95$, F (1, 284) = 13.18, $p < .01$) but not for future decisions ($M_{no\ mb} = 7.86$, $M_{mb} = 6.65$, F (1, 284) = .94, $p > .33$).

Study 3 employed a 2 (Mental budget: Yes/No) x 2 (Decision: Future vs. Implementation of future) x 2 (Mindset: Concrete/Abstract) mixed design (N = 63) (scenario as study 1). Mental budget was a between-subjects factor, decision time frame was a within-subjects factor, and mindset was measured with the behavioral identification form (Vallacher and Wegner, 1989). A repeated-measures ANOVA revealed a 3-way interaction (F (1,59) = 5.55, $p < .02$). This interaction suggests that when consumers operate under a concrete mindset, mental budgets help self-control when they decide on their future consumption ($M_{no\ mb} = 7.25$, $M_{mb} = 4.37$, F (1, 59) = 27.73, $p < .01$) and remain an effective self-control tool when, a week later, they implement their consumption decision ($M_{no\ mb} = 6.39$, $M_{mb} = 4.87$, F (1, 59) = 7.71, $p < .01$). In contrast, when consumers operate under an abstract mindset, mental budgets do not help self-control for future decisions ($M_{no\ mb} = 6.37$, $M_{mb} = 7.85$, F (1,59) = 4.84, $p < .04$) and when the time of the event comes, mental budgets remain an ineffective self-control tool ($M_{no\ mb} = 7.25$, $M_{mb} = 7.20$, F (1,59) = .01, $p > .92$).

Taken together, our three studies support the proposition that mental budgeting is a temporally unstable self-regulatory strategy, in that it is effective for implementing a self-control goal when decisions are made for present consumption (but not for future consumption). Further, while the existing research shows that high-level construals (e.g., an abstract mindset) are better for self-regulation (Fujita and Han 2009; Labroo and Patrick 2009) we demonstrate that low-level construals (e.g., a concrete mindset) can also enhance self-control. We argue and find support for the notion that a concrete mindset facilitates the stability of a mental budget in the long-run because it helps consumers to implement their self-control decision.

Center of Shelf Attention: Understanding the Role of Visual Attention on Product Choice

A. Selin Atalay, HEC Paris, France
H. Onur Bodur, Concordia University, Canada
Dina Rasolofoarison, Aston University, UK

EXTENDED ABSTRACT

When choosing from an array of products, consumers are more likely to choose the option located in the center (*horizontal centrality effect*). This effect is demonstrated in various contexts, when choosing among highlighters, chairs, bathroom stalls and products in a shelf display (Christenfeld 1995; Shaw et al. 2000). This is a relevant phenomenon for marketers; using eye tracking methodology van der Lans et al. (2008) demonstrated that competitive advantage on the shelf is generated mostly by in-store factors rather than out-of-store factors with a ratio of 2:1. In this research, a positive effect of horizontal centrality on choice was found across three studies and product categories (vitamins, meal replacement bars, and energy drinks). Findings from two eye tracking studies (1 and 2) support a visual attention based explanation of horizontal centrality on choice. Study 3 further demonstrated that the central option in the product category is chosen even when the product is not in the center of the visual field.

What derives the horizontal centrality effect? In recent eye-tracking studies, Chandon et al. (2007, 2009) found that brands located in the (vertical and horizontal) center of a shelf are noted more and chosen more often, supporting an attention based explanation. Valenzuela and Raghubir (2009) proposed *center-stage effect* as an explanation: Consumers hold the lay belief that in retail contexts the products placed in central positions are more popular, reflecting the overall quality of the product, which leads consumers to systematically prefer items in the center. Note that, Chandon et al. (2007, 2009) focused only on visual attention, did not measure inferences made about the chosen brand, whereas Valenzuela and Raghubir

(2009) reported an indirect effect through brand inferences, but not through memory based attention.

Research in visual perception identified a crucial role of visual attention in the final moments of the choice task that shapes individual's preference for the eventually chosen alternative, *independent* of the effects of memory or prior preferences (Shimojo et al. 2003; Simion and Shimojo 2006). Shimojo et al. (2003) conducted gaze pattern analyses in a binary choice task, and found that the role of attention on preference for the chosen option is rapid and concentrated in the final moments of the choice task (*gaze cascade effect)*.

This project provides an investigation of consumer search and choice process. Using eye-tracking methodology, in study 1 (N=63), participants were presented with a 3x3 shelf display. The brands were organized in columns such that the effect of horizontal position was isolated. Brands were rotated such that each brand was presented in left, center, or right. Each brand had equal number of facings (3). Other contextual effects (e.g., brand names, background color, readability) were pretested and ruled out prior to study 1.

Participants reviewed each product on the screen as if they were on the store shelf and indicated their brand choice. Next, they were asked to complete a survey that assessed their inferences about the brands, memory based attention, product familiarity and demographics. The product categories were repeated within participants.

Overall, horizontal centrality increased choice by 18.0%. A brand located in the center had a choice frequency of 45.3%, whereas a brand that was not in the center had a choice frequency of 27.3%. An ANOVA revealed a significant effect of horizontal centrality on visual attention captured by eye tracking measures and choice (*p* <

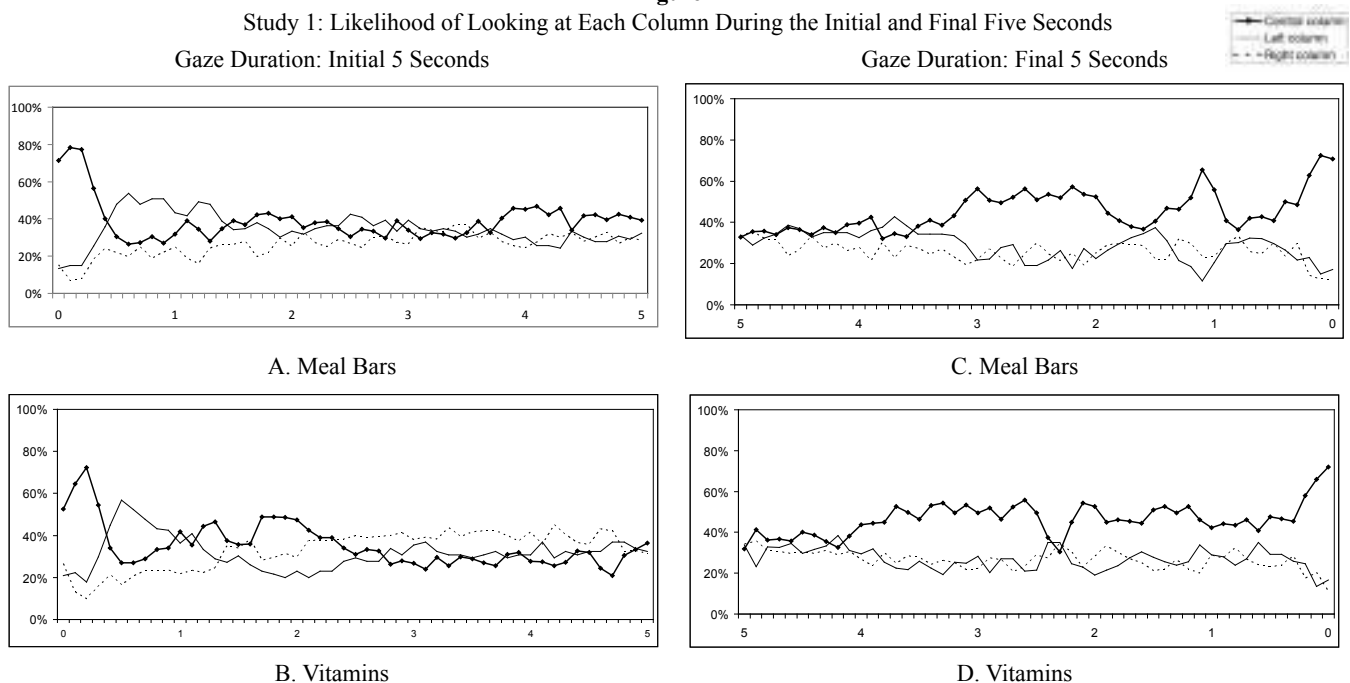
Study 1: Likelihood of Looking at Each Column During the Initial and Final Five Seconds

Gaze Duration: Initial 5 Seconds — Gaze Duration: Final 5 Seconds

A. Meal Bars — C. Meal Bars

B. Vitamins — D. Vitamins


Note that the likelihood to look at the central, left, and right columns are represented by the bold, solid, and dashed line, respectively. Sampling bins are 100 milliseconds.

.05), but not on brand inferences or memory based attention measures ($p > .10$). A multiple mediation analysis revealed that the indirect effect of horizontal centrality on choice through visual attention is significant ($p < .05$). The indirect effects of horizontal centrality on choice through brand inferences and memory based attention were not significant.

Next, gaze analyses explored: (1) Is there a greater tendency to focus on the horizontal center in the *initial* few seconds or *final* 5 seconds of the gaze? (2) Does the higher visual attention on the horizontal center in the initial or final 5 seconds of the gaze duration drive the effect of attention on brand choice? As in Shimojo et al. (2003), gaze likelihood curves were plotted for the initial 5 seconds and final 5 seconds of the choice task (see Figure 1). Although there was a higher likelihood to focus on the central brand in the initial and final 5 seconds, this pattern was consistently significant only in the final 5 seconds. A multiple mediation analysis using visual attention in the initial and final 5 seconds also revealed that visual attention in the final 5 seconds mediated the impact of central location on choice.

Study 2 (N=64) investigated whether the horizontal centrality effect is explained by horizontal centrality of the brand or by centrality on the computer screen. Study 2 extended the design of study 1 by introducing displays that were shifted off the center of the computer screen. Results were similar to study 1 and ruled out screen-based presentation as the possible explanation for the centrality effect ($p < .05$).

In retail contexts, the centrally located product in the array of products in a particular product category may not necessarily be in the center of the shelf space and the consumers' visual field. Would a product placed in the center of an array of products within a category, but to the right or left side of the shelf, still be chosen more often? Study 3 (N=84) addressed this question with tangible products (3D) presented on a shelf. Results showed that the centrally located brand is chosen more often, even when it is not placed in the center of the shelf or the visual field ($p < .05$).

The effect of horizontal centrality on visual attention and choice was demonstrated, and the process of visual attention was explored.

The findings suggest that in the context of choice between unfamiliar yet similar options, horizontal centrality and increased visual attention drives choice. Interestingly the effect of centrality on choice is not due to favorable evaluations of the chosen option. The findings point to horizontal central shelf location as premium location.

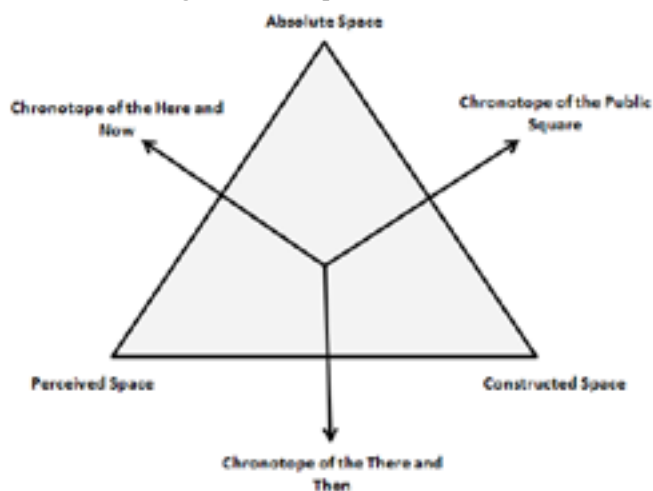
Spatio-Temporal Dimensions in Consumer-Oriented Activism

Andreas Chatzidakis, Royal Holloway, University of London, UK
Pauline Maclaran, Royal Holloway, University of London, UK
Alan Bradshaw, Royal Holloway University of London, UK

EXTENDED ABSTRACT

Research on the interface between politics, ethics and consumer culture has grown substantially since the 1990s (e.g. Arnould 2007; Shah et al. 2007). Encapsulated in terms such as anti-consumption (e.g. Iyer and Muncy 2008), consumer resistance (e.g. Penaloza and Price 1993), radical consumption (Littler 2009) and consumer-oriented activism (Barnett et al. 2011), the extant studies have followed two main paradigmatic traditions. The first takes a more socio-cognitive perspective and attempts to understand instances of consumer activism in terms of individual attitudes and decision-making processes (see Harrison, Newholm and Shaw 2005). The second, paralleling developments within consumer culture theory (Arnould and Thompson 2005), attempts to provide a more contextualised understanding, focusing on themes such as identity projects, consumption communities and socio-economic factors that determine the scope and nature of consumer-oriented activism. Yet, despite significant advancements, the temporal and spatial elements of consumption remain largely unexplored and under-theorised. In fact more generally, researchers have only recently started to explore the spatio-temporal parameters of all consumption activity (e.g. Visconti et al. 2010). Accordingly, in this research we attempt to develop a more nuanced understanding of the role of space and time in consumption, by acknowledging both objectivist and relativist dimensions.

The empirical site of our analysis is Exarcheia, an anarchist neighbourhood in Athens that has been the birthplace of the 2008 Greek riots and is renowned for its anti-capitalist, anti-consumerist ethos. We draw on data that includes field notes, participant observation and interviews, to illustrate how this turbulent area provides a rich site for exploring the relationship of space and time with consumer activism.

Figure 1: Conceptual Framework


Our findings point to a conceptualisation of consumption spaces that moves beyond conventional understandings of actual-material space as simply 'a kind of container in which . . . entities are found and . . . events take place' (Abbott 2008 cited in Hones 2011, 686). In resonance with seminal contributions to spatial studies by Lefebvre, Soja and Harvey, we propose a triadic view of space as *absolute*,

perceived and *constructed*. For instance, whereas *absolute* space in our data included the built environment and its various facets, from street art and graffiti-covered walls to frequent intersections that enable the spread of riots (Makrygianni and Tsadvaroglou 2011), *perceived* space included the more experiential-phenomenological aspects, such as "a sense of tension and urgency" that almost all of our informants mentioned when visiting the area. Finally our notion of *constructed* space includes place as the ever-contested product of social relations (Lefebvre, 1991). Within Exarcheia, this becomes evident in Exarcheia residents' ongoing struggles against the commodification of their city, from throwing bricks and firebombs at Apple stores and Starbucks, to occupying squares and constructing guerrilla parks.

Subsequently, we attempt to theorize the intersection of space with time that is beyond the linear-chrononological (Kern 2003), by drawing on Bahktin's (1981) notion of the chronotope (literally meaning time-space). In analyzing our informants' narratives in relation to (anti-)consumption practices, we identify three key chronotopes, the Bakhtinian *Public Square*, the *Here and Now* and the *There and Then,* that although distinct, they are also interlinked. The chronotope of the public square reflects informants' pride in their communal spaces where many of the anti-consumption practices take place and are shared. For instance one of the Exarcheian public squares used to be a deserted parking lot earmarked for (commercial) redevelopment by the mayor and city planners until it was occupied and bulldozed by locals. It is now transformed into a very impressive park and public space that operates on the basis of anti-commercialisation and gift economy. In talking about the park, many of our older informants mentioned how it reminded them, somewhat nostalgically, the spirit of past Athens, a period in which community living and social interaction around squares was common. Concurrently, residents' attempts to fight against the commodification of their public space, point to that space can be not only the context but also the object of (anti-)consumption; consumption as *in* and *of* space and place (cf. Goodman, Goodman and Redclift 2010). The here and now chronotope relates to experimentations with doing things differently, of creating societies within society and moments of "cracks" (Holloway 2010), as opposed to waiting for mass insurrection and total overthrow of free market capitalism. It is mainly this chronotopic logic that fed into various forms of consumer-oriented activism in Exarcheia, including, among others, various alternative food networks and forums for the exchange of knowledge and services; collectives who contribute to an economy of solidarity by supporting ethical producers and importing coffee from the Zapatistas, collective cooking events, self-managed squats and "no ticket" cinema screenings, music and artistic events. Finally, the there and then chronotope includes residents' utopic visions of an ideal society that makes them continuously question the current socio-economic system, of which consumer culture is a key part.

The third part of our analysis examines the intersection of different spaces and chronotopes. As the surrounding city deeps further into recession and increasingly faces the "there and then" of the past, we observe moments of explosion (solidarity trading events and occupy movements in other neighbourhoods in Athens; cf. Vradis and Dalakoglou 2011) but also of implosion (dramatic fall of living standards and explosion of violence) that (among others) have redefined

the types and nature of consumer-oriented activism. For instance, in some collectives the notion of anti-consumption has become redundant as it has quickly given way to solidarity for all those that now have to live below the poverty line.

In the final part of the article we consider the spatial and chronotopic parameters of alternative consumption spaces and practices. For instance, more conventional forms of consumer activism, such as Fair Trade purchasing and boycotting, are still embedded within a chronotope of a here and now, albeit in spaces that are far less lived and contested (e.g. supermarkets), whereas the chronotope of the public square is to some extent recreated in anti-consumerist festivals (Kozinets 2002) and in frequenting coffee establishments (Thompson and Arsel 2004). Implications and avenues for future research are discussed.

Navigating the Waters: Regulating versus Using Feelings Toward Risky Choices

Eugene Chan, University of Toronto, Canada
Najam Saqib, Qatar University, Qatar

EXTENDED ABSTRACT

Research on how people's feelings toward risky choices affect such choices has been of interest in the past 30 years (Loewenstein et al. 2001; Slovic et al. 2004). We draw upon two streams of research on affect regarding non-risky choices and apply them to risky ones. One stream suggests that people take actions to balance or repair their feelings, known as "affect regulation" (Manucia, Baumann, and Cialdini 1984; Isen 1987), while another stream suggests that people use their feelings as informational input, known as "affect-as-input" (Mayer et al. 1992; Schwarz and Clore 1983). We extrapolate these two streams' predictions regarding *non-risky* choices to make predictions regarding *risky* choices.

People who regulate their feelings make choices that produce a favourable affective outcome. They thus aim to avoid negative outcomes. Over risky gains, which produce positive feelings about possible benefits from taking risks, they avoid risks to prevent losses from accruing and to keep their feelings "in check". Similarly, over risky losses, which produce negative feelings about possible dangers, they would avoid risks for the same reason. By taking risks but losing, the counterfactual that they could have won with certainty would be unfavourable. As such, we predict that people who regulate their feelings *fear* the worst possible outcome that could come from taking risks – over both gain and loss domains. Meanwhile, people who use their feelings use them as a sign about possible directions to take. Positive feelings signal that "everything is okay" but negative ones signal that "something is wrong". Over risky gains, they consider positive feelings toward possible benefits as a sign that they can accrue possible gains, suggesting risk-seeking. Over risky losses, they consider their negative feelings toward possible dangers as a sign that something needs to be done to avoid possible losses, again suggesting risk-taking. As such, we predict that people who use their feelings *hope* for the possible outcome that could come from taking risks – over both gain and loss domains.

Five experiments support our hypothesis. In Experiments 1A and 1B, we primed participants to regulate or use their feelings by having them think affectively or analytically, respectively (Hsee and Rottenstreich 2004). Participants primed to regulate their feelings preferred the certain option in the Asian disease problem (Experiment 1A; Tversky and Kahneman 1981) and were more likely to sell their shares in a hypothetical stock scenario in the disposition effect (Experiment 1B) than participants primed to use their feelings. These findings were consistent over both gain and loss domains (Experiment 1A; Figure 1) and whether the stock portfolio increased or decreased (Experiment 1B; Figure 2).

In Experiment 2, we used a different manipulation of regulating and using feelings. People thinking concretely regulate their feelings, while people thinking abstractly use them, due to the affective feedback loop that exists in concrete but not abstract mindsets (Kivetz and Kivetz, *forthcoming*). We thus primed participants with a concrete or abstract mindset. In a hypothetical gamble between winning $500 and a 50% chance of winning $1,000, or between losing $500 and a 50% chance of losing $1,000, participants primed to regulate their feelings prefer the certain option more over both gain and loss domains than participants primed to use their feelings (Figure 3).

Experiments 3 and 4 shed light on the hypothesized emphasis on fear and hope from regulating or using feelings, respectively. In Experiment 3, we measured participants' tendencies to regulate or use their feelings using the Negative Mood Regulation scale (NMR; Catanzaro and Mearns 1990). Participants took part in a hypothetical lottery similar to Experiment 2. However, before they made their choices, they wrote about what they would do and feel if they either "win" or "lose" by taking the risky option. Findings replicated those from Experiment 2. Participants who regulated their feelings wrote about the worst possible outcome, while those who used their feelings wrote about the best possible outcome – again, over both gain and loss domains. This suggests an emphasis on fear and hope, respectively.

Finally, Experiment 4 used a word-association task to measure participants' tendencies to regulate or use their feelings. First, participants wrote down the first word that came to mind in response to negatively-valenced words such as *cancer*. Then, they wrote down words in response to neutral words such as *chair*. We coded responses on this second task as either positive or negative, as a proxy for regulating or using feelings. Participants indicated their subjective happiness towards winning or losing a series of money from $100 to $1,000. We fitted a regression model in each gain/loss domain for participants who regulated/used their feelings, and included the squared subjective happiness to assess the second-order curvature of participants' utility curves (Figure 4). Participants who regulated their feelings had concave curves, while those who used their feelings had convex curves. These findings suggest risk-aversion and risk-seeking, respectively, over both gain and loss domains.

This research suggests that people who regulate their feelings are risk-averse while those who use them are risk-seeking over both gain and loss domains. This is likely due to the emphasis on fear or hope from taking risks, as Experiments 3 and 4 suggest. We offer an implication for prospect theory: people are risk-averse over gains because they regulate their feelings, but people are risk-seeking over losses because they use those feelings. Our findings bridge research distinguishing between affect regulation and affect-as-input, with that on risky decision-making. Our findings also encourage future research to focus more on anticipated than current feelings. That is, they should emphasize the "prospect" in prospect theory.

The Impact of Goal (Non)attainment on Behavior through Changes in Regulatory Focus.

Danielle Mantovani, Federal University of Parana, Brazil
Paulo Prado, Federal University of Parana, Brazil
Eduardo B. Andrade, University of California Berkeley, USA

EXTENDED ABSTRACT

Based on the regulatory fit phenomenon, the authors examined how goal (non)attainment of a particular goal can influence subsequent behavior through changes in regulatory focus (experiments 1 and 2). Experiment 3 shed light into the boundary conditions of this phenomenon and how emotions play a role into the process.

Feedback about goal progress or goal attainment represents a mundane experience in consumers' lives. A lot has been done to understand how performance feedback impacts motivational aspects such as goal pursuit, commitment and goal revision (Finkelstein and Fishbach 2012). Much less is known, however, on how performance feedback influences people's specific mindsets, and particularly, regulatory focus. Despite the huge literature in the area (Crowe and Higgins 1997; Shah, Higgins and Friedman 1998; Higgins *et al* 2003), the role of previous success and failure on state regulatory focus, and subsequent behavior is yet to be systematically investigated.

According to the classic psychological theories of motivation, it is possible to suggest that success feedback induces approach motivation, whereas failure feedback raises avoidance motivation (Atkinson 1974; Carver and Sheier 1998). Therefore, we hypothesize (H1) that promotion (vs. prevention)-focused message in a subsequent task will be more persuasive after people have *succeeded* in a previous unrelated task whereas a prevention (vs. promotion)-focused message in a subsequent task will be more persuasive after people *failed* in a previous unrelated task.

Achieving (vs. not achieving) a goal, not surprisingly, triggers meaningful emotional reactions (Carver, 2006). People feel happy and proud after accomplishing a task (Higgins *et al.* 2001), whereas disappointment and frustration arise when the goal is not attained (Bosmans and Baumgartner 2005). An open question is the extent to which these emotions contribute to the previously predicted interaction or if a simple cognitive priming of goal (non)attainment suffices to impact regulatory focus. We hypothesize (H2) that emotions play a major role into the process and that the feeling of disappointment and/or frustration (rather than the sheer priming of goal non-attainment) is critical into making people more sensitive to a prevention focus message. Similarly, the feelings of joy and/or pride (rather than the sheer priming of goal attainment) are critical into making people more persuaded by a promotion focus message.

Experiment 1 (n = 148) used a 2 (goal: attained vs. unattained) by 2 (message frame: promotion focus vs. prevention focus) between subjects design to test H1. Participants were informed that the goal of the study was to analyze individual's problem solving skills. The goal (solve the problems) was either attainable or not and participants were randomly assigned to one of the conditions (Puca and Schmalt 1999, Shah and Kruglanski 2002). In the second part of the experiment, participants read one of two advertisements for a brand juice, framed in a promotion or prevention focus manner (adapted from Aaker and Lee 2001). Finally, they evaluated the target product. As expected, participants showed stronger attitude toward the ad and higher willingness to buy the product when being exposed to promotion frame message after having *attained* a goal in previously unrelated task, whereas the opposite was true when participants had *failed to attain* the goal in previously unrelated task. In that case, the prevention focus message dominated. H1 was supported (Attitude; F (1, 144) = 18.58, $p < .001$; $\eta_p^2 = .114$; WTB; F (1, 144) = 12.9, $p < .001$, $\eta_p^2 = .082$).

Experiment 2 (n = 120) was designed to replicate the previous findings and to test the robustness of the effect using a more consequential dependent variable. The procedure followed was similar to the one used in experiment 1, but participants, who had received a U\$3.00 fee, could use the money to purchase the product (the grape juice). Results confirm the evidence that when the goal was attained in a previous irrelevant task, participants paid on average more for the product when the ad message was framed in a promotion (*vs.* prevention) focus manner. The opposite pattern was observed when the goal was not attained (F (1, 116) = 12.78, $p < .001$, $\eta_p^2 = .099$). As expected, a two-way interaction between goal and message frame emerged both for the, supporting H1.

Experiment 3 (n = 240) tested H2 - the role of emotions - and employed a 2 (goal: attained vs. unattained) x 2 (message frame: promotion focus vs. prevention focus) x 2 (task: real vs. hypothetical) between subjects design. In the hypothetical task condition, participants were given instructions about the task and were asked to quickly imagine going through it and attaining (vs. non-attaining) the goal. In the real condition, like in the previous experiments, participants went through the actual task and either attained or not the goal. Participants were then exposed to a promotion vs. prevention message frame in a subsequent unrelated study. In the actual task condition, where participants did feel significantly prouder (frustrated) for having attained (not attained) the goal, the findings replicate the 2 previous studies. In the hypothetical goal condition, however, where participants did not experience stronger feelings of pride or frustration, the interaction went way. Study 3 sets an important boundary condition. Simply priming people with hypothetical goal (non)attainment manipulation is not enough to generate the regulatory fit phenomenon observed in experiments 1 and 2. It requires that people experience the pleasures and pains associated with goal (non)attainment for the effect to emerge.

The Ghosts of Information Past and Future:
Effects of Memory and Motivation on Reference Price

Jolie M. Martin, University of Minnesota, USA
Tomas Lejarraga, University of the Balearic Islands, Spain
Cleotilde Gonzalez, Carnegie Mellon University, USA

EXTENDED ABSTRACT

In recent years, reference-dependence has gained acceptance as a conceptual framework for understanding the way that consumers compare outcomes of their choices to other salient outcomes in their environment. Kahneman and Tversky's Prospect Theory (1979) formalized the idea that consumption utility is determined by the difference of an outcome from a reference point rather than by its absolute value. There exist many real-world examples where reference points accurately describe behavior (Camerer, 2000). Within the domain of finance, for instance, empirical evidence demonstrates robust loss aversion in the reluctance of stock holders to sell below their purchase price (Shefrin and Statman, 1985). However, there is little consensus among researchers about the *ex ante* specification of an individual's reference point in various decision contexts (Klein and Oglethorpe, 1987). Reference points are purported to derive from a range of disparate sources including a consumer's past experiences (Wathieu, 1997), immediate social comparisons (Novemsky and Schweitzer, 2004), and expectations about the future (Koszegi and Rabin, 2006).

The goal of the present research is to explore the contextual factors that impact consumers' formation of reference points so that, ultimately, reference points can be isolated to serve as better predictors of behavior. Here, we focus on reference *prices*, which are the salient dollar amounts to which consumers compare other potential buying or selling prices. Because prices fall along a single quantifiable dimension of money, this narrowed scope eliminates confounds of multi-dimensional comparisons (e.g., "reference points" for vacations). Specifically, we assess how reference prices for stocks are affected by two contextual factors: (1) whether decision-makers have the history of price information available versus relying on memory alone, and (2) whether decision-makers are motivated to adopt a high reference price as sellers or a low reference price as buyers. We hypothesized these factors to influence the use of information in reference price formation in several ways. First, primacy and recency memory effects suggest that the first and most recent pieces of information, respectively, will be recalled most readily (Ebbinghaus, 1913; Hogarth and Einhorn, 1992). We predicted that these memory effects would play a greater role when historical price information was unavailable to decision-makers. Second, both subconscious emotions and deliberative reasoning about prices tend to reflect consumers' motivations (Heath, Larrick, and Wu, 1999: Kunda, 1990). We thus expected decision-makers to focus on favorable reference prices when several were available.

Our methodology was based on that of Baucells, Weber, and Welfens (2011). In several laboratory studies, these authors showed participants the evolution of stock prices over time (revealed on the screen one-by-one), and then elicited reference prices by asking participants the price at which they would feel neutral (neither happy nor unhappy) about selling the stock in the next time period. Every participant did this for the same 60 randomly ordered price sequences, which were designed to differ on five informational variables: first price (*first*), last price (*last*), average intermediate price (*average*), high price (*high*), and low price (*low*). We extended this paradigm by testing how the effects of these variables on reference price differed according to contextual factors of memory and motivation. In

an online experiment conducted in the laboratory, we used the same price sequences and reference price elicitation procedure, but with a 2x2 between-subjects design varying both the presence or absence of the stock history (i.e., a list of previous prices) when participants reported their reference price (*history* = 1 or 0, respectively), and the role of participants as stock seller or buyer (*seller* = 1 or 0, respectively). Eighty participants (35 female; M_{age} = 23.1) completed the study for a flat payment of $10.

Our results show that both memory and motivation interact with objective information to influence reference prices. There are no three-way interactions, so our regression analysis includes main effects of the five informational variables (*first*, *last*, *average*, *high*, and *low*), main effects of the two contextual factors (*history* and *seller*), and the 10 two-way interactions between each of the five informational variables and the two contextual factors (R^2=.11, $F(17, 4782)$=36.3, $p<.0001$). We find a significant main effect of each of the five informational variables except *low*. The coefficient is positive for *first* (β=0.088, p=.008), *last* (β=0.40, $p<.0001$), and *average* (β=0.41, $p<.0001$), which indicates that increasing any of these variables while holding the others constant raises reference prices. However, the coefficient is negative for *high* (β=-0.17, p=.0006), which suggests – less intuitively – that a higher maximum stock price lowers reference price. We attribute this to overcompensation by participants in ensuring that peak information is not weighted too heavily, particularly in light of the recent stock market crisis.

More central to the present analysis are the effects of contextual factors which differ across the four experimental conditions. Although neither main effect of *history* or *seller* is significant, their interactions with the informational variables partially support our hypotheses. Each has a positive interaction with *first* (*history* x *first*: β=0.096, p=.01; *seller* x *first*: β=0.21, $p<.0001$), a negative interaction with *last* (*history* x *last*: β=-0.10, p=.05; *seller* x *last*: β=-0.11, p=.04), and a negative interaction with *average* (*history* x *average*: β=-0.12, p=.05; *seller* x *average*: β=-0.18, p=.005). Taken together, these results demonstrate a stronger effect of primacy than of recency when the price history is available (compared to decay over time during reliance on memory alone), and when individuals are motivated to recoup their purchase price as sellers (compared to buyers who place more emphasis on recent prices). In addition, we observe positive interactions between *history* and *high* (β=0.16, p=.005), and between *seller* and *high* (β=0.15, p=.008), meaning that the availability of historical prices and the motivation to transact at a higher price, respectively, increase weight on the sequence peak as a reference point. We suspect that both factors make this "one-off" piece of information more salient.

We conclude by discussing the role of memory and motivation in shaping reference prices across a range of consumer choices. We also highlight other features of a decision context that might alter information processing, and in turn, reference point formation.

Thank You for the Music! A Working Memory Examination of the Effect of Musical Elements on Verbal Learning

Esther Kang, State University of New York, USA
Arun Lakshmanan, State University of New York, USA

EXTENDED ABSTRACT

Past research examining the effect of music on learning have presented mixed findings. Music in advertisements may attract attention, enhance excitement, or act as mnemonic aids (Seashore 1967). Sometimes, music may reduce memory (Oakes and North 2006; Tavassoli and Lee 2003). This paper extends past research by examining the interactive effect of musical *elements* on learning. Specifically, we focus on musical elements that affect the flow of phonological processing when visual learning of verbal information is of interest. While prior research examines the effect of presence or absence of music and its tempo on memory, to the best of our knowledge, the current research is the first to examine (a) how different characteristics of music – lyrics, tempo and repetitiveness – *interact* to affect learning, and, (b) the *process* underlying this interaction. Substantively, given that music is multi-faceted and complex, an understanding of how individual elements interact to shape learning is pertinent for constructing more effective marketing communications.

STUDY 1:
THE IRRELEVANT SPEECH EFFECT IN MUSIC

Music may be classified into two varieties – purely instrumental or vocal, which typically includes lyrics along with instrumentation. According to Salamé and Baddeley (1982), irrelevant speech inhibits encoding of verbal material on account of the limited capacity of the phonological store – a component of working memory. During learning, visually presented verbal information accesses this store via the process of articulation. Auditory elements also directly access this store (Baddeley 2001). Thus, when music containing lyrics is heard while observing visuo-verbal information, (a) the dual load on the phonological store and (b) articulatory suppression leads to reduced learning of verbal information. Formally,

Hypothesis 1: *Verbal learning will be lower when background music is vocal (vs. instrumental).*

Our experiment followed a single-factor (music: vocal vs. instrumental) design. All participants saw a screen containing product information about a fabric softener on computer while identical music clips (either vocal or purely instrumental) was played in the background. Seventy five undergraduate students participated in exchange for course credit. Supporting H1, a one-way ANOVA on participants' recall of product information revealed a significant main effect ($p<.05$). Specifically, vocal music led to significantly *poorer* recall (Minstru=1.90, Mvocal=1.42; $t(73) = 2.18$, $p<.05$). Study 1 presents initial evidence that vocal music interferes with verbal learning.

STUDY 2: MUSICAL TEMPO AND MUSIC TYPE

According to the theory of changing state effects (Jones, Madden, and Miles 1992), faster music distracts the learner more due to the greater number of changes in 'states' per unit time. Consequently, when tempo is fast, interference from lyrics in vocal music should be more pronounced due to the greater opportunity of sub-vocal repetition of the lyrics themselves, thereby reducing the 'space' available in the phonological store to rehearse visually presented verbal information (Baddeley 2001). Thus,

Hypothesis 2: *Verbal learning will be poorer for vocal music (versus instrumental) when tempo is fast but not when tempo is slow.*

One hundred undergraduate students participated in a 2 (tempo: fast/slow) × 2 (type: instrumental/vocal) laboratory experiment in which they viewed a product information screen with background music. Tempo was manipulated by using two versions of a song (20% slower vs. 20% faster than the original). Manipulation checks revealed that our tempo manipulation was successful (Mfast=4.28, Mslow=2.94; $t(97)=4.66$, $p<.01$). An ANOVA on verbal learning revealed a two-way interaction ($F (1,95) = 4.36$, $p<.05$). Specifically, when tempo was fast, vocal music led to significantly poorer recall (Mfast-instru =3.27, Mfast-vocal= 2.37; $p<.05$) but when tempo was slow, there were no significant differences (Mslow-instru =2.89, Mslow-vocal= 2.80; $p>.05$. Study 2 demonstrates that fast background music with lyrics interferes more with visuo-verbal learning.

STUDY 3: REPETITIVENESS AND MUSIC TYPE

Repetitive patterns readily awaken 'collaborative expectancy' (Burke 1969). Once listeners grasp the trend of a form, they infer how it is destined to develop and they "collaborate to round out its symmetry". Thus, repetitive music should induce attention to and learning of the musical pattern (as opposed to visually observed verbal information). However, when repetitive music is vocal, individuals' tendency to round out the lyrical pattern should lead to greater interference with verbal content learning. In turn, it should lead to lower verbal recall but correlate with greater attention to music. Formally,

Hypothesis 3: *Recall will be lower for repetitive (vs. non-repetitive) music when music is vocal (but not instrumental).*

Hypothesis 4: *Attention to the music will be greater for repetitive (vs. non-repetitive) music when background music is vocal (but not instrumental).*

One hundred and eighteen students participated in a 2 (repetitiveness: repetitive/non-repetitive) × 2 (type: instrumental/vocal) laboratory experiment. We manipulated repetitiveness by reiterating a phrase thrice (once) in the music. Participants' judgments of the music's repetitiveness revealed that our manipulation was successful (Mrepeat= 6.18, Mnon-repeat= 5.23; $t (116) = 3.571$, $p<.01$). Analyses of variance revealed significant two-way interactions for verbal recall ($F (1,114) = 4.38$, $p<.05$) as well as attention to music ($F (1,114) = 4.62$, $p<.05$). Supporting H3, we found that repetitive music led to poorer recall when music is vocal (Mvocal-repeat=2.26, Mvocal-non repeat=2.96; $p<.05$) but not instrumental (Minstru-repeat=2.63, Minstru-non repeat=2.37; $p>.05$. Supporting H4, repetitiveness also elicited greater attention to music when vocal (Mvocal-repeat=5.44, M vocal-non repeat=4.24; $p<.05$) but not when it was instrumental (Minstru-repeat=4.60, Minstru-non repeat=4.62; $p>.05$). These results further support our conjecture that interference appears to be greatest when *vocal* background music is repetitive.

Further, study 3 presents evidence supporting our theory that interference from lyrical elements diminish verbal learning and recall.

CONTRIBUTION

Our research explores the interactive effect of lyrics, tempo and repetitiveness on verbal learning and finds that lyrical content in music often inhibits verbal learning. Importantly, this is more likely under faster tempos and for repetitive music. We also show that attention to music has an opposite pattern vis-à-vis verbal learning. Thus, while vocal background music may inhibit learning of visually presented product information, it also presents the opportunity for increased learning by drawing attention towards the lyrical content. (994 words).

Culture, Relationship Norms, and Perceived Fairness of Asymmetric Pricing

Haipeng (Allan) Chen, Texas A&M University, USA
Lisa Bolton, Pennsylvania State University, USA
Sharon Ng, Nanyang Technological University, Singapore

EXTENDED ABSTRACT

According to the principle of dual entitlement (DE), buyers are entitled to a reference price and sellers are entitled to a reference profit. In a series of studies, Kahneman et al. (1986a 1986b) provide evidence that consumers deem it fair for a seller to 1) increase its price when its costs increase (to protect its reference profit), and 2) maintain its price when its costs decrease (because doing so does not violate the buyer's entitlement to a reference price). This pioneering work naturally begs the question: To what extent is DE a *global* standard of fairness?

Although such a question is not readily answered in one research endeavor, prior research has tended to conclude that DE is relatively robust across consumers (e.g., Frey and Pommerehne 1993, Shiller, Boycko, and Borokov 1991, Bian and Keller 1999, Gao 2009, Urbany et al. 1989). Some intriguing differences have emerged in within-subject testing of DE (Kalapurakal et al. 1991) and in across-country testing (e.g., Kimes and Wirtz 2003, Gao 2009). However, the latter has produced mixed evidence by relying upon direct cross-country comparisons that are confounded and do not readily allow conclusions regarding cultural differences (nor psychological mechanism). The present research addresses this issue by priming culture (and corresponding relationship norms) in order to investigate the effects on consumer fairness response within a DE context.

Cultural differences in social relationships and self-definitions, such as independence/interdependence, are one of the myriad dimensions along which cultures vary (e.g., Hofstede 1980; Markus and Kitayama 1991). Although not without its critics (e.g., Brewer and Chen 2007; Oyserman, Coon, and Kemmelmeier 2002; Shavitt et al. 2006), the distinction between independent and interdependence has received robust support, and has been linked to relationship norms that are exchange- and communal-oriented, respectively (Kim et al. 1995; Triandis 1996, 2001a, 2001b). Indeed, Triandis (1995) argues that an emphasis on communal versus exchange relationships is one of the key defining attributes of interdependence and independence. Communal norms emphasize taking others' welfare and interests into account whereas exchange norms endorse the seeking of benefits in the pursuit of self-interest—and these social norms may serve as the standard by which behavior is judged (e.g., Clark and Mills 1993, 1979; Mills and Clark 1982).

Within a DE context, what are the implications of salient norms driven by culture for fairness response? Consider first the case of asymmetric pricing. Asymmetric pricing appears inconsistent with the communal norms of interdependent consumers. The firm passes on cost increases but does not pass on costs decreases to customers—suggesting that the firm is not emphasizing the welfare and interests of its customers, a violation of communal norms salient among interdependent consumers. In contrast, when practicing asymmetric pricing the firm is acting in a manner consistent with pursuit of the firm's self-interest—and independent consumers guided by exchange norms should be relatively more accepting of such behavior. Accordingly,

Hypothesis 1: *Interdependent (independent) consumers will a) be guided by communal (exchange) norms and b) judge asymmetric pricing as relatively unfair (fair).*

When considering the two components of asymmetric pricing separately, however, it becomes relatively difficult to judge whether firm's pricing actions are consistent with social norms. Put simply, when consumers know *either* the give *or* the take but do not know the give-and-take in the relationship, as when considering each pricing action separately, cultural differences in fairness response arising from social norms are not expected to emerge as strongly. Formally:

Hypothesis 2: *Price fairness response for cost-increase and cost-decrease pricing actions (compared to asymmetric pricing) will be relatively insensitive to cultural differences and corresponding communal/exchange norms.*

H1 and H2 together predict an interaction of culture and pricing and mediation by relationship norms (communal/exchange) that are salient as a function of culture.

A series of experiments investigate the impact of culture and corresponding relationship norms on price fairness. In each study, culture/norms are primed using established techniques. Participants rate price fairness after reading a scenario (adapted from Kahneman et al. 1986a, 1986b) in which a firm i) increases prices to cover cost increases (cost-increase); ii) maintains prices when costs decrease (cost-decrease); or iii) practices both (i.e., asymmetric pricing).

To briefly summarize findings: In Study 1, priming Chinese (vs. American) culture among bi-cultural Singaporean participants (Chen et al. 2005) reduces price fairness perceptions for asymmetric pricing (but not cost-increase and cost-decrease pricing), an effect that is mediated by relationship norms. To provide additional evidence for the underlying process, Studies 2 and 3 examine the role of norms more directly (Spencer et al. 2005). Priming communal (vs. exchange) norms (Aggarwal and Law 2005) or manipulating norms through the use of different industries mimics the effects of priming culture: It reduces price fairness perceptions for asymmetric pricing (but not cost-increase and cost-decrease pricing). Finally, study 4 focuses on asymmetric pricing and manipulates perspective taking (Galinsky, Wang, and Ku 2008) as well as culture. Adopting an other (vs. self) perspective increases perceived fairness among bi-cultural Singaporean participants primed with the Chinese culture, but perspective does not affect fairness perceptions when the U.S. culture is primed. That is, when communal (but not exchange) norms are primed via culture, adopting an other versus self perspective shifts emphasis to the needs of others (i.e., the firm).

In summary, our research provides converging evidence that culture makes salient relationship norms that guide consumer fairness perceptions of firms' pricing actions, especially asymmetric pricing. Our contributions are three-fold. First, we add to the emerging literature on cultural differences in price fairness (e.g., Bolton et al. 2010) by examining the role of culture and corresponding relationship norms, thereby answering Xia et al.'s (2005) call for research on the role of social norms in price fairness. Second, we examine the robustness of the pioneering work on DE in two ways: by comparing consumer fairness perceptions of pricing actions based on DE (i) between joint and separate evaluations, and (ii) across culture and corresponding salient relationship norms. Third, we shed light on the 'economics puzzle' of asymmetric pricing (cf. Peltzman 2000) from the perspective of consumer fairness perceptions.

Effects of Timing of Purchase and Perceived Proximity of Climate Change on Green Product Purchase

Kiju Jung, University of Illinois at Urbana-Champaign, USA
Madhu Viswanathan, University of Illinois at Urbana-Champaign, USA

Dolores Albarracin, University of Pennsylvania, USA

EXTENDED ABSTRACT

Despite concerns about the adverse consequences of climate change, sustainable consumption practices have not increased correspondingly (Bonini, Hintz, and Mendonca 2008). To understand the factors that influence green product purchase and other sustainable consumption practices, we consider three temporal factors, timing of green product purchase, temporal proximity of climate change and temporal order of information presentation. We draw upon construal level theory (Trope and Liberman 2003, 2010), environmental psychology (Gifford 2011) and information integration theory (Anderson 1981; Fishbein and Hunter 1964). Three experiments show consumers' willingness to purchase green products depends on (a) whether they contemplate making the purchase immediately or in the future, (b) the urgency of doing so, and (c) the order in which the purchase consideration and the urgency are called to their attention.

Experiment 1 investigated the effect of the time that consumers consider purchasing green products under conditions in which the possibility of climate change is not called to their attention. Drawing upon construal level theory (Trope and Liberman 2003), we predicted that consumers' intentions to purchase green products would be greater in the distant future than in the near future. Sixty-four participants were randomly assigned to two conditions that differed in terms of timing of purchase (one week later vs. one year later). Specifically, half of the participants were asked to imagine buying green products "a week from now," whereas the other half were asked to imagine buying them "a year from now." Then, in each case, they reported their intentions and attitudes toward green product purchase. As predicted, participants reported greater intentions to purchase green products in the distant future than in the near future. Although participants' attitudes toward purchasing the products also differed, the difference was much less pronounced.

If consumers perceive climate change to not be imminent, they will be more willing to purchase green products in the future than to do so immediately. If they perceive climate change to be imminent, however, they will be willing to purchase green products immediately as well because making the immediacy of climate change salient to consumers at the time they contemplate a purchase decision may motivate them to purchase green products immediately. However, this may be the case only when information of proximity of climate change is already called to attention before considering purchase (climate-change-before order). When the threat of climate change is called to attention later, they may simply adjust the intentions to take this threat into account rather than completely ignoring the threat of climate change, generating piecemeal information integration.

Experiment 2 examined these contingencies by employing a 2 (information presentation order: climate-change-before vs. climate-change-after) × 2 (timing of green product purchase: near future, distant future) × 2 (proximity of climate change: immediate, future) between-subjects design. One hundred seventy-six participants were asked to consider the purchase of green products either "a week from now" or "a year from now." Before considering the purchase of green products, however, participants in *climate-change-before* conditions read a news article in which climate change was described as either an immediate threat or a future one. In *climate-change-after* con-

ditions, however, they did not read the article until after they had considered the purchase. All participants then reported their intentions and attitudes along the scales employed in experiment 1. Participants were generally more inclined to purchase green products in the distant future than in the near future. Three-way interaction of these variables was marginally significant. Supplementary analyses were performed under each order condition separately. When climate change was not an immediate threat, participants reported greater intentions to purchase green products in the future than in the near future. When climate change was imminent, however, this difference was not apparent. When participants were not informed of proximity of climate change until after they had considered the purchase (climate-change-after order), they were more willing to make a purchase in the distant future than in the near future, and this was true regardless of whether climate change was imminent or not. Proximity of climate change had a marginally significant main effect, with participants more willing to make the purchase when climate change is immediate than when it is not. In contrast, attitudes toward purchasing green products did not depend on either the time of purchase or the immediacy of climate change, regardless of presentation order.

Experiment 3 ($N = 275$) replicated these contingencies providing further insight into the processes that underlie them, employing a 3 (information presentation conditions: climate-change-before vs. climate-change-after vs. climate-change-after with integration) x 2 (time of purchase: near future, distant future) × 2 (proximity of climate change: immediate, future) between-subjects factorial design. The procedure employed in this experiment was identical to that employed in experiment 2 with the addition of the integration condition. In this condition, participants were first asked to consider purchasing green products either a week from now or a year from now and then reminded of proximity of climate change, as in climate-change-after conditions. Before doing so, however, they were given instructions that were designed to lead them to postpone making a definite purchase decision until after learning about the climate change information. The effects of experimental variables on purchase intentions in climate-change-before and climate-change-after conditions replicated the results of experiment 2. Of particular interest, however, are the effects obtained when participants were asked to consider a purchase at the outset but were encouraged to integrate the information of proximity of climate change they received afterwards (climate-change-after with integration). The effects in this condition were virtually identical to the effects obtained in climate-change-before conditions, revealing that information integration was the key to the order effect.

In summary, to our knowledge, this article is the first to show how and why both a cause temporality (i.e., proximity of climate change) and a behavior temporality (i.e., timing of purchase) combine to influence purchase intentions. Our findings provide important theoretical and practical insights about the framing and sequencing of climate change information in order to maximize consumers' engagement in sustainable consumption behavior.

Looking For Answers in the Forest Rather than the Trees: Causal Uncertainty Increases Attraction to Abstraction

Jae-Eun Namkoong, University of Texas at Austin, USA
Marlone Henderson, University of Texas at Austin, USA

EXTENDED ABSTRACT

One of the first questions people spontaneously ask themselves in unexpected circumstances is why such things happen (Wong and Weiner 1981). A sudden loss of electricity or internet connection, for instance, will naturally cause consumers to wonder the cause of these events. Three experiments in the present research demonstrate that people seek abstraction (i.e., prefer abstract visual and verbal stimuli) when they lack causal understanding because this process helps extract similarities or the essence across contexts.

People's intrinsic desire to understand causal relationships may come from the fact that understanding causality leads to greater predictability, one of the key antecedents of perceived control (Rothbaum, Weisz et al. 1982). Understanding what caused the previous blackout would help one prevent the next blackout, or at least predict and prepare for it. This leads to a greater control over the situation. Some theorists speculate that predictability or informational control can be gained by creating a constant, eventless environment (Rothbaum, Weisz et al. 1982); this can be challenging if not impossible. One way to deal with this challenge is to extract similarities across different situations and as a result, recover something constant (i.e. a pattern) within the ever-changing environment. Abstraction is an effective way to achieve this goal because when people think about things in more abstract terms, they tend to focus less on temporary, incidental, and contextual information, and instead focus more on central and cross-situationally consistent information (Wakslak, Nussbaum et al. 2008; Ledgerwood and Trope 2010).

We test the idea that when lacking causal understanding about a problem, people seek abstraction and more specifically, similarity across problems to understand what is essential. Study 1 confirms that high causal uncertainty leads people to focus on similarities across problems. Study 2 and 3 demonstrate that high causal uncertainty leads people to prefer abstract (vs. concrete) pictures and advertising message, respectively. In study 3, the effect on preference is diminished after participants engage in abstract thinking. This suggests that causal uncertainty creates a need or goal to think abstractly, which is reflected in their preference for abstract stimuli. By satisfying this need, we found that causal uncertainly no longer influences preference.

In Study1, all participants first recalled a specific relationship conflict and answered some basic questions about it. In the next page, they were asked to write about this conflict with different focuses depending on the condition; In the high (low) understanding condition they focused on causal aspects of the conflict that they understand (do not understand) very well. The dependent measure was a 7-point scale evaluating participants' relative preference for writing an essay about similarities (vs. differences) across other relationship conflicts that they had. As predicted, participants in the low (vs. high) under-standing condition reported greater desire to write about similarities than differences (M = 4.35 vs. 3.56; p = .025).

Study 2 examined the effect of causal uncertainty when a consumer problem (i.e., an Internet service failure) was being experienced at the moment rather than recalled from the past. Specifically, we inserted computer network glitches that significantly interrupted what was supposed to be the main survey - a memory test with a cash prize on the line. After experiencing these frustrating glitches, participants were presented with an "important update" screen notifying them about the Internet problem. In the high causal understanding condition, participants read information about the reason why the problem was happening, while in the low understanding condition the message said the reason was unclear. Both conditions were told that the problem was not resolved. Then, in an allegedly separate survey, they were asked to rate a set of six pictures – three global (abstract stimuli) and three local (concrete stimuli). Results showed that participants in the low understanding condition liked the global (relative to local) pictures more compared to those in the high under-standing condition (M = 1.01 vs. 0.60; p = .029).

Study 3 uncovers the mechanism by satisfying the need for abstraction for some participants before asking about their preferences. The initial procedure of this study was the same as study 1. Participants first recalled a relationship conflict and wrote about certain or uncertain causal aspects. Subsequently, we gave participants either a broad or narrow categorization task to induce abstract or concrete thinking, respectively. The dependent measure was people's relative preference for an abstract (vs. concrete) advertising message. As predicted, a significant Understanding X Categorization interaction emerged (F(1,85) = 4.093; p = .046). In the narrow categorization condition we replicated the finding of study 2; Participants in the low (vs. high) understanding condition showed higher relative preference for the abstract advertising message (M = 4.75 vs. 3.66; p = .029). In the low understanding condition, a broad (vs. narrow) categorization task significantly reduced participants' relative preference for the abstract ad (M = 3.64 vs. 4.75; p = .012). In the broad categorization condition, lack of understanding did not increase participants' preference for the abstract ad message, as their need for abstract thinking was supposedly fulfilled by the categorization task (M = 3.64 vs. 3.79; p = .739).

The present research demonstrates that low causal understanding activates the need for abstraction and more importantly, the need for similarity or essence extraction. We also show that this need is a general motivation that goes beyond the specific problem that activated the need in the first place. Because of this, the need for abstraction can be observed even in unrelated contexts such as evaluating pictures and advertising messages.

Love it or Leave it?
Diverging from Others Depends on Attachment

Yajin Wang, University of Minnesota
Deborah Roedder John, University of Minnesota

EXTENDED ABSTRACT

Consumers use brands to communicate their self-image and reference group membership (Escalas and Bettman 2005). And, consumers also express their identities by avoiding items used by dissimilar groups (Berger and Heath 2008; White and Dahl 2006). White and Dahl (2006), for example, found that men were less likely to choose a 10-oz. steak when it was branded as a "ladies' cut" versus a "chef's cut." Berger and Heath (2008) report that individuals will even abandon products they own if they are adopted by a dissimilar group. After distributing Livestrong wristbands to students in a campus dorm, and asking them to wear the wristbands to support cancer awareness, they sold the same wristbands to "geeky" students a week later. Once "geeks" adopted the wristbands, students in the target dorm abandoned their wristbands.

In this paper, we ask the question: What happens when consumers who have formed a strong attachment to a brand face this situation? Consumers can form strong attachments to brands, especially when the brand is closely connected to one's sense of self (Park et al. 2010). When consumers feel a strong attachment to a brand, will they abandon the brand when a dissimilar group adopts the brand, consistent with prior research?

Across three studies, we find that strongly attached consumers respond differently than prior research would suggest. These consumers do not abandon brands when they are adopted by a dissimilar group. Instead, they respond by expressing a greater interest in the brand, especially purchasing "special products" (such as limited editions and new collections) from the brand. In contrast, consumers with a weak attachment to the brand are more likely to abandon the brand, consistent with prior research.

Our first study replicates the Berger and Heath (2008) field experiment with Livestrong wristbands, including attachment as a moderator variable. Wristbands were distributed to a group of "talented students"—athletes, artists, and musicians—attending a private high school in China. Students were asked to wear the wristbands in support of cancer awareness. A week later, the same wristbands were distributed to a dissimilar group of students at the high school—the campus geeks. After the wristbands were adopted by the geeks, 63% of the talented students with a weak attachment to the Livestrong wristband abandoned it, while only 14% of talented students with a strong attachment did so.

In a second study, we extended these findings by manipulating rather than measuring brand attachment, and examining diverging responses other than abandonment. In the strong attachment group, participants (female business undergraduates) read an article highlighting "Burberry totes" as the perfect accessory for young career women. They were then given the opportunity to use a real Burberry tote to complete several tasks. In the weak attachment group, participants read an article about another tote brand and used this tote to complete the same tasks. Finally, all participants read an article about chic alternatives to diaper bags, which mentioned Burberry totes as a favorite of working moms (dissimilar group). After reading this article, participants in the weak attachment group were more likely to say they would abandon the Burberry brand (e.g., avoid using it), replicating results from study 1. In contrast, participants in the strong attachment group were more likely to say that they would purchase "special products" from Burberry, particularly limited editions and

new collections, which presumably would allow them to differentiate themselves from dissimilar brand users. Thus, weak attachment participants distanced themselves from the brand (saying they would abandon it), whereas strong attachment participants favored distancing themselves from the dissimilar users (saying they would buy special products from Burberry).

In study 3, we examined these patterns with a different brand (Under Armour) and different threat conditions. In prior studies, we compared a threat (dissimilar other using the brand) with a no threat (no one else using the brand) condition. This comparison raises the question of whether the source of the threat is a dissimilar other using the brand *or* just anyone else using the brand (less exclusivity in general). To answer this question, we compared a low threat condition (similar other using the brand) versus a high threat condition (dissimilar other using the brand) in study 3. After brand attachment was measured, participants read a scenario about a day on campus, which included seeing a similar group member (business school student) or dissimilar group member (geeky computer science student) wearing the same Under Armour sweatshirt they were wearing. Comparing these different users, we found the same pattern of results reported for study 2, indicating that it is the dissimilarity of other brand users that drives the abandonment response for weak attachment consumers and the "special product" purchase response for strong attachment consumers.

These findings provide a deeper understanding of how consumers diverge from others. In particular, we show that attachment affects the way consumers diverge. Although we might expect consumers who are strongly attached to a brand to be very distressed when dissimilar users adopt the same brand, and to respond by abandoning the brand, our results are counter to this intuition. These consumers do not abandon the brand and are even willing to purchase new and limited edition items as a way to diverge from others. In contrast, consumers with a weak attachment to a brand are more likely to abandon the brand, consistent with prior research.

When Do Consumers Forgive? A Causal Attribution Model of Marketer Transgression and the Moderating Effects of Self-Construal

Jayati Sinha, University of Arizona, USA
Fang-Chi Lu, University of Iowa, USA
Narayan Janakiraman, University of Arizona, USA

EXTENDED ABSTRACT

Even well-respected, high-reputation brands sometimes fail their customers. For example, the automobile market leader at the time, Toyota, announced three recalls from 2009 to 2010 because of pedal problems. How did the public, especially Toyota's recent and old customers, react to the recent recalls or similar information, what we refer to as brand transgressions in this research? Toyota's plight is not uncommon and the role that consumer-brand relationships play is likely to be of great interest to marketers and researchers.

Prior research on brand transgressions suggests that positive relationships buffer consumer responses to transgressions, such that brands with which consumers have positive relationships are less affected by transgressions, than brands with which consumers have weak or negative relationships. However, recent research identified many boundary conditions for this buffer effect such as emotional bonding with the service provider (Mattila 2001), perceived brand personalities (Aaker, Fournier and Brasel 2004), and relationship norms (Wan et al. 2011).

While we know that some brands take a lesser hit after a transgression than others do, we know little about what drives consumers to either react very or less negatively towards brand transgression. In this research, we use attribution theory (Folkes 1984) to suggest that the reaction to brand transgressions depends on the underlying causal properties of transgressions—stability and controllability. While there is extensive research applying attribution theory to service failures, we believe that our paper, apart from using attribution theory to succinctly explain brand transgressions, extends the theory in two important ways. Firstly, based on construal level theory (looking at the *global trend*, the history of previous experiences with the brand, versus a *local deviation*, the current transgression; Henderson et al. 2006), we suggest that an individual's stability attributions depend on the relationship strength s/he has formed with the brand (H1). These attributions about stability of transgressions in turn influence likelihood of *brand forgiveness*, extent to which an individual is willing to forgive a brand transgression. Secondly, we draw on an emerging doctrine in interpersonal relationship research, suggesting that an individual's reaction to a personal relationship violation is dependent on the extent to which the individual is willing to forgive the violation and the violator (Tsarenko and Gabbott 2006). We show that in a brand context too brand forgiveness is a key mediator (H2).

In order to repair their relationship with consumers after transgressions, in practice, companies usually make some recovery attempts, such as apology and compensations. The use of such recovery methods is fairly widespread in service failure, however, only recently research has focused on the effect of recovery efforts and the role of compensation types (brand-related vs. unrelated; Mogilner and Aaker 2008) in the context of brand transgressions. In this paper, we try to understand whether matching type of compensation with consumers' self-construal explains why some brand transgression recovery efforts succeed while others don't. Building on the cultural differences in attribution tendency (independent/interdependent people refer to controllability/stability of a wrongdoing in deciding to forgive an offender; Takaku, Weiner and Ohbuchi 2001), we suggest that independent (interdependent) consumers will be more forgiving (H3) and prefer brand-unrelated (brand-related) compensations (H4)

when transgressions are perceived controllable (they share positive relationship with the brand).

Study 1, to examine H1, used a 2 (brand relationship: strong vs. weak) × 2 (transgression: controllable vs. non-controllable) between-participants design. We manipulated participant's brand relationship by asking them to list an airline which they have become attached to (strong relationship) or not attached to (weak relationship), and manipulated transgression type by presenting participants with a transgression scenario where the airline they listed cancels a flight due to either flight overbooking (controllable) or weather (non-controllable). Analyses revealed that participants were more likely to think the transgression as temporary when they had strong versus weak relationship with the airline (F (1,118) = 24.56, *p<.001*).

Study 2, examining brand forgiveness as a mediator (H2), used the same design as Study 1, but replaced the dependent measures with (1) brand forgiveness (likelihood to forgive) (2) passive (likelihood to stay away), and (3) active (negative WOM) behavioral intentions. Results showed that when controllability was low, consumers with strong brand relationships were more likely to forgive the brand as they were relatively uninfluenced by an unintentional transgression and were more likely to adopt a passive than active strategy. Conversely, when controllability was high, consumers with strong and weak brand relationships were less likely to forgive the brand because they might feel deceived by the brand and were more likely to disseminate negative WOM. Mediation analyses confirmed that brand forgiveness explained the joint effects of brand relationship and transgression type on consumers' post-transgression behavioral intentions.

Study 3, using a product failure and manipulating self-construal by activating a "I" versus "We" construal, showed a significant three-way interaction among brand relationship, transgression type, and self-construal (F (1,218) = 5.04, *p<.03*). Specifically, participants with interdependent self-construal were more likely to forgive the brand when they had strong prior brand relationship. However, participants with independent self-construal, irrespective of their brand relationships, were more likely to forgive when the transgression was non-controllable versus controllable. These effects remained significant after controlling for consumers' tendency to forgive (TTF) and attitude toward forgiveness (ATF) (Brown 2003). Consistently with Study 2, brand forgiveness predicted the active versus passive behavioral intentions in circumstances involving different brand relationship strength and controllability of transgression.

Study 4, examining the effectiveness of brand-related (i.e., voucher for a future free flight on the Airline) and versus brand-unrelated (i.e., voucher for a free meal at an upscale restaurant) compensations after brand transgressions, demonstrated that regardless of controllability of transgression, interdependent consumers who had strong brand relationships preferred brand-related compensation, and interdependent consumers who had weak prior brand relationships preferred brand-unrelated compensations. However, independent consumers preferred brand related compensation only when transgression was non-controllable and they had strong brand relationships. Moreover, consumers' negative attitudes towards the company were improved by their choice of compensation.

Talking About the Ad Vs. Talking About The Product: What Works And When

Rashmi Adaval, Hong Kong University of Science and Technology, Hong Kong
Maria Galli, Hong Kong University of Science and Technology, Hong Kong
Robert S. Wyer Jr., Chinese University of Hong Kong, Hong Kong

EXTENDED ABSTRACT

When introducing a product with which consumers are unfamiliar, there are various strategic options a company can follow to advertise it. The advertising can be fairly product-centric with the goal of getting consumers to form impressions of the product. Alternately it might focus on drawing attention to the ad to get people to talk about it – the assumption being that this "much talked about" advertising will have a positive effect on product evaluations. To understand how consumers react to such strategies, we examine how the processing goals they have (impression formation vs. communication) interact with their chronic styles of processing (tendency to process information visually vs. verbally) to affect responses to advertising.

Television commercials contain both visual and auditory components. The visual component typically conveys a temporal sequence of events intended to grab attention and, sometimes, portrays conditions in which the advertised product might be used. The auditory component typically describes the product's benefits. We hypothesized that individuals' chronic tendency to process information visually or verbally (see Childers, Houston and Heckler 1985) can influence their evaluations of the products being advertised. However, the nature of this influence depends on their familiarity with the product being advertised and their goal in viewing the commercial. If the goal is to form an "impression," verbalizers (who are naturally predisposed to attend to the auditory portion of the commercial that describes the product's benefits) are likely to evaluate the product more favorably than visualizers. However, if the goal is to "communicate" and tell others about the ad, visualizers, (given their natural predisposition to form a detailed nonverbal representation of the sequence of events observed) are likely to make more favorable product evaluations than verbalizers. We expect these differences to hold only when the product being advertised is relatively unfamiliar, because with familiar products individuals are more likely to base their judgments on their a priori knowledge about its attributes. Such knowledge would obscure any differences in their responses to a commercial promoting the product.

Experiment 1 evaluated this hypothesis. We asked participants to view four TV commercials, two for familiar products and two for unfamiliar products. Some participants were told to form an impression of the products in the commercials and were told that they would be asked to describe these impressions after viewing them. Others were told that we were interested in how people communicate information to others and that after viewing the commercials, they would be asked to describe the events they observed. After viewing the commercials, all participants wrote down either their impression of the product or a description of the events. Finally, they evaluated the products advertised and completed a style of processing scale that was used to categorize them as visualizers or verbalizers.

We expected that the interactive effects of processing goal and processing style implied by our hypothesis would be more evident when the products being advertised were unfamiliar than when they were familiar. Product evaluations were analyzed as a function of processing goal, processing style, and the familiarity of the product being advertised. The data confirmed the implications of our hypothesis. Specifically, the effects of processing style and processing goal on product evaluations depended on product familiarity, as evidenced by a 3-way interaction of these variables, $F(1, 140) = 4.16$, p

$< .05$. Verbalizers evaluated *unfamiliar* products more favorably than visualizers under impression formation conditions (0.41 vs. -.06), but less favorably than visualizers in communication goal conditions (0.62 vs. 1.37). The interaction of processing style and processing goal implied by these differences was significant, $F(1, 140) = 4.03$, $p < .05$. However, the corresponding differences in evaluations of *familiar* products were negligible ($F < 1$).

In a second experiment, we examined whether the time at which the goal is induced matters. Suppose individuals know at the time they view a commercial that they will later be asked to do something that requires a verbal encoding of it (e.g., write down their impressions of the product or verbally describe what they saw). Likely, they will try to code both auditory and visual features of the commercial linguistically at the time of viewing it, in a way consistent with the specific objective. If verbalizers are better able to encode things verbally than visualizers are, and if they use this coding as a basis for their later evaluations of the product, their evaluations may end up being relatively more favorable. On the other hand, suppose individuals view a commercial without any specific objective in mind. Likely, they will pay less attention to the auditory description of the product's features (which is not intrinsically interesting) relative to the visual images, and will form a nonverbally coded episodic model like that assumed by Wyer and Radvansky (1999). In this case, because visualizers should be better able to construct a detailed representation than verbalizers, if they are unexpectedly called upon to evaluate the product, and if they base their judgment on the implications of this representation, they should evaluate the product more favorably than verbalizers.

To assess this, experiment 2 manipulated the order in which the processing goals were induced. Participants were shown a commercial for a familiar product and were given the impression formation or communication goal, either before or after seeing the ad. After providing the corresponding descriptions, they evaluated the product and completed a style of processing scale. The results support the hypothesis: Verbalizers evaluated products more favorably than visualizers when they were given a processing objective at the outset (2.35 vs. 1.34, respectively), but less favorably than visualizers when they had viewed the commercial with no particular goal in mind (1.31 vs. 2.05). The interaction implied by this pattern of differences was significant, $F(1, 106) = 4.30$, $p < .05$, and did not depend on whether participants had a communication objective or an impression formation objective, $F < 1$.

Collectively our results suggest that the strategy (getting people to talk about the ad vs. the product) that is optimal might depend very much on whether the audience consists of verbalizers or visualizers.

Competing Consumers and the Valuation of Products

Gerald Häubl, University of Alberta, Canada
Christian Schmid, University of Alberta, Canada
Hua (Olivia) Lian, University of Alberta, Canada

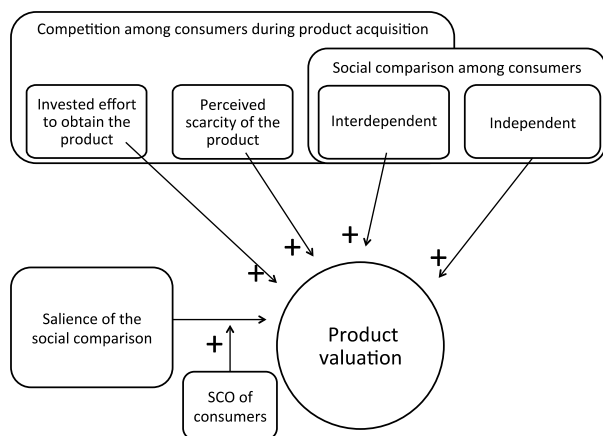
EXTENDED ABSTRACT

While a vast amount of research has examined competition between sellers vying for market share (e.g., Hildebrandt and Klapper 2001; Peattie, Peattie, and Emafo 1997; Zhu, Singh, and Manuszak 2009), competition among consumers is not well understood. This gap in the literature is particularly striking given the increasing prevalence of market mechanisms – such as auctions – that require consumers to compete against each other as they seek to buy products.

We propose that the experiences consumers have in the process of acquiring products affects their subsequent attachment to these possessions. In particular, we hypothesize that the experience of competing against other individuals during product acquisition increases consumers' valuation of a product.

The notion that the experience consumers have when obtaining a product through a particular acquisition mode can affect how highly they value that product is consistent with prior research indicating that consumers construct their value assessments and preferences during the decision making process (Ariely and Simonson 2003; Johnson, Häubl, and Keinan 2007).

We propose that obtaining a product by competing against other consumers differs from typical (non-competitive) means of product acquisition in terms of the following key aspects: First, competing against others to obtain a product requires *effort*. Second, it implies *product scarcity* – i.e., demand for the product exceeds supply. Finally, when there is competition among consumers, not everybody who wishes to acquire the product is able to do so, invoking *social comparison* between those who were and those who were not successful at acquiring the product (Figure 1).

Figure 1:
Conceptual Framework - The Effect of Competition Experience During Product Acquisition on Consumers' Product Valuation


In studies 1 and 2, we disentangle these three aspects of the experience of competing against other consumers – effort, product scarcity, and social comparison – and examine the role of each in consumers' construction of product value. Study 3 focuses on the social comparison (SC) aspect of competition and investigates the moderating roles of competition salience and consumers' social comparison orientation.

STUDY 1

A 2 (SC: yes vs. no) x 2 (effort: high vs. low) between-subjects design was used. SC was manipulated by whether two participants (believed they) had to compete for a single mug based on their performance at solving puzzles (SC) or everyone received the mug irrespective of their performance (no-SC condition). In fact, all participants received a mug. Effort was manipulated via the duration of the puzzle task. The dependent variable – in all three studies – was participants' monetary valuation of the object they obtained, measured via an incentive-compatible BDM procedure.

The results show that both social comparison and effort had significant positive effects on product valuations, and that these were independent (rather than interactive).

STUDY 2

A 2 (SC: yes vs. no) x 2 (scarcity of the object: high vs. low) x 2 (object: mug vs. notice-board) mixed-design was used. Participants were instructed either to compete on a task to win the object (SC) or to simply complete the task to obtain it (no-SC). The probability of getting the object was purportedly either 10% (high scarcity) or 50% (low scarcity). Each participant completed two rounds of the task (one for each object).

The results reveal that both social comparison and scarcity had significant positive effects on product valuations, and that these were independent (rather than interactive).

STUDY 3

This study examines whether competitive social comparison has to be of an interdependent nature, where winning by one consumer implies losing by another (such as within an auction), to increase product valuations. If social comparison is independent, such that winning by one consumer has no implications for the outcome of another (e.g., when they bid in different auctions for the same product), does this effect still hold? We also examine the interplay between the salience of social comparison and consumers' chronic social comparison orientation (SCO). People vary in the degree to which they engage in social comparison. Individuals high in SCO compare themselves more with others and are more affected by the outcomes of social comparisons (Gibbons and Buunk 1999). Thus, high SCOs may value a product more highly if its acquisition involved high salience of SC than if its acquisition involved less SSC, while low SCOs should respond less to the salience of SC.

A 2 (salience of SC: high vs. low) x 2 (nature of SC: independent vs. interdependent) x 2 (SCO: high vs. low, measured factor) between-subjects design was used. Participants completed the study in pairs, with each participant independently solving a number of puzzles as quickly as possible. The two participants in a pair were either introduced face-to-face (high salience of SC) or merely connected via their computers (low salience of SC). In the interdependent condition, participants (believed they) had to outperform their partner at the puzzle task to win a mug. By contrast, in the independent condition, participants believed that each member of the pair completed a separate random draw with an independent 50% chance of winning the mug. In fact, all participants received a mug.

The results reveal no significant difference between the interdependent and independent SC conditions, indicating that both

positively contribute to product valuations. Importantly, there is a highly significant 2-way interaction between salience of SC and SCO ($p<0.01$). Spotlight analysis (Fitzsimons 2008) reveals that, for consumers high in SCO, high (vs. low) salience of SC leads to higher product valuations, whereas it does not affect the product valuations of consumers low in SCO (Figure 2).

Figure 2:
Product Valuation as a Function of the Salience of Social Comparison and Consumers' Social Comparison Orientation
This research enhances our understanding of how the manner in which products are acquired influences how highly consumers value them. It also provides a framework for understanding the implications of competition among consumers that identifies effort, product scarcity, and social comparison as the essential distinct aspects of this type of competition.

Humorous Consumer Complaints

A. Peter McGraw, University of Colorado, USA
Christina Kan, University of Colorado, USA
Caleb Warren, Universita Commerciale Luigi Bocconi, Italy

EXTENDED ABSTRACT

"I should have flown with someone else or gone by car… 'cause United breaks guitars."

When United Airlines refused to compensate David Carroll for his damaged guitar, the musician parodied his negative experience with the company in a YouTube music video. His humorous complaint became a media sensation, leading United to apologize and offer Carroll compensation (Deighton and Kornfeld 2010).

Although complaints typically document dissatisfaction, some complaints intentionally include a positive element: humor. Drawing on marketing and humor research, we introduce the concept of *humorous complaining* and differentiate it from non-humorous (i.e., serious) complaining.

We define a humorous consumer complaint as a behavioral expression of dissatisfaction about a product or service that elicits humor in others. As compared to serious complaints, we hypothesize that:

Consumers enjoy humorous complaints. People pursue and enjoy humorous experiences (Martin 2007). People often dislike attending to others' complaints (Kowalski 1996), but humor can help improve people's attitudes towards experience they would otherwise find annoying and unpleasant, such as advertisements (Alden, Mukherjee, and Hoyer 2000; Eisend 2009).

Consumers judge humorous complainers more favorably. Complainers are often considered annoying or grumpy and may be ostracized by their audience (Kowalski 1996). Conversely, a sense of humor is generally seen as an admirable trait (Cann and Calhoun 2001; Martin 2007).

Consumers pay more attention to humorous complaints. Research in advertising shows that humor attracts attention (Madden and Weinberger 1982; Weinberger and Gulas 1992). Humorous content is remembered better than non-humorous content (Schmidt 1994).

Consumers are more likely to share humorous complaints. Content that elicits positive emotions is more likely to be shared with others (Berger and Milkman 2011). A recent study finds that the perceived humor in a *YouTube* video predicts its number of views (Warren and Berger 2011).

THREE STUDIES SUPPORT OUR HYPOTHESES:

In Study 1, based on random assignment, we asked undergraduates (N=75) to create and post a serious or humorous complaint as a status update on Facebook. In the 24 hours following the posting, participants recorded the number of people who 'liked' the update. Humorous complaints generated significantly more likes than serious complaints (M_{Humor}=9.07, SD_{Humor}=7.16, $M_{Serious}$=5.59, $SD_{Serious}$=4.68; $F(1,71)$=5.67, p<.05). Subsequently, we asked another group of undergraduate students (N=50) to read through the complaints. Half of the participants rated the perceived humor in the complaints and the other half rated how likely they would be to 'friend' a person who posted the update and also how likely they would be to share the update with others. Consistent with our hypotheses, participants were significantly more likely to 'friend' people who posted more humorous complaints (r=.30, p<.01) and significantly more likely to share more humorous complaints with others (r=.52, p<.001).

Study 2 explored enjoyment, likelihood of sharing, attitude towards the complainer and attitude towards the firm using complaint letters. The study used a 2(humorous vs. serious) x 2(bank vs. feminine product) between-subjects design. To obtain the stimuli, we asked a sample of mTurk workers (N=50) to send us the most humorous consumer complaint they could find on the internet. A research assistant blind to the hypotheses screened the complaints for validity and selected the two most humorous complaints. Another research assistant (also blind to the hypotheses) rewrote the complaints to be strictly serious in nature.

Depending on random assignment, undergraduates (N=165) read either a humorous or a serious letter complaining about one of two possible products, and assessed on seven-point scales their enjoyment of the letter, likelihood of sharing the letter, attitude towards the writer of the complaint and attitude towards the firm. Consistent with our hypotheses and the results of our previous study, we find that compared to the serious complaints, participants reported greater enjoyment of the humorous complaints ($M_{Humorous}$=4.60, $M_{Serious}$=3.00, $F(1,163)$=27.25, p<.01), reported being more likely to share the humorous complaints ($M_{Humorous}$=3.65, $M_{Serious}$=2.87, $F(1,163)$=5.66, p<.05) and had a more positive attitude towards the complainer when the complaint was humorous ($M_{Humorous}$=4.52, $M_{Serious}$=3.65, $F(1,163)$=8.69, p<.01). Interestingly, brand attitudes did not differ depending on whether the complaint was humorous or serious ($M_{Humorous}$=3.33, $M_{Serious}$=3.17, $F(1,163)$=.38, p=.54).

Study 3 explored the influence of humorous complaints on brand choice, using online product reviews. If consumers attend more to humorous complaints, then humorous complaints may be more influential when making choices. We used a between-subjects design with 3 conditions (serious complaint and two humorous complaint replicates). To obtain the stimuli for this study, we first randomly selected a negative product review regarding a pair of earphones from Amazon.com. To create the humorous versions of the review, we asked 30 mTurk workers to rewrite the review in a humorous way, and then had a second sample of 39 mTurk workers rate how humorous they found each humorous rewrite. We selected two of the funniest reviews for the study.

mTurk workers (N=148) first read a product description for Brand X, followed by one positive and one negative Brand X review. Next, participants read the description for Brand Y, followed by one positive and one negative Brand Y review. Depending on random assignment, the negative Brand Y review was either serious or humorous in tone (two humor replicates). Participants were informed that they would have the opportunity to win one of the two pairs of headphones and were asked to indicate which brand they preferred.

As hypothesized, participants were less likely to select Brand Y when a negative consumer review of the product was humorous (21.8%) than when it was serious (42.6%; $\chi^2(1)$=6.61, p=.01). Participants exposed to the first humorous review were just as likely (20.9%) to select Brand Y as those who were exposed to the second humorous review (22.4%; $\chi^2(1)$=.03, p>.85).

In summary, the use of humor in consumer complaints can significantly alter the responses of other consumers exposed to them. Because humorous complaints are more enjoyable, attention getting, and more likely to be shared than serious complaints, we suggest that, as was the case with Dave Carroll's complaint, they can be a source of empowerment to consumers who have been wronged by brands.

Improving Associative and Item Memory for Brands Among Elderly Consumers

Praggyan (Pam) Mohanty, Governors State University, USA
S. (Ratti) Ratneshwar, University of Missouri, USA
Moshe Naveh-Benjamin, University of Missouri, USA

EXTENDED ABSTRACT

Prior research in cognitive psychology has found important differences between associative memory and item memory (Clark 1992; Clark and Burchett 1994; Gronlund and Ratcliff 1989; Hockley 1991). While item memory is memory for individual items present in a stimulus episode, associative memory is memory for a combination of two or more items together. Especially germane to the present research is the prior finding that *aging* affects item and associative memory differently. Larger age-related impairments are seen in associative memory than item memory (for a review refer to Old and Naveh-Benjamin 2008; Spencer and Raz 1995).

Item memory and associative memory for brand information are both important for brand building. Memory for item information such as individual brand names or brand logo graphics helps increase brand awareness and keeps the brand salient in the minds of consumers. Associations between the brand and favorable and distinct attributes and benefits work towards the creation of a positive brand image (Aaker 1996, 25; Broniarczyk and Alba 1994; Keller 1993). Overall, brand equity and marketplace success of brands depend upon the creation of high levels of brand awareness as well as positive and distinctive brand images (Warlop, Ratneshwar, and van Osselaer 2005).

Despite the importance of item and associative memory for effective brand building, there has been very little consumer research on how these constructs are different from one another. Further, to the best of our knowledge, there is not even a single published study in consumer research on the effects of aging on item versus associative memory for brand information. This dearth of research is perplexing, given the importance of the elderly consumer to marketers (Yoon et al. 2005). Indeed, current demographic trends suggest that the age segment of 65 and above will increase dramatically over the next two decades, growing to nearly 20 percent of the total U.S. population by 2030. The growth of the elderly consumer segment makes a compelling argument for studying memory issues in this age group.

The aim of this paper is therefore to address an important research gap by studying the effects of aging on item and associative memory for brand elements. We focus not only on memory deficits in elderly versus younger consumers in a branding context, but also investigate how marketers can alleviate such deficits in the elderly. For doing so, we build on prior research in cognitive psychology which has shown that "schematic support" in terms of schemas or prior semantic knowledge within a domain should aid encoding and retrieval of information (Craik and Bosman 1992). Two different forms of schematic support are examined in regard to item and associative memory for brand information among elderly consumers. In study 1, the main question of interest is whether using more versus less meaningful brand elements (i.e., brand logo graphics) will improve item and associative memory for brand information in elderly (vs. younger) consumers. *Meaningfulness* of a brand element is the extent to which an individual has pre-existing semantic knowledge of the element in memory. In study 2, the same type of question is explored in regard to the degree of *relatedness* between brand elements (i.e., brand logo graphics and brand names).

Study 1 (N = 50) used a 2 (elderly vs. younger consumer, between-subjects) x 2 (associative memory for brand information vs. item memory for brand logo graphics, within-subject) x 2 (more vs. less meaningful brand logo graphics; within-subject) mixed factorial design. The dependent variable was recognition accuracy as measured by the proportion of hits minus false alarms (Law, Hawkins, and Craik 1998; Morrin and Ratneshwar 2003). The stimuli were pairs of brand logo graphics and brand names. While brand logo graphics were manipulated to be more vs. less meaningful, the brand names were meaningful ones that were counterbalanced across the more and less meaningful brand logo graphics conditions.

Study 1 results showed that meaningfulness of brand logo graphics helped elderly consumers in remembering brand logo graphics better. Further, there was a two-way interaction between meaningfulness of logo graphics and age in the case of brand logo graphics (i.e., item) memory. Thus, the deficit in brand logo graphics memory between elderly (vs. younger) consumers in the less meaningful brand logo graphics condition was actually eliminated in the more meaningful brand logo graphics condition. In addition, meaningfulness of brand logo graphics enhanced associative memory for brand logo graphics and brand names in elderly consumers. Some interesting results were also obtained in subsequent follow-up analyses where we examined hit rates and false alarm rates separately.

Study 2 (N = 48) used a similar design and procedure as study 1. Results showed that relatedness between brand logo graphics and brand names helped elderly consumers remember the individual brand elements better (i.e., improved item memory). Interestingly, there was also a significant two-way interaction between age and relatedness between brand logo graphics and brand names for item memory. Specifically, elderly (vs. younger) consumers benefited more from relatedness between brand logo graphics and brand names in boosting their item memory performance. Further, relatedness between brand logo graphics and brand names also helped elderly consumers improve associative memory for brand information. Finally, in accord with past research, both studies 1 and 2 demonstrated that in the case of novel brand information, elderly (vs. younger) consumers display a larger deficit in associative memory than item memory, i.e., there was a significant two-way interaction between age and type of memory.

To Think or Not to Think: The Pros and Cons of Thought Suppression

Natalina Zlatevska, Bond University, Australia
Elizabeth Cowley, University of Sydney, Australia

EXTENDED ABSTRACT

Consumers are often faced with failure. They buy things that are never worn. They buy items the day before the item goes on sale. They find out after a negotiation that a friend got a better price than they did. Thinking about failure can be unpleasant. Is trying not to think about the failure a good coping strategy?

Actively suppressing thoughts about the failure may seem like a viable short-term strategy because avoiding the unwanted thoughts means the individual faced with the failure might also avoid the negative feelings associated with the unsuccessful outcome. Thought suppression requires two mechanisms; an operating process to promote the suppression by finding distracting thoughts and a monitoring system to search consciousness for signals of suppression failure (Wegner 1987; 1994). The irony of thought suppression is that the monitoring process causes hyperaccessibility of the unwanted thought. For example, in Wegner's famous white bear studies, not thinking of a white bear requires continuous activation of the thought to ensure it has not come to mind. This monitoring process leads to increased accessibility of the unwanted thought after thought suppression has been discontinued (the rebound effect). If the unwanted thought is not a benign white bear thought, but is instead related to poor consumption, the rebound effect may have important consumption ramifications including poor consumption decisions (Erskine, Georgiou and Kvavilashvili 2010). Independent of rebound effects, thought suppression has been shown to result in poor consumption decisions when suppressing benign white bear thoughts. Vohs and Faber (2007) demonstrate that not thinking about white bears can result in suboptimal consumption decisions because of a reduction in self-regulatory resources. Although we know that depleting self-regulatory resources can be detrimental to subsequent behavior (Baumesiter 2002), it is not clear which of the two processes causes poor decision making when consumers suppress thoughts about their own past failures. In order to understand when the detrimental effects of thought suppression can be eliminated, it is important to determine which of the two processes is depleting. The monitoring process always occurs and cannot be eliminated, while the distracting process can be more or less difficult. We propose that it is not the monitoring process, but the process of finding a distraction that is resource depleting.

In three studies, we show that depletion during thought suppression is not caused by monitoring for the presence of an unwanted thought or the negative affect associated with thinking about failure. We show that it is the process of looking for a distracting thought. In each study, participants work on an unsolvable puzzle task and are given failure feedback. In study one, we manipulate the motivation to thought suppress. In studies two and three, thought suppression is instructed.

The aim of study one (N=61) was to establish that after acknowledging failure, participants engaging in an activity that did not provide sufficiently distracting thoughts, had fewer self-regulatory resources than participants that did not acknowledge the failure (t =2.63, p =.01). Consistent with previous measures of depletion, the volume of food consumed was a proxy for the level of remaining self-regulatory resources (more 'sinful tempting' food consumed = fewer remaining resources: Vohs and Heatherton 2000; Fedorikhin and Patrick 2010). Thought protocols and scales show that participants did try to suppress thoughts after acknowledging the failure.

To more directly test for the depleting effects of thought suppression, we instructed thought suppression and manipulated the effort required to find distracting thoughts by providing cues (vs. not providing cues) reminding participants of the unwanted thought (poor performance) in study two (N =98). The number of times a distraction had to be found during thought suppression was measured by counting the intrusions in the participants' speak-aloud recordings. Hopelessness was measured after the suppression task. Finally, during an unrelated task, participants were told to help themselves to M&Ms. If it's the effort involved in finding a distracting thought drives depletion, then the number of times a distraction had to be found (intrusions), not hopelessness, should mediate the cue/resource depletion relationship.

As expected, participants in the cued condition were more depleted than participants in the no-cue condition (t =-2.41, p =.018). Importantly, the number of intrusions fully mediated the cue/depletion relationship (Figure 1). To eliminate the monitoring process as the explanation for depletion, we manipulated monitoring in study three (N =81). We introduced a control condition where participants were not told to thought suppress, but instead to think about the failure and improvement strategies. They, therefore, didn't need to activate the monitoring process. In two thought suppression conditions, we manipulated the difficulty of finding a distraction following an intrusion by offering (vs. not offering) distracting thoughts. To test the effect across contexts, a more general measure of resource depletion was used; attentional control on a dichotic listening exercise.

Figure 1
Study 2 – Mediation of Cue Manipulation on Consumption via Thought Intrusions

*=p < .05; ** =p < .01
If monitoring, and the subsequent rebound effect, explained the depletion found in studies one and two, then participants in the thought suppression condition should always be less able to perform on a resource demanding dichotic listening task compared to participants in a 'no thought suppression' (control) condition. Instead, we found that thought suppression was only depleting, compared to the control condition, when the distracting thoughts had to be found (t =2.27, p =.03), not when they were offered (Figure 2).

Figure 2
Study 3 – Remaining Self-Regulatory Resources
This research demonstrates that the short-term benefit of suppressing thoughts to avoid the negative feelings associated with failure depletes self-regulatory resources and causes poor consumption decisions. Importantly, we explore reasons for the depletion. We demonstrate that the conscious act of finding a distraction, causes depletion and sub-optimal consumption behavior in a domain completely unrelated to the failure itself.

The findings shed light on a trade-off for consumers dealing with a failure. Either try to feel better now by suppressing thoughts at the risk of a breakdown in behavioral regulation later or wallow in the negative thoughts now, knowing that better consumption decisions will be made in future.

Self-Affirmation Can Backfire For Experts: The Case Of Product Warning Messages

Valeria Noguti, University of Technology Sydney, Australia

EXTENDED ABSTRACT

Protecting self-worth and integrity is a central human motivation (Steele 1988). However, it can lead people to resist threatening information which could otherwise improve their decisions (Sherman and Cohen 2002). Self-affirmation provides one way to overcome this kind of resistance (Steele 1988). As the self-concept is formed by multiple selves which get differentially activated at different moments (Markus and Kunda 1986), affirming one of these selves, for example, 'the benevolent self', activates evidence of self-worth, so the need for self-integrity protection can be relaxed, decreasing resistance to threatening information.

Although affirmation generally eases the acceptance of threatening information, it can result in higher resistance as well. For example, higher resistance is observed when the threat occurs in the same domain as the affirmation (Blanton et al. 1997) because affirmation highlights a person's commitment to the issue and the identity at stake (Sherman and Cohen 2006). As self-affirmation turns one's attention to the adequacy of the self, strengthening the pursuit of self-esteem, people feel threatened by criticism in domains in which they have staked self-worth, and feel pressure to succeed in that domain (Crocker and Park 2004). Therefore, we propose that resistance to threat is triggered by affirmation when consumers have expertise in a domain, as individuals often take pride in learning while experiencing products, and form internal attributions about personal efficacy (Hoch and Deighton 1989).

Surprisingly the role of expertise on self-affirmation effects has been absent from the literature. We start to fill this gap by investigating this question in the domain of warning labels. Product warning labels are used to communicate potential risks of product usage and/or to persuade individuals to behave in a particular manner (Stewart and Martin 1994)w. In this context, one way to accomplish self-protection is to reassure that products with warning labels in one's domain of expertise are valuable. Hence, self-affirmation for experts who are threatened is predicted to lead to more positive product perceptions.

Further, while high self-esteem individuals respond to threats through dominance and competence, low self-esteem people pursue self-esteem by seeking acceptance, for example by looking for reassurance from others or becoming more interdependent (Crocker and Park 2004; Vohs and Heatherton 2001). Evaluating products per se cannot address the social needs that low self-esteem individuals pursue. Therefore, if self-affirmation triggers the self-esteem system, we would expect increases in product perceptions only for high self-esteem consumers because boosting these perceptions can help ascertain the importance of their competence which was threatened.

We report three studies, all with two conditions: affirmed vs. control. In study 1 participants were members of an online panel. The study started with the manipulation (Steele and Liu 1983) in which participants ranked values then explained either why their first ranked value was important to them (affirmed condition) or why their fifth ranked value was important to others (control condition). Next, participants were presented with a can of an unknown energy drink containing a label: "Warning: May cause heart palpitations in caffeine sensitive people. Usage: Max 2 cans daily", and indicated their attitudes toward the drink (α = .89) (unfavorable/favorable, negative/positive, bad/good, nonattractive/attractive). Participants then indicated their expertise (α = .86) on a 7 point scale: "I am knowledgeable regarding energy drinks" and "I have a lot of experience with energy drinks". Given length constraints, we report only the results for those who reported having seen the warning and who were more expert (estimated by mixed models using the continuous expertise measure). More expert, affirmed participants reported more positive (M = 3.98) attitudes than more expert, non-affirmed participants (M = 3.03; $F(1, 79)$ = 5.62, p < .05).

Study 2 was run with students and used a high-involvement product category. After the affirmation manipulation, participants were presented with information about a 3D TV, including a picture of 3D glasses with the label: "Warning: Do not view images too closely or for a long period of time as it may harm your eyesight". Attitudes toward the product (α = .89) were measured, in addition to purchase intentions, and perceptions that the product would sell well. Expertise (α = .77) questions followed: "I am knowledgeable regarding 3D viewing", and "Compared to most other people, I have a lot of experience with 3D viewing (this includes time spent watching movies in 3D)". To measure category effects, participants filled out an attractiveness scale (Boyd and Mason 1999) toward 3D TVs (α = .88). Compared to control participants, for more expert consumers self-affirmation resulted in marginally more positive product attitudes (4.83 vs. 5.43; $F(1, 175)$ = 3.20, p = .08), significantly higher perceptions that the product would sell well (4.20 vs. 4.90; $F(1, 175)$ = 4.01, p < .05) and greater attractiveness of 3D TVs (3.39 vs. 4.43; $F(1, 175)$ = 15.74, p < .001). Although purchase intentions did not significantly increase with affirmation (4.07 vs. 4.56; NS), this is understandable as participants were students.

In study 3, ran with members of an online panel, in the affirmed condition participants were asked to describe two situations in which they acted kindly towards someone else. In the control condition they listed 10 cities in their state. The remaining part was identical to study 2, followed by a measure of implicit self-esteem (ISE), namely a name letters evaluation task (Koole, Dijksterhuis, and Van Knippenberg 2001). The results replicate the previous findings, except that purchase intentions also increased from the control to the affirmed condition (3.94 vs. 5.00; $F(1, 219)$ = 5.89, p < .05). Furthermore, when considering ISE, these results replicate again but only for those high in ISE (except for attitudes, which did not reach significance), not for those low in ISE.

In conclusion, we identify expertise as a significant factor in self-affirmation effects. When expertise is high, self-affirmation may lead threats to become more (rather than less) aversive, in consequence leading consumers to evaluate a product more (rather than less) positively when it contains a warning label. Self-esteem appears as a moderator: affirmation backfires only for high self-esteem experts who perceive a warning label threat.

Transformational Solutions of Self through Companion Animals

Jill Mosteller, Portland State University, USA

EXTENDED ABSTRACT

How consumers manage the dynamics between love and money can be intertwined in a myriad of ways. Based upon the growing presence of companion animals in U.S. households (now estimated at 62%) and related financial spend (over $50 billion in 2011) (APPA 2011), understanding consumers' identity dynamics relating to companion animals may be theoretically insightful. The things we love exert a strong influence on our sense of self (Ahuvia 2005). Companion animals may be classified as extensions of oneself in addition to being associated with significant life events or experiences (Belk 1988; Ahuvia 2005). By understanding the meanings companion animals serve related to a person's self-concept and integration within society may serve as "relationship climate canaries" (Brownlie 2008). Given fundamental human need for social relatedness (Baumeister and Leary 1995) and assertions of decline in one's sense of community (Cushman 1990), do the roles one adopts as it relates to companion animals serve as adaptive solutions for social relatedness?

Consumers' motives for consumption and possession stem in large part from the "meaning of consumption objects and the value that meaning provides" (Richins 1994, 519). In North America, the freedom to create one's identity comes with the consumer responsibility to self-define, suggesting that the "goods" one acquires may be particularly meaningful because they may serve to help construct and communicate one's identity (McCracken 1986). Identities represent self-concepts because they reflect internalized role expectations within social relationships; the goal being to understand and explain how social structures affect self and self affects social behaviors (Stryker 2007).

Noting that "an adequate understanding of human behavior must begin with an exploration of how people define the situation, selves, and others that compose the social worlds they inhabit" (Sanders and Hirschman 1996, 112-113), a phenomenological approach was employed. Depth interviews ranging from one to three hours in length with continued documented conversations and observations covering a five-year period provide the basis for the emergent findings. People who engaged in a variety of animal related roles provided the foundation for this purposeful sample. Observations and conversations with other informants engaged in animal related roles, and people who knew the informants, were added to triangulate and enhance data credibility (Patton 2002).Two selected cases highlight how animal-related roles serve to create a self-conceptual fit within one's community under varying degrees of resource (e.g. money, housing) and social support (e.g. community, family, professional). These two cases depict role trajectories that start, progress, and end on opposite ends of the perceptual map spectrum (social conflict/social support on the x-axis and access to resources draining/gaining on the y-axis). The emotional and financial trade-offs each makes within their respective social structures, inform identity project outcomes.

Role Abandonment to Role Acquisition: Transformative Synthesized Solution: Al

Al's story 'begins' when he was 9 years old with his "own" dog. Due to Al not spending enough time caring for and fulfilling his dog responsibility duties, his parents facilitated the abandonment of his dog caretaker role by returning the dog to the 'pound'. He had no control over the outcome; parents exerted control over resources. Al expressed conflict in terms of love and money, stating how the lack of money causes "love" to go away. To resolve this conflict, Al later worked to become Superintendent of an animal shelter, responsible for hundreds of animals. This role, a symbol of his animal stewardship achievement, helped to resolve his earlier childhood conflict, seeing himself as being a bad dog caretaker. The path from role abandonment to role acquisition illustrates a synthesized solution (Ahuvia 2005) predicated on his love "for all things natural." He constructed a desired self-concept by forcefully going after the roles that developed his animal caretaker ability and enabling him to exert control over animal life and death outcomes through the resources he responsibly managed. Al's identity transformation required him to confront his dark side, as well as others' dark sides concerning animal caretaking. This role acquisition enabled him to exert control over necessary resources so he could manage when and how love would go away.

Role Acquisition to Role Abandonment: Transformative Dysfunctional Solution: Deb

Deb began breeding dogs as a means to earn money while she cared for her mother. Over time she acquired more dogs than she sold. Rising food and care costs related to the growing number of dogs depleted her financial resources. She worked as a vet tech in a nearby city, a role she acquired role from the vet who vaccinated and treated the puppies she bred. Initially, being a vet tech and breeder helped her financially, but Deb's motivations shifted over time. To combat feelings of social isolation and reduced emotional intimacy she experienced after moving from the city back to the country, her animal family became her social surrogate. Social conflict emerged with community members calling the department of agriculture about the growing number of dogs. The sudden death of Deb's mother, a critical source of social and financial support, overwhelmed Deb emotionally and financially. She voluntarily relinquished the dogs to authorities. Deb's case illustrates how one's need for money transformed into a need for love and social connectedness not fulfilled within her community. Deb's sense of alienation and resulting identity emptiness after losing the animals is attributed in part by her inability to manage resources needed to sustain the identity project and confronting her own dark side in the process.

Findings suggest that one's perceived degree of conflict or support within one's social structure influences the construction and evolution of identities and related role behaviors as a means of creating synthesized solutions. These two cases contribute to symbolic interaction by illustrating how social relations (e.g. love) and resources (e.g. money) shape consumers' identity projects with companion animals adding social dimension. For Deb, companion animals were a social surrogate, signaling her growing alienation and distrust of others within her community. For Al, companion animals were a social conduit that enabled a personal transformation, signaling integration and support from others.

Increasing Serving-Size Increases Amount Consumed: A Catch-22

Natalina Zlatevska, Bond University, Australia
Chris Dubelaar, Bond University, Australia
Stephen Holden, Bond University, Australia

EXTENDED ABSTRACT

The effect of serving-size on consumption is well-established (Chandon and Wansink 2011). The larger the serve, the greater the amount consumed. However, what is not clear is the size of the effect, the processes driving the effect, and the conditions under which the effect is stronger or weaker.

The present research used a meta-analysis to quantify the effect of serving-size on amount consumed. We also test two alternate views in the literature for why the effect occurs. The view that the influence of serving-size on consumption volume is a perceptual effect is compared to the view that the effect is a function of a unit-bias.

Extant research shows that people's estimations of serving-size changes tend to be inelastic (Chandon and Wansink 2006; Chandon and Ordabayeva 2009; van Ittersum and Wansink 2012). Generally, the size of the increase is underestimated (100% increase in serving-size leads to a perceived increase of only 50-60%). These published results describe a standard diminishing psychophysical function as described by Weber's Law (1834). Meaning that, although there is a constant linear effect for the ratio of change in serving-size to amount consumed, the change in perceived serving-size does not equate to the actual change in serving-size.

An alternative view suggests a unit-bias drives the serving-size effect (Geier et al. 2006). Individuals generally base consumption around a single unit or serving (e.g. we consume a bowl of soup or a plate of pasta). However, focusing on the consumption of one unit (or even part of one unit) leaves individuals susceptible to variations in the size of that unit (100% increase in serving-size leads to a 100% increase in consumption).

In the present study, we expect that if the serving-size effect results from a unit-bias, consumption would change linearly in direct proportion to serving-size. Conversely, if the serving-size effect results from a perceptual influence the ratio of change in consumption will not directly equate to the actual change in serving-size.

A meta-analysis using 67 separate studies with a combined sample of 2792 respondents, revealed a substantial and significant effect of serving-size on consumption (d=.469,CI95=[.376,.562]). To test for the underlying process of the effect, we regressed the absolute measures provided within each study for both amounts served and amounts consumed. If the serving-size effect is due to a unit-bias, the relationship between amount served and amount consumed should be linear and approaching a slope of one. However, the results show that there is a diminishing impact of serving-size on amount consumed as the size of the serving increases.

While this shows that unit-bias is not the source of the size effect, it does not conclusively show that the source is perceptual. To test whether the process is perceptual, we created a metric that relates the size of change in consumption to the change in serving-size. The change in amount consumed was regressed on the change in amount served.

Our results show that the change in serving-size significantly predicts the change in consumption. Importantly, the regression coefficient tells us that if the serving-size doubles (i.e., the large serve is 100% larger than the small serve), consumption is 22% greater than in the small serve condition. In addition to providing an absolute measure of the serving-size effect, the result suggests that perceptual processes, rather than a unit-bias, drive the effect.

Finally, in an effort to identify conditions under which the effect is stronger or weaker we conducted a moderator analysis. A moderator analysis shows that although the effect varies under a range of conditions, the effect is significantly smaller for children relative to adults. The effect is also stronger when participants were distracted while eating.

To examine how the serving-size effect varies by the significant moderators we entered a dummy variable for children into our regression based on changes in consumption and serving-size. For adults the serving-size effect coefficient is .296 (t=4.88,p<.001) while the coefficient for the dummy variable for children was negative and significant (B =-.110, t=-2.49,p=.005) implying that the coefficient for children is .186. That is, children will increase consumption by 19% if the serving-size is doubled, while adults will increase their consumption by 30%. We also included a dummy variable for food focus, where 1 is no food focus and 0 is food focus. Results revealed a significant coefficient for food focus (B=0.113, t=15.62, p<0.001), implying that when eaters are distracted, and there is a doubling of the serving-size, the amount consumed will increase by 33%.

The results make a number of important contributions. The meta-analysis provides the relative size of the serving-size effect. However, the development of ratio measures of change in serving-size and consumption allows for the absolute quantification of this effect. Consumption can be expected to increase by 22% when the serving-size is doubled. The result shows consumption to be a constant ratio of serving-size and supports the notion that the serving-size effect is perceptual rather than resulting from a unit-bias. And finally, while the effect is fairly reliable and general, it is found to be stronger when consumers are distracted and among adults. The effect is weaker among children.

Some clear public policy implications may be drawn from the findings. First, the size of the serving-size effect should encourage a move away from super-sizing promotions. It might also encourage the adoption of smaller sizes – although to get a 22% reduction in consumption requires a halving of current serving-sizes. The perceptual nature of the effect means that introducing extrinsic benchmarks for appropriate sizing portions (e.g. serving size charts) into the consumption episode should be a more effective strategy in monitoring consumption than adopting rules such as 'always eat half of what you are given'. And finally, as it is encouraging to see that children are less susceptible to the serving-size effect than adults, attention needs to be given to sustaining the apparently natural resistance of children to serving-size manipulations.

In summary, there is a Catch-22 to larger serving-sizes. Serve twice as much; you will eat 22% more!

Exploring African-American Women's
Lived Experiences with Stigma, Identity, and Consumption

Elizabeth Crosby, University of Wisconsin La Crosse, USA

EXTENDED ABSTRACT

A stigma "refers to an attribute that is deeply discrediting" (Goffman 1963, 3). The stigmatized characteristic labels the possessor as different from what is considered "normal" in some way. Furthermore, in order for stigmatization to occur, the attribute must be connected with a negative stereotype. This paper explores African-American women's lived experiences with stigmatization. More specifically, I address the following research questions: (1) How does stigmatization affect African-American women's identities? and (2) How do African-American women manage stigma? Specifically, how do African-American women use consumption to manage stgima?

I employed qualitative data collection methods to tap into African-American women's experiences with stigma. I conducted 23 depth interviews. Informants also constructed collages depicting their identity as African-American women. All informants live in a small city in the Midwest. They come from a variety of social classes and are between the ages of 19 and 56. All interviews were audiotaped and transcribed, yielding more than 650 pages of text. In analyzing both the collages and the written text from the depth interviews, I searched for emergent themes while also engaging in dialectical tacking (Strauss and Corbin 1998).

I argue that stigma significantly affects African-American women's identities and can create identity gaps. The Communication Theory of Identity (CIT) argues that there are four frames of identity: (1) personal, (2) enacted, (3) relational, and (4) communal (Hecht, Collier, and Ribeau. 1993). The personal identity frame is how individuals view themselves while the enacted frame is how people communicate their identity to those around them. The relational frame is others' perceptions of an individual's identity. In the communal frame, society ascribes individuals an identity based on group membership. Because different discourses govern the various identities, discrepancies among the frames can occur, which results in an identity gap (Hecht et al. 1993). Hecht et al. (1993) identify 11 potential identity gaps between frames. Research shows that identity gaps can lead to increased feelings of depression (Jung and Hecht 2008). Identity gaps can also engender feelings of perceived discrimination (Wadsworth, Hecht, and Jung 2008).

In this study, the first identity gap to emerge is the personal-communal gap. None of my informants believe they personify the stereotypes associated with their race and gender. As these women reject the stereotypes society attempts to impose on them, there is a disconnect between their personal identity frame and the communal identity that society ascribes to them. These informants also describe experiencing a communal intra-frame identity gap. While Hecht et al. (1993) explore inter-frame identity gaps (gaps occurring between frames), they fail to consider intra-frame identity gaps (gaps occurring within one identity frame). African-American women can be subjected to two opposing communal identities—one by mainstream society and the other by the African-American community. Intra-frame gaps can be just as problematic for African-American women to manage as inter-frame gaps.

In order to eliminate or reduce the identity gap, individuals can manipulate one of the four frames of identity.

PERSONAL IDENTITY FRAME

One way to eliminate an identity gap is for African-American women to accept the stereotype. The existence of the ascribed communal identity actually results in its internalization into the personal identity frame. This coping strategy is one of the biggest dangers of stereotypes. While none of my informants feel that they fit the stereotypes, they note that constantly fighting stereotyping is difficult and they have been tempted to just accept the identity society ascribes to them. They also discuss how other African-American women they know have internalized the stereotypes. While consumption is not generally used as a management strategy when changing this identity frame, it can be used to facilitate the process. For example, one informant discusses that she has considered if she should accept the gold-digger stereotype and travel to professional basketball games to try to find a rich husband.

COMMUNAL IDENTITY FRAME

African-American women can also attempt to eliminate an identity gap through the communal frame. With these strategies individuals are trying to eliminate the stereotype, thus changing the communal identity. Generally, in order for this to be effective, multiple people must work together to change the stereotype. A notable example of this is the Civil Rights Movement. Attempts to change this frame can be made at the local and national levels. Similar to the personal identity frame, while consumption is generally not the main focus of this management strategy, it can be a part of the strategy. Informants discuss organizing events to educate people on African-American culture in hopes of eradicating stereotypes.

RELATIONAL IDENTITY FRAME

The strategies associated with this frame allow African-American women to distance themselves from the stereotypes associated with their race and gender. The dominant strategy that informants discuss is letting people get to know them as an individual. Through this process those around the individual will realize that she does not fit the stereotype. Individuals can use consumption to help this process. For example, they might have coffee with others while becoming acquainted. However, it is important to note that is not always possible for individuals to get to know every person who may stereotype them. Furthermore, in some cases, an individual might not have the time to get to know the person stereotyping her because of the short duration of the encounter (e.g., during a job interview).

ENACTED IDENTITY FRAME

The strategies associated with the enacted identity frame are consumption laden. African-American women deliberately use consumption to disassociate themselves from particular stereotypes. For example, a common stereotype is that if African-American women have natural hair, they are militant or anti-white. In order to combat this, informants report either processing their hair or wearing a wig, especially in professional contexts. Other women report dressing a particular way to distance themselves from stereotypes.

In this paper I present a theoretical model of how stigma affects identity. I explore how stigmatization affects identity and how consumption is utilized as a management strategy. I hope this paper encourages scholars to revisit the construct of stigma and its importance to the field of consumer behavior.

Don't Put All Your Green Eggs in One Basket:
Examining Self-monitoring and Environmentally Friendly Sub-branding Strategy

Jayoung Koo, University of Minnesota, USA
Barbara Loken, University of Minnesota, USA

EXTENDED ABSTRACT

Motivation

Sustainability concerns in the United States and worldwide have gained much attention in recent years, and companies are jumping on the bandwagon trying to understand strategies to best promote environmentally friendly brand images to consumers. A variety of sub-brand strategies, for example, are found in the marketplace. Toyota entered the hybrid market by introducing the sub-brand Toyota Prius as eco-friendly.

Research is needed to understand whether some sub-branding strategies are more effective than others in influencing consumers' perceptions of eco-friendliness of the overall parent brand. In two studies, we examine whether a strategy in which eco-friendly products are concentrated within a sub-brand is different from a strategy in which eco-friendly products are dispersed across sub-brands. We also examine how the sub-branding strategy interacts with the consumer's level of self-monitoring and variability (similarity or dissimilarity) between the sub-brands.

Hypotheses

Prior research in stereotyping and schematic processing (e.g. Weber and Crocker 1983) finds that when information about one category member is novel or different from the others, it will have less effect on the overall category when it is concentrated within a sub-category than when the same information is dispersed across different sub-categories. The present studies compare concentrated and dispersed sub-branding strategies and their effect on eco-friendly beliefs about the brand. Consistent with previous research, we predicted that the dispersed sub-branding strategy would have a greater impact on consumers' beliefs about the parent brand than the concentrated strategy.

We also predicted that these effects would be reinforced when differences between the sub-brands is high (versus low). Spillover from a brand extension to parent brand beliefs and attitudes (e.g., Lei, Dawar, and Lemmink 2008, John, Loken, and Joiner 1998, Loken and John 1993) has been previously documented. Based on prior research (Weber and Crocker, 1983) we expect that when a parent brand's architecture includes several sub-brands, eco-friendly products of the sub-brands should lead to greater eco-friendly beliefs for the parent brand when the products are dispersed across the different sub-brands than concentrated within a single sub-brand. Low self-monitors may be particularly attuned to differences between these strategies, whereas high self-monitors may be attuned more to other cues as well as strategies. Consumers high (low) in the trait of self-monitoring judge products by their image-enhancing properties more (less) than product performance (Snyder and DeBono 1985), and focus more (less) on behaving appropriately to the situation, they should be more receptive to any attempts by the company to develop an eco-friendly "green" image.

Hypothesis 1:   *When green products are dispersed across several sub-brands (vs. concentrated within one sub-brand), consumers will be more likely to infer that the parent brand is environmentally friendly.*

Hypothesis 2:   *Low (versus high) self-monitors will be more influenced by concentrated versus dispersed strategies.*

Hypothesis 3:   *When sub-brands are dissimilar (vs. similar) to one other, consumers will be more likely to infer that the parent brand is environmentally friendly.*

Method

Study 1 (N=244) was conducted online using MTurk. Participants were shown a catalog of a hypothetical brand of automobiles (CarMak) with four sub-brands (CarMak S, T, V, and R) and four products within each sub-brand. Photos and specifications (e.g., type, horsepower, seats) of all sixteen cars were provided, and eco-friendly CO_2 emission hybrids were indicated. Participants were randomly assigned to either a concentrated strategy (all green brands shown within a single sub-brand) or dispersed strategy (each sub-brand included one green brand). Participants then completed three 1-7 scales (subsequently averaged) about whether the parent brand, CarMak, is environmentally friendly, an 18-item Self-monitoring Scale (Snyder and Gangestad 1986), and participants overall concern for the environment, the latter of which was used in analyses as a covariate. In Study 1, participants were asked to answer questions from the perspective of the consumer.

Study 2 (N=164) used the same procedure as in Study 1, with two differences. First we also manipulated the variability of products by asking participants to write either three similarities or dissimilarities of the four sub-brands (i.e., sedans, trucks, minivans, and SUVs). Second, we did not specify that participants should take the perspective of the average consumer. The latter change was made in case results were affected by participants thinking about what other consumers (rather than themselves) might infer.

Findings

In Study 1, we found support for the first hypothesis. In particular, consumers were more likely to infer that the parent brand was environmentally friendly when the green products were dispersed across sub-brands rather than concentrated ($F(1, 236) = 16.70$, $p < .001$). Second, results supported the second hypothesis. We found a marginally significant interaction effect ($F(1, 236) = 3.14$, $p = .07$) between strategy and self-monitoring such that low self-monitors were more attuned to strategy differences than high self-monitors.

The results of study 2 supported the first hypothesis, replicating Study 1 ($F(1, 155) = 4.05$, $p < .05$). Second, in support of Hypothesis 3, participants were more likely to infer the parent brand was environmentally friendly when they were primed with dissimilarities between the sub-brands than when they were primed with similarities ($F(1, 155) = 13.03$, $p < .001$). Finally, we found a significant three-way interaction of strategy, variability, and self-monitoring. Interestingly, we found mixed support for the second hypothesis. Specifically, compared to high self-monitors, low self-monitors were less influenced by variability (similar vs. dissimilar) than by strategy (concentrated vs. dispersed; $F(1, 155) = 7.75$, $p < .01$).

Contributions

First, the current research provides insights about how to promote a brand's environmentally friendly image by using sub-branding strategies. In particular, dispersed strategies were superior to concentrated strategies. In addition, prior research in stereotyping and schematic processing was successfully applied to the study of green branding, an emerging topic in consumer research. Finally, it proposes a possible extension of self-monitoring to green branding. For example, marketers who are engaged in global branding might want to place different type of advertisement depending on the target consumer (e.g. the Asian culture may have chronically lower self-monitoring compared to Americans, Fuglestad and Snyder 2009).

Food Customization: How Decision Frame Influences Choice

Anish Nagpal, The University of Melbourne, Australia
Jing Lei, The University of Melbourne, Australia
Adwait Khare, The University of Texas Arlington, USA

EXTENDED ABSTRACT

Nowadays, restaurants and food outlets increasingly allow consumers to customize their food, which often involves either a selection or a rejection decision. For example, shop A might allow you to build a food platter by asking you to *choose* from a range of healthy (e.g., carrots, celery) and/or unhealthy (e.g., fried spring rolls, fries) options. Alternatively, shop B might offer a pre-prepared platter consisting of healthy/unhealthy options, but then asks you to customize it by *rejecting* the ones that you don't like. Although prior research has examined the effect of choose versus reject decision frames on the 'quantity' of items selected, (e.g., Dhar and Wertenbroch 2000; Huber, Neale, and Northcraft 1987; Park, Jun, and MacInnis 2000; Shafir 1993, Yaniv and Schul 1997), it has been surprisingly mute on the 'quality' of the choice. What we mean is that although a choose frame may appear to be the 'correct' frame to adopt because it leads to a smaller quantity of items as indicated by past research, it can lead to the false conclusion that a healthier choice has been made. In fact, the opposite might be true because the items selected might be unhealthy. Alternatively, the reject decision frame might appear to be inappropriate as it leads to a larger number of items, hence more calories, but the opposite might be true as the nature of items selected might be healthy.

We draw upon three theoretical frameworks to predict the impact of decision fame on food customisation decisions. First, hedonic attributes (e.g., taste) are weighted more under a reject decision whereas the utilitarian attributes (e.g., calories) are weighted more under a choose decision frame (Bohm and Pfister 1996; Dhar and Wertenbroch 2000). Second, the goal progress literature (Fishbach and Dhar 2005; Fishbach and Zhang 2008) suggests that upon seeing a healthy item, people may feel a sense of vicarious fulfilment that they have progressed towards the health goal, thus permitting them to indulge in unhealthy food (Martin 2007; Wilcox et al. 2009). Third, activation of the long-term health goal upon being exposed to temptations occurs more spontaneously than vice-versa (Fishbach, Friedman, and Kruglanski 2003). Across three studies, we show that the decision frames of choosing versus rejecting have important consequences for food customisation decisions.

In study 1, half of the participants were shown a randomised list of 5-healthy and 5-unhealthy items and asked to check the items they wanted to add to their customisable platter (choose decision frame). The other half were told that a pre-selected platter already included the 5-healthy and 5-unhealthy items, which could be removed by un-checking the items they did not want (reject decision frame). We found that a greater number of unhealthy versus healthy items were included when rejecting (3.82 vs. 3.21; $F(1, 37) = 5.29, p < .05$) but there was no difference in the number of unhealthy versus healthy items when choosing (2.24 vs. 2.68), $F(1, 37) = 1.16$, ns.

In study 1, healthy and unhealthy items were presented mixed together on one page. However, we often select from two separate lists. For example, when customising a sandwich, we may first select from a list of salads (healthy) and then move on to select meats and sauces (unhealthy). In study 2, half of the participants were first shown the healthy list followed by the unhealthy list and the order was reversed for the other half of the participants. Interestingly, we observed a significant Decision Frame x Item Type x Order three-way interaction on the number of items included in the food platter

($F(1, 246) = 4.65, p < .05$). Specific contrasts revealed that under the choose decision frame, although a greater number of healthy (versus unhealthy) items were included (2.90 vs. 2.10; $F(1, 127) = 35.16, p < .05$) under both UH-H and H-UH orders, this difference was marginally greater in the UH-H order than the H-UH order (1.02 vs. 0.58; $t(246) = 1.70; p < .1$). Under a reject decision frame, a greater number of healthy (versus unhealthy) items were included in the food platter (3.80 vs. 2.95; $t(121) = 6.13, p < .05$) in both UH-H and H-UH order. The key takeaway is that consumers should choose sequentially – unhealthy followed by healthy items.

In study 3, we varied the valence of the food platter (in studies 1 and 2, the food platter had a neutral valence) by asking participants to customise a salad (healthy valence) versus a pizza (unhealthy valence). Our results indicated that that a greater number of toppings were selected under rejecting than choosing when customising a salad (6.70 vs. 5.24; $F(1, 174) = 9.55, p < .001$), but not when customising a pizza (5.95 vs. 6.06, ns). Second, in terms of quality, a greater number of healthy (versus unhealthy) toppings were selected when choosing (3.14 vs. 2.42; $t(91) = 3.10, p < .05$), but not under rejecting (3.15 vs. 3.20, ns). Third, when customising a salad, both the decision frames of choosing and rejecting led to an equal number of healthy versus unhealthy toppings. However, when customising a pizza, a greater number of healthy (vs. unhealthy) items were included when choosing (3.50 vs. 2.45; $t(41) = 3.10$, p < .05), but not under rejecting (3.04 vs. 3.02 ($t(45) = .075$, ns).

Our research has several implications. First, it adds to the understanding of how decision frames of choosing versus rejecting influence consumer choices. We show that decision frames not only influence the quantity but more importantly, the quality of the decision. Second, our research suggests that by presenting food choices in the 'right' format (e.g., presenting unhealthy and healthy options separately in the order of unhealthy followed by healthy options), businesses in the food industry can aid the consumer in making healthier choices. Third, and most important, we suggest that consumers have an important role to play in the battle against rising obesity levels. By having the right frame of mind, they can certainly make healthier choices.

Social Support Style and Risky Behaviors in Everyday Life

Lili Wang, Zhejiang University, China
Tanya L. Chartrand, Duke University, USA
Linyun Yang, University of North Carolina, USA

EXTENDED ABSTRACT

The findings of four studies showed that the impact of receiving social support on risky behaviors depends on the style in which the support is provided. Encouraging social support inhibits risky behaviors while controlling social support triggers risky behaviors. We find that the negative relationship between encouraging social support and risky behaviors is moderated by relational concerns and mediated by increased support-based self-esteem. In contrast, the positive relationship between controlling social support and risky behaviors is moderated by independence concerns and mediated by support-triggered reactance.

SOCIAL SUPPORT STYLES

Those who receive encouraging social support are given the opportunity to set their own goals. Support providers serve an ancillary role and offer assistance and moral support when needed (Harber et al. 2005). Examples of encouraging support include encouraging independent problem solving (Grolnick and Ryan 1989), providing reassurance and comfort, and providing options for the recipient to choose from (Overall, et al. 2010). In contrast, controlling social support can be overbearing and intrusive and is characterized by attempts to impose solutions or views on recipients. These behaviors include interfering with the recipient's choices (Lewis and Rook 1999), dictating corrective actions (Cohen and Lichtenstein 1990) and determining how much effort recipients should exert (Taylor et al. 1985).

IMPLICATIONS FOR RISKY BEHAVIORS

From an interpersonal relationship perspective, research suggests that individuals respond positively to encouraging social support and are less likely to engage in risky behaviors (Davison et al. 2003; Reblin and Uchino 2008). From a self-control perspective, research suggests that encouraging social support can enhance self-regulation (Grolnick and Ryan 1989; Fizsimons and Shah 2008). Furthermore, cognitive neuroscience studies find that the brain areas associated with self-control are also tied to regulating risk-taking behaviors (Cohen and Lieberman 2010). Thus, we assume that:

Hypothesis 1: *Encouraging social support inhibits risky behaviors.*

However, Ryan et al. (1983) found that a controlling context or relationship can compromise emotional control (Ryan et al. 1983) and exacerbate problem behaviors in children. Similarly, Petti et al. (2001) found that increased parental control increases the likelihood that adolescents will engage in risky, delinquent and antisocial behavior. More direct evidence is that Landsford et al. (2003) found that children engage in more risky, maladaptive behaviors when their parents make all their decisions for them. Thus, we assume that:

Hypothesis 2: *Controlling social support induces risky behaviors.*

MODERATING ROLE OF RELATIONAL CONCERNS AND INDEPENDENT CONCERNS

Research has found that individuals with high relational concerns value their interpersonal relationships and put much effort into maintaining them (Cross et al. 2000; Swap and Rubin 1983). In contrast, individuals with high independence concerns are more concerned with maintaining their personal rights and autonomy (Cross et al. 2000).

According to our conceptualization, the extent to which support behaviors are helpful depends on the needs and desires of the recipient. Since the benefits of receiving encouraging social support involve enhancement of the relationship between the recipient and provider, recipients for whom personal relationships are important should respond most favorably to encouraging social support and be less likely to engage in risky behaviors. In contrast, the costs of controlling social support stem from diminished feelings of self-reliance and independence, so those who particularly value their autonomy should be especially likely to respond with increased risky behavior. We hypothesize that:

Hypothesis 2a: *Relational concerns strengthen the negative relationship between encouraging social support and risky behaviors.*

Hypothesis 2b: *Independent concerns intensify the positive relationship between controlling support style and risky behaviors.*

UNDERLYING PROCESSES

We propose that encouraging social support will bolster individual perceptions of self-esteem (Dubois et al. 1994; Short et al. 1996), resulting in enhanced self-control (Fitzsimons and Shah 2008; Dubois et al. 2002) and reduced maladaptive, risky behaviors (e.g., delinquency). Implicit bargain theory also provides support for this notion and suggests that people (particularly those high in self-esteem) are reluctant to approach desirable outcomes if doing so will compromise close relationships (Bartz and Lydon 2008; Baumeister et al. 2005; Baumeister and Stillman 2007). Therefore, we hypothesize that:

Hypothesis 3a: *Support-based self-esteem will mediate the effect of encouraging social support on risky behaviors.*

Research has found that when significant others are perceived as controlling or authoritative (Deci and Ryan, 2000), individuals might respond with "reactance" and do the exact opposite of what the significant others want them to do (Brehm and Brehm 1981). We propose that taking risky behaviors is one way to for individuals' to regain their freedom from those offering controlling social support. Given that people view potential gains (such as money) as a source of personal control (Johnson and Kruger 2006), we posit that increased reactance will increase the appeal of risky behaviors because the potential gains of such behaviors become more attractive. Taken together, we hypothesize that:

Hypothesis 3b: *Support-triggered reactance will mediate the effect of controlling social support on risky behaviors.*

EXPERIMENTS AND RESULTS

Using a survey method, study 1 found that while encouraging support inhibited risky behaviors, controlling support enhanced risky behaviors. In study 2, we replicated the findings in study 1 by directly manipulating encouraging and controlling social and measuring risky behaviors with self-report measures and real lab-based behaviors. Study 3 demonstrated that relational concerns strengthened the impact encouraging support had on risky behaviors while independence concerns enhanced the influence of controlling support on risky behaviors. In study 4, we explored possible reasons for the divergent effects of encouraging and controlling support. Results indicated that encouraging support enhances individuals' self-esteem, which in turn facilitate their behavioral adjustments and decrease likelihood they will engage in risky behaviors. In contrast, we found that controlling social support induces reactance in individuals, which in turn increases the likelihood they will engage in maladaptive, risky behaviors in attempt to regain their personal autonomy.

CONCLUSIONS

In sum, this research provides a more nuanced understanding of social support by demonstrating that the specific style in which social support is provided can have divergent effects on maladaptive, risky behaviors. We believe that our research extends the research on social support and interpersonal relationships and provides a new perspective for understanding risky behaviors.

Is Consumer Culture Good for Women?
A Study of the Role of Consumer Culture in Disadvantaged Women's Gender Role Negotiation

Zuzana Chytkova, University of Economics, Czech Republic
Dannie Kjeldgaard, University of Southern Denmark, Denmark

EXTENDED ABSTRACT

The category of gender, a "filter, through which individuals experience their social world" (Bristor and Fischer 1993) is recognized as an important aspect of consumer behavior. Yet, it has been noted elsewhere that it tends to be overlooked in the mainstream consumer research (Schroeder 2003). Particularly, we argue that there is not enough understanding of the role of consumer culture in women's gender negotiation and their emancipation from traditional gender roles, especially so in the case of minority, non-middle class, non-Western women (Catteral, McLaren and Stevens 2005). The lack of these women's viewpoint is increasingly significant, as consumer culture logic is spreading and becoming the dominant ideology in an ever larger part of the world. Furthermore, an increasing number of female immigrants from developing countries are integrated in first world households as they are engaged in paid care work and the ensuant consumption opportunities (however meager) oftentimes lead them to experience emancipation from home culture's traditional gender roles. These renegotiations of gender roles emerging from global cultural flows remain relatively unexplored and the study of this promises further conceptual development of the role and inter-relationship of gender and consumption within consumer culture.

LITERATURE REVIEW

With relation to gender, consumer culture has been traditionally seen by the second-wave feminists as an overpowering force that drives the perpetuation of patriarchy both in feminist and consumer research literature. It is often criticized for picturing women in stereotypical roles or as sexual subjects, creating unattainable beauty myths serving to keep women under patriarchal domination (Bordo 1993; Wolf 2002; Faludi 2006). Such critique, however, reproduces the dichotomy found by feminist deconstructions of marketing literature, i.e. the active, controlling, male marketer/creator and the passive, controlled, female consumer/desctructor (Hirshman 1991, Bristor and Fisher 1993). In this way, this view of market and gender thus reproduces this dichotomy by picturing women as passive consumers uncritically taking over the market representations of herself (Scott 2000, 2005).

Another view has been offered by postmodern feminism that draws inspiration from the liberatory postmodern view of consumption (Firat and Venkatesh 1995), suggesting that through consumption choices women in the postmodern era can escape the construction of femininity imposed upon them (Caterall, Maclaran and Stevens 2005). Critics of this stream, however, draw attention to the fact that such claims do not hold for non-white, non-middle class women not originated in Western countries (McDonald 2000, McRobbie 2000, 2004). Yet, the role of marketplace in these women's gender negotiation has not been explored. There is thus a need to address these issues and study the role of consumer culture in disadvantaged women's emancipation from traditional gender roles. However, the traditional emancipation theories are based on the notion of production: emancipation through participation in the workforce, while we concentrate on the role of consumer culture that favors consumption.

RESEARCH QUESTIONS

Our research question seeks to uncover if and under what circumstances can gender become a resource rather than constriction. In particular, we want to explore if the conditions of late modern consumer culture, precisely because of its accent on consumption rather than production, can act as a facilitator for these processes, offering it potential for disadvantaged women to perform alternative (to traditional) gender roles. In this paper, we investigate if and how exactly do these women use conceptions of gender as a resource on day-to-day basis, altering their gender roles through consumption practices.

METHOD

In order to answer the research questions, we have carried out interviews with fourteen Romanian female immigrants to Italy between June 2008 and February 2009. Two of the respondents were then interviewed again July 2011, which allowed to follow up on processes of gender negotiation individuated in the first round of data collection. Our respondents were 23 to 51 years old and had low-status jobs in Italy. The interviews were transcribed verbatim. Parts of our analysis that deal with the general accounts of gender roles in Romania and Italy concentrate on the interviews with all fourteen respondents, while the two specific informants' accounts are used where we treat the long-term effects of consumer culture on gender construction.

FINDINGS

The respondents have shown to be acculturated into traditional gender role centered on notions of self sacrifice, care and passive endurance of hardships. Such gender role is an evidence of a culture historically centered heavily around production. As Ceaucescu strived to level out the national debt, the whole country revolved around producing as much as possible and the ideal of a woman reflected this trend in that women were expected to sacrifice their own aspirations in order to produce and reproduce (to produce more labor force). Traditional gender roles were enforced without an alternative and gender in this setting thus represented a constriction in self definition.

Our respondents moved to a setting with advanced consumer culture, which is centered on consumption and which offers a different gender discourse, part of which is constructed in and by the marketplace. In the accounts of the informants we have individuated gender resources, some offered by consumer culture, that immigrant women use in their gender role negotiation. Namely, the (global) modern woman discourse found in the marketplace offered individualism, active self-help, free (consumption) choices and the focus on hedonistic and self-enhancement consumption.

Our informants made use of these resources in their gender role negotiation. For instance, for both Georgeta and Elisabeta, our long term respondents, hedonistic consumption has proved to be instrumental in the negotiation of their perception of themselves as women. This perception they had of themselves as women, or their gender, then became a resource in their everyday lives, enabling them to overcome the constrictions of the traditional gender role.

CONTRIBUTIONS

We show that different contexts are gendered in a different way, depending on their focus on either consumption or production. Contexts favoring production (such as those presented by communist regimes) do not offer alternative resources for women to draw on

in their gender negotiation and gender thus becomes a constriction. Consumer culture, on the other hand, with its focus on consumption (constructed as feminine), allows for more gender negotiation space.

We argue that the second wave feminist critique of consumer culture reproduces the same dichotomy it criticizes, i.e. the active producer/passive consumer. Furthermore, the criticism of certain aspects of consumer culture, such as hedonistic consumption, can be seen as instantiation of Western thought, in which what is on the surface is superficial.

Brand Perception: Influence of Gender Cues on Dimensions of Warmth and Competence

Alexandra Hess, the University of Waikato, New Zealand
Valentyna Melnyk, the University of Waikato, New Zealand
Carolyn Costley, the University of Waikato, New Zealand

EXTENDED ABSTRACT

Today's challenge for advertisers is to increase positive brand perception and influence consumers with increasingly low attention spans. Advertisers must find ways to convey the right brand image in a short time and with the restricted mental resources of the consumer. One potential solution is to utilize stereotypes because people activate stereotypes in less than milliseconds, almost automatically (Bargh 1997). Hence, activating stereotype knowledge may influence desired brand perceptions automatically and effectively.

Most stereotypes fall between two robust fundamental dimensions: warmth and competence (Fiske, Cuddy, Glick, and Xu 2002; Fiske et al. 2007). Aaker, Vohs and Mogilner (2010) examined these dimensions and found that people perceive non-profit organizations as warmer than for-profit, but as less competent. Furthermore, perceived competence, rather than warmth influences purchasing behavior.

Aaker et al.'s (2010) research shows that the warmth and competence dimensions influence marketplace decision making. Our study therefore aims to find ways to increase warmth/competence of a brand via subtle cues. Towards this we investigate whether utilizing gender stereotypes in the product description influences the warmth/competence perception of a brand. Further, we investigate how the perception of warmth/competence influences purchasing behavior depending on a product's gender (Fugate and Phillips, 2010). Specifically, we seek conditions where warmth influences purchasing behavior.

THEORETICAL BACKGROUND

The stereotypical woman is viewed as warm, whereas men as competent (Eagly and Mladinic 1994; Eagly, Mladinic, and Otto 1994). What's more, we activate gender stereotypical knowledge on the basis of cues associated to gender stereotypes (e.g. occupation, physical appearance etc.; Banaji and Hardin 1996; Deaux and Lewis 1984). Consequently, those cues could take the form of colors and symbols which are associated with a gender (Fagot, et al. 1997; Leinbach, Hort, and Fagot 1997) and which we believe are triggers for activating gender stereotype knowledge. Therefore, we assume that gender cues incorporated with product descriptions influence brand perceptions along the warmth and competence dimensions. In addition, consumers automatically assign a gender to most products (e.g. hair spray is feminine whereas coffee is masculine; Fugate and Phillips 2010). Hence, in our first study, we estimate the effect of (in)congruence between the perceived gender of the product category and the gender of the subtle cues in the product's description on the product's purchase likelihood.

METHODOLOGY

We first test the effect of gender primes on purchasing intention for masculine versus feminine typed products. Second, we investigate the role of warmth and competence as the mediator for gender prime and purchasing likelihood.

In an online experiment, 204 participants (110 female) were randomly assigned to one of the six conditions of the 2 (masculine vs. feminine product) x 3 (masculine vs. feminine vs. no prime) between-subjects design throughout 3 different product categories within-subject. The gender typed products were chosen on the basis

of a pre-test. The gender primes were symbols and colors which are previously identified as male-typed or as female-typed (Fagot et al. 1997; Leinbach et al. 1997).

Participants evaluated advertisements via seven 7-point scales: purchasing likelihood as well as warmth, kindness, and generosity which comprises the warmth index (Cronbach's α = .85) and competence, effectiveness and efficiency which comprises the competence index (Cronbach's α = .90; Aaker et al. 2010; Grandey et al., 2005; Judd et al., 2005).

We conducted a 2 (masculine vs. feminine product) x 2 (masculine vs. feminine prime) between-subjects ANOVA with purchase likelihood as the dependent variable throughout all product categories. The main effects of product gender and gender prime were insignificant (both ps > .10). However, we found a significant positive interaction effect between product gender and gender prime ($F(1,407)$ = 5.513, p < .02), suggesting that gender primes moderate the effect of gender typed products (see figure 1).

Figure 1
Purchasing Likelihood of Gender Typed Products, Primed with Feminine Cues, Masculine Cues or No Prime
The follow-up planned comparisons reveal for the masculine products that feminine primes lead to a higher purchase likelihood than masculine primes ($t(605)$ = 2.326, p = .02). For the feminine products, masculine primes were not significantly higher compared to feminine primes ($t(605)$ = -1.041, p > .05). Thus, the results indicate that feminine primes increase purchase likelihood significantly when combined with a masculine product.

To test the role of perceived warmth and competence of a brand we conducted two separate mediation analyses between gender primes and purchasing likelihood (Zhao, Lynch Jr., and Chen 2010). The result indicates that warmth mediates the effect of gender primes on purchase likelihood. Namely, the indirect effect from the conducted bootstrap analysis is negative and significant (a x b = -.1415), with a 95% confidence interval excluding zero (-0.2819 to -0.0104). In the indirect path, the masculine prime decreases warmth by a = -0.2499, and holding constant the prime, each unit increase in warmth increases purchasing likelihood by b = 0.5663. We conducted the same anal-

ysis with competence as the mediator and found it to be insignificant with a 95% confidence interval including zero (-0.2549 to 0.0285). Therefore, the results suggest that feminine primes enhance purchase likelihood via increased warmth of the product. Interestingly, we do not find the same effect for masculine primes.

To understand the underlying process of warmth and competence more thoroughly, we are currently conducting further studies, where we manipulate the baseline (warmth/competence) of a brand as well as gender cues.

DISCUSSION AND IMPLICATIONS

Our results indicate that feminine primes enhance perceived warmth which increases purchase likelihood for masculine products. Interestingly, perceived warmth serves as a mediator between prime and purchasing likelihood, yet competence does not.

With our study we directly address Aaker et al.´s (2010) call to investigate conditions under which perceived warmth drives purchasing likelihood. Further, we demonstrate that feminine symbols and colors can trigger feminine gender stereotype knowledge which can be utilized to influence brand perception and consumer behavior.

From a practical viewpoint, our results provide important implications for companies and their marketplace decisions. Thus, companies that sell masculine products are able to utilize female advertising cues to increase their brands perception of warmth, which in turn, translates to a higher purchasing likelihood.

Self-Control Spillover:
Impulse Inhibition Facilitates Simultaneous Self-Control in Unrelated Domains

Mirjam A. Tuk, Imperial College Business School, UK, INSEAD, France
Kuangjie Zhang, INSEAD, France
Steven Sweldens, INSEAD, France

EXTENDED ABSTRACT

Imagine participating in an important meeting. Despite the fact that the meeting already took for hours, there is still a list of decisions to be made. Keeping your attention focused on the discussion requires a significant amount of self-control. Notably, there is a bowl filled with chocolates on the table. How likely would you be to overindulge on the chocolates during this meeting?

One of the most influential theories of self-control predicts overindulgence on the chocolates. According to the strength model (Baumeister 2002), human ability to exert self-control relies on a limited energy resource. Consequently, each act of self-control (e.g., controlling attention) temporarily depletes this resource, resulting in a deteriorated performance on subsequent self-control tasks (e.g., resisting chocolates), termed an 'ego depletion effect'.

Recent findings in (neuro)psychology suggest an alternative outcome. This research suggests that various forms of response inhibition which seem very different on the surface, all originate from the same neurological areas, also referred to as a general inhibitory network (Cohen and Lieberman 2010). Importantly, Berkman, Burklund and Lieberman (2009) show that a consequence of such a general inhibitory network is that inhibitory signals are not completely task specific, but can spill over to unrelated domains and result in unintentional inhibition of unrelated responses, termed an 'inhibitory spillover effect'. Tuk, Trampe and Warlop (2011) show that a physiological form of inhibition (bladder control), can result in more impulse control in the behavioural domain (intertemporal patience). These findings suggest that intentional acts of self-control (of which response inhibition is a crucial property) could actually *facilitate* self-control in unrelated domains.

In the current research, we argue that a crucial determinant for whether one act of self-control deteriorates (ego depletion) or facilitates (inhibitory spillover) self-control ability on unrelated tasks is the timing of the control tasks. Inhibitory signals required for one task are only present *during* execution of this task, and should only facilitate self-control performance on *simultaneously* executed tasks. Conversely, when the self-control tasks are sequential to each other, we expect the ego depletion effect to occur, consistent with a large body of research supporting the strength model (see Hagger et al. 2010, for a meta-analysis). In the first four studies, we test the inhibitory spillover effect in simultaneous self-control tasks, using tasks that are well-known to be susceptible to ego depletion effects when sequentially administered. In a fifth study, we directly manipulate the sequential versus simultaneous nature of the self-control tasks.

STUDY 1

In study 1, participants engaged in a thought listing task. Only participants in the inhibition condition were instructed not to think of a white bear during this task (Vohs and Faber 2007). This was followed by an intertemporal choice task (Li 2008), in which respondents made eight choices between a smaller, but sooner (SS) and a larger but later (LL) reward. Crucially, respondents in the inhibition condition were instructed to *continue* not to think of a white bear during this task. In line with the inhibitory spillover hypothesis, respondents made less impulsive choices in the inhibition condition.

STUDY 2

In study 2, participants engaged in an attention regulation task while watching a movie of an interview. On the bottom of the screen, a series of words appeared. Only participants in the inhibition condition were instructed to ignore these words and focus on the interviewee. Simultaneously, participants received a bowl of crisps to consume *during* the movie. In line with our hypothesis, participants in the inhibition condition consumed less of the crisps.

STUDY 3

In study 3, food consumption formed our self-control manipulation. Respondents engaged in a taste test, and were instructed to consume one crisp from a bowl of crisps. This was followed by the Stroop task. Only participants in the inhibition condition were explicitly instructed to resist further crisp consumption during the Stroop task. Results showed that participants in the inhibition condition made fewer errors on the self-control requiring (incongruent) trials of the Stroop task.

STUDY 4

In order to provide stronger evidence for the inhibitory spillover hypothesis, we examined whether the inhibitory spillover effect is moderated by an interpersonal difference in sensitivity of the Behavioral Inhibition System (BIS; Carver and White 1994; Tuk et al. 2011). In study 4, respondents engaged in the same thought suppression task as in study 1, and continued with this thought suppression during the next task. This was a short self-control scenario (Labroo and Patrick 2009), measuring whether respondents opt for an impulsive or self-controlled option. Results showed that participants in the inhibition condition had a greater preference for the self-controlled option, especially when they have a sensitive BIS.

STUDY 5

In study 5, we manipulated the simultaneity of the self-control tasks. Participants in the inhibition condition were instructed not to feel/express emotions during an emotional movie clip, whereas participants in the control condition could watch this movie freely. In the simultaneous condition, respondents received a bowl of crisps together with this first clip. In the sequential condition, respondents continued with a second movie (where they could feel/express their emotions freely) and received the crisps during this second clip. In line with our predictions, inhibition of emotions resulted in decreased food consumption in the simultaneous condition (inhibitory spillover), but resulted in increased food consumption in the sequential condition (ego depletion), relative to the control conditions. Hence, study 5 provides strong evidence for the crucial role of timing of the control tasks for inhibitory spillover versus ego depletion to occur.

CONCLUSIONS

In five studies, we used a variety of the most well-known paradigms from the ego-depletion literature, but changed the timing of the self-control tasks such that they occurred simultaneously. Consistent with the inhibitory spillover hypothesis we found a self-control boost for simultaneously occurring tasks. Our results suggest that deliberative acts of self-control can facilitate self-control ability on un-

related tasks, when both tasks occur together. These findings provide support for the existence of an inhibitory network, susceptible to inhibitory spillover, and suggest that the predictions of the strength model cannot easily be translated to simultaneous control tasks.

Exploration vs. Exploitation Mindsets in Consumer Search

Valerie Trifts, Dalhousie University, Canada
Gerald Häubl, University of Alberta, Canada

EXTENDED ABSTRACT

Much attention has been devoted to the importance of mind-sets in consumer decision making. A mindset is characterized by the persistence of cognitive processes and judgmental criteria activated in the course of performing a task that generalize to other situations (Xu and Wyer 2007). Much research builds on work by Gollwitzer, Heckhausen, and Steller (1990), examining the influence of deliberative versus implemental mindsets in areas such as sales promotions (Cheema and Patrick 2008), consumer expectations regarding the demands of future tasks (Bosmans, Pieters, Baumgartner 2009), and shopping momentum (Dhar, Huber, and Khan 2007). More recent research has focused on the impact of construal-level (i.e., high-level abstract versus low-level concrete mindsets) to explain various phenomena – e.g., purchase intentions (Goldsmith, Xu, and Dhar 2010), perceived truthfulness of ad claims (Wright et al. 2012), and consumer recycling behavior (White, MacDonnell, and Dahl 2012).

Yet, the role of mindsets in the domain of consumer *product search* is not well understood. The present work introduces and tests the hypothesis that providing initial exposure to multiple products, as opposed to as single product, inhibits consumer search for additional alternatives and results in stronger preference for initially presented products. While some recent work on comparative mindsets (e.g., Xu and Wyer 2007; 2008) has provided insights into how making initial comparative judgments evokes a "which to buy" mindset in subsequent choice tasks, this paper examines how a comparative context can induce an *exploitative mindset*, which renders consumers more likely to search fewer products when making purchase decisions.

Hills, Todd, and Goldstone (2008; 2010) argue that problem solving is often characterized as a search process, involving a trade-off between exploiting old solutions and exploring new ones. They found that exploitation- and exploration-inducing spatial-foraging tasks can prime corresponding exploitation and exploration strategies during subsequent abstract search tasks. In the context of consumer search, we propose that initially presenting consumers with multiple products (vs. only a single product) activates an exploitation (vs. exploration) mindset. Compared to an exploration mindset, an exploitation mindset drastically reduces the number of products that consumers choose to discover through search. Thus, we hypothesize that consumers consider fewer products overall if they initially see two products rather than one, and this in turn increases the probability of a given initially presented alternative to be chosen eventually.

These hypotheses were tested in two computer-based experiments. Study 1 examined the effect of viewing one versus two initial alternative(s) on subsequent search and preference. Participants from an online panel were initially shown either one or two products, described as typical examples randomly selected from a product database. They were then asked to search as many additional products as they wished prior to making choices, across four randomly ordered product categories. Only 55% percent of participants who initially viewed two products engaged in further search, compared to 97% of those who initially viewed one product (85% searched at least two additional products). Poisson regression revealed that, across the four product searches, participants who initially viewed two products searched fewer alternatives (including those initially presented) (M_{view1} = 7.77 vs. M_{view2} = 4.85; Wald = 5.45, p < .05), and spent less time searching (M_{view1} = 106.41 sec. vs. M_{view2} = 82.36 sec.; Wald= 6.21, p < .05) than those who initially viewed only one prod-uct. Separate Poisson regression analyses for each product category support these effects. Participants who initially viewed two products were also significantly less likely to choose one of the subsequently searched alternatives than those who initially viewed only a single product (see Appendix A for detailed results).

In Study 2, a spatial-foraging task (see Hills, Todd, and Goldstone 2008; 2010) was used to more directly test the mindset account of the results from Study 1. Participants from an online panel were randomly assigned to one of six conditions in a 3 (priming task: exploration vs. exploitation vs. no prime) x 2 (number of products presented initially: 1 vs. 2) full-factorial experimental design. Participants in the prime conditions first completed five 2-minute tasks where their objective was to uncover as many of the 580 red dots in a search space consisting of 5,625 squares by moving the cursor throughout the search space. After that, they completed a product search and choice task for a coffee maker. In the exploitation conditions, the red dots were clustered into 4 diamond shapes, whereas in the exploration conditions, they were diffused randomly in the search space (see Appendix B). Participants were shown the time remaining for each search task and the number of red dots they had uncovered, and a monetary incentive based on the number of red dots found was used to make the priming task consequential.

Manipulation check measures for the mindset prime showed that this manipulation was effective. As expected, participants in the exploitation prime condition found more red dots and, critically, navigated the space in more locally concentrated manner, than those in the exploration prime condition (see Appendix B for details). Results for the no prime condition replicate those of Study 1 for all dependent measures (see Appendix C for details). Poisson regression analysis reveals that participants in the exploration mindset searched significantly more products (including the initially viewed ones) than those in the exploitation mindset ($M_{explore}$ = 6.26 vs. $M_{exploit}$ = 4.16; Wald = 9.52, p < .01). Comparison of the control condition to the exploration condition reveals a significant interaction between the priming task and the number of initially presented products for both the number of products searched (Wald = 9.57, p < .01) and the amount of time spent searching (Wald = 6.39, p < 0.05). Moreover, participants in the exploration mindset condition were significantly less likely to choose the first product listed than participants in the exploitation mindset.

Taken together, the results of Studies 1 and 2 suggest that initially presenting consumers with multiple products activates an exploitation mindset, resulting in a drastic reduction in additional search. In turn, this effect on the total number of alternatives inspected influences which product is ultimately chosen.

For Fun or Profit: How Shopping Orientation Influences the Effectiveness of Monetary and Nonmonetary Promotions

Oliver B. Büttner, University of Vienna, Austria
Arnd Florack, University of Vienna, Austria
Anja S. Göritz, University of Freiburg, Germany

EXTENDED ABSTRACT

Different types of promotions have different pros and cons. Monetary promotions (e.g., discounts) can be very effective in producing short-term effects on sales (Alvarez-Alvarez and Vázquez-Casielles 2005), but have negative effects on price sensitivity and brand equity (Yi and Yoo 2011). Nonmonetary promotions (such as sweepstakes or free gifts) do not show these negative effects, but their influence on attractiveness of the offer and marketing share is often lower than that of monetary promotions (Alvarez-Alvarez and Vázquez-Casielles 2005). Thus, to effectively use promotions as a tool, marketers and retailers need to know when and how which type of promotion is the most effective.

The present research examines whether consumer shopping orientation influences how consumers react towards monetary and nonmonetary promotions. In line with research on fit and congruency effects (Chernev 2004; Lee and Higgins 2009), we posit that promotions are more effective when the promotional benefits match a consumer's motivational orientation. Consumers' shopping orientation can be narrowed down to two fundamental motivational orientations: a task-focused and an experiential shopping orientation (Kaltcheva and Weitz 2006). According to the benefit-congruency model of sales promotion effectiveness, monetary and nonmonetary promotions differ in the benefits they provide (Chandon, Wansink, and Laurent 2000). Nonmonetary promotions provide primarily hedonic benefits. This should meet experiential shoppers goals for hedonic stimulation during shopping. Task-focused shoppers should be insensitive to these hedonic benefits, because they focus on efficiency during shopping. Monetary promotions provide primarily utilitarian benefits. This should meet the goals of task-focused shoppers, who focus on maximizing utilitarian shopping value. In addition, experiential shoppers may experience hedonic benefits in terms of pleasure when hunting for price promotions.

Thus, nonmonetary promotions are congruent only with the goals of experiential shoppers, but not with the goals of task-focused shoppers. By contrast, monetary promotions are congruent with the goals of both task-focused and experiential shoppers. This implies that nonmonetary promotions are more attractive to experiential shoppers than to task-focused shoppers. Furthermore, this difference should be less pronounced for monetary promotions.

We examined these hypotheses in two experiments. Study 1 ($N = 217$) applied a 2 x 2 mixed design. Promotion type (monetary vs. nonmonetary) was a within-subject factor. Shopping orientation (task-focused vs. experiential) was a continuous between-subject predictor and was measured using eight items (Reynolds and Beatty 1999). Participants evaluated a number of monetary and nonmonetary promotions for fast moving consumer goods from existing national brands. The results supported the hypotheses. The more experiential a consumer's shopping orientation, the more positive was the evaluation of promotions. This positive relationship was more pronounced for nonmonetary than for monetary promotions.

Thus, Study 1 found that shopping orientation influences how consumers evaluate promotions, and that this influence is moderated by promotion type. Study 2 sought to extend this finding in a number of ways. First, Study 2 examined whether the different reactions to promotions transfer on the retailers offering nonmonetary or mone-

tary promotions. Second, the study included a control condition with a retailer offering no promotions. Third, Study 2 experimentally manipulated shopping orientation, whereas study 1 measured consumers' chronic shopping orientation. Finally, Study 2 used a different and more hedonic product category (entertainment DVD) than study 1 (FMCG).

Study 2 applied a 2 x 3 mixed design ($N = 120$). Shopping orientation (task-focused vs. experiential shopping orientation) was a between subject factor and was manipulated by a scenario (Kaltcheva and Weitz 2006). Promotional strategy (monetary vs. nonmonetary vs. no promotion) was a within-subject factor: Each participant read descriptions of three stores with a DVD department that differed in their promotional strategy. For each store, participants indicated the store attractiveness on three items. The results supported the hypotheses. The store with the nonmonetary promotions was evaluated as more attractive by experiential than by task-focused shoppers. For the store with the monetary promotions, the store evaluation did not differ between the experiential and the task-focused shoppers. Finally, the store evaluation of the store offering no promotions received the lowest attractiveness ratings and these ratings did not differ between experiential and task-focused shoppers.

In sum, the present research supports the assumption that promotions are more effective when they support a consumer in pursuing his or her goals during shopping. Across two experiments, we found that shopping goals as reflected in consumer shopping orientation influenced evaluations of promotions and evaluations of retailers offering promotions. Nonmonetary promotions were more attractive for experiential shoppers than for task-focused shoppers. This influence of shopping orientation was moderated by promotion type: The differences in the attractiveness of promotions between task-focused and experiential shoppers were more pronounced for nonmonetary than for monetary promotions.

The present research extends the benefit congruency framework of sales promotion effectiveness (Chandon et al. 2000) in two ways. First, Chandon et al. (2000) found a congruency effect between promotion type and product type (hedonic vs. utilitarian). We found that there are also positive consequences of a congruency between promotion type and shopping orientation. Second, Chandon et al. (2000) examined the influence of the congruency effect on the market share of brands. We demonstrated that the positive effect of congruency also transfers to the evaluation of a retailer that adopts a monetary versus a nonmonetary promotion strategy. The latter finding suggests that the decision of whether to use monetary or nonmonetary promotions also has consequences for a retailer's image and for consumers' patronage intentions.

The results have also implications for the design of promotions. The results imply that retail and marketing managers can enhance the effectiveness of promotions by customizing promotion type to customers' shopping orientation. Task-focused shoppers should be given monetary promotions because these promotions are more successful with this type of shopper. Experiential shoppers should be given nonmonetary promotions: They react favorably to both nonmonetary and monetary promotions, and nonmonetary promotions do not bring the dangers of lowering expectations regarding prices and increasing price sensitivity. Such an approach offers a trade-off

between the positive effects of promotions (increased sales) and the negative effects of promotions (increased price sensitivity from monetary promotions).

This Number Just Feels Right:
The Impact of Roundness of Numbers on Reliance on Feelings versus Cognition

Monica Wadhwa, INSEAD, France
Kuangjie Zhang, INSEAD, France

EXTENDED ABSTRACT

Consider two consumers who are on the market to buy a camera for an upcoming family vacation. While one of them comes across a camera priced at $200.00, the other comes across the same camera at another store, but priced at $198.76. Given that the camera has all the features required by these two consumers, how would the mere roundedness of the price number impact their preference for the camera? Further, could the price number (200 vs. 198.76) impact the consumers' preference for the camera differently if they were buying it for a class project (a purchase decision that is primarily driven by cognition) instead of a family vacation (a purchase decision that is primarily driven by feelings)? In the current research, we examine the impact of the roundedness of the numbers on consumers' decision making, given the basis of the purchase decision—that is whether the purchase decision is driven by feelings or cognition.

Emerging research on number cognition suggests that rounded numbers are easier to process and therefore are more fluent as compared to non-rounded numbers (McClure 2011). Further, research on fluency and dual processing theories suggest that targets that are fluently processed lead one to rely more on feeling-based inputs while making evaluative judgments, whereas targets that are not fluently processed lead one to rely more on cognitive inputs while evaluating the target (Alter et al. 2007). Drawing upon these perspectives, we hypothesize that rounded prices are likely to facilitate the use of feelings and thereby lead to more favorable product evaluations when the purchase decision is based on feelings. However, non-rounded prices are likely to facilitate the use of cognition and thereby lead to more favorable product evaluations when the purchase decision is based on cognition.

We tested the aforementioned rounded number hypotheses in a series of five studies. Study-1 examined the main hypothesis related to the rounded-number effect. In this study, participants were asked to indicate their purchase intentions for either a bottle of champagne for a friend's birthday (purchase decision based on feelings) or a calculator (purchase decision based on cognition), which was priced at either a rounded number ($40.00) or a non-rounded number ($39.72 or $40.29). Consistent with our hypotheses, rounded price ($40.00) led to enhanced purchase intentions for the champagne compared with either of the two non-rounded prices ($39.72 or $40.29). In contrast, both the non-rounded prices ($39.72 and $40.29) led to enhanced purchase intention for the calculator compared with the rounded price ($40.00)

In Study-2, keeping the product constant, we manipulated the consumption goal the product was stated to achieve. Specifically, participants were asked to imagine buying a camera for a family vacation (hedonic-consumption goal) or for a photography class (utilitarian-consumption goal), with the price tag randomly displayed at either a rounded number ($200.00) or a non-rounded number ($203.96). To make the camera evaluation procedure more realistic, two sample pictures purportedly taken from the camera were presented. Participants first evaluated the sample pictures and then reported their anticipated satisfaction with the camera. A significant price by consumption goal interaction emerged. When buying a camera for a family vacation, rounded price (vs. non-rounded price) led to greater anticipated satisfaction with the camera. In contrast, when buying a camera for a photography class, non-rounded price

(vs. rounded price) led to greater anticipated satisfaction with the camera. The same pattern of results was observed on perceived quality of the sample pictures.

In Study-3, we examine the impact of rounded versus non-rounded prices on product choices. Further, we provide support for our underlying conceptualization by examining the role of one's reliance on feelings versus cognition in mediating participants' product choices. All participants first engaged in a shopping survey and were then informed that they could choose one out of the two equally priced displayed food items as a free gift. The choice set consisted of a food item relatively superior on affective dimension (a chocolate bar) and a food item relatively superior on cognitive dimension (a cereal bar). Both the items were displayed with the same price tag, which was either a rounded-number ($2.00) or a non-rounded number ($1.83). Subsequently participants indicated the basis of their choice on three nine-point items that were presented after the following statement—"My decision about which food option to choose was driven by." These items were anchored by "My thoughts (1)/My feelings (9)", "My prudent self (1)/My impulsive self (9)", and "My calculative judgment (1)/My affective judgment (9)" (adapted from Shiv and Fedorikhin 1999). Responses to these three items were averaged to form a single variable-"decision basis". Our findings show that consumers were more likely to choose the chocolate bar when the food items were displayed at a rounded (vs. non-rounded) price. More importantly, this rounded-number effect was mediated by participants' decision basis. Specifically, rounded (vs. non-rounded) price enhanced participants' reliance on feelings (vs. cognition), and thereby led to greater preference for the chocolate bar over the cereal bar.

In Study-4, we provide stronger support for our reliance on feelings versus cognition conceptualization by examining the role of cognitive resources in moderating the rounded number effects. Prior research suggests that when the processing resources are constrained, relative reliance on feeling-based inputs is enhanced (Greifeneder, Bless and Pham 2010). Drawing upon this research, we argue that rounded prices should lead to more favorable product evaluations when processing resources are constrained. On the other hand, when the processing resources are available, relative reliance on cognitive inputs should be enhanced and thus non-rounded prices should lead to more favorable product evaluations. Participants evaluated a digital camera-binocular either priced at a rounded number ($80.00) or a non-rounded number ($81.43). However, prior to the evaluation task, we manipulated the availability of cognitive resources by asking participants to memorize either a string of seven English letters (high cognitive load) or one English letter (low cognitive load). Our results revealed a significant interaction between price and cognitive load. Specifically, participants in the high (low) cognitive load condition indicated higher purchase intention with the product when it was priced at a rounded (non-rounded) number.

Finally, Study-5 sought to provide further support for our conceptualization by directly manipulating one's reliance on feelings versus cognition before product evaluation. Participants evaluated a digital camera-binocular either priced at a rounded number ($80.00) or a non-rounded number ($81.43). However, prior to the evaluation task, participants were either primed to rely on feelings or cognition (adapted from Hsee and Rottenstreich 2004). Our results revealed

a significant price by priming interaction. Specifically, those in the feeling-prime (cognition-prime) condition indicated higher purchase intention and anticipated satisfaction with the product when it was priced at a rounded number (non-rounded number).

Together, these results suggest that rounded number (non-rounded) prices enhance consumer product evaluations when the purchase decision is based on feelings (cognition), and these effects are moderated by consumers' reliance on feelings versus cognition.

Easy Like a Sunday Morning:
How The Fluency of Analogies Affects Innovation Liking

Antonia Erz, Copenhagen Business School, Denmark
Bo T. Christensen, Copenhagen Business School, Denmark
Torsten Tomczak, University of St. Gallen, Switzerland

EXTENDED ABSTRACT

In the search of successful communication strategies for innovations, authors have identified analogies (Feiereisen, Wong, and Broderick 2008). An analogy compares the novel with the familiar and helps people to utilize pre-existing knowledge to understand the unfamiliar (Gregan-Paxton and Roedder John 1997). The optimal analogy was suggested to allow the consumer to map existing knowledge from a base (e.g., diary) to a target analog (e.g., tablet-PC) to understand the key benefits of an innovation (Hoeffler 2003).

However, people may be rarely able to match each correspondence between a base and a target (Day and Gentner 2007). Instead they may also draw information from how fluent they can process the analogy and interpret these meta-cognitive experiences (Schwarz 2004) in the light of the consumption context (Pocheptsova, Labroo, and Dhar 2010).

In an online-experiment with 503 German consumers, we investigated 1) the processing fluency of analogies, and 2) its effect on innovation liking and purchase intention, testing the usual fluency-liking link and its reversal.

Findings from analogy research indicate a good and sound–and therefore fluent–analogical match as based on relational similarities as well as surface similarities (Gentner and Markman 1995). We therefore hypothesize that *participants will judge an analogy as being more fluent when the base and the target are perceived as similar* (H_1).

In a second step, we aimed at investigating the phenomenon of naïve beliefs which determine how individuals interpret their meta-cognitive experiences. Research found that stimuli which are processed fluently are perceived as familiar and elicit a positive affect in contrast to disfluently processed stimuli (Schwarz 2004). However, think of yourself at the rollercoaster park. Do you go for the well-known and slightly boring or the latest and most exciting ones? Are you better 'safe than sorry' or is your motto 'no risk, no fun'? Authors found that, dependent on the consumption context which may activate a specific naïve belief, consumers prefer a disfluent stimulus, if the disfluent experience is, for example, attributed to adventure (Song and Schwarz 2009), product exclusivity (Pocheptsova et al. 2010) or quality (Galak and Nelson 2010). A similar effect may be true when consumers make decisions about innovative products based on marketing information. On the one hand, they may prefer fluency and like the product better if no additional information is given about the innovative degree of the product, relying on the common naïve belief 'If it is familiar, it must be good.' On the other hand, when an advert clearly indicates the product as an innovation, individuals might prefer disfluency, attributing the feeling of novelty to the innovative degree of the product. We therefore hypothesize that *participants will show increased innovation liking when the analogy is fluent (vs. disfluent)* (H_{2a}). However, *if the advert clearly indicates the product as an innovation, participants will show increased innovation liking when the analogy is disfluent (vs. fluent)* (H_{2b}). The same hypotheses were formulated for purchase intention (H_{3a-b}).

In an online-experiment with a 2 (analogy: similar vs. dissimilar) × 2 (innovativeness claim: without vs. with) between-subjects design, 503 German consumers, consisting of 44.5 % females between 19 and 40 years, were randomly assigned to one of the advertisements and asked to fill in the questionnaire.

A tablet-PC and all-in-one media player device were chosen based on a round of experts (n = 10). Two analogical bases for each product were selected, one similar, containing relational as well as surface similarities (tablet-PC: diary; player: DVD-player), and one dissimilar, containing only relational similarities (tablet-PC: storage room; player: distribution room). An advert with a picture and a one-sentence copy text used the analogy (e.g., "like a diary") as a claim. To manipulate the indication as an innovation, we chose a realistic setting by using the word "innovative" in the copy text ("innovativeness claim"). The manipulation of analogy similarity was deemed successful across conditions ($ps < .05$).

Fluency was measured on a two-item scale. The scale for innovation liking was adapted from Boyd and Mason (1999), and purchase intention was measured by one item.

To test the hypotheses, several 2 (Analogy) × 2 (Innovativeness Claim) ANOVAs were performed followed by planned contrasts.

For fluency, there was a significant main effect of the type of analogy ($F(1, 499) = 27.8, p < .001$) but no effect of innovativeness claim or a significant interaction effect. Results of planned contrasts for the single products revealed that the dissimilar analogy was perceived as more disfluent across conditions and products ($ps < .05$). H_1 could be supported.

For innovation liking, a significant interaction across products was found ($F(1,499) = 4.38, p < .05$). A series of planned contrasts revealed that H_{2a} and H_{3a} could only be supported for the Tablet PC but not for the Media Player.

A significant interaction was also found for purchase intention ($F(1,499) = 5.06, p < .05$). Performing a series of planned contrasts, H_{2b} and H_{3b} could again only be supported for the Tablet-PC but not for the Media Player.

Our study supports the idea that analogies have an effect beyond the content they convey, and, at the same time, adds to the consistency of findings in fluency research. Furthermore, the partial reversion of the fluency effect by using a relatively realistic manipulation contributes to its current theoretical discussion (Galak and Nelson 2010). It further illustrates an important practical insight: explicitly claiming that a product is innovative might interfere with other parts of an advertisement.

We aimed at a somewhat realistic setting by testing true innovations, which had several drawbacks: The selection of stimuli was limited, and confounding variables, such as the visual complexity of the products, may have caused the inconsistent results in reversing the fluency effect. A replication in a more controlled setting with a stronger manipulation in indicating the consumption context and activating a naïve belief will help to produce more consistent results and define a mediating variable for a more profound explanation of the reversal.

The Impact of Flow on Memory and Attitudes For In-Game Brand Placements: The Moderating Role of Brand Congruence and Placement Prominence

Iris Vermeir, University College Ghent and Ghent University, Belgium

Hendrik Slabbinck, Ghent University, Belgium

EXTENDED ABSTRACT

The substantial growth of the video gaming industry has provided advertisers with a 'new' medium to effectively exploit the product placement technique. Academic interest into consumers' reactions to persuasive messages in videogames is increasing (e.g., Cauberghe and De Pelsmacker 2010; Farrar et al., 2006; Mau et al., 2008). However, previous studies scarcely take into account the specific characteristics of the gaming environment (Lee and Faber, 2007). Inherent to videogames is their capacity to force the player into a cognitive state, which approximates a state of *flow*, an intrinsically motivated optimal enjoyable mental state (e.g. Csikszentmihalyi and Lefevre 1989, Cowley et al., 2008). Few studies have examined the influence of game-evoked flow on the cognitive and affective outcomes of in-game product placements (Grigorovici and Constantin 2004; Mau et al. 2008; Nelson et al. 2006). Previous research has produced mixed results, suggesting the presence of moderating variables. Moreover, in previous research flow has often been investigated by measuring telepresence (Grigorovici and Constantin 2004; Nelson et al. 2006), while the latter incorporates only one aspect of flow.

In two studies, we investigate the relationship between *game-evoked flow* and *brand memory and brand attitudes toward brands placed within a video game* and the potential moderating influence of two important dimensions of brand placements i.e. brand congruence and brand prominence. Flow focuses the gamer's attention on the interactive game content (Hoffman and Novak, 1996) resulting in higher memory of this interactive content. This enhanced attention to the central game action is beneficial in terms of memory for congruous (H1a) and prominent (H2) brands, probably because congruous/prominent brands fit better into this central game action. Conversely, incongruous/subtle placements do not benefit from a flow experience, since they are not central to the game action due to their misfit with the game/subtlety. Furthermore, incongruous product placements do not add realism to the game, since they do not match with the game. Conversely, they might even disrupt the sense of realism experienced while playing a video game. Consequently, its ulterior motive (i.e., an attempt to persuade) becomes accessible to gamers, making both gamers experiencing flow versus not experiencing flow, who equally attend to incongruous placements, also equally resist the placement (Campbell and Kirmani, 2000). Therefore, we hypothesize that flow has no effect on attitudes toward incongruous placements (H1b). For subtle placements, increased enjoyment due to flow simply transfers to the brand. Counter argumentation is out of question here, due to the subtleness of the placements. By contrast, previous literature has shown that prominent product placements could entail persuasion knowledge activation and hence, counterarguments (e.g., van Reijmersdal, 2009). However, flow can deplete players' limited cognitive resources in a gaming context (Lang, 2000). Additionally, we could presume that our use of *congruous[1]* prominent placements makes the persuasion motive less accessible, due to their fit with the game. We could then assume that gamers experiencing flow, for whom only limited cognitive resources remain, are less likely to resist the placement (cf. Campbell & Kirmani, 2000). We hypothesize that flow has a favorable effect on brand attitudes for *congruous* prominent placements (H3).

To test the proposed hypotheses we performed two studies. In study one, brand congruence of the in-game advertised brand was manipulated as either congruous or incongruous (Adidas and Visa were identified as the 'congruous' and 'incongruous' brand in a pretest); participants rated both congruous and incongruous brands. In study two, brand prominence of the in-game advertised brand was manipulated as either high or low. Two versions were created with the same congruous brand (i.e., Audi) presented either in a prominent or a subtle way. Participants were randomly assigned to either the prominent or the subtle placement condition. In both studies, game-evoked flow was measured after game play (Refiana et al., 2000) and was used as a continuous variable. The participants were asked to play the video game; afterwards, they completed a questionnaire containing game-evoked flow, recognition (study 1) and implicit memory (study 2) and brand attitude measures. Brand congruence, brand prominence, brand knowledge an socio-demographic variables were also included. Participants (N = 120; N=227) were in the age group of 12 to 59 years (Mean age = 26.57; Mean age= 20) and included both males and females.

An estimated a multilevel logistic regression model shows a marginally significant interaction between brand congruence and flow ($F_{(1,234)} = 2.91$, $p = .08$). Simple slope tests revealed that participants recognized the congruous brand more frequently as flow increased ($F_{(1,117)} = 3.98$, $p < .05$), but no such relationship could be established for the incongruous brand ($F_{(1,117)} =.15$, $p > .05$) confirming H1a. The interaction between brand congruence and flow significantly predicted brand attitudes ($F_{(1,234)} = 8.90$, $p < .01$). Simple slope tests revealed that flow significantly influenced brand attitudes for the congruous brand ($F_{(1,117)} = 4.79$, $p < .05$) but not for the incongruous brand ($F_{(1,117)} =.62$, $p > .05$) supporting H1b.

A binary logistic regression model (study 2) showed a significant interaction effect with placement prominence ($b = 1.15$, Wald $\chi^2 = 14.24$, $df = 1$, $p < .01$). Simple slopes tests revealed that flow was positively related to implicit memory rates for prominent brand placements ($b = 1.11$, Wald $\chi^2 = 11.13$, $df = 1$, $p < .01$), while flow does not influence implicit memory rates for subtle brand placements ($b = -.36$, Wald $\chi^2 =.02$, $df = 1$, $p > .10$) confirming hypothesis two.

Ann ordinary least squares (OLS) regression model showed no significance for either prominence ($\beta = -.043$, $p > .05$), or the interaction between flow and prominence ($\beta = -.047$, $p > .05$) confirming hypothesis three. Our results confirm that experiencing flow while playing a computer game can, in some situations, have a positive effect on memory and attitudes for brands presented during game play.

---

1   Since we expect that congruence is a moderating variable of the flow-outcome relation (cfr. Hypotheses 1a and 1b), we chose one level of congruence (i.e. high congruence) to explore the moderating influence of prominence on the flow-outcome relation.

Segmenting Consumer Reactions to Social Network Advertising

Colin Campbell, Monash University, Australia
Carla Ferraro, Monash University, Australia
Sean Sands, Monash University, Australia

EXTENDED ABSTRACT

Marketers and advertisers have been quick to respond to the shift in online social media activity in a bid to facilitate consumer engagement. In order to optimise social media and social network advertising investments, and the potential to generate online social WOM, knowledge of how consumers interact with the medium is necessary. Fundamental is an understanding of the type of consumers that use social media and social network platforms. Several studies (e.g., Foster, West, and Francescucci, 2011; Ip and Wagner, 2000; Li and Bernoff, 2008; Riegner, 2007; Wiertz and DeRuyter, 2007) provide a basic understanding through segmentations of usage or motivation to participate. This paper offers a more nuanced understanding of how consumers engage with social media by specifically examining response to social network advertisements, which are "a new, rapidly growing, substantively important, and largely unexplored frontier," (Taylor, Lewin, and Strutton, 2011, p. 260). Likewise, instead of a single segmentation base as is common to many previous studies, we employ three segmentation bases: brand engagement, purchase intention and WOM. This paper therefore contributes to existing knowledge through a unique social media segmentation analysis predicated on the behavior a social network advertisement has the potential to engender.

Literature highlights the growing significance of social media in shaping consumer engagement online. Specifically, social media and social network sites have attracted the attention of researchers investigating marketing opportunities (e.g., Fournier and Avery, 2011; Hanna, Rohm, and Crittenden, 2011; Kaplan and Haenlein, 2011a; Kietzmann, Hermkens, McCarthy, and Silvestre, 2011; Weinberg and Pehlivan, 2011), consumer usage and influence (e.g., Katona, Zubcsek, Pal, and Miklos, 2011; Kozinets, de Valck, Wojnicki, and Wilner, 2010; Trusov, Bodapati, and Bucklin, 2010) and the related impact on consumer preferences (Narayan, Rao, and Saunders, 2011; Taylor, Lewin, and Strutton, 2011). Research has also looked at what causes social network advertising avoidance (Kelly, Kerr, and Drennan, 2010) and acceptance (Taylor, Lewin, and Strutton, 2011), as well as consumer-generated conversations and brand engagement (Fournier and Avery, 2011; Muniz and Schau, 2011). However, the literature has not yet fully explored the consumer behaviour effects of social network advertising.

A common thread running through the online and social media segmentation literatures is a focus on general behavior or motivation segmentation bases (e.g., Aljukhadar and Senecal 2011; Sung and Jeon, 2009) rather than specific responses to marketing stimuli. Researchers examining consumers' online social behavior have similarly focused on general segmentation bases such as WOM (Riegner, 2007; Foster, West, and Francescucci 2011), usage (Ip and Wagner, 2000; Taylor, Lewin, and Strutton, 2011) and motivation (Wasko and Faraj, 2000a, 2000b; Wiertz and DeRuyter, 2007; Foster, West, and Francescucci, 2011). This stream of research sheds light on organic consumer behavior online, but provides only tangential knowledge of consumer response to social media advertising. The present study attempts to fill this gap and specifically responds to the need to better understand online social community advertising (Zeng, Huang and Dou, 2009) and user engagement with brands (Foster, West and Francescucci, 2011). In doing so, we explore whether segments of consumers exist based on their level of brand engagement, WOM referral behavior, and purchase intention, all following exposure to a social network advertisement, and profile resulting consumer segments along dimensions of both theoretical and practical importance.

Using survey data from 883 consumers, we identify five segments of response to social network advertising – Passive, Talkers, Hesitant, Active, and Averse – and significant covariates such as information search, convenience, entertainment, age and gender that predict segment membership. Two segments are highly impacted by social network advertising in terms of all behavioural outcomes: brand engagement, purchase and WOM intentions. The larger of these two segments (Talkers, 28%) is relatively high on all behavioural outcomes and information motivation, but weaker in terms of purchase intentions, while the other (Active, 10%) is impacted highly on all outcomes. A third segment reveals a relative level of indifference across the behavioral outcomes (Passive, 29%), but relatively high entertainment motivation and a low convenience motivation. The remaining two segments held low levels of behavioral intention and information motivation.

This paper thus expands current understanding of how consumers respond to social network advertising through a focus on how they are impacted by advertisements in this channel. The findings highlight that two segments, Actives and Talkers (representing 38% share of the market), are highly impacted by social network advertising in terms of brand engagement, purchase and WOM referral intention. Our results also reveal that social network advertising segment membership is associated with psychographic variables such as information motivation and entertainment motivation, as well as age. Specifically, information motivation is a strong determinant of segment membership for Actives and Talkers. While this makes intuitive sense, in that positive effects from social network advertising interactions are therefore linked to consumer's desire for information, it also supports prior theory that those consumers who desire information explore and use new alternatives (e.g., Steenkamp and Baumgartner 1992). We also find that entertainment motivation is a significant predictor of membership for Actives, the segment most engaged in and responsive to social network advertising.

To sum up, our research reinforces that it is problematic to collapse all social network users into one grouping (Hargittai and Hsieh, 2010) and that advertising is more effective for some consumer segments (based on variation in response). Importantly, we identify a large (and likely growing) proportion of consumers (38%) who can be influenced by social network advertising, but also a majority who are not 'in tune' with social networks as an advertising m edium. Nonetheless, given the existence of different segments, there is a need for firms to tailor their social media marketing strategies accordingly. We find that those consumers most engaged with social network advertising also have a high information and entertainment motivation, and therefore informative and entertaining content is most effective.

Producing & Consuming Public Space: A 'Rhythmanalysis' of the Urban Park

Morven McEachern, Lancaster University, UK
Gary Warnaby, University of Liverpool, UK
Fiona Cheetham, University of Salford, UK

EXTENDED ABSTRACT

Over 2.5 billion visits are made to UK parks each year (Greenspace, 2007). Hence, there is, unsurprisingly, an abundance of literature dedicated to parks, especially within the context of urban regeneration (Inroy 2000). However, little attention has been given to how these forms of social space are produced/consumed (Arsel and Bean 2010; Brace-Govan 2010; Costa and Bamossy 2003; Ozalp and Belk 2009; Sherry 2000), or about the temporality of these consumption experiences (Arnould and Thompson 2005). Calls to develop a more detailed understanding of the nature and meanings of consumption-related practices associated with park users have recently been made (Lee, Shepley, and Huang 2009), which suggests an opportunity to offer a more comprehensive analysis of the temporal consumption experiences encountered by urban park users, and the subsequent contribution to a perceived 'sense of place'.

For many industrialised cities, the creation of urban parks in the mid nineteenth century was seen to provide "lungs to the inhabitants of densely populated districts" (Latimer 1987, 7) and a place where the general public could take exercise. Thus, giving rise to a strong correlation between the quality of green space/accessibility to public parks and quality of life (Barbosa et al. 2007). Accordingly, changes were also made to the way that urban park spaces are being produced and managed, moving from city councils merely fulfilling the function of park caretaker to a more strategic and actively 'managed' role whereby planned marketing activities are created to differentiate experience of the locale and (co-)create consumer value (Warnaby 2009).

Public parks and green spaces are "by their nature multifunctional and analysis falls between different academic areas" (CABE Space 2010, 42). Therefore, drawing from sociology's view that "space and the duality production/consumption are thus dynamic concepts based on practices" (Styhre and Engberg 2003, 116), de Certeau's (1984) and Lefebvre's (1991) notion of space as a "practiced place" is employed here. Moreover, as social practice is composed from daily, monthly and annual rhythms as well as natural rhythms, Lefebvre's (2004) concept of 'rhythmanalysis' helps to capture more fully the embodied everyday experience of those who use or pass through the urban park space. Lefebvre suggests that rhythm exists when there is an interaction between a place, a time and an expenditure of energy, and which will incorporate repetition (in time and space), interferences of linear processes (originating from human activity/social practices) and cyclical processes (originating in nature/the cosmos), and a cycle of birth, growth, peak, decline and end. Lefebvre notes the existence of numerous rhythms (i.e. polyrhythmia), which can "unite with one another in a state of health, in normal (which is to say normed!) everydayness" (i.e. eurhythmia), or can be discordant (i.e. arrthymia), which he perceives as "a pathological state" (2004, 16).

The study focuses on parks in the north west of England, UK. To help capture the diversity and complexity of human and non-human interaction in this socio-cultural context, we employ visual ethnography (Pink 2007) and walking interviews with users (Clark 2009). Compared to interviews alone, the use of photographs and film arguably help to capture more fully, the "lived realities of everyday consumption" (Belk and Kozinets 2005, 128). Rather than merely recording movement or repetition of rhythms, our mode of analysis attends to moods, atmospheres and reciprocal interactions between humans as well as between non-human pulses of life, in other words, the ways in which rhythms *animate* the urban and facilitate the creation of a 'sense of place'.

The visual and aural narratives produced as a result of these complimentary methods have helped us to make sense of the temporality of the urban park as a consumption experience. A constant and dominant rhythm identified at all parks is the ebb and flow of user traffic, echoing the linear rhythms of travelling to work or school as well as serving as a constant reminder of the surrounding industrialisation. Unsurprisingly, cyclical rhythms are extremely pronounced in the urban park context, separated by days, nights and seasonal events. Early morning, weekend rhythms are dominated by harmonic non-human interactions between swaying trees and birdsong which later become muffled as the park gates give way to the everyday 'commercial rhythms' of the fast food vendors preparing for the day ahead. From mid-morning to early afternoon, the urban park attracts a diverse range of individuals and groups. As the rhythmic pace intensifies, the exchanges between humans appear organized and amicable.

For the most part, the user's mood is of enjoyment and appreciation - "*Heaton Park would be my favourite...it's a lovely space. It really used to lift my spirits and clear my head especially going for an early morning walk...it was lovely*". However, tensions were evident at times (perhaps in a manifestation of arrthymia), with certain users indicating their annoyance at the intrusions and lack of respect for their space - "*Every time I go to the park jogging I have dogs chase me. A few make contact with my feet and I have no idea if they are going to bite or something*". Social relations brought about by interactions between non-humans and other non-humans were also spoken of by dog walkers – "*the dogs stop and say hello to each other and you kind of naturally speak to the owner and ask them about their dog...so you build up a rapport based on dog ownership*". While recognising the role of urban park managers in 'managing' the aesthetics of the park space and organising seasonal events such as summer concerts and charity 'fun-runs', it is clear that it is the users who are instrumental in co-creating the overall image, ambience and consumption experience of the urban park.

The multiple (poly)rhythms brought about by interactions between place, time and human (and non-human) action, help to illustrate more fully the temporal nature of urban park users' consumption experiences. The paper concludes by discussing how our study helps distance our analysis from wholly textual accounts of park usage as well as providing management and policy recommendations regarding the essence of urban park space.

Trajectories of the Self: A Phenomenological Study of Women's Changing Faces Reflected in Cosmetics Consumption

Chihling Liu, University of Manchester, UK
Debbie Keeling, University of Manchester, UK
Margaret K. Hogg, Lancaster University, UK

EXTENDED ABSTRACT

Past literature indicates the importance of changes in appearance in helping the individual define herself (McAlexander and Schouten, 1989) or cope with problems during liminal states (McAlexander, Schouten et al., 1992). For example, by undergoing plastic surgery, individuals emphasize their role transitions and set out upon a trajectory of identity reconstruction (Schouten, 1991). Nevertheless, plastic surgery is considered to be an extraordinary event, which lies outside individual realms of everyday experience. Therefore, we argue that studies on plastic surgery, whilst useful as setting boundaries for the study of the self, have limited insights in the unfolding drama of the self and the subtle sensitivity of 'individual' in daily life. Paradoxically, 'cosmetics' are a necessity of daily life for many women and for centuries have been utilized to modify or enhance physical appearance. The systems of everyday consumer consumption, e.g. cosmetics, that make us human – appear to be easily overlooked and hide potential meanings from us (Crotty, 1998). This study addresses this opportunity for examining selves in daily transition and cosmetics use across key developmental stages of everyday life (Markus and Wurf, 1987; Schembri, Merrilees et al., 2010; Aguirre-Rodriguez, Bosnjak et al., 2011). We aim to provide a holistic understanding of changes in the issues of sense of self and how cosmetics consumption is used to strategically reflect, protect and impact on the trajectories of the self over the lifetime.

A sample of twenty-six women, aged between 19 and 62, who wore makeup on a daily basis, was recruited for this study. Verbatim transcriptions were generated via phenomenological interviews (Thompson, Locander et al., 1989; Smith, Flowers et al., 2009), regarding their feelings, perceptions and experiences of cosmetics use. The interviews ranged from 1-2 hours. Fictitious names were assigned to all informants, guaranteeing confidentiality. Each interview began with the question, "*when you think about a cosmetics brand, what comes to your mind?*" This question was used to initiate a dialogue on an understandable domain, however, exerted little influence upon the overall course of the dialogue (Thompson, Locander et al., 1990). All other questions emerged spontaneously from the informants' narratives, therefore ensuring restricted influence from the interviewer and allowing informants to make sense of their experiences at their own pace. A hermeneutic approach was adopted to discern the constellation of past-present-future relations that underlies intentionality (Husserl, 1970), e.g., consumer consumption goals, and individual reflections on everyday experiences (Heidegger, 1960; Gadamer, 1993). Consumer depictions about their everyday experiences create temporal trajectories in which a past event is relived in relation to present concerns and used in shaping an envisioned image of the future self (Thompson, 1997). The interview focused on descriptions of consumers' lived experiences in terms of changes in the self over time and the role cosmetics consumption plays in facilitating this experiential journey.

THE TRAJECTORY OF CONTRADICTORY SELVES

This study showed how contradictory selves conflict in the different time frames of past, present and future (See figure 1). Our findings suggest cosmetics consumption is used dynamically as an instrument to enable views of the self and manage changes in priorities over the life course.

Past-present Conflict

For example, Abbie was constantly battling signs of aging. She was at times almost denying this fact and spoke as if she was still young and her complexion was still perfect. At the same time she was torn between two cultures, i.e. Africa (her family roots) and Europe (brought up), and changing society's expectations from the 'old days' to the present, e.g. conform to a certain look.

Present-future Conflict

She anticipated that her future self would be wearing fewer cosmetics, for example, due to the importance of passing the 'right' values to her children, e.g. beauty comes from inside. Nonetheless, she envisaged having more dramatic makeup at night for herself as a woman; and for her husband, in order to feel sexy and attractive as a wife.

Figure 1
THE TRAJECTORY OF CONFLICTING SELVES

Furthermore, in Isobel's set of realities, cosmetics enabled her to have multiple selves, particularly in terms of her conflicting selves; when she wears makeup (e.g., 'demanding', 'tougher' and 'argumentative') compared to when she wears no makeup (e.g. 'timid', 'caring' and 'vulnerable'). Her obsession with cosmetics grew out of childhood issues she faced in the family and at school. She used makeup as a 'shield' to keep people from getting close; and as a 'sword' to be ready to fight back. She was caught in a struggle between wanting to be different and yet be the same, especially during childhood (See figure 2).

Figure 2
As she grew older, she pictured changes in the reasons for wearing cosmetics. She used to wear makeup to hide her problems but in the future, she would hope to only utilize cosmetics to boost her confidence. As she aged, she became more confident and grew more tolerant within herself, like most of our informants.

COSMETIC COMMUNICATION BETWEEN THE SELVES

Cosmetics are used as a mechanism to communicate between the contrasting selves, particularly during major life events. For instance, Nancy was re-applying makeup in a constant manner to communicate between her 'hopeless self' and her 'hopeful self' post-breakup. She strove to depart from the hopeless depressing self and pick herself up as makeup allowed her to be that strong, confident and attractive woman.

Consumption is more than skin deep. Beyond cosmetics consumption, we provide a more enlightened perspective on this very complicated area – how does consumption potentially reflect and impact on issues of sense of self? Our findings offer intriguing insights into changes in the trajectories of the self and identity projects (Arnould and Thompson, 2005). They inform the challenges individuals face to define the self and how cosmetics are used as tools for coping with these challenges in a deeper, more dramatic way. Following on from enhancing understanding of the trajectories of the self, we conclude that the self changes over time and cosmetics consumption provides instrumental values to manipulate and attack others; and to create, re-define and protect the self, responding to transition phases during life.

The BOP Metanarrative: A Critical Exploration

Suparna Chatterjee, Xavier University, USA

EXTENDED ABSTRACT

Stemming from the work of C.K. Prahalad (2006) market development at the bottom of the economic pyramid has emerged as one of the viable alternatives for dealing with the challenge of global poverty. In the present paper, I contend that the "Bottom of the Pyramid" (henceforth BOP) approach is fast emerging as a meta-narrative[1] (a grand synthesizing framework) providing business practitioners and scholars with a template for future research and action aimed at creating market based solutions for poverty eradication (Anderson & Markides, 2007; Hammond & Prahalad, 2004; Karamchandani, Kubzansky & Lawani, 2011; Kasturi Rangan et al., 2007; London & Hart, 2004; Prahalad, 2006; Prahalad & Hart, 2002; Seelos & Mair, 2007; and Vachani & Smith, 2008). As a meta-narrative, the BOP proposition provides a limited set of interpretative frameworks within which a whole host of issues ranging from globalization, poverty, partnerships to markets, enterprise, and development, are understood, represented, and analyzed. Like all meta-narratives, the BOP meta-narrative opens up some kinds of debates and discussions while silencing those that lie outside its interpretative frameworks. Taking an interdisciplinary approach which involves drawing on recent developments in the in fields such as marketing, management, economic geography, anthropology, sociology, and development studies, I subject this emergent meta-narrative to a close scrutiny by highlighting the implicit and tacit assumptions, motivations, and commitments that are mobilized to construct the BOP proposition. With the help of examples drawn from Prahalad's definitive work, "Fortune at the Bottom of the Pyramid," (2006), the present paper attempts to explore the fundamental conceptual and theoretical issues at stake in the BOP proposition, and in so doing, illuminate some of the larger socio-cultural, political, and ethical implications of the project.

Broadly, the paper argues that the BOP project presents an inadequately contextualized and, in many instances, dehistorized understanding of processes and practices that affect the lives of the people at the bottom of the economic pyramid. For instance, the BOP proposition draws on a thin understanding of globalization which compartmentalizes and fragments processes and relations that are, in fact, interconnected and interlinked. Large private firms (one of the principle agents of globalization) are cast as distant and neutral players who somehow remain above and beyond the processes and relations that sustain and energize them. Such a sanitized reading of

the large private sector's involvement in global economy not only exonerates them from taking any responsibility for the uneven and contradictory consequences of their operations; but it also restricts us from thinking about newer ways of building coalitions and solidarities connecting different positions, interests, and stakes in the spirit of mutual recognition and responsibility.

The BOP proposition rests on an essentialist understanding of human nature as reflected in the arguments related to the "enterprising consumers" where the entrepreneurial trait is seen as natural and intrinsic to the consumers at the BOP. Further, the focus on entrepreneurialism as a panacea for all forms of social problems leads to depoliticization of social issues as it rests on an implicit understanding that the locus of "problems" (poverty, jobless, dispossession, environmental degradation, so forth) lies not in institutional, social, political and economic dysfunctions but rather in the individual themselves (Giroux, 1980, pp. 338).

The BOP proposition takes a purely instrumental view of knowledge which leads to abstractions and generalizations about the conditions of life at the bottom of the pyramid. Indeed, the BOP project, as Charusheela and Zein-Elabdin, 2004, in a different context (critique of economics as a hegemonic discourse of modernity) put it, is "epistemologically comfortable" with generating disembodied, context free and value-neutral knowledge. Thus, the BOP program presents economic distress and socio-spatial marginalization of the poor (for example; high population densities in slums in developing countries) as "exploitable observations" (Wilson, 1977 quoted in Giroux, 1980, pp. 334) which is then used as "knowledge" for market development at the bottom of the economic pyramid. This purely instrumental view of knowledge becomes part of the expert vocabulary (expertise) of business disciplines be it management or marketing which ultimately (although unwittingly) desensitizes poverty. It hides more than it reveals about the condition the life at the BOP as it normalizes acute economic upheavals and instabilities by making "the crisis" appear as a normal condition of life at the BOP. The claim of equal partnership between the poor and the large private sector, a central idea in the BOP proposition, is criticized for obfuscating how power works to shape interactions among differentially (hierarchically) located entities in ways which limits the field of possible actions that can be initiated by the more vulnerable "partner." Thus, given the productive capacity of power (to create individuals who are self-directed toward "certain" goals) how can firms and the people from poor communities collaborate?

The paper argues that by glossing over the conceptual and theoretical implications of ideas and concepts mobilized to study people at the bottom of the economic pyramid, the BOP project ends up resurrecting the very biases and prejudices which it allegedly set out to challenge, in the first place. While taking issue with many of the central arguments of the BOP project, the paper is not about a wholesale rejection of the idea of large private sector participation in poverty alleviation; rather the purpose is to confront the blind spots and omissions in the BOP project which serves to undermine its own potential, and in so doing recover in some measure, the emancipatory thrust of the BOP approach. In the concluding section, I maintain that the BOP project will be well served if it remains reflexive (self critical) about its own theories, perspectives, and positions. I contend that an introspective stance would make the BOP project sensitive to the uncertainties and contingencies arising from diverse historical, political, and socio-economic contexts thereby making it

---

1   Meta-narratives can be thought of as dominant paradigms that provide conceptual frameworks and tools to arrive at an understanding and analysis of processes and phenomena under consideration. Colonialism, modernization, development theory, under-development theory are some of the meta-narratives that have structured and shaped our knowledge of colonization, modernity, and development in contemporary times. In his brilliant essay calling for a reconsideration of the claim of value neutrality in social sciences and humanities, renowned African Studies specialist, Allen Issacman (2008) raises an important question about meta-narratives. Following a critique of meta-narratives surrounding the continent of Africa which silences and renders invisible alternative or local knowledge, he writes: "This is not to say that the meta-narratives, paradigms, or chronologies prevalent in the scholarly literature are inconsequential or wrong, but rather that they necessarily constitute only one set of intellectual conventions and representations of reality" (8). Also, it must be recognized that we often use the concepts and tools made permissible by the meta-narrative to critique the meta-narratives. So, instead of claiming a ground outside meta-narratives, the point is to highlight the fault lines that hold together the dominant logic that underwrites meta-narratives.

more circumspect (and less celebratory) about the possibilities and perils of business innovations and ventures aimed to generate profits as well as reduce poverty.

The Effect of Social Networking Orientation on Risk Preference:
The Risk-Taking Capacity Hypothesis

Hakkyun Kim, Concordia University, Canada
Kyoungmi Lee, Yonsei University, Korea
Kiwan Park, Seoul National University, Korea

EXTENDED ABSTRACT

Will consumers' social networking orientations influence their psychological functioning on subsequent tasks in seemingly remote, unrelated domains? Prior research on social capital (Putnam 2000) suggests the distinction between a *bonding* orientation, with which people seek to cement connectedness among exclusive and relatively homogeneous groups, and a *bridging* orientation, with which people focus on creating new contacts with different groups, resulting in spanning diverse social cleavages. We propose that an individual's primary orientation associated with social networking affects subsequent risk-related decisions.

Building on the resource depletion paradigm that suggests that people who engage in an initial self-regulation task perform worse on a subsequent task demanding self-regulation resources (e.g., Baumeister et al. 1998; Baumeister, Vohs, and Tice 2007), we posit that humans have a limited amount of risk-taking resources. Thus, once their risk-taking resources are drained, individuals will act more conservatively in subsequent tasks. Specifically, given that bridging-versus bonding-oriented activities are involved with a higher level of social risk, thereby depleting more resources, we hypothesize that consumers may become more risk-averse after performing bridging-versus bonding-oriented social networking activities. We conducted three experiments to examine this hypothesis.

In study 1, we manipulated social networking orientation by asking participants to perform different types of activities on Facebook. Specifically, participants in the bridging condition were asked to log in to their Facebook accounts, choose some people on their friend lists with whom they had not personally interacted (e.g., someone from a class or friends' friends), and visit each person's Wall. The participants were then asked to spend about 10 minutes reading their friends' recent events and leaving Wall posts. In contrast, those in the bonding condition were asked to choose some people to whom they felt close (e.g., best friends or family members). Then, participants were asked to indicate how much they would consume each of the two food items, GMO (genetically-modified organism) foods or imported vegetables (study 1a) or how much they would engage in a high-risk leisure activity (i.e., Jet Ski; study 1b), on seven-point scales. In study 1a, a 2 (Orientation) × 2 (Food) mixed ANOVA with food as a within-subject factor revealed that people who performed the Facebook task with bridging (vs. bonding) orientation were less likely to consume risky food items ($F(1, 18) = 13.61$, $p < .01$; GMO foods: 3.13 vs. 4.17; imported vegetables: 2.83 vs. 5.00). Similarly, results from study 1b showed that participants who completed bridging-oriented activities reported lower intentions to try Jet Skiing than those in the bonding condition (5.03 vs. 5.98, $F(1, 38) = 4.50$, $p < .05$).

In study 2, we examined whether merely recalling previous networking activities participants had performed would produce similar effects (Usta and Häubl 2011). Thus, we manipulated social networking orientation by having participants recall and write about activities that they had done on social networking sites in the recent past. In the bridging condition, participants wrote about activities intended to newly link them with others, whereas participants assigned to the bonding condition performed the same tasks, but about activities intended to deepen their bonds with close friends. A 2 (Orientation) ×

3 (Food) mixed ANOVA with three high-risk food items (raw meat, GMO corns, and fatty pork belly) replicated the findings of study 1a, showing that regardless of food items, people recalling bridging-related episodes were less likely to consumer risky food items than those recalling bonding-related episodes ($F(1, 66) = 17.28$, $p < .001$; raw meat: 4.58 vs. 5.94; GMO corns: 2.27 vs. 2.83; pork belly: 5.45 vs. 6.09), echoing the notion of people's risk-taking resource regulation.

In study 3, we examined the role of resource depletion as the underlying mechanism to understand the effect of social networking orientation. We used the same Facebooking manipulation as in study 1. For the risk-preference task for our dependent measure, we presented a series of seven scenarios in which participants had to choose whether to write a term paper on either a provocative topic (a risky option) or a conservative topic (a sure option), a modification of Hsee and Weber's (1999) stimulus. On the basis of each participant's choice pattern in the seven scenarios, we assigned the risk-preference index (0 – 7; higher scores indicate more risk-seeking) and used it as our focal dependent measure. We also asked participants to rate how socially risky and stressful they perceived the assigned Facebook activities, on seven-point scales (1 = not risky at all, not stressful at all, 7 = very risky, very stressful). A composite index was formed to operationalize the degree of depletion of risk-taking resources by averaging the two items ($\alpha = .76$). This index served as a mediator to the effect of social networking orientation.

We found that people reported lower scores on the risk-preference index after completing bridging versus bonding task on Facebook (2.81 vs. 3.70, $F(1, 56) = 7.19$, $p < .01$). We also observed that the bridging task was perceived as riskier than the bonding one, suggesting that participants spent more resources completing the bridging versus bonding task (3.55 vs. 2.59, $F(1, 56) = 6.22$, $p < .01$). More importantly, a bootstrapping confirmed the depletion of risk-taking resources as the underlying process by showing its mediating role between social networking orientation and risk preference (a 95% CI: .0080, .3251). We ruled out alternative explanations, such as perceived support from others, self-competence, and self-liking (all F's < 1).

Combined together, these results provide converging evidence that bridging-oriented (versus bonding-oriented) experiences on social networking or even merely recalling such experiences lead consumers to behave in a more risk-averse fashion, be it food selection, leisure activities, or academic decisions. Theoretically, we propose and find that this effect is driven by depletion of risk-taking resources induced by bridging versus bonding social networking task. Given the popularity of online social networking and its potential influence on a variety of unrelated decision domains, the present research promises to advance our understanding of consumers' implicit decision-making processes.

Minority Matters:
The Influence of Minority And Majority Descriptive Norms on Product Choice

Erica van Herpen, Wageningen University, The Netherlands
Hans C. M. van Trijp, Wageningen University, The Netherlands
Mariette van Amstel, Schuttelaar & Partners and Vrije Universiteit, The Netherlands

EXTENDED ABSTRACT

Social norms often have a substantial impact on human behavior (Cialdini et al. 1990; Melnyk et al. 2010). In fact, the influence of descriptive norms is much higher than that of other types of information, even though consumers themselves rate descriptive norms as least important in energy conservation behavior and campaigns using these norms as least motivating (Nolan et al. 2008). Such descriptive norms communicate what is typical in a situation and thereby provide "social proof" of what is effective behavior (Jacobson et al. 2011). They have been successfully applied in marketing campaigns to improve health and safety (e.g., www.mostofus.org).

Studies on these descriptive norms have examined campaigns communicating the behavior of a majority of others. In their study on the reuse of hotel towels, Goldstein et al. (2008) communicated that 75 % of guests participate in the resource saving program, and in a study on energy saving, Nolan et al. (2008) used doorhangers communicating behavior of 99 % of people in the community. These are powerful descriptive norms changing consumer behavior. Yet, sometimes an advocated behavior is performed by only a minority of people: the market share of organic products is low (www.ota.com) and most people fail to eat enough fruit and vegetables according to dietary guidelines (www.cdc.gov). Communicating that most people fail to perform an advocated behavior typically undermines this behavior (Cialdini 2003; Stok et al. 2011). So are descriptive social norms never effective in advocating a desired behavior when this behavior is performed only by a minority of people?

Ample research on minority influence shows that sources advocating minority options can exert influence, albeit less strong and less direct (Horcajo et al. 2010; Wood et al. 1994). Applying this to descriptive norms, this would suggest that descriptive norms of minorities might be able to initiate the desired behavior when the emphasis is not on the failure to perform this behavior by the majority ("people should eat two pieces of fruit each day but only a minority does so") but instead on the advocated behavior itself ("some people eat two pieces of fruit each day"). The latter could activate personal norms and stimulate consumers to focus on the desirability of the behavior. The effectiveness of minority norms could be further enhanced when consumers perceive that the group performing the behavior is growing. After all, economic research on information cascades suggests that the tendency to follow the behavior of others is stronger when the group who is performing a behavior grows (Banerjee 1992; Bikhchandani et al. 1998).

In contrast, the effectiveness of majority norms might not be enhanced by information that the group performing the behavior is growing. A message involving a growing majority may be perceived as 'pushy' and evoke the perception of social pressure. This perceived pressure can undermine the effectiveness of the norm: when consumers perceive a persuasion attempt they tend to counteract this attempt (Clee and Wicklund 1980; Laran et al. 2011).

The two main objectives of the current study are thus to determine (a) whether weak descriptive norms (minority norms) can nonetheless enhance an advocated behavior, and (b) whether especially strong descriptive norms (a growing majority) are indeed less effective in stimulating behavior. We expect that information that a growing group of people are performing a behavior will enhance the influence of minority norms but weaken the influence of majority norms. This is tested in three experiments.

The first experiment (n = 91 students) employed a taste test. Participants chose between organic and regular orange juice, in a 3-group design with no information, majority, or minority norm information (e.g., 20 % of students in a prior study chose the organic juice). Results showed that choice for organic juice was significantly higher for both norms than in the control condition, indicating that minority norms can indeed stimulate behavior.

In the second experiment, students (n = 245) were asked to pick rewards for a series of unrelated studies. They could choose between more or less healthful options (e.g. Vitamin Water vs. Coca Cola). In a 2 by 2 design plus control condition, it was indicated that either a majority or a minority picked healthy snacks, and that this group was growing versus no trend information. Compared to the control condition, all norm conditions raised the number healthy options that were chosen. Additionally, the growing minority and majority norms raised the number of healthy options chosen more than the minority and growing majority norms, as expected. There was no difference between conditions in perceptions of how clear, reliable, and realistic the information was.

Experiment 3 employed a virtual environment with a train station stand of snacks and a quota sample of the general population to validate results. Additionally, time pressure was manipulated. Participants made three store visits, the first without norm information and the latter two with a shelf advertisement promoting fruit and using a similar 2 x 2 between subjects design as in experiment 2. Time pressure was applied in the instructions for one of the two latter visits. Results showed that choice of healthy products was higher for visits with the descriptive norm present rather than absent. Additionally, we found a significant three-way interaction between the type of norm, trend, and time pressure. With time pressure, all norms increased healthy choice, but without time pressure participants returned to unhealthy choices when the shelf advertisement featured a growing majority.

These results have important implications for norm theory. When ability to process information is low, descriptive norms appear to be a heuristic cue triggering behavior (c.f. Jacobson 2010), but when ability to process information is high, the formulation of the descriptive norm matters. Specifically, our results indicate that the band width in which descriptive norms are effective is both more extensive than previously assumed (i.e., minority norms can advocate a desired behavior) and more restrictive (i.e., norms using a growing majority are ineffective).

Fashion Sense:
Chinese Women's Response to Feminine Appeals in Transnational Advertising

Jie Gao Fowler, Valdosta State University, USA
Aubrey R. Fowler III, Valdosta State University, USA

EXTENDED ABSTRACT

Women are, in large part, responsible for the growth in retail sales in China (Rein 2009) and are becoming much more fashion conscious in this dawning consumer culture (China in Focus 1995). According to Rein (2009), Chinese women are spending as much as men on luxury consumption, accounting for 50% of luxury purchases from companies like Louis Vuitton and Gucci. Additionally, Chinese women are becoming much more focused on buying clothing and beauty products and are becoming much more concerned with looking good and looking fashionable.

As such, international fashion magazines and advertising agencies have entered into the Chinese market, helping to usher in a new fashion culture within the country. Much of the images portrayed in these media are simply adapted from Western sources, involving the modification of title, imagery, or copy in advertisements used in different cultures (Buzzell 1968; Reichal 1989; Ricks et al. 1974). Such modification ranges from a nearly complete transformation of an existing ad involving all three aspects or simply translating the copy language that appears in the ads. However, the Western advertisements in fashion magazines often do not change the model for their counterparts in China, leaving many idealized and European-looking (i.e. blonde, and blue-eyed) women in these ads.

As such, a few studies are beginning to look at the impact of fashion advertising on women and women's assessment of that advertising. For instance, Hung, Li, and Belk (2005; 2007) examined images of women in Chinese magazine advertising and developed a typology of the modern woman as portrayed in that advertising, and also examined the response strategies women used to interpret those images. Their study focused on the target audiences for those ads, essentially recruiting women who came of age well after the advent of the open-door policy. We seek to advance their study, examining the responses for feminine appeals in advertising for both the target audience as well as that target audiences' mothers, women who came of age before the open door policy when advertising was still viewed as a suspect aspect of capitalism.

Scholars such as Hirschman and Thompson (1997) and Hung et al. (2006) have conducted research on consumers' response to media images. Hirschman and Thompson (1997) identified three self-referencing responses that consumers employed to describe their relationship with media icons: aspiring/inspiring, deconstructing/rejecting, and identifying/individualizing, which were adapted by Hung et al. (2007). According to Hirschman and Thompson (1997), inspiring and aspiring occurs when a media image is interpreted as representing an ideal self to which the consumer can aspire. Media icons are read as inspirational goals or ideals that the consumer chooses to work towards. In this motivational relationship, many potential sources of disbelief are suspended. Rejecting/deconstructing occurs when the consumer's relationship with the mass media is expressed through overt criticism of the artificial and unrealistic quality of the media representation. Identifying/individualizing describes distinct ways by which consumers negotiate their self-perceptions and personal goals in relation to the idealized images presented in the mass media.

Little is known about how women from a different culture respond to similar advertising within the global marketplace. As such, the purpose of the following paper is to examine the response that Chinese and American women have for such ads found in the pages of their fashion magazines and the inter-generational differences that occur with these responses. To do so, we took a focus group interview approach to address the research purpose. Focus groups are a useful method for gathering ideas and insights for a variety of purposes such as obtaining consumer impressions of advertising copy (Iacobucci and Churchill 2005) or determining the impact of gender on the consumption of advertising (Hogg and Garrow 2003).

Given the purpose of our research concerns how different generations of women in a different culture respond to the feminine appeals in ads, we conducted a variety of dyadic focus group interviews where mother (age between 45 to 60) and daughter (age between 21 to 34) were shown advertising images taken from fashion magazines in both the U.S. and China. Based upon previous research (Chang 2004), the magazines we chose for the study share primary target audiences and are consistent in each country with each ranging between the ages of 21 and 35 (Cosmopolitan 2011; Elle 2011). The participants were recruited through a regional Chinese University and a regional American university of approximately the same size (between 11,000 and 13,000 students.

The results demonstrate that both generational and cross-cultural differences exist in terms of the interpretative strategies that were applied by these consumers. For instance, our American informants very much liked the nurturer appeal present in the advertisements with the U.S. daughters tending to associate the nurturer type with their families and/or mothers and the U.S. mothers identifying with the images in the ads. Conversely, both the Chinese daughters and their mothers rejected the ads outright, claiming that they did not represent their idea of the Chinese nurturer type. In addition, both the American mothers and daughters rejected the professional appeal in these ads, viewing them as fake and unrealistic. On the other hand, Chinese mothers and daughters both appreciated the ad with the daughters often aspiring to be like the image in the ad or, at the very least, aspiring to the professional role in which the image made the most sense.

Our study extended Hirschman and Thompson (1997)'s findings. Women not only can compare the self with the media images but also seeking solutions (e.g., comparing the media icon with friends, relatives, and even strangers). In addition, culture plays a significant element to shape how female consumers perceived the femininity in ads. Finally, there appears to be an authenticity gap in relation to the advertisements. Chinese women saw the nurturer in the ads as inauthentic whereas American women viewed the professional women as inauthentic. This authenticity gap is, of course, culturally bound; however, it also indicates the degree to which femininity and feminine appeals may not be universal in regards to fashion and consumption.

When and How Price-Dropping Serves as a Coping Mechanism for Price-Jolts

Aaron M. Garvey, The Pennsylvania State University, USA
Simon J. Blanchard, Georgetown University, USA
Karen Page, The Pennsylvania State University, USA

EXTENDED ABSTRACT

Imagine you just bought a new designer jacket that you are quite pleased with despite its high price—that is, until you hear that someone else purchased the exact same jacket at a different store for a lower price. We refer to this experience of realizing *post*-purchase that a lower price than the price paid was available as a *price-jolt*. In such situations, how do you feel? To date, and perhaps not surprisingly, research has indicated that such price-jolts significantly decrease satisfaction (Oliver and DeSarbo 1988) and likely result in negative feelings and attributions given the extent to which paying a lower price than retail results in positive affect (Schindler 1998). Building on this research, we consider how consumers cope with such price-jolts. Specifically, we examine how consumers may casually mention to others that they overpaid, which we term *price-dropping,* as a way to cope with price-jolts.

Previous research has shown that name-dropping, where an individual mentions a name in a conversation, is used to manage impressions and enhance self-presentation. For example, individuals that name-drop may be perceived as more likeable and competent when signaling a distant and casual connection with the person whose name was invoked (Lebherz, Jonasa, and Tomljenovic 2009). Similarly, we propose that sharing overpayment through price-dropping may signal pecuniary strength and status that aids in consumer coping with price-jolts (e.g., increased product satisfaction).

This theorizing is supported by recent empirical literature, which indicates that the appeal of many products is due to status needs rather than material needs (Amaldoss and Jain 2005), and that dearth of discounted payment may be perceived as a status signal (Argo and Main 2008). Furthermore, heightened sensitivity to status cues due to individual differences (Lichtenstein, Ridgway, and Netemeyer 1993) or situations (Rucker and Galinsky 2008) may increase signaling tendencies. Thus, consumers experiencing the negative consequences of a price-jolt may obtain psychological status benefits from telling others about their overpayment (i.e., price-dropping).

The results of three studies demonstrate that i) consumers choose to engage in price-dropping if they are naturally sensitive to status or if they are in a status-relevant context, ii) satisfaction with the product is improved when price-dropping, and iii) consumers perceive themselves as wealthier and more popular after price-dropping.

Study 1 explored whether consumers choose to engage in price-dropping after a price-jolt based upon perceived importance of status cues. After imagining purchasing an iPad2 for a given price, participants in the price-jolt (no price-jolt) condition were informed that the product was readily available at a nearby store for a higher (lower) price. Participants then indicated their likelihood to share the price paid if asked. To investigate whether willingness to price-drop depends on consumers' perceived importance of status cues, a multi-item measure of individual prestige sensitivity was recorded (Lichtenstein, Ridgway, and Netemeyer 1993). A significant three-way interaction between price-jolt condition and prestige sensitivity (analyzed continuously) emerged. As predicted, highly prestige sensitive consumers were more likely to price-drop when they experienced a price-jolt than those who did not. In contrast, low prestige sensitive consumers were less likely to price-drop when they were price-jolted than when they were not. Product quality assessments did not differ between conditions, thus precluding a price-quality inference explanation. Consistent with predictions, the desire among prestige sensitive consumers to price-drop suggests that negative effects of unintentional overpayment may be offset by signaling (and thus self-perceiving) heightened status. Subsequent studies examine whether the value obtained from price-dropping is reflected in product satisfaction.

Study 2 was conducted to determine whether product satisfaction is influenced by price-dropping. A 2 (price-jolt: yes/no) x 2 (price-drop: yes/no) between-subjects design with a continuous measure of prestige sensitivity was employed. After reading about their (lack of) price-jolt for the purchase of an Armani jacket, participants in the "no price-drop" condition indicated their product satisfaction. In contrast, participants in the "price-drop" condition were told they shared the actual price paid and the market price with a colleague prior to being asked about satisfaction. A three-way interaction supported our predictions. First, the effect of price-dropping on satisfaction differed by perceived importance of status cues: price-dropping increased satisfaction for high prestige sensitive consumers experiencing a price-jolt whereas low prestige sensitive consumers were less satisfied after a price-jolt regardless of price-dropping. All consumers experiencing a price-jolt (vs. no jolt) without price-dropping were dissatisfied. Notably, the level of satisfaction for price-dropping consumers rivals the level of satisfaction of other consumers who were unexpectedly delighted by under-paying for the same product. Study 2 thus demonstrates that price-dropping following a price-jolt recovers satisfaction for status-concerned consumers.

Study 3 investigated whether price-dropping can aid in coping with a price-jolt (i.e., increase satisfaction) among consumers not perpetually concerned with prestige if a status-relevant context arises. A 2 (price-jolt: yes/no) x 2 (status relevance: important/unimportant) between-subjects design was employed. Specifically, after learning of the same (lack of) price-jolt for the Armani jacket from study 2, the requestor of the jacket price paid was described as either high or low in receptivity to status cues ("…shops at high-end stores…recently vacationed at the Ritz-Carlton" vs. "…shops at discount stores…recently hiked and camped the local Appalachian trail"). Jacket satisfaction and self-ratings on several characteristics were then recorded. A significant two-way interaction confirmed our predictions. Consumers reporting to an audience low in receptivity to status cues were less satisfied in the case of a price-jolt. In contrast, and as predicted, those reporting to an audience receptive to status cues demonstrated full satisfaction recovery (i.e., satisfaction equal to those not experiencing a price-jolt). Mediation analysis suggested that individuals engaging in price-dropping in status-relevant conditions perceived themselves to be wealthier and more popular. Thus, price-dropping provides direct psychological benefits in addition to improving satisfaction.

In summary, this work introduces the theoretically novel concept of price-dropping and explicates how consumers may engage in this behavior to overcome the otherwise negative effects of price jolts. Beyond theoretical contributions to pricing and status literatures, this work has substantive implications, particularly given the abundance of price communications among consumers in social media.

Evidence for and Impact of Non-WTP Reporting in Willingness-to-Pay Surveys

Reto Hofstetter, University of St. Gallen, Switzerland
David Blatter, University of Bern, Switzerland
Klaus M. Miller, University of Bern, Switzerland

EXTENDED ABSTRACT

Knowing consumers' willingness-to-pay (WTP) is fundamental to managers engaging in consumer-oriented pricing strategies and tactics. To gauge consumers' WTP, marketing researchers frequently prefer, and rely on, direct WTP measurement approaches such as the open-ended (OE) question format. The OE question format is widely used by various professional market research firms and compared to indirect approaches to measure WTP (e.g., conjoint analysis) direct approaches have the advantage of simplicity, which explains their enduring popularity with practitioners. They are simple to explain, easy to implement, and never fail to generate timely information at a low cost. In addition, recent research has found that the external validity of direct approaches is not always necessarily inferior to indirect approaches (Miller et al. 2011).

With the OE question format, respondents are directly asked to state their maximum WTP for the specific product under consideration (Arrow et al. 1993; Mitchell and Carson 1989). As this format does not provide respondents with a selection of answering options, the respondents have unlimited degrees of freedom to come up with an estimate of their maximum WTP. This is why the OE question format is also referred to as "price-generation task" (Chernev 2003). These price-generation tasks are very flexible and allow consumers to precisely articulate their willingness to pay. Viewed from an economics standpoint, this flexibility is one of the reasons why price-generation tasks are potentially superior to price-selection tasks as a way to determine WTP if one assumes that consumers have established preferences that can easily be translated into monetary terms (Varian 1999). From a behavioral perspective this, however, is not necessarily the case as respondents have to go through a cognitively demanding multi-stage process to generate the answer (Krosnick 1991). In such situations, when optimally answering a survey question would require substantial cognitive effort, Krosnick (1991) argues that some respondents are tempted to shorten the cognitive route and simply provide a reasonably satisfactory answer instead, a behavior coined as "satisficing". The likelihood of engaging in such satisficing behavior is seen to be regulated by three factors: task difficulty, ability, and motivation. Given that price-generation tasks are generally perceived as difficult because consumers are not used to name their own price, and that some respondents potentially lack ability or motivation to perform this particular task, satisficing behavior is likely to occur in price-generation tasks.

In this paper, we propose that satisficing behavior in price-generation task can lead to a reporting of other price-types than WTP, which are more salient to the respondent and thus require less cognitive effort to generate. In a first study, we test whether the theoretical framework of satisficing can explain this observed behavior. For this purpose, we elicit WTP using both a price-generation and an incentive-aligned task for an innovative digital camera prior to market introduction. We find that 40.71 percent of the test persons indeed do not report their WTP and also find clear evidence that satisficing is more likely to happen among consumers who lack ability and motivation to perform the fully cognitive process of the price-generation task. In addition, expertise can explain the reporting of internal-reference prices instead of WTP. This effect is u-shaped, such that consumers with a low or high level of expertise are the most likely to report internal-reference prices. For consumers with high levels of expertise, this result is intuitive as for them it will require little cognitive effort to come up with an internal reference price relative to the cognitive effort needed to construct WTP. These results are in line with theory and suggest that not all respondents are equally capable of performing the price-generation task. We also find that satisficing has an effect of the external validity of the WTP statements. If a price-type different from WTP is reported, prices are substantially biased. If WTP is reported, this bias was significantly lower. This result is confirmed in both between- and within-subjects data.

In a second study, we replicate the external validity test for a lower-priced product. Again, a large proportion of the respondents report other price-types than WTP (55.72 percent). We find that if all elicited data is used for further analysis, measures that we calculate based on these data were all significantly biased. In contrast, if we focus on data from optimizing respondents, the bias was not only significantly lower, but it fully vanishes. This result holds for a number of statistical tests, such as comparing means or distributions, and also for a managerial relevant test, such as the outcome of a pricing decision based on these data. Interestingly, this group of optimizing respondents does not differ from the sample population in terms of demographics.

We believe that our study is among the first to offer a plausible explanation for the frequently reported hypothetical bias in empirical WTP studies. Our results suggest that consumer responses to price-generation tasks cannot always be interpreted as WTP. Intriguingly, the behavior that leads to this result can come from unlikely sources as experts are more likely to suffer from it. Experts are more likely to have stored internal reference prices. As reporting reference prices requires much less cognitive effort compared to coming up with WTP, they are more prone to engage in satisficing behavior.

Our research is limited in that the price-type selection task does not account for possible uncertainty at the individual level. We do not know if the chosen price-type was the only one that reflected the stated price. However, we would assume that respondents would select the price-type that best reflects the type of the stated price. A second limitation is that it is not guaranteed that the price the respondents state and later identify as WTP truly reflects WTP. Study 1 suggests that even this value can still be biased. This indicates that also other possible explanations besides satisficing may explain the hypothetical bias. It could be worthwhile to take a more holistic approach and test various competing explanations for the bias in one single research setting. We leave this endeavour to future research.

When Good Things Come to an End: Mispredicting Motivation for Unavailable Goods

Yang Yang, Carnegie Mellon University, USA
Carey Morewedge, Carnegie Mellon University, USA
Jeff Galak, Carnegie Mellon University, USA

EXTENDED ABSTRACT

Many, if not all, good things come to an end, and consumer products are generally no exception. Consumers frequently deal with not only acquiring goods and services, but also losing access to them for various reasons. Consumers are not indifferent to loss. When anticipating losing access to a desirable item, consumers' motivation to keep it increases when the loss becomes closer (Kurtz 2008; Shu and Gneezy 2010; Worchel, Lee, and Adewole 1975).

In the current research, we explore the anticipated and actual trajectory of the desire for a good to which one has already lost access. How much will one crave another few days on the beach, for example, a week after returning to work? Is the longing that one anticipates realized, or does the desire to lie in the sun quickly fade when it is replaced by the glow of the computer monitor?

Study 1 examined NFL fans' desire to watch more NFL football games after the end of the 2011 season. The Monday after SuperBowl 46, forecasters reported their desire to watch another NFL football game on that day, and predicted their desire to watch another NFL football game on the subsequent three Mondays. Experiencers reported their desire to watch another NFL football game on each of those Mondays. Whereas forecasted wanting remained constant across the month, experienced wanting significantly decreased over the course of the month. Reported liking for the NFL, however, did not change.

Study 2 examined consumers desire to consume a food after losing access to it. Experiencers watched a 45-minute video. To whet their appetite, experiencers were allowed to eat M&M's ad libitum during the first 5 minutes of the video. They then lost access to the candy for the remainder of the video. At the end of the video, experiencers indicated how many M&M's they would eat if they could right then. Forecasters predicted their desire for M&M's across the course of the video, and predicted the number of M&M's they would want to eat at its end. Whereas forecasters predicted that their desire for M&M's would remain constant over the course of the video, experiencers' reported wanting for M&M's decreased linearly with time. Experiencers also desired fewer M&M's at the end of the video than forecasters anticipated they would desire.

Study 3 examined which of the two possible accounts of the discrepancy between forecasted and reported wanting explains this difference. An attentional account suggests that wanting requires attentional resources, and thus wanting for a stimulus will decrease when attention is directed toward other experiences; a process that forecasters may not anticipate. A motivated reasoning account suggests that experiencers derogate the option that they cannot have due to their own internal self-justification, but forecasters do not anticipate engaging in motivated reasoning. Whereas the attentional account predicts that the degree to which the subsequent experience consumes attention should determine whether wanting remains constant or decreases, the motivated reasoning account suggests that a change in liking should determine whether wanting remains constant or decreases.

In Study 3, all participants first ate ten M&M's and played Whac-A-Mole on a computer for one minute. As a manipulation of attentional resources, participants were randomly assigned to play one of two versions of Whac-A-Mole that were identical in all aspects except for the level of engagement. Experiencers then lost access to the M&M's and played Whac-A-Mole for 20 minutes and reported their wanting, liking, and the extent to which they were thinking about M&M's over those 20 minutes. Forecasters predicted their wanting, liking, and thoughts about M&M's on the same scales.

The attention manipulation had a significant impact on the actual trajectory of desire for M&M's. Experiencers who played the unengaging game reported a lesser decrease in their desire for M&M's than those who played the engaging game. In contrast, forecasters were insensitive to this manipulation. They predicted that their desire for M&M's would remain constant in both conditions. A mediated moderation model showed that the change in attention allocated to M&M's, rather than the change in liking of M&M's, mediated the change in their wanting.

To conclude, we examine consumers' desire for goods to which they lose access in the domains of sports and food, and find that in contrast to their predictions, desires for those goods decrease due to consumers' allocation of attention to alternative experiences. This research should be of interest to marketers interested in consumption, cravings, and more general processes of motivation.

Forced Transformations and Consumption Practices in Liquid Times

Andres Barrios, Lancaster University, UK and Universidad de los Andes, Colombia
Maria Piacentini, Lancaster University, UK
Laura Salciuviene, Lancaster University, UK

EXTENDED ABSTRACT

Literature Review

Throughout life, consumers experience many changes that can impact on and transform their identities. Some of these changes occur naturally as individuals move through their lives (e.g. becoming an adult), while others are the result of more conscious decisions made by individuals (e.g. getting married). From a consumer behaviour perspective, studies have analyzed the support that possessions and consumption practices offer individuals (functionally and/or emotionally) during these changes that are associated with fairly defined points in consumers' lives (McAlexander, 1991, Ozanne, 1992, Curasi et al., 2004, Schouten, 1991b)

An analysis of consumer behaviour studies examining individuals' transformations highlights the prominence of Van Gennep's model of Rites of Passages as a framework to describe and understand these transitions (see for example Curasi et al., 2004, Ozanne, 1992, Young, 1991, Schouten, 1991a). While these studies have provided useful insights into the consumption practices associated with identity transitions, in our understanding Van Gennep's framework does not reflect the evolution of individuals' identity development and performance. Specifically, the framework is not suitable for situations where transformational outcomes are uncertain and/or forced, i.e. where transformations do not have a clearly defined end-state.

Bauman (2000, 2007) has suggested that society has reached a postmodern ('liquid') era in which the social forms cannot keep their shape for long (Bauman, 2007, p. 1). As a result, there is higher uncertainty surrounding individuals' transformations (McCracken, 2008). Building on Hill's work on individual's experiences of homelessness (Hill and Stamey, 1990, p. 96) and extended periods of poverty (Hill, 2001) as triggers of a reconfiguration of the sense of self, this paper focuses on the homeless experience, in which forced and uncertain changing events disrupt individuals' entire life. In so doing, this paper proposes an alternative framework that takes into account the uncertainty that accompanies forced transformations, and the role of consumption during the transformation pathways.

Method

A phenomenological study was adopted, focussing on the specific events that led informants into a state of homelessness. The study was developed as a two-stage process. First, a twelve-month quasi-ethnographical study (Elliott and Jankel-Elliott, 2003) where the lead author volunteered for a charity that supports homeless individuals. Second, long interviews were conducted and focused on homeless people's *retrospective biographical narratives* about the events that led them into a homeless state. The combined database (16 interviews with homeless individuals, and a research journal of the quasi-ethnography study) was analyzed and interpreted using existential phenomenological procedures (Thompson, 1997, Thompson et al., 1989).

FINDINGS AND CONTRIBUTIONS

The study findings reveal a four-stage process of forced self-transformation that takes place across two stressful situations: the triggering events that led informants to lose their home, and their further survival in a homeless state (Figure 1).

Figure 1. Process of Forced Self-Transformation
Source: the authors

a. Initial self-concept

This initial stage refers to the informants' state before the triggering events occurred. All informants' narratives of their lives before entering the pathway to homelessness reflect them as being relatively stable, comprising multiple identifications that together comprised their dominant initial self-concept.

b. Forced identity negotiation

This stage relates to the reactions individuals had while the triggering events occurred, as well as the changes that their identities went through. According to informants' narratives when the trigger events occurred, they initially believed it was a transient situation. Therefore, and despite the uncertainty that surrounded those moments, their initial reaction was to: a) use their remaining economic and social resources (e.g. savings, friends, family) to avoid losing their home, and b) manage the meaning of their possessions to continue performing their identities (Black, 2011).

However, informants realized their homeless situation was not transient and this created a major identity continuity disruption. Informants' narratives reflect a forced identity negotiation processes associated with the identities they wanted to perform and ones they could actually perform. This in turn was related to the props (i.e. possessions and/or practices) they had to support those identities including: the meaning of the remaining possessions, how they supported their identities, and what they could do with them in their current situation.

c. Transition

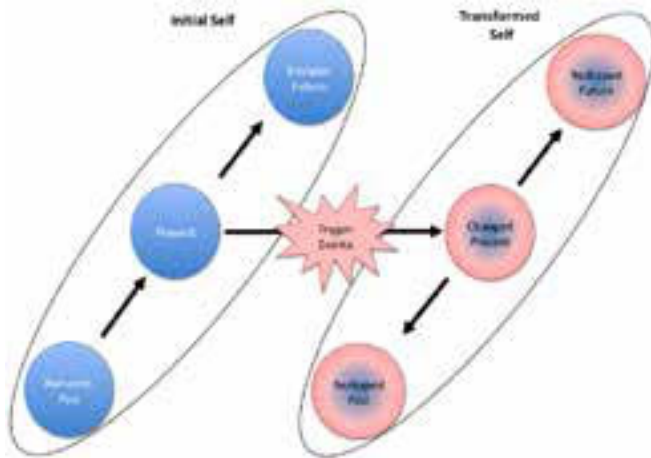
This stage relates to the individuals' confrontation with the consequences of the triggering events. Individuals realized that homelessness was an enduring state and the props they had imagined would assist them to cope with their situation were no longer reliable or available. Their narratives reflect they entered in a transitional state, in which they felt grief for their past; doubts about who they were at that time; and uncertainty about what they would become in the future. In order to cope with the situation, individuals' activities focused on their day-to-day survival including: where to find food (e.g. scavenging), how to obtain money (e.g. begging) and where to spend the night (e.g. sleeping on benches).

Authors have highlighted how consumption activities and possessions help individuals address the ambiguity during transitional times (Noble and Walker, 1997, Fischer and Gainer, 1993, Banister and Piacentini, 2008, Schouten, 1991b). In this specific context, informants relied on different adaptive strategies that helped them to relieve their anxiety. These strategies include compulsive consump-

tion behaviours and/or certain routines that help informants to escape from their current conditions (e.g. walking, reading, drinking).

d. Self-concept transformation

This stage relates to the individuals' reinvention of their self-concept, based on their past experience and their current situation. The informants' narratives reveal how their experience on the streets, and the consumption practices they were forced to perform to survive, helped them to develop new identities. Individuals experience tensions between their past and present self, whose solution can be characterized using Ahuvia's (2005) synthesizing strategy. Both new identities and previous ones evolved, forcing individuals to reinterpret their past, present, and envision lives based on their homelessness experience (Figure 2).

Figure 2. Effect of the trigger event as reflected through informants' past and present narratives


Source: the authors

CONCLUSION

Our study describes the forced self-transformation process individuals experience in their pathway to homelessness. This process represents a framework to facilitate the navigation of this type of transformation and to understand how at times of uncertain life changes consumption practices become key elements in individuals' self-development. Consumption practices served initially as symbols during the forced identity negotiation process. Subsequently, and although these practices did not emerge as identity-laden (day to day survival), they became with time the source for constructing a new self.

Dispositional Greed: Scale Development and Validation

Goedele Krekels, Ghent University, Belgium
Mario Pandelaere, Ghent University, Belgium
Bert Weijters, Vlerick Leuven Gent Management School, Belgium

EXTENDED ABSTRACT

Greed is often invoked to explain non-cooperative behavior in economic games (Stanley & Ume, 1998), resource exploitation (Ludwig et al, 1993) and is considered intrinsic to a materialistic lifestyle (Belk, 1985). Despite this view of greed as a fundamental motive for behavior, no empirical research has investigated individual differences in greed. The current paper aims to contribute by developing a dispositional greed scale.

In layman's terms, greed is commonly defined as "the excessive desire to accumulate more than one needs or deserves". However, this definition is not value-free and uses an external perspective. In academic research greed has been used in varied contexts, from anthropological to psycho-analytical research, leading to a diverse array of definitions. What is important to note is that in many definitions of greed, a key aspect is insatiability: no amount of a given commodity is ever sufficient. Similar to greed, insatiability is more likely to be observed for goals for which no satiation can occur and with no natural upper bound. Hence, the best starting point for this scale development was to equate greed with insatiability. An advantage of such a definition is that it might broaden the contexts as it is applicable to non-monetary outcomes as well.

1. SCALE DEVELOPMENT STUDIES

Based on literature and focus groups, an initial item pool of 60 items was generated. In the first study these greed items were administered to 318 Caucasian Americans (144 males, M age = 44.5, SD = 12.4). An EFA was conducted for trimming and retaining items for the final scale. Items which violated the standard criteria were eliminated from the factor solution, after which three expert judges reviewed the remaining items (Netemeyer et al, 2003). In this process certain items were deleted and others were reformulated.

To further refine the scale, 211 fully employed US citizens (106 males, M age = 45.6, SD = 11.7) responded to the 25 remaining items. The EFA model pointed at two factors but the second factor existed only of reversed items. Following Marsh (1996), a one factor model with method effect (9 items, 3 reversed, α = .81) was found to be the best fit: the χ^2/Df ratio was 2.84, the CFI was 0.98, the TLI was 0.97, the SRMR was 0.028 and the RMSEA was 0.051.

A third study was conducted using the final 9 items (317 fully employed US citizens; 151 males, M age = 44.8, SD = 11.9). The CFA confirmed the one-factor model. Thus, the final greed scale consists of 9 items (including 3 reversed items), with a Cronbach's Alpha of .87 and explaining 72.1% of variance[1].

To check for nomological validity, the greed scale was correlated with other measures. The highest correlation[2] was observed with Richins and Dawson's (1992) materialism (r = .73), but discriminant validity analysis clearly showed greed to be a different construct (Fornell & Larcker, 1981). The correlation with Belk's (1985) materialism was more moderate (r = .43). Furthermore we found correlations of -.34 with gratitude and of .24 with dispositional envy.

2. VALIDITY STUDIES

The results of a fourth study (185 fully employed US citizens; 89 males, M age = 44.5, SD = 12.3) indicate that dispositional greed might be a reaction to personal and resource insecurity. A greedy disposition might be a way to cope with this insecurity. This suggests that greedy people focus on themselves and their own needs. Moreover they feel entitled to more and are focused on achieving. However, a link with social comparison indicates that greedy people are not entirely self-focused. 9 Behavioral items were also added in the questionnaire. The scale showed a high predictive validity (r = .16 to .56), thereby indicating that dispositional greed predicts behaviors generally considered as greedy.

The last study was distributed to respondents that had previously participated in the third study (184 fully employed US citizens; 91 males, M age = 44.9, SD = 11.8). Test-retest reliability proved to be good: the correlation between both studies (three weeks apart) was .83 and the Spearman-Brown coefficient was .91. Also known group validity was tested. We found that men are more greedy than women, $t(182)$ = 2.71. Furthermore, greed was negatively related to religiosity (r = -.22). Finally, respondents working in financial or management sectors were significantly greedier than those working in agriculture, services or arts, $t(63)$ = 2.98.

As the third study found a high correlation with materialism, further analyses were set up to thoroughly investigate the relation between dispositional greed and materialism. We conducted multiple regression analyses with both constructs as predictors to account for a possible overlap with materialism. These analyses show that the established relation between materialism and uncertainty (measured as childhood insecurity and need for control and power) might be mediated by greed. Further, controlling for materialism, greed is not related to well-being. This implicates materialism as more of a dark trait than greed is. Possibly, this may be explained by the fact that materialism is more strongly related to social comparison than greed is. Also while greed is positively related to need for achievement, materialism is negatively related to it. When looking at the behavioral effects of both constructs, we find materialism to be predictive for behavior towards regulation and dispositional greed to be predictive for behavior towards products. Thus, while materialism is known to be connected to a value system focusing on social status and affluence as shown through conspicuous consumption of luxury, dispositional greed is an inner desire to gain more of all kinds of goals and is less focused on others.

3. DISCUSSION

The current research constructed a 9 item dispositional greed scale. Analyses showed greed to be related yet different from materialism. Future research will examine cultural differences and real-life consequences. More specifically, we will look for moderators between dispositional greed and behavioral greed and experiments will be conducted to see how greed affects consumer and economic decisions.

From Commitment to Detachment:
A Historical Analysis of Gift Advertisements by Department Stores in Japan, 1963-2008

Takeshi Matsui, Hitotsubashi University, Japan
Yuko Minowa, Long Island University, USA
Russell W. Belk, York University, Canada

EXTENDED ABSTRACT

This paper analyzes 1,308 gift related advertisements by Japanese department stores in newspapers collected in every five years from 1963 to 2008. Our goal is to understand the dynamics of the shared meaning of seasonal gifts in Japanese society. In Japan, there is a tradition to send gifts to people to whom one is indebted, such as superiors, clients, matchmakers, parents, and relatives on both summer (*ochūgen*) and winter (*oseibo*) gift occasions. Starting in 1964, Japanese department stores opened temporary "gift centers" in their premises for these seasonal gifts, and they have played a pivotal role in developing and maintaining such gift giving rituals in post war Japanese society (Mitsukoshi Honsha 2005).

Gift giving has been an important research topic within the Consumer Culture Theory tradition (Arnold and Thompson 2005). However, contemporary Japanese gift culture has rarely been explored in spite of its importance in the society, with some exceptions (Ito 2011; Minami 1998; Minowa and Gould 1999; Minowa, Khomenko, and Belk 2011; Rupp 2003). Also, while most of the extant research in consumer research has been at a micro level, there is a paucity of research on commercially constructed representation of gift giving at a macro level. This paper tries to open this line of inquiry.

The advertisements were collected from the *Newspaper Advertisement Small Edition*, which compiles the advertisements by industry published in major newspapers each month. We checked every page of the *Small Editions* from 1963 to 2008, every five years, and collected all the gift related advertisements by department stores. There were 581 *ochūgen* and 522 *oseibo* advertisements. Other gift occasion promoted by department stores include Christmas, Fathers' Day, and Mothers' Day. These advertisements were also compared to examine the distinctiveness of the seasonal gift advertisements.

We also conducted interviews about gift-related marketing with store personnel of the eight major national chain department stores in Tokyo in order to check the plausibility of our interpretations of the advertisements. We asked questions concerning the meaning of gift giving culture for Japanese society over the past fifty years. This helped to place the findings from our analysis of advertising within the broader context of societal change.

Two main findings emerged from our historical analysis. First, there has been a coexistence of Japanese and Western cultural references in the advertisements, regardless of year, although seasonal gift giving is deeply rooted in Japanese culture. The apparent reason is that department stores in Japan have been important gatekeepers introducing Western things to Japanese consumers (Creighton 1992). The items introduced in the advertisements have been both from Japan (e.g., Kikkoman soy sauce) and from the West (e.g., Twinings black tea). Also, the advertisements sometimes use both Japanese and Western cultural elements (e.g., a Japanese woman costumed in *kimono* with pasta and ham).

Second, some of the gift items appearing in the advertisements until the 1970s are durable gifts for adult men, such as socks, underwear, and shirts, which then began to be replaced by nondurable gifts for anybody, such as sweets, coffee, and canned foods. Men's wear was popular due to the economic needs of consumers for such "necessity" gifts during the 60s and 70s. Then there was a resurgence of food items as dominant seasonal gifts, while food has generally been regarded as the important gift item throughout Japan's history (Ito 2011). The change may imply that the symbolic meaning of the seasonal gift giving ritual has shifted from commitment to detachment. Sending durables for seasonal gifts requires givers to expend efforts to carefully consider the recipients' needs and tastes because it is possible that the recipients do not like the gifts but cannot abandon them easily as they feel guilty. On the other hand, food gifts are called *kiemono*, defined as "gifts that will disappear after consumption -- such as food, seasonings, detergents, and bathing powder" in Japanese dictionary. *Kiemono* gifts carry a smaller psychological burden than durable gifts for both givers and recipients. If the recipient does not like these things, he or she can give them to somebody else as *osusowake* (sharing with others what has been given) or discard them because they are expected to disappear by virtue of their perishable nature. The decline of communal values as a result of urbanization, the shift of family structures from extended to nuclear, the decline of corporate culture, and the abundance and accumulation of material objects at home contributed to a decrease in the amount of obligatory seasonal gift giving and allowed people to revert to *kiemono* gifts rather than durables. This is strikingly evident in seasonal gift advertisements. The progressive dominance of such *kiemono* gifts is markedly different from other gift giving occasions like Christmas, Mother's Day, Father's day, and Valentine's Day. Our interpretation complements that of Daniels (2001) who interpreted the practicality of consumable gifts in Japan merely due to limited space.

When Hopes are Dashed: Sour Grapes or Searching for Greener Pastures?

Aaron M. Garvey, Pennsylvania State University, USA
Margaret G. Meloy, Pennsylvania State University, USA
Baba Shiv, Stanford University, USA

EXTENDED ABSTRACT

Dashed hopes are powerful experiences in which an overwhelmingly attractive and attainable choice option is dangled in front of a consumer and then yanked away. What impact do dashed hopes have on subsequent preferences? On the one hand, individuals may cling to familiar status quo options (i.e., "sour grapes") as suggested by the robustness of the status quo bias (Knutson et. al. 2008; Samuelson and Zeckhauser 1988) and dissonance research (Festinger and Carlsmith 1959). On the other hand, individuals may abandon the status quo and search for hopeful alternatives (i.e., "searching for greener pastures").

Our research proposes that dashed hopes will lead to abandonment of the status quo under predictable circumstances. Specifically, research examining cognitive hope and outcome-oriented motivation indicates that the denial of a highly desirable outcome may increase pursuit of that outcome (Carver, Sutton, and Scheier 2000; Clee and Wicklund 1980; Fitzsimons 2000; Litt, Khan, and Shiv 2010) and facilitate substitution attempts (Kruglanski et al. 2002; Kruglanski and Jaffe 1998; Snyder 2002; Snyder, Cheavens, and Michael 1999). Moreover, research indicates that individuals may engage in motivated reasoning when hope is threatened (deMello, MacInnis, and Stewart 2007), which may positively bias the interpretation of alternatives to the status quo. Thus, we propose that in the presence of a status quo option, the introduction and subsequent removal of a hoped-for alternative (i.e. a dashed hope) will increase status quo abandonment (H1). Furthermore, this effect will be driven by denigration of the status quo during consideration of the hoped-for option (H2). Finally, motivated reasoning increases when option information consistent with the desired outcome is ambiguous (Mishra, Mishra, and Shiv 2011; Russo, Carlson, and Meloy 2006; Sloman, Fernbach, and Hagmayer 2010). As such, if motivated reasoning underlies the basic effect, abandonment of the status quo due to dashed hopes should increase (decrease) as the ambiguity of alternatives to the status quo option increases (decreases) (H3).

We contribute to the literature by introducing the novel dashed hope effect and explicating its underlying processes. We also provide insights into consumer decision biases. The dashed hope effect is substantively important for a range of consumer-related behaviors (e.g., product launch delays, stock outs, romantic relationships, career management). Four empirical studies provide support for the preceding hypotheses. For brevity, studies 1 and 3 are presented in detail.

Study 1 employed a field setting to determine whether the experience of dashed hopes decreases bias toward a status quo option. H1 was evaluated entirely in the context of real behavior, from endowment and product evaluation, to the experience of dashed hopes, and finally to option selection.

Participants were 43 university staff members. A 2 (Dashed hopes vs. No dashed hopes) x 2 (Status quo: Wine brand A vs. Wine brand B) between subjects design was employed. Volunteers personally evaluated a real bottle of wine (two comparable brands unfamiliar to participants, counterbalanced between dashed hope conditions) with the promise of receiving that bottle of wine upon leaving the building for the day (to establish a status quo option). Later, participants received an email detailing the pick-up location and containing the dashed hopes manipulation; for the dashed hope (control) condition, extra bottles of a fine French chardonnay (wine comparable to the status quo) were to be available. Upon pickup, those in the dashed hopes condition were told that the fine French wine was already gone, and offered the choice between the status quo and a comparable alternative. The control condition simply chose between the status quo and the comparable alternative.

As predicted, selection of the status quo was significantly higher in the control versus the dashed hopes condition (M = 88%; M = 57%; $\chi^2 = 3.87$, p < .05), with no effect of wine brand ($\chi^2 < 1$). These findings are consistent with dashed hopes mitigating the status quo bias, and directly support H1.

Study 2 examined the effect in a second domain (automobiles) and provided insights into the underlying process. Both H1 and H2 were supported.

Study 3 was conducted to evaluate the motivated interpretation of ambiguous information as further evidence of the underlying mechanisms leading to the dashed hopes effect (H3). Specifically, we assess whether abandonment of the status quo is more likely when the ultimate choice set contains an ambiguous (rather than unambiguous) alternative to that status quo.

Participants were 335 undergraduate students in a 2 (Dashed hopes: Present vs. Absent) x 2 (Status quo: Present vs. Absent) x 2 (Option ambiguity: High vs. Low) between subjects design. The choice context involved winning a gift certificate to a fine dining restaurant. A target option was manipulated to be either the status quo or non-status quo (see Sen and Johnson 1997). A choice set of multiple certificates (containing the target option) was then introduced. In the dashed hopes condition, the second option was a world class restaurant; in the non-dashed hopes condition, the second option was comparable to the target option. The second option was then removed for everyone, leading to (not) dashed hopes. In the final choice set, the unambiguous condition described the target option and its alternative in detail, whereas the ambiguous condition described the target option in detail and provided ambiguous information about the alternative. Choice was then recorded.

Binary logistic regression for choice share of the target option revealed the predicted three-way interaction ($\chi^2 = 4.19$, p < .05). Within the ambiguous choice condition, when hopes were not dashed, a significant status quo bias was observed; choice share of the target option was 21% higher when framed as the status quo ($\chi^2 = 5.92$, p < .01). However when hopes were dashed, the status quo bias was non-existent ($\chi^2 = 1.29$, p = .25). For the unambiguous choice condition, a significant status quo bias existed regardless of whether hopes were dashed ($\chi^2 = 12.31$, p < .01). These results directly support H3 and support a process explanation of motivated reasoning for the dashed hopes effect.

Study 4 replicated the overall findings and provided evidence ruling out alternative explanations of anger and simple reactance.

Consumer-Created Advertising:
Does Awareness of Advertising Co-Creation Help or Hurt Persuasion?

Debora Thompson, Georgetown University, USA
Prashant Malaviya, Georgetown University, USA

EXTENDED ABSTRACT

Marketers increasingly are involving consumers to co-create advertising (Moskowitz 2006), presumably because they expect that consumers who were not involved in the co-creation process would find that a message crafted by a fellow consumer resonates with their needs and will respond positively to it. While the message content may well resonate with consumers, what is so far untested is the influence, if any, on message recipients of awareness that a message was created by another consumer. Communicating information about the ad creator to enhance ad effectiveness is a potential opportunity that marketers might be overlooking. In this research, we examine whether knowledge that an ad was created by another consumer affects its persuasiveness.

A priori, it is unclear if awareness that a consumer is the creator of an ad would enhance or undermine ad effectiveness. The literature on source effects suggests that to the extent consumers are perceived as more trustworthy than professional persuaders, disclosing that a target ad is consumer-created should increase message persuasiveness (Wilson and Sherrell 1993). In contrast, regular consumers may be perceived as lacking the skills and expertise needed to create persuasive messages, leading viewers to question the ad's quality and persuasiveness. Consequently, awareness that a consumer created an ad could prompt message counter-argumentation and a decrease in persuasiveness. Across four studies, we examine which of these effects – trust and identification with the ad creator versus questioning of ad creator expertise – is more likely to emerge. In addition, we examine the underlying mechanism and two moderators of the effect: cognitive distraction and source identification.

Study 1 establishes the core effect of awareness that an ad was created by a consumer. One hundred and twenty-five undergraduate students were randomly assigned to a 2 ad creator disclosure (control vs. consumer-created) x 2 ad replicates between subjects design. Participants watched one of two ads for a target product and evaluated the ad and the advertised brand. Before watching the ad, half the participants were informed that the ad they were about to see was created by a consumer. Participants in the control condition were not given any ad creator information. Results reveal a negative effect of disclosing that the ad was consumer-created: Awareness that the ad was created by a consumer lowered ad evaluation ($F(1,114)=4.89$, $p<.05$) and brand evaluation ($F(1,114)=19.27$, $p<.001$), a pattern consistent with heightened skepticism as opposed to trust or identification.

The goal of study 2 was to examine the mechanism by which disclosure of the consumer source may lead to negative responses to the ad and brand. If this negative effect is the result of an effortful judgment correction process prompted by critical thoughts towards the ad creator, the effect should be mitigated when consumers' cognitive resources are constrained (Grant, Malaviya and Sternthal 2004). Findings show that when cognitive resources are unconstrained the outcomes obtained in study 1 are replicated, but under cognitive load, disclosure that a consumer created the ad increased ad evaluation, and mitigated the negative effect on brand evaluation, relative to the control condition. These findings support the notion that the negative response to the disclosure of consumer as ad creator is an effortful process of message correction, which is mitigated or even reserved under distracted viewing conditions.

Studies 3 and 4 explore additional conditions that moderate the negative effect of ad creator disclosure. Both these studies fo-

cus on perceived similarity between the respondent and ad creator, with the expectation that when respondents perceive greater similarity between themselves and the ad creator, they would also perceive greater affiliation, leading to lower skepticism and more favorable ad and brand evaluations. Study 3 manipulates similarity by including a condition where the ad creator was a business-school student. Three hundred and sixteen undergraduate students were randomly assigned to a 3 ad creator (control, consumer-created, student-created) x 2 ad replicate between subjects design. Ad creator information was provided in the same manner as in study 1. The results show that informing respondents that the ad was created by a consumer had no effect on perceived similarity between the ad creator and the respondent, and as in previous studies, decreased ad and brand evaluations. In contrast, informing respondents that the ad creator was a business-school student, increased perceived similarity, enhancing ad ($F(2,304)=18.15$, $p<.0001$) and brand evaluation ($F(2,304)=6.75$, $p<.001$). Analysis of open-ended thoughts suggests that the consumer as ad creator makes viewers more critical of the ad and its content compared to the student as ad creator.

Study 4 examines the effect of perceived similarity with the ad creator via respondents' self-reported brand loyalty. Our expectation was that brand loyal respondents would perceive greater affiliation to the creator of the ad, leading to a positive effect of disclosing the consumer source, whereas low loyalty consumers would show a negative effect of the consumer source. One hundred and twenty-three participants were randomly assigned to a 2 ad creator (control vs. consumer) by 2 (high vs. low loyalty) between subjects ANOVA. Analysis revealed a significant ad creator by brand loyalty interaction for both ad ($F(1, 119)=8.74$, $p<.004$) and brand evaluation ($F(1, 119)=8.43$, $p<.004$). For non-loyal respondents we replicate the negative effect of disclosing ad creator information on ad and brand evaluation, while for loyal respondents, a positive effect of ad creator disclosure is observed.

Taken together, our findings challenge the view that consumer-created ads are processed as word-of-mouth communications from a trustworthy source. Our studies show that (1) awareness that an ad is consumer-created undermines persuasion by triggering a critical mindset towards the ad creator because consumers question the ability of regular consumers to develop effective advertising; (2) the presence of distractions during ad exposure mitigates, and could reverse, this negative effect; and (3) making consumers aware that the ad creator is a member of the same social community (another student) or of the same psychographic community (shared brand loyalty) as the message recipient reverses this effect.

Pictures Versus Words in Changing Implicit Attitudes in Ambush Marketing Disclosure: The Role of Valence of Mental Images

Olivier Trendel, Grenoble Ecole de Management, France
Marc Mazodier, University of South Australia, Australia
Kathleen D. Vohs, University of Minnesota, USA

EXTENDED ABSTRACT

The study of attitude change has for long depended solely on self-reported (explicit) measures of attitudes (i.e. on explicit attitudes). Yet, the development of implicit measures of attitude has challenged the classic view of attitude change that assumes that the old attitude is replaced with a new one (Petty et al., 2006). Implicit measures of attitudes are specialized techniques that rely on respondents' non-declarative responses, instead reflecting particular evaluative associations automatically activated when encountering a relevant stimulus. Because implicit attitudes often diverge from explicit attitudes and because both attitudes independently predict different types of behaviors (Rydell and McConnell, 2006) it is essential to understand the antecedents of both explicit and implicit attitudes change. In this research we compare the effectiveness of counterattitudinal pictures versus text in changing explicit and, more importantly, implicit attitudes in the case of ambush marketing disclosure (a specific case of corrective advertising).

Pictures seem effective to change implicit attitudes (Dasgupta and Greenwald, 2001) and results concerning the impact of textual information on implicit attitude change are mixed (Gregg et al., 2006; Petty et al., 2006; Rydell and McConnell, 2006). Yet, no study directly compares the influence of pictures and text. Dual process models (Gawronski and Bodenhausen, 2006; Sloman, 1996) suggest that explicit attitudes are the result of rule-based processes relying in particular on verbal representations whereas implicit attitudes are the results of associative processes. Moreover, Sloman (1996) suggests that the associative system, hence implicit attitude, should be particularly sensitive to concepts encoded in concrete forms such as concrete images or metaphors (see also the CEST model of Epstein and Pacini, 1999). Therefore, we hypothesize that the relative effectiveness of pictures versus text in changing implicit attitudes resides in the valence of mental images produced by the counterattitudinal information. Concerning explicit attitude change, pictures and text conveying the same information should have the same effectiveness.

We test our hypotheses in the case of ambush marketing, which is the clear intent by a brand to mislead consumers (usually through advertising using event-related elements) into thinking the brand is sponsoring the event (Sandler and Shani, 1989; Meenaghan, 1996). It is perceived as a major threat by event organizers who have therefore undertaken to disclose ambushers to the general public using either press releases or advertisements (Humphreys et al., 2010; International Olympic Committee, 2010).

Because consumers almost never identify ambushers as such (Sandler and Shani, 1989; Meenaghan, 1998), they will form the same often positive attitude toward sponsors and ambushers. We study the change of implicit and explicit attitude toward an ambusher after disclosure of the ambush tactic in the context of the Beijing 2008 Olympics. We specifically compare the effectiveness of disclosure strategies based on text versus pictures.

We conducted 3 pretest-posttest between-subject experiments that used the same underlying procedure. First participants (students) were exposed to pictures of the 2008 Olympic Games and to ads related to this event (including 3 ads for Beifa, the target ambusher brand). The ads for Beifa aimed to deceive participants by giving the impression that Beifa was an Olympic sponsor. Then participants reported their attitudes towards Beifa with an implicit measure based on the Fazio et al. (1986) evaluative priming paradigm and also with a set of rating scales. Next participants were either informed or not about the existence of ambush marketing and about the fact that Beifa was an ambusher. Finally, we measured again implicit and explicit attitude toward Beifa. The different disclosure strategies used were pretested for equivalence in meaning (both explicitly and implicitly using a semantic priming task) and in persuasiveness.

In the first experiment (N=84) with 3 conditions (no disclosure using a neutral article, disclosure with a press article, immediate disclosure at the beginning of the experiment with a press article) we obtained that disclosure using a press article explicitly reporting Beifa's ambush marketing activities, is effective to change explicit attitude toward the ambusher but ineffective to change implicit attitude. This was the case even though respondents had to provide a summary of the article.

In the second experiment (N=70) with 3 conditions (no disclosure, disclosure with 3 drawings, disclosure with 6 drawings) we show that both implicit and explicit attitudes can be changed when drawings (representing the visual parts of rough print ads) are used instead of a press article. Ad copies used brand personification and represented the ambusher stealing money from the IOC. We also obtained that whereas explicit attitude toward the ambusher changed quickly and were not sensitive to the number of ad repetitions (3 versus 6), implicit attitude changed more slowly and decreased from 3 to 6 ad repetitions.

We then performed a pretest (N=113) to identify the characteristics of the mental images that participants had in mind after the different disclosure conditions. We also included a new condition in which we asked participants to visualize Beifa after having read the press article. As expected, valence of mental images differed between disclosure conditions, such as mental images were more negative in the disclosure with drawings conditions and disclosure with news article followed by verbal imagery instruction condition compared to the disclosure with news article condition. All the other characteristics of mental images (e.g. quantity, ease…) did not differ between the disclosure conditions.

In the third experiment ($N=103$) with 4 conditions (no disclosure, disclosure with a press article, disclosure with 6 drawings, disclosure with a press article followed by verbal imagery instructions) we replicate previous findings and, most importantly, found that valence of mental images mediates the relationship between type of disclosure and implicit attitude change but not explicit attitude change (Zhao et al., 2010).

Overall, our results suggest that pictures are superior to text in changing implicit attitudes. Yet textual information that is imagery-provoking can also lead to a change in implicit attitude. These results could explain some of the discrepant findings concerning the effectiveness of textual information in changing implicit attitudes (Gregg et al., 2006).

"I Would Want a Magic Gift":
Desire for Romantic Gift Giving and the Cultural Fantasies of Baby Boomers in Japan

Yuko Minowa, Long Island University, USA
Takeshi Matsui, Hitotsubashi University, Japan
Russell W. Belk, York University, Canada

EXTENDED ABSTRACT

Age and consumer identity are inseparable. Age cohorts, who grow up with the same sociohistorical context, experience the consequences of historical events in similar ways (Jaworski and Sauer 1985). The Baby Boomers in Japan, called *Dankai no Sedai*, or the nodule generation, is defined as the people born from 1947 to 1949. Having grown up in the zeitgeist of the post-war economic miracle, they are often characterized as self-expressive and individualistic consumers (Tsuda 1987). They were the first generation who enjoyed American consumer culture such as blue jeans and rock' n' roll music at a mass level, and were considered as the liberated generation who did not experience the economic problems their parents faced after the World War II (Iwama 1995). Influenced by the Western cultures, some of the Baby Boomers revealed these new values through gift giving practices. They experienced such consumer choice dilemmas for the first time. Among the choices they have faced, we examine their gift-giving behaviors with opposite sex, because identity projects are not atomized but social in nature. As such, gift-giving rituals are considered the appropriate context to understand how they create their identity as women or men through consumption.

In the Consumer Culture Theory tradition (Arnold and Thompson 2005), gift giving has been an important research topic. Most of the prior research has dealt with the North American context (e.g., Belk and Coon 1993; Fischer and Arnold 1990), and Japanese gift culture has not been much explored in spite of its heightened importance in Japan (Minowa and Gould 1999; Rupp 2003). Investigating the gift giving rituals of aging Japanese Baby Boomers is significant for at least three reasons. First, there has not been a study that explored romantic gift giving of aging consumers in Japan. Second, this study investigates the changing meaning of romantic gift giving and the factors that affect changing gift giving orientations throughout the consumer's life. By focusing on the Baby Boomers who have accumulated memories of gift giving over the longer life span, we investigate sociohistorical influences on gift giving practices instead of single gift giving occasions. Third, this study explores whether aging and romanticism are considered incompatible in Japan, because older people's roles are often focused on being grandparents (Kinly and Sivils 2000).

Based on depth interviews with 30 Baby Boom participants, we generated narratives about their experiences of romantic gift giving, gender socialization, memorable gift giving from their youth, and the zeitgeist of historical moments shared by their cohort. All participants were residents of Metropolitan Tokyo. They consisted of 15 males and 15 females, ranging in age from 60 to 65. Occupations varied from a retired former office worker to a taxi driver, a business owner, a college student, and housewives. We also conducted depth interviews with the eight Baby Boom Jr., (age from 37 to 40, four males), and with eight teens (17 and 18 years old, four males) to shed light on the Baby Boomer cohort's characteristics. Interviews lasted between 60 and 75 minutes. The analysis of the verbatim interview transcripts involved an iterative strategy (Spiggle 1994). Repeated ideas and similarities across the transcripts were analyzed by the research team. We developed a holistic understanding that yielded two factors affecting the gift giving orientations of the informants, resulting in taxonomy of four gift orientation types.

Gift giving orientations were influenced by the genealogy of gender domination – whether participants are from patriarchal or matriarchal families of origin– and whether they had euphoric or traumatic gift-giving experience and gender socialization in their youth. A two-by-two cross-classification yielded four types of gift giving orientations: reality adaptor, nostalgia indulger, fantasy seeker, and fantasy avoider (Figure 1). Reality Adapters, who are from matriarchal families who grew up having euphoric gift giving experiences, indicated that they adapt to the changing norms and practices of gift rituals in Japanese society. Nostalgia Indulgers are those from patriarchal families who had euphoric gift giving experiences. Because of the recent post-retirement economic depression, their future prospects are not optimistic and seem to regress toward the past. Fantasy Seekers are those from matriarchal families and who had traumatic socialization experiences. They expressed a strong desire for their dreams to come true through gifts from her romantic partners. Fantasy Avoiders are those from patriarchal families who had traumatic experiences and avoid gift practices that would lead to passionate romantic relationship.

Figure 1: Gift Giving Orientations of Baby Boomers in Japan Genealogy of Gender Domination

	Matrilineal/Matriarchal	Patrilineal/Patriarchal
Euphoric	*Reality Adapter* "My daughter is dry and practical… no gift exchange, but it's her generation." Commensal experience important. Reflection of gender role in gift giving. Similarity of female givers and recipients to mother.	*Nostalgia Indulger* "I would like to have a magic gift… go back to my teens … express my appreciation to the girl who gave me the scarf." Women in the past were virtuous givers.
Traumatic	*Fantasy Seeker* "He remembers everything I say…and makes things into reality [by giving her as gifts]." Giving away gifts is like festival. Materialism emphasized.	*Fantasy Avoider* "I would hate a magic gift." "My father told me not to be obligated to men by not giving them a return gift." Gifts for steady communication. Gives social gifts to multiple men.

(Nature of Gift Experience)

Our study reveals that the intra-cohort variation in romantic gift giving orientations for aging consumers is related to factors beyond historical change. While the fundamental components of romantic love – attraction and attachment - are primarily, panhuman rather than Western emotions, behavioral manifestations of love and emotional expressions are socially cultivated and culturally construed (Jankowiak 2008). As Jaworski and Sauer (1984) argue, cohorts carry the imprint of early socialization forward in time. We found that in regard to romantic gift giving, the socialization factors consist of gender and gift giving socializations. The meanings of romance and romantic gift giving are not static but changing, reflecting transformations in the consumer's life course (Otnes, Zolner, and Lowrey 1994).

Another significant finding from the present study is that intra-cohort variation in gift giving orientations is strongly associated with the genealogy of gender domination of the family in which the consumer grew up. The socially structured nature of family life has a lasting impact on consumption patterns. Japanese consumers from patriarchal families observed their fathers' domination as a reflection of *amae* or emotional dependency. A married woman may allow her husband to behave like *teishu kanpaku*, or "petty tyrant" but

demand that he indulge them with gifts, services, and attention. From these women's perspective, performing as an inferior wife is insulting by today's standards and seems to have left them resentful as manifested in their giving practices. Finally, the conceptual link between romantic gift giving practice and sociohisorically constructed emotions is partly explained by the deployment of cultural fantasies for aging consumers while the meanings of gift giving rituals are renewed and have evolved through the cultural media (Bell 1997).

My LV bag is a Counterfeit:
The Role of Regulatory Focus on Consumer Deceptive Behavior

So Hyun Bae, Nanyang Technological University, Singapore
Sharon Ng, Nanyang Technological University, Singapore

EXTENDED ABSTRACT

Imagine that you are carrying a counterfeit Louis Vuitton bag and you run into someone you know. She starts asking about your bag. Will you tell her that your bag is a counterfeit? Admitting that the bag is a counterfeit would defeat the signaling purpose of using a counterfeit product, but not admitting that the bag is a counterfeit might lead to a potentially embarrassing situation when the deceit is uncovered. This poses a dilemma to most people and prediction of how one would react is far from straight forward.

The consumption of counterfeit luxury brands is a frequently used deceptive strategy to signal status (Van Kempen 2003). People who have a need for status but cannot afford or are not willing to purchase genuine goods are prone to buy counterfeit products (Han, Nunes, and Drèze 2010). However, why are some consumers more likely to admit the truth to others about their counterfeit luxury goods? What situational factors drive consumers to admit or deceive others? On a broader level, how do consumers manage such deceptive behavior? This research aims to address a small slice of this question by examining the impact of regulatory goals and relationship status on consumers' propensity to engage in deceptive behavior.

Regulatory focus theory proposes two systems of self-regulation: a prevention focus that involves security needs, strong oughts and minimizing losses, and a promotion focus that involves nurturance needs, strong ideals and maximizing gains (Higgins 1997). Therefore, prevention-focused people emphasize their obligations and duties to fulfill their needs for security and safety whereas promotion-focused people emphasize hopes and aspirations to fulfill their needs for advancement and gains (Higgins 1997). Furthermore, promotion-focused people are more willing to take risks whereas prevention-focused people are more risk averse (Righetti, Finkenauer, and Rusbult 2011). In this research, we suggest that regulatory focus will interact with relationship status (i.e., in-group vs. out-group) to influence whether consumers will engage in deceptive behavior.

Prior research shows that people have fewer tendencies to engage in deceptive behavior toward in-group members compared to out-group members. According to DePaulo and Kashy (1998), people are less likely to lie in close relationships than in casual relationships for several reasons. First, deceptive behavior undermines close relationship ideals (e.g., openness). Second, since people in close relationships know each other and meet frequently, they may fear that close people will discover the truth more easily (Neziek 1995). Third, people have less confidence about lying to familiar people than to unfamiliar people. Though this is generically true, we argue that promotion and prevention focused consumers will react quite differently to deception to in-group (versus out-group).

Recall from the discussion that prevention-focused people focus on their duties, responsibilities, and ought-self. In the interpersonal context, they should be honest and truthful to their friends because it is an interpersonal duty and obligation. Lying and deceptive behavior is undesirable because it threatens respect and trust, thereby negatively impacting interpersonal relationships (Tyler, Feldman, and Reichert 2006). Therefore, we propose that prevention-focused consumers are likely to admit to their friends (in-group members) that they are using counterfeits in order to fulfill their obligations to their friends. Furthermore, since they are risk averse, they are also less likely to lie to their friends whom know them well and they interact frequently as there is a higher probability that the deceit is uncovered. However, since they do not feel the same duties and obligations to acquaintances (out-group members) and do not interact with them frequently, they are less likely to admit the truth to them.

What about promotion-focused consumers? Since they emphasize achievement and accomplishment, and are generally more willing to take risks to achieve gains, they are less likely to admit the truth, even when there is a chance of their deception being detected by friends. Therefore, regardless whether a target person is a friend or an acquaintance, promotion-focused consumers are less likely to admit the truth. Thus, we propose that prevention-focused consumers are more likely to admit that they are using counterfeit luxury goods to a friend than to an acquaintance, while promotion-focused consumers are less likely to admit regardless of the type of target person. Two studies were conducted to test the hypothesis.

Experiment 1 had a 2(regulatory focus: prevention focus vs. promotion focus) x 2 (target person: friend vs. acquaintance) between-subject design, with 79 female participants. First, regulatory focus was manipulated by using an anagram task. Following this, participants read a scenario whereby a target person (either friend or acquaintance) saw their counterfeit bags and asked them about it. Participants were asked to indicate the extent to which they would admit to the target person that the bag is a counterfeit. Findings showed that prevention-focused consumers were more likely to admit that they were using a counterfeit product to a friend than to an acquaintance. On the other hand, promotion-focused consumers showed no difference in their propensity to admit that the bag was a counterfeit to a friend or an acquaintance.

The design of experiment 2 was similar to that of experiment 1, except that culture was primed instead of regulatory focus. Extensive research (e.g., Lee, Aaker, and Gardner 2000) has shown that people living in Western (independent) cultures are promotion-focused, while people living in Eastern (interdependent) cultures are prevention-focused. To test if the same pattern of results may be obtained using a different form of regulatory focus manipulation, culture was used as a proxy for regulatory focus. The experiment had a 2 (culture priming: US vs. China) x 2 (target person: friend vs. acquaintance) between-subject design, with 79 female participants. Culture was primed by using 12 cultural icons. Experiment 2 found that participants primed by Chinese icons were more likely to admit to a friend than to an acquaintance that the bag was a counterfeit. On the other hand, participants primed by US pictures showed no difference in the likelihood of admission between the friend and acquaintance conditions.

In summary, our two studies demonstrate that regulatory focus is a key factor in understanding consumer deceptive behavior.

Implicit Measures of Motivation: Convergent, Discriminant and Predictive Validity

Alexandra Kraus, Aarhus University, Denmark
Joachim Scholderer, Aarhus University, Denmark

EXTENDED ABSTRACT

The incentive salience theory (Berridge, 1996, 2009; Berridge & Robinson, 1995, 2003) and the differentiation between two neurophysiological separate reward components – motivational wanting (incentive salience of the reward) and evaluative liking (hedonic pleasure associated with the reward) – provides an elegant account for food reward, at least in animal studies. The rather counterintuitive idea that it is sometimes possible to "want" something that is not "liked" or the other way around has inspired many scholars in developing different measures to disentangle both components of food reward in man. Recently, that movement has been criticised as unnecessary and impossible (Havermans, 2011), whereas others replied that it is possible to distinguish both components in human (Finlayson & Dalton, 2012). In the past decade different, rather implicit motivational measures were developed (e.g., Ebstein et al., 2003; Finlayson, King, & Blundell, 2008; Giesen, Havermans, & Jansen, 2010), however, none completely tested under "fair" conditions (i.e., stimuli that do not evoke different social desirability; implicit measures for wanting and liking components).

The aim of this research was to develop and validate implicit measures of motivation that could meet that criticism and that could finally be used as valid measures in consumer research. Therefore, we started out with two existing implicit measures – the implicit association test (IAT; Greenwald, McGhee, & Schwartz, 1998) and a recent published procedural variation, the recoding free IAT (IAT-RF; Rothermund, Teige-Mocigemba, Gast, & Wentura, 2009). The latter test is argued to prevent recoding strategies of the IAT; however, its predictive validity has only been examined in one further study (Houben, Rothermund, & Wiers, 2009). Both paradigms were originally designed to measure the relative strength of associations between two evaluative (e.g., positive, negative) and two target concepts (e.g., two products) to finally asses implicit attitudes. In order to develop measures of implicit motivation both paradigms needed slight modifications. Hence, the two opposing evaluative concepts were replaced with two motivational tendencies (approach, avoidance) and consequently both implicit motivation tests shall be named M-IAT and M-IAT-RF to address this modification. Furthermore, two target products were chosen that would create strong preferences but that would not evoke biases through social desirability or self presentation. Therefore, we decided on wine gum and liquorice – both belonging to the same product category, are equally unhealthy, sized, priced, and nevertheless, only differ in sensory dimensions. The final four concepts were represented by verbal and visual stimuli and reaction-times were recorded as dependent variables. Three studies were conducted.

The aim of Study 1 was to test and validate both measures, whereas Study 2 focused specifically on the discriminant validity of motivational versus evaluative versions of both paradigms. The M-IAT-RF was further validated with different stimuli material in Study 3. All three studies included explicit measures of wanting and liking (visual analogue scales) and a relative behavioural preference was measured as a predictive validation criterion. In Study 1 and 3 this was based on unobtrusive observation of the amount of target products consumed during the session. In Study 2 it was based on simple choices of the two products.

Study 1. 132 native Danish speakers were tested in a two-group between-subjects design (M-IAT vs. M-IAT-RF) with random alloca-

tion. The experimental sessions were divided into three parts: first a pre-test (paper-pencil), then the computer-based implicit motivation test (either M-IAT or M-IAT-RF), and finally a post-test (paper-pencil). All experimental sessions were held individually. Difference scores were calculated from reaction-times in the same way as is usually done in IAT studies (Greenwald et al., 1998; Greenwald, Nosek, & Banaji, 2003). In addition, a latent-difference bifactor model was fitted to the log-transformed, error-corrected reaction-times to obtain a more stringent psychometric representation of the measures. The model was a refined version of the model used by Blanton, Jaccard, Gonzales, and Christie (2006), separating the latent true difference in implicit motivation from common method-variance. The model-fit was excellent for both implicit tests. The M-IAT-RF was highly predictive of behaviour (D-score: $r = .32$; latent-true-difference: $\beta = .58$) and showed strong convergent validity with explicit measures of wanting (D-score: $r = .29$; latent-true-difference: $\beta = .54$). Furthermore, its discriminant validity with explicit measures of liking was satisfactory (D-score: $r = .19$; latent-true-difference: $\beta = .37$). In comparison, the M-IAT was also strongly related to explicit measures of wanting (D-score: $r = .50$; latent-true-difference: $\beta = .53$) but only weakly related to behaviour (D-score: $r = .24$; latent-true-difference: $\beta = .26$). Its discriminant validity with respect to explicit measures of liking was only partially satisfactory (D-score: $r = .48$; latent-true-difference: $\beta = .50$).

Study 2. To test the discriminant validity of implicit measures of motivation (M-IAT and M-IAT-RF) versus implicit measures of evaluation (E-IAT and E-IAT-RF that are commonly used in attitude research), a two-group between-subjects design with random allocation was used. Participants ($N = 181$) either completed two IATs (M-IAT and E-IAT) or two IAT-RFs, respectively. Test order was counterbalanced between subjects. The discriminant validity of the IAT-RF procedures was excellent. The D-score calculated from the M-IAT-RF did not correlate significantly with the D-score calculated from the E-IAT-RF ($r = .23$, *n.s.*). Furthermore, the M-IAT-RF was predictive of behaviour (D-score: $r = .28$; latent-true-difference: $\beta = .70$) whereas the E-IAT-RF was less (D-score: $r = .26$; latent-true-difference: $\beta = .47$). In comparison, the discriminant validity of the IAT procedures was less satisfactory ($r = .40$, $p < .01$) and both IATs were also not predictive of behaviour.

Study 3. To further validate the M-IAT-RF different stimulus material was applied in Study 3 ($N = 40$): wine gum and liquorice were replaced by broader concepts of fruit and chocolate and the behavioural criterion was based on the consumed amount of offered fruit (pieces of banana, apple, and grapes) and chocolate (milk, dark, and hazelnut). Corroborating the result of Study 1 and 2, the M-IAT-RF procedure was highly predictive of behaviour, and showed strong convergent as well as satisfying discriminant validities.

Taken together, it is possible to develop implicit measures of motivation with convergent validities that were as high as those commonly found for implicit measures of evaluation (for a meta-analysis, see Greenwald et al., 2009) and excellent psychometric characteristics. Remarkable, the recently published and slightly modified M-IAT-RF was always superior to the M-IAT, with high predictive validities and clearly distinguishable from implicit measures of evaluation.

Exposure to Food Temptation Improves
Children's Resistance to Similar Food Temptations

Aiste Grubliauskiene, KU Leuven, Belgium
Siegfried Dewitte, KU Leuven, Belgium
Luk Warlop, KU Leuven, Belgium and BI Norwegian Business School, Norway

EXTENDED ABSTRACT

If sweets are present at home, do people consume more of them? The intuitive answer is yes (Chandon and Wansink 2002; Painter, Wansink, and Hieggelke 2002). This expectation is even stronger for children because they are thought to lack elaborative self-regulation strategies and may have not yet developed a clear long-term goal (Mischel and Underwood 1974). We will show, however, how pre-exposure to food temptation actually decreases the consumption of attractive but unhealthy products in children. Being exposed to food temptation without consuming it has been already shown to reduce adults' desire and consumption in a subsequent tempting situation (Dewitte, Bruyneel, and Geyskens 2009; Geyskens, Dewitte, Pandelaere, and Warlop 2008). So far, there has been little research into the effect of pre-exposure in children. Demonstrating the pre-exposure effect in children would suggest that self-control strategies during the exposure are more basic. It also would have important implications for theories on the emergence of self-regulation (e.g. Egan, Santos, and Bloom 2007) and for public policy, which often assumes that restricting access to unhealthy food is the best way to curb obesogenic consumption (Wardle 1990).

So far, conflicting results have been revealed regarding exposure to temptation. Earlier studies (Mischel, Ebbesen, and Zeiss 1972; Mischel and Ebbesen 1970) have demonstrated that food temptation availability reduces self-control in children by decreasing their willingness to wait for a larger reward. More recent findings suggest that self-control improves when a temptation is present (Myrseth, Fishbach, and Trope 2009; Zhang, Huang, and Broniarczyk 2009). A possible explanation for this might be that when exposed to a temptation, people (at least adults) feel conflict and invest efforts to resist a temptation. Another possible explanation for self-control enhancement is that a temptation may be perceived in a different way. A symbolic mode of presentation encouraged children to think more about cognitive rather than affective qualities (Metcalfe and Mischel 1999) and thus facilitated self-control by increasing children's willingness to wait (Mischel and Moore 1973).

Obviously, the way temptation is constructed in the mind influences self-control (Mischel and Moore 1973). After pre-exposure to temptation in a situation where consumption is not appropriate, people seem to activate their self-control operations and facilitate the repetition of these operations when another similar tempting opportunity is present. In one study, after being exposed to a sweet temptation, people reduced the importance of sweetness (Grubliauskiene, Dewitte, and Warlop, in prep.). Thus re-construction of essential temptation dimensions may support the subsequent resistance to temptation. These self-control strategies are less likely in young children. Aiming to resist a temptation, 7 – 11 year old children have been shown to employ simple distraction strategies, such as covering their eyes, but they still do not use cognitive distractions that transform a temptation (Demetriou 2000). Lack of cognitive skills should not prevent successful self-control after pre-exposure if self-control processes are rather simple and automatic. Indeed, it has been shown that pairing positive pictures with a no-go task lowers picture evaluations (Veling, Holland, and Knippenberg 2008). Even 4-year-olds decrease preferences for an unchosen option (Egan et al. 2007). This paper attempts to show that children, while still lacking sophisticated self-regulation skills, are able to automatically change the meaning of products and thus resist a temptation after pre-exposure to it.

In two experiments, we exposed participants to temptation in two successive phases. We manipulated the availability of the temptation (physical or symbolic or not available) during pre-exposure in the first phase. To ensure a self-control conflict, children had to construct a flower from candy (physical pre-exposure condition) or construct a flower from Lego® bricks while a photo with a child happily eating chocolate was present (symbolic pre-exposure condition). In the control condition, children had to construct a flower from Lego® bricks. The second task differed across studies. In Study 1, children (7 – 11) tasted a different type of candy for evaluation, and the quantity consumed served as a measure of children's self-control. In Study 2, children (7 – 8) had a choice between a healthy product (strawberry) and an unhealthy product (chocolate) that were presented in pictures. We investigated differences in total fixation duration (Sutterlin, Brunner, and Opwis 2008) as a measure of preference.

In Study 1, the effect of gender was marginally significant ($F_{(1, 51)} = 3.26, p < 0.1$) which is common in eating experiments, with boys eating more than girls. As expected, there was an effect of pre-exposure to temptation ($F_{(2, 50)} = 3.42, p < .05$) on candy consumption. Simple effects showed that both physical ($M = 1.02$) and, to a lesser extent, symbolic ($M = 1.05$) temptation reduced the consumption as compared to a control condition ($M = 1.34$). These results show that pre-exposure to temptation enhances self-control in children. Study 2 used eye tracking to explore the preference construction process after pre-exposure effect. Findings from Study 2 suggest that pre-exposure to a temptation affects automatic preference. In the physical and in the symbolically presented temptation conditions, fixation duration on a healthy product was longer ($M = 1.42, M = 1.39$ respectively) than in the control condition ($M = 1.07$, physical: $F_{(1, 69)} = 11.49, p < .05$, symbolic: $F_{(1, 69)} = 7.8, p < .05$). Results suggest that healthy food gains attractiveness after exposure to temptation. There were no significant effects for unhealthy products.

Children's self-control increases after pre-exposure to a real or symbolically presented temptation, thereby replicating findings in adults, and suggesting that this type of self-regulation emerges early on in life. Eye-tracking measures show that pre-exposure to a real or symbolically presented temptation increases the attractiveness of healthy options whereas it does not affect the attractiveness of unhealthy options. This pattern may explain why pre-exposure leads to low vice consumption in pre-exposure condition.

Negative Scope Sensitivity:
The Collapse of Feeling-Based Valuation for Multiple Desirable Objects

Kuangjie Zhang, INSEAD, Singapore
Steven Sweldens, INSEAD, France
Monica Wadhwa, INSEAD, Singapore

EXTENDED ABSTRACT

Dual-process theories have identified two distinct consumers' valuation processes, distinguishing between a feeling-based valuation process and a calculation-based valuation process (Epstein 1994; Hsee and Rottenstreich 2004; Metcalfe and Mischel 1999). A calculation-based valuation process relies on a rational and rule-based assessment of the target products, and displays normal scope sensitivity such that more products are valued more. A feeling-based valuation process, on the other hand, is crucially dependent on consumers' integral affective response towards the products and can be surprisingly insensitive to the scope of appetitive objects. For example, consumers display the same willingness-to-pay for five versus 10 Madonna CDs and donate the same amount to save one versus four panda(s) (Hsee and Rottenstreich 2004), a phenomenon termed *scope insensitivity*.

Extending the scope of this stream of research, we argue that increasing numbers of different desirable objects can ironically reduce consumers' feeling-based valuation for these objects. We derive our conceptualization from research on the role of mental imagery in feelings. Specifically, prior research suggests that consumers' affective responses towards the objects is crucially determined by the concreteness and vividness of mental imagery related to these objects (Metcalfe and Mischel 1999; Pham 2007), which form the basis of consumers' feeling-based valuation. However, mental imagery requires processing resources, which are limited in nature and thereby restrain consumers' ability to form concrete and vivid mental images of multiple different objects simultaneously (MacInnis and Price 1987; Shiv and Huber 2000). Therefore, we propose that the degree of concreteness and vividness of the mental images that consumers can generate deteriorates as the number of different objects increases. This leads to our hypothesis that consumers' feeling-based valuation of multiple different desirable objects can be lower than the feeling-based valuation of a single object from that set, a phenomenon we term as *negative scope sensitivity*.

We examined our negative scope sensitivity hypothesis in five studies. In Study-1, we used an implicit measure (adapted from Custers and Aarts 2005) to assess whether consumers are more motivated and thus work harder to acquire a single desirable reward (vs. two equally desirable rewards). After completing several unrelated questionnaires, participants learned that the experiment was almost over and would be followed by one more task (a mouse-click task). They were further told that subsequent to this last task they would receive a lottery ticket entitling them to win a reward. Half of the participants were told that the reward was a movie ticket (single-reward condition), whereas the other half learnt that the reward was a movie ticket plus a music CD (two-reward condition). The movie ticket and the music CD were pretested to be equally desirable. Participants then completed the mouse-click task, wherein they had to click on the computer screens according to a specified pattern. Our dependent variable was the speed with which participants completed this mouse-click task. Consistent with our hypothesis, participants in the single-reward condition were more motivated and worked significantly faster on the mouse-click task than participants in the two-reward condition, even though the total monetary value of the two rewards is twice as high as the value of the single reward.

In Study-2, we examine whether negative scope sensitivity is indeed restricted to feeling-based valuations and does not occur when consumers engage in a calculation-based valuation process. Specifically, we employed a priming task (Hsee and Rottenstreich 2004) to manipulate consumers' reliance on feelings versus calculation. Subsequently, participants were asked to imagine that a local museum was holding an art exhibition, which featured, among others, one painting (vs. two paintings) from the celebrated artist Salvador Dalí. In the single-painting condition, one of the two paintings (pretested to be equally attractive) was randomly chosen and displayed, whereas in the two-painting condition, both paintings were displayed. Our results show that participants who were primed to rely on feelings (vs. calculation) reported higher intention and greater willingness-to-pay for attending the exhibition that featured only one painting (vs. two paintings). However, we observed an opposite effect for participants who were primed to rely on calculation.

Further, prior research suggests that consumers are more likely to use mental imagery to "see how it feels" when they have a hedonic consumption goal rather than a utilitarian consumption goal (Pham 1998). This logic formed the basis of Study-3. Employing the art exhibition scenario in the previous study, we manipulated the consumption goal by asking participants to imagine they wanted to enjoy themselves after a week of hard work (hedonic goal) or they wanted to enrich their knowledge of art history (utilitarian goal). We show that participants with a hedonic (vs. utilitarian) consumption goal reported higher intention and greater willingness-to-pay for attending the exhibition that featured only one painting (vs. two paintings).

In the next two studies, we provide direct support for the role of mental imagery in negative scope sensitivity. Specifically, we argue that consumers who have a greater reliance on mental imagery are more likely to exhibit negative scope sensitivity. In Study-4, we examine the individual differences related to the reliance on mental imagery. Participants first evaluated a vacation package highlighting either one or two appealing vacation experience(s). In the single-vacation-experience condition, the vacation package featured either a picture of snorkeling in the tropical seascapes or a picture of a beautiful ancient temple; whereas in the two-vacation-experience condition, both pictures were featured in the vacation package. Next, participants responded to a Style-of-Processing Scale (Childers, Houston, and Heckler 1985), which distinguishes between individuals with a disposition to construct mental images when processing information (visualizers) and individuals with a disposition to process information semantically without forming images (verbalizers). We show that participants reported higher willingness-to-pay for the vacation package featuring only one vacation experience (vs. two vacation experiences). More importantly, this effect was only observed for visualizers but not for verbalizers.

In Study-5 we directly manipulate the reliance on mental imagery and show that participants who were encouraged to rely on mental imagery reported higher willingness-to-pay for the vacation package featuring only one vacation experience (vs. two vacation experiences). However, this effect disappeared when participants were discouraged from using mental imagery.

In summary, our findings demonstrate that consumers' feeling-based valuation can exhibit negative scope sensitivity, according to

which the valuation of a set of multiple different desirable objects can ironically be lower than the valuation of a single object from that set. We discuss the theoretical and practical importance of our findings.

A Penny Saved is Another Penny Spurned
The Effect of Promotions on Consumer Impatience

Franklin Shaddy, Columbia University, USA
Leonard Lee, Columbia University, USA

EXTENDED ABSTRACT

Consumers enjoy receiving discounts, and retailers frequently appeal to their desire to save money by offering promotions. The present work investigates a potential consequence of exposure to promotions: impatience. Specifically, we propose that promotions heighten consumers' desire for rewards (Wadhwa, Shiv, and Nowlis 2008); such a reward-seeking tendency in turn generates the desire for instant gratification and thus, impatience (Li 2008). Consequently, promotions increase impatience in consumers such that they are both more willing to spend money to avoid waiting and less willing to wait to obtain additional money.

Our proposed account for the impatience consequence of promotions, based on the reward-seeking mindset that promotions trigger, suggests that people with higher predisposed sensitivity toward reward cues should react more intensely to promotions, which possess high incentive value (Chandon, Wansink, and Laurent 2000). In particular, one relevant measure is the behavioral activation system (BAS) scale, which has been linked to affective response tendencies for impending rewards (Carver and White 1994; Gray 1994). We therefore expect any relationship between promotions and impatience to be moderated by BAS sensitivity; that is, the effect should be stronger for people who are high, rather than low, on the BAS scale.

In **Experiment 1**, we tested whether exposure to promotions yields greater impatience by examining willingness-to-pay (WTP) to avoid waiting. We employed a single-factor (prime: *promotions* or *control*) between-subjects design with 72 participants from a national online pool. Participants were first asked to evaluate a poster, which displayed a collection of common products for sale (e.g., candy, chips, gum, etc.), according to several criteria (e.g., products, prices, informational content, etc.). While both posters included the names, prices, and images of the same set of 10 products, participants in the *promotions* condition were also shown the regular undiscounted prices alongside each product; this additional information increased the salience of the price discounts. Next, in a purportedly unrelated follow-up questionnaire, all participants answered a series of questions in response to a hypothetical scenario describing an opportunity to avoid a wait time by paying more (Leclerc, Schmitt, and Dube 1995). Specifically, participants were asked to imagine that while waiting for a bus, they could save waiting time if they were willing to pay extra money. Participants were then asked how much money they were willing to spend to avoid wait times of 30, 60, and 90 minutes, respectively.

Consistent with our hypothesis, higher WTP values for participants in the *promotions* condition were observed. An analysis of variance (ANOVA) revealed a significant main effect of the poster version on overall WTP to save time ($p = .012$). WTP was higher in the *promotions* condition than the *control* condition at each of the 30-minute wait time increments ($p = .023$, $p = .005$, and $p = .038$, respectively).

The next experiment was designed to test the hypothesized reward-seeking account for the observed effect in Experiment 1. Based on this account, while exposure to promotions might generate impatience and induce greater WTP in order to avoid waiting, the relationship between promotions and impatience may also vary by BAS sensitivity, given the high incentive value of promotions (Chandon et al. 2000). Therefore, in **Experiment 2**, besides attempting to conceptually replicate the results in Experiment 1 by utilizing a more subtle experimental manipulation and a different measure for impatience, we also captured BAS sensitivity to assess its moderating effect on the causal relationship between promotions and impatience.

Ninety-three participants from a national online pool were randomly assigned to either a *promotions* or *control* condition. All participants were then instructed to evaluate the technical qualities (composition and lighting) of each of 15 photographs. Those in the *promotions* condition were shown 10 photographs that included signs or labels with promotions-related messages (e.g., discounted prices, limited-time offers, clearance sales, etc.), in addition to five other filler photographs, while *control* participants were shown 10 photographs that included signs or labels with non-promotions-related messages (e.g., biking directions, subway station name, bookshelf filing number, etc.) and the same five fillers. Next, in a purportedly unrelated follow-up questionnaire, participants were asked to make eight binary choices between a smaller-sooner and a larger-later payoff (e.g., $10 tomorrow vs. $12 in 25 days), which were used to measure impatience (Li 2008). Finally, all participants completed the BAS questionnaire (Carver and White 1994), which presented 13 statements (e.g., "When I see something I want, I usually go all out to get it"; "When I go after something, I use a 'no holds barred' approach") assessed on four-point scales anchored by "strongly disagree" and "strongly agree."

Random-effects logistic regression revealed that the difference in the choice outcome (smaller-sooner vs. larger-later) between the two conditions was, indeed, moderated by BAS sensitivity ($p = .037$). Consistent with our prediction, participants with higher BAS sensitivity selected more smaller-sooner payoffs in the *promotions* condition, as compared to those in the *control* condition.

Our work contributes new insights to the literature on the psychological effects of promotions. While promotions provide numerous immediate monetary and nonmonetary benefits for consumers (Chandon et al. 2000), an important consequence of promotions that may undermine longer-term consumer welfare is the impatience that exposure to promotions can generate. More broadly, despite the existence of much prior work that has cast doubt on the adage "time is money" (e.g., Leclerc et al. 1995; Zauberman and Lynch 2005), our findings suggest that consumers' valuation of time can be implicitly influenced by a pervasive monetary factor (i.e., price promotions). Paradoxically, although consumers seek out and take advantage of promotions as opportunities to save money, exposure to promotions may "backfire" such that consumers are worse off financially. In other words, the bargain itself may be more than consumers bargain for. (940 words)

The Role of Personal Relevance in the Effect of Ad Repetition on Attitudes and Choice

Ann Kronrod, MIT, USA
Joel Huber, Duke University, USA

EXTENDED ABSTRACT

The most common reason for an ad that is frequently repeated to become annoying is that ads are not an integral part of the audience's activities, and more specifically, of the audience's communicational activity (e.g. *Edwards, Li* and *Lee* 2002). This may also reduce evaluations of the advertised brand (Wang and Calder 2006). But not in all situations is ad repetition irritating to the same extent. Aaker and Bruzzone (1985) found that the most irritating ads were those that featured women's hygiene products or underwear, and hemorrhoid/laxative products, while the least irritating categories were shampoo, snacks, and cold remedies. This finding can be explained in terms of personal relevance: Women's products are relevant only to the female part of the sample, and so the male part of the sample finds them irritating. By contrast, snacks, shampoo and cold remedies are relatively often consumed by both men and women, and therefore are much more relevant to the sample as a whole. Taking a communicational approach, we define an advertisement as a conversational element in the communication between advertiser and consumer. Grice's Cooperativeness Principle (1975) assumes that, being cooperative, the speaker makes an effort to be relevant, and the addressee assumes the speaker does so. When an ad interferes with a consumer's activity, a non-cooperative mode of conversation may emerge between the consumer and the advertiser, generating justified annoyance. However, when faced with a need to make a consumption choice, the consumer's attitude towards the ad changes if the ad is relevant to the decision. The consumer becomes a cooperative conversation partner and also sees the ad as such. Consequently the ad is no longer annoying and the same attributes which were deemed annoying when no choice was to be made, not only cease to be irritating but also come to be seen as conversationally contributing. Based on this logic we suggest that personal relevance of a product moderates the effect of ad repetition, such that when a product is irrelevant, repetition causes irritation, but when a product is relevant, the otherwise annoying effect of repetition turns into familiarity and liking and results in higher choice of products that are more frequently advertised.

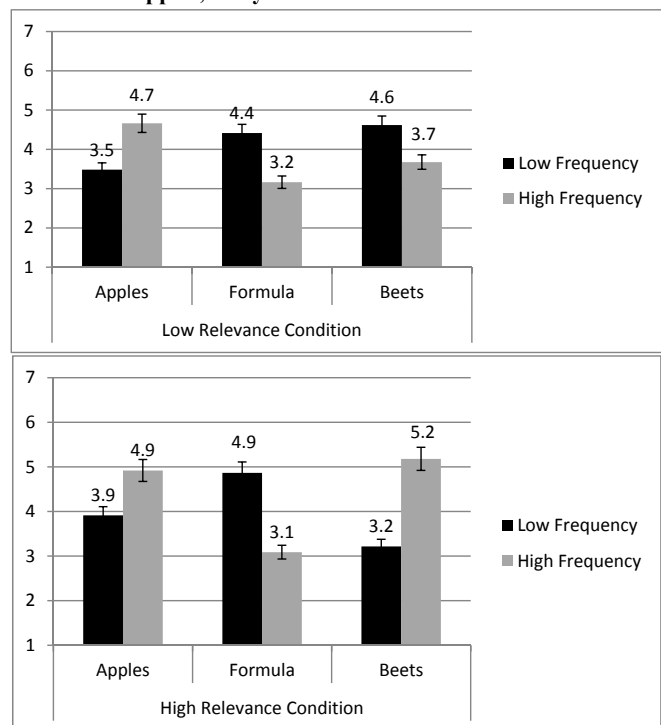
METHOD

We tested our hypothesis in two experiments. Three products, pretested for personal relevance and familiarity, were used: Apples (high in both personal relevance and familiarity), baby formula (low in personal relevance and high in familiarity), and beets (moderate in personal relevance and low in familiarity). Two fictional ads were prepared for each product, resulting in six ads. Ad repetition rate was manipulated, for each product, by making one of the ads pop up frequently (7 times) and the other one infrequently (3 times) during an article reading task.

STUDY 1

In Study 1, participants read an online article while ads repeatedly popped up. Personal relevance of the ads was manipulated within subject (all participants were exposed to ads for apples (personally relevant) and baby formula (personally irrelevant)) and between subjects (the personal relevance of beets, which was ambiguous due to its low level of familiarity, was manipulated between subjects by warning half of the participants that they will have to choose a brand of beets to prepare "*the famous Russian Svekolnik Soup, which is mainly made of beets*"). After reading the article with the popping

ads, participants reported their annoyance with as well as their preferences for the six fictitious brands. The results showed that for irrelevant products (baby formula and the low relevance condition of beets), the brands with frequently repeating ads were deemed more annoying (M=4.7) as well as less preferable (M=1.4) than the brands with infrequently repeating ads. However, this result flipped for relevant products (apples and the high relevance condition of beets): In this case, brands that were frequently repeated were less annoying (M=3.7), and participants preferred them more in a choice task (M=1.8, F(1,78)=18.6,p<.001). See figure 1 below.

Figure 1: The Moderating Effect of Relevance on Positive Attitudes towards high and low frequency repetition of Ads for Apples, Baby Formula and Beets brands


STUDY 2

Using the same stimuli, in Study 2 we manipulated relevance within subjects in a two-stage experiment, with a three-week interval between the stages. In stage 1, all participants read an article while being exposed to the six ads with varying frequencies, and expressed their attitudes toward the six brands. The relevance manipulation came three weeks later, in stage 2. Half of the participants read an introduction inviting them to **a Russian Folklore Party, to which they were asked to bring a Russian dish.** They also saw a picture and a short recipe for the famous **Russian "Svekolnik" Soup.** Participants then had to choose one of the brands of beets they had seen in Stage 1. Following this they answered recall and attitudinal questions regarding all six products. The results showed that whereas in the first stage the beets brand that had been frequently repeated led to higher annoyance (M=4.64) than the infrequent beets ad (M=3.25), on Stage 2, choices of the same brand depended on the relevance manipulation. Namely, participants who did not read the invitation

indicated lower choice of the more frequently advertised brand, consistent with their indications of annoyance regarding these brands in the first stage. However, participants exposed to the Russian folklore party invitation chose more the brand that had been more frequently advertised in stage 1 (Chi^2=11.8,p<.03), that is, the same brand for which they had indicated higher annoyance in Stage 1.

Our results are consistent with research showing that it matters little if consumers instantly like or dislike an ad (Henderson 2007). One past pundit accurately phrased it: "It doesn't matter what they say about you in the press, as long as they spell your name right." The current work presents a new way of looking at advertising as a conversation: An ad is annoying when it violates the conversational norm of relevance, but when it becomes pertinent to consumer needs, attitudes, or intentions, it becomes a piece of fruitful conversation between the consumer and the marketer.

Is Extremeness Aversion Driven by Loss Aversion?
Contrasting Reference-Point Models of Durable Product Choice

Nico Neumann, University of New South Wales, Australia
Ashish Sinha, University of New South Wales, Australia
Ulf Böckenholt, Northwestern University, USA

EXTENDED ABSTRACT

Prospect theory, which introduced the notions of loss aversion and reference-dependent choice (Kahneman and Tversky 1979; Tversky and Kahneman 1991), has gained wide acceptance among scholars in marketing, psychology, management science, and economics. However, as Bell and Lattin (2000, p. 187) note: "it is silent with respect to the origin of the reference points." A great deal of research investigates reference-points in product choice scenarios and finds that the reference point tends to be some adaptive function of past information (Baucells, Weber, and Welfens 2011). However, these findings are almost exclusively based on choice studies of nondurable product categories, such as FMCG-goods (Niedrich et al. 2009) or financial products (Baucells, Weber, and Welfens 2011). In comparison to nondurables, durable products have much longer interpurchase-cycles (Mazumdar, Raj, and Sinha 2005), often coupled with rapid technological progress that makes comparing attribute levels of new alternatives with the previously bought product impractical or impossible. Therefore, we need to understand which reference-point mechanisms appear feasible and most likely in the background of durable product choice.

Furthermore, it is well known that context-effects often influence consumer choice (Bettman, Luce, and Payne 1998). One robust context-effect is extremeness aversion, which refers to the tendency of consumers to avoid products with extreme attribute values, often leading to preference for the middle option(s) in choice sets (Simonson 1989; Simonson and Tversky 1992). Probably the most popular account offered to explain the extremeness aversion phenomenon has been loss aversion: individuals may evaluate the options of a choice set relative to the other options, resulting in the extreme values having the biggest disadvantages (Simonson and Tversky 1992). However, while conclusive in theory, we lack empirical evidence on whether loss aversion actually may cause extremeness aversion.

In this work, we pit various choice models that are based on different underlying reference-point theories against each other to shed light on how consumers form and utilize reference point(s) when choosing from durable products. Within this reference-point analysis framework, we further explore whether framing options as losses and gains accounts for extremeness aversion and whether any potential interplay of loss and extremeness aversion depends on the choice set size. To be able to incorporate individual-specific information, we study choice data from an experimental setting using two durable product categories: laptops and digital cameras. The number of options and positions of extreme products were systematically manipulated to provide a wide range of stimuli for potential loss and extremeness aversion. Following the choice tasks, participants rated the perceived overall quality, the product importance, as well as the individual attribute levels of each presented choice option, using the self-explicated approach (Kivetz, Netzer, and Srinivasan 2004).

Our base model (base) includes only partworth utilities of the attribute levels and product relevance (these variables are part of all models). The base model is benchmarked with various models that include additional parameters to accommodate reference-dependent choice. For instance, the context-dependent reference point model (CRP) employs the mean of the presented options as reference point based on adaptation-level theory (Helson 1964). Evidently, the reference point of the CRP-model varies for each choice set, but is the same for all individuals. In contrast, the expectations model (ERP) uses the same reference point, measured for each individual through the procedure suggested by Janiszewski and Lichtenstein (1999), for all choice sets. The two RP-models are contrasted with a model based on range-frequency theory (Parducci 1965). According to range-frequency theory (RFT), perceptions of stimuli depend on the distance of the range of options and the rank of the option within a set. Thus, the RFT-model represents a multiple reference-points model as RFT implies that consumers compare one option against all options in the contextual set (Niedrich, Sharma, and Wedell 2001).

Finally, we explore extensions of all models (base, RPs and RFT) by additionally including utility components that capture extremeness aversion (models: baseE, CRPE, ERPE, and RFTE). Using hierarchical Bayes, we estimate mixed logit models that allow the impact of context-dependent components (RFT, losses, gains, and extremeness aversion) and other parameters to differ for each individual (Train 2003).

The choice model results indicate that incorporating reference-dependence parameters leads to improvement in both fit and predictive validity, which can be even further increased through the inclusion of extremeness aversion variables. Overall, the CRPE-models outperform the other models for the two tested product categories. These findings suggest that consumers use a single reference point that is adjusted to the presented choice set and stimuli in each choice situation. This reference point mechanism provides strong support for the view that preferences are often constructed rather than recalled (Bettman, Luce, and Payne 1998).

For the CRPE-model, we find significant loss-parameters (taking a classical interpretation of the Bayesian estimates) as well as significant loss aversion for both quality and price for laptops and digital cameras. Moreover, the CRPE-models provide empirical evidence for extremeness aversion, which seems to strongly depend on the size of the assortment: sometimes individuals actually appear to prefer high-end extremes in smaller choice sets according to our data. This is consistent with the notion of the polarization effect that was observed in many choice scenarios involving price-quality trade-offs (Simonson and Tversky 1992). However, when increasing the number of options in the choice sets, we find significant extremeness aversion towards both low- and high-end alternatives. We would like to highlight that these findings on the extremeness aversion patterns were fairly similar across all tested models. This implies that extremeness aversion can be present even when fully accounting for loss aversion (i.e., loss- and gain-framing) and various context mechanisms. We interpret these findings as evidence that loss and extremeness aversion are two independent behavioral phenomena and conclude with a discussion of which other accounts might provide a better explanation of extremeness aversion behavior.

Effects of Set Size, Scarcity, Packaging, and Taste on the Marketing Placebo Effect

EXTENDED ABSTRACT

The marketing placebo effect is defined as *"the influence of consumers' beliefs and expectations, shaped by experiences in their daily lives, on product judgments and services"* (Shiv, Carmon, and Ariely 2005). Shiv, Carmon, and Ariely (2005) demonstrated that consumer expectations mediate the relationship between product beliefs and product efficacy. In three studies, participants consumed an energy drink purported to increase mental acuity followed by a series of word-jumble puzzles. Participants were told either they would be charged $1.89 for the energy drink (i.e., the regular priced condition) or 89 cents (i.e., the discounted priced condition). Not only did participants anticipate that the full priced (vs. discounted priced) energy drink would be more (vs. less) effective, but they also completed more (vs. fewer) puzzles subsequent to consuming the drink.

Participants completed more puzzles because the naïve theory associating price with quality increased nonconscious performance expectancies that the energy drink would improve mental acuity (see Rao and Monroe 1989). Within this stream of research, we investigate how other elements of the marketing mix (beyond price) affect product efficacy. In doing so, we extend theory on the marketing placebo effect and related naïve theories.

STUDY 1: SET SIZE

In a *pilot study*, we manipulated price to replicate the aforementioned marketing placebo effect. This study served to test the stimuli and efficacy measures used in three subsequent experiments. Study 1 investigated the impact of set size on efficacy. It is commonly held that persuasiveness increases as the number of items supporting an argument increases (i.e., the length-implies-strength heuristic; Chaiken, Liberman, and Eagly 1989; Anderson 1967). Given this naïve theory, we hypothesized that a product's efficacy would increase as the number of its positive attributes increases (H1). To test our hypothesis, we experimentally manipulated the number of active ingredients contained in an energy drink and asked participants to consume the beverage before completing a word puzzle (adapted from Shiv et al. 2005). In support of H1, we found that participants randomly assigned to the condition featuring six active ingredients outperformed participants assigned to the condition featuring three active ingredients.

STUDY 2: SCARCITY

Study 2 investigated the impact of product availability on efficacy. According to Cialdini (2009) an item's availability is often used to infer quality or value. This association is so fundamental to human cognition, it is observed in children as young as two (Brehm and Weintraub 1977; Caplan et al. 1991; Cialdini 2009) and for products as diverse as cafeteria food (West 1975), shoes (Tan and Chua 2004), messages (Worchel 1992), wine (van Herpen, Pieters, and Zeelenberg 2009), and cookies (Worciel, Lee, and Adewole 1975). Limited availability rouses interest in a product, increasing the likelihood of either supply- or demand- side inference formation (Kardes 1993; Kardes, Posavac, and Cronley 2004; Kardes et al. 2008; Kruglanski and Webster 1996). Hence, when consumers encounter a scarce product they often attribute its limited availability to inferred demand, which in turn is associated with quality inferences (Parker and Lehmann 2011). Given this naïve theory linking scarcity with increased quality perceptions, we hypothesized that a product's efficacy would increase as its availability decreases (H2). To test our hypothesis, we experimentally manipulated the shelf availability of an energy drink and asked participants to consume the beverage before completing a word puzzle (adapted from Shiv et al. 2005). In support of H2, we found that participants randomly assigned to the limited availability condition outperformed participants in the abundant availability condition.

STUDY 3: TASTE AND PACKAGING

Study 3 investigated the impact of taste and packaging on efficacy. Several studies demonstrate the influence of contextual inputs on subjective consumption experiences of foods and drinks (Lee, Frederick, and Ariely 2006; McClure et al., 2004; Wansink et al., 2000). For example, Raghunathan, Naylor, and Hoyer (2006) found that consumers rated foods labeled "healthy" as worse tasting than foods labeled "unhealthy" and concluded that hedonic pleasures like taste are construed as lacking in virtue compared to objects like health. Moreover, Eccles (2006) suggested that the taste of a cough syrup is likely to influence the occurrence or magnitude of a placebo effect. Consistent with these lines of research, we hypothesized that efficacy would increase as a food item's tastiness decreases (H3). This hypothesis is also consistent with classical conditioning theory. Since the flavor of most medicines is unpleasant (Sharma and Chopra 2010), the repeated association of medicines with unpleasant flavors pairs substandard taste with efficacy expectations.

Similarly, several studies document the influence of product packaging on consumption experiences (Raghubir and Greenleaf 2006). Compared to congruent designs, product designs incongruent with consumer expectations are perceived as more risky (Campbell 1999) and evaluated more negatively (Mandler 1982). Given this naïve theory, we hypothesized that efficacy would increase as a product's packaging typicality increases (H4). To test our hypotheses, we experimentally manipulated the taste and packaging typicality of an energy drink that purportedly relaxed the user and enhanced memory. We asked participants to consume the beverage before completing a memory task. Manipulation checks confirmed that we successfully manipulated taste and packaging typicality. In support of H3, we found that participants randomly assigned to the substandard taste condition outperformed participants assigned to the superior taste condition. Moreover, in support of H4, we found that participants randomly assigned to the typical product packaging condition outperformed participants assigned to the atypical product packaging condition.

In conclusion, this research contributes to the literature by demonstrating that there are unique features beyond price that moderate the marketing placebo effect. Overall, we conclude that any element increasing expectancies of performance should magnify the marketing placebo effect. We have demonstrated that set size, scarcity, packaging, and taste all influence this effect (see table 1). Future researchers can continue to advance our understanding of the marketing placebo effect by exploring additional factors affecting expectan-

cies. This work is vital given the association of product performance with post consumption satisfaction, WOM, brand loyalty, and repeat purchasing behavior (Phillips, Chang Buzzell 1983; Westbrook 1987; Dwyer 1989; Oliver 1993; Day 1994; De Matos et al. 2008).

Table 1: **Performance as a function of expectancies**

Study	Experimental Conditions (N = 400)	
	Low Expectancy	*High Expectancy*
Pilot Study (*n* = 58)		
Price	16.9 (6.2)	22.3 (6.8)
Study 1 (*n* = 58)		
Set Size	20.0 (5.4)	24.4 (7.8)
Study 2 (*n* = 109)		
Scarcity	13.6 (7.12)	16.6 (8.5)
Study 3 (*n* = 175)		
Taste	11.5 (3.0)	13.1 (3.0)
Product Packaging	11.1 (2.6)	13.5 (3.1)

Note: For each row, the means across expectancy conditions differ at the *p* < .05 level. Standard deviations are reported in parentheses.

From the Hands to the Mind: Haptic Brand Signatures

Mathias Streicher, University of Innsbruck, Austria

EXTENDED ABSTRACT

Many consumption situations connect consumers to brands in a physical sense by touch. A famous example is Coca-Cola's contour bottle, which has become the brand's haptic signature and part of consumers' brand knowledge. Here, I address the question of how closely brands are linked to their haptic signatures. In four experiments I show brand-specific knowledge activation from haptic primes with implications for sensory marketing.

Touch is the first sense to develop in the womb presumably providing an early matrix for self-awareness in the absence of the external world (Gallace and Spence 2010) and it is the only proximal sense that connects the percipient directly to the source of experience (Peck 2010). Touch-orientated consumers feel more frustrated and less confident when making product evalu-ations if touch is unavailable (Peck and Childers 2003a) and simply holding products in the hands can promote a sense of psychological ownership (Peck and Shu 2009). While some com-panies already brand haptic sensations very successfully (Lindstrom 2005), research on brand-related touch thus far has received no attention at all, perhaps because the touch sense is still the most underappreciated sense in marketing (Peck and Childers 2007). Previous studies have ad-dressed effects from inter-personal touch (Hornik 1992), touch as chronic need (Peck and Chil-ders 2003b), effects from haptic imagery on psychological owner-ship (Peck and Berger 2009), or cross-modal carry-over effects from nondiagnostic tactile sensations to gustatory judgments of products (Krishna and Morrin 2009).

In the domain of social psychology there is increasing evidence that haptic experience is directly linked to mental concepts in a met-aphorical way such as touching a warm cup activates concepts of social warmth (Williams and Bargh 2008), tactile roughness carries over to the eval-uation of a social interaction (Ackerman, Nocera, and Bargh 2010), or lying in an email increases preference for hand sanitizers to purify the dirty body part (Lee and Schwarz 2010). These mo-dality-specific pathways between haptic sensations and mental concepts suggest a physical-to-mental scaffolding which grist the mills of embodied theorists suggesting higher-order concepts to be ontogenetically scaffolded by concrete bodily experience (Williams, Huang, and Bargh 2009) and grounded in perceptual systems (Barsalou 1999; 2008).

Here, I hypothesize that exposing participants to haptic primes from beverage containers automatically activates the corresponding brand knowledge structures promoting perceptual pro-cessing in other modalities, cognitive accessibility, and prime-congruent brand choices.

To carve out the effects from brand-related haptic input with-out interference from other modalities I conducted four experiments where I exposed participants blindfolded for 1 second under cog-nitive load within an ostensible weight-judging task to beverage containers from dif-ferent brands. Afterwards, they were asked to participate in another unrelated study that was the actual dependent variable. Finally, participants were debriefed whether they had rec-ognized the prime in the weight-judging task to exclude their data if necessary.

In experiment 1 I randomly assigned participants to Coca-Cola glass bottles, Red Bull cans, or a group without treatment followed by an unrelated task that visually presented the tar-get name Red Bull with increasing clarity on a computer screen. Participants were significantly faster to identify the brand name Red Bull if they had been previously exposed to a Red Bull can compared to the other groups (MRedBull = 2.85 sec vs. Munprimed = 3.04 vs. MCoca-Co-la = 3.05; F (2, 111) = 5.244, p = .007; Tukey post hoc p < .05). Ex-periment 2 replicated the results but this time I used the brand name Coca-Cola as visual target and compared Coca-Cola versus Römer-quelle bottles that share basic characteristics such as surface material (glass), container type (bottle), girth, and weight. As expected, the Coca-Cola group was significantly faster to identify the visu-al target Coca-Cola compared to the other groups (MCoca-Cola = 3.09 sec vs. MRömerquelle = 3.27 vs. Munprimed = 3.34; F (2, 177) = 6.294, p = .002; Tukey post-hoc test p < .05). The results show that brand-related haptic sensations automatically increase perceptual fluency cross-modally for the corresponding brand. It seems noteworthy that these effects occurred outside of people's aware-ness. Although the experience of perceptual fluency can influence affective judgments in a posi-tive direction (Reber, Winkielman, and Schwarz 1998) it remains unclear whether this lifts a brand top-of-mind in consumers' consideration set when thinking about brands of a certain prod-uct category.

In experiment 3 I therefore primed participants with either Co-ca-Cola bottles, Römerquelle bottles, or Red Bull cans. In a subse-quent task, I asked them to list brands for the category of beverages. The ANOVA for Red Bull shows that the ratio the brand was listed first (top-of-mind) was significantly higher in the Red Bull condition compared to all other groups (MRedBull = 26% vs. MCoca-Cola = 6% vs. MRömer = 6% vs. Mcontrol = 12 %; F (3, 227) = 5.134, p = .02; Tukey post-hoc p < .05).

Experiment 4 analyzed whether brand-related haptic sensations can actually influence consumption choices. Containers from Coca-Cola, Red Bull, and Römerquelle served as stimuli. After the priming task participants were offered either a Coca-Cola or a Red Bull bev-erage as reward. The ANOVA of a dummy variable (1= Coca-Cola vs. 0 = Red Bull) shows that partici-pants primed with Coca-Cola bottles chose most often Coca-Cola (MCoca-Cola = 64%) while those primed with Römerquelle bottles chose almost equally from the two brands (MRömer = 52%) and those primed with Red-Bull cans chose Coca-Cola least frequently (MRedBull = 39 %) but the most Red Bull (F (2, 167) = 4.160 p = .017; Dunnett-C post-hoc p < .05).

This is the first study to show how brand-related haptic sen-sations automatically activate brand knowledge and how this influ-ences a brand's cognitive accessibility or brand choices. In times of diminishing product life cycles with frequent visual face-liftings, the retention of haptic signatures could perpetuate the bond between consumers and brands and help to reduce commu-nication costs to familiarize consumers with new products or product changes. New products that use established haptic signatures have a greater chance to do better simply because they feel more familiar, facilitate per-ceptual processing, and automatically activate existing brand knowl-edge.

Getting (Ex)cited: The Role of Herding in Driving Citations

Simon Quaschning, University College Ghent/Ghent University, Belgium
Mario Pandelaere, Ghent University, Belgium
Iris Vermeir, University College Ghent/Ghent University, Belgium

EXTENDED ABSTRACT

Citations play a role of ever increasing importance in the academic world. Publishing in top journals and establishing a considerable citation record has become essential for a successful academic career. However, most scientific work never gets noticed (Surowiecki 2005). As many as 20% of all articles are never cited at all, while only a limited number of articles are cited hundreds of times (Mingers and Burrell 2006). Existing literature has argued that the quality of an article is the primary driver of the difference between successful and unsuccessful articles (Mingers and Xu 2010). Moreover, past research has identified other, more quantifiable factors, such as the domain, visibility and personal promotion of an article (Stremersch, Verniers, and Verhoef 2007). In contrast, this paper proposes an alternative explanation: herding behavior.

When selecting sources for their research, academics are often confronted with a seemingly endless amount of information. Moreover, while some articles are clearly better than others, often it is rather difficult to compare their quality. Under such circumstances of uncertainty, people have the tendency to rely on heuristics to filter the abundance of information. According to the Matthew effect, the number of citations itself serves as a cue of quality for researchers. A large number of citations will accordingly lead to a good reputation, which then attracts even more citations (Nederhof and van Raan 1987). Correspondingly we propose that due to herding, articles get cited increasingly more often when they have been cited heavily in the past.

Our prediction is based on theory related to herding behavior and information cascades. When herding occurs, people ignore their own knowledge and instead look at the actions of others (Surowiecki 2005). As such, the number of citations does serve as a cue of quality for researchers. Researchers may believe that the persons before them had better information on the quality of the article than they themselves do and therefore may include the articles in their own research (Bonabeau 2004). However, when this imitation occurs in large numbers, informational cascades are formed (Banerjee 1992; Bickchandani, Hirshleifer and Welch 1992). People will mainly focus on articles with an already established citation count, and the limited number of articles that are already heavily cited tends to accumulate citations rapidly, while a large set of initially uncited articles tends to be (virtually) ignored.

The current paper is the first to illustrate empirically how herding has an effect on the citation record of scientific articles. We tested this idea with a sample of all articles published in five major marketing journals from 1985 to 2001 (*JM, JMR, JCR, MKS* and *IJRM; JCP* has been excluded since articles were only available from 2000), resulting in 2,227 articles. Also, we excluded all editorial content, books- and software reviews and comment sections, because of a significantly different citation profile. For each article, we tallied the number of citations made in each of the 10 years following its year of publication (excluding self-citations).

Consistent with the idea of herding, the results show that a large number of articles barely get cited, while a limited number of articles are cited very often. Interestingly, a multilevel regression analysis indicates that on average, the times that an article gets cited is a concave function of the age of the article: the increase in citations diminishes over time. We tested three models in which we tested if the difference in citation behavior can be explained by herding or by quality.

A first model tested the herding hypothesis, by including the number of times an article got cited in the year before (*autocorrelation*) into our model. The results illustrate that the number of citations in year t is positively related to the number of citations in year $t-1$. Moreover, we find a steeper increase in citations over the years for articles that have been cited heavily in the year before. Rarely cited articles, in contrast, will be cited only sporadically in future years. These findings support the herding hypothesis.

With a second model we tested an alternative explanation. According to the existing literature, the differences in citation behavior can be explained by the articles' quality. Since inherent quality is hard to measure, we relied on the quality assessments of editors and editorial boards (Stremersch et al. 2007). As such, we included *article order* (considered as the editors' assessment of quality and contribution), the journals' *best article awards* and the *article length* (articles with a higher contribution are often allowed to be longer). The results partly confirm the role of quality. While there were no significant effects for article order, we find that article length and awards moderate the increase in citations in the years after publication. In particular, high quality articles will show a steeper increase in citations over the years as opposed to articles of lower quality.

A third model was estimated in which both herding and quality were included simultaneously. The results support both the quality and the herding hypotheses. However, the highly concave function for high quality articles indicates that the number of citations will decrease again after some years. In contrast, the increase in the number of citations over the years is more linear for articles that have been cited more heavily in year $t-1$. Therefore, the findings suggest that, while quality is important in the first years, herding is responsible for the accumulation of citations over a longer period of time.

The current research sheds new light on an often discussed topic: the difference in citations of academic articles. The existing knowledge is challenged and extended by illustrating that the difference between highly and rarely cited articles cannot only be explained by differences in quality, but also by herding. We found that articles that got cited heavily in the past will be cited even more in the future. Next to theoretical contributions, this research also has practical implications. We hope this paper encourages a more careful use of citations as an indicator of article quality.

Unintended Effects of Implementation Intentions on Goal Pursuit Initiation vs. Persistence: Substitution and Acceleration

Jelena Spanjol, University of Illinois at Chicago, USA
Leona Tam, University of Wollongong, Australia
José Antonio Rosa, University of Wyoming, USA

EXTENDED ABSTRACT

When trying to achieve a goal (such as losing five pounds), people run into problems with getting started (begin controlling one's diet), keeping at it (continue cutting out the sugar), or both. Failure at either initiation or persistence in goal striving reduces goal attainment significantly. One way to overcome these challenges is to form implementation intentions (i.e., make detailed plans on when, where, and how to enact goal-directed behaviors, Gollwitzer 1999). Implementation intentions improve action initiation under cognitive load (Brandstaetter, Lengfelder, and Gollwitzer 2001), and shield goal pursuit behaviors from distractions (Bayer, Gollwitzer, and Achtziger 2010). Most implementation intentions research focuses on the outcome (i.e., goal attainment), not distinguishing between initiation and persistence or examining them independently (Gollwitzer and Sheeran 2006). It is unclear if planning out goal-directed behaviors is equally effective for starting and persisting in goal pursuit and what the underlying mechanisms are. The present research addresses this gap.

RESEARCH QUESTIONS

One important condition to the effectiveness of implementation intentions is the perceived level of difficulty of the goal being pursued. The greater the perceived difficulty, the more effective implementations are in improving goal attainment (e.g., Bagozzi and Edwards 2000; Chasteen et al. 2001). Importantly, the same goal can be perceived as more difficult to attain when it is being pursued under regulatory nonfit (Tam and Spanjol 2012), which occurs when a person's regulatory focus (promotion or prevention; Higgins 1997) does not match the goal pursuit strategy employed (eager or vigilant; Higgins 2000). Under regulatory fit, however, implementation intentions do not appear to have any incremental value on goal attainment (Tam and Spanjol 2012).

What is unknown is whether the type of regulatory fit matters to implementation intention effectiveness. The present research examines the impact of implementation intentions under regulatory fit more closely and aims to answer this research question: Do implementation intentions work differently for action initiation vs. action persistence in goal pursuit, and are those effects conditional upon the type of regulatory fit?

LITERATURE REVIEW

When implementation intentions are formed under regulatory fit the effectiveness of implementation intentions is reduced (Tam and Spanjol 2012), due to a ceiling effect, in which the fluency or "feeling right" of a regulatory fit situation provides a boost to goal attainment, leaving little room for the incremental impact from implementation intentions. An alternative explanation is that implementation intentions have opposite effects on goal striving under promotion fit vs. prevention fit conditions, in essence cancelling each other out. Based on the regulatory focus and fit literatures, we propose two unintended effects from implementation intentions under promotion vs. prevention fit: substitution and acceleration.

Substitution effect. Prevention-focused consumers are motivated by obligations and tend to see an adopted goal as a necessity (Liberman et al. 1999) or a minimal goal that needs to be satisfied (Freitas et al. 2002). When goals are construed as obligations or minimal standards to be met, goal-directed behaviors are initiated more quickly (Freitas et al. 2002). Thus, under prevention fit (when prevention-focused individuals pursue goals with vigilant strategies), the salience of minimal goals will be heightened and people will seek to satisfy the need for initiating goal striving as quickly as possible. When asked to form specific plans regarding when, where, and how goal striving will be enacted (via forming implementation intentions), individuals might interpret the act of developing such detailed goal pursuit plans as actual goal-directed behaviors. By forming implementation intentions, prevention-fit individuals then substitute cognitive goal striving for behavioral goal striving, delaying the initiation of goal-directed behaviors.

Acceleration effect. Promotion-focused consumers are motivated by hopes and tend to see an adopted goal as one of many opportunities for accomplishment (Liberman et al. 1999) or a maximal goal that one hopes to fulfill (Freitas et al. 2002). As a result, promotion-focused individuals tend to initiate goal-directed behaviors later (Freitas et al. 2002) but show greater persistence once started. By forming implementation intentions, promotion-fit individuals might accelerate or intensify their goal-directed behaviors to achieve the goal more quickly or more thoroughly and then desist from continuing the goal striving since they might feel they have "done enough."

METHOD AND FINDINGS

We conduct two longitudinal studies to assess whether implementation intentions affect initiation vs. persistence in goal striving differently under prevention vs. promotion fit. Study 1 asked 175 participants (83 females, 92 males) that reported having recently formulated financial goals (reducing debt or increasing savings) when they planned to start working on those goals (initiation). After two months, participants were asked about their likely continuation (persistence) of goal striving. Half of the participants were asked to form implementation intentions. We expected implementation intentions to boost initiation only under promotion fit, and persistence only under prevention fit. As shown in figure 1, initiation was enhanced for promotion-fit participants, as expected. Moreover, in support of our proposed substitution effect, prevention-fit participants delayed starting their goal striving when forming implementation intentions.

We also expected that promotion-fit participants would not benefit from forming implementation intentions to boost their likely continuation of goal striving. We find that promotion-fit individuals report lower persistence when forming implementation intentions.

Since the perceptual forward-looking measure of persistence did not allow us to test the acceleration effect, we conduct study 2, where 183 undergraduate students (112 females, 71 males) participated in a 7-day healthy snacking study. We find that promotion-fit participants do not benefit from forming implementation intentions, as expected.

A third study examining flossing behavior in a month-long time frame is under way to investigate both substitution and acceleration effects in a longer time frame within the same context. Results of this study will be ready for presentation at the conference.

Do Higher Stakes Lead to Better Choices?

Traci Freling, University of Texas - Arlington, USA
Ritesh Saini, University of Texas - Arlington, USA
Zhiyong Yang, University of Texas - Arlington, USA

EXTENDED ABSTRACT

Imagine a situation where a decision maker has to choose from two alternate preventive medications to ward off a threatening disease: one medication is supported by hearsay and anecdotal information, while rigorous statistical evidence favors the other. Common sense suggests that when the threat of such a disease is miniscule, either of the medications may be taken, but when vulnerability to the disease is perceived to be high, the choice is no longer inconsequential. Then, better sense should prevail and the statistically proven medication would usurp the one which is merely supported by anecdotal evidence. Higher stakes would therefore lead to better choices. In this paper, we provide evidence to the contrary. We demonstrate that greater likelihood of an event can lead to more visceral decision-making which can in turn lead to sub-optimal choices.

Normative decision-making models propose that anecdotal information—which describes a specific instance of a phenomenon or event—should be ideally ignored in the presence of contradicting statistical information—provides a numerical summary of a series of instances (Hornikx 2005). This is because the latter is based on a larger sample and should be objectively more reliable in decision making than an isolated anecdote (Ragubir and Menon 1996). However, a substantial stream of literature suggests that such rational disregard rarely occurs, and that anecdotal evidence often overwhelms statistical information (Bar-Hillel 1980; Hamill, Wilson, and Nisbett 1980). Such anecdotal biases have largely been attributed to the greater vividness and ease of processing that characterizes stories, as compared to statistical forms of data which tend to be more pallid and require more cognitive effort to process (Hamill et al. 1980).

In four studies, we investigate how contextual cues influence consumers' reliance on anecdotal information. We propose that the anecdotal bias should be less salient in high- versus low-involvement conditions, based upon the Elaboration Likelihood Model (ELM; Petty and Cacippo 1986). However, high-involvement does not always reduce the anecdotal bias. In situations where high-involvement induces a high level of perceived vulnerability among consumers, high-involvement can in fact increase the anecdotal bias, a phenomenon we call the "visceral compatibility effect" (study 1). We propose that emotional engagement underlies the visceral compatibility effect, mediating consumers' reliance on anecdotal information when involvement is enhanced by increasing vulnerability—and effect we test in study 2. We also examine the moderating role of consumers' holistic-analytical thinking style. Holistic thinking encourages context-dependence, which we believe will make people more cognizant of the visceral nature of the decision context, and therefore be more susceptible to its influence. As such, we expect that holistic (vs. analytic) thinking participants will display greater variance in anecdotal bias as a function of perceived vulnerability. Studies 3 and 4 provide consistent findings in support of our expectations, using chronic and situationally primed thinking styles, respectively.

Study 1 (N=293) featured a 2 (Involvement Type: non vulnerability-based vs. vulnerability-based) × 2 (Involvement Level: low vs. high) between-subjects design. We designed a decision scenario in which participants were asked to choose between two different automobile insurance policies for an extended travel in a foreign country: one option was statistically superior, while the other was anecdotally superior. In the vulnerability-based condition, participants' involvement level was manipulated through the information about the destination's ranking on automobile accidents in that country. In the non vulnerability-based condition, vulnerability was maintained at a moderate level. Participants assigned to the high-involvement condition were asked to provide reasons for their choice, whereas those in the low-involvement condition were prompted to make a choice without being asked to provide reasons. Immediately following the involvement manipulation, participants chose one of the two insurance policies.

Consistent with our expectations, we found that increasing involvement did not always result in reduced anecdotal bias (see Table 1). When involvement was enhanced by engaging in reasoning, it indeed did reduce this bias, as predicted by ELM. But when involvement was enhanced by increasing perceived vulnerability, anecdotal bias in fact increased, thereby confirming our visceral compatibility hypothesis.

Table 1: Study 1 Results: Choice of Anecdotally Superior Insurance Option

Involvement Type	Involvement Level	
	Low	High
Non vulnerability-based manipulation	49%	36%
Vulnerability-based manipulation	38%	50%

Study 2 (N=199) used the same research design, but provided further evidence for our principal hypothesis using a different choice scenario (i.e., participants were asked to choose between two different medications for a stomach virus that sometimes affects tourists in a particular foreign country) and measured emotional engagement (a potential mediator). As expected, Involvement Type moderated the effect of Involvement Level on anecdotal bias and on the level of emotional engagement elicited by high vulnerability (see Table 2). Further, under the vulnerability-based condition of Involvement Type, the effect of Involvement Level on consumers reliance on anecdotal information is mediated by emotional engagement.

Table 2: Study 2 Results: Choice of Anecdotally Superior Drug Option

Involvement Type	Involvement Level	
	Low	High
Non vulnerability-based manipulation	35%	15%
Vulnerability-based manipulation	27%	42%

Study 3 examined how individuals' chronic thinking style influences susceptibility to the visceral compatibility effect using a 2 (Vulnerability: low vs. high) x 2 (Thinking Style: analytic vs. holistic) between-subjects design. Results confirmed our expectation that vulnerability causes greater susceptibility to the anecdotal bias in holistic- versus analytic-thinking participants (see Table 3). Study 4 was similar to Study 3, except that we manipulated analytic-holistic

thinking. Again confirmed our expectations about the moderating role of holistic-analytic thinking style (see Table 4).

Table 3: Study 3 Results: % Choice of Anecdotally Superior Drug Option

Chronic Thinking Style	Perceived Vulnerability	
	Low	High
Holistic	31%	53%
Analytic	44%	45%

Table 4: Study 4 Results: % Choice of Anecdotally Superior Drug Option

Manipulated Thinking Style	Perceived Vulnerability	
	Low	High
Holistic	23%	57%
Analytic	29%	31%

Our findings demonstrate a counterintuitive result (i.e., that higher involvement can lead to greater susceptibility to anecdotal evidence, seemingly in contradiction to the ELM framework) and provide consistent support for the proposed visceral compatibility hypothesis. Study 1 reconciles contradictory predictions, demonstrating that high-involvement can decrease or enhance the anecdotal bias, depending on whether it is accompanied by high-vulnerability. Study 2 replicates this finding in a different decision context and identifies emotional engagement as the mechanism underlying the visceral compatibility effect. Studies 3 and 4 reveal that holistic-analytic thinking style constitutes a boundary condition for the visceral compatibility effect.

Remembering Better or Remembering Worse: Age Effects on False Memory

Priyali Rajagopal, Southern Methodist University, USA
Nicole Votolato Montgomery, College of William & Mary, USA

EXTENDED ABSTRACT

Research in memory has focused on understanding the origins, characteristics and consequences of false memory (Rajagopal and Montgomery 2011). However, there has been little focus on variables that moderate false beliefs about past experiences. In this paper, we examine one such variable – age.

Research suggests that older adults are more prone to memory deficits. For example, Skurnik et al (2005) found that older adults were more likely to forget the context of a claim over time (true vs. false) and therefore were more likely to mistakenly believe it to be true. Consistent with this research, our expectation was that false memories would be more pronounced for older versus younger adults. That is, older adults would be more likely to report having tried a product that they had not in reality tried.

Study 1 was a 2 (age: old vs. young) x 2 (imagery: high vs. low) between subjects study (n = 104). Thirty-four respondents were students (M_{age} = 20.5 years), while seventy were older adults (M_{age} = 62.2 years). All respondents read a set of 10 advertisements (1 target, 9 fillers) for different products that utilized a real brand name with a fictitious variant name (e.g., Gatorade Zoom). The target product was for Orville Redenbacher's Blue Corn microwave popcorn. The high and low versions of this ad were pretested to ensure that the two versions of the ad varied only in terms of their imagery-evoking ability and not dimensions such as meaningfulness, believability etc.

After reading all the ads, respondents reported their task involvement on a 3-item scale (α = .87) to ensure that differences in involvement could not explain our results (p's > .05). One week later, they completed an online survey that contained the dependent measures.

Our key dependent measures were false memory and attitude strength. False memory was assessed using two different measures. The first measure was a dichotomous measure wherein respondents selected all the products that they thought they had ever tried from a list of fifty different products including the target brand. Our second measure was a set of four statements about the target product, from which respondents were asked to choose all the statements that applied to them. The statements attempted to delineate false memory about the product (e.g., "I have purchased this product", "I have seen this product in local grocery stores" and "I have heard about this product from friends or family members") from accurate memory about the product ("I have seen an advertisement for this product in another study"). For reporting purposes, we summed the first three statements as our measure of false memory. We collected responses to the statements for three filler brands in addition to the target product.

We used attitude predictiveness as our measure of attitude strength. Attitudes were measured using a four-item scale (bad-good, negative-positive, unfavorable-favorable, undesirable-desirable, α = .88). Purchase intentions were measured using a single item scale ("How likely are you to purchase Orville Redenbacher's blue corn popcorn the next time you are purchasing microwave popcorn?").

RESULTS

False Memory. We found a significant interaction between age and imagery on the product usage memory measure ($\chi2$ (3) = 8.91, p < .05) and the false statements (F (1, 100) = 4.12, p < .05), with the older adults reporting a lower incidence of false memory as compared with the younger respondents. Thus, a larger number of younger respondents selected the target product when they viewed the high imagery ad (28.5%) as compared to the low imagery ad (10%), but there was no significant difference between the high (5.5%) and low imagery (2.9%) ad conditions for the older respondents. Similarly, younger respondents choose a larger number of false memory statements when they viewed the high imagery ad (M = .86) as compared to the low imagery ad (M = .30; t (100) = 2.66, p < .05), with no differences between the two conditions for the older respondents (M_{high} = .30, M_{low} = .26, t (100) < 1). There were no differences in the selection of the correct memory statement ($\chi2$ (3) = 1.03, p > .1). These results suggest that age moderates the creation of false memories such that older respondents are *less* susceptible to the creation of false memories through advertising.

Attitude strength. Regression analyses revealed that attitudes significantly predicted purchase intentions for the young respondents who viewed the high imagery ad (β = .59, p < .05), but not the other experimental conditions ($\beta_{young, low\ imagery}$ = .29, p > .1, $\beta_{old, high\ imagery}$ = -.22, p > .1, $\beta_{old, low\ imagery}$ = .17, p > .1). Thus, consistent with the results for memory, we find that attitude-intent correlations are significant only when false memory is reported. This further suggests that the false memory effect is found only for the younger respondents.

These results suggest that age moderates the creation of false memories such that older respondents are *less* susceptible to the false experience effect than younger respondents. This is contrary to our predictions and is a very interesting finding because it is also contrary to the findings from past research that has consistently documented a memory disadvantage with age.

We propose that our findings occur because older adults may suffer from a decline in the ability to image, which decreases the creation of false memories via high imagery advertising. To that end, we have two unreported studies that further examine the moderating effect of age using different techniques to instantiate false memory (e.g., repetition, writing detailed experiences), consistent with past research (Garry et al. 1996). In study 2, respondents are asked to write detailed information about erroneous autobiographical experiences. In study 3, we test whether repeating ads can attenuate the differences in false memory between the two age groups since research has shown that repetition can aid memory for older adults more than younger adults. In addition, we also collect information on frequency of consumption, product familiarity and knowledge to rule out the possibility that differences in these variables may underlie the findings.

Dynamic Patterns of Intra-Shopping Spending for Budget and Non-Budget Shoppers

Daniel Sheehan, Georgia Institute of Technology, USA
Koert van Ittersum, Georgia Institute of Technology, USA

EXTENDED ABSTRACT

Much of our current understanding about how consumers shop for goods and services is based on a cross-sectional analyses of end-of-trip variables (e.g., basket composition, spending). However, research increasingly examines intra-shopping decision-making processes to gain an understanding about how spending unfolds during a single shopping trip. Dhar et al. (2007), for example, study the impact of an initial purchase on subsequent decisions. Stilley and colleagues (2010), in turn, examine how shoppers shift their spending between planned and unplanned items. Following this paradigm, the present research examines how shoppers' spending decisions, pertaining to each individual product choice, change as a function of their cumulative spending during a single shopping trip. Building on recent research that shows the differentiating effects of budget constraints on shopping behavior (Van Ittersum et al. 2010, 2011), we examine this for budget versus non-budget shoppers.

Intrigued by the idea of whether cumulative spending during a shopping trip influences subsequent purchase decisions (spending $2.25 vs. $3.75 on eggs), we conducted a simple exploratory lab experiment where participants were asked to make sixteen subsequent choices from one of two products (for different product categories). The results revealed a U-shaped relationship between the cumulative amount of money spent and the relative spending on an individual item. Shoppers are more inclined to purchase more expensive items early and towards the end of the shopping trip, but are more inclined to purchase less expensive items halfway through their shopping trip. Interestingly enough, this relationship takes on an inverted U-shape when shoppers are budget constrained. Halfway through the shopping trip, budget shoppers actually spend relatively more on individual items than their non-constrained counterparts ($F(1,59)=5.4$, $p<.05$).

To explain the origin of these unique relationships between cumulative spending and the relative spending on an individual item, we build on research on the pain of payment (Prelec & Loewenstein 1998) and regulatory resources (Baumeister 2002), both of which have shown to influence shopper decision making (Thomas et al. 2011). The literature on the pain of payment suggests that pain of payment increases with spending. We extend this to propose that for non-budget shoppers, the pain of payment evolves concavely throughout a shopping trip (as the relative pain of payment of the last $1 spent is less compared to the first $1 spent). For budget shoppers, however, we hypothesize an S-shaped relationship, as the money left in their budget reduces the pain of payment early in the shopping trip (Heath & Soll 1996). We further expect to find differences in the speed with which budget versus non-budget shoppers deplete their regulatory resources. While both groups of shoppers are expected to deplete resources in a convex manner, the resource depletion of budget shoppers is expected to occur more quickly due to the additional need of monitoring the spending (Van Ittersum, et al. 2010). Both sets of unique patterns help explain the differences in the relationship between the cumulative amount of money spent and the relative spending on an each purchase between budget and non-budget shoppers. We conducted two independent studies to provide evidence for the proposed mechanism.

STUDY 1: PAIN OF PAYMENT

To observe how shoppers' pain of payment evolves during a single shopping trip, we asked participants to complete a simulated shopping task containing 30 randomized purchase decisions. For each decision, participants selected one out of four choice options. After randomly assigning participants to a budget or non-budget condition, we measured each participant's pain of payment (Thomas et al. 2011) after 5, 10, 15, 20, 25, or 30 decisions (between-subjects). Consistent with expectations, the pain of payment evolves concavely during the shopping trip ($\beta decision=.09$, $p<.01$; $\beta decision2=-.02$, $p<.05$). Furthermore, budget shoppers experience significantly less pain than non-budget shoppers halfway during the trip (3.4 vs. 4.5, $F(1, 53)=4.57$, $p<.05$), but not at the beginning or end of the shopping trip.

STUDY 2: REGULATORY RESOURCES

The setup of this study was similar to that of Study 1, with the exception of the measurement task within each shopping trip. In study 2, participant's resources were measured by observing their persistence on an anagram task (Vohs et al. 2008) after a specified number of purchase decisions (identical to Study 1). Consistent with expectations, the regulatory resources deplete during the shopping trip ($p<.05$) and slightly quicker for budget shoppers ($p<.10$). Furthermore, by the end of the shopping experience, there are significant differences in the persistence of budget and non-budget shoppers (252 vs. 140 secs., $F(1, 27)=5.57$, $p<.05$).

STUDY 3: ONLINE SHOPPING EXPERIMENT

As the exploratory lab study was a small controlled laboratory experiment, we conducted a final field experiment in a mock online grocery store. Subjects were randomly assigned to a budget conditions (budget vs. non-budget) and asked to shop with a pre-tested shopping list. This online grocery store contains more than 3000 products, and for items on the shopping list, subjects were able to choose from between five and fifteen product alternatives (e.g., blueberry bagels, plain bagels) from between two and eight different store and national brands. We coded the relative spending of each subjects decisions throughout the experiment. A repeated measures analysis reveals the predicted quadratic interaction between budget and purchase decision ($F(1,92)=11.53$, $p<.01$). Furthermore, consistent with the pilot study, the conventional wisdom that non-budget shoppers always spend more than budget shoppers is only found in the beginning and end of the shopping trip. In the middle of the shopping trip, budget shoppers actually spend slightly more (1.08 vs. 0.98, $F(1,92)=3.48$, $p<.10$).

Our research makes three important contributions. First, this research is among the first to examine shoppers' intra-shopping trip decision-making and its subsequent spending consequences. Second, significantly extends literature on pain-of-payment (Prelec & Loewenstein 1998) by demonstrating the evolution of pain of payment within a shopping trip for budget and non-budget shoppers, as well highlighting a point in a shopping trip when pain experienced by budget shoppers actually decreases. Finally, this research provides insights on both the rate and consequences of regulatory resource depletion for budget and non-budget shopper

Effective Substitution: The Drawback of High Similarity

Zachary G. Arens, Jesse H. Jones Graduate School of Business, USA
Rebecca W. Hamilton, Robert H. Smith School of Business, USA

EXTENDED ABSTRACT

Consumers frequently substitute for products that are out-of-stock (Emmelhainz, Stock, and Emmelhainz 1991; Peckham 1963), too expensive (Bucklin and Srinivasan 1991), too unhealthy (Tuorila, Kramer, and Cardello 1997) or otherwise unattainable. Despite the prevalence of substitution, there is little research on what makes a replacement product an effective substitute. This research investigates the relationship between product similarity and substitution. We show that although consumers believe that highly similar products are better substitutes, in fact moderately similar products more effectively satisfy the consumer's desire for the original. For example, if a consumer is looking forward to a Coca-Cola but finds it unavailable, our data suggest that another brand of cola (a highly similar product) will be a worse substitute than a lemon-lime soda (a moderately similar product), although the consumer believes the opposite.

Substitutes are defined as products that fulfill the same goal (Kruglanski et al. 2002; Lewin 1935). The degree of substitutability between products is not a fixed property but can vary depending on the particular goal at hand (Ratneshwar, Pechmann, and Shocker 1996; Ratneshwar and Shocker 1991). Typically substitutability is measured by examining the change in quantity demanded of one product in response to a change in the price of another (Hicks 1963; Slutsky 1960) or by the likelihood of consuming one product after consuming another (Lattin and McAlister 1985). In this research, we operationalize effective substitution as the degree to which a replacement product fulfills the consumer's desire for the unattained product.

Because a replacement product is intended to fulfill the goal associated with an unattained product, consumers often choose replacements that share features with the unattained product (e.g., Yelp Review 2012). Thus we propose that consumers will predict that highly similar products will be better substitutes than moderately similar ones. However, in contrast to consumers' beliefs, we predict that moderately similar products will serve as more effective substitutes than highly similar ones. While earlier work on substitution using the task-interruption paradigm (Child and Grosslight 1947; Lissner 1933) suggests that similar substitutes will be more effective than dissimilar substitutes, we focus on the difference between highly similar and moderately similar products.

We propose that moderately similar substitutes will be more effective because they prompt an abstract view. The goal that motivates consumption of a product can be viewed at different levels of abstraction (Huffman, Ratneshwar, and Mick 2000; Vallacher and Wegner 1987). If a dissimilar (versus similar) replacement encourages consumers to think about the motivation for consumption abstractly (e.g., drinking soda instead of drinking cola), this could make the replacement seem better suited to fulfill the goal. Following this logic, a moderately similar replacement will appear less satisfactory and, as a result, be a less effective substitute than a moderately similar one.

Our first study demonstrates these effects by comparing consumer's beliefs about substitution with their experiences. Participants were led to believe that they would eat Cheerios, but instead were given Merry-O's, a fictitious brand of breakfast cereal. Some participants, the forecasters, imagined eating Merry-O's, and predicted how effectively it would substitute for Cheerios, while the others, the experiencers, actually ate Merry-O's (which in reality

was Cheerios) and then rated how well it substituted for Cheerios. In the highly similar condition, Merry-O's shared a number of features with Cheerios (e.g., similar packaging and both are "a good source of fiber") and in the moderately similar condition, Merry-O's had more distinct features (e.g., dissimilar packing and "a good source of vitamins and minerals" compared with Cheerios which was "a good source of fiber"). As shown in figure 1, the forecasters predicted that Merry-O's would be a more effective substitute in the highly similar condition than in the moderately similar condition whereas experiencers showed the opposite pattern. Notably, these effects cannot be explained by participants negatively characterizing Merry-O's as a copycat brand.

Figure 1. Substitution Effectiveness
Our second study extends the first by demonstrating that satisfaction with the replacement product mediates the effect. As part of an ostensible taste test participants were given a choice between drinking Coke and Pepsi in one condition and Sprite and 7up in another condition. Later, participants were told that the soda they had selected was out of stock and were given one of two replacement beverages: a store brand of cola or a store brand of lemon-lime soda. Thus, all participants either received a moderately similar beverage (lemon-lime when they expected cola or cola when they expected lemon-lime) or a highly similar beverage (e.g., cola when they expected cola). The results showed that the moderately similar replacement beverage was consistently a more effective substitute than the highly similar beverage. For instance, lemon lime soda was a better substitute for Coke than for Sprite. This effect of similarity on substitution effectiveness was mediated by satisfaction with the replacement.

Our third study provides support for the underlying mechanism: the degree to which participants think abstractly or concretely about their consumption goal. Participants evaluated 16 classic songs and were told that they would get to listen to their favorite. However they were later told that their favorite song was unavailable and listened to a replacement song that was either moderately or highly similar based on their similarity ratings. Replicating our previous results, a moderately similar song was more satisfying and a better substitute than a highly similar one. Providing support for our predictions about the abstractness of participants' thinking, the result was mediated by the specificity of the purpose, suggesting that a moderately similar replacement prompts an abstract view, making the replacement more satisfying and a more effective substitute.

In summary, our research suggests that the lay theory that highly similar products make the best substitutes is incorrect. Instead, moderately similar replacements encourage consumers to adopt an abstract view, making the replacement a more effective substitute. By improving our understanding of the determinants of effective substitution this research offers insights to help consumers make better choices and help firms design products to better suit their needs.

The Effect of Message Credibility, Need for Cognitive Closure, and Information Sufficiency on Thought-Induced Attitude Change

Bruce E. Pfeiffer, University of New Hampshire, USA
Hélène Deval, Dalhousie University, Canada
David H. Silvera, University of Texas at San Antonio, USA
Maria L. Cronley, Miami University, USA
Frank Kardes, University of Cincinnati, USA

EXTENDED ABSTRACT

Substantial research on self-generated persuasion has demonstrated that simply thinking about an attitude object can result in more extreme attitudes toward the object (e.g., Tesser, 1978; Tesser, Martin, & Mendolia, 1995). This mere thought effect suggests that when people think about attitude objects, they generate additional attitude-consistent thoughts leading to greater attitude polarization. Although research in this area has investigated several moderating factors (e.g., Judd & Lusk, 1984; Linville, 1982; Millar & Tesser, 1986; Tesser & Leone, 1977), most of the research looks at constraints that attenuate but not reverse the effect. It has been suggested, however, that under some situations people may generate attitude inconsistent thoughts resulting in a depolarizing effect (e.g., Marsh & Wallace, 2005). Further, it has been shown that if people have too much time to think, they may lose the motivation or ability to generate additional attitude-consistent thoughts, leading to a loss in thought confidence and resulting in attitude depolarization (Clarkson, Tormala, & Leone, 2011).

This research investigates source effects as another depolarizing variable and two additional moderating variables, need for cognitive closure and information sufficiency. Consumers have many resources for gathering information about products that vary in perceived objectivity. Source effects play an important role in consumer attitude formation and product evaluations and have been shown to operate at varying levels of processing (Kang & Herr, 2006) depending on ability and motivation (e.g., Petty & Cacioppo, 1986). Whether consumers view an ad as informative and accurate or persuasive depends on the ambiguity of the information and the motivation to think about the implications of the ad (Hung & Wyer, 2008). Consumers generally expend little cognitive effort when presented with advertisements (Hung & Wyer, 2008). When people are motivated to consider an advertisement, they are likely to consider that the advertiser's claims are generally exaggerated and designed to persuade (Persuasion Knowledge Model; Friestad & Wright, 1994).

Need for cognitive closure (NFCC) (Kruglanski & Webster, 1996) refers to a desire to form a definite opinion ("seize") and to maintain the opinion once it is formed ("freeze"). Since people high in NFCC are more likely to "seize" and "freeze" on an evaluation, they should be less likely to adjust an evaluation once it is formed. Low NFCC consumers should be more likely to draw additional inferences, allowing for attitude polarization. Further, it is possible that enough diagnostic information may override a source effect. The "set-size effect" (Anderson, 1967, 1981; Yamagishi & Hill, 1981, 1983) has demonstrated that as the number of attributes used to describe a person or object increases, the overall evaluation becomes more extreme. If enough positive information is provided, it may not matter as much whether the source is credible or not.

Experiment 1 was designed to investigate source effects in relation to attitude change. Participants were asked to imagine that they were shopping for a new cell phone plan and were provided with a brief description of a plan. Participants were informed that the information was either taken from an advertisement (low credibility) or from an article in Consumer Reports Magazine (high credibility). Participants then rated their attitudes toward the plan. Next, participants were asked to either think about the plan (thought task) or work on a crossword puzzle (distraction task) for 90 seconds. They then rated their attitude toward the plan a second time. A polarization score was computed using the difference between the attitude score at time 1 and time 2. A 2 (thought vs. distraction) X 2 (source credibility) ANOVA revealed a significant two-way interaction. As expected, participants in the thinking condition adjusted their attitude from time 1 to time 2, while those in the distraction condition did not. When the source was credible a polarization effect was found. When the source was less credible, a depolarized effect was found.

Experiment 2 further investigated the depolarizing effect, while including NFCC as a potential moderator. This study was identical to experiment 1 except only the low credibility source (advertisement) was used, and participants completed the 42-item NFCC scale (Webster & Kruglanski, 1994). A regression analysis revealed a significant two-way interaction. As expected, a depolarizing effect was found in the thinking condition, but only when NFCC was low. No change was found in the distraction condition regardless of NFCC.

Experiment 3 extended the findings of experiment 2 by manipulating NFCC while also considering the potential moderating effect of set-size on polarization. Participants were asked to imagine that they were shopping for a new laptop computer and were presented with a description. They were informed that the information was taken from a recent advertisement. The amount of descriptive information varied (four vs. eight pieces of information). NFCC was manipulated via an accountability manipulation (e.g., Tetlock, 1985). The attitude measure and thought/distraction task were the same as the previous studies. A 2 (thought vs. distraction) X 2 (set size: large vs. small) X 2 (NFCC: high vs. low) ANOVA revealed a significant three-way interaction. We found the same depolarizing effect in the small set-size condition as in experiment 2. A thought-induced depolarization effect was found but only for those low in NFCC. No change was found in the distraction condition regardless of NFCC. In contrast, we found a marginally polarizing effect in the large set-size condition. A thought-induced polarization effect was found but only for those low in NFCC. No change was found in the distraction condition regardless of NFCC. Apparently the larger set-size doesn't just attenuate the source effect, but also reverses it.

This research provides important new insight into self-generated persuasion. Source effects can result in polarizing effects if the source is credible but depolarizing effects if the source is less credible. Further, thought-induced attitude change depends on varying levels of NFCC and information sufficiency.

Diversity Appreciated?
A Visual Longitudinal Analysis of Ukraine's Nation Branding Campaigns

Luca M. Visconti, , ESCP Europe, France
Mine Üçok Hughes, Woodbury University, USA
Ruben Bagramian, Woodbury University, USA

EXTENDED ABSTRACT

This paper discusses the nation branding efforts of Ukraine, a post-communist country, since gaining its independence from the Soviet Union in 1991. In detail, our study aims at: i) highlighting the specifics of nation branding campaigns for Ukraine, whose communist past fuels a nation image problematic to promote; and ii) grounding future research that will analyze the power dynamics between Ukrainian citizens and international tourists who are the main audience for these campaigns.

Nation branding falls within the field of place branding (Fan 2009; Gnoth 2002; Hanna and Rowley 2008) that covers an array of studies differing in terms of: i) unit of analysis (city versus nation), ii) stakeholders (local and national governments, citizens, companies, and the media), and iii) objectives of enhancing exports, protecting local/national production, attracting tourists and investors, and facilitating international relations (Papadopoulos 2004). It also shows differences from the country-of-origin research. While the latter holds companies' perspective and leverages the place to improve the attractiveness of other products designed/assembled/produced in that place, place branding literature fosters the perspective of governments and individuals (tourists and local dwellers) and considers the place as the main object of market exchange (Anholt 2004; 2011).

Existing research on place branding can be divided into managerially or conceptually driven studies. Managerial projects explore the application of marketing to improve the economic development of the place (Anholt 2004; 2011; Fan 2009; 2006; Giannopoulos, Piha and Avlonitis 2011; Jaffe and Nebenzhal 2001; Kotler and Gertner 2002). More conceptual projects investigate connections between place, city and nation branding (Hanna and Rowley 2008), the boundary between place branding and country-of-origin (Papadopoulos 2004) or between nation brand and nation branding (Fan 2006) and the differences between corporate and place branding (Kavaratzis 2005).

Our research analyzes longitudinally the nation branding campaigns of Ukraine. With a population of around 45 million, Ukraine has been developing an increasingly tight relationship with the EU (http://eeas.europa.eu/ukraine/index_en.htm). Several reasons justify the choice of our empirical setting: i) the country is transitioning from a central economy to a market economy, thus striving to develop a nation brand far from Soviet associations (Nordbeg and Kuzio 1998), ii) the difference of this nation brand from Western nation brands makes it an intriguing case in studying the specificities of nation branding in transitioning economies, iii) longitudinal analysis of Ukraine's nation branding campaigns is made possible by its twenty years of independence, and iv) more recently the UEFA 2012 Football Championship supports the economic and managerial relevance of this research.

Our data set includes five major nation branding campaigns that Ukraine has conducted over the last 11 years. We collected Ukrainian short promotional videos, logos, press articles and press releases, and other broadcast materials as well as monitored web sites, blogs and forums. Data analysis is consistent with established procedures of interpretive research in general (Spiggle 1994) and of visual analysis in particular (Schroeder 2002; Scott 1994). The research team is comprised of three researchers, one from the USA, one from Western Europe, and a third from Ukraine, thus facilitating a derived etic approach to data analysis (Berry 1989).

Our findings show two main drivers steadily directing Ukraine's nation branding efforts. Firstly, Ukraine has built its new identity by *stating what it is not*—a communist country—instead of conveying a clear, assertive image of what it is. In an attempt to distance itself from its communist past, its campaigns try to reassure local and international audiences of the "modernization" undertaken by Ukraine. This finding is also supported by other studies focusing on nation branding in post-communist countries (Anholt 2007; Kaneva 2012; Kaneva and Poescu 2011; Kemming and Sandikci 2007). Secondly, Ukraine's nation branding campaigns portray a wide range of visual information that is at times incongruous with each other. Ukrainian nation brand is a collection of folkloristic, architectural, natural, economic, urban, and social elements. The promotional videos illustrate the appeal of clean cities, happy people, a healthy life style, elegant architectural landmarks, and beautiful nature. Catchy slogans such as "Switch on Ukraine" or "High Time to See Ukraine" were created to show the attractiveness of Ukraine, primarily to foreign tourists. However, these all result in a string of campaigns where a lot is shown but nothing is clearly said. These two findings demonstrate that the stigma for Ukraine's past reverted traditional principles guiding nation branding campaigns from an assertive communication approach (what the nation is) to an avoiding approach (what the nation is not), and from a frontal positioning (a few key nation identifiers) to a smokescreen of overlapping elements, which—we argue—are due to the willingness to divert audience's attention from the communist past and an enduring uncertainty about extant national identity. However, despite its multiple nation branding efforts ever since its independence, Ukraine's perceived difference from other Western nations presents a disvalue to both its government and international audiences. In the Brand Index ranking provided by Future Brand, out of 110 nations Ukraine dropped from position 75 in 2009 to position 99 in 2010.

With reference to the second research objective, our analysis indicates that the sense of superiority for the market economy of the Western world has been transferred to *a sense of superiority of international visitors toward local citizens*. The campaign "Ukraine. All about U" may appear as an innocent attempt to attract tourists. However, looking at it from a different perspective, we argue that tourists are given the power to consume, modify, and divert the meanings grounding Ukraine's national identity, thus turning power dynamics to their advantage.

Our work advances nation branding literature by showing that this literature is not culturally neutral and embeds deep post-colonial, Western, capitalistic values and norms, which post-communist countries have problems to elaborate when transitioning toward the market economy. Paradoxically their adherence to capitalism maintains these countries in a state of subjection and helps twist the application of nation branding principles, thus maintaining their gap even further.

Should You or Could You? The Effect of Social Influence in Text Warnings Against Product Placement and the Moderating Role of Self-Monitoring

Tina Tessitore, Ghent University, Belgium
Maggie Geuens, Ghent University, Belgium

EXTENDED ABSTRACT

Product placement (pp) is a paid inclusion of brands in mass-media programming (Balasubramanian 1994), for which persuasion knowledge (PK) (i.e., the knowledge people rely on to deal with a persuasion attempt) is not always activated (Friestad and Wright 1994; Wei, Fischer, and Main 2008). The European Union (2009) authorized pp on the condition that this covert practice is clearly identified to viewers. Hence, research on warnings for pp becomes important in the marketing and public policy domain. In this respect, it is essential to test *which types of warnings* are most effective (for *which types of persons*). Moreover, resistance is a conscious process, requiring cognitive resources (Campbell and Kirmani 2000). Hence, consumers must consciously recall/recognize the brand for resistance to occur. Moreover, brand recall reflects attention to the placed brand, which might increase its accessibility in viewers' minds, increasing their likelihood of choosing the brand (Van Kerckhove, Vermeir, and Geuens 2011). Consequently, we hypothesize that purchase intent is higher with than without brand recall, when no (effective) warning is provided. Therefore, we also consider brand recall in this research.

A number of researchers has proven the importance of explicitness in warnings (i.e., "the specificity or detail with which potential injury consequences are described" (Laughery et al. 1993, p.598) to increase warning effectiveness, mostly in the context of product hazards (e.g., Trommelen 1997; Frantz 1994). In the subtle and less dangerous context of pp, explicitness in a warning can perhaps counterbalance the subtleness of pp as a persuasion tactic, making the tactic's ulterior motive more salient. As such, a text warning, containing information about pp, may be effective to activate PK and hence, to enable resistance.

In Study 1 (*N*=119), we investigated the effectiveness of a text warning to enable viewers to counteract pp influence on their purchase intent. We manipulated warning presence (text warning: yes vs. no) and measured brand recall. A two-way ANOVA revealed two significant main effects, which were qualified by an interaction effect. Specifically, when the brand is recalled, purchase intent is significantly lower in case of a text warning versus no warning. When the brand is not recalled, no resistance is found. Furthermore, only in the control group, brand recall led to higher purchase intent than no recall.

In some occasions, warnings can lead to reactance against the warning itself (Bushman 1998; Bushman and Stack 1996). Reactance theory (Brehm 1966) states that when a person feels obliged to adopt an opinion or certain behavior, he could perceive his freedom to be constrained, making him more likely to react against the communicator. In our case, a warning that is perceived as more stringent, would then be less effective. Consequently, it seems important to identify a potential moderator of the effectiveness of text warnings that drives potential reactance.

To this end, we investigated in Study 2 (*N*=86) whether the type of social influence comprised in a warning (i.e., informational versus normative warning) can moderate the effectiveness of text warnings. Normative warnings can be perceived as more stringent, since they contain norms and expectations of a certain group, compared to informational warnings, which contain pure objective information. Consequently, we hypothesize that normative warnings are less effective than informational warnings to counteract pp influence.

 A between-subjects design with three conditions (no vs. informational vs. normative warning) was set up. An ANOVA (warning x

brand recognition) revealed a significant interaction effect. In case of brand recognition, an informational warning significantly deteriorated purchase intent compared to no warning. No significant differences were found between the other conditions. So, although there is an indication that an informational warning is more effective than a normative warning in comparison with no warning, no direct difference between both warnings is found. Without brand recognition, we found no significant differences. Again, only in the control group, brand recognition entailed more purchase intent than no recognition. Moreover, an ANOVA on PK-activation revealed only two significant main effects. Brand recognition led to more PK than no recognition. Moreover, both warnings entailed more PK-activation than no warning. No significant difference is found between both warnings. Furthermore, we wanted to explore whether PK-activation drives the effectiveness of these warnings to resist pp influence compared to a situation without warning. Since no direct difference was found between both warnings on purchase intent and PK-activation, we constructed a new variable, coded as warning - including both the informational and normative warning - versus no warning. Bootstrap analysis (Preacher and Hayes 2004) shows evidence for mediation by PK-activation of the diminishing effect of warnings (versus no warning) on purchase intent in case of brand recognition.

A last issue that we consider, is which type of social influence in a warning is most effective for which type of person? With regard to social influence, self-monitoring is a relevant personality variable to contemplate. High self-monitors are more sensitive to others' expectations and norms (Snyder 1974), making us assume that they will be less likely to react against a normative warning than low self-monitors. Hence, for high self-monitors, a normative warning is expected to be more effective than an informational warning.

In Study 3 (*N*=109), we manipulated social influence (informational vs. normative warning), measured self-monitoring (Lennox and Wolfe 1984) and only considered those people who recalled the brand. A two-way ANOVA revealed a significant interaction effect. For high self-monitors, a normative warning seems to be more effective than an informational warning to resist pp influence on purchase intent, whereas no difference is found between the two warnings for low self-monitors.

This research has both theoretical and practical contributions. First, it reveals the important role of brand recall/recognition in both persuasion as well as resistance processes of pp. Second, resistance can be triggered by a text warning. However, we recommend to consider both the type of social influence comprised in the warning and the type of group the warning is targeted to. Popular blockbusters could for example attract more high self-monitors than alternative movies.

"I Apologize. I Understand Your Concerns": When an Empathetic Apology Works

Kyeong Sam Min, University of New Orleans, USA
Jae Min Jung, California State Polytechnic University at Pomona, USA
Kisang Ryu, Sejong University, Korea

EXTENDED ABSTRACT

An apology is a powerful tool to repair broken relationships among individuals. However, we know very little about *when* and *why* some apologies are more effective than others because academic research on apology has mainly focused on examining a victim's reaction to an apology relative to no apology (Brown, Wohl, and Exline 2008; Wooten 2009). This research addresses these two important questions. Specifically, we explore how an apology works when it is offered after (i.e., delayed apology), rather than before (i.e., immediate apology), victims have their concerns heard. Services marketing researchers have shown that an immediate apology has a more favorable impact on consumer satisfaction than a delayed apology (Smith, Bolton, and Wagner 1999; Wirtz and Mattila 2004). Yet, there is contradictory evidence that a delayed apology can be more persuasive than an immediate apology. According to Frantz and Bennigson (2005), victims are likely to be ready to accept an apology after they have their concerns expressed and heard. Such a delayed apology is viewed as more empathetic and sincere and less superficial than an immediate apology. To resolve the apparently conflicting findings in the literature, we examine the situations that influence the apology timing effect.

LITERATURE REVIEW AND HYPOTHESES

Building on Fehr and Gelfand (2010), we predict that the relative advantage of a service person's delayed (vs. immediate) apology exists only when consumers know that they are likely to interact with the same service person in the future. According to Fehr and Gelfand (2010), the effectiveness of an apology depends on whether an offender's apology is consistent with the way victims view their relationship with the offender. They show that victims with a relational self-view are more likely to forgive an offender when the apology focuses on empathic concerns. As a result, we hypothesize that, for those who have a high expectation to interact with the same service person, the service person's apology will be more effective if it is offered after consumers have their concerns heard, compared to if it is immediately offered. In contrast, for those who have a relatively low interaction expectation, the service person's empathic apology will not be matched with their view on the relationship. For them, it will be more forgiving to get a prompt apology instead of a delayed apology.

According to Zhao, Hoeffler, and Zauberman (2011), individuals whose main focus is on the process of consuming a hedonic product tend to rely more on cognitive and effortful processing, whereas individuals whose primary focus is on the outcome are more likely to rely on affective and effortless processing. By the same token, we argue that consumers in the high interaction expectation situation will focus more on a process of their service experience than those in the low interaction expectation situation. Unlike the latter, the former are likely to believe that their relationship with the same service person will continue. Thus, we predict that the relative effectiveness of a delayed (vs. immediate) apology in the high expectation condition will be predominantly driven by a cognitive process (e.g., "The service person understand my concerns"), whereas the relative effectiveness of an immediate (vs. delayed) apology in the low expectation condition will be mainly guided by an affective process (e.g., "I do not feel angry").

METHOD AND FINDINGS

In the first three scenario-based experiments, we used a 2 (apology timing: immediate vs. delayed) x 2 (interaction expectation: high vs. low) between-subjects design. We tested how the timing of a service person's apology operates when the consumer described in the scenario received services that were slower than did other consumers. Experiment 1 examined the moderating role of interaction expectation at a restaurant. We manipulated the apology timing based on whether a service person apologized either before (i.e., immediate apology) or after consumers had their concerns heard (i.e., delayed apology). Additionally, in the high (low) expectation condition, participants were led to believe that they were likely (unlikely) to interact with the same service person. As predicted, we found that the delayed apology produced greater post-apology satisfaction than the immediate apology in the high expectation condition, whereas the apology timing effect was reversed in the low expectation condition.

Experiments 2 and 3 replicated and extended previous findings in the context of hotel and hair salon services, respectively, by testing underlying processes and ruling out alternative accounts. As in experiment 1, we found the same interaction effect on post-apology satisfaction between apology timing and interaction expectation. Next, we observed that the apology timing effect was differentially mediated by cognitive and affective reactions, depending on interaction expectation. Using bootstrapping methods with two mediators (Preacher and Hayes 2008), we consistently showed that for the high (low) expectation condition, the apology timing effect was mediated only by cognitive (affective) reactions.

In experiment 4, we employed a 2 (apology timing: immediate vs. delayed) x 2 (interaction expectation: high vs. low) x 2 (expression of empathy: yes vs. no) between-subjects design in a hair salon service scenario. We investigated whether the apology timing effect would be weaker when a service person's empathy is removed from the apology. We varied the presence of a service person's expression of empathy, and also used tip size as a new dependent variable. As expected, we found the joint effect on consumers' post-apology tip size between apology timing and interaction expectation only when the service person expressed empathy, but not when the service person did not express any empathy.

CONTRIBUTIONS

The main contribution of this research is its novel findings that the apology timing effect depends on whether the consumer expects to interact with the same offender in the future. We extend Frantz and Bennigson (2005) and Fehr and Gelfand (2010) by documenting boundary conditions for the apology timing effect (experiments 1 to 4) and identifying the underlying processes (experiments 2 and 3). Particularly, we confirm that empathy is a key ingredient for success of a delayed apology (experiment 4).

Monetary Incentives and Pro-Social Behavior in Idea Co-creation

Christoph Ihl, RWTH Aachen University, Germany
Alexander Vossen, RWTH Aachen University, Germany

EXTENDED ABSTRACT

Instead of solely using in house R&D, the use of external ideas has become popular and accepted among organizations in various industries. Prevalent examples for this are firm-initiated innovation or ideation contests, which can be defined as a competitive activity hosted by an organization in order to gather external ideas from consumers with respect to specific topics (Piller and Walcher 2006). Typically, the hosts incentivize consumers' contribution by offering a monetary reward.

Within this paper, we show that the decision to offer such a monetary incentive greatly influences consumers' exerted effort. For showing this, we incorporate three different aspects that play a key role in how monetary incentives are perceived, namely the amount of monetary incentives offered (low vs. high), the organizational stereotype of the host (for-profit vs. non-profit) and the task domain (commercial ideas vs. pro-social ideas).

Concerning the role of monetary incentives, prior research shows ambiguous findings. Since ideation resembles a creative task, it profits from high levels of intrinsic motivation (Burroughs et al. 2011). Many authors therefore highlight the negative impact of monetary incentives, since they lower intrinsic motivation (Ryan and Deci 2000) and lead to a crowding out (Frey and Oberholzer-Gee 1997). However, marketing literature proves evidence for the opposite showing that awarding participants can indeed be beneficial (Toubia 2006; Burroughs et al. 2011). These ambiguous results show that it seems beneficial to further explore the role of monetary rewards as an incentive for participation in idea co-creation.

Regarding the organizational stereotype of the host, the predominant examples of ideation contests consist of many large companies, like for example Dell (Bayus 2011). However, more recently non-profit organizations have also begun to host ideation contests for pro-social topics. Contrarily to all for-profit examples, many of them do not provide a monetary incentive to the participants. Hence, the question arises if this is the right choice.

For for-profit hosts, Harhoff and Mayrhofer (2010) argue that monetary incentives are mandatory, since ideation contests resemble a form of innovation, where the host is capable of systematically utilizing the outcome of an innovative community. However, it remains questionable if this is also valid for non-profit organizations, since consumers perceive non-profits differently from for-profits (Aaker, Vohs, and Mogilner 2009).

Finally, we examine the impact of the task domain. Heyman and Ariely (2004) find that monetary incentives have an ambiguous effect depending on for what they are offered. They explicitly differ between money markets, where relations among actors are based on the basis of economic principles, and social markets, where relations among actors are based on social exchange. Consequently, the impact of monetary rewards in money markets, where people intend to earn money, is positive, while it has a negative impact in social markets, where people intend to engage socially. This is closely related to the task the hosts ask for, since the actual perception of the relevant market could change, when, for example, a for-profit firm asks for a pro-social task or the non-profit host asks for a commercial task. When outside their original activity domain, consumers could perceive a lack of competence for both kinds of organizations. Following Vohs, Mead, and Goode (2006), who find that monetary incentives have a strong signalling effect, Aaker et al. (2009) find that monetary rewards can be used to signal competence, which could also be the case for monetary incentives offered for idea co-creation participation.

Hence, we postulate the following research questions: (1) Is the effect of monetary rewards different for non-profit and for-profit organizations? (2) Is the effect of monetary rewards different, when organizations ask for tasks outside their original domain?

For testing our assumptions, we choose to run an online scenario based choice experiment with different scenarios of idea contests. For data collection, 537 participants are recruited by an online panel. All participants are shown four different possible idea contest scenarios dealing with cars and mobility. This leads to a total of 2148 observations. For the scenarios, we use a reduced design that includes the three main factors of interest and additionally factors that are included as controls. Two of these factors are within factors, namely the host (non-profit vs. for-profit) and the monetary incentive (low amount vs. high amount), and one is a between factor, namely the task domain (pro-social vs. commercial).

Due to the nested nature of our data (four observations per participant), we use a Random Coefficients Zero-Inflated Negative Binominal Model with the hours participants would invest in the contest as a dependent variable. Following the procedure for inter-action terms in non-linear models suggested by Greene (2010), all interaction effects are plotted in order to interpret their effect.

Results show that indeed monetary rewards play an important, yet ambiguous role as an incentive for participation in idea co-creation. Whether this role is positive strongly depends on who offers the monetary rewards (the host's organizational stereotype) and for what they are offered (the task domain). For both organizational stereotypes, monetary incentives work as suggested by literature–they are beneficial for for-profits (Harhoff and Mayrhofer 2010) and negative for non-profits (confirming literature on crowding out). However, when outside their original activity domain (when for-profits ask for pro-social tasks and a non-profit asks for commercial tasks) both need to introduce monetary rewards in order to signalize competence and the willingness to utilize the consumer generated ideas.

Our study contributes to theory by showing that monetary rewards for a pro-social task do not necessarily lead to a crowding out. Moreover, it shows that monetary rewards can indeed fortify pro-social behavior, if they are used by the for-profit host to show competence and willingness to utilize the idea. Further, we contribute to motivational theory by giving further examples for the fact that the efficiency of monetary incentives is contingent not only on the traits and preferences of individuals, but also on the circumstances under which they are provided, in this case for what and by whom they are offered.

Targeted Marketing and Customer Search

Nathan Fong, Temple University, USA

EXTENDED ABSTRACT

Can personalized marketing efforts inhibit customer exploration? It has become common practice for retailers to personalize direct marketing offers based on customer transaction histories. Targeted email offers featuring products similar to a customer's previous purchases generate higher response rates, but also have the potential to affect customer search behavior. A closely matched offer may encourage a customer to start the search process, leading to increased search activity. Alternatively, providing customers with closely matched offers may weaken their propensity to search beyond the targeted items. In a field experiment using email offers sent by an online wine retailer, targeted offers result in less search activity on the retailer's website. In a second study, transaction data from an online ticket exchange shows that, after receiving targeted offers, customers are less likely to broaden their purchasing to new genres. These findings indicate that targeted offers carry a hidden cost: a decrease in customer exploration and discovery.

PREDICTIONS AND BACKGROUND

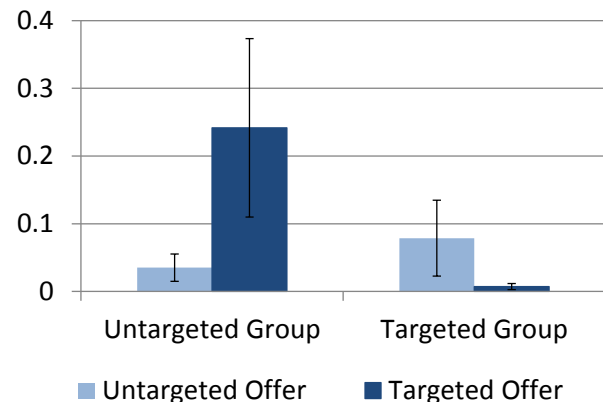
The trend towards increased personalization in electronic environments has the potential to affect the dissemination of new ideas. This could affect citizens learning about different perspectives or scientists learning about new research (Van Alstyne and Brynjolfsson, 1996, 2005); it could also affect how consumers learn about new products. Online retailing has provided better access to a wide range of niche products, which has necessitated tools to help manage the time and effort of search (Brynjolfsson, Hu, and Smith, 2003). Retailers have quickly adopted various forms of personalization that aim to improve the efficiency of a retailer's communications to its customers. One of the most common tactics is to use targeted offers that send customers information on products that a retailer believes the recipients will be interested in. As targeted offers have become increasingly prevalent in online retailing, it is important to understand all of the consequences, such as the potential effect on customer information search behavior.

Are customers more or less inclined to search when you offer them something they have bought in the past? One hypothesis is that an appeal that is aligned with a customer's revealed interests may secure the customer's attention, and encourage them to explore the retailer's other offerings. Dhar, Huber, and Khan (2007) showed that an offer that is more likely to be purchased can create shopping momentum, which makes additional purchasing more likely. Alternatively, by emphasizing products from a familiar category, a targeted offer could result in quick evaluation and curtailed search for other products. In a sequential search model, considering a higher-valued option is more likely to terminate the search process (Weitzman, 1979). Intuitively, by providing something interesting to look at, a targeted offer makes it harder to find something more interesting, lowering the value of continued search. The primary empirical contribution of this article is to examine how these factors play out in the context of targeted offers.

Previous research has examined how the Internet and information technology have affected search behavior. Häubl and Trifts (2000) looked at how recommendation agents (algorithms that provide personalized lists of recommended products) and comparison matrices (which typically line up alternatives in columns, and attributes in rows) affect online shopping behavior. They found that these tools allowed customers to search more efficiently, making better purchase decisions while reducing the number of alternatives they viewed. Research has also looked at how retailer actions affect customer exploration; for example, the visual layout of product information can affect the intensity of exploratory search (Janiszewski, 1998). The studies in this article find that targeted offers result in less search activity, but this is not simply saving time; there is less of the exploratory search that can expose customers to a broader range of products.

METHOD AND FINDINGS

The first study is a field experiment run with the cooperation of an online wine retailer. Customers in a targeted group were randomly assigned to receive offers for wine from two different regions, one of which (the targeted offer) matched the regional preferences revealed by their purchase histories. Their activity was compared to that of an untargeted control group, whose purchase histories did not match either offer. Detailed web browsing data for these customers was collected over a several day period. Unsurprisingly, the targeted customers were more likely to click through to the offer, and were more likely to purchase the offer. However, page views and similar metrics show that targeted emails decreased customer search activity for other products (see figure 1). This supports the hypothesis that targeted offers result in decreased information search.

Figure 1. Wine Retailer Information Search Response


Note: Depicts the average number of page views categorized as customer search for products other than the offer, such as browsing product categories and product pages (interaction is significant $p<.05$)

The second study used data on experimental email marketing campaigns run by an online ticket exchange. The firm sent emails promoting different genres of events, to groups of customers who either had (targeted) or had not (untargeted) previously bought tickets to the genre. Their behavior was compared to that of a holdout (no offer) group. Analysis of the ticket sales data shows that, after receiving targeted offers, customers are more likely to purchase from the target genre. However, they are also less likely to buy tickets for events in new categories, excluding the target genre and any other genres they had previously purchased in (see figure 2). This suggests that the curtailed search following targeted offers is not simply saving customers time, but it reduces exploratory search that could affect future purchasing.

Figure 2. Online Ticket Exchange Sales Response
Note: Depicts the proportion of customers purchasing from a new genre during the 28 day observation period following the offer (interaction is significant $p<.05$)

CONTRIBUTIONS

These field studies demonstrate how targeted offers result in decreased search activity and narrower subsequent purchasing activity. Conversely, less targeted offers can expose customers to a broader range of products, and lead to consideration of new products. Broader awareness could generate cross-selling opportunities and increase sales diversity, improving customer retention and lifetime value. If relying heavily on targeted offers, the retailer sacrifices opportunities to bring attention to products for which a customer has low awareness. Thus, retailers should balance the need for immediate sales response with measures that encourage exploration and sustain customer interest.

The Traffic Light Colors Red and Green in the Context of Healthy Food Decision-Making

Joerg Koenigstorfer, Pennsylvania State University, USA
Andrea Groeppel-Klein, Saarland University, Germany
Friederike Kamm, Saarland University, Germany
Michaela Rohr, Saarland University, Germany
Dirk Wentura, Saarland University, Germany

EXTENDED ABSTRACT

Traffic light-colored nutrition labeling may help consumers make healthy food choices (FSA 2009). The underlying assumption is that the colors green and red automatically activate the associated meanings ('go' for green, 'no-go' for red) when assigned to more or less healthful foods, thereby implying automatic approach-avoidance reactions. However, there is evidence that the meanings of colors change with contexts (Maier et al. 2009). Although traffic light colors have been learned in traffic (Bargh 1992), it is unknown whether this automaticity transfers to food contexts.

RED (GREEN) AND AVOIDANCE (APPROACH) BEHAVIOR OF FOODS

Evaluative connotations of attitudes to foods are activated automatically and linked bi-directionally to the motor behavior of individuals (De Houwer and De Bruycker 2007; Van den Bergh, Schmitt, and Warlop 2011). Pulling or pushing movements toward or away from one's body are indicators of innate motor behavior (Chen and Bargh 1999; Solarz 1960). Individuals' tendency to approach healthy food (pull) and avoid unhealthy food (push) may be affected by the traffic light colors red and green–i.e., complementary colors in the color wheel. Red carries the negative meaning of danger or failure, while green is less arousing and represents safety (Elliot et al. 2009). However, individuals may react more strongly to red-unhealthy (vs. green-healthy) pairings, because they are more sensitive to negative (vs. positive) product attributes (here: unhealthiness) providing greater information diagnosticity (Balasubramanian and Cole 2002; Moorman 1996).

Hypothesis 1 *Red (vs. green) intensifies automatic avoidance reactions towards unhealthy foods; for healthy foods, green (vs. red) does not intensify approach reactions.*

APPROACH-AVOIDANCE TASK STUDIES

Laboratory study 1 used a 2 (food: healthy vs. unhealthy) × 2 (color: green vs. red) × 2 (movement: toward vs. away) repeated-measures design to test hypothesis 1. Twenty black-and-white drawings of pre-tested healthy and unhealthy foods were presented on a white background within a red- or green-colored circle. Participants ($n = 179$) were asked to categorize each food as either healthy or not by moving a PC mouse toward or away from themselves.

Reaction times were recorded and used as dependent variable in a repeated-measures ANOVA yielding the proposed three-way-interaction of food category × color × movement, $F(1, 178) = 6.05$, $p < .05$, $\eta^2 = .033$. The two-way interaction effect between color and movement is only present in unhealthy foods, not in healthy foods. A relative index of the automatic approach-avoidance tendency was calculated to describe this effect. Follow-up study 2 ($n = 95$) using the same approach-avoidance task with the colors pink and blue–they are analogous to red and green and have the same chroma and value–finds that the enforcing avoidance effect is unique to red, and that this effect cannot be attributed to a mere increase in attention to the colors. Thus, hypothesis 1 is supported; the implicit meaning of red (danger) transfers to food contexts and reinforces avoidance of unhealthy foods, whereas green (representing safety) does not increase approach towards healthy foods.

TRAFFIC LIGHT-COLORED NUTRITION LABELS

Uncertainty remains about whether the implementation of traffic light colors on nutrition labels guides consumers' actual buying behaviors, and which consumers profit most. The goal conflict theory of eating (Stroebe et al. 2008) proposes that self-control conflicts between indulgence and healthy eating impact consumers' reactions to food items. Tasty foods (indulgences) trigger hedonic thoughts in low self-control consumers (Papies, Stroebe, and Aarts 2007). The salience of traffic light colors, in particular red on unhealthy food items, may inhibit this tendency, inducing avoidance reactions (Fishbach and Shah 2006), and thus lead to healthier decisions. We expect that high self-control consumers do not respond to the colors, because their decision-making is affected less by self-regulatory primes (Fishbach, Friedman, and Kruglanski 2003).

Hypothesis 2 *Low self-control consumers make healthier in-store choices when traffic light colors are implemented on front-of-pack nutrition labels; for high self-control consumers, no differences are found.*

IN-STORE STUDIES

Study 3 was conducted in a supermarket to test hypothesis 2. A one-way factorial (nutrition label with traffic light colors vs. without coloring) between-subjects design was applied. A retailer allowed us to manipulate product packages of one category (pasta and sauce). An expert rating of the products' healthiness based on their nutrient profiles with 162 dieticians reveals varying degrees of healthiness. Colored labels were implemented accordingly (FSA 2009): the unhealthiest (healthiest) products showed three macronutrients labeled red (green), the second unhealthiest (healthiest) products two macronutrients labeled red (green), and so on.

Participants ($n = 184$) were asked to buy four products for the purpose of the study (cover story: orientation in supermarkets during shopping). A shopping list was given to them that included one pasta meal of their choice. Self-control was measured using Giner-Sorolla's (2001) scale ($\alpha = .72$).

The unhealthiness of the product choice according to the mean expert ratings (*1 = very healthy*, *20 = very unhealthy*) was used as dependent variable in a moderated regression analysis including the manipulation (traffic light colors = 1, no coloring = –1), mean-centered self-control, and their interaction as independent variables. The proposed interaction between the labeling and self-control emerged ($b = 0.76$, $p < .05$). Among low self-control consumers (–1 *SD*), the traffic light-colored labels led to healthier choices ($b = -0.51$, *SE* = 0.20, $p < .05$), whereas there was no effect on high self-control consumers (+1 *SD*; *NS*). Follow-up study 4 ($n = 152$) replicates these findings for a different product category (cereal bars).

CONTRIBUTIONS

This study extends research into automatic approach-avoidance behaviors, introducing the notion that colors–particularly red–affect individuals' motor behavior not only in cognitive tasks (Mehta and Zhu 2009), but also in food contexts. It may be considered positive that approach behavior is not enhanced when green is related to healthy food, because this may indicate a mechanism of protection against the feeling of pre-commitment and, hence, overconsumption. This research also contributes to the goal conflict theory of eating (Stroebe et al. 2008) showing that low self-control consumers, despite close physical distance to food temptations, are affected by traffic light-colored nutrition labeling.

The Importance of Warmth and Competence in the Acquisition and Retention of New Customers

Iana A. Castro, San Diego State University, USA
Scott Thompson, University of Georgia, USA
James Ward, Arizona State University, USA

EXTENDED ABSTRACT

According to the stereotype content model (SCM), humans evaluate others along two fundamental dimensions, warmth and competence. Warmth is an assessment of others' intent to help us or harm us, and is tapped by our perceptions of others' honesty, sincerity, trustworthiness, and helpfulness. Competence is an assessment of others' ability to carry out their intentions and is tapped by our perception of others' intelligence, skillfulness, determination, and industry. Thus, the SCM argues that people are strongly disposed to evaluate others' warmth and competence, and that such judgments have strong links to emotional reactions and action tendencies. Supporting the SCM, a growing oeuvre of studies show that warmth and competence underlie our perception of and behavior toward other human groups, and that warmth judgments are "primary" – that is, the first judgment made and the perception most strongly related to emotional reaction and behavior toward others (Fiske, Cuddy, and Glick 2007).

Although studies of social perception have typically found judgments of warmth to be more influential than judgments of competence (e.g., Cuddy, Fiske, and Glick 2007), studies of customer purchasing decisions have found the opposite. For example, Aaker, Vohs, and Mogilner (2010) found that consumer purchase intentions are better predicted by competence perceptions than warmth perceptions. In the services literature, warmth related perceptions have been shown to be critical in judgments of service quality and satisfaction (e.g., Parasuraman, Zeithaml, and Berry 1985). Nevertheless, in a service encounter study, Grandey and colleagues (2005) found that service provider warmth impacted customer satisfaction only when the service provider performed competently.

In summary, past studies of the impact of warmth and competence perceptions on consumer choice and satisfaction have found results in conflict with the larger body of work in social psychology that identifies warmth as more influential than competence in determining behavior toward a group. How might the discrepancy be explained? First, consumer anticipation of the length of a relationship with a firm could impact the relative importance of the firm's warmth versus competence. Second, a consumer's degree of experience with a brand should impact the relative influence of firm warmth versus competence on purchase decisions. Warmth is a primary judgment because it is important to gauge others' intentions, so once intent has been revealed by action, the importance of judging intent for the next round of interaction should wane, as the importance of gauging competence waxes. Across three studies, we find support for our predictions.

Study 1 determined the role of warmth judgments versus competence judgments in deciding which company to hire and asked participants to rate a list of competence and warmth traits on how important they would be when selecting a company. The results supported the prediction that competence plays a more important role when selecting a company, contrary to the presumed primacy of warmth. However, the decision involved a one-time transaction. It is possible that warmth may play a larger role in decision-making if consumers are anticipating an ongoing relationship.

To address this question, in Study 2 we conducted an experiment in which participants were presented with a company description that manipulated the warmth and competence dimensions. The experiment used a 2 (warmth: low, high) x 2 (competence: low, high) between-subjects design. Participants were then asked to determine their likelihood of hiring the company for an ongoing relationship. Our results suggest that warmth is consistently valued over competence when an ongoing relationship is anticipated (interaction effect: $F(1, 118) = 16.14$, $p < .001$; $M_{\text{High Warmth High Competence}} = 5.47$, $M_{\text{High Warmth Low Competence}} = 3.26$, $M_{\text{Low Warmth High Competence}} = 1.93$, $M_{\text{Low Warmth Low Competence}} = 1.71$). Specifically, participants were most likely to hire the company when it was high on warmth and competence, with second preference being a company that was high on warmth and low on competence. Furthermore, when the company was low on warmth, differences did not emerge between the competence dimensions, suggesting that in the absence of warmth, level of competence did not matter.

In Study 3, we examined how the role of warmth and competence changes as consumers acquire experience with a firm. We followed the same procedure as in Study 2 and measured their attitudinal loyalty toward the company, word of mouth intentions, purchase intentions, and stability during the course of an interaction that included a service failure. The results indicate that prior to a service experience, warmth was consistently valued over competence. Furthermore, given a choice between either warmth or competence, customers will forgo competence in favor of warmth (attitudinal loyalty interaction effect: $F(1, 368) = 10.36$, $p < .01$; $M_{\text{High Warmth High Competence}} = 3.91$, $M_{\text{High Warmth Low Competence}} = 2.45$, $M_{\text{Low Warmth High Competence}} = 2.08$, $M_{\text{Low Warmth Low Competence}} = 1.38$; other measures followed the same pattern).

Next, participants were shown a description of a service failure in which participants ordered a product from the company, received a different product than the one ordered, and then wrote the firm to ask for a correction of the problem. The scenario ended as the consumer awaited the firm's response. Following this service failure, the importance and impact of warmth begins to fade. The only measure that warmth plays a larger role on than competence is stability, or the probability that a failure will occur again (interaction effect: $F(1, 364) = 8.18$, $p < .01$; $M_{\text{High Warmth High Competence}} = 4.23$, $M_{\text{High Warmth Low Competence}} = 2.91$, $M_{\text{Low Warmth Low Competence}} = 2.57$, $M_{\text{Not Warm Not Competent}} = 2.10$). This suggests that warmth judgments are dominant over competence judgments prior to service interactions. However, once customers have an experience with the company, the information from the event begins to upstage these perceptions of warmth, and competence becomes increasingly important. Nonetheless, companies that are high on warmth *and* competence still benefit on the key outcomes of word of mouth and purchase intentions compared to those who are not, which suggests that brand personality can buffer the impact of an initial service failure, but only for those that have both a warm and competent brand personality.

Gift Cards and the Social Relationship

Kunter Gunasti, University of Connecticut, USA
Michelle F. Weinberger, Northwestern University, USA

EXTENDED ABSTRACT

Through selection and presentation, gift givers communicate to the recipient about the strength and nature of the relationship (Caplow 1982; Joy 2001) and ultimately reinforce or reformulate the social tie (Ruth, Otnes, and Brunel 1999). Most research examines gifts given from a giver to the recipient in a relatively usable, final form (see Sherry 1983). Yet a gift card is different; the recipient must take additional action to finish the gift and make it symbolically successful. Despite pervasive use of gift cards in the marketplace, little research has looked at the role of the social relationship in card use.

Imagine that John receives a bookstore gift card. Will he buy videogames, what he really wants, even though the giver clearly wants him to buy books? Would he re-gift it for his sister? What if the giver is his close friend, or someone rarely seen? Our research focuses on the different ways in which gift card recipients finish the gifting process and the social drivers of their actions.

We hypothesize that gift recipients will be more affected by the intentions of the givers (communicated via visual cues on the gift card: card merchant, overall theme, giving occasion) when the giver and recipient are in a close relationship. When completing the gift, close (vs. distant) recipients will try harder to subtly ascertain and fulfill the giver's intentions, at times overriding their own desires and making less economically rational decisions by spending more. Our theorization suggests that in the case of the gift card, relationship reformulation does not fully occur on gift receipt (Sherry 1983); instead, the process is extended while recipients finish the gift physically and symbolically.

In study 1, participants read a scenario about a girl receiving a bookstore gift card with a book picture on it from a close vs. distant giver. It indicated that the girl did not have time to read but she enjoyed music. Then participants described how she should spend the gift card. When it came from a distant giver, none of participants thought the recipient should buy books (vs. the intended gift). When it came from someone close, 14% indicated that she should buy books, even though it wasn't what she wanted. Participants were more likely to use moral language as guiding their imperative for her to use the card on herself when it was from a close giver.

In study 2, a 2 Relationship (Close vs. Distant) x 2 Store Theme on Gift Card (Generic Store/No Picture vs. Sports Store) design was used. Participants identified either a close friend or someone with whom they were not close who then ended up giving them a $75 gift card for Kleine's, a new store. The gift card either displayed no picture or a sports theme. Participants were taken to Kleine's store website to choose among 9 products, 3 categories (sports, cameras, luggage) x 3 three price levels (high, equal, low). For close givers, the sports themed card led to significantly higher preferences for sports goods; for distant givers, the card format did not affect the choice of sports goods. When the givers were close (vs. distant), more recipients spent above the value of the gift card out of pocket.

In study 3, students were given a $50 Generic vs. Birthday Theme Target gift card by their "significant other" and told that they go the store to use the card. However, the jacket they wanted to buy is $57 at Target and available for $45 elsewhere. Participants were further informed that they also needed to purchase a grill for a friend. When the gift card had a birthday theme, participants were more likely to pay the premium, purchasing themselves the jacket as a birthday gift. The non-birthday themed card almost doubled the number of recipients who chose not to fulfill their significant others' intentions, using the gift card for someone else.

In sum, over the course of three experiments, we revealed that implicitly recipients take on additional relational work to fulfill the giver's intentions when they feel close to the giver. To do this, recipients use three visual cues to interpret the givers' intentions for the gift cards' use: store/merchant of the card, general theme, and gift occasion. Although some might claim that economically the gift card is only a vehicle for transferring funds, this study shows that in certain cases the card becomes infused with meaning and becomes a symbolic vehicle. Yet only recipients who feel close to the giver feel a moral obligation to do additional relational work to ascertain and fulfill the givers wishes even when it is incongruent with the recipient's own desires and is the less economically rational use of the funds.

The Construction of Cosmetics-Consuming Women Through Generational Families in Brazil's "New Middle Class" Context

Roberta Dias-Campos, Federal University of Rio de Janeiro, Brazil
Leticia Moreira Casotti, Federal University of Rio de Janeiro, Brazil

EXTENDED ABSTRACT

Theory on consumer socialization has described the cognitive aspects of consumer formation (Roedder, 1999), coupled with extensive measurement developments on family influence on individual decisions (Moschis, 1985, 1988; Commuri, Gentry, 2000; Thompson, Laing, Mckee, 2007; Götze, Prange, Uhrovks, 2009). Nevertheless, less attention has been made to the social context to consumer formation (Ward, Klees and Wackman, 1990). Besides, the socialization field has been historically based on a positivistic perspective, which could benefit from contributions of an interpretative and cultural approach (Hirschman, 1986; Holbrook and O'Shaugnessy, 1988; Arnould and Thompson, 2005; 2007) and from social sciences theory itself, as new form of lens to consumer socialization studies (Bourdieu, 1979; Rocha-Coutinho, 2006; Darmon, 2006; Foucault, 1984; Dubar, 2009).

This study aims to provide a social and cultural perspective to the theoretical domain of socialization of consumer (Ward, 1974; Moschis, 1985, 1988), through the use of interpretative tools to investigate beauty consumption in the Brazilian middle class. It seeks to understand beauty consumption itineraries among three generations from the same family – grandmother, mother and daughter. A both social and generational approach (Shah and Mittal, 1997; Bertaux, 1997; Alberti, 2005; Atkinson, 1998; Lins e Barros, 2006) was adopted to investigate family transmission dynamics, which constitute rich laboratories to consumer socialization, within the chosen micro-social scale of a qualitative and interpretative research design (Desjeux, 2004; Cova and Cova, 2002).

Different qualitative methods were considered to allow data triangulation and the emergence of natives' point of view (Geertz, 1979): in-depth life story interviews (McCracken, 1988; Bertaux, 1997) combined with in-home observations (Rodhain, 2008; Alami; Desjeux; Garabuau-Moussaoui, 2009). Fifteen families were selected by a professional recruiter, and 30 interviews were carried, totalizing a 6 hours minimum interview per family. For the third generation, children aged from 4 to 10, data was gathered in informal conversations, interview with adults and observation of their living space. Social-economic sample definition was inspired by the emergence of a new Brazilian "middle class", result of an uprising within the social pyramid. This new large group rapidly conquered its space in "cold" statistic studies, but remains largely unknown due to lack of research capable of describing its diversity.

The family life stories enabled the identification of a socialization process from a social point of view. Based on Bourdieu's social perspective on socialization, the analysis pointed out to four different construction moments of the beauty consumer: the development of taste, the rehearsal by mimicking, the consumption premiere and the adjustments phase.

In the development of taste, rules and judgment are incorporated to form consumers' values, sense of taste and femininity. Even before girls can understand the meaning of daily care rituals, they begin to incorporate a silent group of values that will shape their appreciation of themselves and others. Manicure and hair treatments such as straitening (for the curly hair), for example, are internalized as basic practices and values for displayed femininity in adult life in Brazil.

The rehearsal by mimicking marks the beginning of concrete action, even if still in the form of childish games. Girls are often observed playing with makeup or giving themselves a "manicure", from the frequent observation of their mothers and sisters. At this moment, they are not yet consumers, but they are playing as one.

The consumption premiere moment is identified not only by the use of beauty products as a full consumer, but also by the emergence of shopping habits and new use occasions. This premiere may be prompted by events such as the 15th birthday (a still important tradition in Brazilian middle class), the first job, the beginning of going-out with friends without parental supervision, and a first romantic relationship.

After a while, consumers get to know better their consumption needs as well as products, brands and services available. At this moment they enter the last stage, where adjustments are made to their childhood practices, and they start searching solutions, better suited for their grown-up needs. At this moment, the consumer seems to start his adult consumption phase, and the socialization process finds its end.

Particularly in Brazil, an important generational gap seems to indicate uneven family influence, according to different product categories. Life story of interviewed consumers shows a large distance between grandmothers and mother social roles. While the first ones were centered on the household and family activities, the next generation tries to make room for career and education. They get married later and have fewer children, on one side, and strike for gathering more educational degrees, on the other. This gap determines different forms of family influence in operation. While the older generation (grandmothers) relied more on maternal counseling for consumption decisions, the mothers' generation combines both pairs and family as source of consumption guidance. Depending on the category analyzed, the family influence will be greater or diminished. The most striking example is the consumption of makeup products as means to build a more professional presentation. For this category, interviewees indicated friends and colleagues as the main consumption reference. Nevertheless, for hair treatments, family is still the central unit of influence, determining patterns for volume control standards.

Finally, in order to reduce risk in adopting unknown treatments that, for instance, may affect hair structure - such as the "progressive brushing" – consumers adopt a strategy of triangulating opinions from three particular influence groups: specialists (that provide technical expertise), the media (that guarantee the wide use of the treatment) and the family (that confirm the treatment adaptability to a particular kind of hair). These three sources are continuously confronted in a *confirmatory cycle* that tries to reduce the risk of adopting new hair solutions. This strategy has not been identified on previous research with upper class consumers in Brazil (Casotti, Suarez and Campos, 2008).

This paper aimed to contribute to consumer socialization research, by offering a social and interpretative perspective. It proposes four stages for consumer socialization from a contextual and social standpoint. Additionally, it discusses specifics aspects of Brazilian middle class consumption, determined by generational changes and particular social network dynamics.

Cruising the Unadulterated Terrain of Consumption:
Rural Snowmobilers' Interpellation through Collective Simplicity

Soonkwan Hong, Michigan Technological University, USA

EXTENDED ABSTRACT

Consumer research has thus far been virtually taciturn about poor consumers in rural areas who have less access to, or interests in what has been normalized as mainstream lifestyles in urban, suburban, or exurban areas. Bourdieu's (1984) cultural and symbolic capital that embodies tastes (consumption practices) and configures the consumer's ideological position has instead been the focus of various analyses of contemporary status consumption phenomena (Holt 1997; Ustuner and Holt 2010; Ustuner and Thompson 2012). Nonetheless, the economic capital, as a boundary condition of consumption, needs to be considered more essential rather than tangential when exploring marketplace performances by the poor (Bauman 2007).

The current literature employing discourses about the intersection between consumption and social status explains that cultural capital operates as a determinant of lifestyle choices (Holt 1997), a basis for aesthetic and ideological claims (Holt 1998), a catalyst for socially stratified consumption (Ustuner and Holt 2010), and a requisite for a smoother acculturation process (Ustuner and Holt 2007). The listed research, however, has not documented how consumers with low economic capital in a highly developed country carry on their identity projects and execute their ideological positioning in the immensely hierarchical field of consumption. Therefore, this research aims to explicate the process in which relatively deprived consumers build social capital, cultivate cultural capital, and potentially rearticulate the meaning of symbolic capital.

The interwoven and thus inseparable connections among social status, interpellation, and consumer identity have been illuminated (e.g., Kozinets 2008). However, the social aspect of the dynamics does not necessarily address the plasticity of social constraints (i.e., habitus), made possible by individual consumers' agentic endeavors (see Bourdieu1990a). While different kinds and degrees of capital constitute habitus, it is not totally predestined boundary of individual ideological positioning. Bourdieu is never a determinist (Bourdieu1990b). Nor are consumers. The sociocultural backdrop for an individual is also reflexively malleable insofar as one empowers oneself as an ideologically autonomous agent, rather than incapacitating him/herself based on the notion of habitus' reproduction of itself (Calhoun et al. 1993; Henry 2005). Interpellation imposes personal and social identity (status) upon an individual and concomitantly sets limits that make individual desubjugation possible (Butler 1997, 2002). Social power relations, norms, dominant ideologies, mainstream consumer culture, and episteme together create an arena wherein consumers can stylize themselves as agents at the limits of their socially interpellated being, as long as they espouse critical mode instead of obedient mode (cf. Foucault 2003). Critical resistance to what orthodox interpellation process inculcates is witnessed in the context of rural snowmobilers, especially when consumers with low economic capital collectively governmentalize not only their identities, but what governmentalizes them as well.

In order to unpack the "critical interpellation" process embraced by rural snowmobilers, a snowmobilers' club in the Upper Peninsula of Michigan was contacted for participatory observation and unstructured depth interviews. Twelve members participated in the interviews at their homes and outdoors as the weather permits. The interviews ranged from 45 minutes to 150 minutes, and observation was conducted as often as possible at such places as bars, gas stations, grocery stores, hotel lobbies, and other local shops that the snowmobilers frequented. The author also participated in road trips and rallies to different places. Fieldnotes, photographs, and videos were kept. Based upon the conventions of hermeneutic approach (Thompson, Pollio and Lacander 1994), the informants' narratives and lived experiences were explicated, employing semiotic clustering method (Feldman 1995).

Rural snowmobilers rearticulate the meaning of social stratification of consumption and dismantle the relevant sociocultural fields in which players are expected to comply with the logic of "foreclosure (subordination)." Six distinct thematic manifestations of rural snowmobilers' ontological positions were identified, three of which contrast the other three with respect to ethics, social status, and ideology (see Figure 1). Owing to the harsh conditions (cultural, economic, and climatic) of rural life, snowmobilers subordinate their desires and aspirations as contemporary consumers to self-discipline and self-preservation. Simultaneously, the mirror images of such hardship, as postmodern lifestyles, and the subsequent pragmatic positioning of rural snowmobilers' sociocultural statuses are also uncovered as rearticulation and reconfiguration of their own styles of being, or emerging statuses. Such highly agentic repositioning and transformation of their personal and social identities take place in a collective setting, in which constant interactions with other snowmobilers enhance the camaraderie amongst them, as "narrowcasted" and "enclaved" social capital.

Ethical consumption practices facilitate snowmobilers' interpellation, as they subscribe to Nietzschean notion of indebtedness, which determines the degree of ethicality. Abnegation of extensive use of credit cards, excessive domestic wastes, gluttony, and materialistic worldview in general is what stylizes their statuses as ethical consumers whom relatively affluent consumers seeking new statuses emulate and simulate. The reflexivity between their consumption practices and the newly developed lifestyles in mainstream consumer culture also creates an ideological niche where poor consumers find a new status that is both subsistent and stylish.

A simple life is what rural snowmobilers collectively pursue, and it signifies environmental consciousness, human ecology, communal harmony, and cultural preservation. The nuanced dissimilitude between their everyday practices and the movement of responsible consumption in the mainstream consumer culture caused by varied levels of economic capital is sublimated into a new source of cultural and symbolic capital. The bases for the novel type of cultural capital comprise habits, skills, and knowledge about thrifty living and self-sustainability. By the same token, rural snowmobilers rewrite the prescribed recipe for symbolic capital, as they earn socio-politically high-ranked position of conscientious consumers.

The reflexive interpellation process brought out in the context provides a platform for researchers to enunciate how poor rural consumers maintain ontological security (Giddens 1991). The received view of inherited and institutionalized cultural and symbolic capital is not necessarily applicable to the context where upward sociocultural mobility can be collectively achieved through agentic appropriation of highly stylized and politicized consumer movements. Avenues for future research extend to the theoretical and empirical junction between anti-consumption and conscientious consumption where both practices bestow unique ideological positions on consumers. Perhaps poor conscientious consumers co-opt socioculturally distanced simulacra to glamorize their lifestyle.

Eat to Be Fit or Fit to Eat?
Restrained Eaters' Food Consumption in Response to Fitness Cues

Joerg Koenigstorfer, Pennsylvania State University, USA
Hans Baumgartner, Pennsylvania State University, USA

EXTENDED ABSTRACT

It is recommended that individuals exercise regularly (Haskell et al. 2007). However, today's environment provides many apparent substitutes for physical activity. This research investigates whether and how fitness cues – both cues that are incidentally present in the environment and cues that are integral to food products (e.g., as part of the packaging) – affect food consumption volumes and whether the relationship is moderated by individual differences and product perceptions.

CONCEPTUAL FRAMEWORK

We propose that both dietary restraint and the perception of food as 'good' or 'bad' impact the relationship between fitness cues and consumption. Dietary restraint refers to chronic eating patterns by individuals who are guided less by their internal feelings of hunger and more by external factors and a constant concern with weight control and dieting (Bublitz, Peracchio, and Block 2010). Restrained eaters often experience conflicts between the goal of eating enjoyment and the goal of weight management (Stroebe et al. 2008). Furthermore, restrained eaters tend to think heuristically about food and view food as either more (allowed) or less (forbidden) suitable for achieving long-term goals (Oakes and Slotterback 2005). If product categories are perceived as dietary-forbidden, both incidental and integral fitness cues should inhibit restrained eaters' tendency to approach tasty but unhealthy food and *decrease* consumption relative to when the concept of fitness is not salient (Anschutz, van Strien, and Engels 2011; Fishbach and Shah 2006).

In contrast, when product categories are perceived as dietary-allowed, we expect the opposite effect. In this case, the compatibility of eating with long-term health benefits reduces the conflict between eating enjoyment and weight management and may liberate restrained eaters from pursuing their dieting goals (Fishbach and Dhar 2005). Therefore, both incidental and integral fitness cues are hypothesized to *increase* consumption for restrained eaters when the product category is dietary-allowed.

Previous research has implicated a variety of mechanisms that may increase or decrease food consumption, including biased product perceptions (calorie under- or over-estimation; Wansink and Chandon 2006) and biased self-perceptions (the extent to which consuming a food affects the perceived closeness to desired fitness or body weight; Geyskens et al. 2007). We examine which of these accounts is most consistent with the effect of fitness cues on consumption for restrained eaters.

EMPIRICAL STUDIES AND MATERIALS

We conducted four studies to test these hypotheses. Studies 1a and 1b assessed the consumption of dietary-forbidden (potato chips) and dietary-allowed (yogurt and granola) foods (both pre-tested, 150 kcal per serving) in response to incidental fitness cues. Study 1a (n = 132) used a two-group design in which either fitness or neutral concepts were primed supraliminally via a scrambled sentence task. After the priming task, participants had a chance to sample a dietary-forbidden food (potato chips) and their consumption was assessed unobtrusively. Dietary restrained eating was assessed via Herman and Polivy's (1980) scale (α = .78). A moderated regression analysis with prime (neutral = 0, fitness = 1), mean-centered dietary restraint,

their interaction, gender, BMI, perceived tastiness, and hunger as independent variables and the number of calories consumed as the dependent variable revealed the expected two-way interaction between prime and dietary restraint (b = –7.74, p < .05, model R^2 = .15). There was no effect of the prime on consumption for unrestrained eaters, but restrained eaters consumed significantly less when they were primed with fitness (b = –7.60, p < .01).

Study 1b (n = 166) was similar in design to study 1a, except that the product category was dietary-allowed (yogurt and granola). As expected, there was a significant interaction between prime and dietary restraint (b = 5.83, p < .05, model R^2 = .22). The fitness prime had no effect for unrestrained eaters, but restrained eaters consumed significantly more when they were primed with fitness (b = 4.57, p = .01).

Study 2 (n = 162) investigated the effect of integral fitness cues on consumption of dietary-allowed food (trail mix) using a two-group design in which participants had a chance to sample (under the pretence of a taste test) either a Fitness Trail Mix or simply a Trail Mix. Consumption was measured unobtrusively, and dietary restraint was measured with Van Strien et al.'s (1986) scale (α = .91). As expected, there was a significant interaction between fitness cue and dietary restraint (b = 68.33, p < .05, model R^2 = .19). The fitness cue had no effect on unrestrained eaters, but restrained eaters consumed significantly more trail mix when it was labeled Fitness Trail Mix (b = 85.90, p < .01).

Study 3 (n = 104) examined potential mediators of this effect. The design was similar to study 2, except that we asked participants to rate the perceived calorie content per serving (150 kcal, presented in bowls) and their perceived closeness to desired fitness and desired body weight (0 = *far away*, 100 = *fully reached*). The results of moderated regression analyses showed that a fitness cue on the product did not have a differential effect on calorie estimates of restrained and unrestrained eaters (b = –1.98, p = .85, *NS*). However, the interactions of dietary restraint with closeness to both desired fitness (b = 1.65, p < .05) and body weight (b = 2.54, p < .001) were significant. Spotlight analyses showed that restrained eaters saw themselves as closer to their desired fitness and body weight in the Fitness Trail Mix condition.

CONTRIBUTIONS

Our research shows that fitness cues primarily influence the amount of food consumed by restrained eaters, and that the direction of the effect depends on whether (isocaloric) food is perceived to be dietary-forbidden or dietary-allowed. Although liberation processes in restrained eaters have previously been shown for diet- and health-related primes (Papies and Hamstra 2010) and for certain food attributes (e.g., 'haloes' associated with low-fat; Wansink and Chandon 2006), we demonstrate that they also occur in response to fitness cues. Despite the fact that the focal goal of becoming more fit is actually not fulfilled by eating food associated with fitness, consumption of dietary-permitted food increased for restrained consumers.

How Accidents Can Be Good For the Brand: The Role of Accident-Brand Stereotype Match and Self-Brand Congruity in User Accidents

Tarje Gaustad, BI Norwegian Business School, Norway
Jakob Utgård, BI Norwegian Business School, Norway
Gavan J. Fitzsimons, Duke University, USA

EXTENDED ABSTRACT

Bad things happen, even to good brands. Sometimes brands get involved in negative events that they could do little to avoid. Cars are crashed, knives used to kill, alcohol abused, and firms cannot always influence these events. In 2008, there were almost four million serious road accidents in Europe and North America combined (UNECE 2011). Consumers are frequently exposed to these accidents in the media or on the road. Car accidents are negative events with sometimes tragic consequences, but they also have interesting branding implications. How does exposure to a car accident affect attitudes to the car brand?

When the brand is little to blame for a negative outcome, consumers tend to judge the brand lightly (Klein and Dawar 2004). Research shows that consumers with strong brand commitment react less negatively when presented with negative information about the brand (Ahluwalia, Burnkrant, and Unnava 2000). Aaker, Fournier, and Brasel (2004) demonstrate that mistakes and transgressions have less negative impact for exciting brands than for sincere brands. This indicates a relationship between expectations based on brand personality and how consumers respond to transgressions.

Building on this, we hypothesize that match between the accident and brand associations (stereotypical accident) increase fluency of the currently held brand associations and polarize attitudes. We base this on the availability-valence hypothesis (Kisielius and Sternthal 1986) which argues that judgments depend on the valence of information available in memory. If the accident's characteristics match consumers' associations of the brand, the accident will increase fluency for those associations and lead to a valence polarization of the existing brand attitudes (positive attitudes becoming more positive and negative attitudes becoming more negative). We use self-brand congruity as a proxy for the valence of the existing associative network available in memory. For consumers who feel congruency between their own self-image and the brand (self-brand congruity), a stereotypical accident confirms pre-existing brand associations and strengthens positive attitudes. For consumers who do not feel congruent with the brand, a stereotypical accident confirms existing negative associations and strengthens negative attitudes.

Study 1 investigates how match/mismatch between the accident and brand associations influence consumers' judgments. Undergraduate students (n=103) participated in a 2 (stereotypical vs. non-stereotypical accident) × self-brand congruity (measured) between-subjects experiment. First, we measured participants' attitude and self-brand congruity (Sirgy 1982) to BMW. Next, respondents read a newspaper article about a BMW car crash. The article was similar for both conditions except from the description of *how* the accident happened. We manipulated the accident to be stereotypical (racing in high speed) or not stereotypical (crossing over into the wrong lane) of BMW. Pretests had confirmed that the speeding accident was significantly more typical for BMW than the other accident ($p = .03$), but that they were equally serious ($p = .4$). Last, we measured perception of the accident and change in attitude to BMW.

We conducted multiple regression with change in attitude to BMW after reading the newspaper article as a dependent measure, and experimental condition (not stereotypical accident=0, stereotypical accident=1), self-brand congruity (continuous variable), and their interaction as independent variables.

The results showed a negative effect of type of accident ($\beta = -2.02$, $t = -3.26$, $p < .01$), meaning that participants evaluated BMW more negatively after reading about the stereotypical accident (versus non-stereotypical), even though the two accidents are equally serious. As expected, the interaction between type of accident and self-brand congruity was significant ($\beta = .51$, $t = 3.32$, $p < .02$), also after controlling for pre-attitude to BMW. Investigation of the interaction confirmed the predicted significance and non-significance of slopes, as well as contrasts at low and high levels of self-brand congruity.

The results confirm our hypothesis. Participants who do not feel congruent with the brand decrease their brand evaluation after learning about an accident that confirms their brand associations, while participants who feel congruent with the brand increase their evaluation when an accident confirms their brand associations.

In study 2, we seek to replicate the findings by including a condition with a car brand that is not strongly associated with high speed and racing (Toyota), and to rule out the alternative explanation of "high speed" as a signal of high performance. To explain the results, high speed needs to be a positive performance signal for those feeling congruent with any car brand (whether or not the accident matches brand associations) and similarly negative for those who do not feel congruent.

Online respondents (n =287) participated in a 2 (high speed accident vs. wrong lane accident) × 2 (BMW vs. Toyota) × self-brand congruity (measured) design. The procedure was similar to study 1, except for the "Toyota-condition".

We conducted multiple regression and the three-way interaction (brand, accident type, and self-brand congruity) yielded the expected result ($\beta = .016$, $t = 2.01$, $p < .05$). Separate analysis of the BMW condition and the Toyota condition also show the expected results, with a significant two-way interaction between accident type and self-brand congruity ($\beta = .16$, $t = 2.90$, $p < .01$) in the BMW condition and no interaction in the Toyota condition ($\beta = .00$, $t = -.053$, $p =.96$).

The results replicate the findings from study 1, and confirm that the effect is dependent on a match between the user accident and brand associations.

This research suggests that accident "stereotypicality" influence brand evaluations. Participants evaluate the brand more negatively after learning about an accident that matches brand associations than an accident that does not match brand associations. However, this effect interacts with participants' felt self-brand congruity, suggesting that stereotypical accidents polarize brand evaluations. Those participants who feel that the brand is "like them" increase their brand attitudes if the accident is stereotypical, whereas those participants who feel that the brand is not "like them", decrease their attitude if the accident is stereotypical of the brand.

Tell Me What to Do When I am in a Good Mood,
Show Me What to Do When I am in a Bad Mood:
Mood as a Moderator of Social Norm's Influence

Vladimir Melnyk, Maastricht University, The Netherlands
Erica van Herpen, Wageningen University, The Netherlands
Arnout Fischer, Wageningen University, The Netherlands
Hans C. M. van Trijp, Wageningen University, The Netherlands

EXTENDED ABSTRACT

Social norms are an influential driver of consumers' preferences in different domains of everyday life (Cialdini et al., 2006; Melnyk et al., 2009) and are extensively used in marketing campaigns. The influence of social norms may depend on the mood that consumers experience while being exposed to them (Bless et al., 1990), but also on the formulation of the social norm. Social norms can be formulated as descriptive or injunctive norms (Cialdini et al. 1990). Descriptive norms describe the typical behavior of others, and set behavioral standards from which people may not want to deviate (Schultz et al. 2007). Injunctive norms prescribe a behavior, and refer to what people should do in a given situation.

Despite a large body of research on social norms (see Goldstein & Cialdini, 2009) and on the role of mood in consumer behavior (see Gardner, 1985) little is known about the effect of mood on social norms' influence. This paper argues and shows that each norm formulation can be differently affected by mood due to mood-protection and the mood-repair mechanisms. That is, individuals are motivated to maintain the mood when they are already in positive mood, but engage in mood repair when they are in negative mood (Hirt & McCrea, 2000).

Importantly, because of these mechanisms, positive and negative moods can result in different effects on the amount of cognitive effort that people exert (Isen et al., 1985). When in positive mood, individuals avoid investing cognitive effort unless doing so promises to enhance their positive mood (Bohner et al., 1992; Wegener et al., 1995), and they show more compliance with requests, compared to negative mood (Forgas, 1998). In contrast, when in negative mood mood-repair mechanism stimulates individuals to invest cognitive effort to find ways of improving their mood (Clore et al., 1994; Hirt & McCrea, 2000).

This difference in the amount of cognitive deliberation under positive and negative mood can lead to different perceptions of injunctive compared to descriptive social norms. Previous research has shown that injunctive norms have a smaller influence on the advocated behavior, when consumers cognitively deliberate upon them (Melnyk et al., 2011). This is because injunctive norms by conveying an explicit and straightforward request can be perceived by consumers as a limitation to their freedom and can therefore trigger them to counter-argue (Mann & Hill, 1984). In contrast, in positive mood the mood-protection mechanism should decrease the likelihood of thoughts against such a request (Batra & Stayman, 1990). Therefore we expect a higher responsiveness towards injunctive norms in positive mood compared to negative mood.

Hypothesis 1:   Injunctive norms have a greater influence on attitudes, behavioral intentions and behavior under positive than under negative mood.

For descriptive norms negative mood should not decreases their influence, because due to the mood-repair mechanism consumers are more likely to cognitively deliberate upon the messages (Clore et al., 1994), and this can increase the influence of descriptive norms (Melnyk et al., 2011). The mood-repair mechanism also simulates consumers to think about solutions to improve their mood. Descriptive norms can present such a solution, by providing "social proof" of what is likely to be effective behavior (Cialdini, 2006; Reno et al., 1993) and beneficial behavior (Schultz et al., 2007). Furthermore, Griskevicius et al. (2009) showed that a descriptive norm message with a social proof appeal ("most popular"), was persuasive when people experienced negative feelings (fear), but was counter persuasive when people experienced pleasant feelings (romantic desire). This can make descriptive norms more influential under negative than positive mood.

Hypothesis 2:   Descriptive norms have a greater influence on attitudes, behavioral intentions and behavior under negative than under positive mood.

These hypotheses are tested in two experiments.

Experiment 1 ($N = 140$) had a 2 (mood induction: negative vs. positive) $\times$ 3 (norm formulation: descriptive vs. injunctive vs. no norm) between subjects design. For *mood manipulation*, participants were asked to recall either a negative life event (negative mood condition), or a positive life event (positive mood condition). *Norm formulation* was manipulated by a short statement on the background of a neutral picture with chocolate: *"Did you know that nowadays most WUR students buy fair trade chocolate?"* (descriptive norm condition), *"Did you know that nowadays most WUR students think you should buy fair trade chocolate?"* (injunctive norm condition), and *"Did you know that nowadays there is a possibility to buy fair trade chocolate in any supermarket?"* (no norm condition). At the end of the experiment participants were offered an opportunity to make a donation to a well-known fair trade organization "Oxfam-Novib" from their monetary reward for participation.

Experiment 2 ($N = 160$) examines the proposed underlying mechanism of cognitive deliberation by testing if preventing people from deliberating decreases the moderating effect of mood. It had a 2 (mood induction: negative vs. positive) $\times$ 2 (norm formulation: descriptive vs. injunctive) $\times$ 2 (cognitive load: high vs. low) between subjects design. The manipulations of mood and norm formulation were similar to Experiment 1. *Cognitive load* was manipulated by asking participants to either remember a 7-digit number (high cognitive load) or a 1-digit number (low cognitive load).

Consistent with our expectation the results obtained from the two experiments show a fundamental difference between injunctive and descriptive norms. Injunctive norms lead to more positive attitudes and intentions under positive (vs. negative) mood, whereas descriptive norms lead to more positive attitudes and intentions under negative (vs. positive) mood. Furthermore, we show that this effect translates to actual (donations) behavior. Experiment 2 shows that the effect is due to cognitive deliberation, as the effects disappear when cognitive deliberation is hindered.

Our results indicate that social norms should be carefully chosen, and used depending on the context in which the information supported by the norm is processed by the consumer. The study has

theoretical implications as well. Previously, negative mood was shown to decrease consumer's evaluations of received information and persuasive messages (Miniard et al., 1992). This paper shows that mood not only changes the responsiveness of consumers to social norms for attitudes and intentions, but it does so differently for the two norm formulations. In particular, the negative effect of bad mood on responsiveness to persuasive information can be reversed by using descriptive norm formulations rather than injunctive norms.

This research contributes to our understanding of the influence of social norms on decision making by showing how mood affects the influence of descriptive compared to injunctive norm formulations on consumers' attitudes, purchase intentions, as well as on real behavior.

Consuming the Cyborg

Arundhati Bhattacharyya, York University, Canada
Richard Kedzior, Bucknell University, USA

EXTENDED ABSTRACT

Pace-makers have been placed in the body for the last 50 years. Abilities enhancing micro-chips have been grafted into the human body for the last 15 years (Naam 2005; Warwick 2004). Despite these identity-problematizing developments (Williams 1997), extant consumer research on individuals' engagement with *active*-technology (stimuli-responsive technology like micro-processors, as opposed to inert Silicone implants) remains limited to contexts where such technology is external to the body. The current study seeks to correct this oversight by examining the lay discourses surrounding active-technology embedded bodies. Specifically, we ask:

1. What are the discourses surrounding active-technology embedded human bodies?
2. When would such bodies be construed as threatening?
3. What discourses facilitate the acceptance of such bodies?

LITERATURE REVIEW

Extant consumer research exploring consumers' reactions to technology (Mick and Fournier 1998, Kozinets 2008) is rooted in contexts where active-technology is physically external to the body. The exceptions that discussed the Cyborg (an active-technology embedded human), have used the term either as a metaphor (Giesler and Venkatesh 2005), or an image (Campbell, O'Driscoll and Saren 2006), thus overlooking actually existing active-technology embedded bodies. The "leaky" figure (Haraway 1991) of the Cyborg is an apt context for studying consumer interpretations about technology embedded bodies since, by dissolving several body-oriented boundaries (Haraway 1991), the Cyborg problematizes the West's maximal privileging of the body (Johnston 2001). While cyber-theologians have hailed boundary-dissolving technologies as the route to humans' technological salvation (Wertheim 1999; Haraway 1991), their assumption has been based on Futurists' views, not on actual lay discourses. While the body in recent consumer studies has received a lot of attention (Hung and Labroo 2011; Labroo and Neilsen 2010; McFerran, Dahl, Fitzsimons and Morales 2010; Thompson and Hirschman 1995; Schouten 1991), the body embedded with technology has remained under-researched. This paper seeks to examine lay discourses around active-technology embedded human body, here termed the Cyborg.

METHODOLOGY

For the purpose of this study we conducted a netnographic investigation of an online discussion forum which was formed around a YouTube video documenting lived experiences of an active-technology embedded body. The naturally occurring discussion, generating 730 posts, extended across 3 years (2009-2012). Concomitant to our research questions, we adopted a discourse analytical approach to explore the dataset.

FINDINGS

The initial data explorations revealed a technological continuum of acceptance where certain forms of technological enhancements were desirable and approved of (e.g. pacemakers), whereas others (e.g. implanted chips enabling extra experiences and abilities) were approached as dangerous and threatening. We next investigated the reasons why technology was construed as threatening in the context of an enhanced body. Our analysis unearthed the following three predominant discourses that framed threat as:

1) **the ability of technology to take control over human beings**: The fear of humans giving up control of their thoughts, actions and feelings to the embedded artificial processor is palpable in the following representative excerpt:

*"... Like that, **we will eventually become biological masses who have everything done for them by machines**. It sickens me to think there is a chance it becomes real."*

2) **the ability to use technology to control other humans**: The concept of the cyborg is feared as an elitist way of gaining control over "the masses", as the following comment exemplifies:

*"**The only sector that matters in this issue is the rich elite**... **No technocrat or anything of the sort will be above the secret societies that remain in charge**, and ill* (sic) *die with a weapon on hand before i* (sic) *let those new world order a******* **ever get my mind and soul into their matrix of evil**."*

3) **the loss of human identity and selfhood**: As underscored by the following comment, being a cyborg is equated with losing the essence of what it means to be human, and crucially, losing what one perceives as one's self.:

*"... the only thing i fear is ...before u know it the entire brain has been completely replaced with synthetic parts to "improve" man. **it's at that point u'd have comitted** (sic) **suicide (in a sense) because it is now a machine that has copies of your memories, mannerisms, and personality... but it's not u** anymore..."*

Additionally, our data revealed the existence of three discourses which facilitated the acceptance of technologically enhanced bodies. They can be summarized as:

1) **problematizing the natural**: What is considered natural, including earlier species, is positioned as something that has existential flaws, with the Cyborg conceived as the route to transcend extermination. For example:

*"Ever heard of the Neanderthal? Take a guess why Homo Sapiens won out in that evolutionary competition.(If you guessed better technology and willingness/ability to adapt you guessed right, a **Sapiens for Sapiens sake is the Neanderthal of the future**.)"*

2) **naturalizing the technology**: An alternative discourse offers the Cyborg as an inevitable, part of the natural order of things, only faster, as is underscored by the following:

*"Going cyborg is just like **advancing naturally. The difference is that it is a million times faster** .... **I think it is inevitable** and one day everybody will have some enchantments."*

3) **sacralizing the cyborg**: In response to *"We shouldn't play to be God."*, one of the responses was, *" Why not? **We invented God in the image of what we aspired to be, so let's become that image**. :)"*

CONTRIBUTION

The study sought to examine the lay discourses around consumption of body-embedded active-technology. In doing so, it added to the growing literature on consumers' engagement with active technology which has hitherto overlooked the phenomenon of technology internal to the body and also to the research on consumer bodies which has neglected technology-enhanced body. The study revealed that contrary to cyber-theologians' theorizations, lay interpretations of active-technology embedded in the body ranged from acceptance of certain active-technology that helps individuals function as hu-

mans (for eg,the pacemaker) to utter rejection of active-technology that enhances humans' normal abilities (for eg, in the case of the cyborg). While a few deployed certain acceptance strategies, the majority's rejection stemmed from fear and threat centred around a perceived loss of control across various domains.

Infectious Counterfeiting:
Labeling Products as Fakes can Contaminate Perceived & Actual Efficacy

Moty Amar, OAC, Israel
Ziv Carmon, INSEAD, Singapore
Dan Ariely, Duke University, USA

EXTENDED ABSTRACT

Counterfeiting is a rampant worldwide phenomenon with substantial economic and societal consequences. Whereas macro level consequences have been extensively studied, customer-level consequences of this phenomenon—the focus of this paper –are not well understood. Our research suggests that merely presenting products as counterfeits can contaminate them psychologically. Importantly, this can result in poorer perceptions and lower actual efficacy. Briefly, the notion is that counterfeiting is a moral offense, affecting perceptions & efficacy. This is because the moral offense causes a sense of moral disgust (Schnall et al.,2008), which like physical disgust follows sympathetic magic laws (Greene et al., 2001) of contagion and similarity (Frazer 1890/1959). Labeling a product as counterfeit can thus contaminate both that product and similar non-fake products. The results of three experiments support the predicted effect and its explanation.

The goal of Experiment 1 was to study our ideas in the field. In this experiment, 61 experienced-golf players were presented with 2 identical putters (a golf club used to hit the ball into the last hole) and were told that one of them was real and the other one a fake. They were then asked to determine, to the best of their ability, which putter was real and which a fake. Next, they were randomly placed in one of two experimental conditions: putt with the non-fake club first, or putt with the "fake" club first. Their goal in both conditions was to sink the ball in the hole, or get it as close as possible to the hole if they missed it. As predicted, participants played better with the non-fake club than with the "fake" one. Specifically, participants playing with the non-fake club sunk the ball in the hole more than those who played with the "fake" club (14 times versus 7 times; $t(59) = -5.89$, p $<.05$), and brought it closer to the hole when failing to sink it (M=24 versus M=32; $t(59) = 2.58$, p$< .01$).

In Experiment 2, 42 participants were presented with two different Parker fountain pens, and were told that one of them was real and the other a fake. They were asked to use each pen to trace a line from the start of a maze to its end, trying to avoid touching the contours. After completing the task with both pens, participants were asked to evaluate each pen. As predicted, across different measures, pens were rated less favorably when they were said to be fake than when they were said to be non-fake. Specifically, compared to the non-fake pen participants rated the "fake" as significantly less comfortable, of lower quality, and as less appealing. Furthermore, results of the maze task, suggest that deleterious effects of believing that a product is fake may not limited to participants' reported evaluations, and also affect efficacy. Participants who completed the task using the "fake" pens performed significantly worse than those who used the non-fake pens, touching the lines of the maze more frequently. This effect was, in turn, was mediated by participants' attitudes towards using the fake pen, per the procedure recommended by Zhao, Lynch, and Chen (2010).

In experiment 3, we examined whether fake products negatively affect similar non-fake products. Eighty three participants were randomly allocated to one of two conditions. In the first condition, participants were presented with 2 different pairs of Chloe (a prestigious designer brand) sunglasses and were told that one of them was real and the other a fake. Participants then tried on the sunglasses, exam-ined them, and compared them to another (third) pair of sunglasses that the experimenter presented. In the second condition participants followed same procedure except that they were told that both sunglasses were non-fake. Results show that participants who first saw a "fake" product rated the subsequent non-fake product lower than participants who first saw a non-fake product. Specifically, compared to participants who first had a non-fake pair of sunglasses, those who first had the "fake pair" reported that they saw significantly less well with the non-fake sunglasses, and rated them significantly lower on comfort, perceived quality and liking. Note that the non-fake product being rated more poorly when it was tested after the "fake" product versus when it was tested after a non-fake one, conflicts with prediction of an alternative account whereby differences in ratings are an artifact of participants' tendency to compare the second pair of sunglasses to the first.

Altogether, this paper illustrates harmful effects that counterfeiting can have from consumers' perspective. We show that merely presenting a products as a counterfeit can hurt perceptions and even objective efficacy. Theoretically, this work adds to the emerging research streams on psychological contamination, on marketing effects of disgust, and on placebo effects of marketing actions. Practically, our

findings, suggest that counterfeiting may be more damaging than previously believed, due to effects we document, and in particular effects on non-fake versions of the product.

Recovering From Ethical Failures:
Role of External Attribution and Monetary Compensation

Sekar Raju, Iowa State University, USA
Priyali Rajagopal, Southern Methodist University, USA

EXTENDED ABSTRACT

Research has found that denying ethical failures elicits more favorable attitudes than accepting them (Ferrin et al 2007) due to the differential inferences people draw from the failure (Reeder and Brewer 1979). An ethical failure is more diagnostic in judging moral character and hence likely to have greater informational value and impact on judgment. This suggests that the effect of accepting ethical failures is difficult to overcome. However, the literature on moral disengagement (White, Bandura and Bero 2009) provides insight into recovery strategies from ethical transgressions. We focus on two such alternatives that are often observed in a marketing context – external attribution and monetary compensation.

Attributing a failure to outside sources is commonly adopted by firms (e.g. Ford/Firestone). External attribution shifts the culpability of the unethical act away from the firm. By attributing the failure to an outside party, firms can restrict the negative association of having committed an unethical act and consequently reduce the future likelihood of repeating the act. In other words, the diagnostic value of the ethical failure for consumers is reduced. Thus, when the failure is attributed externally, consumers will have more favorable attitudes and intentions towards the firm, greater trust in the firm and be less likely to believe that the firm will make similar errors in the future, as compared to when the firm accepts the failure. Finally, there will be no differences in attitudes, intentions, future likelihood estimates or trust in the firm when the firm externally attributes the failure as compared to when the firm denies the failure.

Monetary compensation, however, attempts to shift the focus away from the failure and its consequences to resolution of the failure. Therefore, we expected to find that this response would improve consumer attitudes but would not improve intentions or reduce the future failure likelihood.

In real life, consumers often hold varying levels of trust in a company. We therefore also hypothesize that under conditions of low prior trust, there will be no differences in consumer responses towards the firm between offering monetary compensation, accepting, externally attributing or denying the failure.

STUDY 1 (N = 154)

Design: 2 (prior trust: high versus low) x 3 (recovery: accept, deny, external attribution) between subjects study. The dependent measures included attitudes towards the firm, trust in the firm, likelihood of future transgressions by the firm and behavioral intentions towards the firm (7-point scales).

We found a significant interaction between prior trust and company responses on attitudes (F (1, 147) = 7.62, p < .01), intentions (F (1, 147) =10.3, p < .01, post-failure trust (F (1, 147) = 4.89, p < .01) and future likelihood of failure (F (1, 147) = 2.73, p = .06). Planned contrasts revealed that when trust was high, externally attributing the failure led to results that were no different from denying the failure (p's > .1). However, when trust was low, externally attributing the failure did not improve any of the dependent measures as compared to accepting the failure.

In addition, a mediation analysis revealed that the response significantly predicted post-failure trust in the company (F (1, 71) = 7.14, p < .01) and likelihood of future failures (F (1, 71) = 6.97), p < .01); the likelihood of future failures significantly predicted post-

recovery trust in the company (β = .68, p < .05), and when both the type of response and likelihood of future failures were included as predictors of post-recovery trust, only likelihood of future failures remained a significant predictor (F (1, 70) = 19.85, p < .01) and the type of response was non-significant (F (1, 70) = 2.33, p > .1). Thus, external attribution reduces the diagnosticity of the ethical failure and thereby improves consumer perceptions of the firm.

STUDY 2 (N = 147)

In study 2, we varied the failure context (environmental damage) and conducted a 2 (prior trust: high versus low) x 3 (response: accept, deny, external attribution) between subjects study. We replicated the findings from study 1 and found a significant interaction between prior trust and type of response on consumer attitudes (F (2, 140) = 3.57, p < .05) and post-recovery trust (F (2, 140) = 3.49, p < .05). Under high trust, external attribution elicited responses that were no different as compared to denying the failure (p's > .1) but were significantly higher than when the failure was accepted (p's < .05) but under low trust, external attribution elicited results that were no different from accepting the failure.

STUDY 3 (N = 200)

Design: 2 (prior trust: low versus high) x 4 (responses to failure: accept, deny, monetary compensation, external attribution) between subjects study. We used the same scenario and dependent measures used in study 1.

We found the expected interaction between prior trust and company responses on attitudes towards the firm (F (3, 192) = 3.0, p < .05), intentions towards the firm (F (3, 192) = 4.39, p < .05) and post-failure trust in the firm (F (3, 192) = 2.29, p = .07). We replicated the pattern of results for external attribution that was found in study 1. Thus, external attribution improved attitudes and intentions and lowered future likelihood of failure when trust was high.

When prior trust was high, monetary compensation improved attitudes, but not intentions, trust or future failure likelihood, as compared to accepting the failure. Thus, externally attributing the failure was better than offering monetary compensation in terms of future intentions and diagnosticity. Also as predicted, there were no differences between any of the four conditions on attitudes, intentions, post-failure trust in the firm or the likelihood of future failures when prior trust in the firm was low (all p's > .1). Thus, any response to an ethical failure appears to require a modicum of trust in the firm in order to be successful.

CONTRIBUTION

While prior research has shown that denying ethical failures is the only option to retain favorable consumer attitudes and intentions, we identify exceptions to this finding. We show that external attribution reduces the perceived diagnosticity of ethical failures, leading to more favorable attitudes/intentions towards the firm while monetary compensation can improve attitudes, but not future intentions. We also identify an important moderator to these effects – prior trust in the company.

Cultural Effects on Perception and Cognition:
Integrating Recent Findings and Reviewing Implications for Consumer Research

Minas N. Kastanakis, ESCP Europe, UK
Benjamin G.Voyer, ESCP Europe, UK

EXTENDED ABSTRACT

Research increasingly suggests that cultural differences may account for variation in cross-cultural consumer reactions to several phenomena of interest to marketing scholars and practitioners, including consumer expectations, evaluations and reactions to service (Zhang, Beatty and Walsh 2008), or attitudes to consumerism in general (Tse, Belk and Zhou 1989). Despite the growing interest – focusing mainly on consumers' behaviors – relatively little research has examined cross-cultural differences or similarities in pre-behavioral processes such as perception and cognition – with little attempt aiming at explaining, synthesizing and extending existing evidence, especially in the light of the latest developments. Given the central role played by perception and cognition in subjective human experience and eventual behavior (Varela, Thompson, and Rosch 1999), studying cross-cultural differences in pre-behavioral domains is important in order to ultimately understand differences in cross-cultural consumer behaviors.

LITERATURE REVIEW AND CONCEPTUAL FRAMEWORK

Drawing upon the literature on cross-cultural, social, and cognitive psychology, as well as neuroscience, we offer a review of the role played by cultural environments and stimuli in shaping individual perception and processing of information (i.e. cultural conditioning effects). The idea of culturally-conditioned behavior emerges from recent developments in several cross-cultural disciplinary fields. Culture, acting as a "lens", affects the basic sensory perceptions and modes of information processing by providing to humans sets of values, life expectations, modes of living, and codes of conduct (Markus and Kitayama 1991) through which people experience the world around them. Although perceptions and cognitions are mainly dependent on sensory inputs, they also involve a variety of top-down processes that are automatically recruited from cultural artifacts to actively construct a conscious percept from the input (Kitayama, Duffy, Kawamura, and Larsen 2003). Hence, basic exogenous sensory inputs (colours, sounds or other stimuli) cannot fully account for the emerging percept: they are modified by factors endogenous to the perceiver such as cultural expectations, values, or needs (Bruner 1957). However similarities also exist: for example the meaning of certain percepts (like the degree of symmetry of a human face) is universal across cultures.

We incorporate in our review – as a guiding conceptual framework – two recent trends reflecting a fast moving field. Firstly, we highlight new findings in the relationship between culture and self-construal (Markus and Kitayama 1991), a culturally-shaped individual difference variable in terms of independent and interdependent self-perception, which appears to be a key conveyor of cross-cultural values on individual perceptions, cognitions, and behaviors (Kastanakis and Balabanis 2011). Secondly, we introduce recent research evidence (Nisbett and Masuda 2003) suggesting that the physical environment and other culture-specific stimuli such as language (e.g. alphabetic vs. ideographic/phonetic languages) can – in conjunction with processes of cultural learning – affect both information perception and processing, as a result of brain plasticity.

Our review (key highlights in Table 1) uncovers cross-cultural differences in terms of sensory, environment/aesthetic, and perception of emotions. We also find differences in self- and group/other-perception. In addition, we find a number of cognitive differences in information processing, categorization, memory, and the processing of persuasion messages; as well as in decision-making, self-esteem, attributions and perspective-taking.

Table 1
Culturally-conditioned perceptual & cognitive orientation(s): Individualistic/Independent vs. Collectivist/Interdependent

		Individualistic/independent orientation	Collectivist/interdependent orientation
Perception	*Self-perception*	Autonomous, detached, differentiated	Inseparable, connected, non-differentiated
	Perception of others/groups	Group exists to serve individual needs	Individuals exist to serve group needs
	Perception of emotions	Individual-orientation, de-contextualized, non-relational	Group-orientation, contextual, relational
	Perception of the environment and aesthetic preferences	Analytical, focal	Holistic, contextual
	Sensory perception	Several differences between the two orientations across sensory channels	
Cognition	*Perspective-taking*	Low perspective-taking ability, egocentric errors, insider perspective	High perspective-taking ability, less egocentric errors, outsider perspective
	Attributions & causal judgments	Tendency for dispositional attributions	Tendency for situational, contextual attributions
	Self-esteem	High need for self-enhancement	Low need for self-enhancement
	Information processing	Field-independent, focal, analytical	Field-dependent, contextual, holistic
	Categorization	Rule-based, categorical	Relational
	Memory	Self-related memories	Other-related, relational memories
	Processing of persuasion messages and decision-making	Central-orientation (content of message), uncomfortable with contradictory information	Peripheral-orientation (how is the message delivered), comfortable with contradictory information

We encounter a series of striking findings that, taken together, consistently point towards two distinctive perceptual/cognitive orientations. We, therefore, suggest that there are two types of culture-dependent (or "culturally-conditioned", in accordance with existing terminology) perceptual and cognitive orientations which we define as the overall, culture-specific, processes by which sensations are selected, organized and interpreted (culturally-conditioned perceptual orientation); as well as the overall, culture-specific, mental processes involved in gaining knowledge and comprehension – including thinking, knowing, remembering, judging and problem-solving (culturally-conditioned cognitive orientation). These are the "individualistic/independent", mostly encountered in the Western world; and the "collectivist/interdependent", mostly in the East (however, we also include studies on non-Asian collectivist cultures, such as Africa).

IMPLICATIONS AND DIRECTIONS FOR CONSUMER RESEARCH

As global consumer psychology research is in its infancy (Shavitt, Lee, and Johnson, 2008), we propose an agenda for future research along the lines of this review. We need to explore in more depth the propositions that natural environments (Nisbett and Masuda 2003) and language (Ji, Zhang, and Nisbett 2004; Ross, Xun, and Wilson 2002) are cultural factors that directly affect human perception and cognition. Nisbett and Masuda (2003) suggest that environments influence perception; and, more convincingly in our opinion, the resulting perceptual preferences prompt people to (re-) produce different environments. For example, because Asians tend to focus broadly on the field and attend to a large number of elements, they seem to (re-) construct environments with a large number of elements; Westerners focus, more narrowly, on a smaller number of elements and seem to prefer (and build) environments with a smaller number of elements. Hence, research could examine the relationship between different retailing environments and perceptual preferences. In addition, there is evidence that language can trigger a culture-bound view of the self and that East-Asian and Western identities may be stored in knowledge structures activated by their associated language (Ji et al. 2004; Ross et al. 2002). Research could explore related questions, such as how this phenomenon could affect the cultural consumer identities of multilingual new generations.

Another promising avenue for research opens from recent developments in neuroscience – suggesting cross-cultural differences in terms of neural correlates of various consumption-related mechanisms (Ames and Fiske 2010). For example, Gutchess, Welsh, Boduroĝlu, and Park (2006) found that, when looking at pictures, Americans used more regions of the brain typically involved in the processing of objects, compared with Chinese. Other cross-cultural neural differences in information processing and perception, that invite interesting questions, include the taste of branded vs. non-branded products (McClure, Li, Tomlin, Cypert, Montague, and Montague 2004) and perception of colors (Davidoff 2001).

Overall, despite the youngness of the field of cross-cultural neuroscience, recent findings appear promising and need better integration in the consumer psychology literature. In this review we show how consumer research can benefit from embracing innovative approaches in viewing the world and appreciating the diversity offered by multiple perspectives originating outside the mainstream consumer psychology domains.

An Exclusionary or Integrative Approach to Goal Conflict: The Moderating Role of Mindset Abstraction

Fang-Chi Lu, University of Iowa, USA
Jooyoung Park, University of Iowa, USA
Dhananjay Nayakankuppam, University of Iowa, USA

EXTENDED ABSTRACT

Pursuit of a certain goal (i.e., managing weight) is often challenged by the presence of alternative goals (i.e., enjoying a tasty chocolate cake). How individuals solve this goal conflict and manage multiple goals has been an important topic of self-regulation (Emmons King & Sheldon 1993; Shah 2005).

Because multiple goals compete for one's available resources, the classic approach to resolving goal conflict usually involves a tradeoff. An individual has to exercise a goal choice through (1) *goal prioritization*: focusing on more important goals and temporarily withdrawing alternative goals (Shah 2005; Simon 1967) or (2) *goal shielding*: cognitively inhibiting alternative goals that compete for one's resources (Kuhl 1984; Shah Friedman & Kruglanski 2002). Recently, Kopetz et al. (2010) propose an alternative solution to goal conflict, quest for multifinal means which afford simultaneous pursuit of several goals. For example, one can attain the goals of maintaining slim figure and food enjoyment at the same time by choosing tasty, low-calorie foods. They further argue that a quest for multifinal means should be preferred over the goal-choice approach because individuals intend to maximize the return on their investment.

The current research proposes that the approach to goal conflict resolution differs depending on one's mindset. Construal level theory posits that individuals can represent an object at different levels of abstraction, where abstract mental representations are schematic and extracting the gist from available information and concrete representations are relatively unstructured and including contextual features (Liberman Trope & Wakslak 2007). It has been shown that abstract (vs. concrete) construal enhances searching for similarities (vs. dissimilarities) of given stimuli (Förster 2009). Building on construal level theory, we argue that concrete thinkers, adopting an exclusionary approach, will use a goal-choice strategy. They will shield the focal goal from alternative goals (Hypothesis1) or prioritize their goals (Hypothesis2) when a focal goal is highlighted. However, abstract thinkers, adopting an integrative approach, will search for multifinal means when facing goal conflicts (Hypothesis3). Three studies were conducted to examine these hypotheses.

Study1, to examine Hypothesis1, used a 2 (mindset: abstract vs. concrete)×2 (goal commitment: strong vs. weak) between-participants design. Participants first performed a mindset manipulation task, either comparing a traditional camera with a digital camera or comparing two digital cameras (Malkoc Zauberman & Bettman 2010). They then listed a personality characteristic which they had a slight (vs. strong) desire to attain. After that, they listed other personality characteristics that you were also trying to attain in addition to the one previously listed. We measured the extent of goal shielding by counting the number of alternative personality characteristics listed. Results showed a significant mindset-goal commitment interaction ($F(1, 147)=6.76$; $p=.01$). Specifically, participants with concrete mindset listed fewer alternative characteristics when the focal goal commitment was strong ($M_{strong}=2.86$ vs. $M_{weak}=4.9$); however, participants with abstract mindset listed similar numbers of alternative characteristics regardless of goal commitment ($M_{strong}=4.7$ vs. $M_{weak}=4$).

Study2, testing Hypothesis2, measured perceived importance of alternative goals after the introduction of a focal goal. We recruited participants who had not had lunch and had intention to have lunch later that day. We enhanced focal goal (having lunch) importance by using a fictitious scientific report discussing the importance of lunch. After that, participants were asked to list three activities they had planned for the rest of that day. Then, they completed the same mindset manipulation task in Study 1. Finally, they rated the importance of having lunch and each of the three planned activities. Regardless of the mindset manipulation, participants listed similar activities, such as "doing homework," "going to class," and "exercising." Also, participants perceived having lunch equally important across conditions ($M_{abstract}=5.31$, $M_{concrete}=4.47$, $p=.1$). More importantly, abstract thinkers perceived the first and the second alternative goals ($M_{1st-alternative}=6.69$, $M_{2nd-alternative}=6.63$) more important than concrete thinkers did ($M_{1st-alternative}=5.07$, $M_{2nd-alternative}=5.67$) ($p's<.05$), suggesting that concrete thinkers tended to prioritize goals. Study1 and 2 provide supporting evidence for the goal-choice behavior of concrete thinkers.

To test Hypothesis3, Study3 used a 2 (mindset: abstract vs. concrete)×2 (focal goal importance: high vs. control) between-participants design. We first activated two eating goals, food enjoyment and weight control, by asking participants to what extent they chose foods based on their taste or caloric content. Then, we manipulated the importance of a focal goal (food enjoyment) by asking participants to list either three advantages and three disadvantages of choosing tasty foods (high focal goal importance) or three advantage of choosing tasty foods and three advantages of choosing low-caloric foods (control condition where both goals are equally important). After that, participants performed the same mindset manipulation task as Studies1&2. Finally, participants were asked to list the foods they desired to have for dinner that day. We followed a similar procedure used by Kopetz et al. (2010) to compute two separate scores for each participant, representing the instrumentality of their listed foods to the goal of food enjoyment and weight control, respectively. A significant two-way interaction ($F(1, 123)=4.9$, $p<.03$) demonstrated that the expansion effect of goal importance on mean set size found in previous research (Kopetz et al. 2010) mainly occurred in concrete mindset, but not in abstract mindset condition. Concrete thinkers listed more foods in the condition of high focal goal importance ($M_{highimportance}=5.06$) than in the control condition ($M_{control}=3.69$); while abstract thinkers listed similar numbers of foods ($M_{highimportance}=4.27$ vs. $M_{control}=5.32$, n.s.). Further examining the instrumentality of food items listed by abstract versus concrete thinkers in the control condition, we found that the foods listed by abstract thinkers were equally instrumental to both goals (*evidence of a quest for multifinal means*); whereas, concrete thinkers listed food items which were more instrumental to the food enjoyment goal (*evidence of goal shielding*).

The current research has both theoretical and managerial contributions. First, it contributes to the goal conflict literature by identifying mindset abstraction as a key moderator. Second, it implies that mindset abstraction matters if marketers want consumers to see the benefits of a hybrid product, a product satisfying multiple goals. Marketers can better communicate multiple benefits of their products using abstract mindset framing.

Compliments Made Me Bolder: The Role of Self Construal and Brand Status in Brand Attachment and Product Evaluation

Fang Wan, University of Manitoba, Canada
Letty Kwan, Nanyang Technological University, Singapore
Amitava Chattopadhyay, INSEAD, France
Hesham Fazel, University of Manitoba, Canada
CY Chiu, Nanyang Technological University, Singapore

EXTENDED ABSTRACT

Compliments are conducive to social interactions and communications. Little research has been done to examine the psychological underpinnings of the observed cultural differences in response to social and brand compliments. Even more scarce attention has been given to extend research on compliments to study the impact of brand compliments on consumers' evaluations and preferences of the focal brand as well as subsequent product evaluation. Our work set out to study cultural difference in compliment appreciation (Study 1) and further investigate its implications in brand usage contexts (Study 2 and 3). In these three studies, we use self-construal as a proxy to cultural differences in the interdependent and independent culture. In the last two studies, we recruited participants from Asia and North America and studied the cultural difference in the brand attachment associated with brand compliment and in effect of compliment on the subsequent product evaluation.

Self construals are often used as a proxy to uncover cultural differences: how individuals classify or perceive themselves according to the constituted cultural values they follow (Singles & Brown, 2001). In North American culture, the normative imperative is to become independent from others and to determine and convey one's unique attributes (Markus & Kitayama, 1991). However, Asians cultures have interdependent self-concepts stressing on connectedness between themselves and others (Morris & Peng, 1994; Hong et al., 2000).

North Americans, who typically have independent self-construals, are likely to view social compliments as a matter of personal choice, indicative of compliment givers' genuine liking of self, therefore, are more likely to appreciate social compliments. Individuals with interdependent self construals view compliment givers as more likely to have ulterior motives (Park, 1998). Therefore we propose that individuals with independent self construals are more likely to appreciate social compliments than those with interdependent self construals. We further propose that brand status moderates the relationship of self construal and compliment appreciation. Interdependent individuals will feel less appreciative than self interdependent individuals when receiving a compliment about their usage of a low status brand (Study 2).

We further attempt to study how culture specifies the effect of compliments on high status brand usage. Research on status and power (Galinsky, Gruenfeld, and Magee 2003, Rucker, Galinsky, and Dubois 2011) suggest that these extrinsic cues can affect consumers' motivations of brand and product usage. We argue that the Interdependents (vs. independents) are more sensitive to brand status as it signifies the perceived popularity of the brand among others in the social group. Therefore, compliment of a high status brand usage makes the interdependent (vs. independents) appreciate the brand more (Study 3 and 4). However, we argue that for the interdependent (vs. independents), this brand attachment is driven by other-focused brand perceptions such as perceived popularity of the brand among one's social group, instead of ego-centric brand perceptions such as the fit between brand and self image (Study 4). And lastly, we propose that once complimented by the usage of high status brand, the

need for seeking status and approval is satiated (Galak, Redden and Kruger 2009), Asians (the Interdependents) are less likely to seek social approval and more likely to make norm-inconsistent evaluations and favour products with less dominant status (Study 5).

Study 1 examined the impact of self construal on social compliment appreciation. Participants were asked to read a scenario where their product usage is compliment "I like your sweater." Then they filled out a survey measuring their appreciation of the compliment with 2 items (appreciation & grateful α = .73), and their cultural orientations with 24 items self-construal scale (Singelis, 1994), self-independent 12 items (α = .76) and self-interdependent 12 items (α = .79). We eliminated participants who score higher (lower) than the average score on both independents and interdependent scale. This procedure enabled us to use data from 79 participants, 41 independent, 38 interdependent. ANOVA test confirmed our expectation that the interdependent were less likely than the independents to feel appreciative of a social compliment appreciated when receiving a compliment (F = 2.915, p = .09).

Study 2 examined the moderator effect of brand status in the relationship between self construal and on compliment appreciation. Self construal was constructed similarly as in Study 1. Brand status was manipulated via varying a scenario where compliment was made about Gucci, high status (vs. Joe, low status) sunglasses (manipulation successful). As expected, ANOVA test on appreciation yielded only the significant interaction effect of brand status and self construal (F=5.85, p<.05), suggesting the interdependents (vs. independents) appreciated compliments on high status brand; the pattern was reversed when brand status was low.

Study 3 adopted the same design as in Study 2 but shifted gear towards examining participants' attachment with the brand (7-point scales such as feeling connected, loyal and attached, alpha=.89). Regression analysis with brand attachment as dependent variable yielded a significant effect of brand status (b=4.22, t=1.98, p<.05), significant effect of self construal (b=1.40, t=2.13, p<.05) and a significant but negative interaction (b=-.88, t=-1.95, p<.05). To uncover the interaction pattern, we dichotomized self construal and ran an ANOVA test, yielding a significant interaction effect (F=3.23, p<.05). As expected, the Interdependents (vs. independents) were more bonded with the brand when status was high, whereas the reverse was true for low status brand.

Study 4 intended to replicate findings in Study 3 with culture as the independent variable. We focused on high status brand (perception of Gucci is consistent across culture, mean of prestige in Asia=5.79 vs. in North America=5.77 out of 7 point scale, t<1). Study 4 found that when complimented on a high status brand usage, Asians feel more indebted to brand compliments (F=8.51, p<.001) and bonded with the brand more than North Americans (F=7.69, p<.01) as Asians would be more likely to perceive that high status brand is favoured by others in their social group than North Americans (F=3.68, p<.05). On the other hand, North Americans were more likely to attribute compliments of brand usage to ego-centric reasons such as brand and self image fit (F=6.87, p<.01) and tended

to think users of high status brand were more materialistic (F=13.21, p<.001), explaining their low endorsement of the high status brand.

Study 5 examined the impact of compliment of high status brand usage on motivations and subsequent product evaluation. We found that when given the brand compliments, compared to North Americans, Asians tended to be less likely to seek for social approval (mean=3.46 vs. 3.86, F=3.62, p<.05), less likely to view high status brand users to be materialistic (mean=3.79 vs. 4.57, F=15.66, p<.001). Satiation of status via brand compliments made Asians favour minority-status painting (liked by fewer people), a preference-reversal given that the Interdependents focus on group harmony and endorse less unique options (Markus and Kitayama 1991).

Mythologized Glocalization of Popular Culture: A Postcolonial Perspective

Soonkwan Hong, Michigan Technological University, USA
Chang-Ho Kim, Nam-Seoul University, South Korea

EXTENDED ABSTRACT

Over the past decade, Korean popular culture (KPC hereafter) has increasingly gained enormous recognition in East and Southeast Asian countries, and the popularity currently extends to the Middle East, former Soviet Union countries in Central Asia, and even European countries. Previously dominated by American and Japanese popular cultures, Asian popular culture is currently transforming itself into a "neo-cultural imperialism" mode.

Popular culture has been one of the topics in consumer culture theory for its function as a transmitter of marketplace ideologies (Belk and Pollay 1985; Hirschman 1988, 1990), an indispensable element of local identity construction (Kjeldgaard and Askegaard 2006), and a portrayal of hegemonic brand culture (Thompson and Arsel 2004). However, it is rarely studied in its entirety, as a symbolic and ideological product that one cannot simply reject, and its globalization process has been understudied.

In recognition of popular culture's theoretical significance as a key driver of current consumer culture in Asia, this study will delve into two main research questions: 1) What are the cultural connotations of KPC, as opposed to American or Japanese popular culture, for Asian consumers with respect to their identity, lifestyle, and ideology? In other words, why do Asian consumers superannuate the almost "orthodox" representation of today's culture (American pop culture) and choose to fetishize a new ideology? 2) How is the globalization process of KPC discernible from that of hitherto predominant popular cultures?

One particular characteristic of cultural pluralism in popular culture is that it necessitates multi-directional, rather than top-town, or unidirectional movement of cultural elements among several cultures (Appadurai 1990). As a result, cultural hybridization is intensified by the perpetual tension between acceptance and resistance, as well as amid the "triumphantly universal and resiliently particular" (Appadurai 1990, p. 308). That is, the hybridized cultural products undergo a serious, long-term ideological process, which might be seen as a series of fads and trends (Figure 1). KPC's globalization is in accordance with Lévi-Strauss' (1963) understanding of the mythological structure of paradoxical resolution of binary oppositions.

Postassimilationist discourse contests the idea that the acculturation process is linear, easily traceable, and mostly characterizable (Askegaard et al., 2005; Oswald 1999; Peñaloza 1994). KPC's cultural outlook resonates with postassimilationists' standpoint as it facilitates heterogeneous, nondeterministic, and liberatory cultural enterprise among consumers of the new acculturation agent (Iwabuchi 2001; Ryoo 2005). The unique patterns and characteristics of KPC engender *third space* as the term BhaBha (1994) used to describe the challenge of explicating a new phenomenon in which alternatives or an indigenous mixture of discourses epitomize and texturize the hybridity.

A netnographic study combined with critical discourse analysis is conducted due to the unique discursive and reflexive ground of KPC that absorbs counteracting perspectives and manifests in harmony with the particular cultural landscape. One of the most popular Korean TV dramas, *Dae Jang Geum* (DJG), is chosen in the context of Hong Kong. Newspaper articles (417) were collected from Hong Kong and Mainland China between 2004 and 2005. From the articles, three characteristics of each report were identified: executional style, main theme, and sociocultural influence. Concurrently, textual data from six websites based in Hong Kong, including fan forums, discussion boards, and the main actress' fan-site, were collected from the same period of time. This attempt is to trace the relationship between discursive movements observed in newspapers and the grassroots practices.

The glocalization of KPC in Hong Kong underwent a cyclical formation process, in which the discursive drives of newspaper articles triggered tensions and development of particular social discourses. The first discursive phase detailed a taste-based class discourse among Hong Kong audiences, consistent with the main theme of the drama that depicts some elements of social stratification. In the second discursive stage (late 2004), changes in the newspaper discourses activated public sensibility of ethnic identity as a crucial discursive aspect of glocalization. In the following period (early 2005), a more pertinent discourse to postassimilationists' critique was galvanized. As fans of DJG started to fantasize about the characters and the story line on the websites due to the drama's novelty and cultural kinship, discussions of its positive and negative implications also took place. The last phase (late 2005) of the glocalization process of KPC in Hong Kong can be portrayed as a reflexive and yet transient ideology (*zeitgeist*). KPC was normalized and instilled in everyday life of Hong Kong consumers because the newspapers begun featuring interviews of the celebrities about their personal lives and heralded normal activities (e.g., cooking, shopping, and night life in Korea) practiced in Korea, as though the culture needed not be kept exotic any longer and became a part of daily life in Hong Kong. In each phase, observed tensions among consumers were resolved as the newspaper discourses redirected the public attention to a new discourse. However, concurrently, critical voices about class, ethnicity, and cosmopolitanism existed amid the discursive movements. The cultural pendulum of rejection and acceptance of the foreign popular culture is omnipresent and self-perpetuating, but not as the momentum of glocalization. Rather, the driving force of glocalzation is the continuing dynamics between the institutional reality-engineering practices on newspapers and grassroots responses to the new socio-politico-cultural episodes.

Glocalization process of popular culture cannot be reduced to a "uni-discursive" thesis that immortalizes the themes of cultural imperialism. Future research opportunities include juxtaposition of the ascent movement of KPC with the "demise of the imperial," witnessed in Asia. It is uncertain whether the cultural plurality that has been inculcated means coexistence of new ideologies with the dogmatic, or overthrow of Hollywood and MTV. The reaction from the losing party is of special interest because it may attempt to turn the temporarily calmed popular cultural outbreak upside down. Globalization of popular culture necessitates hybridity that uses the same traditional ingredients but transforms into a new taste based on a new cultural recipe. The paradoxical nature of KPC appears to be the same as the self-perpetuating theme of globalization, but the very paradox is what makes it "popular."

Different Ways of Saying Goodbye:
Outlining Three Types of Abandonment of A Product Category

Maribel Suarez, Federal University of Rio de Janeiro / COPPEAD, Brazil
Marie Agnes Chauvel, Federal University of São João del Rei, Brazil

EXTENDED ABSTRACT

Creation of meaning via consumption involves positive and negative choices, but several scholars and practitioners' efforts have been devoted to positive aspects (Lee, Fernandez and Hyman 2009). In the context of the recent interest in anti-consumption, various studies have focused on more extreme and thus more "visible" manifestations of anti-choice such as, for example, actions involving boycotts or aversion to companies and brands (Hoffman and Muller 2009; Sandikci and Ekici 2009; Cromie and Ewing 2009; Yuksel and Mryteza 2009). However, little attention has been directed to investigating abandonment which refers to the deliberate choice of giving up something previously consumed. (Hogg, Banister and Stephenson 2009).

Some authors relate abandonment behaviors to social transition, that is, changes in the life-cycle or status of individuals (Young 1991; Roster 2001; Hogg et al. 2009). Hogg and Banister (2001) propose that in order to maintain a positive self-image – or at least a normative self-standard - consumers avoid risks, rejecting products, brands or suppliers that are associated with undesirable or negative stereotypes or reference groups. Hogg et al. (2009) present abandonment, aversion or avoidance behavior as the desired reaction to protect self-esteem and avoid self-concept humiliation.

In this paper, we look into meanings that motivate the abandonment of a product category and also the meanings abandonment gives rise to. The research used a qualitative methodology to collect and analyze data obtained from in-depth interviews with 16 Brazilian consumers who gave up automobile ownership. This category was chosen due to its intense symbolic dimension, with previous studies evidencing its relation with self-concept (Grubb and Hupp 1968; Belk 2004), capacity to engender life-style and social class stereotypes (Belk, Bahn and Mayer 1982; Dalli and Gistri 2006) and potential to tangibilize ideologies (Hirschman 2003; Brown, Kozinets and Sherry 2003; Luedicke and Giesler 2008). Interviews lasted between 60 and 240 minutes and were taped and transcribed (around 450 pages of text). This analysis sought to find, refine and develop concepts, themes and events that could be codified and inter-related in order to construct theoretical proposals (Strauss and Corbin 1998).

In the literature, abandonment is described as the act of giving up something previously consumed, thus presupposing that a deliberate choice was made (Hogg 1998; Hogg et al. 2009). The interviews, however, suggest that, rather than being a discrete event, an action or decision that is circumscribed by a given moment, abandonment is in fact a process. The accounts of former automobile owners revealed that various informants kept the same vehicle for long periods of time (in some cases years), even without using it, before selling it. Standing idle in the street or garage, without an effective functionality, the car ended up contradicting the prevailing social view that it is an indispensable product, thus signaling the possibility of life without a car. The promise of autonomy and mobility expressed in the product's advertising is erased little by little by a practice that shows that life is possible without it. Whether consciously perceived by the consumer or not, this period characterizes abandonment, a kind of discarding ritual (McCracken, 1986), which allows the meanings that motivated the purchase to be "cooled" and legitimizes the decision to sell.

The analysis also outlines three types of abandonment: contingent, positional and ideological:

CONTINGENT

In this kind of abandonment the consumer is forced to leave the category due to a conflict between objectives or practical and material limitations. Although they value the functional and/or symbolic benefits that the product confers, matters related to money, health, access to the product, space, family pressure, may lead the consumer to abandon it. This is the case of Jorge, an informant that still takes part in an on-line community of car owners which he never abandoned even after selling his car. Jorge does not identify himself with the abandonment of the category and describes his abandonment as provisional and situational.

POSITIONAL

This is motivated by the demarcation of a symbolic distance in relation to consumers of the category. Thus, the decision expresses a difference and generates a sense of distinct identity for individuals. Leonard, one informant, has a good salary and job stability, but preferred to sell the car and recognizes that he is different from most people: "I have a tendency to question things a lot. I'm critical about everything. Several people think I disagree just for the sake of it." Leonard does not consider the symbolic benefits that a car could confer on its owner, valuing only its transportation function. "Because if you have a car and don't use it, but think that it provides you with some kind of benefit, you're not rational".

IDEOLOGICAL

It is different from other types on account of its collective perspective. Consumers believe that society (and not just themselves individually) should abandon or rethink that consumption. This is the case of Eurico, an informant that advocates the use of the bicycle as a solution for the problems generated by motorized transport. In his interview he associates the car with individualism, with private space and isolation, to the detriment of the collective space. The philosophy of a more sustainable form of consumption helps Eurico to construct a differentiated and positive identity that Cherrier (2009) describes as the "hero identity": a way of acting that requires dedication and commitment to redefine and restructure daily life, articulating new meanings for consumption. Eurico seems to adopt this role and indeed he prides himself on already having convinced "various people to adopt the bicycle as a means of transport".

Analysis suggests that abandonment can operate affirmative and positive differentiation and reinforce self-esteem, helping individuals to constitute identities and signal important changes in their lives. In abandonment, the individual foregoes the functionality related to the product. The symbolic associations, however, continue to be used, created and manipulated even after abandonment happens. When they speak of the benefits and advantages of abandonment, consumers "make use" and "take advantage" of the meanings of the discarded category.

Marketplace Performances in Emerging Economies:
Eliciting the Asymmetric Interactions Between Service Providers and Western Tourists

Nacima Ourahmoune, Reims Management School, France

EXTENDED ABSTRACT

While tourism is presented as virtuous for the developing countries in general, it is argued in this paper that it also generates social exclusion, gender asymmetry and that it perpetuates ethnic tensions. An ethnographic inquiry into Punta Cana's All-inclusive resort hotels in the Dominican Republic allows the author to interpret the disciplinary policies implemented by the transnational tourism industry that impedes cultural hybridity and exacerbates social, gender and ethnic hierarchies and stigmas. In particular, the narratives that emerge from the field rely on day - night / outside - inside the resort logics as spatio-temporal landmarks which rhythm the activities of visitors and locals. They are materialized by two locations: the beach and the disco, where power struggles are in play.

The author proposes a socio-spatial analysis that accounts for the tourism industry's attempt to frame a specific script or experience for the transnational tourists and to control and discipline the locals privatizing Dominican land. Far from the cultural hybridity promoted in its brochures, the transnational tourism management policies tend to reinforce power structures variously in terms of gender, ethnicity and social positions. However, the findings also account for the temptation for tourists and locals to contest those boundaries; in particular a sense of agency is manifest in constructing Caribbean identities within this context.

Dominican development policies

Emerging economies are insufficiently researched compared to western contexts (Jafari, Suerdem, Firat, Askegaard, Dalli, 2012), this study is a contribution to the thin body of research that tackles marketplace performances that occur and involve non-western consumers. Also, Askegaard and Linnet (2011) appeal for a broader understanding of consumption phenomena studying not only the micro-context as it is mostly the case in consumer research but enlarging the spectrum eliciting the findings within what the authors called "The context of the context". Understanding the meanings of the relationships between service providers and tourists calls a deep attention to the development policies in the Dominican Republic.

The Dominican Republic is the second largest country in the Caribbean; it covers two-thirds of *La Isla Hispaniola* that is shared with Haiti. Like many developing countries, the Dominican Republic was an agricultural exporter. Tremendous shifts in the DR's economy have recently occurred. The service sector has largely overtaken other activities, mainly due to the development of tourism as the result of a governmental effort since the early 1970s. Transitional economies often recognize that tourism is a good way to bring foreign investment and currency into the domestic market. It also diminishes the dependency on agricultural products and or natural resources, which are subject to market fluctuations. Foreign investment before the 60s (Trujillo Era) was very limited in an unstable economy seen as risky by investors. Now, with the booming tourism industry, investment is rather seen as attractive by foreigners and it is no surprise that they own most of DR's resorts. This is especially so since all the governments starting in the 1970s, and in light of the IMF recommendations, offered them many tax benefits (Haggerty, 1989). On the other hand, the island has become a favorite destination for westerners due to its inexpensiveness (many devaluations of the Dominican Peso), proximity to Canada and the US, and not least its 800 miles of beautiful beaches and the variety of aquatic activities and landscapes it

offers. In twenty years, the number of visitors increased by 15 times reaching over 3.7 million in 2010 (From Banco Central de la Republica Dominicana).

METHODOLOGY

By focusing on tourism in terms of consumption, commodification, and the political and cultural economy, the relationships between tourism, globalization, people and place are explored in an empirically grounded but theoretically informed analysis. The marketplace performances under-investigation are embedded in the broader socio-historic realm described earlier. However, unlike a body of research in Anthropology (Kempadoo, 1999, Brennan 2004) that tackled specifically sex workers' representations in the Caribbean, I locate this study in the context of crowded, close, safe, family resorts in Punta Cana as an apparent quiet and impersonal transnational place. I specifically investigate Local workers at large/ Western Tourists interactions in the context of holidays. Escaping usual images of female sex workers or the interactions of young male "beach boys" with aged female tourists allows the author to shed light on other forms of interactions between service providers and consumers in the Caribbean.

I conducted a four-year ethnographic study, with over 20 weeks in the field. I met a group of Dominican people, some of the Animation staff in a resort representative of the local offer, *Ifa Villas Bavaro Hotel,* several times during different stays, enriching the data collection. Some informants stayed in contact with the author via social media allowing on-going discussions. I did share activities with informants (local dance, disco, visit of native towns/family…). I performed observations, informal/formal interviews; hundreds of photographs were also taken to perform a semiotic analysis (Floch, 1989). In depth Interviews took place in Punta Cana, lasted 40min-2h. I interviewed Dominican men and women working in Punta Cana's resorts, male and female tourists, neophytes and connoisseurs of the Dominican Republic and, Haitians working in a resort or on the *Playa Bavaro* Beach. These interviews followed McCracken's (1988) recommendations and allowed a maximum of freedom to the informants to tell their stories without setting a structured agenda for the interview. The role of the interviewer was to ask for descriptions and details while the major themes under investigation appeared spontaneously during a "natural conversation" (Thompson, Locander and Pollio 1989).

FINDINGS AND DISCUSSION

In this section I discuss the themes and observations that emerged from the field as regard the socio-spatial organization of a transnational space in a third world country. I pay particular attention to the interactions between the diverse social actors involved. I will insist on the role played by the tourism industry in conveying dialectics of power, ethnic, and gender stigma in the Dominican Republic.

At the beach…

Usually All-Inclusive resorts enable guests to travel between the hotel and the enclosed beach facilities without entering public space or encountering local inhabitants. The beach is often the place where public vs. private space mediates the opposition between tourists and locals. There is a tendency among the resort hotels to privatize the public beach, and therefore to exclude locals at the margins. *Chaises*

longues and private guards ensure the boundaries between them. But sometimes locals and tourists contest those boundaries: on Sundays sometimes some Dominican attempt to sit just next to some hotel chaises longues and argue with the private guard that *"this is Dominican land!"* they should not be forbidden to stay there. And the security guard answers, *"Sorry my friend, I am doing my job!"* Also, some tourists go for a walk on the beach, trying to find a part of the beach that is more "authentic" and often find at the end of it, -this is to say the liminal space- an informal or improvised Haitian market. Here tourists enter in contact with the population at the margins of Dominican society, offering mainly Haitian paintings and cheap beauty services (such as hair braiding…Dominicans do not braid their hair as Haitians do, as a denial of their African origins…).

The beach is then clearly a space of social and race power struggles. The sociospatial dialectics of power involve 4 types of populations on Dominican beaches, transnational tourists, Dominicans and Haitians officially paid by the resort hotels as service providers for tourists who apply transnational management rules, the inhabitants of *La Comunidad* and beach visitors on their day-off, illegal Haitian workers who propose services and goods (hair braiding, paintings…) at a lower price than hotel gift shops and Beauty services. All hotel employees invoke crime and danger when leaving the official hotel beach area. The same partitioning of the beach is observed in many Dominican regions.

> "It is very dangerous for you to leave the beach hotel that is safeguarded by our security team and also to buy any items from *Haitianos*, they are dangerous and known for crime …and anyway the items you buy there are cheap souvenirs, those people are really involved in crime and drugs, and HIV…stay away from them for your own security" (Hotel concierge, April, 2009)

The lead agency in this policing of difference is the *Policia Turistica* (POLITUR), specialized tourism police under the aegis of the state secretary for tourism. Beyond law enforcement, the POLITUR's role is to ensure licensed vendors do not annoy tourists, and that unlicensed vendors, beggars or sex workers and largely those who work in the informal economy are excluded from the *Zona turistica*. The POLITUR often engage in cleaning campaigns (*limpiar la calle*) to clean the tourist zone from rubbish and exclude undesirable social elements such as Haitian migrants. These cleaning campaigns are often conducted with the sponsoring of Punta Cana Tourism Development Association.

As a young Haitian working informally with tourists on the beach put it:

> "The POLITUR are our nightmare, a constant stress for us, even if I have lived here for 10 years I feel the hate from everywhere. *Don't stay here* is the sentence I have certainly heard one million times in my life…this is why I try my best to find a solution to join my relatives in the Bronx… Dominicans hate us because we are smart, we speak languages and we are not lazy like them, if the POLITUR were not there and we had documents to work, there would be no jobs for them but you know the POLITUR and the resort managers it's the same racists!...The tourists, I mean the ones who aren't afraid of us, they like me because I am educated, I can spend a nice time with them speak English and French fluently, we (Haitians), we are different from the Latinos you know" (François, 29)

Actually, the POLITUR do not only deny Haitians access to touristic zones but also all informal workers. There are several issues here: the price of the license is high; no license is issued without birth certificates that many Haitians and Dominicans of Haitian descent fail to obtain, but also poor Dominicans from rural regions whose birth was not officially declared and who even seem to be threatened with expulsion to Haiti if they fail to prove their citizenship.

> "I know a woman, a cleaning lady, she was fired after 3 months in the resort as she failed showing her documents, she paid people to help her produce those documents but she never managed to obtain a birth certificate…It's better for her to go back to the countryside otherwise she might be mistaken as an illegal Haitian!" (Claudio, 34)

Citizenship is here a key element for securing a job and the traffic of documents among Haitians is quite a common story. Not only are the poor marginalized but as Playa Bavaro is treasured by the government -being ranked among the 10 most beautiful beaches in the World- and because of other regions' reputations regarding prostitution (e.g. Sosuà; Bocca Chica), "a zero sex workers on Playa Bavaro" policy is enforced by the POLITUR to guarantee the family atmosphere that is targeted by the tourism industry. Doing so, this does not discourage diverse forms of prostitution or "sex romances" that are very difficult to untangle and that often start at resort nightclubs.

At The Disco…

At night, tourists and locals gather in all-inclusive resorts discos. For the tourism industry it is the only way to fabricate a tropical Latino fantasy in this transnational space. Latino music and local dancers serve as a mean of differentiation from other destinations. Dominicans are often allowed to join tourists in the resort's disco, changing status from employees (with uniforms that are used to discipline their behavior) during the day to clients (displaying personal fashion codes) as they pay for their drinks. Nevertheless once again management rules impede tourists/locals interactions: close physical contact between clients and employees is forbidden, entering a client or employee's room is impossible. The strict surveillance from managers and security guards is obvious and feared by employees who can loose their job instantly if they do derogate to those rules. This context is the most difficult aspect of the job mentioned by the employees as they live in the resort sharing rooms with co-workers without any intimacy and getting two days off out of nine or ten days of hard work. Their family usually lives three to five hours away from the hotel, which means they spend most of their day off traveling by bus. Most of the hotel workers are young single parents who provide for their babies and families by accepting better-paid jobs in the tourism industry. This isolation is in particular experienced as somehow emasculating by the young men; although they also report satisfaction from being in contact with tourists in a beautiful environment, many of them use the term *progresar* to refer to their hope of upward social mobility by interacting with foreigners which echoes Ustuner and Thompson service providers' discourses in Istanbul (2012).

Yet, some Locals/ tourists contest those rules. Dominican male agency is emphasized through romances with young tourists. Competition to enhance their status within the employee peer group is as important as the rivalry over seduction with male tourists. Bodies, possessions and brands are manipulated as signs to convey specific discourses on sex, gender, ethnicity and social status. At a micro-level, intimate interactions between tourists and locals reveal the reproduction of power relations while male locals also show a sense of agency trying to take advantage of this situation both emulating

white male consumers and exaggerating stereotypes of hyper-masculinity.

In this context, Dominican men literally take possession of the space - the disco floor - as a response to the emasculating tourism management. They reverse the situation by appearing very confident asserting their skills/competencies: easy contact with women; showing off by dancing and inviting women; display of bad boys fashion codes emulating hip hop celebrities; display of muscular bodies and a "cosmeticized" appearance.

These young female/ young male Caribbean interactions shed light on a reality ignored in previous ethnographies in the Dominican Republic (Kempadoo 1999, Brennan 2004, Gregory 1997) that analyze young Caribbean men with older White women and often presented by the popular media. Escaping those clichés makes it possible to account for a much complex gender game in a transnational context. For the female tourists encountered, those men represent a way to escape everyday narratives, and insert liberating, differentiating social discourses. They are aware of their agency as citizen of the western world but still state that they are attracted by what some informants term the "beauty", "sexiness", "manliness", and even the "machismo" of those men, who also pay them so much "attention" which is not the case of western men, who use "pseudo-egalitarian" schemes to avoid being "involved" and "gentle". These quite naïve assertions fuel idealized images of the foreign, exotic other who, via possessions (global tech, fashion brands and music), seems even closer. On the other hand, different strategies are at play for male hotel employees, some just want to have fun and forget tough working conditions, some (a minority) try to get a western girlfriend to settle abroad, some would like to have a nice time and hope for presents and/or money. However, most of them state they would not go with any women if she is "too old", "unattractive". Such behavior remained an exception during my several weeks there. For some men, it is an opportunity to express their "personality" through clothing and less controlled behavior than during the day, for instance some Haitians keep their long braided hair that is often forbidden by the management and confide about their cultural specificities while they are told not to voice they are Haitian it in the hotel. Meeting tourists - as seeming equals - helps reduce vivid internal tensions and reinforce self-esteem according to various informants.

"I don't have the possibility to share a meal with the tourists, all day I smell pizza and I can't get any unless some tourists hide some and bring me a slice, do you think this is normal? But when the night comes, it is like in Hector Acosta's song, I don't have money, I can't bring you to Europe and all the stuff but I am sure with me you feel happy… (big laughs)" (Melvin, 29)

In this context, complex representations of relationships which are forbidden by the management increase the sense of transgression by all actors transforming their initial representations and displaying seemingly opposite desires- the desire for the seductive foreign and the desire for the authentic local (Wilk, 1995). On the other hand, logics of co-dependencies (Ustuner and Thompson, 2012) disrupt traditional social status games and hierarchies and object/subject dialectics. Here especially hybrid identities are experienced as various capital games are emphasized. Seduction assets in a holiday resort are more valued than anywhere else. The mastery of Latino dance also empowers Locals over tourists although power structures are still at stake as Locals remain under surveillance. The only way they can escape it is leaving the resort for the night which can cause money issues as they depend on the female tourists to follow them

and, obviously, pay the expenses. In a sense, impeding close Locals/Tourist interactions ends up encouraging informal prostitution.

Interesting are the reactions of some young male tourists that either admire the successes of Locals with female tourists or often express a frustration while facing female tourists consuming the racialized fantasy of Latin hyper-masculinity.

"I will never come back to the Dominican Republic, it is my third and last time here… it's not possible to meet nice girls I mean tourists, they are all with the Dominicans, they don't pay attention to us. The worst of it is …those people in Spain, the girls would never look at them! Anyway they would not be even able to enter the disco I am used to going to…I don't know what's wrong with these girls, I am sure they know those men have 15 girlfriends at the same time" (Ricardo, 32, Spanish, Wholesaler)

Here some informants activate classist and/or colonial discourses; it is also representative of other tourists' behaviors that avoid any particular contacts with locals except getting the best service for a minimum price. Especially during slack season weekends, some resorts are filled with Dominican families, NGOs or companies paying for their stay. Many tourists report they wish this did not happen as *"it disrupts the whole thing!"* as a woman put it, or *"Dominican Rep. without the Dominicans is much better: I will never come back to this hotel!"*

It is noteworthy that skin-capital and citizenship become in this context socio-economic capital that blurs habitual social taxonomies (and the marginalized citizenship issues mentioned earlier). Some tourists from lower classes feel superior and are viewed as rich by employees, while some service providers are much more educated (doctors without jobs for instance), speaking several languages and trying to interact with western middle-class women whose financial independence is seen as a potential liberation.

CONCLUSION

As we have seen, the cultural hybridity that is a consequence of mass-tourism is nevertheless perceived as a threat to the seamless atmosphere of tourism and the principle of social exclusion. This unruly hybridity risks disrupting the binary oppositions undergirding the industry's symbolic economy between "guests" and "hosts", between subjects and objects of consumption and between cosmopolitan contemporaneity and the charm of, in this case, virgin beach-town tropical island. It is this subversive hybridity, a symbolic as much as an economic threat that the tourism industry tends to exclude.

The thick descriptions of the context organized in spatio-temporal landmarks help to convey the experience of different sets of actors interrelated in a network of performances leading to experiences of transformation in transnational places. The research contributes to three areas: global service providers/consumers' interactions, acculturation processes and social class deployment in less industrialized consumer cultures.

Uppers and Downers: Conveying Product Activity Level with Diagonals

Ann Schlosser, University of Washington, USA
Ruchi Rikhi, University of Washington, USA

EXTENDED ABSTRACT

Perrier recently changed its packaging by orienting its horizontal logo to an upward diagonal, while Snapple has done the reverse. Although such changes may be part of routine brand updating, we propose that the direction of diagonals can have a significant influence on product judgments. Prior research has proven that the visual aspect of ads can convey semantic information and thus have important persuasive effects (Peracchio and Meyers-Levy 2005; Scott and Batra 2003). We contribute to this literature in at least three ways: by demonstrating that the direction of diagonals can (1) convey different amounts of activity, and thus differentially influence (2) product expectations, and (3) both pre- and post-consumption judgments.

Although conveying activity in a logo has been identified as an important design element, what makes a logo more or less active has yet to be specified (Henderson and Cote 1998). There exists initial evidence that diagonal (vs. vertical) orientations reflect dynamism (Peracchio and Meyers-Levy 2005). We extend this research by proposing that the direction of diagonals can convey different degrees of activity and effort, and thus differentially affect persuasion. Specifically, a line that slopes from the lower left to the upper right is an upward diagonal, whereas a line that slopes from the upper left to the lower right is a downward diagonal. The art literature suggests that the orientation of objects can convey movement. Specifically, whereas a horizontal line has been likened to an object lying flat (Gaffron 1956) and being static (Arnheim 1974; Wofflin 1950), diagonal lines differ in their direction, thereby conveying movement (Arnheim 1974; Gaffron 1956; Wolfflin 1950). Because visual information is processed from left to right (Deng and Kahn 2009), we argue that an upward (vs. downward) diagonal will convey greater movement/activity and thus be less relaxing. Indeed, upward (downward) diagonals are often described as ascending (descending; Gaffron 1956).

We test our account across three studies. In study 1, we test whether individuals process images from left to right, and infer that upward (vs. downward) diagonals convey more activity and success. To test this, 143 participants were randomly assigned to a 2 (orientation: upward vs. downward) x 3 (order: heatmap, activity items, or rest item measured last) design. After being shown an upward diagonal or downward diagonal, participants clicked on where the line starts. As predicted, an orientation main effect was nonsignificant for the x-coordinate ($F(1, 165)<1$), but was significant on the y-coordinate ($F(1,165)=1028.80$, $p<.001$) with values indicative of the left region of the grid. Participants also rated the line on a number of attributes. Consistent with the art literature and our theorizing, activity perceptions were greater for upward than downward diagonals ($M = 4.84$ vs. 4.00, $F(1, 137)=5.20$, $p < .05$), whereas at rest perceptions were greater for downward than upward diagonals ($M = 4.13$ vs. 3.25, $F(1,137)=4.23$, $p < .05$).

In studies 2 and 3, we varied whether individuals' goals favor activity or rest. If upward (vs. downward) diagonals convey greater activity, then they should lead to higher product expectations and evaluations with active (vs. relaxation) goals. In study 2, 108 participants were randomly assigned to a 2 (goal: adventure vs. relaxation) x 2 (diagonal: upward vs. downward) design. Participants were told they were planning an adventure or relaxation vacation before viewing an ad, in which the text and images emphasized either an upward or downward diagonal. For attitudes toward the resort, a goal x diagonal interaction was significant ($F(1,105) = 15.31$, $p<.001$). When adventure was primed, attitudes were higher in the upward than downward condition, whereas when relaxation was primed, attitudes were lower in the upward than downward condition ($Fs(1,103)> 5.81$, $ps<.05$). A similar pattern emerged for purchase intentions (PI) toward the vacation package ($F(1,103) = 6.35$, $p = .01$). As before, when adventure was primed, PI was higher in the upward than downward condition ($F(1,103)=5.79$, $p<.05$), and when relaxation was primed, PI was lower in the upward than downward condition, although this difference was not significant ($F(1,103) = 1.12$). Still, PI was higher for those in the downward/relaxation than downward/adventure condition ($F(1,103)=8.59$, $p<.005$). Furthermore, willingness to pay (WTP) was higher in the downward/relaxation than upward/relaxation condition ($F(1,103)=4.37$, $p<.05$). In contrast, WTP was somewhat (but not significantly) higher in the upward/adventure than downward/adventure condition ($F(1,103)=1.45$, NS).

Study 3 used a 2 (claim: energizing vs. relaxing) x 2 (diagonal: upward vs. downward) design for a hypothetical beverage claiming to either promote energy or relaxation. This product category was selected because energy and relaxation drinks are popular among this generation (Stacy 2011). Based on prior research (Shiv, Carmon and Ariely 2005), we predict that if diagonal orientation influences activity-level expectations, then activity-level experiences (i.e., feeling energized or relaxed) should vary depending on whether the claim is congruent. To test this, 141 participants viewed the beverage packaging that varied in claim and diagonal orientation, and then drank a purported sample of the beverage, which was the same water for everyone. For all of the dependent variables, goal x diagonal was significant ($Fs(1, 134)>4.41$, $ps< .05$). As predicted, in the relaxed condition, satisfaction was higher when the diagonal was downward than upward, whereas in the energized condition, satisfaction was higher when the diagonal was upward than downward ($Fs(1, 138)>4.11$, $ps<.05$). Moreover, participants in the relaxation condition reported feeling more relaxed when the diagonal was downward than upward ($F(1, 138)=5.59$, $p<.05$), whereas there was no significant difference in the energizing condition ($F(1,138)<1$). In contrast, participants in the energizing condition reported feeling more energized when the diagonal was upward than downward ($F(1, 138)=6.11$, $p<.05$). However, in the relaxation condition, participants reported feeling more energized when the diagonal was congruent—that is downward than upward ($F(1, 138)=6.91$, $p=.01$). Bootstrapping methods support that feeling relaxed (and energized) mediated the effect of diagonals on satisfaction in the relaxing condition, whereas feeling energized was the mediator in the energizing condition.

In summary, this is the first empirical research demonstrating that upward and downward diagonals convey different degrees of activity, and thus differentially influence product expectations and pre- and post-consumption judgments.

Who Made This Thing? How Designer Identity and Brand Personality Impact Consumers' Evaluations of New Product Offerings

Matt O'Hern, University of Oregon, USA
Lan Jiang, University of Oregon, USA

EXTENDED ABSTRACT

Today, companies across a wide range of fields (e.g., Procter and Gamble, YouTube, Threadless.com) are adopting *external innovation* programs that allow individuals outside the firm to directly participate in the new product development (NPD) process. Although interest in customer involvement in NPD is increasing among marketing scholars (e.g., Franke, Keinz, and Steger 2009; Moreau and Herd 2010), much of the research has focused only on the mass-customization context and has explored how consumers' active participation in personalizing their own products influences their subsequent evaluations. The current study extends existing research by focusing not on customers who are actively involved in NPD, but on the broader segment of customers that simply consumes new product offerings. More specifically, this research explores whether consumers' product evaluations depend on the identity of an external designer (i.e., a fellow customer or an independent professional designer) and examines the role that brand personality may play in influencing consumers' reactions.

We propose that consumers will prefer customer-created new products when an exciting brand personality is present, but that this preference will be reversed in the presence of a sincere brand personality. This is due to the different focuses elicited by these two distinctive brand personalities, whereby excitement shifts consumers' focus toward the process used to create a product but sincerity draws the focus toward the outcome. When the focus is on the NPD process, firms that encourage customers to create new product concepts are seen as more democratic and customer-oriented (Fuchs and Schreier 2011). However, when the focus is on the outcome/product, consumers will be more likely to link the designer's professional status with the expertise necessary to create an innovative, highly effective product.

Study 1 adopts a 2 (Designer Identity: Customer vs. Professional) x 2 (Brand Personality: Sincere vs. Exciting) between-subjects design. A fictitious new product was created as the stimulus. In the customer condition, we introduce the product creator as a loyal customer, while in the professional condition the creator is a professional. Personality is manipulated through text, taglines, logos and website visuals, following Aaker et al. (2004). The key measure is consumer liking and participants were also asked whether they viewed the focal product / the process used to create the product as innovative and effective. The 2 x 2 ANOVA showed a two-way interaction ($F(1,141) = 6.68$, $p < .05$). When an exciting personality was present, subjects who were told that the creator was a fellow customer indicated a higher liking for the product. In contrast, when evaluating the sincere version, participants preferred the professionally created product.

When asked to evaluate the innovativeness and effectiveness of the NPD process, participants rated the process as being more innovative and effective when the designer was a customer. However, when asked about the innovativeness and effectiveness of the product itself, participants who learned that the product was created by a professional designer rated it as being more innovative and effective. Follow-up mediation analysis revealed that consumers prefer professionally designed products, because they view the end product as more innovative and effective and that consumers exhibit greater liking for customer creation, because they perceive the NPD process as more innovative and effective.

Study 2 further identifies the role of process vs. outcome orientation by directly manipulating consumers' focal orientation to concentrate on either process or outcome. This study adopts a 2 (Designer Identity) x 2 (Brand Personality) x 2 (Focal Orientation) between-subjects design. Another fictitious new product was used to increase generalizability. Results revealed an interactive effect of identity and personality ($F(1,134) = 9.13$, $p < .005$) and an interaction between designer identity and focal orientation, (i.e., process vs. outcome) ($F(1,134) = 11.02$, $p < .05$). The pattern showed that the moderating role of focal orientation is in parallel with the role of brand personality, such that a focus on process leads to a preference for customer creation as the exciting personality does, while a focus on outcome results in increased liking for professional creation as the sincere personality does.

Study 3 examines the timing of consumption as a boundary condition. We expect that if the product is to be consumed in the immediate future, attention will shift from brand personality and focus on more tangible product attributes, thus limiting the impact of personality. Study 3 adopted a 2 (Designer Identity) x 2 (Brand Personality) x 2 (Consumption Timing) between-subjects design. In the near future condition, participants were told to imagine that they have a time-critical project, i.e., to remodel their room before the coming weekend. In the distant future condition, they were told to imagine remodeling their room several months in the future. A 2 x 2 x 2 ANOVA on liking revealed a three-way interaction ($F(1,165) = 5.70$, $p < .005$). In the distant future condition, the results replicated the previous findings. Interestingly, when the time constraint was imposed, only a main effect of designer identity emerged, so that participants in both the sincere and exciting conditions indicated a greater liking for the professionally created product ($Mc = 4.21$ vs. $Mp = 5.17$; $F(1, 159) = 5.01$, $p < .01$).

Across three studies, our research makes three important contributions. First, we show that brand personality plays a significant role in determining whether customers respond more positively to products designed by fellow customers or by professional designers. Second, our research sheds light on the mechanism through which designer identity impacts consumers' new product evaluations and demonstrates that this relationship depends on whether customers are process-oriented or outcome-oriented. Finally, this study identifies a boundary condition in the form of consumption timing and demonstrates that the interaction effect between designer identity and brand personality is attenuated when customers contemplate making an immediate purchase.

Managerially, our research provides important insights for marketers. Our findings suggest that exciting brands could benefit from highlighting the active role that customer designers play in the external innovation process. Conversely, managers of sincere brands may wish to highlight the expertise of professional designers when mentioning an external innovation program in their marketing communications.

I Think I Can, I Think I Can: Brand Use, Self-Efficacy, and Performance

Ji Kyung Park, University of Delaware, USA
Deborah Roedder John, University of Minnesota, USA

EXTENDED ABSTRACT

When individuals struggle with a difficult and challenging task, can using a brand with a strong image related to the task's domain empower them to perform better? For example, can individuals perform better when engaging in strenuous physical exercise if they wear Under Armour accessories (athletic image) while exercising? Our answer is yes. We propose that using brands with strong images while performing a difficult task can enhance feelings of self-efficacy (beliefs in one's capabilities; Bandura 1995) in a domain related to the brand's image, and this heightened sense of self-efficacy can lead to better task performance.

Further, we propose that the self-efficacy effect is not experienced by everyone—it depends on the implicit self-theory held by individuals (Dweck 2000). Individuals who endorse entity theory ("entity theorists"), who view their personal qualities as something they cannot improve through their own direct efforts, will rely on feelings of self-efficacy that using brands can trigger to perform better on difficult tasks. In contrast, individuals who endorse incremental theory ("incremental theorists"), who view their personal qualities as something they can develop through their own direct efforts at self-improvement, will be less reliant on the self-efficacy effect of brands. Thus, we predict that brand use will result in a heightened sense of self-efficacy and better task performance for entity, but not incremental theorists.

We examine these propositions in three studies. In a first study, we examined the effect of using an MIT pen on performance for a challenging GRE test. The MIT brand is strongly associated with the image of "intelligence", and we expected that using a pen embossed with the MIT name would enhance GRE test performance for entity, but not incremental theorists. Undergraduate students were given 30 minutes to take a GRE test that consisted of 15 difficult and 15 easy math problems. Implicit self-theory was measured prior to taking the test. As expected, *entity theorists* who used the MIT pen (vs. regular pen) *performed better* on the 15 difficult GRE problems, where test takers tend to struggle the most and the beneficial effects of using the MIT pen should be most pronounced. In contrast, the performance of incremental theorists did not vary across pen conditions. Additionally, incremental theorists performed more poorly than entity theorists using the MIT pen. Simply using the MIT pen without having training opportunities to directly improve their intelligence did not enhance performance among incremental theorists.

In a second study, we extended our findings using a different brand (Gatorade) associated with a different brand image (athletic) and a different type of task (strenuous athletic task). Also, we manipulated beliefs in entity versus incremental theory (Chiu, Hong, and Dweck 1997) prior to brand usage. Participants were invited to evaluate a new bottled water from Gatorade (athletic brand) or Ice Mountain (control brand). In the Gatorade condition, participants drank cold tap water in a cup featuring the Gatorade brand name and logo; in the Ice Mountain condition, they drank the same water in a plain cup. They were asked to drink water continuously while exercising with a hand-grip, which had a counter to record the number of times the hand-grip was pressed. This athletic task is initially easy, but gets harder (due to fatigue) as the hand-grip is pressed more times. As expected, participants in the *entity theory* condition *performed better* on hand-gripping (higher hand grip count) when drinking Gatorade (vs. Ice Mountain) water. In contrast, those in the incremental theory condition performed similarly regardless of the water they drank.

Additionally, their performance was lower than that of entity theorists who drank water from the Gatorade cup.

In a third study, we examined the mechanism underlying increases in task performance for entity theorists observed in the first two studies. Participants read several articles, including one about Gatorade that presented evidence that Gatorade increases athletic performance (high brand effectiveness) or does not increase athletic performance (low brand effectiveness). Next, participants completed the hand-grip task while drinking the tap water in the Gatorade cup. Finally, participants rated the degree of confidence they had about their ability during the hand-grip exercise (self-efficacy measure). If entity theorists (but not incremental theorists) derive a sense of self-efficacy from using brands such as Gatorade, which allows them to perform better on strenuous athletic endeavors, only entity theorists should be affected by the manipulation that Gatorade can (vs. cannot) make you a better athlete. Our results supported this line of reasoning. Entity theorists showed a heightened sense of *self-efficacy and performance* on the hand-grip task in the high (vs. low) brand effectiveness condition. However, incremental theorists did not show such a difference. More importantly, results from a *mediation analysis* showed that using Gatorade in the high (vs. low) brand efficacy condition enhanced self-efficacy among entity theorists, which led to better performance on the hand-gripping exercise.

Our findings show, for the first time, that using brands can be beneficial for consumers who find it difficult to believe that they can improve their abilities through their own direct efforts at self-improvement (entity theorists). Using a brand with a strong image empowers entity theorists to perform better on difficult and challenging tasks in a domain related to the brand's image. Using an MIT pen empowered entity theorists to perform better on difficult GRE questions (study 1) and drinking tap water from a Gatorade cup empowered them to perform better on a physically challenging athletic exercise (study 2 & 3). Brands can activate goals (Fitzsimons, Chartrand, and Fitzsimons 2008), but when tasks are difficult and challenging, simply possessing a goal to perform well may not be sufficient. A cognitive appraisal of personal efficacy is required to increase the level of challenge that individuals are willing to undertake and to encourage them to mobilize effort to perform well (Zimmerman, Bandura and Martinez-Pons 1992). For people (entity theorists) who need an external cue to enhance appraisals of one's capabilities, using brands provides the needed boost.

Beyond Seeing McDonald's Fiesta Menu:
The Role of Accent in Brand Sincerity of Ethnic Products and Brands

Marina Puzakova, Oregon State University, USA
Hyokjin Kwak, Drexel University, USA
Monique Bell, Drexel University, USA

EXTENDED ABSTRACT

The ascent of Hispanic-Americans as the largest U.S. minority has encouraged firms to start utilizing ethnic brand crossovers (e.g., McDonald's "Fiesta" menu). One effective way of engaging ethnic groups has been the use of ethnic accent in firms' branding messages (McDonald's use of Hispanic-accented spokespersons to tout its "Fiesta" menu). Indeed, accent induces enduring personality impressions (e.g., sincerity; Bresnahan et al. 2002; DeShields, Kara, and Kaynak 1996). Despite the powerful impact of accent in communicating personalities, scholarly research investigating the role of accent in brand communications has been limited. Understanding whether and under what circumstances a spokesperson's accent is likely to affect brand sincerity can provide marketers of domestic and ethnic brands with another marketing tool to strategically manage their brands' personalities.

Relying on a prosodic theory of accents, we propose that Hispanic accent's specific prosodic features (i.e., the acoustic language features such as pitch, rhythm, and intonation; Ramus et al. 2000) are perceived as more sincere (Ray 1986). Given that a spokesperson's accent is evaluated in part by the prosodic characteristics of the speaker's native language and that those prosodic features uniquely influence sincerity evaluations, our first hypothesis is that an advertisement using a Hispanic accent will be perceived as more sincere than a brand advertised using an American (standard) accent.

In Study 1, we used a 30-second radio advertisement for a fictitious brand of chocolate that included a verbal message discussing product characteristics and void of salient brand personality cues. As predicted, the results of a 2 (gender of the spokesperson) x 2 (spokesperson's accent: Hispanic vs. American) between-subject ANOVA ($n = 60$) revealed that Hispanic accent leads to higher brand sincerity perceptions. Consistent with previous literature, brand sincerity also predicted consumers' attitudes toward the brand.

Furthermore, while it seems sensible to employ a Hispanic-accented speaker to evoke brand sincerity impressions for an ethnic brand (e.g., Chipotle Mexican Grill), might there be greater advantages of using an American-accented speaker to enhance brand sincerity perceptions of a brand with American roots, however, in a traditionally ethnic product category (e.g., McDonalds' burritos)? We define brand ethnicity as consumers' perceptions that the brand originated from a specific ethnic culture. In accord with the dynamic constructivist theory of culture (Torelli and Ahluwalia 2012), people develop representations of what trait characteristics are associated with certain cultures. For American consumers, the associations of warmth and sincerity of Hispanic cultures are highly accessible and consensually shared (Cuddy, Fiske, and Glick 2008). Such group stereotypes are transferred to products, brands, and people originating from the cultures (Chattalas, Kramer, and Takada 2008). As prosodic features of Hispanic accent create greater perceptions of brand sincerity (Study 1), and as Hispanic "brand ethnicity" alone induces sincerity perceptions, our second hypothesis is that a match or mismatch between the spokesperson's accent and brand ethnicity is likely to play a significant role in either boosting or inhibiting brand sincerity inferences. Hypothesis 2 was tested in Study 2 ($n = 60$). We recorded 30-second radio commercials featuring a fictitious American brand, Joe's Burgers, and a fictitious Hispanic brand, Carlos' Tacos (both

identified though a pretest as ethnically salient), using either American- or Hispanic-accented spokespersons. Respondents rated brand sincerity ($\alpha = .88$), brand attitude ($\alpha = .96$), strength of their American identity (covariate was insignificant), and the ad's realism (no differences across conditions). No main effects of accent or brand ethnicity were detected. However, a significant interaction effect between brand ethnicity and accent emerged. That is, a spokesperson's Hispanic (American) accent created enhanced perceptions of brand sincerity for ethnic (domestic) brands.

Will the moderation effect of brand ethnicity hold when brand ethnicity is incongruent with product ethnicity? Product ethnicity associations are highly accessible, deeply embedded in consumers' interpretations of brands, are not easily affected by local branding efforts (Eckhardt 2005), and may become an important factor in evaluations of an unfamiliar brand (Nebenzahl and Secunda 1993). In addition, consumers show low levels of brand origin recognition for frequently purchased goods because this information is deemed non-diagnostic for purchasing decisions (Samiee, Shimp, and Sharma 2005). Thus, as product ethnicity is more likely to dominate brand ethnicity perceptions, our third hypothesis is that product ethnicity-accent congruity is likely to induce stronger effect on brand sincerity than brand ethnicity-accent congruity.

In Study 3 ($n = 94$), 30-second radio commercials for an American (Hispanic) product category and Hispanic (American) brand name, Carlos' Burgers (Joe's Tacos) were used. A significant interaction effect between incongruent product-brand ethnicity and accent emerged. Planned contrasts showed that in the commercial about the American (Hispanic) product with a Hispanic (American) brand name, an American (Hispanic)-accented spokesperson induced higher brand sincerity than when a spokesperson had a Hispanic (American) accent. In support of hypothesis 3, these results demonstrate that a congruity of an accent with a product ethnicity, versus brand ethnicity, drives brand sincerity perceptions.

Our research contributes to the literature by demonstrating how the use of Hispanic versus American accent affects the way consumers perceive brand sincerity. In resonance with source congruity theory, we find that a match between an accent and a product ethnicity boosts brand sincerity perceptions. Finally, this research deepens our understanding of the interaction effect of brand and product ethnicities that both determine more effective selection of a spokesperson accent. Overall, our findings have significant implications for brand managers as they consider using accented spokespersons to engender sincerity perceptions for brands that cross ethnic boundaries.

For Love of Brand and Community: Why Self-Brand Connection Changes the Nature of Social Comparisons Involving Prestige Brands.

Jill Sundie, University of Texas at San Antonio, USA
Daniel Beal, Rice University, USA
Andrew Perkins, University of Western Ontario, Canada
James Ward, Arizona State University, USA

EXTENDED ABSTRACT

Nearly all consumers have coveted at least one prestige branded product (Taylor and Harrison 2008). Imagine a boy infatuated with Ferrari automobiles since age 8, displaying Ferrari posters on his bedroom wall, and reading any car magazine that featured the Ferrari. Unable to afford one himself, how would this now grown man respond when confronted with a peer who owns and drives his beloved vehicle? Such upward social comparisons are often emotionally laden, prompting feelings of inferiority and envy (Smith and Kim 2007). Sundie et al. (2009) demonstrated that envy generated by possession of a prestige product can quickly transmute into hostile, aggressive emotions. While the rapid transmutation of envy into hostility is conceptualized as a self-protective response, aimed at alleviating the self-threat posed by the upward comparison (Smith and Kim 2007), these feelings can prompt attitude change and behaviors that may ultimately be damaging to the prestige brand (Sundie et al. 2009).

Must the aspiration to obtain a prestige product always transform envy into hostility during social comparison? In the present research, we examine how, and why, strong connections between the self and the brand (Escalas and Bettman 2003) can change the emotional experience of social comparisons involving those brands. In the first study, we examine whether implicit self-brand connections can reduce the threatening nature of an upward comparison involving a prestige branded product. Study two examines a potential mediator of the effect of self-brand connection on hostile responses to envy in social comparison--felt connection between the self and other *owners* of the prestige brand. A summary of our findings is: To the extent that people feel a strong *self*-connection to the prestige *brand*, envy is less likely to transmute into other hostile emotions during an upward social comparison involving that brand. A key variable accounting for *why* a strong self-brand connection weakens the envy-hostility link during social comparison is the felt connection between the self and other *owners* of the prestige brand.

Study 1 examined how self-brand connection (assessed with a self-brand implicit association test or IAT; Perkins and Forehand 2012) affected the emotions experienced when making an upward social comparison based on a prestige brand (Lexus). After completing a self-Lexus IAT, 125 participants read a short social comparison scenario about someone fairly similar (another college student) who owned a sporty Lexus (price and picture of vehicle were provided). They then were asked about their emotional responses to this scenario (e.g., happy, envious; instructions and measures taken from Sundie et al. 2009). Finally, dispositional envy was measured as a control variable (Smith et al. 1999). We anticipated and found that implicit self-brand connection moderated the link between envy and hostility, such that stronger self-brand connections reduced the transmutation of envy into other hostile emotions (β for interaction = -.15, $p<.05$). Because self-brand connection was measured implicitly, it is highly unlikely that it influenced responses to the subsequent emotional measures (i.e., reducing the potential for demand effects). The fact that a range of emotions (very positive to very negative) were assessed after the presentation of the social comparison scenario also reduces the possibility of any demand effects (Sundie et al. 2009).

In research examining *antecedents* of self-brand connection (Escalas and Bettman 2003; 2005), consumption of a brand by reference group members, or brand associations consistent with the in-group, predicted developing a self-brand connection. Here, we examine *consequences* of self-brand connection for emotions experienced in a status consumption context, where social comparisons routinely occur. Intergroup emotions theory (Mackie et al. 2000) posits group identification (Turner 1991) will encourage positive emotional responses to group members possessing social advantages. Thus, the more individuals see another who possesses an envied product as a part of the self, the less inclined they should be to experience negative emotions. We hypothesized that felt connections between the self and *brand owners* may account for the dampening effect of self-brand connection on the envy-hostility link common to social comparisons involving status products.

Study 2 was designed to replicate study 1 findings, but extend upon it in two key ways: by using a validated *explicit* measure of self-brand connection (Escalas and Bettman 2003), and by examining a potential mediator of the moderating influence of self-brand connection on the envy-hostility link during social comparison (i.e., testing for mediated moderation). 305 participants completed the study for course credit. Participants selected a desirable luxury car from eight options, then reported their connection with that brand, α = .91. Next participants read a social comparison scenario featuring a peer who owned that prestige vehicle. Participants then reported their emotional responses to the scenario (as in study 1) and the extent to which they felt connected to owners of that prestige vehicle--this connection measure depicted increasingly overlapping circles (e.g., Tropp and Wright 2001); one circle represented "Me"; the other circle represented "Owners" of the luxury car. Dispositional envy was again measured as a control. Mediated moderation was tested using a path-analytic framework, consistent with the most recent published recommendations (Edwards and Lambert 2007). As anticipated, the interaction effect of self-brand connection and envy on hostility was mediated by the same interaction involving the overlap-with-brand-owners measure (see Figure 1). The indirect effect linking SBCx-Envy to Hostility is significant at p = .05, using Mplus' bootstrapped standard errors.

This research contributes to the envy literature, helping to clarify when envy will transmute into hostility during social comparison. Our studies also contribute to the literature on self-brand connection by showing that felt connection with brand owners (not just connection between self and the brand) changes the nature of social comparisons involving prestige brands; dampening hostile reactions to envy evoked by a similar other who owns a coveted brand. We also demonstrate this effect of self-brand connection in social comparison is driven by felt overlap with prestige brand owners. Our results imply that to the extent luxury good marketers can encourage brand coveters to feel connected to brand owners (e.g., through clubs, discussion forums, reality television), they may succeed in dampening hostile envy.

Do You Believe in Love at First Sight? I Do: Implicit Self-Theories and Attitude Strength

JaeHwan Kwon, University of Iowa, USA
Dhananjay Nayakankuppam, University of Iowa, USA

EXTENDED ABSTRACT

A consistent finding in the attitude literature is that strong attitudes are products of effortful cognitive elaboration (Petty and Cacioppo 1984; Petty and Wegener 1999). We argue that the link between elaboration and attitude strength could be more complicated.

Dweck, Chiu and Hong (1995) have identified two distinct implicit self-theories—entity vs. incremental theory—and have shown that each theory has a variety of influences on the theory holders' information processing and judgments. People who endorse entity theory (entity theorists) believe that their personal traits (i.e., personality, intelligence, and morality) are fixed, while people who endorse incremental theory (incremental theorists) view their personal traits as malleable. This line of research has found that individuals can extend their implicit self-theories: individuals apply their beliefs in personal traits not only to themselves, but also to other individuals.

We propose that individuals can extend their implicit-self theories, even to products or brands, and that implicit self-theories will affect individuals' attitude formation processes. Specifically, entity theorists will form attitudes toward products or brands more quickly (i.e., with less elaboration), but the strengths associated with the attitudes will be stronger than incremental theorists. That is, depending on implicit self-theories, individuals may form strong attitudes without elaboration.

STUDY 1: THE RELATIONSHIP BETWEEN IMPLICIT SELF-THEORY AND ATTITUDE FORMATION TIME AND ATTITUDE STRENGTH

We investigate whether entity theorists take less time than incremental theorists to form attitudes toward brands, and whether the strengths associated with the attitudes formed by entity theorists are stronger than those by incremental theorists. Attitude formation time was measured using Media Lab software while each participant viewed a computer screen showing a print ad for a new brand and indicated his or her attitude on a like-dislike dichotomous scale. After a thirty-minute lag, attitude strength was assessed both by metacognitive measures (direct responses; e.g., "How certain are you about your opinion?") and by attitude accessibility (indirect responses: response latency to access and express an attitude).

The results support our prediction that an individual's dispositional implicit self-theory orientation affects his/her attitudes, attitude formation time, and attitude strength. The results illustrate that, compared with incremental theorists, entity theorists quickly form attitudes that are congruent with the position of a persuasive message (ß = -.37, t (62) = -2.99, p < .01). Further, even though they formed attitudes quickly, they held the attitudes more strongly than incremental theorists (ß = .26, t (62) = 2.09, p < .05).

STUDY 2: THE CAUSAL IMPACT OF IMPLICIT SELF-THEORY ON ATTITUDE FORMATION TIME AND ATTITUDE STRENGTH

We validate the causal relationships between implicit self-theory and attitudes. In Study 1, we did not address the question of causality. In Study 2, we manipulate an individual's implicit self-theory orientation using the generalized implicit self-theory manipulation technique (Chiu, Hong, and Dweck, 1997).

The results replicated those of Study 1: entity theory priming reduced the time taken to form attitudes (F (1, 105) = 18.12, p < .001), but increased the strength associated with the attitudes (F (1, 105) = 6.71, p < .025).

STUDY 3: COGNITIVE ELABORATION—THE DIFFERENCE IN ATTITUDE FORMATION PROCESS BETWEEN ENTITY AND INCREMENTAL THEORISTS

Next, we manipulate the argument quality of a persuasive message (strong vs. weak argument) and examine if the level of cognitive elaboration is different between entity and incremental theorists when forming attitudes.

The results support the idea that the strong attitudes formed by entity theorists are not the results of effortful cognitive elaboration. The two-way, implicit self-theory by argument quality interaction on attitude demonstrates that only incremental theorists were affected by argument quality manipulation, whereas entity theorists were not. Incremental theorists formed more message-congruent attitudes under the strong argument condition and less message-congruent attitudes under the weak argument condition (F (1, 77) = 10.52, p < .001). In contrast, attitudes formed by entity theorists did not differ by argument quality manipulation (F (1, 77) = .20, NS). These results demonstrate that entity theorists exerted low levels of cognitive elaboration, whereas incremental theorists exerted high levels of elaboration. Nevertheless, attitude strengths of entity theorists were significantly greater than those of incremental theorists (p < .025). Taken together, although they did not exerted effortful cognitive elaboration when forming attitudes, entity theorists formed stronger attitudes than incremental theorists. These findings contradicts with the prior notion that strong attitude is a product of effortful cognitive elaboration.

STUDY 4: WHAT THEN MAKES ENTITY THEORISTS FORM STRONGER ATTITUDES THAN INCREMENTAL THEORISTS?

We prepared four consumer reviews on the 3D-TV (two positive and two negative) and then made four different combinations: positive-to-positive, positive-to-negative, negative-to-positive, and negative-to-negative. Participants read only one of the four combinations.

The results reveal that entity theorists are likely to stick to the attitude formed based on first reviews, and they are not be willing to adjust it after second reviews are provided, while incremental theorists put more weight on second reviews. The purpose of Study 5 was to explore how and why entity theorists form and hold strong attitudes without elaboration. Our results give us an interesting explanation: entity theorists believe that everything is fixed, so that they do not need to adjust their attitudes once formed. As a result, they do not need to process all of the information available; they focus on only the first few pieces of information when forming attitudes, while incremental theorists focus on more recent pieces of information.

SUMMARY

The present study extends our understanding of the effect of implicit self-theory on the attitude formation process. Entity theorists form strong attitudes without effortful cognitive elaboration. Specifically, entity theorists form attitudes more quickly toward products and brands, and they hold these attitudes more strongly than incre-

mental theorists. Our findings contribute to both the implicit self-theory and attitude strength literature.

Good or Bad, We Want It Now:
Resolution Theory Explains Magnitude Reversal in Intertemporal Choice

David Hardisty, Stanford University, USA
Kirstin Appelt, Columbia University, USA
Elke U. Weber, Columbia University, USA

EXTENDED ABSTRACT

Across four studies, outcome magnitude has opposite effects on intertemporal choice for gains and losses: consumers discount small gains more than large gains, but discount small losses *less* than large losses. Thought listings show that this is mediated by consumers' desire to resolve gains and losses as soon as possible.

Consumers often discount future consequences, for multiple reasons (Lynch and Zauberman 2006). The "magnitude effect" describes the fact that large gains are discounted more than small gains (Chapman and Elstein 1995; Estle et al. 2006; Thaler 1981). For example, someone might choose $10 today versus $11 in a year, yet prefer to wait for $11,000 in a year rather than take an immediate $10,000, even though in both cases the later amount is 10% larger than the sooner amount. In these earlier studies, the choice options always paired a smaller, sooner amount with a larger, later amount, so it was impossible for participants to express zero or negative discount rates. Thus, although some people might rather pay $10 immediately rather than $9 in a year (to get the loss over with), this preference could never be expressed. A pilot study we ran suggests that when negative discount rates are allowed, losses may show a *reverse* magnitude effect: Consumers considering small losses were indifferent between paying $10 today and $9.70 in six months (a -6% discount rate), whereas those considering large losses were indifferent between paying $1,000 today and $1,070 in six months (a 13% discount rate).

Although several models have been proposed to explain the magnitude effect (al-Nowaihi and Dhami 2009; Benhabib, Bisin, and Schotter 2010; Loewenstein and Prelec 1992; Scholten and Read 2010), none predict the interaction of magnitude and sign. To fill this gap, we propose *resolution theory*: Consumers have a psychological desire to resolve both gains *and* losses immediately, and this desire is combined with multiple other factors (such as uncertainty, see Table 1) to ultimately predict time preference. In the case of gains, people want the gain immediately to satisfy their desire for positive outcomes and to avoid feelings of deprivation while waiting (Hoch and Loewenstein 1991). When combined with other factors, which also favor the immediate gain, the resulting discount rate is high. In the case of losses, people want to get the loss over with immediately to close their mental books on the loss and avoid having to allocate attention and emotional capacity (e.g., dread) to looming future losses (Harris 2010; Loewenstein 1987). When balanced against other factors, which instead favor the delayed loss, the resulting discount rate is low. In both cases, the desire to resolve gains and losses is relatively insensitive to magnitude; it is a constant that is added to other attractions of the immediate reward (an assumption supported by Benhabib et al., 2010, for the domain of gains), rather than a parameter that multiplies the immediate reward's utility.

Importantly, resolution theory makes the prediction that *negative* discounting of losses will occur when amounts are small enough, because the cost of waiting is a constant that is added to the disutility

Table 1. *Summary of major factors hypothesized to determine intertemporal choices for gains and losses.*

Motivational Factor	Description	Makes people prefer to have…	Scales with magnitude?
Opportunity cost and investment (Franklin 1748; Samuelson 1937)	Resources can be invested and earn interest or otherwise grow over time	Gains now and losses later	Yes
Uncertainty (Patak and Reynolds 2007; Takahashi, Ikeda, and Hasegawa 2007)	Delayed gains and losses may never be realized	Gains now and losses later	Yes
Resource slack (Zauberman and Lynch 2005)	Expecting to have more resources in the future means that immediate resources are more dear than future resources	Gains now and losses later	Yes
Resolution (Benhabib et al. 2010; Harris 2010; Loewenstein 1987; O'Donoghue and Rabin 1999)	Psychological desire to resolve events immediately	Both gains and losses now	No
Other factors, such as social norms and ideals (Krantz and Kunreuther 2007)	Variable, but often suggest that individuals ought to delay gratification	Variable, but often postponing gains and attending to losses immediately	Variable

of the larger later loss. Negative discounting implies that outcome values intensify (i.e., positives become more positive and negatives become more negative) the further they lie in the future; in the case of losses, negative discounting means a preference to have losses sooner rather than later. For example, some people might rather pay $10 immediately rather than $9 in a year, to satisfy their desire to get the loss over with. In this case, a full *reversal* of the magnitude effect when comparing small and large losses is understandable.

METHOD

In four separates studies (total $N = 856$), participants made a series of choices between immediate and future gains and losses of different amounts. Three of these studies were run online with national samples and hypothetical outcomes, and one study was run in the lab with a student sample and real intertemporal gains and losses (in the range of $5 to $100). In two studies participants used an established type-aloud protocol (Hardisty, Johnson, and Weber 2010; Weber et al. 2007) to record their thoughts before making their decisions. Participants subsequently categorized their own previously recorded thoughts according to the factors listed in Table 1.

RESULTS

In all four studies, participants discounted small gains more than large gains, replicating the magnitude effect, and discounted small losses less than large losses, reliably establishing the reverse effect of magnitude on losses. Zero and negative discount rates were quite common when considering small losses; 78% of participants expressed this preference. In contrast, only 23% of those considering large losses, 2% of those considering small gains, and 2% of those considering large gains showed zero or negative discount rates.

Prior to making their choices, participants listed an average of 3.4 thoughts. As predicted by Resolution Theory, the proportion of resolution thoughts was significantly lower for large magnitude outcomes than for small magnitude outcomes. In other words, when participants considered $10, they frequently mentioned their psychological desire to resolve the situation as soon as possible, whereas when participants considered $10,000, other concerns were more prominent. Also as predicted, the proportion of resolution thoughts mediated the effect of magnitude on discount rates for gains and losses.

DISCUSSION

Our findings may offer some guidance to policy-makers hoping to encourage future-oriented decision making (i.e., low discount rates). As suggested by both previous research and the present findings, patience for gains may be encouraged by focusing on large magnitude outcomes. For example, an individual may be encouraged to save for retirement if the benefits of saving are aggregated over ten years of savings, rather than one year or one month. As the present research shows, however, the same strategy should *not* be applied to losses; consumers are motivated to take care of small losses immediately, but large losses are likely to be postponed until later. Therefore, a strategy of aggregating credit card debt or other debt into one large lump sum may be counterproductive, and lead consumers to delay paying off the large debt. Rather, breaking the problem down into smaller pieces that can be taken care of immediately should be more effective. Consumers will often choose to get losses over with immediately, but only if they are small and manageable.

Accentuate the Positive: How Identity Affects Customer Satisfaction

Tilottama G. Chowdhury, Quinnipiac University, USA
Kalpesh K. Desai, State University of New York, Binghamton, USA
Lisa Bolton, Penn State University, USA

EXTENDED ABSTRACT

Consumers use products to create and communicate their identities (Kleine, Kleine, and Allen 1995; Sirgy 1982). As self-relevant social categories (e.g., male, college student), identities can appropriate associations belonging to brands and form connections between brands and consumer self-concepts (Escalas and Bettman 2003). Past research has shown that salient identities guide thinking, judgment, and behavior (Tajfel and Turner 1979), including brand preference (Escalas and Bettman 2005) and choice (Berger and Heath 2007). Compared to analytic thinking, identity-driven thinking leads to judgment that resists change (Bolton and Reed 2004). Surprisingly, prior research has not yet examined the robustness of identity-driven judgment to direct product experience—an issue that Swaminathan, Page, and Gurhan-Canli (2007) exhort academics to investigate. Specifically, the present research asks: How will identity-based thinking affect (dis)satisfaction with an experience?

Research in the disconfirmation paradigm of product satisfaction suggests that post-choice satisfaction is based on the performance of the product relative to a comparison standard, typically, pre-choice expectations (e.g., Cadotte, Woodruff, and Jenkins 1987; Oliver 1989). That is, performance above (*below*) expectations leads to satisfaction (*dissatisfaction*). Prior research has also provided evidence that cognitive cues, such as brand name (Richardson, Dick and Jain 1994) and product category (Stayman, Alden, and Smith 1992), can alter satisfaction. For example, the match/mismatch between expectations engendered by product category and product taste (in the fruit juice category) influenced satisfaction, independent of product taste (Stayman et al. 1992).

While brand and category labels are cognitive cues that influence evaluations through expectations, we argue that identity is a motivational cue that will operate primarily through performance perceptions. Prior research (Oyserman (2009) suggests that consuming identity-linked products imbues choice with more meaning, that is, expressive rather than utilitarian. Thus, a positive experience with the product will enable identity-primed consumer to enjoy both the expressive and utilitarian "components" of the product, resulting in greater satisfaction compared to non id-primed consumers who will avail only of the utilitarian element of product consumption. In contrast, a negative experience fails to deliver on functionality but also denies identity-expression to identity-primed consumers; if so, then identity-priming may exacerbate dissatisfaction following a negative experience. However, Oyserman (2009) proposes an opposite effect suggesting when products are identity-congruent they are preferred despite negative performance: "once a product is identity-congruent, it becomes what 'we' use, separate from utilitarian concerns". Given these two opposing effects, no net effect of identity on satisfaction with a negative experience may emerge.

Hypothesis 1: *Identity-based marketing will moderate the impact of product experience on customer satisfaction such that a) customers will be more satisfied following a positive experience when the product primes identity (versus not); and b) dissatisfaction with a negative experience will not differ as a function of identity.*

In contrast to category schema and brand names which are cognitive cues that evoke specific product expectations, identity is a motivational cue. Thus, the impact of identity on satisfaction is posited to occur via performance perceptions rather than expectations. That is, identity-based thinking will lead consumers to perceive performance as more superior when positive. Inasmuch as negative experience is unambiguously inconsistent with identity, then no identity-driven 'bias' is expected to emerge for a negative experience.

Hypothesis 2: *Performance perceptions will mediate the effects of identity and experience on satisfaction.*

Because the positive experience hypothesis is primarily driven by the motivational element of using the identity-linked product, we expect this effect to manifest only when consumers feel comfortable expressing or using their identity-driven interpretation of product performance. Specifically, we expect the effect posited in H1a to be stronger when consumption is either private or in the company of others who share the same identity (versus others who do not share the identity or who are of unknown identity). That is, identity enhances satisfaction with positive experiences when the setting favors identity-expression; otherwise, identity effects will not emerge.

Hypothesis 3: *Identity effects on satisfaction with a positive experience will emerge when consumption is private or the audience shares the same identity (vs. unknown or different).*

Six experiments were conducted to investigate these hypotheses. Across all experiments, identity was primed (vs. not) via an advertisement. Participants were then asked to imagine themselves as a customer and reported expectations. Participants then experienced (either real or imagined) the product, and experience valence was manipulated (along with other factors germane to hypotheses). After experience, satisfaction and perceived product performance were measured.

Study 1 examined real experience. Analyses revealed a significant identity by experience interaction on customer satisfaction ($F (1, 68) = 4.94$, $p < .05$) such that identity increases satisfaction with a positive but not negative experience. Study 2 replicated this interaction for an imagined product experience ($F (1,159) = 6.2$, $p = .01$) and demonstrated mediation by perceived product performance. These results support H1 and H2.

Studies 3 and 4 test boundary conditions on the phenomenon. Specifically, the identity effect was enhanced i) for private (vs. public-identity unknown) consumption [($F (1,160) = 5.09$, $p < .05$] and ii) when the purchase decision was made by another (vs. self) [($F (1, 52) = 9.80$, $p < .01$]. Finally, studies 5 and 6 test generalizability of our findings to i) another identity and to ii) service recovery (vs. a negative experience). (Details omitted for brevity's sake.) These results support H1—H3.

Together, these findings make four contributions. First, prior research has tended to investigate identity effects on judgment and choice and has not, to our knowledge, examined identity effects on satisfaction. We find that identity effects emerge for positive experience but do not emerge for negative experience—suggesting an important constraint on the 'power' of identity posited in prior research.

Second, our results point to mediation by performance perceptions. That is, identity-based thinking influences satisfaction through motivated interpretation of the experience (versus expectations). Third, our research identifies a boundary condition for the positive effects of identity on satisfaction: private or public consumption in which identity-expression is not constrained. Finally, these findings contribute to the satisfaction literature by investigating the role of identity in consumption and as a driver of customer satisfaction.

Cultures of Caring Consumption: Social Support and the Self in the Myeloma Community

Susan Dunnett, University of Edinburgh Business School, UK
Paul Hewer, University of Strathclyde, UK
Douglas Brownlie, University of Stirling, UK

EXTENDED ABSTRACT

"You just don't get the pros and cons and things with your doctor, you don't understand treatment options, what's coming down the pipe… I was at one of the support group meetings and we were just going around the room talking about things and [the group leader] mentions "XXX is thinking about [getting] a transplant". So they kinda went around the room, and as you know in these groups um, it's just a great big pot of everything you can think of, every combination of something that people have gone through… So that group is real important. I come back with stuff from the group that I bring to my doctor: "Why aren't we looking at this or that? When are we going to be testing for this? You know, what's the future treatment plan?" (Interview Data).

This study explores the ways in which the collective practices of consumption community formation and sustainment can be understood as a *technology* (Foucault, 1988) employed in the *caring for oneself* (Foucault, 1986). Taking inspiration from studies which have broadened out the domain of consumer research to include diverse groups living with serious illness (Adelman 1993; Kates, 2002; Pavia and Mason, 2004; Wong and King, 2008), the context for this investigation is the U.S. Myeloma community[1]. Through a phenomenological approach, utilising non-participant observation and depth interviews (Thompson et al., 1989; Turner and Wainwright, 2003; Forss et al 2004), attention is drawn to the importance of collective practices which emerge from community-based, patient-led support groups; particularly a network of 3 patient-led, community-based support groups in the Mid-west, accessed through a group leader who acted as gatekeeper. A period of contextualisation, drawing on informal interviews with community members and community-produced secondary data, was followed by non-participant observation at support group meetings over a period of 4 months. Subsequently 20 face-to-face depth interviews were carried out with 15 Myeloma patients and their spouses or family members - "carers", as they are known.

We employ a consumer research lens (Lupton, 1997; Henwood et al, 2003; Kates, 2002; Pavia and Mason, 2004; Wong and King, 2007), to explore the co-creation of social resources within such groups. As our interview data reveals (see above), the support groups are discursively positioned as receptacles of first-hand market information, with much of the narrative exchange within the group being concerned with navigating and (re)calibrating one's relationship with the healthcare, pharmaceutical and health insurance industries. Crucially this culture of information-exchange fosters a sense of belonging through the care for oneself and others. Or, as Foucault would have preferred: "The care of the self – or the attention one devotes to the care that others should take of themselves – appears then as an intensification of social relations." (Foucault, 1986: 53). The support groups operate as consumption communities where culturally accepted self-care practices deemed necessary to 'living with myeloma', are shared amongst patients and their carers (Whelan 2007).

Through our analysis we reveal a range of collective practices which emerge from this 'intensification of social relations' (Foucault, 1986). Crucial amongst these are the sharing and mediating of information, helping, storytelling and the fostering of personal responsibility and obligation. Such practices serve to sustain, replicate and energise the collective, but also to intensify the responsibilities of individual members through their participation. Carrying out the business of *identity work*[2], informants report being empowered with a sense of self-confidence and a new-found ability to negotiate various healthcare systems (Lo and Stacey 2008). The Myeloma community, through its cultivation of social and agentic practices, thus provides a space for members to 'forge new meanings and incorporate these meanings into changing self-conceptions' (Kates 2002: 636).

The medical marketplace is a realm where high-stakes decisions - concerning treatment, care, quality of life or insurance and other administrative matters - are made (Wong and King 2008; Botti et al 2009). We find that support groups function to provide patients with the emotional, social and knowledge resources to carry out complex decision making. Such is the focus on marketplace knowledge that we conceptualise support groups as a consumer-led solution to the dark side of consumer/patient empowerment – the burden of personal responsibility (Lupton 1997; Davies and Elliott 2006; Shankar et al 2006; Markus and Schwartz 2010). The study at hand is a demonstration not only of the ways in which community is (to use Foucault's term, 1988) a *technology* employed to develop the self and navigate the medical marketplace, but how a consumption collective – in its mutual disclosures, trust, shared hope, sense of belonging and other-centred ethos – can produce valuable emotional bonds and social resources. The extant literature has identified that consumption communities provide social support to members (Shouten and McAlexander 1995; Fournier and Lee 2009) but has been slow to explore this helping behaviour. By doing so, we answer Kozinets' (2002) call for consumption communities to be characterised as an 'ameliorative' to the effects of the marketplace (ibid: 34).

The study concludes that the robust and flexible culture of these support groups is crucial for understanding the transformation of the patient. The personal movement revealed is from a position of passivity, fear and objectification to one of *perceived* control, understanding and skilled navigation of the healthcare market. The resources constructed by such community-based support groups thus offer members access to and participation in a wealth of social practices for self-enhancement which transform the patient into an agent. Lupton noted (1997) that where the patient as consumer is examined, the privileged representation is that of 'dispassionate, thinking, calculating subject'; a depiction which draws heavily on models of consumer behaviour where consumers are seen as rational, economic decision-makers who benefit from sovereignty of choice.

---

1   Myeloma is an incurable, chronic form of bone marrow cancer. It is estimated that there are 75,000 – 100,000 myeloma patients at any one time in the USA, and upwards of 15,000 in the UK. Patients may have the disease for several years and it is characterised by periods of active disease and remission (Durie, 2003). Symptoms of this disease include pain, bone loss, anaemia and immune system suppression. Treatment is usually in the form of chemotherapy and/or stem cell transplantation.

2   Here we rely upon Schwalbe and Mason-Schrock: "anything people do, individually or collectively, to give meaning to themselves or others. Identity work is thus largely a matter of signifying, labelling, and defining. It also includes creation of the codes that enable self-signifying and the interpretation of others' signifying behavior." (1996: 115).

The archetypal counterpart to the consumerist patient is the passive or dependent patient, a model of unquestioning compliance (Lupton 1997). The study at hand unearths the lived experience beyond these simple conceptualisations; its contribution lies in the foregrounding of an under-researched aspect of communal consumption – the sharing of social support resources in order to realise agency within service interactions.

Everyday Objects of Desire:
Dimensions of Design Innovation and the Centrality of Product Aesthetics

Harold Cassab, University of Auckland, New Zealand
Claudiu Dimofte, San Diego State University, USA

EXTENDED ABSTRACT

It is commonly accepted that response to design novelty is influenced by perceptual fluency, either directly via affective evaluation of visual stimuli (cf. Winkielman et al. 2006), or indirectly via increased satisfaction generated by resolving a moderate challenge in stimulus evaluation (Reber, Schwarz, and Winkielman 2004). In addition, expertise facilitates the identification of sources of novelty and the efficient processing of product information (Alba and Hutchinson 1987). The link between novelty and consumer attitudes, however, is not entirely determined by perceptual fluency. Central to the response to design innovation are individuals' inferences about what the product affords (Hoegg and Alba 2011) and the importance of novelty in general for the user.

We propose that consumer preference for high versus low product novelty is jointly explained by the level of aesthetic infusion and its congruency with the perceived core value of the product (i.e., hedonic or utilitarian benefits). Yet previous research is ambivalent about the direction of the congruency effect. It is possible that products featuring high levels of design innovation will garner more favor if consumers find the aesthetic infusion congruent with the hedonic value they derive from the product (cf. Creusen and Schoormans 2005). In other words, hedonic products provide aesthetic design as a typical benefit, and presumably more thereof enhances the offer. However, it is also possible that design infusion into incongruent, utilitarian categories creates an unexpected consumer benefit through spillover inferences and thus more design innovation preference (cf. Hagtvedt and Patrick 2008). In other words, utilitarian products do not provide aesthetic design as a typical benefit, and presumably its additional inclusion enhances the offer. Research by Bertini, Ofek, and Ariely (2009) is informative and suggests that "non-alignable innovations" (i.e., utilitarian products featuring improvements in form and hedonic products with functional improvements) will garner more consumer preference. Thus, we posit that *consumer preference will be stronger for hedonic (utilitarian) products featuring innovation in function (form)*.

Differences in consumer response to innovative products are also related to individual traits such as need for uniqueness, variety seeking, or design sensitivity (Bloch 1995). The latter has been captured in consumer research via the *centrality of visual product aesthetics* (CVPA) construct (Bloch, Brunel, and Arnold 2003). Yet consumers generally find it hard to articulate the reasons why they prefer specific designs (Creusen and Schoormans 2005), and a much consumer research (e.g., Chartrand 2005) has been arguing for the role of automaticity in information processing and decision-making. In further support for the importance of automatic cognition, there may also be a disconnect between consumers' explicit responses and nonconscious reactions to innovation (see Wilson, Lindsey, and Schooler 2000). Thus, individuals may [claim to] like novel designs more in their explicit evaluations than their automatic responses would suggest, perhaps in order to appear more sophisticated. Conversely, they may erroneously argue that product innovativeness is not an important factor in their product assessments, when that is in fact very much the case (perhaps because they see themselves as reflective and not impulsive processors, cf. Strack, Werth, and Deutsch 2006). We examine the role that consumers' innate automatic preference for innovation plays in explaining CVPA effects on innovative product evaluations. We thus hypothesize that *automatic reactions to novelty mediate the effect of CVPA on consumer attitudinal response to innovative new products*.

STUDY 1

The first study assesses the extent to which there are different marketplace reactions to innovation based on two specific dimensions of design innovativeness (i.e., focus on function or form). In addressing H1, we evaluate the conditions under which design innovation in form is more or less likely to be attractive relative to functional innovation. We also evaluate the extent to which complementary improvements are better received by consumers faced with innovative products. Participants were randomly exposed to the picture of a purportedly new, innovative product and subsequently asked their opinions about it. Two product categories were employed: one pretested to be utilitarian (toothbrushes) and one hedonic (sunglasses). The design was a 2 (product value: utilitarian or hedonic) X 2 (dimension of innovativeness: functionality or aesthetics) X 2 (CVPA: low or high) factorial with the first two variables manipulated and the latter measured. The results (see Table 1) argue for a basic consumer preference for innovation in function for hedonic products and in form for utilitarian products. Innovative products are preferred more strongly by consumers high on CVPA. These consumers seem to universally prefer functional enhancements, whereas those low on CVPA seem to react more positively to nonalignable enhancements to both product types.

STUDY 2

This study evaluates the hypothesis that consumer attitudinal responses toward innovative products are generally spontaneous and automatic (see Veryzer 1999 for a related point). This argument suggests that the effect of CVPA is fully mediated by automatic, implicit responses to novelty. Results support the claim that consumers of high CVPA are more likely to appreciate innovative marketplace products. Their explicit liking for such products is based on an automatic, instinctive attraction to innovation and novelty (measured via the Implicit Association Test – Greenwald, McGhee, and Schwartz 1998), explaining why they like innovation in terms of both design and function, as well as for both utilitarian and hedonic products. The implicit appreciation of innovative designs explains the connection between CVPA and explicit attitudes.

STUDY 3

The final study assesses the effect of dimension of design innovativeness (i.e., function or form) for a more complex product category that is not disposable and thus entails more risk and requires more careful processing. We therefore extend the generalizability of our conceptual framework and also improve on the previous studies in two important ways. First, we evaluate the extent to which innovation enhances perceived value by including a control (i.e., no innovation condition) as the critical benchmark. Second, we replicate the automatic mediation effect of study 2 by having subjects perform IATs that involve actual product pictures as stimuli, as opposed to generic innovation-related words. Results are once again supportive of both hypotheses (see Table 2).

Table 1: Product Attitudes In Study 1

Product Value:	Utilitarian				Hedonic			
Improved:	Function		Form		Function		Form	
	Mean	S.E.	Mean	S.E.	Mean	S.E.	Mean	S.E.
Low CVPA Attitudes	3.50	.41	4.14[a]	.19	3.67	.30	3.07[b]	.23
High CVPA Attitudes	4.76	.28	4.42[a]	.28	5.23[b]	.27	3.75[c]	.29

Means within *the same* row with different *superscripts are significantly different* at *p* < .05 or lower.

Table 2: Product Attitudes In Study 3

Improved:	Nothing		Function		Form	
	Mean	S.E.	Mean	S.E.	Mean	S.E.
Low CVPA Attitudes	3.40[a]	.29	4.32[b]	.21	4.99[c]	.19
High CVPA Attitudes	2.79[a]	.20	4.95[b]	.23	5.41[b]	.18

Means within *the same* row with different *superscripts are significantly different* at *p* < .05 or lower.

Inter-Racial Couples, Household Decision-Making and Contextual Influences on Consumer Acculturation

Wakiuru Wamwara-Mbugua, Wright State University, USA

EXTENDED ABSTRACT

This research examines household decision-making among inter-racial couples where one or both of the partners is an immigrant. Spousal decision-making is a culturally situated phenomena (Webster 2000) and it is increasingly clear that household decision making models developed for western "deciders" are inadequate when the "deciders" are non-western. (cf. Webster 2000; Wamwara-Mbugua 2007). Additionally, contextual influences (Schwartz et al. 2010) on immigrant acculturation highlight the need for research on spousal decision-making in non-western cultural contexts. Gendered patterns of behavior are extremely important in household decision-making. Qualls (1987) noted the impact of sex role orientation in household decision-making, while Webster (1994) highlighted the general consensus by researchers of the traditional role specialization in decision-making. For example, males were found to be dominant in decisions such as automobile purchase (Green et. al 1983), insurance (Davis and Rigaux 1974), while female dominant decisions included appliances (Green et al. 1983); groceries (Davis and Rigaux 1974) and washing machines (Woodside and Motes 1979). The female dominant decisions have been associated with the women's role as homemakers.

Prior research (Green et. al 1983) suggested that as nations become developed, that household decision-making becomes less-husband dominant. However, in the case of grocery shopping (a predominantly female preserve), a country's increased development should result in increased husband involvement in grocery shopping. In a study of Singaporean husbands, Piron (2002) found that husbands had lower levels of involvement with grocery shopping and that the wives were the principal deciders. This was attributed to Asian males and families being more traditional and less open to modern behaviors than their western counterparts (Piron 2002). Ethnicity has been found to be an important influencer of decision-making (Maldonaldo and Tansuhaj 1999; Webster 1994). Immigration presents immigrants with numerous decision-making opportunities and Berry (1980) has suggested that the immigrant experience is influenced by whether the immigrant wants to retain his/her culture of origin or whether s/he desires to have positive relations with the host culture. Answers to this yes/no questions results in a typology with four outcomes: integration, separation, marginalization and assimilation: with integration being the best strategy for immigrants' mental health. Food is central to our identity and oftentimes displays our cultural heritage. Consequently, food consumption and acquisition is an excellent area in which to investigate immigrant household decision-making processes among inter-racial couples in a non-western context.

Method: The data for this study is drawn from a larger study of thirty-three immigrants. Twenty one of these immigrants were married and eleven individuals were in interracial marriages. Research informants were recruited using the snowball method. The informants are from many different regions of the world, namely: Europe, North and South America, Africa, Asia, Australia and the Middle East. Consistent with research practices in Kenya, a government research permit was obtained before the research commenced. All interviews were conducted in English, in Nairobi, Kenya. Informants were assured of confidentiality and anonymity. The interviews were audio-taped, transcribed and analyzed by means of coding patterns and the constant comparative method (Glazer and Strauss 1967).

Findings: In most cultures, women have primarily been responsible for food acquisition and preparation. Therefore, it would likely follow that since the women were doing most of the food preparation that they would have a strong influence on the type of food consumed within the home. Nonetheless, in our research we found that with one exception, all food consumption and acquisition decisions were husband dominant. Berry (1980) suggested that for the best mental health that immigrants should integrate aspects of their own culture with that of their host culture. In this case we see an integration of the dominant culture in Kenya by making this decision husband dominant. In general, in Kenya, (a patriarchal society) women are overly concerned with ensuring that their husbands' food needs are met.

Six out of the ten informants were married to Kenyan men; two respondents were married to Kenyan women and three were in inter-racial-inter-country marriages while eleven were in same-race-same-country marriages. With one exception, informants ate food aligned with the husband's culture and more often than not completely ignored the "food culture" of the woman. The women adjusted and learned how to consume the food associated with the husbands' cultures while the men in general did not learn how to eat or appreciate the food associated with the women's cultures. One explanation for the observed findings is that the immigrants have integrated the "male dominance" culture evident in Kenya. Although a country's level of development has been shown to be correlated with increased wife dominance in decision-making, our research suggests that the reverse can happen. We find that when individuals from highly developed countries immigrate to a less developed country, they begin to adopt the behaviors and attitudes of those around them. Another possible explanation for the "husband dominance" in food consumption can be attributed to the availability of cheap labor. In Kenya, most middle-class families have "live-in house-help. Consequently, in spousal dyads where the husband was Kenyan, then the "cook/maid" would prepare the local foods. In instances where the husband was non-Kenyan, then the couples hired and trained a maid to cook the non-Kenyan foods. Nonetheless, the preferred non-Kenyan food was aligned with the husband's culture.

Conclusion: This research highlights some important issues: a) the development of a nation can indeed influence gendered patterns of decision-making. While researchers have demonstrated the movement of decisions towards less husband dominance as the nations develop, we demonstrate that when immigrants from more developed countries immigrate to less developed countries, their decision making patterns may return to more husband dominant decision-making. We attribute the return to husband dominance to the following: a) the integration of dominant culture's values and decision making patterns; b) the existence of cheap labor in these countries may mitigate these decisions and may facilitate the dominance of one decision-making pattern over another. Additionally, this research highlights the need to engage in research outside of western cultural contexts particularly with non-western deciders.

Something to Chew on:
Mastication based on Food Haptics and its Impact on Calorie Estimation

Dipayan Biswas, University of South Florida, USA
Courtney Szocs, University of South Florida, USA
Aradhna Krishna, University of Michigan, USA
Donald Lehmann, Columbia University, USA

EXTENDED ABSTRACT

Can haptics influence calorie perceptions? We focus on haptic properties of food and suggest that since food haptics directly impact mastication (chewing), they can also impact calorie estimation. Higher mastication (based on rougher versus smoother and harder versus softer foods) is proposed and demonstrated to reduce calorie estimation. Focusing on calorie estimation is relevant given rising obesity and need for healthy eating (Chandon and Wansink 2011). While emerging work on haptics has examined other factors (Peck and Wiggins 2006), hardness and texture properties of objects remain uninvestigated within the consumer behavior literature.

FOOD TEXTURE, MASTICATION, AND ASSOCIATIVE LEARNING

Typically, high-calorie/high-fat foods like butter, cream, and cheese, tend to have smooth, soft, and/or creamy textures. In contrast, lower calorie foods like raw vegetables, crackers, and cereals, tend to be rougher and harder. We propose that repeated exposure to this pattern of experience whereby unhealthier (healthier) food items tend to be smooth (rough) or soft (hard) results in learned associations between the haptic properties of the food and the level of healthiness of the food. Research in the domain of associative learning theories suggests that the co-occurrence of two stimuli results in the formation of an associative link (Van Osselaer and Alba 2000). When the two stimuli are repeatedly juxtaposed, the link strengthens, and over time can become a predictive rule that consumers apply to other stimuli or new contexts (McSweeney and Bierly 1984). Hence, we hypothesize:

Hypothesis 1: *The Food Haptics – Perceived Calorie Effect, whereby consumers will perceive foods with soft (vs. hard) or smooth (vs. rough) textures as being higher in calories.*

When consuming food under high cognitive load, consumers pay less attention to all the senses (Elder and Krishna 2010). As such,

Hypothesis 2: *With less attention paid to eating (e.g., greater time pressure), the food haptics-perceived calories effect is attenuated.*

BMI AND CALORIE PERCEPTION

Prior research suggests that BMI is an important factor in food choices and influences consumers' perceptions of foods (Irmak et al. 2011). Studies show that consumers with high BMIs are more sensitive to the hedonic properties of foods (Chandon and Wansink 2011), and more likely to inaccurately estimate nutritional properties of foods (Carels et al. 2006). Consistent with this, studies also suggest that consumers with high BMIs focus less attention on high calorie foods (Graham et al. 2011) and are less sensitive to the attributes of unhealthy foods because they consume these foods frequently (Stewart et al. 2010). Hence, the learned associations between food haptics and calories are less likely to form for high BMI consumers. In fact,

the desire to eat high calorie foods may even reverse this associative learning if it does occur. We propose:

Hypothesis 3: *BMI will moderate the food haptics-perceived calorie effect so that the "higher mastication-lower calorie" perception will be reversed for higher BMIs.*

STUDIES

We tested our hypotheses in three experiments. Study 1 had two manipulated conditions (carrot texture: rough vs. smooth). Consistent with H1, participants rated the smooth (vs. rough) textured carrots as higher in calories. Taste perception measures revealed similar values across both conditions, ruling out perceived taste as the underlying process for perceived unhealthiness (Raghunathan et al. 2006).

Study 2 tested H2 with a 2 (hard vs. soft chocolates) X 2 (time pressure: low vs. high) between subjects design experiment. We manipulated time pressure based on prior studies (Siemer and Reisenzein 1998). The results support H2; under low time pressure, calorie estimation was higher for the soft (vs. hard) chocolate but the effects got attenuated under high time pressure.

Finally, a field experiment at a restaurant (Study 3) tested H3, with a 2 (hard vs. soft cookies) X 2 (BMI: normal weight vs. overweight) between subjects design. BMI was manipulated as in previous studies (Chandon and Wansink 2007). Consistent with H3, calorie perception was higher (lower) for the soft (vs. hard) cookie for normal weight (overweight) participants.

Collectively, the results of the three experiments reveal interesting theoretical and practical insights regarding the effects of mastication and food haptics on calorie estimations.

Lies, Damned Lies, and Statistics:
Risk Reduction Framing and the Power of Prominent Brands

Robert Madrigal, University of Oregon, USA
Catherine Armstrong Soule, University of Oregon, USA
Leslie Koppenhafer, University of Oregon, USA

EXTENDED ABSTRACT

Would you be more persuaded to purchase a medication that advertises a 50% reduction in your risk of suffering a side effect or one that advertises a reduced risk from 2 (i.e., starting risk) to 1 (i.e., modified risk) case per 100,000? The former represents a conditional probability referred to as a relative risk reduction, whereas the latter is a natural frequency called an absolute risk reduction. Both estimates are correct, as the 1 per 100,000 is an absolute difference that represents a 50% reduction in risk. The two presentations differ in how they are framed.

Understanding how consumers process risk perceptions matters not only from a managerial perspective because it is necessary for good decision-making, it also matters because it provides theoretical insights that have implications for consumer welfare and public policy (Menon, Raghubir, and Agrawal 2008). Despite how helpful statistical information might be, consumers are often unable to discern the meaning of such information. This is especially problematic when information is presented in a way that at best doesn't tell the whole story and, at worst, is deceptive (Boush, Friestad, and Wright 2009).

Research has shown that a relative frame is more persuasive because it has a larger magnitude than its corresponding absolute frame (Gigerenzer 2002). It is therefore not surprising that marketers frequently use relative framing in product claims. Yet, without baseline information that allows for its calculation, a relative frame offers little diagnostic insight. Unfortunately, consumers often suspend their natural skepticism and do not counter-argue when presented with a statistic because of its apparent precision. Instead, consumers trust the presumed authority of the source (Sowey 2003).

Our research considers the moderating effect of brand prominence on responses to risk reduction framing. A brand's prominence may be derived from factors such as market share, brand awareness, visibility, and share of voice. Research has shown that consumers make numerous inferences based on market prominence (Johar and Pham 1999; Kirmani 1990; Kirmani and Wright 1989; Pham and Johar 2001). Prominent brands represent knowledge structures that function as judgmental heuristics. Such structures contain learned associations linking the brand to product quality and therefore provide the basis for a judgment without the need for extensive processing of specific attribute information (Maheswaran, Mackie, and Chaiken 1992).

Four studies are reported that test eight hypotheses. Study 1 finds that consumers prefer options framed in relative (vs. absolute) terms. Study 2 results speak to the heuristic power of brand prominence. For both actual and generic brands, prominence superseded risk framing in that no framing effect was found when the new product was associated with a prominent brand. However, given a non-prominent brand, consumers used risk framing as a basis for forming new product performance expectations and likelihood of recommending. Also, the direct effect of prominence on judgments was mediated by brand trust. Moreover, after accounting for prominence, trust moderated the effect of framing for an actual brand. Risk framing had no effect when trust was high. When trust was low, however, relative (vs. absolute) framing elicited higher expectations and greater likelihood of recommending.

Hypothesis 1: A product option framing risk reduction in relative (vs. absolute) terms will be preferred regardless of whether baseline information is presented.

Hypothesis 2: A new product claim framing risk reduction in relative (vs. absolute) terms will elicit (a) increased performance expectations, (b) greater consumer understanding, and (c) less purchase anxiety.

Hypothesis 3: An ordinal interaction is expected such that (a) product expectations and (b) recommendation likelihood will be reduced in response to a new product claim by a less prominent brand that uses absolute framing compared to a less prominent brand using relative framing or a more prominent brand that uses either absolute or relative framing.

Hypothesis 4: Brand trust will mediate the direct effect of brand prominence on (a) performance expectations and (b) recommendation likelihood.

Hypothesis 5: A new product claim framed in relative (vs. absolute) terms will elicit greater (a) performance expectations and (b) recommendation likelihood when brand trust is low. No such difference is expected when brand trust is high.

Hypothesis 6: In contrast to the lack of a risk framing effect on new product expectations for a prominent brand found in study 2 (see H3a), a risk framing main effect is expected such that an absolute (vs. relative) frame will elicit lower product expectations for a prominent brand when numeric information is presented graphically.

Hypothesis 7: Given a text only presentation, low numerates' performance expectations will be greater when (a) the new product claim is presented in relative (vs. absolute) terms, and (b) brand trust is high (vs. low). No such differences are expected for high numerates.

Hypothesis 8: Compared to those receiving instruction only about how absolute and relative risk reductions are calculated, respondents who receive additional instruction as to marketers' intent will perceive greater deception following exposure to a marketing claim that uses a relative risk reduction frame.

A boundary condition of presentation vividness was investigated in study 3. We found that brand prominence was ignored in favor of relative (vs. absolute) framing when risk information was

presented graphically. In contrast, study 2 results were replicated when the same information was presented textually. Also explored was the individual difference variable of numeracy (Peters et al. 2006). Study 3 indicates that respondents – especially low numerates – place greater emphasis on brand prominence than risk framing when information is presented textually. However, given a graphical presentation, a brand's prominence is ignored in favor of how the risk reduction is framed.

Our final study explores whether consumers view the use of relative framing to be deceptive. Even though a relative frame with no baseline information provides no diagnostic insight, consumers may simply expect marketers to present their products in the best possible light. However, the use of relative framing is in fact an attempt to mislead because it deliberately omits important information that may have otherwise affected the consumer's decision and is therefore deceptive (Boush et al. 2009).

In order to understand the stimulus, respondents were told they must first read a passage that explained how baseline information is used to calculate absolute and relative risk reductions. In the "absolute frame only" condition, respondents were then shown the starting and modified risks used to calculate the relative risk reduction included in the stimulus. The same information was given to the "absolute frame plus instruction" condition, but they were also told that marketers use relative (vs. absolute) framing because the number appears larger. No mention was made as to the ethics of the tactic. All respondents were then presented with a product claim using a relative frame with no baseline information. No differences were found for performance expectations ($p = .91$) or recommendation likelihood ($p = .18$). However, those receiving additional instruction found the tactic more deceptive than did those who did not ($p < .02$).

In sum, direct-to-consumer advertising for products designed to reduce risk relies on consumers' ability to understand statistical information. Yet, our results suggest that consumers instead rely on heuristics when forming judgments. If faced with just a risk reduction ratio in a new product claim, consumers make their assessment on the basis of a relative frame, even though it is of little diagnostic value. In contrast, risk framing is ignored altogether when the new product is introduced by a prominent brand. This effect is obviated when risk reduction is communicated graphically. Finally, consumers do not view the use of a relative frame to be misleading even if they are aware of how it is calculated. Its use is viewed as deceptive only after they learn marketers' intent for using the tactic.

Will Power Lead to Variety Seeking in Sexually Related Consumer Choices?

Duo Jiang, University of Illinois at Urbana-Champaign, USA
Sharon Shavitt, University of Illinois at Urbana-Champaign, USA

EXTENDED ABSTRACT

People who have power have often been observed (or caught) seeking sexual variety (e.g. President Bill Clinton, Italian Prime Minister Silvio Berlusconi). Indeed, power and sex are closely linked (Buss 1994). For example, people with power are evaluated as sexier (Martin 2005), males primed with power-related stimuli evaluate opposite-sex subordinates as more sexually attractive (Bargh, Raymond, Pryor, and Strack 1995), and having power over an opposite sex person activates sexual concepts that persist over time, indicating the activation of a mating goal (Kunstman and Maner 2010).

How will this link between power and sex impact choices in the consumption domain? We explore how feelings of power (powerfulness or powerlessness) affect variety seeking for consumer choices that are sexually relevant -- i.e., choices involving cues that could activate sexual or mating goals (Dahl, Sengupta, and Vohs 2009; Janssens, et al. 2011; Lin 1998). We predict that either powerfulness or powerlessness could shift attention towards sexual cues, but because powerful people expect access to a variety of mates, powerless people may engage in compensatory efforts in the consumption arena. Specifically, they may seek variety in daily product choices that are sex-relevant. In three studies, we examine how feelings of [not] having power influence consumer variety seeking and consistently find that people feeling low in power (LP) versus high in power (HP) preferred more variety, but only for choices that were sex-relevant.

Power feelings were primed using the same episodic recall task in all studies (Galinsky, Gruenfeld & Magee 2003). In Study 1, after recalling a past experience of either being powerful ($n = 23$) or powerless ($n = 24$), participants chose between magazines with either a single model or multiple models pictured on the cover. Each participant made binary choices for eight pairs of magazines among which four pairs had attractive human models on the cover (sex-relevant condition: female or male pop stars) and four pairs had attractive non-human models (sex-irrelevant condition: animals, buildings). The dependent measure of variety seeking was the total number of times one chose the magazine with multiple models, with a separate index (from 0 to 4) for human-model and non-human-model magazines. Results showed that LPs chose multiple models more often for the human-model magazines ($M = 1.83$, $SD = 1.20$) than HPs did ($M = 1.17$, $SD = 1.11$), $F (1, 45) = 3.79$, $p <.06$, but did not differ in variety seeking for non-human-model magazines (LP: $M = 2.00$, $SD = 1.10$; HP: $M = 2.39$, $SD = 1.37$). $F (1, 45) = 1.16$, N.S. Hence, Study 1 suggests that when choices were potentially sexually relevant, LPs compared to HPs chose a greater variety (of cover models), whereas this pattern disappeared when choices were presumably not sexually related. Results for a separate no-power prime group (n = 24) fell between LP and HP results, though not significantly different from either.

Because the magazine covers in this study may not necessarily have activated sexually relevant thoughts, we addressed sex relevance directly in Study 2 by framing the same product choice as either relevant or irrelevant to dating. After recalling a powerful ($n = 50$) or powerless ($n = 48$) experience, participants imagined themselves in a scenario in which they ordered dessert for either a party or reception they are hosting. The event was described either as a party in which they might meet attractive people to date (sex-relevant) or as a reception in which they might meet recent grads who could offer internship opportunities (sex-irrelevant). Participants ordered 12 desserts out of five different options (cakes, pies) to serve at this event. When the choice was framed as sex-relevant, LP participants ordered more types of desserts ($M = 3.54$, $SD = 1.06$) than did HP participants ($M = 2.73$, $SD = 0.83$), $F (1, 94) = 7.08$, $p <.05$. However, when the choice was framed as sex-irrelevant, LPs and HPs ordered a similar amount of variety (LP: $M = 2.96$, $SD = 1.20$; HP: $M = 3.04$, $SD = 1.20$), $F (1, 94) = .07$, N.S. Thus, consistent with the prior study, when the choice was sexually relevant, powerless versus powerful people chose more variety, but when the choice was not sexually relevant, this difference disappeared.

Next, we addressed whether the effects were due to LPs engaging in enhanced variety seeking or to HPs being less interested in variety compared to baseline feelings of power. In Study 3, after recalling a powerless ($n = 37$), powerful ($n = 40$), or neutral experience ($n = 42$), participants were asked to customize a box of Godiva chocolates as a birthday gift either for their significant other (sex-relevant) or their important co-worker (sex-irrelevant). As before, when the gift was for a significant other (sex-relevant), LPs chose more kinds of chocolates ($M = 6.41$, $SD= 1.73$) than HPs ($M = 4.59$, $SD = 1.44$) or controls did ($M = 4.68$, $SD = 1.46$), $F (2, 113) = 6.13$, $p <.05$. Post-hoc results showed that LPs significantly differed from HPs, $F (1, 113) = 12.066$, $p <.05$, and controls, $F (1, 113) = 9.312$, $p < .05$, but HPs did not differ from controls, N.S. However, when the gift was for an important co-worker (sex-irrelevant), LPs did not differ from HPs and controls (LP: $M = 6.35$, $SD = 2.06$; HP: $M = 6.44$, $SD = 1.65$; Control: $M = 6.26$, $SD = 2.07$), $F (2, 113) = .05$, N.S. The same pattern emerged in a separate replication study (N = 89) in which people made a binary choice between a high-variety and low-variety box of chocolates. Thus, in addition to replicating Study 1 and 2, Study 3 revealed that when choices were sex-related, feeling powerless led to choosing more variety than would normally occur.

In sum, across three studies, LPs chose more variety than HPs and control people did when choices were sex-relevant, but not when they were sex-irrelevant. This was observed across a number of products and ways of manipulating sex-relevance such as magazines with attractive human models (Study 1), foods to serve possible dating partners (Study 2), and gifts for a long-term significant other (Study 3). The findings suggest that compared with high power people who might have ready access to a variety of real mates, low power people have to settle for variety in their chocolates and magazines.

Influenced by the Context: The Role of Thinking Systems in the Use of Contextual Cues

Ryan Rahinel, University of Minnesota, USA
Rohini Ahluwalia, University of Minnesota, USA

EXTENDED ABSTRACT

Consumer decisions are often influenced by the context within which they are made. For example, exposure to colors (Berger and Fitzsimons 2008), products (Lee and Labroo 2004), and brands (Ferraro et al., 2009) can systematically shift consumer choices. Although we know much about the contextual features that may influence choices, we know little about who is more likely to be influenced by which type of contextual cues. In this paper, we use Cognitive-Experiential Self-Theory (CEST) to understand how individual differences in thinking systems lead to decisions that are influenced by the decision context.

CEST (see Epstein 1994) suggests that humans have both a rational system and an experiential system. Whereas the rational system is slow, rule-based, contemplative, and deliberative, the experiential system is rapid, affect-based, action-oriented, and associative. Past work suggests that the two modes operate according to a dominance model, whereby one mode is likely to dominate thinking – typically the experiential system, unless the rational system is activated (temporally or chronically), in which case it tends to take over (Kahneman and Frederick 2005; Shiv and Fedorikhin 1999). This model implies that experiential and rational thinking are bipolar constructs, such that a higher activation of one system indicates a lower activation of the other. However, scale development studies by Pacini and Epstein (1999) found no relationship between the two thinking modes, suggesting that the two systems are independent. Therefore, contrary to the dominance model, we argue for a balance model which, in addition to the dominance cases where the activation of one system exceeds that of the other, also considers conditions of balanced thinking modes or simultaneous activation of both systems (either both relatively low or both relatively high). We posit that it is these latter two groups of individuals who tend to be more influenced by contextual cues.

The rationale for this prediction differs across the two balanced groups (i.e., low-lows and high-highs). Low-lows are likely to lack internally generated inputs for guiding a decision, given low activation of both the experiential and rational systems which account for the majority of decision inputs. Therefore, they are likely to turn to the decision context for cues. Conversely, high-highs, with two highly activated systems, are faced with the dilemma of choosing a system when faced with a decision, especially since the two systems often produce diverging outputs (Kirkpatrick and Epstein 1992). Therefore, compared to the dominant system groups, high-highs will also be more likely to turn to the decision context for cues. These differing rationales also allow us to predict the types of cues in the decision context that will influence their decisions. Low-lows, who do not have the cognitive resources for assessing the relevance of a cue, will be likely to turn to contextual cues that are highly accessible, for making their decisions. Conversely, high-highs, who have ample resources to assess the relevance of a cue, will be likely to focus on the most diagnostic contextual cues.

We tested these predictions in a series of studies. Across the studies, we measured experiential and rational system activation using the REI-40 (Pacini and Epstein 1999). In Study 1, we tested the basic prediction that low-lows and high-highs make decisions influenced by the contextual cues. We used the context of grocery shopping, where the items placed in the shopper's basket are likely to function as a contextual cue, making complementary products not only more accessible (Lee and Labroo 2004) but also more diagnostic (i.e., situation-appropriate), calling for increased purchase likelihood of complementary products for both these groups (as compared to their one-system dominant counterparts). Participants (n = 118) completed a simulated grocery shopping task in which they made a series of choices in the given product categories, subsequent to which they were asked to name three additional items they would buy on their shopping trip. The complementarity of these items to the target basket items was assessed. Regression analyses yielded the expected interaction and simple-slope analyses confirmed the prediction that low-lows and high-highs listed more complementary items than their dominant-system counterparts.

In the next two studies, we tested the predictions relating to differential cues and their underlying mechanism by manipulating the accessibility and diagnosticity of the contextual cues. Study 2 (n = 104) replicated Study 1 with one exception. The relative accessibility of the shopping basket was lowered, while keeping its diagnosticity high, by introducing an alternative high accessibility/low diagnosticity cue in the context (via a short story immediately after the product choices). The regression analyses revealed that, as expected, only the high-highs were influenced by the diagnostic contextual cue (shopping basket), demonstrating an increased level of complementary purchases. In Study 3 (n = 98), we took the opposite approach by using a contextual cue that operated on accessibility, but not diagnosticity, processes. We accomplish this by using a perceptual fluency paradigm adapted from Berger and Fitzsimons (2008). Participants completed a short questionnaire on product preferences using either a green or purple pen. They were then asked to choose two options in two different categories (candy and pop) of eight options each. There were two green options and two purple options in each category. We predicted that the pen color would make other similar-colored products more accessible and therefore chosen more often by low-lows, who rely on accessibility-based processes; however, such an effect would not emerge for high-highs. Our expectations were supported, with the low-lows choosing more color-consistent options than the other three groups.

These findings contribute to the consumer behavior literature in several ways. First, they enrich the theory of thinking systems by examining the decision making for low-lows and high-highs and demonstrating that these groups merit further attention and examination in the literature. Second, we identify consumer groups who are most likely to use contextual cues as inputs in their decision making. Finally, our findings distinguish between different types of contextual cues and demonstrate how their usage may differ based on individual differences in thinking systems. Future research can build on this work by investigating the implications of conceptualizing thinking systems and decision cues in these ways.

In The Mood for Special Experiences:
The Impact of Day-to-day Changes On Consumers

Jiska Eelen, University of Amsterdam, The Netherlands
Kobe Millet, VU University Amsterdam, The Netherlands
Luk Warlop, KU Leuven, Belgium and Norwegian Business School (BI), Norway and BI Norwegian Business School, Norway

EXTENDED ABSTRACT

When you find yourself in a novel situation, would you engage in novel consumption experiences, or would you prefer stable ground and stick to what you know? Empirical research has proved both ways for consumers who experienced large changes in life. Severe changes in people´s environment seem to enhance preference for familiarity. Oishi and colleagues (2012) studied residential mobility and showed that it led to anxiety and increased familiarity liking. However, it is also well-known that moderate levels of novelty lead to curiosity and exploration (Berlyne 1950). Consistent with this reasoning, Wood (2010) found that students who first moved to campus were more likely to be attracted to new or unfamiliar products. Therefore, different life changing events may lead to both familiarity-seeking (Oishi et al. 2012) and variety-seeking (Wood 2010). Nevertheless, literature is remarkably silent about the impact of day-to-day changes on consumer decisions. Therefore, the focus of the present project is on the impact of day-to-day changes on consumption.

Contrary to experiencing large changes in life, consumers frequently find themselves in unexpected situations. Hence we seek to find out how such novel environmental cues affect consumer behavior. We propose that subtle changes in the environment make people feel more special and choose more special consumption experiences, whereas more blatant changes in the environment make people choose comforting familiar consumption experiences. In five experimental studies we find that subtle unusual or novel circumstances (i.e., environmental changes, and unusual actions) boost unique consumption experiences, like the preference for scarce products and uncommon holiday destinations, and the willingness to try out new products. Moreover, we show that blatant changes in the environment reset familiarity-seeking. These studies are in line with priming literature documenting that subtle primes lead to assimilation effects, and blatant primes lead to contrast effects (Martin 1986). In particular, novelty gives rise to special and unique feelings. Subtle novelty leads participants to consumptions in line with primed feelings of uniqueness, whereas intrusive novelty leads consumers to choose familiar options. Alternative explanations driven by difficulty, mood regulation, increased self-awareness, lower self-confidence, and self-efficacy are discussed and ruled out.

OVERVIEW OF STUDIES

In five experimental studies we showed that subtle novel situations prime special consumption. Different manipulations and dependent variables were used to show the robustness of the effect. In four studies, subtle novelty was induced by having participants engage in a usual or unusual task (different tasks across studies), in one study the environment itself was changed. Whereas the first three studies focused on subtle novelty, and the process of priming feelings of uniqueness, the last two studies explicitly measured and manipulated subtle versus blatant novelty, and explored the differential impact on consumption.

In the first study, subtle task unusualness (i.e., right-handers performed a task with the right or left hand) affected novel consumption experience. We found that participants in a subtle unusual situation expressed a higher interest in trying out new products than participants in a usual situation. The second study showed that subtle task unusualness (similar task to study 1) increased the likelihood of choosing a scarce, and hence more unique, product for consumers with a low need for uniqueness to the level of those that were high in need for uniqueness showing a chronic interest in novel and special products (Tian, Bearden, and Hunter 2001). This suggests that novel circumstances prime the drive to be special. Indeed, study 3 provided evidence that participants in the unusual condition showed a momentary drive to feel unique in comparison with those in the usual condition (similar task to study 1).

In two additional studies we showed that only subtle but not blatant environmental changes led to special consumption experiences. In study 4, participants described their ideal holiday destination while being in a usual or unusual environment (i.e., seated on a common or uncommon ergonomic chair). We found that participants in the unusual situation described more unique holidays than participants in the usual situation. Importantly, within the unusual condition, those that found the unusual situation disturbing described more common holidays. This indicates that more intrusive novelty leads to increased familiarity-seeking. In study 5, we manipulated, rather than measured, the impact of subtle and blatant changes. Participants performed a choice task by means of the computer mouse (usual) or by touching the screen (unusual). As expected, we found that the task affected choice for uncommon holiday destinations. Only when novelty was subtle did participants choose more uncommon destinations. When novelty was made explicit at the start of the task, preferences were reset to common destinations, similar to the level of the usual condition. Interestingly, the impact of subtle novelty was mainly driven by participants who were not habituated to touch screens and experienced the situation as truly novel.

DISCUSSION

We studied the impact of temporary and subtle deviations from common experience on consumers, and found that these cues led to more special and novel consumption experiences. By breaking the daily grind, marketers can evoke feelings of uniqueness among consumers and make them more likely to enjoy temporary offers or try out new products. It is especially interesting that the unusual experience can be subtle and entirely unrelated to the consumer choices that follow. Our research suggests that day-to-day changes can be a powerful tool to change habitual behavior, unless novelty becomes too intrusive. Our results help interpreting the seemingly opposite findings for the impact of different life events on consumption (Oishi et al. 2012; Wood 2010), as they may have been more or less intrusive for consumers. Future research should investigate whether the phenomenon described relies on a concept prime (i.e., activation of novelty), a goal prime (i.e, be unique), or a mindset prime (i.e., explore the environment).

Self-Construal and the Identifiable Victim Effect

Tatiana M. Fajardo, University of Miami, USA
Jiao Zhang, University of Miami, USA

EXTENDED ABSTRACT

Past research has established that victims who arouse stronger affective reactions have a higher chance of being helped. In general, identifying a victim increases emotional arousal and consequently a donor's willingness to contribute. This phenomenon has become known as the identifiable victim effect (Jenni and Loewenstein 1997; Small and Loewenstein 2003; Kogut and Ritov 2005; Small, Loewenstein, and Slovic 2007). We examine how self-construal moderates the effect of victim identification. The concept of self-construal originates from research on cross-culture differences. According to Markus and Kitayama (1991), Western cultures construe the self as separate from their social context, emphasizing autonomy (i.e. an independent self-construal). Whereas, eastern cultures typically consider the self part of the broader social context (i.e. an interdependent self-construal). Research on self-construal suggests that although independents rely on their feelings in making decisions, interdependents may suppress their emotions (Markus and Kitayama 1991). Therefore, our central premise is that compared to individuals with an independent self-construal, individuals with an interdependent self-construal will not be motivated by victim identification. Furthermore, we propose that the moderating effect of self-construal will be mediated by individuals' feelings of empathy.

We tested our propositions in four studies. In Study 1, participants were recruited to participate in an unrelated study. Participants were informed they would receive $2 in exchange for their participation. At the end of this unrelated survey participants completed a self-construal manipulation; they were asked to read a paragraph describing a trip. In the independent self-construal condition, all pronouns referred to the singular *I, me,* or *my*. In the interdependent self-construal condition, pronouns referred to the plural *we, us,* or *our* (Brewer and Gardner, 1996). Following this manipulation, participants were told that they had completed their task and earned the $2. On this same screen, participants were told that the experimenters were collecting donations and presented a donation appeal featuring either a group of 100 unidentified children, one unidentified child, or one child identified by name, age, and picture. Participants were given the opportunity to donate a portion of their payment. A significant two-way interaction emerged. Participants in the independent self-construal condition donated a higher portion of their payment when presented one identified child than when presented either one unidentified children or 100 unidentified children. Participants in the interdependent self-construal condition donated a lower portion of their payment when presented one identified child than when presented one unidentified child. There was no difference in the amount these participants donated to 100 unidentified children and one identified child. These results provide support for our premise that the identifiable victim effect is stronger among independents than among interdependents.

In Study 2, participants were shown a product positioned to prime either an independent or interdependent self-construal (Aaker and Lee 2001). They were then informed that sales of the product would benefit a charity concerned with protecting endangered wildlife; descriptions randomly included or omitted the picture of an endangered animal. Participants were asked their willingness to pay for the product. A self-construal by victim identifiability two-way interaction emerged. When the product primed an independent self-construal inclusion of the picture increased participants' willingness

to pay. In contrast, when the product primed an interdependent self-construal inclusion of the picture did not increase participants' willingness to pay. The results of Study 2 indicate that the basic finding documented in Study 1 applies to cause-related marketing contexts and to animal victims as well as human victims.

In Study 3, we examined the mechanism underlying the impact of self-construal on the identifiable victim effect. We propose that self-construal moderates the effect of victim identification on individuals' willingness to donate by influencing the effect of victim identification on individuals' empathic feelings toward the victim. We tested this prediction by measuring participants' empathic feelings (empathetic concern and empathetic distress) and showing that they mediated the findings documented in Study 1. Several other potentially relevant factors (perceived closeness of the victim, sense of urgency, etc.) were measured but none of these additional measures could serve as a mediator.

Study 4 further examined the mechanism underlying the impact of self-construal on the identifiable victim effect by testing the moderating effect of cognitive load. Based on the previous research showing that individuals rely more on their affective reactions when under high cognitive load (Shiv and Fedorikhin 1999; Small and Verrochi 2009), we expected that the impact of self-construal on the identifiable victim effect would be weaker when individuals are under high load. Participants were randomly assigned to the eight conditions of a 2 x 2 x 2 design. The first factor was self-construal. The second factor was cognitive load. We adopted the manipulation used in Shiv and Fedorikhin (1999); immediately after the self-construal manipulation, participants were presented and asked to hold either a two-digit or a seven-digit number in their heads throughout the remainder of the study. The third factor was victim identifiability. Results revealed a significant three-way interaction effect between cognitive load, self-construal, and victim identification. When cognitive load was low, we see a similar pattern to what was shown in earlier studies. Under high cognitive load neither the independent self-construal nor the interdependent self-construal participants favored an identifiable victim.

The results of these experiments indicate that the positive effect of victim identification is seen only among those with an independent self-construal. As we have shown, victim identification can end up having a negative impact on interdependents. An implication of our research is that providing potential donors with a picture of a victim to try to appeal to their emotions and enhance donation intent is not always a good idea. Charitable organizations and companies engaging in cause-related marketing ought to consider the characteristics of their target consumers when deciding whether to provide vivid, personal information about the victims who need help.

When Empathic Managers Become Consumers: A Self-Referential Bias

Johannes Hattula, University of St. Gallen, Switzerland
Walter Herzog, WHU – Otto Beisheim School of Management, Germany
Darren W. Dahl, University of British Columbia, Canada
Sven Reinecke, University of St. Gallen, Switzerland

EXTENDED ABSTRACT

How do managers predict consumer preferences? Over the past decades, numerous studies on this topic have been published (e.g., Gershoff, Mukherjee, and Mukhopadhyay 2008; Hoch 1987, 1988; West 1996). In this line of research, it has been argued that cognitive empathy, defined as the mental process of putting oneself into the shoes of consumers to understand their needs, supports managers in their construal of consumer preferences (Dahl, Chattopadhyay, and Gorn 1999). The present research, however, reveals an adverse effect of cognitive empathy in this context. Our findings suggest that cognitive empathy makes salient managers' personal consumption preferences, thereby biasing their prediction of consumer preferences.

THEORY

It seems reasonable to assume that managers have two identities: their professional identity as managers and their personal identity as consumers (Ashforth and Johnson 2001). In this research, we hypothesize that cognitive empathy increases the salience of a manager's consumer identity. Empathic managers put themselves into the shoes of consumers which means that they play the role of a consumer, imagine to act and feel as a consumer, and they simulate consumers' product and service experiences (Dahl et al. 1999; Stotland 1969). That is, empathic managers assume the mental processes of a consumer, which in turn is likely to activate the manager's consumer identity.

With an increasing salience of the manager's identity as a consumer, personal consumption preferences might become accessible (Zhang and Khare 2009), thereby influencing the manager's construal processes and decisions. Hence, we argue that cognitive empathy increases the impact of a manager's personal consumption preferences on predicted consumer preferences.

> Hypothesis: Cognitive empathy increases the influence of a manager's personal consumption preferences on predicted consumer preferences.

Note that in general, it is expected that empathic persons are able to abstract from their personal preferences (Decety and Jackson 2004; Preston and de Waal 2002). In this context, however, the opposite might be true. We test our hypothesis in two empirical studies.

STUDY 1

Ninety-three marketing managers (mean age: 41.44) were recruited to take part in a case study on a product development process in the automotive industry. Participants first indicated their personal preferences for car attributes by assigning importance weights to six product features. Specifically, they were asked to assign 100 points to the following car attributes: design, performance, dependability, comfort, sustainability, and prestige (Horsky and Nelson 1992). By using a constant sum scale, we explicitly capture trade-offs between the product features (Krosnick and Alwin 1988).

Subsequently, participants were asked to assume the role of a manager of a hypothetical car manufacturer and steer the development process of a new car model. They were then provided with recent market research data on consumer preferences for each product feature. Moreover, participants were asked to define the character of

the new model by assigning 100 points to the six product features. In particular, we asked participants to define the character of the new model in line with the preferences of a typical consumer in the market. Finally, we measured their degree of cognitive empathy during the case study (Davis 1980).

Assigned weights in the management task were then regressed on managers' personal importance weights, cognitive empathy, and the interaction of both variables. For each product feature, we find a positive effect of managers' personal importance weights and a positive interaction effect, supporting our hypothesis that cognitive empathy increases the influence of managers' personal consumption preferences on predicted consumer preferences.

STUDY 2

Since the findings of study 1 are based on self-selection into high/low empathy groups, we experimentally manipulated cognitive empathy in study 2. To enhance generalizability, study 2 is based on a case study on communications management.

For this study, we recruited 231 marketing managers (mean age: 45.31). In a first part, framed as a consumer study on personal identity and advertising effectiveness, participants watched two real ads of the luxury watch manufacturer Rolex and indicated their personal liking of each ad on an 11-point Likert-scale. In the second part, they were asked to assume the role of the head of marketing of Rolex. They were randomly assigned to either the "cognitive empathy" or "no cognitive empathy" condition. Participants in the cognitive empathy group were asked to describe a typical target consumer of Rolex, to imagine the target consumers' thoughts when watching the two ads, and to anticipate potential reactions to the ads. We assumed that participants had a clear impression of a prestige-oriented target consumer of Rolex (Puligadda, Ross, and Grewal 2012). Participants in the "no cognitive empathy" condition did not receive such instructions (Galinsky, Wang, and Ku 2008). Finally, participants estimated target consumers' evaluations of each ad on an 11-point scale. None of the participants was able to infer the true goal of the study.

The manipulation of cognitive empathy was successful (the cognitive empathy measures from study 1 were used as manipulation check). To test our hypothesis, we regressed predicted consumer evaluations on managers' personal liking scores, the cognitive empathy manipulation, and the interaction of both variables. For both ads, we find a positive effect of managers' personal liking scores and a positive interaction effect. Overall, study 2 replicates the findings of study 1 and supports the hypothesis that cognitive empathy increases the influence of managers' personal preferences on predicted consumer preferences.

CONCLUSIONS

This paper investigates an empathy-caused self-referential bias in managerial predictions of consumer preferences. The findings of two studies in distinct contexts and using different preference measures demonstrate that cognitive empathy increases the influence of managers' personal consumption preferences on predicted consumer preferences.

Our research makes a number of contributions. First, it extends previous research on managerial predictions of consumer prefer-

ences by showing the counterintuitive influence of cognitive empathy. Second, we introduce an identity-based perspective arguing that cognitive empathy increases the salience of a manager's consumer identity. Third, it underlines the importance of investigating managers' consumer identity and their personal consumption preferences.

How to Persuade 100,000 Friends? Understanding Blogs as One-to-One Mass Media

Soyean (Julia) Kim, Boston University, USA
Seema Pai, Boston University, USA
Frédéric F. Brunel, Boston University, USA
Barbara A. Bickart, Boston University, USA

EXTENDED ABSTRACT

Rumi: "It's a day of errands for me.. wearing vintage collar, Ralph Lauren blazer, Zara skirt, Céline bag, and Rag & Bone boots."

Comment: "I remember that blazer! It's super old, right? It's neat to see how it still fits into your style like 5 years later haha."

Comment: "You always look great when things get hectic. And I've told you before how well you wear Céline."

This posting by famous fashion blogger Rumi (fashiontoast. com) along with two of the many comments that she received on that day illustrates how Rumi has successfully created a communication environment where brands are discussed and celebrated but also one where friendships and intimate relationships might prevail. Although it is unlikely that Rumi has a meaningful relationship with each of her 133,672 readers, it is clear that many of them believe they have a relationship and close friendship with her. They relate to and connect with her at an interpersonal level, sharing slice of life stories, remembering past events, and engaging in brand level discussions. This level of closeness is rather counterintuitive especially if we consider that blogs are, by definition, a form of broadcast media in which a blogger shares his or her views with a large audience. In this paper, we examine how bloggers like Rumi develop different communication strategies that allow them to achieve specific objectives.

BLOGS AS ONE-TO-ONE MASS MEDIA

Blogs are "frequently updated web pages with a series of archived posts, typically in reverse-chronological order" (Nardi et al., 2004, p.1). Blog content can be provided by an individual writer or can be curated from a variety of sources (Blood 2002; Herring et al. 2005). In either case, blogs function as a mass communication medium in which content provided by a particular source is distributed to a large audience (Hoffman and Novak 1996). As such, we would expect blogs to function similarly to other mass media (Katz and Lazarsfeld 1955). We find, however, that the rules that govern one-to-many media do not apply to blogs and in fact, these rules are adjusted to create a personal and intimate relationship between bloggers and readers. Thus, drawing from persuasion theory and observation of a variety of blogs, we develop a theoretical framework that explains how blogs can be categorized based on audiences' perceptions and how bloggers use different strategies to shape or shift their audiences' perceptions and increase the persuasiveness of their messages.

Specifically, we propose a categorization scheme for blogs based on *the perceived target audience (mass versus one-to-one)* and *the perceived level of the blogger's commercial interest (explicit commercial interests versus no explicit commercial interests)*. Our proposed scheme provides insights to marketers looking to leverage social media marketing strategies as well as to bloggers attempting to maximize the persuasiveness and reach of their communication. Using this scheme, we categorize blogs into four types: *Commercial*, *Market Maven*, *Commercial Friendship*, and *Community-Based Friendship*.

BLOGGERS' COMMUNICATION STRATEGIES

Our qualitative research suggests that bloggers can implement two key communication strategies: (a) *illusion of relationship* and (b) *ambiguity in commercial interests* to shift their audiences' perceptions and thus make their messages more effective and persuasive. *Illusion of relationship* refers to a strategy that bloggers use to shift readers' perceptions of the blog away from a mass audience toward a one-to-one audience. The strategy creates a feeling of intimacy and personalized relationship between bloggers and their audience. *Ambiguity in commercial interests* refers to a strategy that bloggers use to deemphasize the presence of commercial interests. It disguises or hides the bloggers' commercial motives behind the communication.

By using the *illusion of relationship* strategy, bloggers can shift audiences' perception of their blogs from *Commercial* to *Commercial Friendship* and *Market Maven* to *Community-Based Friendship*. This perceptual shift from mass to one-to-one may create a feeling of intimacy, increase the level of trust, and enhance the quality of the blogger-audience relationship. As illustrated by our data, such a shift can be achieved through increases in: (i) the depth and breadth of self-disclosures (Cozby 1973; Derlega and Berg 1987; Jourard 1971), (ii) the frequency and duration of interactions (Altman and Taylor 1973; Delia and O'Keefe 1979; Little 1972; Werner 1957), and (iii) the perception of shared common interests (Morry 2005; Rose 1985; Weiss and Lowenthal 1975).

The use of the *ambiguity in commercial interests* strategy can shift audiences' perceptions of blogs from *Commercial* to *Market Maven* and *Commercial Friendship* to *Community-Based Friendship*. This perceptual shift from commercial to non-commercial creates a feeling of benevolence and care and increases audiences' trust towards the blogger, thus reducing the likelihood that persuasion knowledge is activated and that consumers invoke strategies to resist persuasive attempts. Because bloggers may want to avoid such resistance, they may try to hide or obfuscate their commercial interests. Ambiguity in commercial interests can be attained through: (i) hiding commercial interests (Boush, Friestad, and Rose 1994; Campbell and Kirmani 2000; Ford, Smith, and Swasy 1990; Friestad and Wright 1994, (ii) stressing benevolent communal interests (Kozinets et al. 2010), and (iii) mixing diverse topics and content types (Simon 1996). We present examples of each of these tactics drawn from our qualitative research.

CONCLUSION

In sum, this research presents a conceptual framework to explain how persuasion works in blogs. This framework is based on qualitative data and theory from persuasion knowledge (Friestad and Wright 1994), mass communication (Katz and Lazarsfeld 1955), word-of-mouth (Dichter 1966; Henning-Thurau et al. 2004), communication norms/motives (Rubin, Perse and Barbato 1988; Sundaram et al. 1998), relationship (e.g., self-disclosure (Cozby 1973; Derlega and Berg 1987), and intimacy (Jamieson 1998; Reis and Shaver 1988). Our work provides a broad view of how blogs operate, which should apply to many situations. For example, we expect that these ideas hold both when blog content is seeded by marketers (e.g., Kozinets et al. 2010) as well as when content is self-generated by the blogger. Thus, this framework extends the persuasion and WOM literature to address current changes in the structure of communication.

Street Credibility:
What is it? Who has it? Why is it so Appealing to Diverse Consumer Groups?

Delancy Bennett, University of Massachusetts, USA
William Diamond, University of Massachusetts, USA

EXTENDED ABSTRACT

Celebrity endorsers are featured in 10 to 20 percent of commercials in the United States (Agrawal and Kamakura 1995). While firms have invested significant capital in celebrity endorsers, they traditionally shy away from those who have been involved in illegal or immoral acts (Briggs 2009; Creswell 2008). However, the rules of endorser selection appear to be changing. Recently, a new type of endorser whose celebrity is built in part upon criminal activity or violent history has emerged. These celebrities, often rappers, successfully endorse major brands such as Vitamin Water and Chrysler. They are often described as having another form of credibility—street credibility (Spiegler 1996). Patrick (2005) suggests that these street credible celebrities will replace athletes as the most important product endorsers. Therefore, it is important to determine the nature of street credibility, who has it, and how is it gained. As well, we need to understand how diverse consumer groups relate to these endorsers.

This paper will define the emergent construct of street credibility, delineate its antecedents, provide exemplars, and assess the attraction to street credible endorsers by diverse consumer groups. We will use Kohli and Jaworski's (1990) framework for developing emerging constructs. We begin by reviewing the literature on celebrity endorser credibility and integrating insights from research in anthropology and sociology relevant to the construct of street credibility. Next, we report findings from a series of field interviews exploring street credibility.

LITERATURE REVIEW

Early scholarly work on endorser credibility focuses on the moderators of source effectiveness. These studies suggest that trustworthiness, expertise and attractiveness are the most important elements of endorser credibility (Friedman, Santeramo, and Traina 1978; Hovland and Weiss 1951; McGuire 1985; Ohanian 1990).

McGuire (1985) suggests that similarity is an antecedent of attractiveness. Thus inner city consumers may be attracted to street credible endorsers based on their similar personal histories. However, this neglects to explain the popularity of street credible endorsers with other consumers. Before addressing this issue, we next will explore the literature on street credibility.

Researchers in the areas of marketing, sociology, and criminology use the term street credibility to refer to a reputation gained through acts of street crime and adherence to street codes in poor urban settings (Brunson and Stewart 2006; Grint and Case 1998). However, they stop short at providing a concrete definition of street credibility.

METHOD

To develop a definition of street credibility, we consulted existing ethnographic, anthropological and sociological studies regarding street culture (i.e. Bourgois 2003; LeBlanc 2003). Following the works of Burton, Cherlin, Winn, Estacion, and Holder-Taylor (2009) and Charmaz (2006), our approach was not completely inductive grounded theory. Rather we employed a modified form of grounded theory using "extant theory and ethnographic studies" to build a foundation for an emerging construct (Burton et al. 2009, 1107-1124).

This analysis resulted in our discovery of five areas producing respect within street culture: (1) ability to thrive, (2) acquisition of street smarts, (3) displayed toughness, (4) acquisition of material possessions and sexual conquest, and (5) the ability to achieve "cross-over dreams." Following the work of Kohli and Jaworski (1990) we next looked for commonalities between these studies and our fieldwork.

We used theoretical sampling (Glaser and Strauss 1967) to select 34 interview respondents in two U.S. communities. The first community represented inner-city consumers and the second represented consumers outside the inner-city.

The first author interviewed 21 African-American and Latino college students who grew up and attended high school in Harlem. While the interviews allowed for new questions to be generated based on respondents' feedback, all respondents were asked to define street credibility, and asked how it was gained, lost, transferred, used, and differentiated from other constructs such as "cool."

The second set of interviews built upon our findings by developing an understanding of how mainstream, non-inner-city consumers thought about street credibility. We interviewed 13 Caucasian and Asian students who grew up in mid- to small-sized towns from middle class to upper class families in the northeast.

To define street credibility, we followed the work of Kohli and Jaworski (1990) and Burton et. al. (2009) on construct development and used data from both the ethnographic studies on street culture and our field work to identify the antecedents of street credibility and produce an empirically grounded definition.

FINDINGS

This synthesis resulted in a definition of street credibility based on the identification of three main factors: "authentic origins in street life", "the acquisition of power", and the "width of the gap between the one's origin and one's current level of power." Our research further suggests that the diminishment of street credibility will occur when it is publically known that the street credible person has undergone a significant decrease or reversal in the elements of power.

Finally, while both groups show evidence of attachment to the endorsers and their histories, the inner-city consumer's view is more in line with traditional literature. These consumers see the endorser more through the lens of an aspiration reference group. However, the non-inner-city consumer is drawn to the street credible endorser as a form of entertainment. That is, as (Gilroy, Grossberg, and McRobbie 2000) posit, these consumers are drawn to street credible endorsers as their world provides an interesting form of exoticism and fantasy.

CONTRIBUTIONS

We contribute to the work on celebrity endorsement by empirically defining the construct of street credibility and by explaining the attraction that street credibility affords celebrities in diverse consumer groups. Contrary to traditional theories of endorsement and source persuasion, for many consumers street credibility is not related to trustworthiness or similarity. This insight challenges the current body of endorsement literature and leads to better understanding of credibility. Further research is needed to learn what product categories benefit most from street credible endorsers. In addition, research

must focus on the development of scales to measure the aspects of street credibility.

Taking the Complexity Out of Complex Product Customization Decisions

Christian Hildebrand, University of St. Gallen, Switzerland
Jan R. Landwehr, Goethe University Frankfurt, Germany
Andreas Herrmann, University of St. Gallen, Switzerland
Gerald Häubl, University of Alberta, Canada

EXTENDED ABSTRACT

The customization of products based on consumers' idiosyncratic preferences has significant potential in terms of providing consumers with offers that match their personal preferences, as well as increasing their product satisfaction, loyalty, and willingness-to-pay (Alba et al. 1997, Ansari and Mela 2003, Franke et al. 2010). Recent research suggests that each of the two most common modes of product customization – (1) the "by alternative" mode of having consumers choose from a pre-specified set of alternatives and (2) the "by attribute" mode of asking consumers to customize every attribute and attribute level of the product (Valenzuela et al. 2009) – has distinct limitations from the consumers' perspective.

On one hand, the "by attribute" customization mode can reduce choice complexity and increase consumers' satisfaction with their product choices (Valenzuela et al. 2009). On the other hand, however, such comparisons among attribute levels can increase perceived tradeoff difficulty among attributes (Dhar 1997, Nordgren and Dijksterhuis 2009) as well as such customization systems may be challenging to consumers, requiring them to process an increased number of attribute information in parallel (Huffman and Kahn 1997).

Inspired by past research on multi stage decision processes by which consumers typically reduce the number of possible alternatives first, before applying more compensatory or non-compensatory decision rules on the remaining alternatives (Beach 1993, Häubl and Trifts 2000), we propose a two-step customization mode which is intended to reduce difficulties in current customization formats. Similarly to typical two-stage decision processes for information effort reduction (Bettman and Park 1980), the proposed customization mode is based on a two-step decision process in which consumers first select one of a small number of pre-specified prototypes, and then create their final customized product by further refining their initially selected product. Thus, instead of choosing from a large set of attributes and simultaneous tradeoffs among attribute levels, consumers choose from a smaller set of alternatives first, before conducting local tradeoffs in a subsequent customization task.

Evidence from three experiments shows that this two-step model of customization (TMC) outperforms the two predominant customization modes on a number of important outcome dimensions (e.g., reduced choice complexity, increased preference certainty, greater satisfaction with the self-designed product, etc.) and how the effectiveness of the TMC is moderated by the number of pre-specifications and different information formats.

In experiment 1, we examined whether the TMC mode results in higher preference certainty, greater product satisfaction, and reduced choice complexity, compared to the two predominant customization formats of an either "by attribute" or "by alternative" customization. Participants in the TMC condition were presented with a randomly chosen set of nine pre-specified prototypes and asked to select their preferred one, and then had the opportunity to customize the selected product in a second step. We recruited 126 participants from an online consumer panel for the experiment. As predicted, participants in the TMC condition were significantly more satisfied with their customized product, more certain about their preference, and perceived the process of customization as less complex. Furthermore, two multiple mediation models tested the TMC mode against each of the two predominant customization modes and revealed additional evidence that the TMC mode outperformed both of these through the mediating role of preference certainty, satisfaction, and process complexity on consumers' ultimate probability to buy the customized product.

In experiment 2, we examined the moderating role of different pre-specification descriptions to increase consumers' degree of certainty during the customization process. In particular, we manipulated the number of pre-specifications (4 vs. 15) and type of attribute descriptions (quantitative vs. qualitative), and examined how these factors influenced participants' preference certainty. We expected that consumers only navigate through quantitative attribute descriptions effectively if they need to make a small number of comparisons. In line with our prediction, quantitative attribute descriptions were only beneficial in the case of a small number of pre-specifications and less beneficial in the case of a large number of pre-specifications. Furthermore, we uncovered the influence of a novel moderator regarding the influence of a large number of alternatives on preference certainty: although we found that more alternatives do not necessarily reduce certainty directly (in line with Scheibehenne et al. 2010), our results reveal that this effect is moderated by consumers' need for cognition (NFC), such that low NFC consumers were less certain when choosing from a larger set of alternatives, adding an important new facet to our understanding of choice overload and its consequences.

Finally, experiment 3 was conducted to investigate the influence of different TMC procedures for generating pre-specifications. In particular, we examined the influence of different sources of pre-specifications (chosen by other consumers vs. no information; learning task of the mass customization system vs. no learning task) on the degree of deviation from pre-specifications. The learning task was manipulated by asking participants to make five domain-related choices, which were used to select the optimal bundle of pre-specifications. Building on previous research in the area of identity signaling (Berger and Heath 2007), we predicted that consumers would diverge from their initial choice if they conducted the learning task and believed that pre-specifications were chosen by other consumers. In line with our prediction, participants in the preference learning condition deviated significantly from their pre-specification if they believed that pre-specifications were based on what other consumers have chosen. Furthermore, this increased deviation (measured by the Euclidean distance between pre-specification and customized product) resulted in a significant decrease in final product satisfaction ($b_{deviation}$ = -.26, p < .001; R^2 = .08, N = 331).

Our findings contribute to the literature in three ways: First, we provide empirical evidence that the TMC mode outperforms current customization modes, resulting in beneficial effects from a consumer perspective when navigating through mass customization systems. Secondly, we revealed that qualitative in contrast to quantitative attribute descriptions may help consumers to navigate through a large number of attributes in such systems. Finally, we provide additional evidence for backfire effects of preference learning tasks when providing subsequent information that alternatives were based on previous choices of other consumers, making distinction motives for self-designable products increasingly salient.

Two wrongs CAN make a right:
The influence of salient self-attribution on self-image and subsequent goal pursuit

Nina Gros, Maastricht University, The Netherlands
Kelly Geyskens, Maastricht University, The Netherlands
Caroline Goukens, Maastricht University, The Netherlands
Ko de Ruyter, Maastricht University, The Netherlands

EXTENDED ABSTRACT

Consider yourself indulging in your delicious warm popcorn in the movie theater: will the subsequent exposure to thin models in the commercials or movie influence your self-perception? How will this exposure to a goal related cue (i.e. thin model = dieting) immediately after having engaged in goal-inconsistent behavior (i.e. eating popcorn ≠ dieting) influence your self-image?

Based on previous research showing that negative affect that is attributed to the self will motivate behavior (Duval & Lalwani, 1999), we expect that a confrontation with a goal related cue (e.g. a thin model) after having engaged in goal-inconsistent behavior (e.g. eating an unhealthy snack) can drive goal motivation. More specifically, we conjecture that the increased salience of one's own goal failure (e.g. diet failure), triggered by the combination of these events, will lead people to attribute the resulting negative affect to themselves, which in turn will motivate them to change the self (Dana, Lalwani, & Duval, 1997; Duval, Silvia, & Lalwani, 2001). This implies that individuals will not only try to restore/enhance their self-esteem but they will also strive to change the self in order to match the violated goal. Counter intuitively, this entails that individuals that encounter a goal related cue after having engaged in goal inconsistent behavior end up feeling better about themselves compared to individuals that encountered only one or none of these events. Interestingly, this even leads to enhanced goal performance in subsequent, unrelated, situations.

Study 1 (N=120) investigates how exposure to a goal related cue after engagement in goal-inconsistent behavior influences individuals' self-image. We hypothesize that exposure to a goal related cue right after having engaged in goal-inconsistent behavior stresses the attribution of the failure to the self. Consequently, emotion regulation processes will be triggered in order to cope with this negative affect, resulting in enhancement of one's self-image.[1] A 2 (goal-inconsistent behavior: eat complete muffin, no eating) x 2 (goal reminder: thin models, control[2]) experimental design tested the isolated effects of goal-inconsistent behavior (eating a muffin) or goal reminder (being exposed to thin models in advertisements) against the condition in which participants engaged in goal-inconsistent behavior prior to being exposed to the desirable end-state. We measured self-image in a series of 16 self-image dichotomies (e.g. strong-weak, in control-out of control) (adjusted from McFarlane, Polivy, & Herman, 1998). The resulting interaction effect on self-image (F(16, 93) = 2.340, p < 0.01) indicates that, in line with previous research (e.g. Henderson-King, Henderson-King, & Hoffmann, 2001), the single exposure to thin models negatively affects self-image. Interestingly, however, these negative effects were suppressed when participants engaged in goal-inconsistent behavior prior to the exposure to the thin models.

In Study 2 (N=58) we test whether the failure attribution to the self and the resulting attempt to amplify and restore the self-esteem is reflected in an increased signature size, as an implicit measure of self-esteem (Zweigenhaft, 1977; Zweigenhaft & Marlowe, 1973). The results of a 2 (goal inconsistent behavior: eat complete muffin, no eating) x 2 (goal reminder: thin models, control) experimental design indicate a significant interaction effect (F(1,53)=11.272, p < .01). More specifically, participants who engaged in goal-inconsistent behavior (ate a muffin) before being exposed to the goal related cue (thin model) significantly increased their signature size compared to participants that either were only exposed to the thin model or only engaged in goal-inconsistent behavior. The results of Study 2 support the hypothesis that exposure to a goal related cue right after having engaged in goal inconsistent behavior triggers self-enhancement strategies.

In the third study (N=51), we investigate whether this increased self-enhancement has a positive effect on goal performance in subsequent unrelated situations and we generalize the previous findings to a studying context. A 2 (goal inconsistent behavior: above average leisure activity, average leisure activity) x 2 (goal reminder: attractive job advertisements, control) between subjects design was conducted, measuring signature size and amount of M&M's consumed in a subsequent taste test. The results indicate a significant interaction effect (F(1,47)=6.13, p < .01) for signature size. More specifically, participants who were told that they engaged in goal-inconsistent behavior (i.e. spend more time than average on leisure activities) before being exposed to the desired end-state (i.e. attractive job advertisements) significantly increased their signature size compared to participants in the other conditions. Additionally, we find a significant interaction effect on the consumed amount of M&M's (F(1,47)=4.97, p < .05), showing that participants that engaged in goal-inconsistent behavior before being exposed to the desired end-state consumed less M&M's during a subsequent taste test, indicating that they are better at controlling themselves in an unrelated domain. A mediated moderation model (Muller, Judd, & Yzerbyt, 2005; Preacher, Rucker, & Hayes, 2007) showed that signature size partially mediated the effect of consumption, implying that the self-enhancement leads participants to actually perform better on a goal task in a different domain.

Taken together our results indicate that, counter intuitively, encountering a goal related cue subsequently to having engaged in goal inconsistent behavior (=goal failure) triggers self-enhancement strategies to restore self-esteem which even has a positive effect on subsequent goal performance. Coming back to our movie example, this implies that seeing a thin model in the movies after having indulged in popcorn will make you feel better than the person next to you seeing the thin model without having indulged in an unhealthy snack. More interestingly, this will even enable you to outperform your neighbor on subsequent goal pursuits even in unrelated domains. (Word count: 959)

---

[1] Important to note is that participants who engaged in eating the muffin before exposure to the thin models in the advertisements did not differ in the self-image ratings from the control condition.

[2] The control condition that is influenced by neither the goal inconsistent behavior nor the goal reminder provides a baseline measure of individuals' self-image.

The Sleeper Framing Effect: The Influence of Frame Valence on Immediate and Retrospective Experiential Judgments

Mathew S. Isaac, Seattle University, USA
Morgan Poor, University of San Diego, USA

EXTENDED ABSTRACT

One of the most pervasive findings in framing research is the valence-consistent shift (Levin et al. 1998, 160); that is, positively valenced frames are preferred over equivalent negatively valenced frames. For example, ground beef labeled as 75% lean (positive valence) has been shown to receive more favorable evaluations than ground beef labeled as 25% fat (negative valence), even though the two alternatives are identical (i.e., 75% lean = 25% fat) (Levin 1987; Levin et al. 1985). Most of the framing research documenting valence-consistent shifts has explored how labels influence judgments of prospective or hypothetical consumption (e.g., LeBoeuf and Shafir 2003; Levin et al. 1985; Levin, Schnittjer, and Thee 1988).

In contrast, the present research examines how frames interact with actual consumption episodes to influence not only immediate judgments (i.e., judgments made during or immediately after a consumption episode) but also retrospective judgments (i.e., judgments made when reflecting back on a consumption episode). Unlike judgments of prospective or hypothetical consumption, we find evidence that exposure to a positive or a negative frame has little effect on judgments that are made immediately after an identical consumption experience. However, following a short delay, we demonstrate that the valence-consistent shift reemerges when consumers make retrospective judgments about their consumption experience, which we term the *sleeper framing effect*.

We attribute the sleeper framing effect to differences in how consumers integrate experiential information (e.g., taste, smoothness) and frame information when making immediate versus retrospective judgments. For immediate judgments, we believe that consumers emphasize their actual experience over framing because experiential information is particularly vivid (Paivio 1971) and may therefore be preferentially active in working memory. Our claim is supported by the results of a single study conducted by Levin and Gaeth (1988), which showed that the lean/fat frame effect described earlier had no effect on taste judgments when respondents were able to actually sample the beef immediately beforehand.

However, for retrospective judgments, when both experiential information and frame information would have shifted into long-term memory, we expect that experiential information may have less impact than non-experiential information (such as frames) on retrospective judgments made after a short delay. This prediction is based on prior research documenting the extreme fragility and distorted recall of experiential information (Galin 1994; Robinson and Clore 2002; Snodgrass 1997). In sum, our theorizing predicts that the valence-consistent shift found in the framing literature will disappear when consumers are asked to make experiential judgments immediately after being exposed to a valenced frame and consuming a product, but will reemerge when consumers are asked to make retrospective experiential judgments. Across three experiments, we provide evidence of a robust sleeper framing effect and demonstrate that it occurs because of variation in how consumers use different informational inputs (i.e., experiential vs. frame) when making judgments.

In experiment 1, we provided an initial demonstration of the sleeper framing effect on experiential judgments. Participants were first exposed to one of two logically equivalent frames, either positive or negative in valence, and subsequently engaged in the same sensory experience (i.e., listening to an unfamiliar song). Frame valence was manipulated by telling participants that recent market research had found that 50% of college students either liked (positive frame) or disliked (negative frame) the song that they would be hearing. Timing of evaluation was manipulated by having half of the participants provide an evaluation of the song immediately after the listening task, whereas the other half provided a retrospective evaluation 40 minutes later (following an unrelated filler task). Results were in line with our theorizing; frame valence had no influence on immediate experiential judgments but had a significant impact on retrospective judgments.

Although the results of experiment 1 were consistent with our theory, a rival explanation might attribute our results to an interaction between the timing of the evaluation and the order of information presentation, irrespective of whether either input was experiential or non-experiential. For example, one might argue that the sleeper framing effect observed in experiment 1 was caused by a *recency effect* for immediate judgments (where the sensory experience influenced evaluations the most since it was the last informational input received) and a *primacy effect* for retrospective judgments (where frame valence influenced evaluations the most since it was the first informational input received). This rival explanation is consistent with research showing that recent items in a list are better recalled immediately after exposure to the list because the recent items are still present in working memory, but that the primacy effect prevails when the entire list has shifted to long-term memory.

In experiment 2, we aimed to show that the sleeper framing effect could not be attributed to an interaction between the timing of the evaluation and the order of information presentation. We did this by reversing the order of information presentation so that all participants received experiential information before encountering our framing manipulation. If the serial order explanation was more parsimonious, we should have obtained a data pattern opposite to the one observed in experiment 1. However, even when using a different experiential domain (the visual experience of watching a black-and-white film clip), we found the same pattern of results as in experiment 1.

In experiment 3, we provided more direct process evidence for our proposal that the sleeper framing effect arises because of differences in the processing of experiential information versus frame information. Using a new sensory dimension (taste), we were able to eliminate the valence-consistent shift observed in earlier studies for retrospective judgments by encouraging participants to mentally relive their earlier experience. Furthermore, we collected thought listings to show that experiential information becomes more salient when retrospective judgments are made while mentally reliving an experience as compared to merely recalling a recent experience.

In addition to enriching our understanding of framing effects and experiential consumption, the sleeper framing effect has important implications for consumer choice, since immediate and retrospective judgments routinely influence the subsequent decisions and behaviors of consumers.

An Examination of the Effects of Market Returns and
Market Volatility on Investor Risk Tolerance and Investment Allocation Decisions

Courtney M. Droms, Butler University, USA
Kurt Carlson, Georgetown University, USA
William G. Droms, Georgetown University, USA

EXTENDED ABSTRACT

The 2008 credit market debacle and subsequent "Great Recession" accompanied by the stock market crash of 2008 has caused many investors and their advisors to reevaluate their risk tolerance and investment asset allocation choices (McCarthy 2009). In light of the so-called "Black Swan" events of 2008, many financial institutions and investment advisors are rethinking the advice they give to both individual and corporate clients about the level of risk that is appropriate to meet their investment objectives. There is now an effort underway by many financial institutions to overhaul the advice they give to both individual and corporate clients about the level of risk suggested for their portfolios (Mannes 2009).

One way in which investment advisors attempt to do this is by assessing an investor's risk tolerance and advising that the individual make certain portfolio choices based on their amount of risk tolerance. Risk tolerance is a term that has been used repeatedly in the financial literature to describe how much risk an individual or family is willing to undertake (or tolerate) in their account portfolio. In the current literature, risk tolerance is considered to be a trait that individual's possess and as such is not susceptible to market conditions and market movement (Bateman et. al. 2010; Corter and Chen 2006; Dulebohn 2002).

There is one study that we are aware of that demonstrates based on an analysis of secondary data that investment risk tolerance moves with the direction of the market. However, it is our belief that the movement of risk tolerance of an individual is more complex than solely increasing when the market increases and decreasing when the market decreases (Yao, Hanna, and Lindamood 2004). In this research, we see to contribute to the risk tolerance literature by examining if tolerance depends on market volatility and market returns. The literature suggests two possibilities for how these two factors might interact to determine risk tolerance.

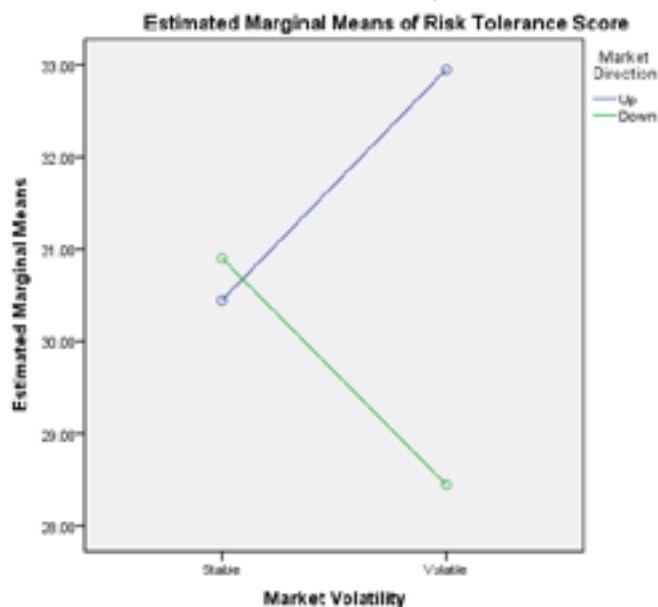
The first possibility, the *variance as risk hypothesis*, suggests that greater variance produces greater risk (Harlow and Rao 1989). The idea here is that when variance is high, investors perceive risk. Thus, their tolerance for risk depends on what that risk did for them recently. If recent returns were positive, then the risk was good. However, if recent returns were negative, the risk was bad. The second possibility is the semi-variance as risk hypothesis, which suggests that investors only perceive risk when losses result (Estrada 2007; Fama and French 2010). The idea here is that market volatility will only matter for risk tolerance when recent returns were negative because when returns are positive, investors don't perceive risk.

If risk tolerance responds to changes in market volatility and recent returns, then the variance as risk hypothesis predicts that recent returns will influence risk tolerance when there is a lot of risk (i.e., when volatility is relatively high) in the market. Specifically, under high volatility, positive recent returns will increase risk tolerance and negative recent returns will decrease risk tolerance, but when volatility is low, recent returns will not alter risk tolerance. In contrast, the semi-variance account suggests that when returns are positive, there will be no difference in risk tolerance across market volatility levels because no risk will be perceived. In contrast, when returns are negative, the semi-variance hypothesis predicts that risk tolerance will

be lower for high variance than low variance because that is where perceived risk will be greatest.

To test between these two hypotheses, we used a 2 (Market Volatility: Low vs. High) x 2 (Market Returns: Increasing Market Returns vs. Decreasing Market Returns) between-participants design with 177 individuals (104 males, 73 females) between the ages of 18 and 83. Participants saw one of four graphical depictions of the market and a brief description of the market returns and market volatility conditions and were then asked a series of questions about their tolerance for risk in their investment decisions.

Results revealed a significant interaction between market volatility and market returns on risk tolerance ($F(1, 173) = 4.328$, $p < .04$). Decomposition of this interaction provided support for the risk and variance hypothesis because there was no difference in risk tolerance across positive and negative market returns when market volatility was low. Specifically, market investors were equally tolerant of risk regardless of whether the market was rising or falling ($M_{up} = 30.45$, $M_{down} = 30.91$, $t(87) = -.282$, *ns*, See Figure 1), so long as there was little volatility in the market. In contrast, when the market was volatile, investors' risk tolerance depended on recent market returns. Specifically, participants were more tolerant of risk when the market was going up than when the market was going down ($M_{up} = 32.95$, $M_{down} = 28.45$, $t(86) = 2.574$, $p < .02$).

Figure 1:
Effects of Market Returns and Volatility on Risk Tolerance


When these results are generalized to a large number of investors, this data may explain investor behavior during stock market "bubbles." As volatile markets move up, investor risk tolerance increases resulting in investors accepting increasing risk and contributing to the expansion of the bubble. In fact, it is likely that investors perceive accepting higher levels of risk as the key to success in a

volatile and rising market. But when the volatile market turns down, risk tolerance plummets and investors begin to "de-risk" their portfolios by selling volatile assets and moving to less volatile assets, thus driving prices ever lower as the bubble bursts.

In addition to providing a new account for bubbles, this research shows that an investor's risk tolerance is not as stable as it has been portrayed previously. Practically, this research suggests how to examine investors' "true" risk tolerance. Namely, risk tolerance could be examined for low and high volatility markets with recent positive and recent negative returns and then averaged across all of these conditions to obtain a relatively general measure of risk tolerance for each investor. In addition, this research could assist government agencies and public policy groups in forecasting how individual investors may act as markets change.

Shifting Away From Discomfort:
Managing Decision Difficulty Through Emotion Regulation

Stephanie M. Carpenter, University of Michigan, USA
J. Frank Yates, University of Michigan, USA
Stephanie D. Preston, University of Michigan, USA
Lydia Chen, University of Michigan, USA

EXTENDED ABSTRACT

Consumers are faced on a daily basis with difficult decisions in complex choice environments, and many of these decisions involve the careful weighing of options before a choice can be made. Research on pre-decisional coherence shifting (Simon, Krawezyk, and Holyoak 2004; pre-decisional distortion; Russo, Meloy and Medvec 1998) indicates that changes in the desirability and importance of choice alternative features begins prior to making a choice, rather than following the choice. Proposed mechanisms for why coherence shifting occurs, however, have been limited. Research suggests difficult decisions that are likely to create cognitive dissonance (Cooper 2007) are associated with a heightened arousal state or a feeling of discomfort. One method for measuring physiological arousal is with the skin conductance response (SCR), which is measured by attaching electrodes to the palm of the hand to detect slight changes in skin perspiration that reflect sympathetic activation. A seminal study on cognitive dissonance and skin conductance response (Croyle and Cooper 1983) indicated that cognitive dissonance increased SCR, and that resolving cognitive dissonance weakened the high arousal state.

The research described here sought to determine whether feature conflict arising from lacking a clearly dominant option produces a feeling of discomfort, which, in turn, leads some individuals to regulate this discomfort. We propose that coherence shifting reduces decision conflict, which in turn aids in the management of discomfort. We predicted that individuals who coherence shift would feel less of the discomfort that is often experienced when an individual must make a difficult choice between two competing alternatives, each of which includes both positive and negative attributes. In each of three studies, individuals who exhibited high levels of coherence shifting were hypothesized to do so as a consistent strategy for regulating feelings of discomfort, as reflected in lower physiological arousal and decreased perceived decision difficulty.

In Study 1, fifty-nine university undergraduates participated individually in a computerized procedure using an established coherence shift paradigm (Simon et al. 2004). Individuals were informed that they would be participating in a physiological study on decision making, and skin conductance response electrodes were attached to the palm of each participant's non-dominant hand. All participants rated the desirability of a number of possible job attributes, and then weighted how important these attributes were in a typical decision context. Participants were then shown the attributes of two specific job offers that varied on the dimensions of commute time, salary, office space, and vacation package. After viewing the offers, participants rated the desirability of the attributes and weighted attribute importance a second time. Participants then indicated their choice leanings. An interim task was given prior to participants making their final choices, followed by a third rating of attribute desirability and weighted importance.

In the studies conducted by Simon et al. (2004), coherence shifting was measured as a change in the attribute desirability and importance ratings at each time point to be consistent with the eventually chosen option. We replicated these general findings that individuals shift their desirability and importance ratings toward their final choice leanings. Analyses were conducted using a median split on the degree of coherence shifting, with the dependent variables representing SCR during the maximal decision window of 2000ms–3000ms. Results indicated that participants with high levels of coherence shifting on importance weightings also had significantly lower SCR (p < .05) across study blocks. Analyses were conducted to measure coherence shifting with respect to the specific study blocks. These revealed that participants who changed their importance weights the most also had significantly lower SCR (p < .05) across blocks. Further, the degree of coherence shifting with respect to the job offer attributes correlated significantly with perceived difficulty for both the desirability ratings (r = -.36, p = .005) and the importance weightings (r = -.53, p < .05), indicating that high coherence shifting was associated with less perceived decision difficulty.

In Study 2, one hundred and thirteen university undergraduates were recruited to participate individually in a laboratory study. Feelings of discomfort were manipulated to determine whether experiencing discomfort would lead to decreased coherence shifting among individuals who self-report less emotion regulation (Gross 1998). Using a difficult anagram procedure, participants were induced into a high discomfort, low discomfort, or baseline (no anagram task) condition. Following the discomfort manipulation, participants completed the job offer coherence shifting paradigm (Simon et al. 2004) described in Study 1. Results indicated that those who were induced to experience high discomfort and did not self-report emotion regulation tendencies shifted significantly less than those in a low discomfort or baseline condition (p < .05), supporting our argument that coherence shifting is a strategy used to regulate feelings of discomfort.

In Study 3, thirty-three university undergraduates were recruited to participate in a two-part study. Participants were brought back to the study for two separate sessions, held one week apart, to make two separate difficult decisions involving feature conflict. Decision tasks were counterbalanced across weeks. One task was the same job offer choice used in Studies 1 and 2, and the other task was a consumption choice involving selecting an apartment to rent. As predicted, some individuals consistently shifted more often than others across different decision occasions (p < .01), and this coherence shifting was correlated with self-reported emotion regulation tendencies (p < .05).

This research suggests that difficult decisions involving feature conflict are capable of producing feelings of discomfort, which some individuals manage via pre-decisional coherence shifting. These data are consistent with our proposed model of feature conflict leading to feelings of discomfort, which some individuals regulate through coherence shifting. Additional research is being conducted to further establish the proposed causal sequencing. These findings shed light on the basic mechanisms underlying decision making and provide important implications for why people use different choice strategies in complex consumption environments.

"That Ad's Been Retouched? – That Can Be Me!":
The Persuasive Impact of Advertising Disclosure and Body-Image Idealization

Rania W. Semaan, American University of Sharjah, UAE
Stephen J. Gould, Baruch College/CUNY, USA
Bruno Kocher, HEC Paris, France

EXTENDED ABSTRACT

A common advertising tactic is to digitally manipulate models' images to enhance their looks. Research has found that exposure to media images depicting the thin-ideal body affects one's self-concept and product evaluations. However, despite their impact on advertising effectiveness, (Hafner and Trampe 2009) there is limited research that considers that the thin ideal is not only heightened through using slender models but also through their digital manipulation (Hitchon and Reaves 1999). Research on eating disorders suggests that mass media should be required to inform consumers of these computer-modified images, though without examining the consequences (Thompson and Heinberg 1999).

The present research looks at the exposure to digitally manipulated thin-idealized body images on consumers' product and self-evaluations. It also highlights the effects of disclosing such manipulation. We investigate the effects of such disclosure in terms of one-sided versus two-sided advertisements (ads featuring only positive appeals versus those with both positive and negative content, Etgar and Goodwin 1982). We posit that a disclosed retouched ad would be perceived as less honest than a disclosed un-retouched ad indicating that consumers perceive it as two-sided. This leads to higher preference for disclosed retouched ads and more favorable brand evaluations.

We also explore social comparison theory in explaining the ads' effects on consumers' self-evaluation. When individuals are exposed to comparison targets, they selectively compare themselves to these targets and evaluate their own performance where (dis)similarity generates (contrast) assimilation effects (Mussweiler 2003). Moreover, comparison targets affect people only when they are perceived as more inspirational and their achievement is attainable (Lockwood and Kunda 1997). Thus, we predict that when exposed to retouched advertisements depicting thin-attractive models, consumers will experience a contrast in their self-evaluation. However, this dissimilarity will dissipate once they are told that this advertisement has been digitally enhanced, thus leading them to experience assimilative self-evaluation and that perceived attainability of the model's attractiveness mediates this effect.

STUDY 1

Study 1 investigates whether when consumers are informed of digital manipulation, their brand evaluations for an imagined perfume brand, Espoire, will be higher after exposure to a retouched (vs. un-retouched) ad and whether this effect is mediated by perceptions of ad honesty. A 2 (Ad: (Un)retouched) x 2 (Disclosure: (No) Disclosure) between-subjects design was applied to a sample of 143 females.

Results revealed a significant two-way interaction on attitude towards the ad (A_{ad}) $F (1, 138) = 5.946$, $p < .01$), where consumers evaluate the retouched ad ($M_{No Disclosure} = 3.700$, $M_{Disclosure} = 5.649$) more favorably than the un-retouched ad ($M_{No Disclosure} = 2.686$, $M_{Disclosure} = 3.129$) whether they were told that the ad has (has not) been digitally-enhanced or not. Results also show a significant two-way interaction on brand evaluations (F (1, 139) = 4.118, $p < .05$) where participants evaluated the brand in the retouched ad more favorably ($M = 5.108$) than in the un-retouched ad ($M = 3.724$) when told the

ad has (has not) been digitally enhanced. However, when no such disclosure was provided, consumers' brand evaluations did not differ. Planned contrasts revealed that, within the retouched ad, participants like the retouched ad and brand more when told the ad has been digitally-enhanced versus when no such disclosure is provided.

Following Zhao, Lynch, and Chen (2010) a mediated-moderation was performed. The analysis revealed that ad honesty significantly mediates the effect of ad × disclosure on A_{ad}, brand evaluations, and purchase intentions, such that participants perceive the disclosed retouched ad as less honest (two-sided) and therefore prefer it, evaluate the brand better, and have higher purchase intentions than for the one-sided advertisements.

STUDY 2

Study 2, using the same brand as in Study 1, explores the moderating effect of disclosure of thin-idealized body images on females' self-evaluation as a form of social comparison. We also examine the mediating effects of perceived attainability of the ad × disclosure interaction on self-evaluation.

Concerning product evaluations and ad honesty as a mediator, the results replicate Study 1. We also found a significant ad × disclosure interaction effect on participants' self-evaluation (F (1, 172) = 6.731, $p < .01$). Participants had higher self-evaluation when exposed to a disclosed retouched ad ($M = 5.142$) than a disclosed un-retouched ad ($M = 4.407$) or an undisclosed retouched ad ($M = 4.365$). When no disclosure was provided, participants' self-evaluation was not significantly different when exposed to a retouched or un-retouched ad.

Perceived attainability mediates the effect of image × disclosure interaction on self-evaluation such that participants who were exposed to the retouched ad and were told that it was retouched perceived that the model's looks are more attainable than all others thereby increasing their self-evaluations. However, attainability is not a significant mediator for the ad × disclosure interaction on A_{ad}, brand evaluations, and purchase intentions.

STUDY 3

In Study 3 we aim to investigate a boundary condition for the effects found in study 2. We employed a 2 (Disclosure: No(Disclosure) x 2 (Product: Problem-solving vs. beauty-enhancing) between-subjects design using only the retouched ad. Problem solving is a product that fixes a beauty problem (body lotion) whereas beauty-enhancing products do not necessarily hide a beauty problem (perfume).

Results reveal a significant two-way interaction (p < .05) such that participants have a higher ad and brand preference and higher purchase intentions for body lotion than for perfume when it is disclosed that the ad has been retouched. However when no such disclosure is provided, their preferences are not significantly different across the two types of product ads.

DISCUSSION

This research suggests that disclosure of digital-enhancement generates higher brand evaluations. Two studies show that consumers prefer retouched ads especially when told these ads have been digitally enhanced. Contrary to prior research, we demonstrate that

even though consumers judge the digitally enhanced advertisement to be less honest, they evaluate brands more favorably and are more willing to buy them when displayed in retouched ads. Analysis also revealed that consumers' perceived attainability explains the effect of disclosed enhancement on self-evaluation. Research, managerial and public policy implications which incorporate not only the more conventionally perceived, negative effects, but also the more counterintuitive, positive effects of retouching may be drawn for these findings.

On the Impact of Prior Ideas on Ideation Performance in Ideation Contests

Suleiman Aryobsei, University of St.Gallen, Switzerland
Reto Hofstetter, University of St.Gallen, Switzerland
Andreas Herrmann, University of St.Gallen, Switzerland

EXTENDED ABSTRACT

Ideation contests are increasingly held among employees and consumers (solvers) to support the innovation process particularly during the early stages of new product development (Boudreau, Lacetera, & Lakhani, 2011). In such contests, solvers generate ideas for how to solve innovation problems and hereby compete for financial rewards that will be granted to the best ideas, which are chosen by the idea seeker (Terwiesch & Ulrich, 2009). Frequently, such contests are held publicly and the whole solution space of ideas is accessible to all solvers at any time (Dell's IdeaStorm, 99designs). While prior literature mainly focuses on privately held or "parallel search" contests (Kornish & Ulrich, 2011), little is known about the optimal design of publicly held contests. In this project, we investigate how solvers behave in public ideation contests and how the contest outcome depends on prior information on the content and the context of the ideas.

THEORY AND HYPOTHESES DEVELOPMENT

Theory is mixed in predicting the impact of prior ideas on ideation performance. According to the recombinant growth theory, the creation of new ideas is commonly defined as the new recombination of existing ideas (Hadamard, 1949; Jeroen, 2008; Koestler, 1964; Weitzman, 1998). In ideation contests, solvers are able to further develop and recombine existing ideas. Though, we hypothesize that allowing for recombination of prior ideas improves the overall ideation performance and the specific nature of the prevalent information (degree of quality and novelty) influences the nature of the newly developed ideas.

Reversely, knowledge of the solution space can impede creativity to the extent that solvers seek conformity with existing ideas instead of generating new ideas (Smith, Ward, & Schumacher, 1993; Smith & Tindell, 1997). In a contest situation, we hypothesize that solvers will especially build upon existing ideas with high quality ratings. Building upon ideas that are presumed to have a higher chance of winning is in line with a behavior that aims at maximize the odds of winning the reward of the contest when a seeker's tastes are difficult to observe. We argue that such behavior can be counterproductive since the diversity of the solution space will ultimately be reduced, with negative impact on the overall quality of the contest outcome (Terwiesch & Xu, 2008).

ANALYSIS OF FIELD DATA

We analyzed a large-scale dataset of an online ideation platform, including 100 contests, 2,300 active solvers, and over 40,000 ideas. By using a text-mining approach we detect the number of similar words as an indicator for the similarity of the content of any pair of two submitted ideas. A high overlap of similar words between ideas is an indicator for a high degree of confirmation.

On the analyzed platform, submitted ideas are presented in a chronological order to the solvers. Though, very recent submitted ideas are more prevalent than earlier submitted ideas. We found that new submitted ideas had a high similarity to recent prior ideas. Figure 1 indicates that there is a significantly higher similarity of new ideas to very recent submitted ideas than to older ideas ($\beta = -.00059$, $t(1057) = -93.29$, $p < .001$). Furthermore, solvers were more likely to build upon highly rated ideas compared of lower rated ideas ($\beta =$

.01313, $t(29) = 2.80$, $p < .01$). Figure 2 shows the average similarity of ideas depending on the rating by the community of the previous submitted ideas. Highly rated ideas were more likely to be used as a basis compared to lower rated ideas.

Figure 1: Average similarity of ideas depending on their distance in their chronological order ($R^2 = .90$, $F(1, 1057) = 8703.62$, $p < .001$).
Participants rather confirmed ideas very recent submitted ideas than more early sent ideas. Very recent sent ideas were mere prevalent to the solver than more early send ideas.

Figure 2: Average similarity to new developed ideas depending on the number or rate ups (community rating) of the existing ideas ($R^2 = .21$, $F(1, 29) = 7.84$, $p < .01$).
Solvers rather confirmed ideas with a high number of rate ups than ideas with a low number of rate ups.

In addition, we found that recombining existing ideas has positive influence on the quality the new developed ideas ($\beta = .018079$, $t(29) = 3.07$, $p < .01$). Figure 3 shows the average similarity to previous submitted ideas depending on the rating of the new developed

ideas. Ideas with high similarity to previous submitted ideas were rated higher than ideas with a low similarity to existing ideas.

Figure 3: Average similarity to previous submitted ideas depending on the number or rate ups of the new ideas ($R^2 = .24$, $F(1, 29) = 9.45$, $p < .01$).
Ideas with a high number of rate ups are more similar to previous submitted ideas than ideas with a low number of rate ups.

EXPERIMENT

We further conducted an experiment with a 2x2 full-factorial between-subjects design. Each solver was asked to generate novel ideas to the same ideation problem. Before entering an own idea, he saw three existing ideas that varied by their quality and the novelty. 272 participants took part in this study and delivered ideas. After the experimental contest was held, the novelty and quality of the submitted ideas were evaluated by 265 judges using a web-based interface (similar to Girotra, 2010). The ideas were presented independently in a random order and each idea was evaluated by about 30 judges. We found significant main effects: The quality of the submitted ideas was higher, if solvers had seen high quality example ideas ($M_{LowQ} = 3.51$; $M_{HighQ} = 3.67$; $F(1, 272) = 1.65$; $p = 0.029$). Furthermore, the degree of novelty of submitted ideas was higher if solvers had seen more novel example ideas ($M_{LowN} = 3.62$; $M_{HighN} = 3.81$; $F(1, 272) = 4.21$; $p = 0.041$).

CONCLUSION

Our results show that solvers are indeed influenced by the nature of the extant ideas in open ideation contests. We found that in line with recombinant-growth theory, ideas that build upon existing ideas tend to be better evaluated. Our results suggest that this is due to the self-organizing behavior of the community reacting sensitive to quality signals in a situation of high uncertainty about a seeker's tastes. Newly entering solvers look out for these signals that can guide their ideation effort into a direction that ensures maximization of the odds to win the contest. Community ratings, which are also publicly available, can provide such guidance when seeker feedback is missing. As a result, the ratings guide new users to high quality ideas which can then be further recombined for even better ideas. While increasing quality of the good ideas, such behavior ultimately leads to increased conformity with existing ideas.

In conclusion, our findings suggest that seekers that ought to maximize the quality of the best ideas should perform public ideation contests and allow for quality signaling during the contest. Seekers that intend to maximize the variance of the solution space, however, might be better off to keep their contests privately.

When the Crowd is Divided: Perceptions of Dispersion in Word-of-Mouth

Stephen He, Georgia Institute of Technology, USA
Samuel Bond, Georgia Institute of Technology, USA

EXTENDED ABSTRACT

Empowered by information technology to seek the opinions of others, consumers are more likely than ever to encounter a mixture of positive and negative word-of-mouth for the same product or service. Given that consumers generally prefer certainty to uncertainty, intuition suggests that they will favor products with consistent WOM (Matz and Wood 2005; Urbany, Dickson, and Wilkie 1989). However, a survey of online platforms reveals that the distribution of customer ratings is often highly disperse or bimodal (Hu, Pavlou, and Zhang 2009), connoting substantial uncertainty and decision risk (Meyer 1981). Greater dispersion of WOM has been shown to lower sales and satisfaction in certain contexts (Moon, Bergey, and Iacobucci 2010; Zhu and Zhang 2010), but findings in other contexts have been mixed (Clemons, Gao, and Hitt 2006; Martin, Barron, and Norton 2008).

Drawing on research in social perception (Boldry and Kashy 1999; Nisbett and Kunda 1985) and attribution (Folkes 1988; Kelley 1973), we propose that WOM dispersion often stem from two general sources: 1) uncertainty in product performance, and 2) idiosyncrasy in preferences across reviewers (taste variability). Prior research using expert ratings and online reviews has focused primarily on the first of these sources. For products characterized by low taste variability, WOM can be viewed as a proxy for product quality; hence, high dispersion indicates inconsistent performance and is aversive (Price, Feick, and Higie 1989; West and Broniarczyk 1998; Sun 2011). We propose that for products characterized by high taste variability (e.g., art, restaurants), variation in WOM may also be attributed to idiosyncrasy among reviewers, or 'mixed opinions.' In these cases, high dispersion may be acceptable if consumers are both aware and tolerant of divergence in taste (Berger and Heath 2007; Cheema and Kaikati 2010).

To summarize, we predict that the influence of WOM dispersion on liking and choice will be moderated by taste variability: when perceived taste variability is low, greater dispersion will be detrimental, but this effect will be attenuated when perceived taste variability increases. Our hypotheses were examined in four studies involving hypothetical decision scenarios. In all studies, subjects were given displays of WOM distributions that included both an overall 'average' rating and the distribution of ratings around that average (using a horizontal bar chart). In terms of expected utility, this format allowed us to vary both the expected outcome of choosing the product (its average rating) and the risk of a obtaining a worse outcome (its dispersion).

Study 1 used a mixed factorial design including perceived taste variability, WOM average, and WOM dispersion. Taste variability was manipulated through product category: based on pretesting, we selected desk lamps and framed paintings for the low- and high-variability conditions, respectively. For each product, a set of sixteen scenarios was presented within-subjects. Each scenario described one focal product and its reviews. The scenarios crossed four levels of average rating (4 through 7 out of 10) with four levels of dispersion (high: $var > 8.00$, medium: $var \approx 2.00$, low: $var < 1.00$, and zero: $var = 0$). Participants (189 undergraduate students) evaluated all scenarios, one at a time, and reported their purchase intention.

In the analyses, purchase intention was mean-centered to allow comparisons between product categories. ANOVA revealed the predicted interaction between dispersion and product category ($F(3, 1349) = 2.55$, $p = .05$), and follow-up comparisons were consistent with our hypotheses. When dispersion was low, participants expressed similar purchase intention for lamps and paintings; when dispersion was high, they were less likely to buy lamps than to buy paintings.

Study 2a and 2b expanded the investigation to consumer choices. In study 2a, 61 paid participants made a series of choices based on WOM information. The choice scenarios included two target categories (lamps and paintings) separated by various fillers. For the two target categories, participants were asked to choose from a pair of similarly attractive options with distinct mean and variance. Analyses were conducted by comparing the relative shares of each option. As expected, choices differed reliably across taste variability ($\chi^2(1) = 3.97$, $p = .05$), such that the high-average / high-dispersion option (A) was chosen more often for paintings than for lamps.

Study 2b included 79 paid participants and was similar to Study 2a, with two major differences. First, two product categories were added: flash drives (low taste variability) and downloadable music albums (high taste variability). Second, the stimuli were constructed so that Option A 'dominated' Option B. Analyses of participant choices again revealed a reliable difference across taste variability conditions ($\chi^2(1) = 25.51$, $p < .001$). Moreover, despite having lower expected value and higher variance, the 'dominated' option was chosen by almost half of participants (43%) in categories with high taste variability.

Study 3 (132 paid students) removed potential confounds by holding constant the focal product category (hotels). Taste variability was manipulated directly, by telling participants that the WOM was posted by either a diverse group of reviewers or a group of college students. Dispersion was manipulated between-subjects: high ($var = 3.59$) or low ($var = 0.95$). Participants observed the WOM information and reported their intention to purchase a coupon for the hotel. In addition, they completed an attribution measure designed to collect evidence for our hypothesized process (see below).

Analyses revealed both a main effect of dispersion and a dispersion * taste variability interaction ($F(1, 128) = 4.60$, $p < .05$). Although more dispersion reduced purchase intention in general, the effect was smaller when WOM was provided by a diverse group of reviewers than by college students alone. The attribution measure provided further support for our model: when dispersion was high, participants were more likely to attribute dispersion to 'something about the hotel' if they believed the ratings came from a homogenous group of reviewers.

Taken together, our results demonstrate that consumers' reaction to dispersion in product WOM depends on the way that dispersion can be attributed. These findings have important implications for researchers exploring the impact of WOM and the processing of statistical information, as well as practitioners facing divided consumer opinions of their offerings.

Consuming 'Media Trash:' When "Bad" Becomes "Good"

Björn Bohnenkamp, University of Muenster, Germany
Caroline Wiertz, City University London, UK
Thorsten Hennig-Thurau, University of Muenster, Germany

EXTENDED ABSTRACT

Using a multi-method approach, we explore the concept of "media trash" and investigate why consumers with different levels of cultural capital seek the consumption of these particular media offers despite or even because of their questionable quality.

RESEARCH TOPIC AND QUESTION

Media consumption is one of today's most important consumption activities, with U.S. citizens spending more than 11 hours a day engaging with various media offerings (eMarketer 2011). The question of what constitutes "quality" in such offerings has been hotly debated among media scholars ever since the rise of reality TV formats and more recently user-generated content platforms (e.g., McCabe and Akass 2007). In consumer research, Holbrook (1999) states that the success of media offerings is grounded in popular appeal as opposed to "good taste" –and the commercial success of certain TV formats, movies, and books that are the opposite of 'critically acclaimed' seems to support his theory. While some studies identify general reasons for consuming reality TV shows (e.g., Papachrissi and Mendelson 2007) and particularly the quest for authenticity through the consumption of these shows (Rose and Wood 2005), they fail to address the startling question of why "bad taste" can be attractive. The aim of this study is to investigate what consumers mean when they refer to "media trash" and why consumers sometimes prefer the consumption of products of lower quality *purposefully because of* this lower quality (e.g., watching a "bad" reality TV show such as 'Wife Swap' just because it is so "bad").

LITERATURE REVIEW

In the popular press, the expression "media trash" is used frequently but without a clear definition or explanation. As an academic concept, the term "trash" is used in media studies for popular or pulp fiction (e.g., Bloom 1996), for a specific kinds of visual style in television (e.g., Caldwell 1995), or specific genres like soap operas, talk shows or B-movies (e.g., Kael 1969). In consumer research, the startling purposeful consumption of lower quality products has not been discussed, with the exception of Holbrook (1999, see above). However, a small body of research has investigated the consumption of special TV formats that fall into this category, namely soap operas (Russell, Norman, and Heckler 2004) and reality TV (Rose and Wood 2005). Russel et al. (2004) show that consumers develop a relationship with TV programs and their characters, and that the intensity of this "connectedness" how their behavior is influenced. Rose and Wood (2004) comment on the rise of reality TV formats and argue that consumers seek authenticity through the consumption of these particular TV formats. The question of why consumers seek the consumption of certain media offerings *despite* or even *because of* their questionable quality remains unanswered.

METHOD

We opted for an inductive multi-method approach to collect our data. First, we collected 1520 articles in relevant German newspapers and magazines that mentioned the word "trash" in the context of media. Second, we collected survey data from a representative sample of the German population (n=580) to understand which particular media offers were consumed regularly and how they were rated on a variety of quality and content dimensions.

The core data are semi-structured depth interviews with 38 consumers about one media offering that we selected based on the survey results: the German version of the reality TV show "I'm a Celebrity... Get Me Out of Here!" This TV show was one of the most relevant media offerings mentioned in German newspapers and magazines; it was known by nearly all consumers, and consensually described as "trash." The interviews took on average one hour and focused on when, how and why participants watched this show. Moreover, we also asked questions about our participants' general taste in media and their media consumption rituals.

FINDINGS

Based on a content analysis of the newspaper articles and the survey results, we developed an overview of current (German) media offerings which are commonly evaluated as trash, both by experts and by consumers. The term is most often used in association with television shows, but also newspapers, music, books and movies. We identified eight markers of "media trash" based on how consumers distinguish between offerings that they would describe as trash or non-trash. At least one of the markers presented in Table 1 has to be present for a media offering to be considered "trash."

Table 1: Eight Markers of Media Trash

Marker of "Media Trash"	Representative Quotes (translated from German)
Intellectually undemanding content	"It's just entertainment TV without any educational background." "Superficial person, who benefits from the stupidity of the people."
Low formal quality	"Cheap production, bad actors, pointless scenarios."
Low authenticity	"Nothing is real; everything is fake but touted as true." "It's completely posed."
Repeated emotion-seeking patterns	"Always the same – the Cobra team manages all situations and saves the world for us." "All songs are the same."
Absurd and unrealistic content	"The story is absolute wacky." "Absolute nonsense, but more than just funny."
Exaggerated content	"The gonzo headlines above badly researched articles."
Inappropriate content	"Distasteful and degrading to people and animals." "Sold voyeurism."
Arousal-seeking content	"Explicit description of sexual practices." "Exorbitant presentation of violence and blood."

An important finding is that the valence of these markers, despite appearing negative on first sight, is in fact dependent on each consumer and each media offering. For example, the newspaper "Bild"—comparable to the "Daily Mail"—was described by many consumers as being a favorite newspaper *because of* its low intellectual demand and its absurd and unrealistic content. In this sense, "bad" can indeed become "good" and the consumption of media trash is enjoyable for consumers.

This enjoyment, however, creates a conflict for consumers with high cultural capital when defining their social identity. They develop a number of arguments which "justify" trash consumption to reshape their own self-concept and to re-emphasize their cultural capital.

Furthermore, beyond the general notion of cultural capital, consumers display a media-specific capital. Consumers who have both a high involvement and a deep knowledge of a medium often watch bad taste offerings to reflect on the media-specific genre conventions on a meta-position.

Finally, consumers integrate trash media in a hypermedia consumption experience: During trash consumption they post their feelings and attitudes via Facebook, Twitter, and other social networking services. Not the actual media offering itself, but the communication among a subculture of consumers (Kates 2002, Schouten and McAlexander 1995) is the main reason for consumption.

CONTRIBUTIONS

Our project contributes to consumer research by shedding light on the markers of "media trash" and the reasons why consumers choose to consume these specific media offerings. We pay special attention to the social and cultural background of this consumption practice, and structure our understanding of the phenomenon with Bourdieu's theory of practice (Bourdieu 1977, 1984) and a broad range of media theories (e.g., Adorno and Horkheimer 1973; Hall 1973).

But How Did You Expect To Feel?: The Motivated Misremembering of Affective Forecasts

Mathew S. Isaac, Seattle University, USA
Alexander Fedorikhin, Indiana University, USA
David Gal, Northwestern University, USA

EXTENDED ABSTRACT

Following an event, people often reflect on how it compared to their expectations. For example, after a political election, people might consider whether they had correctly predicted the winner, the winning margin, or even their own feelings about the result. Extant research has shown that when actual forecasts and experiences are discrepant, people attempt to resolve this dissonance by recalling their forecast as being closer to the experience than it actually was. Although this hindsight bias (Fischoff 1975) occurs when experiences diverge from actual forecasts, little is known about how people recall their forecasts when their experience is similar to the actual forecast.

In the present research, we demonstrate that when experiences are concordant with actual forecasts, a novel bias may occur. Across three studies, we show that people tend to recall their affective forecast as being less favorable than both their actual forecast and their experience. We claim that people misremember their forecasts in this way so as to make their experience feel more surprising to them, which we describe as "illusory surprise." Since surprising outcomes are often more elating than expected outcomes (Mellers et al. 1997, Filipowicz 2006), we hypothesize that people derive affective benefits from misremembering their forecasts. Specifically, we demonstrate that people report greater affective arousal at the time of recall when they misremember their forecasts, which has implications for subsequent choices that they make.

Experiment 1 was a field study where movie theater patrons forecasted what their enjoyment of a movie was likely to be before seeing it. Afterwards, participants noted their actual enjoyment of the movie and then recalled their affective forecast. Subsequently, participants read the description of another movie from the same genre and indicated their intention to see it. We reasoned that participants experiencing greater illusory surprise when recalling the prior movie would be more inclined to watch another movie. In line with our theorizing, recalled forecasts of participants were significantly less favorable than both their experience and the actual forecasts they made earlier. Furthermore, experiences and actual forecasts did not differ; that is, participants actually enjoyed their movie as much as they had anticipated but reported recalling that they would not enjoy it as much as they had. We also found that that illusory surprise predicted participants' likelihood to watch another movie, such that those who misremembered being surprised by the movie they had seen were also more likely to watch the new film. Thus, illusory surprise appears to affect subsequent choices.

In Experiment 2, participants watched and evaluated an identical, neutral film clip. Expectations were manipulated beforehand, such that some participants were induced to believe that the clip would be positive, negative, or neutral. When participants' actual forecasts deviated significantly from their experience, we found strong evidence of the hindsight bias; that is, people tended to recall their forecast as being closer to the experience than it actually was. However, when actual forecasts matched their experience, participants misremembered their forecasts as being less favorable than both their experience and their actual forecasts. Irrespective of whether their surprise was real or illusory, participants who reported being surprised by the clip experienced greater affective arousal at the time of recall.

Experiment 3 provides evidence that the illusory surprise effect has a motivational basis. Participants who were given financial incentives to accurately recall their forecasts did not exhibit illusory surprise; however, we replicated our illusory surprise effect when accuracy incentives were not provided.

In sum, the present research shows that when experiences converge with expectations, the hindsight bias is unlikely to occur. However, even when experiences and expectations align, people may not recall their affective forecasts accurately. People evidently are motivated to convince themselves that a good-as-expected experience was unexpectedly good. Furthermore, this illusory surprise effect can actually alter the choices that participants subsequently make.

You Can't Always Forget What You Want:
Social Identity and Memory for Identity-based Advertising

Amy N. Dalton, Hong Kong University of Science and Technology, Hong Kong
Li Huang, City University of Hong Kong, Hong Kong.

EXTENDED ABSTRACT

Sigmund Freud's (1915) notion of memory repression, or motivated forgetting, suggests that people cope with unwanted memories by burying them deep in the mind, where they can lie dormant for weeks, years, or even a lifetime. Although Freud's theory has intrigued the world and stimulated fascinating research, it also has been fraught with controversy and empirical challenges. We draw on research on social identity and threat-induced coping to examine motivated forgetting in the context of memory for social identity-linked advertising.

Part of the difficulty in demonstrating motivated forgetting lies in isolating it. Memories people are motivated to forget are often threat-provoking memories they neglect to encode in the first place, so forgetting can be attributed to encoding processes rather than retrieval processes (Sedikides, Green and Pinter 2004). In contrast, consider cases where an intervening event makes otherwise neutral or positive memories difficult to confront. The death of a loved one, for example, makes retrieving fond memories of that person painful. Such contexts allow for a clean test of motivated forgetting because the threat is separated from the learned content. A similar separation can be achieved in a social identity threat paradigm that presents relatively neutral identity-linked content, facilitates its encoding, and then introduces social identity threat to motivate its forgetting.

The identity-linked content we use is identity-linked sales promotions, which target consumers based on an aspect of social identity, like gender, race, or nationality. Identity-linking occurs when firms strategically offer deals like "10% discount for senior citizens" or "Ladies receive 1 free drink." Because our participant population is comprised of HKUST students, our experiments used sales promotions offering 10% discounts to HKUST students. To facilitate encoding of the identity-linked promotions, we first prime students' university identity and then present the identity-linked promotions (mixed in with identity-neutral promotions). After viewing the promotions, participants are exposed to a social identity threat, a fictitious news article indicating that HKUST is underperforming relative to other local universities. After the threat, we measure memory for the identity-linked promotions in a standard old-new recognition task that presents the 20 old promotions along with 20 new ones (some identity-linked and some identity-neutral).

Using this basic framework, we test the hypothesis that even relatively neutral content can be forgotten if the content is identity-related, the identity to which that content relates is subject to threat, and consumers are motivated to protect against threat. We propose that the motivation to protect against threat depends on consumers' sense of connection to the threatened social identity, with high identifiers being more motivated to protect against threat and therefore more likely to forget identity-linked content when threatened.

Study 1 shows that priming a social identity has a positive effect on memory for identity-linked promotions. If, however, the primed identity is threatened, then the effect is reversed (i.e., consumers forget the promotions). As predicted, this effect is moderated by strength of identification, with high identifiers exhibiting better memory for identity-linked promotions when the relevant identity is primed, but worse memory for identity-linked promotions when the primed identity is threatened.

Study 2 tests the hypothesis that identity-linked content is not forgotten, it is simply not explicitly retrieved when the identity is threatened. In support of this theorizing, measuring memory implicitly reveals good memory performance even under threat. Again, this effect is moderated by strength of identification, with high identifiers exhibiting better implicit memory for the promotions under threat.

Study 3 tests the hypothesis that mitigating the threat via an identity affirmation task restores memory for otherwise forgotten identity-linked promotions. Moreover, this study shows that affirming the university identity restores memory for identity-linked promotions, but affirming aspects of self identity or other social identities does not have this effect. Again, the results are moderated by strength of identification, with high identifiers exhibiting better memory for identity-linked promotions when the threatened aspect of identity has been affirmed, but worse memory for identity-linked promotions in the absence of identity affirmation.

This research documents an elusive memory phenomenon, motivated forgetting, and offers a theoretical framework that predicts situations in which it is likely to occur, what memories are forgotten, and who is motivated to forget. This study also contributes to research on identity-linked marketing. With mass marketing on the decline, firms increasingly rely upon targeted marketing tactics like identity-linking, but despite its widespread use, the efficacy of identity-linking remains unclear. By examining motivated forgetting in the context of identity-linked promotions, we hope to not only advance theory about motivated forgetting, but also address factors that cause consumers to remember or forget identity-linked promotions.

The Individual Propensity to Take a Smell at Products

EXTENDED ABSTRACT

Although the importance of the olfactory system for animals is well understood, its importance for humans is still underresearched. In terms of the sense of smell, marketing research has predominantly investigated effects of product-specific scents as well as effects of in-store aromas on decision-making (e.g., Bosmans 2006). The issue of consumers actively using their olfactory modality in purchase decision-making has largely been neglected. It seems plausible that consumers differ in terms of their individual need for taking a smell at products given the observed variation in sensory needs and habits. Peck and Childers (2003) have shown that such individual differences do exist in the preference for haptic information ("Need for Touch"). Previous consumer research has disregarded the question whether "Need for Smell" exists as a personality trait. The present paper contributes to the exploration of the proposed construct of "Need for Smell" (NFS) in two ways. In a first step, we aim at conceptualizing NFS giving rise to the development of a measurement scale. As a second step, the proposed instrument is tested empirically. We present the first results of the development of a measurement scale for the "Need for Smell" construct (NFS scale) based on the Rasch model for measurement.

The definition of NFS as a personality variable follows the conceptualization of "Need for Touch", that is, the preference for haptic cues suggested by Peck and Childers (2003). Thus, we define NFS as an individual's propensity to gain and utilize information obtained through the olfactory system during the assessment of a product in a purchase decision. If a high NFS cannot be satisfied, the consumer is expected to experience discomfort and uncertainty about the product. In the worst case, the consumer refrains from buying the product. Obstacles that impede olfactory sensations are manifold. The packaging of products, for example plastic wrapping of fruits, may interfere with the consumer's intention to take a smell. Online shopping rules out the possibility of smelling altogether.

Hence, investigating the differential role of the need for olfactory cues among consumers promises to contribute to a more comprehensive understanding of consumer behavior. Building upon different streams of literature from multiple scientific disciplines resulted in initial assumptions about the dimensionality of the construct. We expect NFS to be a multidimensional construct, comprising instrumental (cognitively-toned) and autotelic (hedonically-toned) facets. In the behavioral domain, experiments suggest odour being related to associative learning, emotion and decision-making (Cupchik and Phillips, 2005). The olfactory system has direct anatomical linkages to the limbic system, making it the sensory modality most closely related to brain regions associated with emotions (Wrzesniewski, McCauley, and Rozin, 1999). Moreover, a good sense of smell is capable of eliciting positive emotions (Bosmans, 2006), suggesting the existence of an affectively-(hedonically)-toned dimension. Regarding the assumption of a cognitive dimension, evolutionary biology informs us that odour perception controls domains such as regulation of mood and cognition or food selection (Li, Moallem, Paller, and Gottfried, 2007). Hence, the instrumental dimension refers to pre-purchase smell that serves as an indicator for product evalua-

tion (e.g., quality assessment or expected functional and economic value). Moreover, it is goal-oriented (e.g., making a good choice). Product assessment based on olfactory input can also have an evolutionary foundation, as the smell of a potential food item informs us about its being toxic or distasteful.

Item generation for the NFS scale followed the process utilized by Peck and Childers (2003) and Richins and Dawson (1992). An extensive literature review and three focus group discussions led to the generation of 72 items referring to three different aspects of NFS. A subsequent quantitative pre-study administering an online questionnaire (n=165; convenience sample) aimed at a first empirical investigation of the psychometric properties of these items. The items were presented with a seven-point rating scale, ranging from 'strongly agree' to 'strongly disagree'. By means of traditional scale analysis using exploratory and confirmatory factor analysis as well as modern test theory (Rasch model for polytomous items), unsuitable items were identified and omitted. The majority of the items deleted at that stage either showed ambiguity or poor wording. A set of 35 items was retained representing three different but correlated dimensions of NFS: an instrumental dimension of NFS (11 items referring to a general instrumental facet in terms of "taking a smell facilitates choice and/or adds another informational cue"); an evaluative dimension (12 items) capturing the need for checking the product quality, which is at least partly rooted in evolution, in terms of "using olfaction to prevent negative or even harmful consequences"; and an autotelic dimension which covers the idea that taking a smell at products can be an enjoyable end in itself.

The second quantitative study utilized a representative sample (n=552) and served the purpose of cross-validating the findings of the quantitative pre-study as well as identifying redundant items. The psychometric assessment was based on the Rasch model for measurement using RUMM 2030 (Andrich, Sheridan, and Lou 2010). The three anticipated dimensions were widely confirmed, while several items showed a clear indication of redundancy. Their omission led to a set of 21 items, 8 of which measure the instrumental NFS dimension, 7 items capture the evaluative dimension, while 6 items quantify the autotelic dimensions of NFS. The three dimensions are correlated between 0.74 and 0.85.

So far the proposed existence of a latent variable NFS finds positive evidence in the data. Further studies are needed in order to reinvestigate the suitability of the suggested conceptualization, the dimensionality, and the validity the scale. In particular, discriminant and nomological validity of the NFS scale are to be investigated. Since the sense of smell is subject to individual biological differences as well as to changes related to for instance ageing (Milotic, 2003), biological factors might determine the individual level of NFS. In terms of consequences of NFS, the predictive power of NFS in the context of purchase-related phenomena is to be assessed in experimental settings. In all likelihood, the perceived importance of sensory modalities will vary between types of products (Schifferstein, 2006) and depend on the phase of product usage (Fenko, Schifferstein, and Hekkert, 2010). Ultimately such studies will reveal the relevance of NFS compared to other explanatory constructs.

When Status Pulls You One Way and Another: A Dilemma for Sustainable Investments

Hannah Winkler von Mohrenfels, Frankfurt University, Germany
Corinne Faure, Grenoble Ecole de Management, France
Daniel Klapper, Humboldt University Berlin, Germany

EXTENDED ABSTRACT

According to the Forum for Sustainable and Responsible Investment (US SIF 2012), Sustainable and Responsible Investments (SRIs) roughly account for 3 trillion dollars, that is, about 12% of the total US investment market. Compared to traditional investments, SRIs are not only focusing on financial performance but also on ethical and environmental considerations. Our purpose in this research is to investigate whether status motives, which have been shown to foster pro-social behavior, are also effective in convincing consumers to invest in SRIs.

Griskevicius, Tybur, and Van den Bergh (2010) show that activating status motives is an effective mechanism in making consumers choose pro-social goods. They explain this phenomenon through costly signaling theory: individuals willingly incur the cost of purchasing a product that shows their care about others (or the environment) and use this cost as a signal to increase their status in society (their ability to incur altruistic costs is a signal of their superior status). Activating status motives therefore favors pro-social behaviors. Our focus in this research is to test whether this theory, applied so far to material products, can be extended to SRIs.

Costly signaling theory implies that an altruistic action can be used as signal to others. Because investments are private (unlike the products studied in previous research so far, investments are not potentially visible after the purchase), we suggest that status motives are not sufficient to trigger costly signaling activities; in fact, we argue that status motives are only functioning when the purchase is visible, so that it has some signaling value (Glazer and Konrad, 1996; Harbaugh, 1998); Milinski, Semmann, Krambeck, and Marotzke, 2006).

Consumers have been shown to behave quite differently for material goods and for money. As shown by Morewedge, Holtzman, and Epley (2007), simply thinking about financial accounts is enough to activate wealth considerations in consumer minds. In a recent paper, Goldstein, Johnson, and Sharpe (2008) explore consumer preferences for retirement products; they show that when confronted to financial products, consumers weigh in their expected future wealth with the costs incurred for each product. Furthermore, previous research suggests that individuals acquire wealth not only for the consumption that can be derived from it, but because of the status inducing effect of the money itself: individuals who care a lot about their (financial and social) status in comparison to others are especially interested in maintaining their wealth by gaining money (Bakshi and Chen, 1996); in contrast, persons with a lower income help others more, even if it is harder for them to afford (Piff, Kraus, Côté, Cheng, and Keltner, 2010; Rucker, Dubois, and Galinsky 2011)greater exposure to threat, and a reduced sense of personal control. Given these life circumstances, one might expect lower class individuals to engage in less prosocial behavior, prioritizing self-interest over the welfare of others. The authors hypothesized, by contrast, that lower class individuals orient to the welfare of others as a means to adapt to their more hostile environments and that this orientation gives rise to greater prosocial behavior. Across 4 studies, lower class individuals proved to be more generous (Study 1. In general, caring about status should make investors more averse to poverty and therefore make them choose investments that promise to increase their wealth quickly.

For the purchase of SRIs, we suggest that these two phenomena occur concurrently and we therefore expect consumers to face a dilemma. On one hand, according to costly signaling theory, status motives (and visibility) should make SRIs attractive. On the other hand, to the extent that SRIs are typically less attractive financially than traditional investments, consumers are likely to concentrate on lost future wealth, and therefore on the associated loss in future status associated with a lower investment yield. We therefore predict that when status motives are activated, SRI purchase will only improve in the case where the purchase is made visible; when the purchase is private, we expect status motives to activate concerns about future status loss and therefore to be counterproductive for the purchase of SRIs. We test these predictions in an experimental context.

Our main study consists of a (2 by 2) between-subject experiment, in which we manipulate status motives and decision visibility. 566 individuals (218 women, average age of 30.3 years) participated in the experimental study in exchange for the chance to win some Amazon vouchers. Status motives were manipulated using the scenario developed by Griskevicius et al (2009), in which participants are asked to project themselves in their first day on the job at a new company, with a detailed description focusing on high status features. To manipulate visibility, participants in the public condition were asked to imagine making their investment decision in the presence of an investment consultant and told that they would receive an email containing an evaluation of their performance in comparison to other participants; they were asked for their e-mail address. Participants in the private situation received no such instructions. After receiving background instructions about investment decisions, participants were asked to choose between a conventional investment and a pro-social one (SRI); the conventional product slightly outperformed the SRI. Demand checks at the end of the study revealed that no participant correctly guessed the purpose of the experiment.

We predicted that status activation would hurt SRI choice when choices are kept private and would only benefit SRI choice when choices are made public. Indeed, our results show that making choices public when status motives are active (and this, even though our visibility manipulation actually focused on performance) systematically increased SRI choice ($\chi^2(1) = 22.447$, $p < .01$). Moreover, as predicted, for private choices, status manipulations hurt the probability to choose SRIs over traditional investments ($\chi^2(1) = 5.036$, $p = .025$).

In further analyses, we replicated these patterns of results for a higher performance gap between conventional investments and SRIs and also investigated personality difference factors such as participants' income and experience with investment products.

Our research contributes to the growing literature on pro-social consumption. Our results are consistent with costly signaling theory: we show that visibility increases the likelihood of pro-social behaviors. Compared to recent literature in this area however, our results indicate that for private decisions, status activation can be counterproductive for products such as SRIs where status also activates concerns about potential future wealth loss. This study therefore provides a refined perspective on the effects of status and visibility on pro-social consumption, and offers first policy implications for SRI promotion.

When More Leads to Less: Greater Attentional Bias for Emotional Information is Negatively Associated with Self-Reported Feelings

Daniel Fernandes, Erasmus University Rotterdam, The Netherlands
Bart de Langhe, University of Colorado, USA
Stefano Puntoni, Erasmus University Rotterdam, The Netherlands

EXTENDED ABSTRACT

Social scientists often rely on self-reports to assess emotional experiences. Self-reports of emotional experience are an important tool for understanding and predicting judgment and behavior (Schwarz, 1999). A crucial assumption is that individual difference variables that are positively correlated with the intensity of emotional experience are also positively correlated with self-reports designed to measure that experience. This manuscript documents a violation of this assumption. Individuals who display greater attentional bias for emotional information—and hence experience emotional stimuli as more intense—report to be affected less by emotional stimuli.

Individuals automatically assess the emotional significance of stimuli in their environment (Ochsner & Feldman Barret, 2001). This default, low-road emotional sensitivity drives attention. Individuals who perceive a stimulus as more emotionally intense pay more attention to it (Phelps, 2006). Attentional bias is often assessed by measuring how performance on a focal task suffers as a result of automatically attending to task-irrelevant emotional information.

It seems reasonable to assume that people who display greater attentional bias also report feeling more intense emotions when explicitly asked. For example, greater attentional bias is associated with more intense cardiovascular reactivity to emotional stimuli (Jamieson, Nock, & Mendes, in press) and predicts changes in anxiety (Osinsky et al., in press). However, self-reported feelings are not only determined by the intensity of the to-be-rated emotional experience (i.e., true score) but also by the interpretation of the instrument used to probe it (i.e., measurement error). Respondents typically report their experienced emotions by selecting a response option on a rating scale (e.g., a seven-point scale ranging from "not at all happy" to "very happy"). Besides automatically assessing the emotional intensity of the target stimulus, respondents also assess the emotional intensity of the rating scale anchors. The perceived emotional intensity of rating scale anchors is negatively associated with self-reported feelings (Ostrom, 1966). This is because people who perceive a verbal anchor as more emotionally intense are less likely to endorse it, thus providing lower ratings of emotionality (De Langhe, Puntoni, Fernandes, & van Osselaer, 2011). Thus, greater attentional bias may show a negative correlation with self-reported feelings.

In sum, we propose two countervailing forces. Individuals with greater attentional bias should experience target stimuli as more emotionally intense, but should also perceive emotional verbal anchors on the scale as more intense. The first mechanism should lead to a positive association between attentional bias and self-reported feelings; whereas the second should lead to a negative one. Which of these effects dominate is an empirical question. We conducted six studies to assess the relationship between individual differences in attentional bias and self-reported feelings using a variety of target stimuli (e.g., textual vs. pictorial) and of positive and negative emotions. We assessed participants' attentional bias for emotional information using the emotional Stroop task (Williams Mathews, & MacLeod, 1996), the most frequently used paradigm to assess attentional bias. In this task, participants are asked to indicate as quickly as possible the color of emotional and neutral words. Because emotional words grab attention, performance on the color naming task tends to be worse when the word displayed is emotional. The comparison between reaction times for emotional and neutral words thus reflects one's level of attentional bias for emotional information (i.e., the emotional Stroop score).

In our studies, participants completed the emotional Stroop task and either before or after indicated their feelings after seeing an emotional target stimulus. In study 1, we find a negative correlation between participants' emotional Stroop score and self-reported feelings. In studies 2A and 2B, we also measured self-reported emotional sensitivity (using the Emotional and Interpersonal Sensitivity Measure, EISM; Bloise & Johnson, 2007). The EISM assesses people's beliefs about how sensitive they are to emotional events. It should therefore not be surprising to find a positive correlation between EISM and self-reported feelings triggered by an emotional stimulus. Consistent with our predictions, whereas the emotional Stroop score is negatively associated with self-reported feelings, EISM is positively associated with self-reported feelings. In studies 3A and 3B, we manipulated the amount of elaboration on scale anchors to test whether the negative correlation between attentional bias and self-reported feelings indeed stems from an automatic emotional reaction to scale anchors. In study 3A, half of participants were asked to elaborate on the meaning of the scale anchors before rating, whereas the other half did not receive these instructions. The negative effect of attentional bias to emotional information is attenuated when participants are asked to elaborate on the anchors. In study 3B, we asked half of participants to rate their emotional reactions using large font anchors and the other half to rate using normal font anchors. We find that, when participants use large font anchors (and elaborate more on them), the negative correlation between attentional bias and self-reported feelings is attenuated.

Marketing researchers often study people's emotional experiences by asking them how they feel. But do people who report feeling more emotional really experience more intense emotions? Researchers have criticized the use of self-reports in emotion research because of their low correlation with actual experiences (e.g., due to socially desirable responding). We highlight a different problem. People who display greater attentional bias for emotional information report feeling less intense emotions, implying a negative correlation between actual and reported feelings.

Emotional Marketing:
How Pride and Compassion Impact Preferences for Underdog and Top Dog Brands

Mark Staton, Western Washington University, USA
Neeru Paharia, Georgetown University, USA
Christopher Oveis, University of California San Diego, USA

EXTENDED ABSTRACT

In this research we investigate the impact of the emotions of compassion and pride on both brands that are viewed as strong or weak ("top dogs" versus underdogs), on marketing actions that are compassion-oriented or pride-oriented, in addition to investigating individual differences of people who perceive themselves as high on socioeconomic status (strong) versus those who are lower on socioeconomic status (weak). Participants primed with feelings of compassion show a preference for weaker underdog brands; however when primed with pride they show a preference for stronger top dog brands. In study 2, those with lower socioeconomic status prefer underdog compassion appeals more than underdog pride appeals to a higher degree than people of high socioeconomic status. Taken together, these studies provide promising evidence on the interaction of compassion and pride on strong or weak brands, valence of marketing actions, and personal feelings of power.

Compassion enhances perceived self-other similarity, in particular to those vulnerable and weak. Conversely, pride elicits feelings of being different from vulnerable others, and more similar to those that are considered strong (Oveis, Horberg and Keltner 2010). By extension we propose that feelings of compassion and pride can enhance feelings of similarity, and therefore purchase interest, for brands that exhibit qualities of being strong or weak. Research on top dog and underdog brands has explored how brands can be perceived as strong or weak based on their market position (Hoch and Deighton 1989), or on their brand origin story.

We hypothesize that primed compassion will result in preferences for underdog brands over top dog brands and conversely, primed pride will result in preferences for top dog brands over underdog brands. We also hypothesize that cause-related marketing emphasizing compassion for vulnerable others will be more impactful than pride related appeals for underdog brands, especially for those of low socioeconomic status.

STUDY 1: COMPASSION AND PRIDE INFLUENCE UNDERDOG/TOPDOG BRAND PREFERENCES

Participants were recruited through Amazon.com's Mechanical Turk, and were randomly assigned to one of 4 experimental conditions in a 2 (compassion v. pride) x 2 (underdog v. top dog) between-subjects design.

Participants were induced to feel compassion or pride, read a brand biography for an underdog or top dog company, and then rated their preference for the company on the following dimensions: how much do you identify with the brand (1=very little, 7=very much), how much do you like the brand (1=very little, 7=very much), and how likely are you to purchase the brand (1=very unlikely, 7=very likely). These three ratings were summed to create a brand preference composite (alpha=.84).

RESULTS

A 2x2 ANOVA revealed a significant interaction of induced emotion (compassion vs. pride) and brand status (underdog vs. top dog) on brand preference, $F(1, 95)=8.54$, $p<.01$. Consistent with our hypotheses, simple effects analyses revealed that participants induced to feel compassion preferred the underdog brand (M=14.88, SD=3.15) significantly more than the top dog brand (M=11.52, SD=4.83), $t(47)=2.87$, $p<.01$, whereas participants induced to feel pride preferred the top dog brand (M=13.40, SD=4.20) more than the underdog brand (M=11.44, SD=5.52); however, this latter effect did not meet conventional levels of significance, $t(48)=1.41$, $p=.16$.

STUDY 2: HOW PRIDE AND COMPASSION CAUSE-RELATED MARKETING APPEALS INTERACT WITH SOCIOECONOMIC STATUS

In Study 2, rather than priming compassion or pride, we aimed to show that an ad that elicited feelings of compassion would be viewed more favorably for those with a low socio economic status. We used cause-related marketing ads and predicted that individuals with low subjective SES would respond more positively to compassion-inducing appeals than pride-inducing appeals due to their personal weaker status.

Participants were recruited through Amazon.com's Mechanical Turk service, and were randomly assigned to one of four conditions in a 2 (compassion vs. pride-inducing ad) x 2 (underdog vs. top dog brand) between-subjects design.

Participants first completed the McArthur subjective SES measure (Kraus, Piff and Keltner 2009), wherein participants place themselves on one of ten "rungs of a ladder" representing their place in their community, and then their place in the United States (alpha=.87). Next, participants read either one of two brand biographies and then viewed either a Compassion CRM advertisement or a Pride CRM advertisement for that brand.

Participants then indicated their preference for the brand as follows: how much do you identify with the brand and how much do you like the brand. These items were summed to form a composite brand preference measure (alpha=.83).

We examined separately how brand preferences interacted with consumers' subjective SES in the top dog and underdog condition by regressing brand preference onto ad condition (compassion vs. pride), subjective SES, and their interaction (ad condition*subjective SES).

Consistent with our hypothesis, a significant interaction was observed such that low-SES and high-SES participants responded differently to compassion- and pride-inducing ads from underdogs, $b=.91$, $t(99)=2.06$, $p=.04$. Simple slope analyses revealed that both low-SES, $b=-3.51$, $p<.01$, and high-SES participants, $b=-1.69$, $p<.01$, preferred underdogs significantly more with a compassion-inducing ad versus a pride-inducing ad. The interaction shows that the low-SES slope was significantly steeper than the high-SES slope suggesting that the effect was stronger for those of low-SES.

DISCUSSION

In two experiments, we have shown that compassion and pride can impact attitudes towards "top dog" and "underdog" brands. In Study 1, we illustrated how incidental feelings of compassion will lead to higher attitudes for underdog brands, while incidental feelings of pride will lead to higher attitudes for top dog brands. In Study 2 we illustrated that for underdog brands, compassion appeals are preferred by low SES participants, however this effect is muted for those with high SES.

Theoretically, we believe that this line of research is important by illustrating that the sense of similarity to strong or weak others found in pride and compassion respectively are not just in play with people, but with brands as well. Managerially, we believe that we are further uncovering the information perceived by consumers through relative market position. Also, we show that there are personal factors that influence the impact of cause-related marketing messages.

Ridiculing the Working Class and Reinforcing Class Boundaries:
The Chav Myth and Consumption in the Night Time Space

Hayley L. Cocker, Lancaster University, UK
Maria Piacentini, Lancaster University, UK
Emma N. Banister, University of Manchester, UK

EXTENDED ABSTRACT

Prior CCT research has investigated marketplace myths that "permeate consumer culture" (Thompson 2004, 162), and has understood these myths as "cultural resources that attract consumers to a consumption activity or brand" (Arsel and Thompson 2011 791). Research on identity myths however, has focused on devaluing and undesirable myths such as the southern white identity myth (Thompson and Tian 2008) and the hipster myth (Arsel and Thompson 2011). Whilst Arsel and Thompson's (2011) study enriched our understanding of how consumers' branded by an undesirable marketplace myth attempt to demythologize, further research is needed to explore how and why consumers use marketplace myths to ridicule and stigmatize others. In a separate stream of research, consumer researchers have applied and extended the work of Bourdieu (1984) and the concepts of habitus, field and capital to stress the continuing relevance of social class as an analytic category and advance our understanding of the relationship between social class and consumption (e.g. Holt 1997, Allen 2002, Henry 2005). We bring together recent streams of research on social class and identity myths to explore the link between class-based identity myths and consumption and the role of such myths in reinforcing social class boundaries. In order to demonstrate how young middle-class consumers mobilize the 'Chav' myth, we focus on a specific consumption context where this process is particularly visible - consumption in the nighttime space (e.g. bars, clubs).

Whilst we didn't initially set out to explore the 'Chav' myth, the young participants in our study frequently relied on this myth when discussing their identity (who NOT to be) and framing their consumption behavior (how NOT to consume). The wider study of which this data is a part, explored young people's alcohol consumption in relation to different aspects of the self (positive and negative). A total of 91 participants (aged 16-18) were recruited via four different educational institutions. Data was collected in five phases, drawing from Bahl and Milne's (2010) multi-method approach to identifying multiple selves in participants and exploring consumption from the lens of different selves. We used a combination of written answer booklets, projective techniques and visual research methods (e.g. qualitative clustering task and 3D avatar creation) to elicit young people's constructions of the self. This was followed by individual, paired and group interviews to explore alcohol consumption in relation to different aspects of self.

The term 'Chav' emerged in the UK around 2004, replacing the term 'underclass' and various regional terms (e.g. 'Townies' and 'Scallies') as a way of describing the white working-class. The 'Chav' myth incorporates highly stereotypical notions of the working-class and rests on the belief that there are "entire communities around Britain crawling with feckless, delinquent, violent and sexually debauched no-hopers" (Jones 2011, 80), airbrushing the reality of the working-class lifestyle "out of existence in favor of the chav caricature" (Jones 2011, 11). 'Chavs' have been referred to as a youth 'subculture' (Hollingworth and Williams 2009) and a 'phenomenon' (Hayward & Yar 2006) and similar to the working-class youth subcultures studied by the Center for Contemporary Cultural Studies (CCCS) in the 1970's, such as Teddy Boys, Mods, Skinheads and Punks (see Hall and Jefferson 1976 and Hebdige 1979), the 'Chav' identity has developed around "particular activities, focal concerns and territorial spaces" (Clarke 1976, 14). CCT literature has focused its attention almost exclusively on "self-selecting or achieved (vs. ascribed) subcultures" (Schouten and McAlexander 1995, 43) and subcultures where "membership is usually conscious" (Kates 2002, 397), such as the Gay subculture (Kates, 2002), 'New Bikers' Harley-Davidson enthusiasts (Schouten and McAlexander 1995), Star Trek Fans (Kozinets 2001) and Goths (Goulding and Saren, 2009). In contrast, 'Chav' is tied to an ascribed class-based identity, is a collective label attached to members of the working-class by the dominant class and is used to ridicule (Wooten 2006) and demonize. Membership is often unconscious, in the sense that the majority of so-called 'Chavs' do not readily identify as such, and whilst it may be relatively easy for most people to become a Star Trek Fan or a Goth, it's extremely difficult for middle-class consumers to become a 'Chav' given the strong ties to locality and social class.

Findings from our study emphasize the ways in which young middle-class consumer's draw from the 'Chav' identity myth to construct, support and enhance the self. More specifically, the 'Chav' myth provides these young consumers with a concrete idea of who not to be and is used to reinforce the divide between the 'Chavs' and the 'Chav-Not's'. Similar to Ustuner and Holt (2010) who stressed the importance of the Western Lifestyle myth in relation to status consumption in Turkey, we highlight the relationship between myths and class-based consumption in a Western context. Whereas Ustuner and Holt's (2010) study looked at HCC consumers approaching a desirable marketplace myth, our study focuses on young consumers' avoiding an undesirable marketplace myth. We discuss in detail how young middle-class consumers in the UK mobilize the 'Chav' myth and how this serves to create and reinforce social class boundaries, within the context of the nighttime space. We found that young middle-class consumers draw from various aspects of the 'Chav' myth (e.g. particular dress styles, music preferences and demeanor) to identify, label and ridicule members of the working-class and to inform their consumption choices in the nighttime space (e.g. certain brands of alcohol, clothing styles, music genres as well as certain places and spaces were closely tied to the 'Chav'). Whilst certain aspects of the 'Chav' myth (e.g. violent behavior) played a role in creating boundaries, other aspects of the 'Chav' myth (e.g. clothing styles and brands) were used as a form of identity play and ridicule (e.g. chav-themed fancy dress parties). Additionally, we found that nightlife providers play a role in creating 'divisions in the dark' and reinforcing class boundaries (e.g. door policies refusing entry to those wearing brands associated with the 'Chav'). Our research offers valuable theoretical insights by enriching our understanding of how class-based identity myths are mobilized by consumers and serve to reinforce social class boundaries.

When Soft Drink Taxes Don't Work: A Comparative Study

Andrew Hanks, Cornell University, USA
Brian Wansink, Cornell University, USA
David Just, Cornell University, USA

EXTENDED ABSTRACT

Taxes on energy-dense foods and beverages have been proposed to address the growing obesity problem (e.g. IOM, 2009; Brownell and Frieden, 2009; Jacobson 2004). Average daily sugar consumption, estimated at 11.1 teaspoons per person (Smith, Lin, and Lee, 2010) prompted the Institute of Medicine, the Center For Disease Control and Prevention and several State and local governments to propose a tax on sugar-sweetened beverages, such as full calorie soft drinks (Patterson 2008; IOM Report 2009; Roehr 2009; Rudd Report 2009; Smith, Lin, and Lee 2010). The aim of such a tax would be to reduce calorie intake, improve diet and health, and generate revenue that governments could use to further address obesity-related health problems (Brownell and Frieden 2009; Duffey et al. 2010; Jacobson and Brownell 2000; Powell and Chaloupka 2009, Smith, Lin, and Lee 2010).

Unfortunately, whether taxes on sugar-sweetened beverages have significant impacts on weight is not well understood. Recent estimates regarding the sensitivity of demand for sugar-sweetened beverages to changes in its own price suggest that a 1% increase in the price of sugar-sweetened beverages leads to a decrease in demand for these beverages from 0.8% to 1.2% (see Andreyeva et al. 2009; Brownell et al. 2009). Yet, there are negligible impacts on BMI for adults (Fletcher et al. 2011). This could be due to substitution towards other energy dense goods or a lack of tax saliency at the time of purchase. Finally, much of the previous research has relied on observational data and the effects of state wide sugar-sweetened beverage taxes on aggregate demand, or even BMI. Thus, while these studies are extremely useful, they impose strong assumptions on consumer preferences and data may lack sufficient variation to identify behavior.

Our objective is to compare the results from a controlled field experiment (List 2011; List 2009; Levitt and List 2009; Harrison and List 2004) to previous findings and demonstrate the impact that a tax on full calorie beverages has on the volume purchased of full calorie soft drinks and diet soft drinks. In the experiment, we imposed a 10% tax on full-calorie beverages, and other foods with few nutrients per calorie, on a randomly selected subset of our study's 113 participating households. Individual household purchases at a participating national grocery chain were recorded from August 2010 through February 2011. In August prices remained the same but in September through February, those in the tax group paid an additional 10% for low-nutrient and high-calorie foods and beverages. Although the tax included all foods and beverages with few nutrients per calorie, we focus on purchases of full calories soft drinks and its closest substitute, diet soft drinks.

Compared to data used in previous research, a controlled field experiment allows us to identify how individual households respond to the tax, identify differences in behavior between the tax and control groups, and makes the tax much more salient than the state imposed tax. To analyze the data we collected from the participants, we relied on a random effects panel regression technique with robust standard errors. With this estimation technique we estimate the impact that the tax had on purchases of full calorie soft drinks and its natural substitute, diet soft drinks.

In Figure 1, we plot the average monthly fluid ounces of full calorie soft drinks purchased form Aug-Feb, where fluid ounces in each month were differenced from fluid ounces purchased in August. Even though those in the tax group decreased fluid ounces purchased of full calorie soft drinks, those in the control group did as well. Yet over time, the impact of the tax diminished, though there is some evidence of seasonal variation.

Figure 1: A Tax on Full calorie soft drinks has No Impact on Fluid Ounces Purchased
This similarity in tax and control group behavior is illustrated in Figure 2. The tax appears to have an affect on fluid ounces of full calorie soft drinks purchased between August and September (the first and second bars in the figure for the tax and control treatments), but this behavior is not much different than what we observed in the control group. If purchases for September through November, or even for September through February, are averaged, it is clear that any effect that may have occurred eventually diminished.

Figure 2: Plots of Averages over the Course of the Experiment Demonstrate that the Effect of a Full Calorie Soft Drink Tax Wears Off Over Time
We then estimated the parameters in our regression equation, using either fluid ounces of full calorie or diet soft drinks purchased as the dependent variable. In Table 1, we report that over the course of the study, the tax had no statistically significant impact on fluid ounces of full calorie soft drinks purchased, which is consistent with the unconditional data presented in Figures 1 and 2. Even though we

do find a marginally significant result in purchases of full calorie soft drinks by households in December, an increase of 39.2 fluid ounces, (unreported) regression results demonstrate that the tax has no significant impact in the holiday months. We do find, however, that families with at least two children purchased 52.4 more fluid ounces per month after the tax was imposed, which is approximately equal to four additional 12 oz cans. This could be attributed to resistance to a tax, especially in families with several children who have a strong demand for full calorie soft drinks. This finding still warrants further investigation into the behavior of households with multiple children.

Diet soft drinks, the most intuitive substitute for full calorie soft drinks, were not affected at all by the tax. This, along with our previous results, suggests that a salient tax of 10% on full calorie beverages is insufficient to reduce consumption of full calorie soft drinks, and in larger families, actually increases purchases. Furthermore, households did not substitute towards the next best alternative, diet soft drinks. These findings contribute to the current literature by presenting results from a study where the salience of a tax is not in question and a change in behavior related to the tax is identified by the experimental design. Second, these results uphold the notion that similar taxes on full calorie beverages have no impact on overall health outcomes.

Table 1: A Tax on Sugar-Sweetened Beverages Has no Significant Impact on Fluid Ounces of Full calorie soft drinks or Diet Soft Drinks Purchased

Independent Variables	Dependent Variables	
	Full calorie soft drinks	Diet Soft Drinks
Tax	-6.8	6.5
September	-24.6	-20.9
October	6.0	-32.9
November	21.3	-11.7
December	39.2*	4.2
January	4.2	-2.7
February	0.1	2.8
Married	-1.5	-22.0
No Response (marital)	-37.6	-2.5
$10K-40$K	-3.3	-59.3
> $70K	-1.1	-8.1
No Response (income)	31.3	-5.3
> 1 Child	54.5**	-3.6
Constant	73.9***	151.2**

Results are coefficients from two separate panel regressions of fluid ounces of soft drinks purchased on dummy variables for the tax treatment, months in the experiment, and other household characteristics.

A Weight On Your Shoulders Makes You Pull Your Weight

Minkyung Koo, University of Illinois at Urbana Champaign, USA
Mina Kwon, University of Illinois at Urbana Champaign, USA
Sharon Shavitt, University of Illinois at Urbana Champaign, USA

EXTENDED ABSTRACT

Research on metaphorical thinking has shown that physical experiences are linked to one's thoughts and feelings (e.g., Lakoff & Johnson, 1980, 1999; Landau, Meier, & Keefer, 2011). For instance, physically experiencing a heavy (vs. light) weight increases judgments of importance (Ackerman, Nocera, & Bargh, 2010; Jostman, Lakens, & Schubert, 2009; Zhang & Li, 2011). We argue that the way in which weight is borne can also activate metaphorical thinking. People often use the metaphor "weight on the shoulders" to mean a burden or responsibility for something, which suggests that a heavy burden on the shoulders can increase willingness to take responsibility for a joint effort.

Study 1 demonstrated that merely imagining the experience of a heavy (versus light) weight on one's shoulders has this effect. Participants ($N = 36$) were randomly assigned to imagine wearing either a heavy or a light backpack. They then ostensibly prepared to work with other students in a group project simulation and indicated their willingness to contribute and amount of effort they would put into the project. Imagining wearing a heavy (vs. light) backpack increased feelings of responsibility for and willingness to contribute to the upcoming project ($M_{Heavy} = 5.18$; $M_{Light} = 4.49$), $F(1, 34) = 5.37$, $p < .05$. The results support the effect of the metaphor "weight on the shoulders." Yet, it is possible that actually carrying a heavy (vs. light) weight would result in burden and fatigue that may dampen these effects.

Study 2 was designed to test whether physically experiencing a heavy weight exerts the same effect as imagination did in Study 1. We also sought to support more directly the role of metaphorical thinking by examining whether this effect depends on where the weight is borne. Participants ($N = 184$) were randomly assigned to wear either a heavy or a light backpack on their shoulders, or to hold either a heavy or a light folder on their forearm. Because the same weight is experienced as heavier when carried on the arm (vs. shoulders), we calibrated the actual weight in order to equate subjective weight experiences across the two conditions. Participants reported their perceived weight of the backpack they were wearing or the folder they were holding (1 = very light; 7 = very heavy). There were no differences between the two heavy conditions ($M_{arm} = 3.93$; $M_{backpack} = 4.04$), $F < 1$, or the two light conditions ($M_{arm} = 1.67$; $M_{backpack} = 1.68$), $F < 1$. As before, the study was ostensibly a group project simulation. Participants indicated their willingness to contribute to the group and amount of effort they would put into the project. All participants completed these ratings while standing and carrying the weight on their shoulders [forearm]. Supporting the role of metaphorical thinking, the heavy (vs. light) weight effect was observed only when people carried the weight on their shoulders ($M_{Heavy} = 5.06$; $M_{Light} = 4.42$), not when they held a similar weight on their forearm ($M_{Heavy} = 4.76$; $M_{Light} = 4.82$), $F(1,180) = 4.01$, $p < .05$.

Study 3 addressed a closely a closely related metaphor, "a weight *off* one's shoulders" in order to provide more evidence for the role of metaphorical thinking. If a heavy burden increases felt responsibility to the team, the opposite should be the case when the burden is removed from one's shoulders, according to a metaphorical account. In other words, it is expected that those who take off a heavy backpack will be less willing to contribute to a group than those still wearing a heavy backpack. An alternative account is that the weight effect observed in the previous studies is the result of semantic prim-

ing of "hard work" that is associated with a heavy backpack. If the results reflect semantic priming activated by a heavy backpack, there should be no difference in willingness to contribute between those still wearing and those who just took off a heavy backpack. However, if the effect is due to metaphorical thinking, there should be a difference between these two groups.

Participants ($N = 91$) were randomly assigned to one of the three conditions: heavy backpack on, heavy backpack off, no backpack control. Participants in the first two backpack conditions were asked to wear a heavy backpack. After filling out a short survey and therefore experiencing the heavy weight on their shoulders for a few minutes, one group of participants were asked to take off the backpack (backpack off) while the other group kept it on (backpack on). Those in the control condition were asked to complete the study while standing as in other conditions. We found that people felt less willing to contribute to an upcoming group project after taking off the heavy backpack (i.e., taking a weight off their shoulders) than while wearing the backpack ($M_{on} = 5.55$; $M_{off} = 5.07$), $F(1,62) = 3.89$, $p < .05$. Neither group differed from the control condition ($M_{control} = 5.23$) in willingness to contribute. These findings support the role of metaphorical thinking and suggest that this effect is not an outcome of semantic priming.

CONCLUSION AND FUTURE DIRECTIONS

Supporting the role of metaphorical thinking, imagining or experiencing a heavy weight on one's shoulders increases felt responsibility and intentions to contribute. This effect does not emerge when weight is on one's forearm. Finally, taking weight off one's shoulders apparently has an unburdening effect. Our findings are counterintuitive in that one may expect people to be less willing to contribute effort when they are burdened and fatigued by carrying a heavy weight. This research has novel implications for understanding the drivers of felt responsibility in other contexts. For instance, consumers experiencing a product failure might assign more responsibility to themselves when carrying a heavy versus light weight on their shoulders. Future research can shed light on the underlying processes of this metaphorical effect and its generality to other consumer judgments.

A Meta-Analytic and Psychometric Investigation of the Effect of Financial Literacy on Downstream Financial Behaviors

Daniel Fernandes, Erasmus University Rotterdam, The Netherlands
John G. Lynch, Jr., University of Colorado, USA
Richard Netemeyer, University of Virginia, USA

EXTENDED ABSTRACT

Consumers' financial world used to be more forgiving. Consumers face increasing demands to ensure their own financial security via borrowing, saving, and managing their day-to-day budgets (Boshara et al. 2010). A generation ago, one did not need to know as much to avoid large financial mistakes that are now much more common. These increasing demands on consumers have led many analysts to point to the importance of financial literacy. Many nations around the world have calls for building financial literacy as a capability in the citizenry, spending billions of dollars worldwide to improve financial behavior. Financial literacy is a specialized kind of consumer expertise or knowledge pertaining to how one manages one's financial affairs (Remund 2010). Prior qualitative literature reviews had reached starkly different conclusions about whether financial literacy had "inconsistent" effects or effects so small that government policy promoting financial literacy was misguided.

We scrutinize the effect of financial literacy on downstream financial behaviors via rigorous meta-analysis of 137 papers and 164 studies published in a broad array of disciplines. We include studies of the effects of consumers' measured financial literacy and of financial education interventions. We grouped the types of dependent variables in eight different categories: 1) "Save" (amount saved for retirement), 2) "Plan" (level of planning for retirement), 3) "Debt" (level of debt for each respondent), 4) "Stock Ownership" (how much is invested in stocks), 5) "Investment" (amount invested or return), 6) "Cash Flow Management" (ability to perform healthy financial behaviors in a day-to-day basis), 7) "Plan Activity" (participation and contribution to retirement plans) and 8) "Inertia" (the likelihood to choose default options rather than choosing actively).

The integrated effect size (corrected for sample weighting) is "small" and significant (r = .066, p < .001). (By convention, r ≤ .10 is small; .10 < r < .40 is medium; and r ≥ .40 is large.) These results were based on 165 independent studies and 558,208 cases. Critically, we found significant heterogeneity in effect sizes obtained (Q = 2,784, p < .001), indicating that moderating variables might help explain the variance in the effect sizes. Our primary hypothesis was that this heterogeneity could be explained by larger effect sizes for studies measuring financial literacy rather than manipulating some financial education intervention. Results supported this conjecture: average effect-size was on the low end of "medium" for measured financial literacy (r^2 = .013 for 83 effect-sizes, r = .116, CI_{95} = 0.112 to 0.12) and quite "small" for manipulated financial literacy (r^2 = .001 for 82 effect-sizes, r = .033, CI_{95} = 0.029 to 0.036). As expected, the effect-size of manipulated financial literacy on downstream financial behaviors increases with more hours of instruction and shorter time delay between the intervention and the measurement of financial behavior. But even semester length classroom instruction explained only about 0.3% of the variance in later financial behavior. One explanation is that, interventions produced only small improvements in financial knowledge that serve as a manipulation check for the interventions in 12 studies (sample-weighted r = .056, CI_{95} = 0.043 to 0.068). We conclude that correlational and econometric studies that measure literacy find moderate connections to subsequent financial behaviors, but studies of the effects of financial literacy interventions show weak and almost null effects.

If it is so difficult to intervene to improve downstream financial behaviors, why is measured literacy such a potent predictor of healthy financial behaviors? We thought that the stronger effects of measured financial literacy may be due to either problems of measurement of financial literacy or to the omission of other traits that are correlated with, but distinct from, financial literacy. We follow up our meta-analysis with two primary research studies investigating the psychometric properties of measured financial literacy, its discriminant validity in relation to other constructs, and its nomological validity in predicting downstream financial behaviors. We develop from published items a brief, unidimensional measure of financial literacy from a pool of items used in prior work. We reproduce a number of published findings wherein measured literacy predicts financial behaviors when entered along with demographics. However, we find that the predictive effects weaken dramatically when we include measures of other correlated traits. We discuss the implications of our findings for research on financial literacy and for public policy and private investment in financial education.

In conclusion, forces in the legal, business, and social environment make today's financial world a much more dangerous place for consumers than what their parents faced a generation ago. This observation and a large literature connecting financial literacy to downstream financial behavior has been the impetus for a broad examination of financial literacy and efforts to improve it by governments, employers, and NGOs. Literally billions of dollars are being spent to promote financial literacy. We conducted a meta-analysis to evaluate whether, across all studies, financial literacy is connected to financial behavior. We found a large split between econometric or correlational studies that related measured literacy to financial behavior and experiments or quasi-experiments where there was some manipulation of an educational program intended to improve financial literacy, and thus, downstream financial behaviors. This dissociation occurs in part because financial interventions targeted at changing financial literacy are not effective (especially those with only a few hours of intervention and a long delay between intervention and behavior). Is the solution then to increase the effort towards financial interventions and invest more money on financial education? The answer is no. This is because the effect of financial literacy on financial behaviors is explained by other psychological traits that are not easily changed. In sum, financial interventions often don't work and the effect financial literacy on behavior seems to be explained by correlates of financial literacy. This poses a challenge for financial educators and policy makers about how best to foster healthy financial behaviors.

Gleaning Signals from Soldout Products

Xin Ge, University of Northern British Columbia, Canada
Paul R. Messinger, University of Alberta, Canada
Yuanfang Lin, University of Alberta, Canada

EXTENDED ABSTRACT

This article examines one type of market signal — a soldout product — and the inferences that purchasers make when they observe a soldout product. The notion that preferences of some consumers can shape those of others has been studied in the literature on social influence involving word of mouth, opinion leaders, reference groups, and herd behavior (Godes and Mayzlin 2004; Summers 1970). But inter-personal influence can emerge even without explicit communication or direct observation of other people's behavior. We argue that a soldout condition (when a certain product is sold out) is a market signal that accompanies an indirect mechanism of inter-personal influence on consumer choice.

We consider consumers who are initially uncertain about their preferences for a product, perhaps because they have never tried the product before. A soldout condition is interpreted as a signal that other consumers find the soldout product desirable. We develop and test a model whereby consumers (positively) update their expected preferences for the remaining products that are similar to the soldout product. We call the inference arising from a soldout product, the "preference signaling" effect.

The change in perceived desirability of a product, arising from observed market factors, is consistent with the concept of constructive preferences (Bettman, Luce and Payne 1998; Lichtenstein and Slovic 2006; Tversky and Thaler 1990). According to this view, preference is an evolving, context-dependent process. In the current article, the mechanism of preference construction is modeled as Bayesian updating; and a soldout condition constitutes a signal upon which an update is formed. The current research, thus, demonstrates how Bayesian thinking can underlie preference construction.

To motivate our hypotheses, we develop two Bayesian models: an attribute-free benchmark model and an attribute-based model. Both models require assumptions about consumer beliefs about previous store inventory levels and traffic/visits of other consumers to the store. In the former model, we derive the basic "preference signaling effect" and a boundary condition (whereby the market segment that gave rise to the soldout condition is unrepresentative of the focal consumer's preferences). In the attribute-based model, we demonstrate that soldout alternatives can give rise to the well-known attraction effect (Huber, Payne and Puto 1982; Huber and Puto 1983), which we distinguish from the preference signaling effect. We further demonstrate that a soldout condition can induce attribute weight shifts along the key attribute dimensions of products. We derived four hypotheses from these models.

Hypothesis 1:   *A soldout condition will cause increased consumer preference for an available option similar to the soldout product.*

Hypothesis 2:   *The soldout condition increase consumer preference for an available option (similar to the soldout product) only when the decision maker perceives him/herself to be similar to those who have purchased the soldout product. When a decision maker perceives him/herself to be different from those who purchased the soldout prod-*

uct, the soldout condition will not influence the decision maker's choice.

Hypothesis 3:   *The soldout condition will lead consumers to accord more importance to the attribute dimension on which the soldout product (and the target product) has a high value relative to the rival.*

Hypothesis 4:   *The combined influence of a preference signaling effect and an attraction effect for a similar available option in a soldout condition will be the strongest when the soldout product is inferior to the available option, followed by the case when the soldout product is equal to the available option, and the weakest when the soldout product is superior to the available option.*

These hypotheses were substantiated by with three experiments involving children's toys, exercise classes, and hotels for Hawaii beach vacations. Experiment 1 demonstrated a preference signaling effect, whereby the presence of a soldout product induced a greater choice share for a similar remaining option (H1). Experiment 2 supported a boundary condition whereby, if the soldout condition is attributable to consumers in a segment very different from the focal consumer, then the preference signaling effect does not occur (H2). Experiment 3 provided support for an attribute weight-shift effect (H3) and also showed that an inferior soldout product adds to the preference signaling effect whereas a superior soldout product lessens the preference signaling effect, consistent with H4 concerning the positive and negative attraction effects triggered by soldout products.

To the best of our knowledge, this research is the first to illustrate how Bayesian thinking can constitute a behavioral theory that explains "preference construction" in the face of market signals. This article illustrates an example of preference construction — where consumer preferences are formed or reformed, on the fly, by factors in the purchase environment. We show that a preference signaling effect is an outcome of Bayesian inference-making from soldout product signals. It would be desirable for future research to examine whether other forms of preference construction can be supported with models of Bayesian inference-making.

In particular, Lichtenstein and Slovic (2006, p. 1) argued that preference construction may arise when (1) some of the decision elements are unfamiliar; (2) preferences are unclear and it is difficult to make tradeoffs; or (3) positive and negative feelings are difficult to translate into a numerical response. Lichtenstein and Slovic (2006) also argued that the first situation (unfamiliarity) is rarely studied. This article implicitly restricts attention to such situations where consumers are considering unfamiliar decision options. It would be desirable to extend Bayesian models of thinking to other types of situations where preference construction is commonly employed — involving either tradeoffs between conflicting attributes or numerical quantification of preferences or probabilities. The literature has framed preference construction as a criticism of classical utility theory. From a conceptual perspective, we look forward to application of Bayesian thinking, along the lines illustrated in this article, to help begin to reconcile classical utility theory with the idea of preference construction.

Taking Dogs to Tourism Activities:
Examining a Pet-Related Constraints Negotiation Model

Annie Chen, University of Westminster, UK
Norman Peng, University of Westminster, UK

EXTENDED ABSTRACT

As modern individuals place more value on tourism and become more attached to their pets, growing business opportunities and challenges exist for the tourism industry. Pet-related products (including services) were a US $41 billion industry in 2007, which was ten times more than in 1997 (Chen, Hung, and Peng, 2011). Because the majority of pet owners (75%) consider their pets to be their children (Serpell, 2003, p.84), a large number of owners purchase luxury pet goods, such as pet beds that cost $700-$800 (Cavanaugh, Leonard, and Scammon, 2008; Ridgway, Kukar-Kiney, Monroe, and Chamberlin, 2008). When owners begin to treat their pets better and become more attached to their pets, they also place more value on tourism activities (e.g., American, the British, and Germans). Because of these trends, it is more likely that animal companions will influence owners' tourism participation intention and that some owners will consider taking their pets to tourism activities (Carr, 2010; Chen et al., 2011). This development could have significant implications for marketers and for the literature on tourism participation.

To date, consumer and tourism literature have not fully addressed this issue beyond a general analysis that taking pets to activities is difficult, requires extensive planning, and is more challenging than not taking pets (American Veterinary Medical Association, 2009; Chen et al., 2011). To contribute to the literature and further investigate a pet's influence on its owner's participation of tourism activities (Carr, 2010), this study examines the following question: 'What are the factors that influence an owner's intention to take pets to tourism activities?' To examine this question, this study modified the model of leisure constraints by focusing on a pet's tourism constraints (Jackson, 1993; Hung and Petrick, 2010; Son, Mowen, and Kerstetter, 2008). In addition to pet constraints, this research also tested how an owner's motivation to take a pet to tourism activities and his/her ability to negotiate for needed resources (e.g., time, money, transports) would affect his/her tourism intention (White, 2008; Wilhelm Stanis, Schneider, and Russell, 2009). The following are this research's hypotheses and framework (Figure 1).

Hypothesis 1: A pet's specific constraints will negatively influence its owner's intention to take the pet along for tourism activities.

Hypothesis 2: A pet's interpersonal constraints will negatively influence its owner's intention to take pets when undertaking tourism activities.

Hypothesis 3: A pet's structural constraints will negatively influence an owner's intention to take the pet on tourism activities.

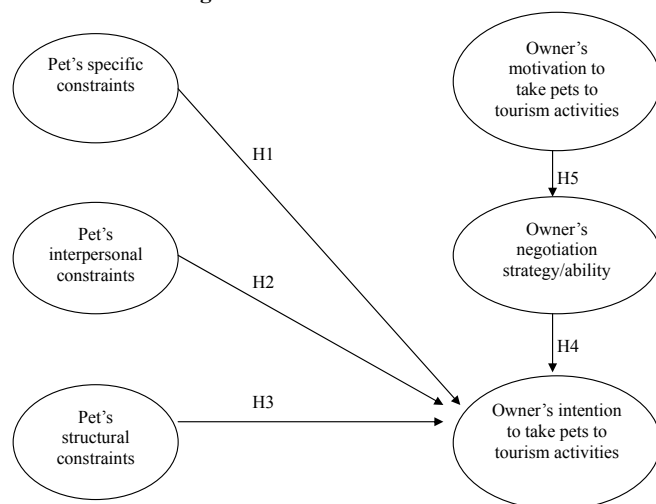
Hypothesis 4: An owner's negotiation ability/strategy will positively influence his/her intention to take pets on tourism activities.

Hypothesis 5: An owner's motivation to take pets on a tourism activity will positively influence his/her negotiation ability and/or strategy.

To examine this study's hypotheses, qualitative and quantitative exploratory pilot test were conducted. After these steps, survey for the main research was finalized and five tourism activities were selected (Chen et al., 2011; Nyaupane, Morais, and Graefe, 2004; Son et al., 2008; White, 2008). The activities were nature sightseeing, visiting cultural sites, recreation, participating in events, and participating in other tourism activities that lasted four hours or more. 251 British adult dog owners were recruited through an onsite purposive sampling method. The sampling areas included the Greater London area, the Southwest, the Midlands, and the Northeast. From the results, 203 surveys were deemed effective, resulting in a valid return rate of 80.8%. All variables in this study's model were measured with multiple items. After examination, all variables are reliable

SPSS 17 and AMOS 5.0 were used to analyse the data. As recommended by Anderson and Gerbing (1988), a two-step approach to structural equation modelling (SEM) was used. After the overall measurement model was found acceptable, the structural model was again tested with the entire sample (N=203). The model fit was good (χ^2=368.961, df=187, RMSEA=0.072, CFI=0.917). According to Fornell and Larcker (1981) and Bogozzi and Yi (1988), composite reliability (CR) should be greater than 0.6 and AVE should be above 0.5 to achieve discriminant validity. Base on result of this research, both of these validities are achieved.

The structure estimate of −0.286 (t=−1.673, p<0.1), −0.789 (t=−6.063, p<0.001), and −0.286 (t=−1.673, p<0.1) show that pet specific constraints, interpersonal constraints and structural constraints have a significant and negative effect on an owner's intention to take pets on tourism activities. As a result, H1, H2, and H3 are supported. In other words, the more constraints the pets have, the less likely it is that their owners will take them to tourism activities. For H4, this study's finding supports the hypothesis that the owner's negotiation ability/strategy will positively affect the owner's intention to take pets on tourism activities. H4's structure estimate was 0.311 (t=2.212, p<0.05), indicating that the more negotiation ability/

Figure 1. Research Framework


strategy the owner possesses, the more likely it is that he/she will have the intention to take pets along for tourism activities. Lastly, H5, which states that the owner's motivation to take pets along for tourism activities will positively affect his/her negotiation ability/strategy, is significantly supported. The structure estimate for H5 was 0.625 (t=5.869, p<0.001). A pet owner is more likely to have a higher negotiation ability/strategy if he/she is highly motivated to take pets along for tourism activities. To test the mediating effects of motivation on negation ability/strategy, a Sobel test was performed (Sobel, 1982). Because the Z value was found to be greater than 1.96 (Z=5.955), negotiation strategy/ability was determined to fully mediate the relationship between motivation and participation.

In conclusion, this study identified and examined the factors that can affect an owner's intention to take pets to tourism activities. The results confirmed that a pet's associated constraints (i.e., pet-specific constraints, interpersonal constraints, and structural constraints) could negatively influence an owner's intention to take pets to tourism activities that they want to attend. In particular, a pet's interpersonal constraints (e.g., other participants do not like pets) will affect an owner's intention most significantly. Despite pets having constraints, if the owner is motivated and has the requisite negotiation ability/strategy, he/she will still plan to undertake tourism activities with his/her pet.

Consuming Branded Stories:
A Netnography of Fashion and Luxury Blog Consumption

Gachoucha Kretz, ISC Paris School of Management, France

EXTENDED ABSTRACT

Blogs have grown rapidly in the last six years. A Mc Kinsey study has reported consumers growing interest in blogs: nearly four in five active Internet users visit social media including blogs to look for product information (NM Incite 2011). Blogs thus contribute to online consumption culture and processes, which justifies better understanding of blog content and impact on consumers.

Blogs offer consumer-generated content and particularly brand and product narratives that can bring "targeted, precise, influential comments and feedback" (Kozinets 2006, 138) both to readers and brands. In particular, fashion and luxury blogs provide consumption or branded narratives helping blogger's identity (Kretz 2010; Zhao and Belk 2007) construction while cultivating consumerist values and consumer culture through conspicuous consumption or brand mentioning. These narratives can be regarded as branded stories told by real characters that sometimes attract large audience.

How people consume stories has been quite substantially studied. Levy (2006) presents a detailed review of scholars of our field who have explained how people consume stories. Particularly, commercials or TV programs have been studied as persuasive stories with effects on consumers. Audience response to stories has been measured through attitude toward ads (McQuarrie and Mick 1999) or perceptions of the surrounding material world (O'Guinn and Shrum 1997) or described through gendered interpretation processes (Stern 1993). Levy (2006, 453) comes up with a breaking new approach of story consumption by exploring how stories are 'consumed, that is, taken up, internalized and transformed'. Outside the consumer research field, media research has addressed long unanswered questions about what the audience 'does' with stories with Katz and Liebes (1986), Ang (1985), Radway (1984) and Hobson (1982).

Overall, existing research shows that readers make use of stories to keep informed; entertain; create and update identities; settle life projects; socialize and communicate and train imagination and emotion. The stories underlying such results, however, are mostly fictional, related to myths or to historical facts. But what happens in the case of blogs that provide branded narratives from real consumers?

How consumers internalize and transform marketing content through branded stories published in blogs is a relevant question for marketers. It raises the issue of a blog's influence toward its audience, particularly regarding the readers' subsequent behavior, while escaping the strict cases of the 'typical endorser' (Friedman and Friedman 1976) or of the 'market maven' (Feick and Price 1987). While no precise short-term action is expected from fiction or myth readers, blog readers should at least better know and like the mentioned brands and at best, purchase them. Therefore, we are here focusing on the effect of branded narratives on blogs' audience and particularly on how they impact consumers' everyday lives.

We have explored audience behavior through Netnography (Kozinets 2010) from 2005 to December 2011, focusing on specific dimensions including: types of blog reading behavior; motivations to read and integration of blog reading in everyday life occupations. Twenty popular (A-list) fashion and luxury blogs – that is blogs attracting the most readers – have been identified to 'thickly describe' and interpret (Erlandson et al. 1993) reader behavior dimensions in commenting, interactiong and linking. The selected A-list fashion blogs mostly mention luxury fashion brands, which explains why we address them as luxury ones. Twenty readers of those popular blogs have been simultaneously selected for member checks through in-depth interviews (Kozinets 2010) and further explanation of their reading behavior and blog reading everyday life consequences. Readers consisted of people who commented or not.

We found that consumers read fashion and luxury blogs like any other story and for the same reasons mentioned by existing research. Blog reading becomes part of an everyday self-indulgence routine sometimes without any goal except for entertainment or discussion with peers and authors and sometimes focused on information search or brand and product recommendation. Readers take up blog stories differently from 'regular' stories because they come from real mundane people they feel are more trustworthy, passionate and thus knowledgeable about specific topics. Like for (auto)biography, bloggers are easier to identify with, to inspire from and model after and thus are more influential in triggering purchase behavior.

Theoretically speaking, we have observed an overall shift in the dynamics between brands and consumers in the marketplace, regarding involving brands and products like luxury and fashion ones. Specifically, we have discovered that purchase decision depends not anymore on the brands advertised but on the quality of the relationship held between the blogger and the readers. Readers who experience parasocial or social interactions with their favorite bloggers more often transform reading into purchase when the product is affordable. Bloggers, however, are expected to abide by a tacit initial contract, that is to remain true their initial content and to their relationships with their audience, if they want to maintain that influence. The present research extends Kozinets et al. (2010)'s findings on consumer-brand relationships to end readers and consumers who internalize the marketing content already filtered by the bloggers.

Our contribution is also empirical. Readers follow blog consumption strategies: they read many blogs every day, but do not internalize them the same way. Depending on the type of popular blog considered ('Celebrity', 'Character', 'Spokesperson' or 'Buddy') they will respectively seek for 'Initiation', 'Inspiration', 'Information' or 'Imitation'. With 'Initiation' they look for backstage and secret insights from the luxury world; with 'Inspiration', they look for atmospheres and creative ideas to take away and adapt for themselves; with 'Information', they merely want to gain knowledge about the luxury world and with 'Imitation', they expect recommendation and products and brands to purchase to construct identities.

Better knowledge of such reading strategies will lead brand managers to avoid mistakes in addressing bloggers and to identify potential spokespeople more efficiently. Indeed, blogs offer access to a wide audience through the blogger as an influencer. However, managers should check the audience reading strategies and expectations: Initiation and Inspiration can only lead to brand awareness building and image bolstering while Information can initiate shopping trips and Imitation can trigger actual purchase.

False but Persuasive Information: The Automatic Success of Infomercials

Claudiu Dimofte, San Diego State University, USA
Richard Yalch, University of Washington, USA
Kyra Wiggin, University of Washington, USA

EXTENDED ABSTRACT

Infomercials exemplify promotional messages wherein extraordinary claims abound. Given their reputation for exaggeration, the persuasion knowledge model (Friestad and Wright 1994) would suggest that consumer skepticism would render them ineffective. However, their continued existence and success indicate that infomercials influence many consumers. Explaining the popularity of an industry employing claims that are "too good to be true" challenges traditional persuasion models (e.g., Petty and Cacioppo 1981). This research presents a novel perspective based on a dual processing framework and experimental support for it.

Conceptual Framework. Infomercial producers employ an intuitive approach to selling that is universally alluring (Donthu and Gilliland 1996). They appeal to basic human needs related to consumers' hopes and desires – an effective way to influence people (MacInnis and de Mello 2005). Visually demonstrating the product claims (as incredible as some may be) makes infomercials more difficult to refute than reading information about these claims. FTC rules against deception may actually benefit infomercials, as consumers might erroneously assume a de facto approval, following the "if it is on TV, it must be true" fallacy that would not extend to print versions.

We propose that the infomercial paradox (persuasion without explicit product claim acceptance), occurs because the claims are also not completely rejected. This state of neither belief nor disbelief motivates consumers to satisfy their curiosity by trying the product and hoping for performance as claimed. In a consumer research classic, Maloney (1962) proposed that the disbelief most people experience when encountering exaggerated product claims is often overwhelmed by an innate curiosity. When advertising information conflicts with extant beliefs, the resulting dissonance must be somehow appeased, often by yielding to the message and trying out the product in an attempt to re-adjust personal brand attitudes (Maloney 1963). His results suggest that advertising that causes consumers to not believe the message claims but arouses their curiosity may be the most effective form of new product advertising.

We propose a two-factor model for explaining the persuasive effects of infomercial-type messages that is derived from "illusion of truth" research that distinguishes between information learning (an explicit process) and truth judgments (often an implicit process). This research (e.g., Gilbert, Krull, and Malone 1990) demonstrates that individuals often accept information as true unless they explicitly evaluate it as false. In the case of infomercials, it is possible that curiosity about the claims and difficulty in directly refuting them because of their convincing visual presentation inhibits the rejection process, especially at an implicit level. Consumers' explicit assessments of the veracity of infomercial claims based on the source may be consistent with their desire to portray themselves as not gullible and naïve (Chapman and Beltramini 2000). However, research on implicit associations often shows an inconsistency between how individuals respond explicitly and implicitly (Greenwald, McGhee, and Schwartz 1998) and their automatic tendencies to link thoughts (even rejected or conflicting beliefs) in memory (Dimofte and Yalch 2011).

Methods for minimizing the appeal of infomercials are suggested by findings (e.g., DiFonzo and Bordia 2002) that inducing skepticism in consumers when they view claims made in doubtful communications reduces their effectiveness. This can be implemented by providing consumers with discounting cues about the infomercial message that highlight the falsity of the claims made therein. However, timing of the discounting cues is important. In the context of demonstrating a sleeper effect, Pratkanis et al. (1998) reported that providing a credibility undermining discounting cue before message exposure eliminates the sleeper effect whereas presenting it after the message results in one. The before presentation alters how the information is processed and stored, whereas the after presentation does not. Thus, if consumers are forearmed with easily retrieved explanations for the deceptive visuals, the infomercials should not be persuasive. On the other hand, once false beliefs have been learned and implicit associations created, they are often difficult to extinguish. Information undermining the credibility of the infomercials will not be effective when presented after exposure to the infomercial.

Study 1. To address the curious nonbelief phenomenon, a first experiment was run that involved exposing subjects to a video excerpt from an infomercial for the Ultimate Chopper or the same information content in a textual presentation format. The infomercial was presented alone or preceded / followed by a discounting cue (an excerpt from an investigative report highlighting the product's false claims). Explicit measures were collected (brand rating, believability, curiosity, etc.) after the presentation. Finally, participants performed one of two Implicit Association Tests (Greenwald et al. 1998) looking at novel automatic associations created for the Chopper and a competing brand (Henckels). The items used in the IATs assessed the relative association between the brands and truthfulness attributes (believable/ unbelievable in IAT_1) or curiosity attributes (boring/interesting in IAT_2).

Results (see Table) showed that presenting the infomercial by itself was the most persuasive at both explicit and implicit levels, suggesting that the specific format of this marketing communication is indeed conducive to attitude change. Interestingly, the same information presented in a text format was deemed most believable but performed the worst in terms of eliciting curiosity and attaining persuasion. Exposure to the discounting cues either before or after the infomercial was successful in eliciting suspicion and hurt both explicit believability and curiosity, but only the pre-exposure cue lowered the infomercial's persuasive impact (in line with Pratkanis et al. 1988). Despite the explicit effects of the postexposure discounting cue, the infomercial was nevertheless perceived as relatively believable and elicited curiosity at implicit levels.

Conclusion. In summary, it appears that infomercials are successful because they stimulate a curious nonbelief that operates differently at the explicit and implicit levels. Explicitly, consumers are curious but reject the product claims as unbelievable. However, at an implicit level, consumers are both curious and more accepting of the product claims (i.e., they now have a stronger implicit association between the claims and the advertised brand compared to a nonadvertised brand). The implicit effects are most critical because they seem resistant to efforts to undermine the credibility of the infomercial by providing discounting cues.

Table 1: Means for main dependent variables in Study 1

	Infomercial	Discounting Cue + Infomercial	Infomercial + Discounting Cue	Text
Believability	4.45	3.71[a]	3.59[b]	4.78[a,b]
Curiosity	4.48	3.98	4.19	4.32
Attitudes	7.65[a,b]	5.93[a]	6.48	5.98[b]
Implicit Curiosity	.23[a,d]	.11[b,d,e]	.20[c,e]	-.29[a,b,c]
Implicit Believability	.31[a,b,c]	.01[a,d,e]	.16[b,d]	-.19[c,e]

9-point scale for attitude, 7-point scales for believability and curiosity; IAT means are D-measure. Values with shared superscripts are significantly different at $p < .05$ or lower

Social Power and Financial Risk Taking: The Role of Agency-Communion

Didem Kurt, Boston University, USA

EXTENDED ABSTRACT

Often described as individuals' ability to control resources of their own and others without social interference, power has been shown to impact different aspects of human behavior. Recently, researchers have begun to explore the effects of power on individuals' consumption and spending patterns. This stream of literature documents that experiencing a state of powerlessness versus powerfulness leads consumers to spend more money on status related items (Rucker and Galinsky 2008), as well as on the items they purchase for others versus themselves (Rucker et al. 2011). In the present research, I investigate an alternative channel through which social power can influence consumers' welfare, namely financial risk taking.

Consumers often face risky monetary decisions such as investing in a stock versus bond fund, buying a lottery ticket or making a bet in a gamble. These decisions, in turn, have important implications for their welfare and well-being. However, little is known how individuals' interactions with others influence their financial risk taking. A recent study by Levav and Argo (2010) demonstrates that an interpersonal touch (i.e., a comforting pat on the shoulder by a female experimenter) increases individuals' propensity to make risky financial decisions. In this study, I focus on the link between financial risk taking and a more prevalent social force that generally has negative connotations, i.e., social power.

I propose that having power versus lacking power over others does not unconditionally affect people's risky financial decisions. Rather its impact depends on individuals' agency-communion orientation. Agency refers to a tendency to reflect on one's individuality and emphasizes the self and its separation from other organisms, while communion refers to the merging of an individual in a larger organism and social connections with others (Bakan 1966). I argue that feeling powerful versus powerless leads to greater financial risk taking only for agentic individuals. I built my prediction on Chen et al.'s (2001) relationship-orientation based conceptualization of power's effects, which proposes that self-focused individuals associate social power with self-interest goals, whereas other-focused individuals link power with responsibility goals. That is, agentic individuals experiencing a state of power take greater financial risk since increased wealth can fortify their powerful position and help them maintain their status. On the other hand, taking risk to enhance wealth and maintain the status associated with power is inconsistent with communal goals. Thus, agentic individuals with high (versus low) power are expected to make riskier financial decisions, whereas communal individuals with high (versus low) power are predicted to refrain from taking higher financial risk.

Study 1 employs a 2 (power: high vs. low) x 2 (orientation: agency vs. communion) between-subjects design (N = 94). Power was manipulated using an episodic priming task adapted from Galinsky et al. (2003) and agency-communion orientation was measured. Following previous research (e.g., Kurt et al. 2011), I created a measure to assess relative agency orientation, "ACDIF", by subtracting each respondent's communion score from his/her agency score. Participants were asked to imagine that they were given $100 and told that they could participate in a 50-50 gamble in which they could win an additional $100 or lose $10, $20,…, or $100. They indicated whether they would accept each of these offers. Among the offers accepted by a participant, the highest amount s/he is willing to risk to earn additional $100 is the dependent variable. As predicted, I found a significant interaction between power and ACDIF ($\beta = 3.56$, $p < .05$). Post-hoc analysis reveals that the slope for high ACDIF (i.e., agentic) participants is positive and significant (b = 5.031, $p < .05$), indicating that the experience of power increases agentic individuals' tendency to take financial risk. However, the slope for low ACDIF (i.e., communal) participants is negative and insignificant (b = -3.575, *ns*). The next study tests the underlying mechanism for this effect. Specifically, I argue that high power leads agentic individuals to take more financial risk only when self-benefit obtained from the risky decision is high.

Study 2 employs a 2 (power: high vs. low) x 2 (orientation: agency vs. communion) x 2 (self benefit: high vs. low) between-subjects design (N = 307). Power and self-benefit were manipulated, whereas agency-communion orientation was measured. Participants were asked to imagine that they have participated in a charity event where they can play "Odd-Even?", which is a game of chance based on correctly guessing whether the winning number is odd or even, and that they have $100 to bet. Participants assigned to the high (low) self-benefit condition were told that they can keep 75% (25%) of their winnings, whereas 25% (75%) of their winnings are automatically donated to the charity. I found a significant three-way interaction among power, self-benefit, and ACDIF ($\beta = 2.25$, $p < .05$). More important, the slope for high ACDIF and high self-benefit is positive and significant (b = 6.495, $p < .05$), suggesting that agentic individuals with high power take higher financial risk when the positive outcome of the risky decision benefits mostly themselves. In contrast, they take less risk when self-benefit is low (b = -5.421, $p < .05$). However, having power versus lacking it does not have any impact on financial risk taking of communal individuals regardless of the level of self-benefit.

Study 3 tests the underlying process via mediation analysis (as outlined in Zhao et al. 2010) and employs a 2 (power: high vs. low) x 2 (orientation: agency vs. communion) between-subjects design (N = 84). Participants were asked to imagine that they would allocate their $5,000 between a stock fund and a bond fund. Again, there was a significant interaction between power and ACDIF ($\beta = 6.00$, $p < .05$). As expected, agentic individuals with high power take more risk and invest a higher percentage in the stock fund (b = 10.274, $p < .05$). More important, this effect is mediated by the extent to which participants associate power with self-interest goals measured using a two-item scale (e.g., "Power should be used to benefit the self"). Specifically, the estimated 95% confidence interval around the indirect effect of power on % allocated to the stock fund through self-interest goals does not contain zero (0.12 to 4.40), supporting mediation.

Overall, the present research demonstrates the asymmetric impact of social power on financial risk taking of agentic and communal individuals and contributes to the literature in several important ways. First, this research adds to the growing body of work examining the role of social power in consumer behavior. Second, it furthers our understanding of how consumers' interactions with those around them influence their financial risk taking. Finally, it contributes to the recent literature on the link between consumers' agency-communion orientation and their monetary decisions.

When Up Is Down: Natural Height Congruency in Product Evaluation

Michael Giblin, University at Buffalo, USA
Aner Tal, Cornell University, USA
Brian Wansink, Cornell University, USA

EXTENDED ABSTRACT

Despite the endless variety of products and customization options that saturate the world's markets in nearly every domain, marketing campaigns have a tendency to be one minded about certain beliefs, such as the superiority of high shelving space over low shelving space. This view is supported by metaphor research. However, situations may arise in which items shelved high up are at a disadvantage due to a violation of consumer expectations of "natural height".

Contemporary metaphor research suggests that metaphorical constructs become deeply rooted in our basic understanding of a phenomenon, forming a solid way of conceptualizing such abstract phenomena using physical concepts. With the vertical height metaphor, height is presented as the concrete infrastructure that metaphorically orders clusters of abstract ideas, such as good and bad, sophisticated and simplistic, and powerful and powerless (Lackoff and Johnson, 1980). However, what if item placement violates our expectations of where the item should naturally appear? In those cases, could up be bad and down good?

The benefits of congruency have been shown in a wide array of domains. Consumers weigh dimensions of a product more heavily when it is compatible with their goal (Tversky, Sattath, &Slovic, 1988). Extensive research on expectation congruency has given rise to theories of a confirmation bias (Watson, 1960), as well as disconfirmation processes (Cohen & Goldberg, 1970) leading to positive and negative affect. Congruency has proven an important factor in consumer responses to products (Chandon et al., 2010, Olshavsky and Miller, 1972, Spangenberg et al., 2005).

Congruency effects have been demonstrated in the realm of vertical height (see Landau et al., 2010, Meier et al. 2006, 2007, 2009 2011). Participants performed a musical task more quickly and efficiently when the vertical orientation of three keys was congruent with pitch (high key=high pitch, low key=low pitch) (Keller & Koch, 2008). Meier and Robinson (2004) found that participants were able to evaluate positive and negative words more quickly if the words were presented in congruent positions to valence (positive up, negative down). Across four studies, we demonstrate how natural-height congruency affects evaluations, overriding a general up=good tendency.

In study 1, four fruit that grow either high (apples, bananas) or low (melons, tomatoes) were placed on high or low displays, such that one each of the high and low fruit was in its proper position, and one each was in an incongruent position (e.g., lower shelf for bananas). Participants (N = 69) were instructed to take each fruit from its place and rate how tasty the fruit would be on a scale of 1 to 9 (not at all to very much). Fruit taste was rated higher for fruit placed in a position matching their natural growth height (6.68) than for fruit placed in a mismatched position (6.02) : $F(1, 62) = 15.71$, $p = .0002$.

In study 2 (N=50) we sought to replicate the findings of study 1 in the realm of consumer products, eliminating alternate explanations for study 1 that may claim that natural fruit height is in direct correlation with freshness (an apple on a tree vs. on the ground). Here, women's clothing was evaluated as more attractive (9-point scale) when placed at a position matching their natural height. Upper clothes (blouse, sports-bra) were rated more highly on upper shelves, but lower clothes (skirt, panties) were rated higher on lower shelves. No such effect was found for men's clothing. Thus, in a joint model containing both types of clothes there was a significant interaction between condition and gender of clothing: $F(1, 49) = 7.27$, $p = .01$. In this joint model the effect was non-significant (p>.1). However, a contrast for women's clothing only was significant: $F(1, 49) = .546$, $p = .02$. This finding suggests that while natural order congruency tends to lead to higher ratings, the underlying force driving this effect is susceptible to subtle differences such as preconceived notions of clothing gender.

Consequently, study 3 examined a less gender-specific domain: sports balls. While our previous studies have focused on natural height in the sense of where one general sees an item, study 3 turns its focus to utility, or where an item would naturally be most readily accessible and usable. One naturally high (volleyball) and one naturally low (soccer ball) sports item was used. Items were chosen to be as similar as possible in size, function, and familiarity. Participants (N=96) rated their willingness to buy each item. Participants had higher willingness to buy for volleyballs when placed on a higher shelf (5.02 vs. 3.91), but lower willingness to buy for soccer balls placed on a higher shelf (3.81 vs. 4.57): $F(1, 88) = 5.25$, $p = .02$.

To support the idea that it is learned natural height associations underlying our effect, in study 4 we plan to use ambiguous items with no obvious natural height and assign participants randomly to natural height conditions. By manipulating what participants believe to be the natural height of items, we can examine what role preconceived notions play in perceived congruency and subsequent affect. Participants will be given surveys that begin with a paragraph about each item that includes its natural height. We expect more favorable evaluations for highly shelved items for which we create an "up" expectation, and lower evaluations for upper shelved items for which we create a "down" expectation.

Rather than finding a dominant up = good effect, the current research found that items may be evaluated better when placed on lower shelves if they are naturally associated with lower height. We find a reversal of the positive associations elicited by increased vertical height when up is an unnatural position for an item. Collectively, these results argue against the generality of the up = good metaphor, arguing that instead up is good when up is natural, whereas down can be good when down is natural. Theoretically, such findings indicate metaphorical mappings may not be as general as once thought. Pragmatically, they indicate the limitation of the general belief that upper shelves are better shelves.

Sadder, but Not Wiser: The Myopia of Misery

Jennifer S. Lerner, Harvard University, USA
Ye Li, Harvard University, USA
Elke U. Weber, Columbia University, USA

EXTENDED ABSTRACT

Intertemporal choices, which require a decision between a sooner (usually smaller) reward and a later (usually larger) reward, are pervasive in daily life and have important consequences. Given the choice between a sooner reward and a later reward, people typically choose the sooner reward, exhibiting in economic terms irrationally high discount rates, which have been linked to a multitude of undesirable consequences including insufficient savings, drug use, and obesity.

Although emotion is often posited as the main driver for irrationally high discount rates (Bazerman and Moore 1990; Loewenstein, Read, and Baumeister 2003), no studies have tested for their causal role, except for some recent research finding that positive emotion reduces the preference for present over future outcomes (Ifcher and Zarghamee 2011; Pyone and Isen 2011). On the other hand, the appraisal-tendency framework (Lerner and Keltner 2000, 2001) posits that sadness is characterized by appraisals of experiencing irrevocable loss and thus is accompanied by action tendencies to change one's circumstances, perhaps by seeking immediate rewards (Lerner, Small, and Loewenstein 2004). Consistent with this view, research has found that individuals induced to feel sad spend more to purchase items and demand less to sell their possessions than do neutral individuals (Lerner et al. 2004). Sadness has been shown to trigger a generalized devaluation of the self (Cryder et al. 2008), which creates an implicit desire to enhance what William James (1890) called the "material self."

Three incentivized experiments randomly assigned decision-makers to emotional states to test the hypothesis that sadness, but not other negative emotions, would increase impatience in intertemporal choices. Experiment 1 induced 202 participants (57% female; ages 18 to 63) to feel neutral, sad, or disgusted using standard protocols including watching a video and writing an essay. The emotion-induction procedure was effective in both magnitude and specificity. Sad-condition participants reported feeling more sad than feeling neutral, or any other measured negative emotion, including anger and fear. Comparable specific effects were found for the neutral and disgust conditions.

Participants then made 27 choices between receiving cash today (between \$11-\$80) or more cash (between \$25-\$85) in the future, ranging from 1 week to 6 months (Kirby, Petry, and Bickel 1999). We used maximum-likelihood estimation to fit choices to an exponential discounting function, $D(t) = \delta^t$, where *smaller* values of δ (the annual discount factor) indicate more impatience. Results for hyperbolic discounting were similar. Even though induced sadness should be irrelevant to these decisions, it exerted strong, unique effects on discounting. Sadness significantly increased preference for immediate rewards. In monetary terms, whereas the median sad participant accepted \$37 today rather than wait 3 months to receive \$85, the median neutral participant required \$56 today. Importantly, disgusted participants discounted about the same as neutral participants did and less than sad participants did.

Experiment 2 applied Query Theory (Weber et al. 2007), a cognitive process model of preference construction, by asking 189 participants (70% female; ages 19 to 69) to list their thoughts before making intertemporal choices between receiving \$50 today or amounts between \$55 and \$105 (in \$5 increments) in 3 months. Participants provided their thoughts on this choice, made their decision, and subsequently coded their thoughts on whether each one favored receiving the money now, later, both, or neither. Sad participants were again more impatient than neutral and disgusted participants, valuing \$50 in a year's time \$6.50 less. Moreover, Experiment 2 identified a mechanism for how sadness affected discounting: reasons for the immediate reward came to mind sooner and more frequently when participants had been made sad.

Experiment 3 introduced a new question. Does sadness produce a general increase in impatience or is its effect limited to choices offering an immediate payoff? A key innovation in modeling discounting distinguishes between two types of processes that are represented in the quasi-hyperbolic discounting function, $D(t)=\beta\delta^t$, for $t > 0$ (Laibson 1997; O'Donoghue and Rabin 1999). One process (δ) reflects economically rational—i.e., time-consistent—exponential discounting of rewards that is sensitive to the length of delay, t. The other process, "present bias" (β), discounts all future rewards when there is *any* delay (regardless of its length) and therefore cannot be strictly rational. We tentatively hypothesized that sadness would increase the desire to get something *now*, not just sooner, and should therefore increase present bias (β) more so than it increases time-consistent discounting (δ). Experiment 3 asked 203 participants (66.5% female, ages 19 to 68) to make 42 choices between A) immediate rewards versus later rewards; or B) later rewards versus even later rewards. As predicted, sadness resulted in greater impatience for A choices, but not B choices. Sad participants preferred immediate rewards to later rewards more strongly than neutral participants, but were no more generally impatient. That is, sad participants were more *present-biased* (Laibson 1997).

Sadness may make people wiser in some contexts (Alloy and Abramson 1979), but in our experiments, it made them more impatient, not an attribute associated with wisdom. Across three experiments, the median sad participant valued future rewards (i.e., delayed by three months) 13% to 34% less than the median neutral-state participant. Moreover, sadness increased present bias, consistent with the idea that immediate rewards can be self-bolstering.

These experiments demonstrated the causal effects of sadness on impatient intertemporal choices. For ethical reasons we could not induce high-intensity emotion. Observed effects arose from low-intensity, experimentally-induced feelings of sadness that would undoubtedly be dwarfed by the real-life sadness people may experience after the death of a loved one or after a devastating natural disaster. Strong feelings of sadness over the loss of a family member can thus be expected to show far greater effects on the many high-stake intertemporal decisions involved in settling the deceased person's estate. Sadness and depression are also common experiences for people who have been laid off. Our results suggest that such individuals might exacerbate their financial hardship by making intertemporal consumption decisions that favor immediate consumption more than is warranted or wise.

Walk A Mile In *My* Shoes: Psychological Ownership And Psychological Distance

Bart Claus, Iéseg School of Management, France

EXTENDED ABSTRACT

Ownership is a key concept to set consumer behavior apart from related disciplines. Nevertheless, the psychological nature of this construct has been grossly understudied. Our studies use CLT to show that ownership is related to psychological closeness, and conversely, low construal levels facilitate seeing objects as one's possessions.

INTRODUCTION

Ownership of products and its transactions has recently been highlighted as one of the core topics unique to consumer research (MacInnis & Folkes, 2010). While extensive research has reported on effects of ownership – e.g. the endowment effect (Thaler, 1980), the mere ownership effect (Beggan, 1992), – much of this literature takes a transactional perspective where ownership is acquired or lost in a "legal", objective way. This approach has banned the difficult to measure psychological state of ownership to a 'black box' between its antecedents and consequences. Only recently, consumer literature has begun to look at psychological ownership as a distinct phenomenon (Morewedge, Shu, Gilbert, & Wilson, 2009; Peck & Shu, 2009). The perspective of psychological ownership allows to think about ownership as a continuum (to what extent do your children feel the house they live in is theirs, although legally they probably have no claim?) and also permits a distinction between an affective and an ownership component in the study of ownership transactions (Shu & Peck, 2011).

However, this understanding is far from complete, and it is here that we aim for a contribution, by relating psychological ownership to the well-established concepts of psychological distance and Construal Level Theory (CLT) (Trope & Liberman, 2010). Many authors discussed the importance of "an association" between a person and objects in the genesis and perception of ownership (Beggan & Brown, 1994; Friedman, 2008). in terms of Here we test the hypothesis that the "(strength of) association" underlying psychological ownership can be seen as psychological closeness, with effects as predicted by CLT. The studies reported below test this hypothesis.

OWNERSHIP AND CONSTRUAL LEVEL

These studies aimed at testing whether owners think about objects in a more concrete way, a prediction based on CLT that should hold if owned objects are indeed lower in psychological distance than non-owned ones.

Study 1a used scenario's (Wakslak, Trope, Liberman, & Alony, 2006) to find that, when asking participants to classify objects in groups, professional movers made fewer categories (M = 1.97, SE = .059) than the owners of the objects to move ($M = 2.15$, $SE = .063$; $t(85) = 2.07$, $p < .05$). The same difference was observed between insurance brokers (M = 1.98, SE = .059) and the owners of objects ($M = 2.17$, $SE = .065$; $t(85) = 2.12$, $p < .05$).

Study 1.b. omitted the third person perspective present in 1.aa., showing an interaction effect ($F(1,71)=10.14$; $p<0,005$) indicating that participants were quicker to detect a detail-change between two near-identical pictures of a cup they were asked to imagine was theirs, relative to non-owners ($t(71) = 2.18$, $p < .05$). The opposite was true for global, contextual changes ($t(71) = -2.35$, $p < .05$).

Study 2 elaborated on the previous results by showing how typical endowment studies can be explained in terms of changes in construal level (CL): participants were asked to evaluate an owned [non-owned] flat and list all places of significance in it (could be rooms or parts of rooms). This measure was used to assess the level of detail participants used in their thinking as a proxy for their construal level. Results showed an indirect effect of the ownership manipulation on valuation of the apartment, mediated by the number of places mentioned ($M = 9641.63$, $SE = 5119.59$, $LL99\% = 1676.18$, $UL99\% = 22224.50$). Actually, the same is true when we replace valuation with a scale of perceived ownership (Peck & Shu, 2009) ($M = .16$, $SE = .10$, $LL95\% = .0013$, $UL95\% = 0.39$).

CONSTRUAL LEVEL AND OWNERSHIP

Mirroring the previous studies, we also tested whether a concrete mindset would instigate effects that are usually the result of ownership manipulations.

In study 3.a., a cup was shown and participants were asked to list reasons either why or how a cup can be used. We then gauged participants' perceived ownership and valuation of this cup, finding an indirect effect where perceived ownership functioned as a mediator between the manipulation and valuation ($M = .30$, $SE = .16$, $LL95\% = .050$, $UL95\% = 0.63$).

Study 3.b. again used a manipulation of psychological distance, i.e. physical distance (Fujita, Henderson, Eng, Trope, & Liberman, 2006), where by means of perspective in a picture, an object (in this case a parker pen in an ad) is represented as close or far. Again, we found that manipulating psychological distance is related to ownership, as we found an indirect effect of this manipulation on valuation of this pen, mediated by perceived ownership ($M = .62$, $SE = .32$, $LL95\% = .095$, $UL95\% = 1.37$).

DISCUSSION

In several studies, we show that ownership is associated with lower levels of construal, and that in turn, lower construal level facilitates feelings of ownership. We consider our contribution to be twofold. First, we demonstrate that psychological distance is an important driver of psychological ownership. We start building a more explicit and comprehensive theoretical account of psychological ownership in which earlier studied idiosyncratic drivers of ownership effects can be embedded. Second, we use that framework to make new predictions about effects that further help our understanding of the nature of psychological ownership. Obvious implications might be found in store atmosphere design, in research that investigates the modalities of (psychologically) long-distance shopping (i.e. internet, mail order, future delivery, etc.) or perceptual effects in advertising. As the proposed framework allows for clear hypotheses about the processes that relate owners to their possessions, other future research could deal with the investigation of characteristics that loop back and forth between owners and their possessions. It would for instance be easy to imagine that self-worth affects the importance we attach to our possessions, and our findings could shed new light on the well-established idea that we derive status from certain types of possessions. In short, we are convinced that the theoretical step our work makes can spur future research in a host of domains.

Reducing Majority Customers' Prejudiced Behavior in Inter-Ethnic Service Encounters - Applying a Stress and Coping Framework.

Simon Brach, Friedrich-Schiller-University of Jena, Germany

Arne Albrecht, Friedrich-Schiller-University of Jena, Germany
Patrick Hille, Friedrich-Schiller-University of Jena, Germany
David Dose, Friedrich-Schiller-University of Jena, Germany
Mario Schaarschmidt, Friedrich-Schiller-University of Jena, Germany

EXTENDED ABSTRACT

Research on prejudiced behavior in services has largely focused on discriminative actions committed by majority employees towards minority co-workers (e.g. Cortina 2008) or customers (e.g. Crockett, Gier, and Williams 2003; Walsh 2009). With few exceptions (Bendick 2007; Cocchiara and Quick 2004; Etgar and Fuchs 2011; Hekman et al. 2010), the investigation of customers' prejudiced behavior towards minority service employees has been largely neglected. These studies show that customers' discriminative behavior towards minority service employees has several negative effects on employees' health and motivation (Bendick 2007; Cocchiara and Quick 2004). Furthermore, racial bias negatively affects majority customers' evaluations of minority service employees' performance, the service setting and the overall company (Etgar and Fuchs 2011; Hekman et al. 2010).

We based our research on the stress and coping framework by Trawalter and colleagues (2009). The framework suggests that behavior within inter-ethnic contact situations, like inter-ethnic service encounters, depends on the outcome of the comparison of two appraisal processes—situational demands and available (physical, cognitive and social) resources. If the relevant resources available are sufficient to meet the situational demands, positive behavior will result. If the demands are higher than the resources available, negative or discriminative behavior will result. As inter-ethnic contact situations are perceived as more demanding for the parties involved compared to same-ethnic contact (e.g. Page-Gould, Mendoza-Denton and Tropp 2008) the stress and coping framework predicts that inter-ethnic service encounters are likely to be characterized by negative (e.g. discriminative) behavior of majority customers towards minority service employees. The stress and coping framework further predicts that by increasing relevant (e.g. social) resources, negative behavior in situations with higher demands like inter-ethnic service encounters can be neutralized.

METHOD

We employed an experimental video-based paradigm from research on inter-ethnic contact situations (Vorauer and Turpie 2004). Videotaped inter-ethnic compared to same-ethnic service interactions between majority participants and confederate service employees are analyzed by independent raters to test the predictions derived from the stress and coping framework. Raters' codings of participants' behavior served as the dependent variable in the analyses. During the interaction participants rated their perception of the social resources provided by the employee.

FINDINGS

The results show that majority participants' discriminate against minority service employees. This supports the first prediction from the stress and coping framework. Further, the results indicate that majority participants' discriminative behavior towards a minority service employee is influenced by the level of social resources, provided by the service employee during the inter-ethnic service encounter. The results reveal that if majority participants perceive the level of relevant resources provided by the minority service employee as being high, discriminative behavior towards minority service employees is neutralized. This finding is in agreement with the second prediction from the stress and coping framework.

CONTRIBUTIONS

Our findings suggest that discrimination toward minority service employees in inter-ethnic contact situations is not a forgone conclusion. By drawing on the stress and coping framework we provide a theoretical basis for discrimination in inter-ethnic contact situations which emphasizes the importance of resources; therefore, there is scope for influencing the occurrence of discrimination towards minority service employees.

Inter-Consumer Competition:
When Consumers Compete in the Marketplace for Products, Services, and Prizes

Derick F. Davis, Virginia Tech, USA
Kimberlee Weaver, Virginia Tech, USA

EXTENDED ABSTRACT

Consumers must compete among themselves for a variety of goods, services, discounts, and prizes available in the marketplace. For instance, consumers compete with one another when they enter a sweepstakes, contest, or lottery, they also compete when bidding in an auction, making dinner reservations on Saturday night, when waiting in line for black Friday deals, or when submitting an offer on a house or rental application in a tight market. Here we are interested in factors that influence consumers' motivation to engage in competition with other consumers. Our investigation builds upon a recent finding from social psychology referred to as "The N-effect" which states that as the number of competitors increases, competitive motivation decreases, even when the rewards and outcomes are held constant (Garcia and Tor 2009).

The current studies advance this theory by assessing whether the features of two types of common contests where consumers compete, lotteries where contestants simply enter their names in a drawing, and competitions where contestants must submit a skill-based work, will moderate the effects of group size on consumers' motivation to engage in consumer competition in the marketplace.

Past work on competition in marketing has focused almost exclusively on the firm-perspective of competing for customers or pioneering/competitive advantage (e.g. Day and Wensley 1983; Golder and Tellis 1993; Hunt and Morgan 1995; Schmalensee 1982) or utilizing a game theoretic approach (e.g. Moorthy 1985). One exception is auction theory (see Klemperer 1999) and the use of auctions as a context for consumer research (e.g. Ariely and Simonson 2003; Hoffman, Menkhaus, Chakravarti, Field, and Whipple 1993). Auctions are an interesting context to examine consumer competition, but differ fundamentally in several theoretically relevant ways. First, to win an auction one can always spend more, but in some consumer contests – such as those involving skill – consumers are bound by their abilities or effort and an increasing outlay of money will not guarantee success. Second, auctions are dynamic, and bidders can observe other bids and update accordingly. Most consumer contests are static, or include several static steps – consumers cannot see other submissions and update their own, for instance. Other work on competition has examined it in terms of payoffs, decisions, and strategies. Here, we are interested in the internal motivational forces that impel consumers to compete in the marketplace. We are interested in how one-shot consumer contests of different formats and sizes affect the likelihood of consumers to compete. To the best of our knowledge, very little research has been conducted on these topics.

Liu et al. (2007) utilize a game-theoretic approach to suggest optimal designs of consumer contests. They draw a distinction between "lottery-like" contests where the winner is determined by chance, and contests where the winner is determined by who performed the best on a specific skilled task. Here we compare skilled consumer contests to "lottery-like" contests and assess how consumers' motivation to participate is affected by the number of competitors involved in the contest. Skill is not systematically varied in the original *N*-effect paper; however, we examine this variable in the present research because it is relevant to participation in consumer contests. If social comparison drives the N-effect (Garcia and Tor 2009) effect than we should observe it more in skilled than non-skilled contexts, because people will be more likely to compare to others in situations involving skill. On the other hand, if the N-effect is driven by a simple diffusion of competition, a psychological situation that may occur if people simply become less interested in competing when there are more people, than we should observe the N-effect in both types of contests.

In Study 1, participants imagined they were entering an essay contest (skilled) or a random lottery drawing (non-skilled) sponsored by an online travel booking service. The prize was an all inclusive travel package. Participants' competitors were either other students in their experimental session (about 10) or all students completing experiments that semester (about 1,000). The top 20% of entrants would win the prize.

Participants were more likely to enter the lottery than the skilled contest, ($F(1, 40) = 18.09$, $p < .001$). This main effect was qualified by an interaction, ($F(1, 40) = 4.98$, $p < .04$). Participants were less likely to enter the essay contest when the group was large ($M = 3.0$) than when it was small ($M = 4.73$), $t(1,20) = 2.67$, $p < .015$), the N-effect. This difference did not materialize for participants entering a lottery ($M_{large-lottery} = 5.8$ vs. $M_{small-lottery} = 5.6$; ns). These results suggest that the size of the competition group affects consumers' participation in skill-based contests but not non-skilled ones.

Based on Langer's work on the illusion of control, we predicted that consumers selecting their own number in a lottery-like contest may treat it like a skilled task compared to those assigned a number. To test how this would affect consumer motivation, consumers in study 2 imagined competing in a contest with 100 [1,000] other consumers to win a $100 prepaid debit card. Half chose [were assigned] their raffle number. Tickets to enter the contest cost $5 and 2% of the entrants would win the prize. There was an interaction between the size of the competition group and choice versus assigned numbers on likelihood to enter the raffle, $F(1, 100) = 6.27$, $p < .02$. Consumers choosing their number ("skilled" condition) were more likely compete when faced with a small group ($M = 4.0$) than when faced with a large group ($M = 2.8$), $t(1, 52) = 2.60$, $p < .02$. In contrast, the competitive motivation of consumers assigned a number were not affected by group size ($M_{large} = 3.6$; $M_{small} = 3.2$, ns). Results from a third study conceptually replicated study 2 in a more realistic context with consumers from the general population.

This initial investigation begins to identify some of the conditions under which the size of the competition group affects consumers' motivation to compete in the marketplace. This work has implications not only for consumer contests but for other areas where consumers compete amongst each other.

The Category Size Bias and Consumers' Perceptions of Risk

Mathew S. Isaac, Seattle University, USA
Aaron R. Brough, Pepperdine University, USA

EXTENDED ABSTRACT

When judging the likelihood of an event, decision makers are often influenced by irrelevant categorical information. For example, prior research finds evidence of a border bias in which people perceive a disaster as less severe when it originates from another state rather than from an equidistant origin in the same state (Mishra and Mishra 2010). Other findings show that probability judgments of a focal outcome are sensitive to the number of categories into which alternative outcomes are classified, even when such categorization is irrelevant to the judgment (Koehler 2000; Tversky and Koehler 1994; Windschitl and Wells 1998).

In contrast to prior research, we examine how the *size* of a category into which a particular outcome is classified influences consumers' probability judgments and corresponding perceptions of risk. Specifically, we argue that an outcome will be perceived as more likely to occur when it is part of a large (versus small) set of potential outcomes. For example, due to the fact that there are more black pockets on a roulette wheel than green pockets, novice gamblers may perceive a higher probability that the ball will land on the "black two" pocket rather than the adjacent "green zero" pocket. This constitutes a decision bias because the odds are identical that the ball will land on each individual pocket regardless of its color. This bias in probability judgments is likely to influence a gambler's perceptions of risk and the corresponding amount he would be willing to bet on each option.

We attribute this category size bias to a transference process whereby people believe that characteristics of a category (e.g., its propensity of being randomly selected) apply not only to the category as a whole, but also individually to each member of the category. In the roulette example, where individual pockets are categorized by color, people mistakenly overestimate the probability of the ball landing on any individual pocket that happens to be black because of their accurate impression that the ball is more likely to land on a black pocket than a green pocket. This erroneous assumption that each individual member of a category is infused with the overall category's characteristics can cause people to overestimate the probability of outcomes classified into large groups and underestimate the probability of outcomes classified into small groups.

Three studies test our prediction and theory. In Study 1, we demonstrate the category size bias by asking participants to judge the probability of selecting a particular ball (#8) from an urn containing 15 numbered balls. Participants judged the probability of selecting ball #8 to be higher [lower] if it was the same color as many [few] other balls in the urn, even though this color-based categorization was unrelated to the selection likelihood of a particular ball. The observed category size bias was consistent with our theorizing.

Study 2 shows that the category size bias is a function of our proposed transference process. We asked participants to estimate the odds of a particular team winning the NCAA college basketball tournament; lower odds denote higher probabilities and vice versa. Before providing their odds estimate, participants were informed that the team's mascot was either part of a large category (e.g., one of many animal mascots) or part of a small category (e.g., one of few human mascots). Importantly, the basis of categorization was nondiagnostic of the team's likelihood of success in the college basketball tournament. Furthermore, unlike Study 1, our dependent measure in Study 2 was such that lower numerical values suggest higher probabilities of occurrence. This design allowed us to test whether the category size bias is driven by transference or anchoring because each explanation makes opposite predictions. An anchoring account would suggest that participants anchor on category size and respond with a large number (which signifies a lower probability of winning) when the team's mascot is part of a large category. In contrast, a transference account suggests that respondents would be sensitive to what the category size implies about probabilities, such that they should respond with a small number (which signifies a higher probability of winning) when the team's mascot is part of a large category. The results of Study 2 are consistent with our proposed transference explanation but inconsistent with an anchoring account.

Study 3 provides further evidence of transference in the category size bias by showing that variation in the salience of the category moderates the magnitude of the category size bias. Specifically, participants were asked to judge the probability that rolling a die would result in a particular outcome. We found that participants inflated the probability of rolling a 'T' on a die with 26 letters when its membership in the relatively large category 'consonant' was more (vs. less) salient. Conversely, when the small category 'vowel' was more (vs. less) salient, participants underestimated the probability of rolling the vowel 'A'. This suggests that category salience influences the extent to which transference occurs and therefore, the degree to which consumers are biased by category size.

Overall, this research contributes to our understanding of how categorization can influence consumers' probability judgments and perceptions of risk. Furthermore, our findings suggest that healthy behaviors may be promoted through the strategic presentation of risk-related information. For example, policy-makers may contribute to cancer prevention and early detection by grouping lung cancer with a large (vs. small) number of other potential health risks in messages targeted at consumers. A higher perceived risk of contracting lung cancer may encourage consumers to visit their doctor for regular screenings and avoid risky behaviors such as smoking. Future research may further examine the process underlying the category size bias, including whether categorical information influences probability judgments during encoding, retrieval, or both.

Choosing an Experience Over a Product:
Uncertainty, Holistic Processing and Price Sensitivity

Iñigo Gallo, University of California Los Angeles, USA
Sanjay Sood, University of California Los Angeles, USA

EXTENDED ABSTRACT

Recent research in consumer behavior is paying increasing attention to differences between experiences – "events that one lives through" – and products or material possessions – "tangible objects, kept in one's possession" (Van Boven and Gilovich 2003). These authors propose that experiences are better at advancing happiness, and investigate the reasons why. Nevertheless, we do not yet have a clear understanding of how consumers choose between a product and an experience. We propose that, because consumers find a significant degree of uncertainty when evaluating an experience, there are important differences in how they evaluate and choose an experience versus a product. First, consumers evaluate experiences holistically and products analytically; second, consumers rely on price as a cue for the quality of the experience. We present support for our theory along three studies.

VALUE OF ADDITIONAL INFORMATION

Nelson defined experiences as goods for which most qualities cannot be determined prior to purchase (Nelson 1970). Additionally, intangibility makes experiential aspects of consumption difficult to evaluate (Zeithaml 1981), and experiences in general difficult to compare (Carter and Gilovich 2010). Indeed, traditional marketing models have difficulty capturing experiential aspects of consumption (Holbrook and Hirschman 1982). We suggest that even if consumers have access to additional information on an experience, this will not reduce their uncertainty and lack of confidence in their ability to make a good choice. This is because many experiential attributes must be "seen, heard, tasted, felt, or smelled to be appreciated properly" (Holbrook and Hirschman 1982).

INFORMATION PROCESSING

Second, we propose that holistic processing is more compatible with experiences and helps consumers' uncertainty. This is due to different characteristics of experiences. Consumers shift to holistic processing as the comparability of objects decreases (Bertini, Ofek, and Ariely 2009). This matches with experiences, which are difficult to compare (Carter and Gilovich 2010). Also, holistic processing is used by consumers who lack knowledge on a specific category (Sujan 1985). This seems appropriate for experiences, for which consumers find evaluation difficult without inspection (Nelson 1970). Finally, holistic thinkers look for multiple relevant causes and factors in a decision (Nisbett et al. 2001), which fits another characteristic of experiences: an attribute space that is less defined and more subjective (Holbrook and Hirschman 1982).

PRICE AS A QUALITY CUE

Finally, we propose that a second way in which consumers deal with uncertainty when evaluating an experience is by using price as a quality cue. This parallels research showing that, in situations where other information is not available, price becomes an indicator of quality (Zeithaml 1981). We propose that this is specific to experiences, and not to products.

STUDY 1

Participants are asked to consider a 3D TV that is framed as either a product or an experience (Carter and Gilovich 2012). We manipulate the number of attributes that participants can consider (three or six). Those evaluating the product-framed TV report being better informed and more confident in making a good decision when they consider more attributes. On the other hand, for those considering the experience-framed TV, increasing the attribute information has no effect. Both interactions were significant: confidence ($F(3, 217) = 4.77, p < .05$) and product explanation ($F(3, 217) = 4.11, p < .05$).

STUDY 2

Study 2 tests our hypotheses regarding the compatibility of holistic processing and experiences, and the use of price as a quality cue for experiences. We manipulate the price and the composition of the choice set. Participants were assigned to one of eight conditions: 2 (processing style: analytic/holistic) x 2 (choice set: product vs. product/product vs. experience) x 2 (price: same/different [20% increase]). Processing style was manipulated according to Monga and John (2008). Consistent with our hypotheses, there is a significant main effect of holistic processing on the choice of experiences ($X^2(1, N = 154) = 4.89, p < .05$). Holistic processers chose the experience more often ($M_{experience} = 67\%$) than analytic processers ($M_{experience} = 49\%$). Also, price increase influenced choice share for analytic processers. In a product vs. experience choice set, the share of the experience increased when its price increased. This effect was specific to experiences: in a product vs. product choice set the share of the product decreased when its price increased. The interaction of price with type of choice set was significant ($F(1, 167) = 13.23, p < .001$). We propose that consumers rely on price as a quality cue for the experience, and therefore choose the experience more often when its price increases. We test this explanation in study 3.

STUDY 3

Study 3 tests our process explanation based on uncertainty. We focus on the analytic conditions from study 2. We manipulate the degree of uncertainty in the choice by supporting the product and experience information with endorsements. Participants in the control condition continue to choose the experience more often when its price increases (consistent with study 2). On the other hand, participants do not show this effect when their uncertainty has been reduced. In line with basic economic intuition, they choose the experience less often when its price is increased. This interaction was significant ($F(1, 279) = 4.22, p < .05$). This is consistent with our explanation based on uncertainty.

This research offers insight on how consumers evaluate and choose experiences differently from products. Because consumers' evaluation of experiences is uncertain, consumers rely on holistic processing and use price as a quality cue for experiences. Also, due to the experiential nature of the attributes, having access to more information does not heighten consumers' confidence or their perceived level of information.

Order Effects of Sampling Sequential Products with Similar Versus Dissimilar Sensory Cues

Dipayan Biswas, University of South Florida, USA
Lauren I. Labrecque, Loyola University Chicago, USA
Donald Lehmann, Columbia University, USA
Ereni Markos, Quinnipiac University, USA

EXTENDED ABSTRACT

Experiential products such as food/beverages and fragrances tend to be rich on sensory cues, such as color, taste, and smell (Morrin and Ratneshwar 2003; Krishna 2012). In addition, these types of products often facilitate sampling opportunities for consumers before they make purchase decisions. While consumers often sample a single product, they also on other occasions sample a sequence of experiential products before making a purchase decision. Importantly, sometimes these sampled products are similar to each other on sensory aspects, such as on taste/color (e.g., Diet Pepsi and Diet Coke) and sometimes the products are dissimilar to each other on sensory aspects (e.g., Diet Pepsi and Sprite Zero).

Despite the existence of such sampling practices, it is not clear as to how the order in which different types of experiential products (similar versus dissimilar) are sampled influences consumer choices. There has been very limited research examining order effects of sampling products that are high on sensory and experiential aspects (Biswas et al.[2010] and Mantonakis et al. [2009], being the notable exceptions). Interestingly, these two studies report different results in terms of order effects of sampling a limited number of experiential products. For instance, Mantonakis et al. (2009) examined the order effects of sequential sampling of wines and found that the participants demonstrated primacy effects, whereby they often preferred the wine sampled first. In contrast, Biswas et al. (2010) found recency effects, whereby experiment participants indicated stronger preference for the experiential product (e.g., beverages/music) sampled last. The findings of our research help resolve the apparent inconsistency in the findings of these prior studies. We test our hypotheses with the help of three experimental studies.

We propose that in a sequence of two products, when the sequentially sampled products are similar to each other on sensory aspects (e.g., taste, color or smell), there will be a more favorable evaluation of the product sampled first. In contrast, when the sequentially sampled products are dissimilar, there will be more favorable evaluation of the product sampled last.

This is because, when sampling sensory-rich products in a sequence, the experience of sampling the immediately preceding product will influence the evaluation of the subsequent product (Chernev 2011). Thus, in a two product sequence, the first product would serve as a reference point for the evaluation of the second (Chernev 2011; Novemsky and Ratner 2003). In essence, we examine order effects of sampling experiential products and the moderating effects of similarity of the products in the sequence. We propose that when the sampled products have sensory similarity, there will be an assimilation effect in terms of memory trace formation for the second sampled product. However, when the sampled products have sensory dissimilarity, there will be a contrast effect while forming the memory trace for the second product. In order to further investigate the underlying process, we also examine the effects of distraction and the effects of an induced goal in the form of hunger. We hypothesize that these effects will hold under low hunger, but under high hunger, consumers will have more favorable evaluation of the product sampled first. These propositions are consistent with findings in prior studies conducted across different domains (e.g., Chernev 2011; Mussweiler 2007; Zhu and Meyers-Levy 2009) and to the best of our knowledge, this is the first research to examine these issues.

We test our hypotheses with the help of three experimental studies. We use food products (beverages and chocolates) because these products are experiential in nature and are high on sensory aspects (Shiv and Nowlis 2004). Study 1 examines how the level of similarity/dissimilarity between experiential products in a sequence influences order effects of sampling. The results show that when the products are dissimilar, there are recency effects; however, when the products are similar to each other, there are primacy effects. Study 2 examines how reduced processing motivation might affect the results observed in Study 1. The results of Study 2 show that the effects observed in Study 1 are moderated by consumers' distraction levels; that is, distraction attenuates the effects observed in Study 1. Finally, Study 3 examines the effects of an induced situation where processing motivation is likely to be higher. Specifically, Study 3 examines the effects of hunger on evaluation of sequential experiential products in a restaurant setting. The results of this study reveal that the effects observed in Study 1 hold under low levels of hunger but there are only primacy effects when consumers are very hungry.

In conclusion, the results of two laboratory experiments an one field experiment show that the order in which consumers sample experiential products and the level of similarity between the products influence consumers' choices. When sampling a sequence of two experiential products such as flavored beverages or chocolates, consumers prefer the first product in the sequence when they are similar, but prefer the second product when they are dissimilar. The order effects of sampling similar versus dissimilar products are attenuated when consumers are highly distracted due to reduced cognitive capability. Also, when the sequential products are sampled under high levels of hunger, consumers prefer the first sampled product.

A key theoretical contribution of this research is that it potentially reconciles differences in recent research findings on order effects in the context of experiential products (Biswas et al. 2010; Mantonakis et al. 2009). This research also has managerial implications, especially in the area of product testing. Order effects such as those illustrated here can bias testers' evaluations of products since the assimilation or contrast effects produced when tasters are asked to sample and compare multiple test products may result in poor product performance when the product goes to market.

Carrying the Torch for the Brand: Inferring Brand Attachment From Logo Signals

Ted Matherly, Oklahoma State University, USA
Amna Kirmani, University of Maryland, USA

EXTENDED ABSTRACT

Brands frequently support advertising strategies through promotional items, such as hats, t-shirts, or stickers with the brands' logo. When consumers use these items, they build awareness for the brand and provide information to observers about their relationship with the brand. We consider the inferences observers draw from signalers' use of a brand's core products to those drawn from signals not requiring the individual to own or use these products. For example, an individual who does not own one of Apple's core products (e.g. a computer or smart phone) can still wear an Apple t-shirt. We refer to these as product signals and logo signals, respectively. Specifically, we propose individuals using logo signals will be viewed as attached to the brands they signal with.

Considerable research has examined consumer signaling through brands (Berger and Heath 2007; Escalas and Bettman 2003; Han, Nunes and Dreze 2010; Kirmani 2009), but work has largely focused on product signals. We consider how differences in the attitude functions that observers associate with the use of logo and product signals impact inferences about consumers' relationships with the brand. Consumers frequently use branded products for their utilitarian functionality and to satisfy value expressive attitude functions; that is, they allow consumers to affirm their attitudes, values and personality (Grewal, et al. 2004), and to communicate their self-view to others (Wilcox, Kim and Sen 2009). An observer may utilize these choices to learn about the signaler. For product signals, observers may infer utilitarian and value expressive attitude functions guide signaler behavior. However, because logo signals possess little marginal functional utility compared to a similar unbranded product (Heath, Ho and Joshi 2011), it is signalers using logo signals would do so because of utilitarian attitude functions. Instead, they will be seen to do so in service of a value expressive function.

An inference that a signaler is value expressing through a logo signal suggests the brand is an important part of her self-concept and that she is attempting to communicate about her relationship to the brand, which is consistent with high brand attachment. Brand attachment is defined as "the strength of the bond connecting the brand with the self" (Park, et al. 2010). Attachment contains both cognitive and emotional components reflecting the extent to which the brand reflects the self (Thomson, MacInnis and Park 2005; Swaminathan, Stilley and Ahluwalia 2009). Because logo signals are associated with value expression, we expect individuals using logo signals will be viewed as attached to the brands they signal with. In contrast, product signals, used for utilitarian or value expressive reasons, would be less likely to lead to an inference of brand attachment. We propose that individuals using logo signals will be viewed as more attached to brands compared to those using product signals, and that this process is mediated by inferences about signalers' value expressive behavior.

Prior literature reveals that individuals expend resources to develop relationships with brands to which they are attached (Park et al. 2010), and observers infer that when actors expend resources on something that the thing is meaningful to the actor (Kirmani 1990; Morales 2005). These expenditures are costs to the signaler, including monetary, opportunity and social costs (Park, et al. 2010). We propose that when observers determine individuals have incurred costs to acquire their logo signals, observers will infer that the signaler is more attached to the brand, and to be doing so in service of

value expressive functions at greater rates compared to those using less costly logo signals. These inferences about value expression will drive attachment inferences.

In our first study, we considered the effects of signal type and logo signal costs on inferences of value expression and attachment for two different brands. Participants viewed images of an individual using a product signal (the brand's core product), low cost logo signal (a t-shirt) or high cost logo signal (a brand logo tattoo). Attachment inferences were higher for the low cost logo signal compared to the product signal, and similarly higher for the high cost logo signal compared to the low cost logo. This effect was mediated by inferences of value expression. The second study replicated these findings using two different brands within a different category (coffee shop coffee), as well as a more direct manipulation of logo signal costs by comparing $20 and $85 t-shirts.

In our third and fourth studies, we considered potential differences between brands in terms of the brand's self-expression potential (SEP); that is, the extent the brand's products is seen as having an intrinsic value expressive function. For example, a Rolex watch would be viewed as more self-expressive than a cup of coffee. For brands higher in SEP, attachment inferences for product signals should increase and the differences observed between product and logo signals in the prior studies may be eliminated. In the third study, we employed a similar design to prior studies, using two high SEP brands identified in pretests. Consistent with expectations, higher attachment inferences for product signals eliminated the difference between product and low cost logo signals, while attachment inferences for high cost logo signals were higher. In the final study, we employed a single brand, and used participants' ratings of the brand's SEP as a continuous independent factor. Participants were shown an image of a person using a product or low cost logo signal. For participants who viewed the brand's SEP as low, spotlight analysis indicated the signaler using the logo signal was viewed as more attached compared to one using a product signal. For those who viewed the brand's SEP as high, this difference was eliminated.

The results of our studies suggest that logo signals can be used by individuals to convey attachment to brands, and further identify the role of value-expression as a mediator of these inferences. We show that as individuals invest resources in their logo signals, they are viewed as more attached to their brands, and we also identify a boundary condition for the observed differences in the form of a brand's self-expression potential.

Balancing the Basket:
The Role of Shopping Basket Composition in Embarrassment

Sean Blair, Northwestern University, USA
Neal J. Roese, Northwestern University, USA

EXTENDED ABSTRACT

Mellish: "I'll get a copy of Time magazine. And I think I'll take Commentary and the Saturday Review. And let's see, Newsweek. I'll just… grab one of these… *[slyly picks up a pornographic magazine]* I'll take 'em all."

Cashier: "Hey, Ralph, how much is a copy of Orgasm?"

Mellish: "…Just put 'em in a bag, will you?"

In this exchange from the film "Bananas," Woody Allen's character, Fielding Mellish, is in a store to purchase a pornographic magazine. Fearing that others will observe his purchase, he grabs several additional magazines in an attempt to hide his true shopping objective. Unfortunately, the strategy fails when the cashier's request for a price check makes the embarrassing product painfully salient to everyone within earshot.

The traditional explanation for this strategy is that additional purchases mitigate embarrassment because they reduce the salience of the embarrassing product (Brackett 2004; Lewittes and Simmons 1975). According to this *product prominence hypothesis*, products are either embarrassing to buy or they are not, and embarrassment results to the extent that an embarrassing product is salient in the context of the shopping basket. From this argument follows the intuitively appealing prediction that purchasing any additional product that is not itself embarrassing to buy will mitigate embarrassment relative to purchasing the embarrassing product alone.

Indeed, this prediction is consistent with the conventional wisdom, as reflected in a survey in which we asked consumers about their intuitions regarding this strategy. The data showed that the majority (81%) believed that purchasing a non-embarrassing product in addition to an embarrassing product would always be less embarrassing than purchasing the embarrassing product alone. When these respondents were asked why they believed the additional product would attenuate embarrassment, the majority (88%) provided a response implicating a shift in focus away from the embarrassing product.

Contrary to the conventional wisdom, we show that embarrassment does not decrease monotonically with additional purchases. Moreover, we show that these additional purchases, which are not embarrassing in and of themselves, can paradoxically exacerbate embarrassment, such that consumers expect purchasing non-embarrassing products in addition to an embarrassing product to be *more* embarrassing than purchasing the embarrassing product alone.

In this context, we argue that the impact of an additional purchase on embarrassment is a function of the extent to which it balances against the undesired persona communicated by the embarrassing product, such that the more it counterbalances (vs. complements) the undesired persona, the more it will attenuate (vs. exacerbate) embarrassment. We label this proposition the *balanced basket hypothesis* and attribute the effect to embarrassment being a function of the impression made by the shopping basket as a whole rather than by its constituent products. We test this hypothesis in a series of four experiments.

In experiments 1A and 1B, we sought to demonstrate that embarrassment is not monotonically decreasing with additional purchases but is instead a function of shopping basket composition such that additional purchases attenuate (vs. exacerbate) embarrassment when they are unrelated (vs. complementary) to the embarrassing

product. Respondents were told to imagine that they were purchasing either *The Complete Idiot's Guide to Improving Your IQ* or *The Complete Idiot's Guide to Handling a Breakup* and were asked to rate how embarrassed they would feel. Half of the respondents were told that they were buying the book by itself whereas the other half were told that they were also purchasing a box of tissues and a pint of cookie dough ice cream (unrelated to the book on IQ but complementary to the book on handling a breakup). Results revealed the predicted interaction ($F(1, 91) = 8.03$, $p < .01$) such that the additional items attenuated embarrassment for respondents purchasing the book on improving IQ ($M = 2.87$, $SD = 1.66$ vs. $M = 4.88$, $SD = 1.45$; $F(1, 91) = 13.34$, $p < .001$) but not for respondents purchasing the book on handling a breakup ($M = 4.80$, $SD = 1.79$ vs. $M = 4.64$, $SD = 2.16$, respectively; $F(1, 91) < 1$, NS). Experiment 1B used joint evaluation to show that the additional products significantly exacerbated embarrassment in the breakup book condition where the additional purchases were complementary ($M = 5.23$, $SD = 2.34$ vs. $M = 4.08$, $SD = 2.18$; $F(1, 38) = 13.06$, $p < .001$). Thus, purchasing complementary products that would not be embarrassing to buy separately made the purchase of an embarrassing product even more embarrassing than purchasing the embarrassing product alone.

Experiment 2 sought to demonstrate that an additional purchase is more (vs. less) effective at attenuating anticipated embarrassment when it is perceived to be more (vs. less) effective at counterbalancing the undesired persona communicated by the embarrassing product. Respondents were told to imagine they were purchasing a Justin Bieber album and were asked to rate both how embarrassed they would feel to purchase the album by itself and how embarrassed they would feel to purchase the album along with an Adele album. We measured counterbalance perception by asking respondents to rate the extent to which buying the Adele album (vs. the Justin Bieber album) would accurately reflect who they are. A significant interaction between shopping basket composition and counterbalance perception emerged ($B = -.15$, $\beta = -.09$, $p < .05$). Spotlight analysis (Aiken and West 1991; Fitzsimons 2008) at 1.5 standard deviations below the mean of counterbalance perception indicated that purchasing the Adele album in addition to the Justin Bieber album had no impact on anticipated embarrassment relative to purchasing the Justin Bieber album alone ($B = -.18$, $\beta = -.04$, $p > .35$). In contrast, the corresponding analysis at 1.5 standard deviations above the mean of counterbalance perception revealed the Adele album significantly decreased anticipated embarrassment ($B = -1.10$, $\beta = -.24$, $p < .001$). Thus, the same additional purchase was more effective at attenuating anticipated embarrassment when it was perceived to be more effective at counterbalancing the undesired persona, independent of its effect on the perceptual salience of the embarrassing product.

To provide evidence for the robustness of the balanced basket hypothesis to scenarios involving real behavior, experiment 3 employed a field study to demonstrate that shopping basket composition can cause embarrassed consumers to strategically alter their purchase decisions even when doing so is economically disadvantageous. Participants in this experiment were required to go to a drug store to purchase either condoms or anti-gas medicine. They were given the option of purchasing the product by itself or of purchasing the product along with a box of tissues and a bottle of lotion (unrelated to anti-gas medicine but complementary to condoms).

The experimenters paid for the purchases and participants were allowed to keep whatever products they purchased, thus providing an economic incentive for all participants to purchase the additional products. We measured participants' level of public self-consciousness (PSC; Fenigstein, Scheier, and Buss 1975) and predicted that individuals would be more likely to avoid additional complementary (vs. unrelated) purchases when they were higher in PSC than when they were lower in PSC, because avoiding embarrassment is a more compelling motive for these individuals. Supporting our predictions, a logistic regression predicting choice of purchasing the additional items revealed a significant interaction between the assigned product and PSC ($B = -.39$, $\beta = -.41$, $p < .05$) after controlling for purchase familiarity (Dahl, Manchanda, and Argo 2001). Spotlight analysis 1.5 standard deviations below the mean of PSC indicated an equivalent likelihood of choosing the larger basket regardless of which product was assigned for purchase ($B = -.17$, $\beta = -.04$, $p > .90$), indicating that individuals lower in PSC were likely to purchase the additional products regardless of whether they were unrelated or complementary. In contrast, the corresponding analysis at 1.5 standard deviations above the mean of PSC revealed a reduced likelihood of choosing the larger basket when condoms were assigned for purchase as compared to when anti-gas medicine was assigned for purchase ($B = -4.34$, $\beta = -1.11$, $p < .05$, one-tailed). Thus, individuals higher in PSC were more likely to sacrifice their own economic self-interest when the additional items were complementary in order to avoid embarrassment.

Across these four studies, we find consistent support for our hypotheses regarding the role of shopping basket composition in embarrassment.

Reading Smiles to Read Minds: Impact of Positive Facial Affective Displays on Perceptions

Ze Wang, University of Central Florida, USA
Fan Liu, University of Central Florida, USA
Huifang Mao, University of Central Florida, USA

EXTENDED ABSTRACT

Emotions may influence the judgments and behaviors of both people who feel emotions and people who observe the expressions of emotions. There have been extensive research on consumers' emotional experience, yet we know considerably less about consumers' perception of emotional expressions (Andrade and Ho 2009), let alone the role of facial affective displays in social interactions. This is surprising, because marketers and even consumers ubiquitously use strategic modification of the emotional expressions in an attempt to influence a third party.

In this research, we attempt to contribute to this under-researched area about consumers' perception of facial affective displays. We focus on positive affective displays (PADs) for their ubiquity in the public display of emotions. In presenting oneself in social interactions, people deliberately report higher levels of happiness relative to their internal affective states, because people intuit that the intensity of PAD is associated with how likeable a person is (Clark, Pataki and Carver 1996). However, perceivers' reactions can be complex and may not fulfill displayers' intentions. Will PAD intensity always enhance perceptual ratings? Which factors may moderate the relationship between PAD intensity and perceptions? Under what conditions will a maximal PAD boomerang? This research addresses these questions.

The ecological view of emotion research (Fridlund 1994) suggests that emotional expressions are communicating signals serving social functions. Emotional expressions communicate rich and important information about displayers' attitudes, goals, and intentions to the observers. Deighton and Hoch (1993) suggest that consumers, even as quite dispassionate observers, can be aware of the feelings of another and understand the intention and meaning of the affective displays. Judging facial expressions of positive emotions alone, higher intensity of positive emotion displays have been found to associate with more favorable perceptual ratings of the expresser being more willing to affiliate, competent, confident, or more trustworthy (McGinley et al. 1987; Mueser et al. 1984).

Consumers often do not judge facial affective displays in a vacuum. They rely on two pieces of information to make inferences: the information derived from facial emotional cues and the information about expresser's situation (Carroll and Russell 1996). When PADs are presented in a positive context (e.g. with positively-framed verbal content), PAD intensity enhances perceptual ratings or behavioral intention of the observers. However, when PADs are presented in a negative context, perceives may find the two sources of information incompatible. A high-intensity positive expression activates negative ascriptions of the displayers' intentions and goals (e.g., ulterior motives to manipulate or impress perceivers) and may be perceived as inappropriate. Moreover, because perceivers' inferences about the perceivers' mental states on the basis of the PAD intensity and differentiate the implication of medium or maximal smiles in light of other informational cues are effortful and entail deliberation. Constraints on perceivers' cognitive capacity will decrease the likelihood for accurate differentiation based on PAD intensity.

We test the aforementioned hypotheses in a series of three experiments. We conducted a pilot study (N=347) with a 6 (smiling strength: 0%, 20%, 40%, 60%, 80%, 100%) × 2 (displayer's gender; male or female) between-subjects design. The experimental stimuli were facial portraits from MSFDE database and coded using FACS as muscle configuration of 0, 12, 12+25, 6+12+25, 6+12B+25, and 6+12C+25. The results elucidate that perceivers do differentiate different types of PADs and only a main effect of smiling strength on perceptual ratings was found.

In Study 1, we examine how contextual cues moderate the impact of PAD intensity on perceptions. The experimental stimuli consist of a flyer advertising a public health seminar offered by a local university. 178 local residents were recruited and interviewed to complete a short questionnaire in public areas. A 2 (Smiling strength: 40%, and 100%) × 2 (ad valence: positive and negative) ANOVA on attitude toward the ad showed a significant interaction effect. Supporting our hypothesis, when the contextual valence is positive, PAD intensity positively impacts the perceivers' reactions. When the contextual valence is negative, maximal PADs boomerang, leading to lower perceptual ratings and less favorable attitudinal or behavioral responses. Study 2 examines the psychological mechanisms underlying the effect, whether it is due to perceivers' strategic inferences or emotional contagion. We assessed changes in participants' positive and negative feelings and their cognitive inferences about PAD appropriateness. We used the bootstrapping procedures (Preacher, Rucker, and Hayes 2007) to test the multiple-mediator mediated moderation models and found support that perceivers' cognitive inferences about the emotional appropriateness, but not changes in perceivers' feelings, mediate the interaction effect of PAD intensity × information valence on perceptual ratings. Study 3 further explores the boundary conditions of moderation effects in previous studies by manipulating participants' cognitive load. We found that even a lower level of cognitive load (a memory task of 2-digits number) prohibits the activation of the deliberative mind-set of cognitive inferences based on PAD intensity.

Our findings make several theoretical contributions. The present research is the first to systematically investigate the impact of PADs of different levels of intensity on perceptions. This expands the prior research on facial emotional expressions in still image (Knutson 1996; Small and Verrochi 2009) from valence contrast (positive, neutral, versus negative) to a fine-grained differentiation with the positive realm. More importantly, this research highlights that PADs are not always perceived favorably and highlight the importance of congruence between the emotional intensity and situational cues. The well-intended maximal PADs may boomerang when perceived as inappropriate. We also shed light on the psychological drivers and boundary conditions of these effects.

These findings are also important for practitioners. Smiling is easily perceptible and influential. If effectively manipulated, it can favorably impact customers' judgment of the displayers' dispositional traits, as well as the evaluative judgment of the related objects (attitude toward the ad). By understanding the boundary conditions and factors that moderate the impact of facial affective displays, marketers can tailor their affective display to optimal level and avoid the situations when the well-intended positive display goes unrequited or even backfire.

Film Festival 2012

Same Same but Even Better!

Marylouise Caldwell, University of Sydney
Paul Henry, University of Sydney

This year The Annual USA ACR Film Festival showcased films of particularly high quality, regardless of the level of experience and the technology used. Some researchers/film-makers just starting out, used I-Pads and web-cams to collect footage and thereafter edited their clips using Windows Movie-maker or Apple I-movie. The results were very professional, suggesting that sophisticated equipment and high level skills are not necessary to create great consumer research films and win acceptance to ACR film festivals. Rather the key to successful submission remains a compelling story about consumers expressed clearly. Others who'd been in the film-making game a bit longer with greater access to funding, used high-definition cameras and Final Cut Pro to edit their films as well as create animated graphics. The resulting film festival program was one of wide diversity in terms of both content and style. The juror's first prize *The Pere-Lachaise Cemetery: Between tourist experience and heterotopic consumption* by Stephanie Toussaint and Alain Decrop explored how tourists and Parisian residents make use of the cemetery, significantly showing that many use attendance as a means of paying homage to modern-day celebrities such as Jim Morrison who have been laid to rest there. Others see it as a means of maintaining a rich spiritual life that allows them to say connected with tradition, history and human kind more broadly. This film impressed both judges and reviewers because of its ability to capture the atmosphere of the cemetery and the emotion-laden yet varied responses of consumers. In contrast The People's Choice Awards *Differing Everydays: Planning and Emergence in Mundane Routines* by Karolus Viitala and Joel Hietanen looked at how young affluent Finnish consumers negotiate everyday life, a topic of deservedly increasing fascination to consumer researchers. The judges considered this work remarkable due to its sophisticated theorization and cool stylistic. The remaining films covered topics such as the impact of Middle Eastern culture on hospitality consumption, how consumers proactively rejuvenate and/or use public spaces, the impact of age on consumption, how competing sub-cultures engage in intra-brand community conflict, the re-adaptation processes of consumers upon returning home after living abroad, the impact of physical space and time on everyday on consumer behavior, what motivates high risk sport and consumers' perceptions of music authenticity. Finally we are glad to say that ACR film festivals are thriving, being hosted all over the world, thereby providing a highly distinct and stimulating addition to the word and numeric based scholarly output otherwise found at ACR conferences. We remain indebted to Russ Belk and Rob Kozinets for founding this noble enterprise and facilitating the presentation of a huge body of filmic works that continue to inspire ACR film-makers. We wish the very best to all ACR members. Please continue to submit your best work the ACR film festivals. See you in Barcelona next July or otherwise it's "Chicago Chicago our kind of town," October 2013. Best wishes, Marylouise and Paul.

Perceptions of Music Authenticity

Paul Barretta, University of Texas - Pan American, USA
Yi-Chia Wu, University of Texas - Pan American, USA

Perceptions of music authenticity are important to both evaluation of music, and word-of-mouth in today's socially networked world. The producers present the results of two studies through examples and evidence of an authentication process that consumers use to evaluate music and musicians.

Aging and the Changing Meaning of Consumption Experiences

Raquel Castano, Tecnológico de Monterrey, EGADE Business School, Mexico
Claudia Quintanilla, Tecnológico de Monterrey, EGADE Business School, Mexico
Maria Eugenia Perez, Tecnológico de Monterrey, EGADE Business School, Mexico

Like all major life transitions, aging and retirement produce new self-identities that are reflected in the way consumers give meaning to their lives. These findings highlight differences related to age on the goals accomplished through consumption and also show how temporal orientation affects the meaning of consumption experiences.

Co-Creation and Co-Production of Value: The Emergence of Competing Brand Subcultures

Jacob Hiler, Louisiana State University, USA

What happens when different subcultures both love a brand, but for very different and often mutually exclusive reasons? This research investigates what happens when these subcultures acknowledge each other's presence, interact and influence each other's enjoyment of the product, and ultimately attempt to influence the evolution of the product.

Parklife

Morven McEachern, Lancaster University, UK

The concept of space and place is central to understanding everyday life. Using an ethnographic approach, this film explores the consumption experiences encountered by park users. The interconnectivity of space, rhythm and consumption help to co-create the consumption experience, thus, helping to transform the everyday into something special.

Differing Days - Planning and Emergence in Contemporary Mundane Routines

Karolus Vittala, Aalto University, Finland
Joel Hietanen, Aalto University, Finland

This videography illustrates how our everyday life is a flux of emergent relations—one in which our conventional notion of cognitive agency may have much less to do with than we tend to allow. It seems that we plan ahead only to become swept away by the moment.

The Père-Lachaise Cemetery: Between Touristic Experience and Heterotopic Consumption

Alain Decrop, University of Namur, Belgium
Stéphanie Toussaint, Université Catholique de Louvain, Belgium

This videography offers an ethnographic analysis of the Père-Lachaise cemetery, a major tourist site of Paris. The film shows how the sacred and profane dimensions of consumption are entangled in the visiting experience through a series of symbolic behaviors and rituals that make the cemetery a heterotopia.

Living Abroad and Coming Back to Brazil: Analysis of the Acculturation and Re-adaptation Process of Brazilian Consumers

Simone Vedana, UFRGS, Brazil
Teniza da Silveira, UFRGS, Brazil

This study investigates the effects of the consumer acculturation process during and after an experience of living abroad. The 21 consumers surveyed showed changes in eating habits, in purchase decision processes, in cultural identity, and in their satisfaction with products and services in Brazil, among other results.

Arab Hospitality

Russell W. Belk, York University, Canada
Rana Sobh, University of Qatar, Qatar

We examine contemporary Arab Hospitality in Qatar and UAE at three levels: home hospitality, commercial hospitality, and hospitality toward the foreigners who comprise the majority of the populations in both countries. We find that divergences in these practices unify some and alienate others within Arab Gulf cultures.

Spaces and Temporarility

Joel Hietanen, Aalto University, Finland
Elina Koivisto, Aalto University, Finland
Pekka Mattila, Aalto University, Finland
Anastasia Seregina, Aalto University, Finland

In this video, we adapt the radical humanist non-representational perspective in order to bring about new ways of thinking and to question both the conventional social constructivist perspective and what video can epistemologically express as a spatio-temporally situated medium.

Labour of Love: Reforging Community Ownership and Identity

Matthew Alexander, University of Strathclyde, UK
Kathy Hamilton, University of Strathclyde, UK

This film focuses on consumer adoption of train stations and demonstrates how local communities can work with market forces to retain a sense of place through environment enhancements. In contrast to guerrilla community activity studies, we demonstrate how firm involvement can legitimize community actors and co-create mutual benefits.

Fear and Flow: Climbing the Bugaboos, British Columbia

Tommy Chandler, Backcountry.com, Utah, USA
Jeff Foreman, North Georgia College and State University, USA
Aditi Grover, Plymouth State University, USA
Karen Hood, University of Arkansas at Little Rock, USA

Rock climbing is often featured as a metaphoric illustration in business instructional and inspirational materials. As in business, rock climbing involves a balance of flow and fear. We capture the combination of the two in our short video exploring rock climbers doing what they love in the Bugaboos, British Columbia.

Roundtable Summaries

ROUNDTABLE
Different Methodological Approaches to Studying Transformative Consumer Research:
What Can We Learn from Each Other?Participants:

Chair
Julie L. Ozanne, Virginia Tech, USA

Laura Peracchio, University of Wisconsin-Milwaukee
Rebecca Ratner, University of Maryland
Carlos J. Torelli, University of Minnesota, USA

During David Mick's ACR Presidential Address TCR was coined as "consumer research in the service of quality of life" (Mick 2006, p. 3). By focusing on how consumer research can actively look to improve the lives of consumers, TCR has gained prominence as a field in both academia and practice. Since this time, a number of initiatives have been undertaken to further encourage TCR, including special issues in journals, such as the Journal of Consumer Research, Journal of Business Research, Journal of Research for Consumers, and the Journal of Public Policy and Marketing. TCR has also supports a bi-annual TCR conference, an edited volume (Mick et al. 2011), a dedicated list-serv for TCR researchers, special sessions and roundtables at North American and Regional ACR conferences, and an increasing number of competitive papers presented at ACR conferences that have a TCR focus. All this resonates with the overall health of the TCR field, but does not give us reason to be complacent in advancing its cause, particularly as TCR's growth has signalled an increasing diversity of research paradigms and methodologies actively engaging in the field.

It is believed that if TCR is to maximize its service to consumers, then a more connected effort is needed to avoid fragmentation of the field. This roundtable proposes to bring scholars operating within different methodological frameworks together to see what can be done to create greater understanding as well as better research that serves consumers through a collective effort.

Roundtable Motivation

Previous roundtables have often included scholars from differing methodological stances, but none have primarily addressed the means by which diverse research methods can be used synergistically to encourage higher quality TCR and an improvement in consumers' quality of life. For example, Baker, Hunt, and Mick (2007) discussed various means of advancing the field, but not specifically on methodological biases. Strahilevitz (2010) included researchers conducting research with diverse methods as part of a prior ACR roundtable, but the issue of methodological divide was not overtly discussed. Similarly, Veer and Hunt (2008), Veer and Austin (2010) and all engaged with large groups of academics, but the diversity of the group was not addressed as part of the roundtables. Furthermore, published papers in top-tier journals using both qualitative and quantitative data, such as Botti, Orfali, and Iyengar (2009) are rare, but have the potential to provide significant advances in TCR thinking. Thus, this roundtable will not engage in an ontological debate of whether one paradigm is better than the other (Weber 2004), but focus more on how collaboration and integration of differing perspectives can be used to benefit the field.

Roundtable Purpose and Aims

By drawing together TCR scholars to specifically discuss the value of methodological diversity in the field, it is expected that former research connections will be strengthened and that new ones will be formed, creating a closer community with a better understanding of the diverse ways that different paradigms are addressing mission and purpose of TCR. This will be achieved through:

1. An increased understanding and appreciation of the diversity in the TCR field.
2. Greater dissemination of TCR related work currently being undertaken by ACR members.
3. Greater communication of the goals of TCR, and how these goals can be achieved through multiple approaches.

Simply by engaging in this an open dialogue, it is expected that transformation would occur. This is not a forum to discuss which stance is more valid than the other, but to discuss how collective action can be taken to benefit consumers. This is the overarching aim of TCR and will continue to be at the heart of this roundtable.

Roundtable Structure and Content

By proposing a forum based on open dialogue it is more likely that the purpose of the roundtable are achieved. The discussion will be led and facilitated by the roundtable discussant, Prof. Julie Ozanne. The roundtable will propose the following questions but also allow the discussion to naturally evolve as necessary. The questions have been designed to specifically drive forward appreciation of the value of diverse research approaches, as well as collaboration. A critical lens will be taken to the field with an aim to enhance the development of TCR as a field. The proposed questions are:

1. Beyond ontological differences, what successes and failures have established TCR scholars had with conducting and disseminating their work from multiple research paradigms?
2. How have established TCR researchers from both research paradigms overcome issues with IRB and other Ethics approval processes?
3. How can collaborations and networks best be formed that encourage increased appreciation for diverse approaches to carrying out TCR? Should the two methodological stances simply stay separate and only address research questions that fit with their own research paradigms and techniques?
4. What steps need to be taken in order to ensure the longevity and relevance of TCR in the coming years?
5. Has there been resistance to carrying out TCR from within one's business school? What advice do panellists have for framing TCR work, regardless of its methodological approach, for a promotion and tenure committee?

Contributions and Implications

Although it is, for the most part, accepted that different research methods offer value depending on the aims and assumptions of the research, a greater integration and understanding of how researchers can work together to promote TCR is needed. This roundtable aims to explicitly discuss the differences and work more to increase synergies by bringing together prominent TCR scholars and interested participants. Having an appreciation for how methodological biases can be both beneficial and detrimental to TCR will aid in the development of the field, as well as better prepare new TCR scholars embarking in this area. The roundtable could also allow for discussion of how to collaborate more effectively with other diverse groups, such as TCR scholars internationally, or the importance of engaging persons from multiple backgrounds in a TCR project, such as academics, practitioners, public policy makers and consumers. It is hoped that by facilitating this discussion, this round table will be transformative for the participants, attendees and the field. Pre-conference discussion will be facilitated through online forums, such as the TCR Facebook page, dedicated email lists and the TCR Google resource page, which was recently set up by the TCR advisory committee.

</div>

What is the broad topic?

Although most work on addiction has focused on substance abuse such as drugs, alcohol, and tobacco, there is a growing recognition that addiction is manifested in domains beyond substance abuse, suggestive of common underlying causes leading to varying maladaptive responses (Martin et al. 2012). For example, the fifth edition of the Diagnostic and Statistical Manual on Mental Disorders (DSM-5) recognizes disorders such as pathological gambling as a new category of "behavioral addiction" alongside substance abuse (American Psychiatric Association 2013). However, for many consumption behaviors, such as shopping, technology use, hoarding, overeating, plastic surgery, use of pornography, kleptomania, dietary supplement usage, religious convictions, and exercise, there is an ongoing debate as to whether they fit the clinical definition of addiction. The diversity of potentially addictive consumption behaviors raises an important question that we need to address: how do individuals move on a continuum from engaging in seemingly normal consumption behaviors to engaging in potentially addictive behaviors characterized by uncontrolled use and frequency of the behavior?

What is the motivation for organizing roundtable around this topic?

The notion that addiction is a temporal process and that one should take a holistic view (across all consumption phases) underlies this roundtable discussion. The power of marketing cues is believed to have the potential to heavily influence the path that individuals take both towards becoming addicted as well as moving away from maladaptive consumption and addiction. Marketing cues can make salient the rewards of an increase in frequency of the behavior as well as highlight the potentially dysfunctional nature of that same increase in consumptive behavior. However, to understand the role of marketing cues in the process of becoming addicted, we first need to explore the meaning of addiction as well as the meaning of "not being addicted" to a behavior or a substance.

Our key focus is to explore the marketing cues that act as catalysts to influence this movement toward and away from potentially harmful behaviors that result in addictions, and to present some research directions (see Figure). Consumer research has a long tradition of examining how consumers react differentially to both subtle and not so subtle cues in their environments that may influence behavior. Indeed, marketing cues could easily facilitate the development and entrenchment of addictive consumption behaviors or, alternatively, inhibit them.

Our premise begins with the non-use and normal consumption phases. Most consumers remain in these two stages without progressing to the pre-addiction or addiction phases. The pre-addiction phase begins with an increase in frequency and time spent in a consumption behavior evolving into a dependence on the consumption behavior as a vital part of the individual's life leading to negative consequences. There is an adaptive part, where the behavior is manageable, and a maladaptive part, where the behavior begins to be problematic but still controllable, to the pre-addiction stage through which consumers can cycle through without ever moving into the addiction stage. However when consumers begin to lose the ability to control consumption, the shift from maladaptive to addictive consumption begins. This final phase is characterized by movement into physical and psychological addiction. Even while in the addiction stage, there is the possibility through warnings, willpower, therapeutic interventions and treatment, for consumers to exhibit restraint or possibly rehabilitation which may move them back down the continuum towards adaptive or normal consumption, or even non-use.

Numerous individual differences are likely to influence how consumers react to marketing cues that may facilitate movement towards addiction in the pre-addiction phase. Because many forms of consumption that may lead to harmful behavioral patterns are unavoidable (for example, eating, shopping, exercising), relevant marketing cues are also difficult to escape. And yet not all consumers are equally susceptible to marketing cues, particularly those cues that may influence behaviors associated with the pre-addiction phase.

At what point do marketing cues begin to negatively influence consumption behaviors that result in harmful outcomes. Moreover, what marketing approaches and theories are best in triggering contrast effects (where intake is perceived negatively) leading to less consumption, as opposed to assimilation effects where more consumption is perceived as optimal. While marketing cues can be indicted as the culprit in

possibly facilitating if not causing addictive behaviors, they can also serve as the first line of defense in the prevention of such harmful behaviors.

Understanding how and when exposure to marketing cues progresses or even impedes individual consumer's movement along the adaptive-maladaptive consumption continuum is a critical research area where a gap in the knowledge remains. Uncovering the determinants of this process has significant implications for both public policy and marketing management. It is imperative that consumer behavior researchers continue to investigate the phases of and the mechanisms that drive consumption behavior toward addiction in order to develop a more holistic and efficacious view of consumption overall.

Who is likely to benefit from attending the roundtable?

This roundtable will be of interest to both experienced researchers who have been working in the area of extreme, maladaptive or addictive consumption and new researchers who are looking to incorporate a conceptual framework as they consider future research. We also believe that researchers studying goal related behaviors in some pervasive areas as food consumption and financial decision making may be interested in the relevant addictive underpinnings of these often impulsive or compulsive behaviors. We believe the dialogue developed in preparation for and during this roundtable discussion is an imperative for consumer behavior researchers as we strive to develop research that not only helps firms but also helps transform consumers and their experience to a more adaptive and proactive level.

ROUNDTABLE
Evolutionary Consumption:
Methodological Pluralism, Interdisciplinarity, and Consilience (Unified Knowledge)

Chair
Gad Saad, Concordia University, Canada

Participants
Joshua Ackerman, MIT, USA
Sarah E. Hill, Texas Christian University, USA
Kristina Durante, University of Texas at San Antonio, USA
Jill Sundie, University of Texas at San Antonio, USA
Eric Stenstrom, Concordia University, Canada
Tripat Gill, Wilfred Laurier University, Canada
Bram Van den Bergh, Erasmus University Rotterdam, The Netherlands
Gad Saad, Concordia University, Canada

Broad topic for discussion and enquiry?

A growing number of consumer scholars are becoming interested in the application of evolutionary psychology and related biological formalisms to the study of consumer behavior. The infusion of evolutionary principles in consumer behavior affords many benefits including increased consilience (unified knowledge) and the generation of novel hypotheses and research questions that would have otherwise been difficult to posit void of an evolutionary lens (Saad, 2007, 2011; Saad & Gill, 2000). In addition to the latter two epistemological advantages, evolutionary psychology promotes methodological pluralism as well as a strong ethos of interdisciplinarity (Garcia et al., 2011). Accordingly, the theme of the roundtable discussion will be to highlight each of these valuable benefits by drawing on numerous examples from the participants' research streams. This will then be followed by an exploration of future avenues of research at the nexus of evolutionary psychology and consumer behavior.

Motivation/purpose for organizing the round-table on this topic?

The purpose of the roundtable discussion is to highlight the integrative capacity of evolutionary psychology in the study of consumer behavior along both the methodological and epistemological fronts. In describing the state of the field of psychology, Sternberg and Grigorenko (2001) argued that many psychologists suffer from methodological and field fixation. Methodological fixation is well captured by Abraham Maslow's famous statement: "When the only tool you have is a hammer, every problem begins to resemble a nail." Field fixation refers to the trepidation with which psychologists venture outside (if at all) of their designated sub-disciplines (e.g., social psychology, cognitive psychology, clinical psychology, etc.). These forms of fixation happen in many disciplines including consumer behavior. For example, marketing scholars will often define themselves via the methodological approaches that drive their research streams (e.g., "I am an experimentalist," "I am a modeler"), or via the main cognate disciplines in which they received their training (e.g., cultural anthropology, social psychology, etc.).

By the very nature of its integrative meta-framework, evolutionary psychology engenders a plurality of methodological approaches (and dependent measures) as well as interdisciplinary pursuits, and as such reduces the likelihood of succumbing to methodological fixation. Furthermore, evolutionary psychology is antithetical to field fixation, as its epistemological tenets allow for its application across all of the behavioral sciences. Hence, consumer psychology, social psychology, cognitive psychology, clinical psychology, and cultural psychology can all be tackled from an evolutionary perspective. Evolutionary principles are not constrained by any disciplinary or sub-disciplinary boundaries, and in this sense offer consumer scholars the capacity to easily traverse across numerous areas of inquiry.

The participants of this roundtable have each tackled topics that would have been very difficult to broach void of a physiological/evolutionary lens. How does the menstrual cycle affect women's consumption (Durante et al., 2011; Saad & Stenstrom, 2012)? Does conspicuous consumption affect men's testosterone levels (Saad & Vongas, 2009)? How do evolutionarily relevant primes (e.g., mating motives) affect individuals' proclivity to engage in conspicuous consumption (Griskevicius et al., 2007; Sundie et al., 2011)? What are the neuronal activation patterns implicit to brand categorization (Yoon et al., 2006)? Does the sex ratio in a population affect financial decisions (Griskevicius et al., 2012)? How extensively do men and women search for information prior to making a mate choice (Saad, Eba, & Sejean, 2009)? Do products of popular culture (e.g., song lyrics or movie plotlines) reveal a shared and universal human nature (Saad, 2012)? Do consumers' decision making styles possess genetic underpinnings (Saad & Sejean, 2010)? Does the digit ratio affect men's proclivity for risk taking (Stenstrom et al., 2011)? Does the viewing of scantily clad women affect men's discounting rates (Van den Bergh, Dewitte, & Warlop, 2008)?

These innovative research questions, all of which are rooted in evolutionary/biological realities, have necessitated the use of novel methodological approaches and dependent measures including functional magnetic resonance imaging, hormonal/salivary assays, panel data across a full menstrual cycle, naturalistic experiments using Porsches and decrepit sedans, content analyses of cultural products, a twins registry, a process-tracing computer interface, historical economic data, and anthropomorphic measurements. This methodological diversity is perfectly congruent with this year's ACR theme of "appreciating diversity."

To reiterate, the goal is to have attendees walk away from the roundtable discussion with an appreciation of the epistemological and methodological pluralism afforded by an evolutionary approach. In doing so, this will hopefully encourage ACR scholars to explore how evolutionary-level theorizing might complement their individual research streams.

Who is likely to benefit from attending the round table?

Given that the driving theme of the roundtable is methodological pluralism, consilience, and interdisciplinarity, it is hoped that this inclusive message will resonate with many ACR attendees. This is precisely the point of the roundtable, namely that all consumer scholars stand to benefit from knowing how evolutionary principles might complement their various research streams. Saad (2007, chapter 2) offered ways by which areas that consumer scholars have typically been interested in including perception, attitude formation, decision making, learning, motivation, emotions, personality, and culture, can each be tackled from an evolutionary perspective. Hence, the raison d'être of the roundtable is to create a discussion centered on breaking down otherwise rigid disciplinary, methodological, and epistemological boundaries.

Facilitation of pre-conference discussions

The organizer of the roundtable (Gad Saad) will ask each participant to prepare a few examples from their research streams that highlight instances of methodological pluralism/diversity, consilience, and/or interdisciplinarity that were uniquely driven by the evolutionary lens. These will be collated into a working document that will then be passed around among all of the participants via email for comments and further suggestions. Once a clear outline of the session emerges, the organizer will post this tentative agenda at the ACR Facebook group site and the ACR Knowledge Exchange forum as a means of generating interest among the larger community. Schedule permitting, a get-together at the conference will be organized (prior to the roundtable) to go over key points to be discussed at the session.

The Editors and Associate Editors of the Journal of Consumer Research (JCR) will be conducting a roundtable to train reviewers and discuss the review process in general. They will explain what makes a great review, discuss how reviews are advisory to the editors, review the trainee program, and answer any questions.

ROUNDTABLE
Conversations on the Sacred and Spirituality in Consumer Behavior

Chairs
Diego Rinallo, Bocconi University, Italy
Pauline Maclaran, Royal Holloway, University of London, UK

Participants
Pauline Maclaran, Royal Holloway, University of London, UK
Russell W. Belk, York University, Canada
Stephen J. Gould, Baruch College, USA
Elif Izberk-Bilgin, University of Michigan, USA
Richard Kedzior, Hanken School of Economics, Finland
Robert Kozinets, York University, Canada
Hope Jensen Schau, University of Arizona, USA
Linda Scott, University of Oxford, UK
John F. Sherry, University of Notre Dame, USA
Eric J. Arnould, University of Bath, UK

Spirituality, once considered one and the same as religion, has attracted significant attention in the social sciences that, in the decades after the counterculture of the 1960s, have examined the secularization of society and the postmodern behavior of spiritual seekers, who mix and match from different sources to customize their spiritual beliefs and practices. In consumer research, spirituality per se has attracted limited explicit attention (for notable exceptions, see Hirschman, 1985; Holbrook, 1999; Gould, 1991; Moisio and Beruchashvili, 2010). Spirituality is however an element of the liberatory postmodernist quest to re-enchant human life (Fuat Firat and Venkatesh, 1995) and magical thinking in consumer behavior (Dion and Arnould, 2011; Fernandez and Lastovicka, 2011; St. James, Handelman and Taylor, 2011). Moreover, it is implicitly inherent in two influential streams of consumer research: (1) materialism, and (2) the sacred (as opposed to profane) aspects of consumer behaviour.

Materialism

Materialism is the idea that everything is made of matter. Most religions see the Divine as transcendent rather than immanent, that is, the creator is separated from the physical creation, which is often considered a distraction to the soul's spiritual journey, when not intrinsically evil. Accordingly, excessive pursuit of material goods is criticized as a hindrance to spiritual pursuits (see Belk, 1983). Materialism and spirituality do not, however, oppose each other. Religious/spiritual beliefs are reified in material culture (McDannell, 1995; Morgan, 1999; Moore, 1995), in the form of sacred images, devotional and liturgical objects, buildings and other places of worship, works of art, mass-produced consumption goods and entertainment products, and the practices surrounding these material objects (rituals, ceremonies, prayer, mediation, display, pilgrimage, worship, magic, study, etc.). Such consumption is not however exempt from critiques, ranging from bad taste (e.g., Catholic kitsch) to the more extreme accusation of spiritual materialism (Rindfleish, 2005; Trungpa, 1973).

Gould (2006) warns against conflating spirituality with spiritual materialism. He defines the latter as "the coopting of spiritual meanings and practices in the service of the material life of the self and then conflating them by rationalising that one is engaging in spirituality. For instance, one may use spiritual practices to reduce tension so one can get along better in the world as opposed to using them to seek some sort of spiritual fulfilment or enlightenment" (Gould, 2006: p. 65). Based on a Buddhist perspective, Gould (1992, 2006) suggests that spirituality can fruitfully engage with matter in ways different from asceticism. For example, alcohol, whose abuse is condemned by ascetic religious paths, may be employed under the right circumstances for spiritual transformation, like experiencing altered states of consciousness that might accelerate one's spiritual pursuits. From this perspective, consumption of goods, services and experiences can indeed provide the material means to achieve spiritual goals.

Sacred and Profane

In 1989, Belk, Wallendorf and Sherry argued that consumption may be a vehicle for experiencing the sacred, proposing that two processes are evolving in contemporary societies. One is the increased secularization of society and institutional religions. The other is the sacralization of the secular in the spheres of politics, science, art and consumption. Since Belk et al.'s (1989) publication, the sacred has become a frequently invoked conceptual category to refer to those aspects of consumer behavior that go beyond the satisfaction of functional needs, including those that do not necessarily involve transcendent or ecstatic experiences.

For example, Fournier (1998) draws on theories of animism to develop brand-consumer relationship theory; others have conceived certain types of brand-consumer relationship as based on devotion (Pimentel and Reynolds, 2004; Pichler and Hemetsberger, 2007). Reference to the sacred, re-enchantment and transcendence is also frequent in studies of extraordinary consumer experiences as different as river rafting (Arnould and Price, 1993; Arnould et al., 1999), consumer gatherings such as the mountain men rendezvous (Belk and Costa, 1998) and the Burning Man event (Kozinets, 2002; Kozinets and Sherry, 2003; Sherry and Kozinets, 2003, 2007), skydiving (Celsi et al., 1993), and mountain climbing (Tumbat and Belk, 2011). Spiritual elements are present not only in experiences that immerse consumers in nature, but also in those referred to as artificial, marketer-made consumptionscapes, such as disco clubs (Goulding et al., 2002, 2009), art exhibitions (Chen, 2009) and retail spaces (Borghini et al., 2009; Dion and Arnould, 2011; Kozinets et al., 2002, 2004; Sherry, 1998; Sherry et al., 2009).

Brands are also sometimes conceived in spiritual or even religious ways. In their ethnography of Harley Davidson bikers, Schouten and McAlexander (1995) observe that the "Harley consumption experience has a spirituality derived in part from a sense of riding as a transcen-

dental departure from the mundane" (p. 50). Muñiz and Schau (2005), in their analysis of the abandoned Apple Newton community, identify several supernatural, religious and magic motifs in their informants' narratives. Belk and Tumbat (2005) develop the notion of brand cult and identify the sustaining myths that underlie the religious aspect of Macintosh consumption. Also popular management books provide guidance on how to create brand cults and turn customers into "true believers" (Atkin, 2004; Ragas and Bueno, 2002).

Spiritual elements are perhaps even more prominent in entertainment brands based on science fiction, fantasy and horror genres (e.g., X-Files, Kozinets, 1997; Star Trek, Kozinets, 2001; Star Wars, Brown et al., 2003). By introducing "fantastic" elements, these brands familiarize their audiences with supernatural beings (e.g., angels, vampires, fairies, aliens) and phenomena (e.g., magic, miracles) that are not supposed to exist from a secular, atheist standpoint.

Starting a conversation on the sacred and spirituality in consumer behavior

The idea of this roundtable session is to reflect again on the sacred in consumer culture, disentangle the different typologies of the sacred, and put spirituality back in. To facilitate pre-conference discussion, and as a tribute to the conference's theme of "appreciating diversity", we will circulate articles exploring different theoretical perspectives on the sacred, spirituality and spiritual diversity, including some written for a forthcoming book entitled Spirituality and Consumption edited by Rinallo, Scott and Maclaran. We will also create a Facebook group, to be widely promoted, to ensure the conversation extends beyond roundtable participants.

Market System Dynamics: The Value of and the Open Questions Associated with Studying Markets in Consumer Culture Theory

Chairs
Anton Siebert, Witten/Herdecke University, Germany
Anastasia Thyroff, University of Arkansas, USA

Participants
Ashlee Humphreys, Northwestern University, USA
Eminegul Karababa, Middle East Technical University, Turkey
Gokcen Coskuner-Balli, Chapman University, USA

Dannie Kjeldgaard, University of Southern Denmark, Denmark
Melea Press, University of Bath, UK
Eric J. Arnould, University of Bath, UK
John W. Schouten, Aalto University, Finland
Jeff B. Murray, University of Arkansas, USA
Anastasia Thyroff, University of Arkansas, USA

A thriving and diverse body of research that explicitly explores the creation, formation, and reshaping of markets has recently emerged in the consumer literature. This research places markets as social systems at the center of their analysis and examines how they are created and/or change through the discursive negotiations and the practices of various market stakeholders. As a nascent research area that has not yet been captured by overviews, however, it is still conceptually underdeveloped, lacks an agreed upon label and has no clear research agenda. To change this and facilitate the interaction among scholars, a roundtable provides an excellent opportunity.

Studying markets as social systems that are shaped by multiple actors and constitute specific forms of social reality is of increasing interest to consumer culture theorists (Giesler 2008; Humphreys 2009, 2010a, 2010b; Karababa and Ger 2011; Press and Arnould 2011; Zwick, Cayla, and Koops-Elson 2002; Penaloza and Venkatesh 2006; Thompson and Coskuner-Balli 2007). For example, Giesler (2008) illustrates how consumers and producers variously interpret the salient narrative of intellectual property in order to construct legitimacy for their activities in the cultural creative sphere. In his theorization, cultural conflict among opposing market stakeholders drives the formation of market structures. Employing institutional theory from sociology, Humphreys (2010a) shows the rhetoric and strategic efforts used by leading members of the casino gambling industry in cooperation with multiple stakeholders to create and maintain the industry. Humphreys portrays market creation as a political and social process of legitimation. Karababa and Ger (2011) investigate how struggles between the pursuit of pleasure and religious morality composed a coffeehouse culture and an active consumer subject in the early modern Ottoman era. Illustrating the alliance and transgressions of consumers and marketers against the enforcements of the state and the religious authority over time, the authors demonstrate that market formation is a sociocultural, political, and moral phenomenon located in the broader public sphere.

However, as in every research area in its nascent state, several questions remain to be explored, linkages need to be interrogated and established, and definitions have to be found. To explore what needs to be done in the area of market system dynamics, we conducted email exchanges and a Facebook discussion with key players. Several issues emerged:

What is the relationship between market system dynamics research and other areas of study?

Some participants brought up that other social sciences have already developed very interesting approaches to studying markets as social systems. Kjeldgaard listed work from sociology (Slater and Tonkiss 2001; Callon 1998), anthropology (Applbaum 2003; Lien 1997; Garsten and de Montoya 2004), economic sociology (Granovetter 1985, as referenced by Shankar), history (Schwarzkopf 2009), and interdisciplinary work such as Friedland and Robertson 1990. Furthermore, in the marketing landscape there is macromarketing work (Layton 2011; as mentioned by Arnould), market managerial scholarship, and work by researchers in the strategy realm (e.g. Peter Dickson and Bob Lusch; as mentioned by Rindfleisch). Do we contextualize, enrich, embed, and pattern their findings, or do we actually deviate from some of the more established economic and sociological concepts?

How should this research be defined?

The terms market formation (Press and Arnould 2011) and formations (Zwick et al. 2002), market creation (Humphreys 2010a), and market system dynamics (Giesler 2008) have been used recently. Although systemic thinking is increasingly supported in the marketing field (e.g. Layton 2011), Giesler noted that "[c]alling something a system is, in very consequential ways, looking for organization, meaning, harmony, purposeful structure, functionality, wholeness, etc. while de-emphasizing externalities, problems, leakages, and contradictions."

What are some of the unintended consequences of studying markets?

One participant said that we usually assume that markets are producers of value (e.g. identity value, economic value, structural value, technological innovations). What falls off of the analytic radar when assuming this primary role of markets? Adopting a more critical perspective, Giesler said that markets could also be regarded as agents or strategic consumers: "[H]ow do markets actively reconfigure social and cultural spheres in ways that maximize their economic and ideological returns?" How should market-focused CCT research in the future pick these consequences up?

What are future research directions?

For example, the current market legitimation theorization draws mainly upon institutional theory from sociology. Veresiu said that assemblage theory or actor-network theory provide alternate perspectives that have yet to be fully employed by consumer researchers. Giesler added that a historical understanding of how our own views of the market emerge and evolve over time relative to political, social, and economic events and broader institutional transformations could be worth future exploration. Critical work could address the role that humanistic researchers play in giving markets authenticity, meaning, integrity, and the ability to function and regulate effectively. Given the great work on markets outside of the consumer literature, however, Shankar noted that we were coming late to this game. So what can we as consumer researchers contribute?

These and other questions should be the focus of our roundtable. We hope that by finding answers and finding new questions we help develop this research agenda, which we consider to be an important source of innovation in the ACR and CCT vicinity.

The organizers will continue to facilitate pre-conference interaction among researchers with an interest in market system dynamics. Discussions on Facebook have proven to be useful in raising greater interest in the topic and the event of the round table. Complemented by email exchanges, these (and other) forms of pre-conference interaction helped to co-create this proposal and will be very important for the success of the roundtable.

As market system dynamics is a fundamentally interdisciplinary and diverse research stream that stretches across the vast field of consumer research as well as the social sciences more broadly, we aim at bringing together scholars with diverse theoretical and methodological backgrounds, not only CCT researchers. This is needed to look at what consumer research focusing on markets has done in the past, where it stands in the present, and what needs to be done to make this a fruitful exercise of scholarly activity in the future.

ROUNDTABLE
"Death and All His Friends":
The Role of Identity, Ritual, and Disposition in the Consumption of Death

Chair
Susan Dobscha, Bentley University, USA

Participants
Jenna Drenten, John Carroll University, USA
Kent Drummond, University of Wyoming, USA
Terrance Gabel, University of Arkansas, Fort Smith, USA
Chris Hackley, Royal Holloway, University of London, UK
Sidney J. Levy, University of Arizona, USA
Jeffrey Podoshen, Franklin and Marshall College, USA
Dennis Rook, University of Southern California, USA
Katherine Sredl, University of Notre Dame, USA
Rungpaka Amy Tiwsakul, Durham University, UK
Ekant Veer, University of Canterbury, NZ

</div>

This roundtable examines death as a topic with almost endless potential for consumer research projects with different foci and various methodologies. Death studies is an emergent subfield in other disciplines, notably sociology and history, as researchers are beginning to discover its many complexities and layers. This roundtable comfortably reflects the diversity theme of the conference because death is inherently cultural and governed by local, national, and global norms and customs, and is subject to consumer cultural forces. .

The purpose of this roundtable is to begin a discussion on the broad connections between death and consumption and to foster research linkages among members of the ACR community. Given the strong interest in the topic by researchers at all stages of their careers (doctoral students to full professors) and the inescapable amount of diversity built into the topic, it is clear that this roundtable will be of interest to a wide variety of scholars across content and methodological paradigms. .

Attitudes toward death change slowly over time. Until the Romantic era, death was treated as a banal, expected experience, often taking place at home with all family members present, including children (Aries 1974). Religious, especially eschatological concerns, shifted the conduct of death. What started as an experience organized by the dying person himself evolved into emotional expressions by the living and with modernity a need to hide the inevitability of death to the dying person, to spare him "the ugliness of dying" (Aries 1974).

The management of death has legal, ethical, financial, environmental, commercial, and social implications., including the disposition of possessions through wills, the implications of cryogenic storage, the environmental consequences of burial practices and the emerging 'natural burial' industry. The commercial enterprises focused on death-related consumption continue to grow and are placed squarely at the center of consumers' preparation for or reaction to the death of a loved one.

There seems to be two broad research domains when thinking about death. The first domain encompasses the ritual aspects of death. Turley and O'Donohoe's work on consumption during bereavement (2005) and Bonsu and Belk's work on death rituals in Ghana (2003) are excellent examples of the relationship between consumption and death rituals.

The second domain appears to relate to identity and meaning made of death by the dead, the dying, and the living. . Death impacts the identities of the living, as well as those of the dead. As Davies stated, "at death, identity is altered not only through the loss of figures who have served as sources of identity but also by the new responsibilities which the living must take on themselves."

The members of this roundtable have projects in various phases that encompass some aspect of death. The work can be loosely categorized across five broad themes. Jeffrey Podoshen, Kent Drummond, and Dennis Rook are examining the consumption of death in two radically different contexts. Podoshen is looking at death tourism in the black metal subculture while Drummond examines the blockbuster museum exhibit BodyWorlds, which places highly stylized cadavers in life-like positions. Rook has gathered data about longevity trends, changes in the leading causes of death, and actuarial statistics about the percent of any age cohort who are living (dead), which provide a basis for further study of the salience and anticipation of death.

Rungpaka Amy Tiwsakul and Chris Hackley, and Susan Dobscha are looking more broadly at the role of consumption in death rituals. Tiwsakul and Hackley are looking at death rituals in Asian culture while Dobscha is looking at the emerging consumption phenomenon of "green", "sustainable", or "natural" burials.

Katherine Sredl's work is focusing on death as a metaphor for transition in her exploration of the Museum of Broken Relationships whereby jilted partners leave artifacts from failed relationships as a way of finding closure.

Ekant Veer is looking at disposition activities when death is imminent. His research examines how people who know they are dying give away their possessions. And finally, Terrance Gabel and Jenna Drenten study post-mortem rituals among the living. In particular, Gabel looks at how online memorialization practices reflect a new approach to mourning by an almost reversion to medieval rituals that were more social and communal vs. the current way of mourning that is more private and affect-minimizing. He also differentiates between the idea of physical death, which is typically immediate, and social death, which can continue for many years. Drenten looks at the practice of gift-giving to the dead by the living in her study of consumers who continue to buy gifts for loved ones well after their death.

This roundtable serves to ask 3 key questions related to death and consumption:
1. Are current conceptualizations of death sufficient? Do these conceptualizations hinder future research on the topic?
2. What ethical concerns are raised when doing research in this area?

3. What is the role of material goods and their consumption in understanding (a) the evolving meaning of death, and (b) the evolving meaning and practice of mourning and memorialization?

The session organizer will provide a synopsis of the session for publication in the proceedings.

Darren W. Dahl, University of British Columbia, Canada
Leslie John, Harvard University, USA
Ayelet Gneezy, University of California San Diego, USA
Uri Simonsohn, University of Pennsylvania, USA
Leif D. Nelson, University of California Berkeley, USA
Joe Simmons, University of Pennsylvania, USA
Sarah Moore, University of Alberta, Canada
Michael I. Norton, Harvard University, USA

</div>

The world has changed. We are now surrounded by a wealth of data in ways never before imagined. Loyalty cards record purchase, scanner panel data records basket size, and shopping cart trackers record movement through the store. Blogs record thoughts and opinions, Facebook tracks what topics are discussed, and search data records what people are interested in learning more about. With a couple of mouse clicks we can find everything from sports scores and stock prices to newsgroups and which baby names are popular.

How can consumer behavior researchers use these new data sources to enrich their research? How can we get access to this data? What are its benefits compared to lab experiments? What are some of the issues researchers face when moving outside the lab?

This roundtable will bring together a diverse group of behavioral researchers to discuss using field data in behavioral research. The group is a mix of senior and junior researchers, both more and less quantitatively inclined, all of which have figured out creative ways to use field data to enrich their research programs. They have conducted field experiments at Disney World, scraped sports score from the web, and coded customer service calls. They've measured the collective mood using blogs, had employees work while walking on treadmills, and examined student's report card to measure academic performance. Building on these experiences, they will share insights with the audience and exchange ideas about how to better incorporate these alternate sources of data into our research programs.

Detailed Description and Format

The laboratory experiment has always been the behavioral researcher's fruit fly. The relatively sterile environment allows for careful manipulation and measurement. You can tightly manipulate one key factor, holding everything else constant, and examine its causal impact on a dependent variable. The internal validity and experimental control lab experiments provide are ideal for teasing out complex psychological mechanisms.

But exactly because the lab environment is so simplified, people often wonder about the strength or importance of effects shown there. The real world is a noisy and complicated place. Lots of things are going on at once. Do the effects we've observed in the lab really hold in the field? And do they have a consequential impact on real behavior?

The session will answer these, and related questions, as it enriches the audience's understanding of how to use field data in behavioral research. The format will be as follows:

1)Concrete Examples: To give the audience a concrete sense of the breadth of what is possible, each roundtable participant will provide one short example of how they have used field data to enrich their work (approximately 3-4 minutes, 1-2 PowerPoint slides at most). This will include:

a)A brief overview of the project

b)Why they felt field data was useful (better than the lab or just valuable in a different way)

c)How they got the data

d)How they used the data

The point of these presentations will be to provide a breadth of concrete experiences to help the audience get a better sense of the space.

2)Broader Themes: The groups will then have a broader discussion regarding some key questions.

a)How do you get field data? We'll talk about different approaches to acquiring data including contacting companies, using Webcrawlers or scraping data from the web, and archival research.

b)What are the benefits of field data? We'll talk about external validity, the ability to compute effect sizes, and how such data can help communicate your effects to a broader audience.

c)But can we show causation? Many people may have already thought about field experiments, but for most experimentalists datasets are less common. But are datasets only good for showing correlations or can more be done? We'll start by talking about some of the ways that field data can provide correlational support for behavioral theories. Then we'll talk about methods like regression discontinuity and natural experiments that allow researchers to make causal inference from correlational data

d)How will reviewers react? We'll talk about experiences in the review process, complications involving showing experimental and non-experimental data, and how editors feel about such data (roundtable members Darren Dahl, Jeff Inman, and Uri Simonsohn are all Associate Editors)

e)But I'm not good with statistics! We'll talk about how to analyze field data and whether and when it is useful to bring in more quantitatively minded colleagues

Who is likely to benefit: Given the wide-range of types of data that are available, and the clear benefits of using such data to augment one's research program, this roundtable should benefit all consumer behavior researchers. It should be particularly valuable for doctoral students and junior researchers who are thinking of novel ways to test their research questions.

In summary, this roundtable will bring diverse perspectives together to shed light on how to use field data in behavioral research. Pre-conference discussion has already begun and will be facilitated through emails and discussion among the group of participants. The session is particularly relevant to ACR's theme of appreciating diversity, because it showcases diverse ways to test research hypotheses.

ROUNDTABLE
Reading the Mind of the Consumer:
Promises and Challenges of Predictive Methods in Consumer Neuroscience

Chair
Ming Hsu, University of California, Berkeley

Participants
Ming Hsu, University of California Berkeley, USA
Uma Karmarkar, Harvard Business School, USA
Karim Kassam, Carnegie Mellon, USA
Tom Meyvis, New York University, USA
Hilke Plassmann, INSEAD, France
Akshay Rao, University of Minnesota, USA
Baba Shiv, Stanford University, USA
Monica Wadhwa, INSEAD, France
Carolyn Yoon, University of Michigan, USA
Drazen Prelec, Massachusetts Institute of Technology, USA
William Hedgcock, University of Iowa, USA
Adam Craig, University of South Florida, USA
Mili Milosavljevic, Stanford University, USA
Angelika Dimoka, Temple University, USA
Nina Mazar, University of Toronto, Canada

Topic and Motivation

"Mind Reading" and Predicting Cognitive States: Can we predict behavior of consumers from their brain activity? Can we generalize predictions about behavior, generated from the brain activity in our subject samples, to the population at large? In short, are we able to "mind read"? These are provocative questions that may seem to be squarely in the realm of science fiction, but progress in the intersection of neuroscience, psychology, and machine learning is making this an increasingly likely proposition. Early examples have demonstrated how neuroimaging data can be used to predict the cognitive states, including whether participants were viewing faces versus non-faces, tools versus non-tools, and, more ambitiously, the contents of natural scenery images. More recently, these studies have scaled up to more complex and abstract constructs, including the contents of specific scenes that participants were watching, or the efficacy of social marketing campaigns.

Not surprisingly, these studies have been widely reported in the popular press, and have fueled expectations that we will soon be able to probe into the mind of consumers and predict when, where, and what they will buy. This leap from reconstructing our perception of the physical world to our inner thoughts and feelings, however, is a formidable one, and only recently are we starting to grasp the conceptual and technical hurdles. To use an analogy, this would be akin to predicting not only what moviegoers are watching, but also what they are thinking and feeling.

Bridging Neuroscience and Consumer Behavior: In essence, these so-called "decoding" studies have taken the traditional approach in neuroimaging and turned it upside down. Historically, neuroimaging studies have sought to map the set of brain regions that respond systematically to experimental manipulations of cognitive states and/or behavior. In consumer neuroscience, for example, there have been several studies that have investigated brain regions that respond differentially to branded vs. unbranded items, or when making inferences about brands vs. about people.

In contrast, decoding studies ask the question, "Are there patterns of brain activity that can be used to identify, or reconstruct, the outputs of the experiment, either in terms of the cognitive states, or the elicited behavior?" In particular, two new areas in cognitive neuroscience raise the provocative possibility of being able to do just what consumer researchers have sought for years: to be able to look into the mind of a consumer, by-pass socially desirable responses, and predict a consumers decisions based on patterns of neural data alone. The first area involves the prediction of individual level behavior based on patterns of neural data. Using machine learning techniques that allow for multivariate statistical analysis, algorithms can be developed which classify behaviors based on prior behavioral exemplars. The second area involves neural "focus groups" which seek to utilize neural data to inform population level inferences beyond the ability of behavioral approaches alone.

Goal of the Current Roundtable

Despite the similarities in purpose between these new techniques, however, many differences exist that make it difficult for researchers with diverse backgrounds to initiate collaborative efforts: first, these methods make different assumptions regarding the relationship between neural structures. Second, the data required for machine learning analyses necessitates novel experimental design compared to traditional neuroimaging designs. Third, the two methods require substantially different levels of neurocognitive theory.

This roundtable will serve as the starting point for discussion and collaboration between researchers interested in utilizing neuroscientific data for predictive studies and those behavioral researchers interested in merging neural study data with secondary data. We have drawn together a diverse panel of experts in neuroscience and decision research to explore the strengths and limitations of each emerging technique. Several specific issues to be discussed are:

1. Conceptual and technical background of predictive methods.
2. Discussion of past experiences of panel members who have researched worked with multivariate imaging data.

3. The most promising conceptual and methodological frontiers for applying predictive methodologies.

Interested and Likely-to-Benefit Audiences

This roundtable should be of interest to all consumer researchers, including both those who use biological methods and those who do not. Those interested in prediction of individual level neural data would find this roundtable stimulating and informative regarding the application of emerging techniques to address existing consumer research issues. For traditional consumer researchers, the discussion of existing and emerging techniques from the intersection of neuroimaging, machine learning, and decision-making, would provide a broader scope which would allow more nuanced discussion about appropriate analysis techniques.

A primary challenge to wider adoption of these approaches in consumer behavior is the complexity of the tools involved, and requires considerably more technical expertise than traditional neuroimaging approaches. However, despite their interest in predicting behavior, consumer researchers in each area are only infrequently exposed to the key assumptions and existing limitations of the other. Hence this roundtable's key contribution lies in actively addressing the assumptions and limitations of each predictive method.

Facilitating Pre-Conference Discussions

In order to facilitate pre-conference discussion that is both provocative and informal, we plan to utilize the ACR knowledge exchange forum and moderated emails between participants. Participants will be encouraged to provide informal summaries of existing research efforts along with discussion points focused on the challenges faced in applying predictive methodologies. These materials will be collected by the organizers and distributed to the finalized list of participants. Thus, these preconference efforts should maximize the value and vigor of the session itself.

Working Papers

1. Better Together or Alone? Joint vs. Individual Goal Pursuit

Lauren Trabold, Baruch College/CUNY, USA
Stephen J. Gould, Baruch College/CUNY, USA

We examine the commonly held lay theory that pursuing a goal with a partner will have a positive influence on goal pursuit. We aim to establish whether collaborating with someone with the same goal positively influences perceptions of the goal, and also examine its objective effect on goal progress.

2. Planning to Fail? The Role of Implementation Intentions in Emotional Responses to Goal Failures

Jason Stornelli, University of Michigan, USA
J. Frank Yates, University of Michigan, USA

We explore the role of planning in emotional responses to goal failure and demonstrate that forming detailed implementation plans makes post-failure regret more likely and intense. Further, we show this process is associated with subjective feelings of closeness to the desired outcome, independent of the objective distance to the goal.

3. Knowing What I Want: Alignability, Attentional Focus, and the Identification of Consumption Goals

Michael Hair, Georgia Institute of Technology, USA
Samuel Bond, Georgia Institute of Technology, USA

Our research addresses the direct benefits of goal identification on decision outcomes. In three studies, we demonstrate how conscious consideration of one's consumption can be beneficial or harmful. We explore the effects when non-alignable attributes are the basis for choice, or when goal-relevant attributes have limited influence on decision quality.

4. Lay Theories in Consumer Goal Setting and Striving: The Case of Weight Loss

Mariam Beruchashvili, California State University, Northridge, USA
Risto Moisio, California State University. Long Beach, USA
James Gentry, University of Nebraska-Lincoln, USA

Although consumer goals and lay theories have been examined separately in prior research, no studies investigate whether implicit theories of personality influence the goals consumers set and how they strive to attain those goals. In the context of Weight Watchers, we address this theoretical oversight.

5. From Apples to Alcopops: The Forbidden Fruit Effect on Supersized Alcoholic Beverages

Cassandra Davis, University of Arkansas, USA
Elizabeth Howlett, University of Arkansas, USA

The increasingly dangerous consequences of alcopops have led policy makers and health advocates to champion warning labels and restrictions for these products. This research examines the potential consequences of these actions and posits that these regulations will create a forbidden-fruit effect, such that consumers will find alcopops more desirable.

6. Knowing When to Assimilate and When to Contrast: Self-Control and the Influence of Contextual Order

Kelly L. Haws, Texas A&M University, USA
Joseph P. Redden, University of Minnesota, USA
Scott Davis, Texas A&M University, USA

We explore the role of self-control in consumption contexts where assimilation and contrast effects emerge. This research reveals that the presentation order of food stimuli (healthy vs. indulgent or ambiguous) has a striking impact on both consumer evaluations of healthiness and the amount consumed.

7. All Things Considered: When the Budgeting Process Promotes Consumers' Savings

Min Jung Kim, Texas A&M University, USA
Haipeng (Allan) Chen, Texas A&M University, USA

We examine when the budgeting process can promote consumers' savings. Results show that when consumers consider spending and savings goals to the same extent, the budgeting process makes them perceive savings goals as being more important, which in turn increases the amount of money saved.

8. Implementation Intentions as Self-Regulation Tool for Low- and High-Level Impulsive Buyers: A Behavioral and Neurophysiological Investigation

Isabella Kopton, Zeppelin University, Germany
Bruno Preilowski, Zeppelin University, Germany
Peter Kenning, Zeppelin University, Germany

In postmodern societies, impulsive buying has become increasingly prevalent and can even transition to pathological compulsive buying with negative consequences on consumers' well-being. This paper analyses the effectiveness of self-regulatory implementation intentions to control impulsive buying behavior. Results suggest that implementation intentions are a valuable tool for decreasing impulsive buying tendencies.

9. Joe vs. joe: Turning to One's Partner vs. Favorite Product in Emotion Regulation

Danielle J. Brick, Duke University, USA
Hannah Honey, Duke University, USA
Gráinne M. Fitzsimons, Duke University, USA
Gavan J. Fitzsimons, Duke University, USA

We compare negative emotion regulation strategies of support from partner vs. the consumption of a favorite beverage. When the negative emotion is irritation (vs. sadness or anxiety) a larger number turn to their product. Furthermore, those who imagine product consumption (vs. partner support) in the irritation condition report more reduced feelings of irritation.

10. The Influence of Social Relationships on Self-regulatory Focus in Buying for Others

Huimin Xu, The Sage Colleges, USA
Paul M. Connell, City University London, UK
Ada Leung, Pennsylvania State University Berks, USA
Cuiping Chen, University of Ontario Institute of Technology, Canada

Existing research often treats self-regulatory focus as a situational variable that can be made temporarily salient by task framing. Our research posits self-regulatory focus as an inherent characteristic of social relationships. Making purchase decisions for a particular social tie elicits a certain self-regulatory focus.

11. When Self-Serving Does Not Serve the Self: The Role of Serving-Style in Food Consumption

Anna Linda Hagen, University of Michigan, USA
Brent McFerran, University of Michigan, USA
Aradhna Krishna, University of Michigan, USA

Consumers increasingly consume food that is prepared and served by others. Three studies establish that self-serving a chosen food (re)instigates feelings of responsibility for the food, that consumers assume responsibility in a self-serving manner depending on the food's health-value, and that health-value and serving-style together shape consumers' self-conscious feelings after consumption.

12. When Do Consumers Compromise on Calories? Exploring the Attraction and Compromise Effects in Food Choice

Ryall Carroll, St. John's University, USA
Beth Valen, Fordham University, USA

Prior research shows that providing calorie information on menus leads to changes in consumer choice. We explore whether attraction and compromise effects occur when consumers are presented with calorie information on menus.

13. Changing Implicit Beliefs through Advertising: Exploring One of the Origins of the "Unhealthy=Tasty" Intuition

Carolina Werle, Grenoble École de Management, France
Olivier Trendel, Grenoble École de Management, France

Unhealthy foods are implicitly associated with good taste and this intuition influences taste perceptions, favoring the consumption of unhealthy options and contributing to obesity epidemics. In two studies we show that this intuition is culture dependent and that advertising images can change the implicit belief in the intuition.

14. Toward a Gender-Specific Emotional Eating Model: The Role of Self-Esteem and Emotional Intelligence

Paula C. Peter, San Diego State University, USA
Sukumarakurup Krishnakumar, North Dakota State University, USA

With a first empirical study, we show that males are more susceptible to emotional eating when their self-esteem and emotional intelligence (EI) are low. These findings provide initial support for a gender-specific emotional eating model, where males might benefit from an EI-specific intervention in order to reduce emotional eating.

15. The Effect of Pictorial Cues of Food on Restrained vs. Unrestrained Eaters

Nguyen Pham, Arizona State University, USA
Maureen (Mimi) Morrin, Rutgers University, USA
May Lwin, Nanyang Technological University, Singapore
Melissa G. Bublitz, University of Wisconsin Oshkosh, USA

This research represents a preliminary exploration of how exposure to highly craved but forbidden food pictures impacts hunger and guilt among restrained and unrestrained eaters, providing insight into the mechanisms associated with overeating via abandonment of long-term health goals.

16. Ironic Effects of Food Commercials: When More Food-Related Mental Images Make You Eat Less

Carolina Werle, Grenoble École de Management, France
Mia Birau, Grenoble École de Management, France

Food ads allowing imagining high-caloric foods consumption may increase feelings of fatness, characterizing the thought-shape fusion (TSF) phenomenon. Study 1 shows that a food advertisement inducing TSF increases food restriction intentions. Study 2 explores the TSF mechanism and shows that a high imagery-evoking food advertisement reduces subsequent food consumption.

17. Consumers' Alternative Dietary Lifestyles – A Narrative Approach

Anniina Luukkonen, Aalto University, Finland
Ilona Mikkonen, Aalto University, Finland
Elina Koivisto, Aalto University, Finland

The present study reports preliminary findings from a project on consumers' alternative dietary choices. It takes a narrative approach to explore how consumers make sense of their decision to reject official nutrition recommendations, and why they choose to follow a diet not generally accepted as healthy.

18. Happy Fat or Staying Thin? Evolutionary Motives Underlying Consumer Food Choice

Rob Richerson, University of Kentucky, USA
Blair Kidwell, Ohio State University, USA
Virginie Lopez-Kidwell, University of Kentucky, USA

We propose a new perspective for understanding healthy eating that explores social factors and the underlying evolutionary motives that influence eating behaviors. Specifically, we explore how evolutionary motives for affiliation in social groups and mate retention in personal relationships drive consumers to match the unhealthy or healthy eating styles of others.

19. Food in Motion

Michael Giblin, University at Buffalo, USA
Aner Tal, Cornell University, USA
Brian Wansink, Cornell University, USA

The current research examines the implications of product motion on consumer evaluations of attributes such as weight and overall appeal. We argue and demonstrate that a product shown moving will be evaluated more favorably. These effects might be due to associations of freshness with movement.

20. Oh Dear, I'm So Confused: Cognitive and Affective Coping Strategies to Deal with Consumer Confusion in the Food Market

Inga Wobker, Zeppelin University, Germany
Peter Kenning, Zeppelin University, Germany

In complex markets, poorly-informed consumers use different strategies to reduce information asymmetries. They may use cognitive mechanisms such as screening to acquire information and affective mechanisms such as trust for complexity reduction. This paper presents an analysis of these strategies in food distribution. Results suggest consumers with affective strategies use less cognitive coping.

21. It's Not Just Numbers: Nutrition Information Disclosure is Perceived as a Social Identity Threat by French Consumers

Pierrick Gomez, Reims Management School and Université Paris Dauphine, France

This research examines whether nutrition information disclosure can threaten the national identity of French consumers. Results of an experiment reveal that nutrition information disclosure impairs information processing of participants for whom French identity is made salient. Two additional experiments will investigate the influence of social identity threat induced by nutrition information disclosure on dietary choices.

22. When Dieting in Your Mind Brings Cake in Your Mouth

Jiah Yoo, Yonsei University, South Korea
Youngwoo Sohn, Yonsei University, South Korea

This study examines whether activating a dieting goal in the mind can induce a potential problem in regulating eating behaviors. The results reveal that for consumers who see themselves as unsuccessful dieters, activating dieting goals in their minds actually increases the desire to consume tempting foods, compared to consumers in the neutral condition.

23. Self-Construal and Self-Affirmation Effects in Effortful Customer Experiences

Prakash Das, University of Calgary, Canada
James Agarwal, University of Calgary, Canada

Across two studies, we show that primed self-construals have differential effects on company and self attributions, and judgments about the effortful tasks. In difficult tasks, those primed with an independent self-construal blame the company more than those primed with an interdependent self-construal. Further, self-affirmation moderates these effects more for independents than interdependents, suggesting self-affirmation produces greater self-threat reduction for the former compared to the latter.

24. The Persuasiveness of Abstract vs. Concrete Language in Commercial and Non-Commercial Settings

Peeter Verlegh, University of Amsterdam, The Netherlands

The present studies examine how the impact of language on persuasiveness is moderated by the context in which the language is used. We focus on one particular aspect of language (language abstraction), and show how its impact differs between non-commercial contexts like word of mouth, and commercial contexts like advertising.

25. Better in the (Near) Future: Biased Temporal Conceptions of Team Identification

Jesse S. King, Oregon State University, Cascades, USA
Colleen C. Bee, Oregon State University, Cascades, USA

The current research investigates temporal self and other biases among fans' evaluations of sports teams. Our findings suggest that fans appreciate a home team more for their future potential than for what they have been in the past. Additionally, our results demonstrate an increased optimism for one's own team.

26. The Moderating Role of Construal Level on Effectiveness of Purchase-Contingent Donations

Nara Youn, Hongik University, South Korea
Yun Lee, Virginia State University, USA

We document that the effectiveness of purchase-contingent donations moderated by customers' construal level differs by product type. Specifically, abstract thinkers evaluate the product more favorably when the donation is linked with a hedonic product, and the guilt of consuming the hedonic product is alleviated significantly more for abstract thinkers than concrete thinkers.

27. Activating Multiple Facets of the Self: Identity-Signaling and Brand Personality

Marilyn Giroux, Concordia University, Canada
Bianca Grohmann, Concordia University, Canada
Frank Pons, Université Laval, Canada

Using a multi-method approach consisting of qualitative and quantitative studies, the authors examine the impact of identity salience on preferences for the different dimensions of brand personality. Results from those studies demonstrate that consumers' motivations to express parts of their identities influence their preferences for brands.

28. Impression Management Practices of Stigma-Conscious Communities: The Case of an Online Pro-Smoking Forum

Navin Bahl, University of Hawaii, USA
Namita Bhatnagar, University of Manitoba, Canada
Rajesh V. Manchanda, University of Manitoba, Canada
Anne Lavack, Kwantlen Polytechnic University, Canada

We integrate literatures from consumption communities, stigmatization, and tobacco control to understand how smokers engage in impression-management practices to counteract stigma. Results of a netnography unearth impression- management practices (namely, enabling, compromising, and curing) inherent within an online pro-smoking community. We propose implications for theory and practice.

29. Putting Myself in your Shoes: The Role of Identification in Persuasion

Anne Hamby, Virginia Tech, USA
Meghan Pierce, Pontificia Universidad Católica de Chile, Chile
Kim Daniloski, University of Scranton, USA

While source characteristics contribute to persuasion in informational messages, identification with characters is more influential in a narrative context. The results of two studies indicate that level of identification with an author has a positive impact on attitude toward the focal subject in the narrative context.

30. Self-Construal as a Cultural Mindset and its Relevance for Automatic Social Behavior

Geetanjali Saluja, HKUST, Hong Kong
Rashmi Adaval, HKUST, Hong Kong

Past research has looked at how a context cues cultural mindsets. These mindsets, in turn, trigger cognitive procedures that help collectivists connect and integrate, and individualists pull apart and separate. This paper explores how such cognitive procedures impact automatic social behavior upon exposure to a member of a social category.

31. Self-Construal Moderates the Effect of Fear of Failure on Donation Likelihood

Lale Okyay-Ata, Koç University, Turkey
Baler Bilgin, Koç University, Turkey
Zeynep Gürhan-Canli, Koç University, Turkey

This research shows that self-construal moderates the effect of fear of failure on donation likelihood. An independent self-construal decreases and an interdependent self- construal increases donation likelihood. The effects are expected to be mediated by the perceived distance from others, via perceived uncertainty and loss of control.

32. Dynamic Co-Creation: Moving Beyond Foucault to Understand the Ideological Field of Parenting

Alexander S. Rose, University of Arkansas, USA
Robin L. Soster, University of Arkansas, USA
Kelly Tian, University of Wyoming, USA
Randall L. Rose, University of South Carolina, USA

Data from eight depth interviews reveal a dynamic formation process of parental ideology, contrasting sharply with previous mechanistic conceptualizations. The hegemonic discourse of therapeutic culture commodifies familial relations and parental know-how, bringing the parent-child relationship into the market. Both endorsements of, and resistance to, the discourse grant it legitimacy.

33. Children's Preferences of Package Design

Dan Zhang, City University of New York, USA
James Hunt, Temple University, USA
C. Anthony Di Benedetto, Temple University, USA
Richard Lancioni, Temple University, USA

This research explores children's preferences of package design on shape (straight or rounded), figurativeness, and complexity. Analysis of data from 766 children 3-12 years of age reveals children generally prefer rounded package shapes and realistic, figurative package designs. Furthermore, preferences for complex package shapes increase with age.

34. Innovation for Your Parents? The Impact of Lay Theories of Innovativeness on Upward Intergenerational Gift Giving

Jianping Liang, Sun Yat-sen University, China
Hongyan Jiang, China University of Mining & Technology, China

Little work explicitly considers the determinant factors for adult offspring acting as innovation influences on their parents. This paper investigates an ignored but important phenomenon; i.e., upward intergenerational gift giving of innovation, and examines the interplay of two dimensions of lay theories of innovativeness. We offer counterintuitive results.

35. Who Spends More on Children's Education: "I" or "We"?

Lingjiang Tu, University of Texas at San Antonio, USA
Yinlong Zhang, University of Texas at San Antonio, USA

Three studies show that interdependent self-construal induces more parental education spending than independent self-construal, and this effect is reversed when parent's feeling of failure is primed. Furthermore, the moderating role of failure on a self-construal effect is mediated by parental identity salience.

36. Ethno-Culturally Diverse Social Ecosystems

Esi Abbam Elliot, University of Illinois at Chicago, USA
Joseph Cherian, George Washington University, USA

This study seeks to explore how cultural diversity influences social networking behaviors in consumer communities. We administer a survey to various racial groups in five communities in the Lake County district in Chicago. The findings demonstrate cultural diversity in dynamic social networks -- a phenomenon we name ethno-culturally diverse social ecosystems (EDSO).

37. Cultural Identity and Brand Relationships: Negotiating Brand Meanings in a New Cultural Context

Anna Jansson Vredeveld, University of Connecticut, USA
Robin A. Coulter, University of Connecticut, USA

As consumers move across geographic spaces, they encounter culturally and contextually dependent meanings of brands. Findings from semi-structured interviews with nineteen sojourn consumers provide insights into how these consumers interpret brand meanings across cultures. We explore the implications of consistent and incongruent brand meanings for new and existing brand relationships.

38. Style Reimagined: Exploring Fashion and Identity among South African Smarteez

Kevin Thomas, University of Texas at Austin, USA
Guillaume Johnson, University of the Witwatersrand, South Africa
Marike Venter, University of the Witwatersrand, South Africa
Kristin Stewart, University of Texas at Austin, USA

This paper explores style and identity among the Smarteez, a youth subculture in South Africa. Using several ethnographic techniques, we demonstrate that the Smarteez use elements of style to reify nonconformist aspects of self, aid in the performativity of identity factors, and promote a uniquely cosmopolitan worldview.

39. A Cross-Cultural Comparison of the Impact of Consumers' Conspicuous Consumption Orientations on Brand Attitude and Purchase Intention

Xia (Linda) Liu, Louisiana State University, USA
Alvin C. Burns, Louisiana State University, USA
HongYan Yu, Sun Yat-Sen University, China

This research compares the impact of conspicuous consumption orientation on brand attitude and purchase intention across individualistic and collectivistic cultures.

40. Does Accent Matter? The Impact of Ethnic Similarity and Product Congruence on Spokesperson Credibility and Purchase Intention

Aarti S. Ivanic, University of San Diego, USA
Kenneth Bates, University of San Diego, USA
T. Somasundaram, University of San Diego, USA

This research examines whether and when firms should use accented spokespersons in radio ads. A 2 x 2 between-subjects experiment finds spokespeople are evaluated more positively and have greater perceived credibility when there is high listener-spokesperson similarity. Purchase likelihood is highest when there is high listener-spokesperson similarity and spokesperson-product congruence.

41. Acculturation, Brand Personality and Brand Preferences

Umut Kubat, University of Pittsburgh, USA
Vanitha Swaminathan, University of Pittsburgh, USA

The present research examines the relationship between acculturation, brand personality and brand preferences, in the context of bilingual advertising. We hypothesize that biculturals will not demonstrate a strong affinity to any particular brand. We further test how bilingual advertising can enhance biculturals' brand preferences, and how brand personality moderates this relationship.

42. Decoding BE-Commerce: The Invisible Hand of National Culture

Lei Song, Drexel University, USA
Srinivasan Swaminathan, Drexel University, USA
Rolph E. Anderson, Drexel University, USA

A lab experiment reveals significant differences between Chinese and U.S. consumers in their reactions to deviations between the actual service delivered and the service level promised. We find that Chinese consumers exhibit more tolerance to negative disconfirmation, and less reactions to positive disconfirmation than U.S. consumers.

43. Disentangling Two Types of Country of Origin: The Interactive Effects of Brand Origin and Product Origin on Persuasion

Sangwon Lee, Ball State University, USA
Xin He, University of Central Florida, USA

This research examines the joint effects of brand origin and product origin on persuasion. Through two experiments, we show that brand origin moderates the effect of product origin on consumer attitudes. Further, we demonstrate the mechanism underlying the interactive effects of brand origin and product origin through consumer involvement.

44. Exposure to Chicken-Abuse Images Has More Impact than that of Cows on Targeted Meat Consumption among a Sample of Japanese Consumers

Douglas Trelfa, Tamagawa University, Japan
Carolina Werle, Grenoble École de Management, France

This research examines denial and meat preferences among Japanese consumers exposed to disturbing images of animal abuse on factory farms. Findings suggest that consumers react differently to targeted animal products (chicken vs. beef) and may even increase consumption of targeted meat after viewing these images.

45. Gender Identity Politics and Consumption: Mobilizing Scottish Masculinities through Relational Consumption Practices

Wendy Hein, University of London, UK

Invigorated by recent debates about nationalism in consumer research, this paper presents findings from an ethnographic study that explored young Scottish male consumers. Depicting participants' mobilizations and manifestations of national identifications through gendered consumption, it seeks to contribute to an understanding of how gender relations interact with identity politics.

46. Constructing Ethnic Identity through Mealtime Rituals and Practices

Amandeep Takhar, University of Bedfordshire, UK
Pepukayi Chitakunye, University of KwaZulu-Natal, South Africa

This research examines the significance of mealtime rituals and food consumption practices in constructing individual ethnic identity. Using the third generation of the British Sikh community as the research context, I seek to understand how the acculturative and re-acculturative characteristics of mealtime rituals impact their individual identity projects.

47. Hey Y'all: Exporting Southern Food Culture, Implications for Brand Meaning and Local Consumer Identity

Catherine Coleman, Texas Christian University, USA

Through in-depth interviews and archival data, this research uses an interpretive case method at the intersection of food meaning, cultural identity, person branding and authenticity to examine the meanings ascribed to brand, community and self by local communities when their identities are exported globally through cultural brands.

48. The Making of an Everyday Concubine: Accounting for Simultaneous Love of Modernity and the Recently (Re-)Discovered Ottoman Heritage

Cagri Yalkin, Kadir Has University, Turkey

The aim of this paper is to explore how Turkish female consumers negotiate opposing ideologies in soap operas. Self-identified secular consumers are interviewed about the Ottoman-era based soap-opera *Muhtesem Yuzyil*. I identify empowered female characters as embodying the modernist ideal. Furthermore, consumers experience guilty pleasure when watching the sexualized Ottoman harem as it opposes the Islamist ideal.

49. Power over When: If Time is Human, Humans Act When They Want

Frank May, University of South Carolina, USA
Ashwani Monga, University of South Carolina, USA

In this research, we explore the humanness of time and demonstrate that consumers can exhibit a "power over when." Specifically, when time is perceived to be human, high-power (vs. low-power) individuals perceive a power over when to do something, and show little concern for the time dimension of intertemporal options.

50. Gifting Lightly When Feeling Powerful: Self-Construal, Power, and Gifting Anxiety

Fang Wan, University of Manitoba, Canada
Mehdi Akghari, University of Manitoba, Canada
Annika Sun, University of Manitoba, Canada
Yuwei Jiang, Hong Kong Polytechnic University, Hong Kong

Results of two experiments illustrate that high Interdependents experience more gifting anxiety than low Interdependents. The effect disappears when a feeling of higher psychological power is induced.

51. Will Purchasing from Groupon Make A Lonely Consumer Feel Empowered? Loneliness and Preference for Group-Buying Purchase Experiences

Hangeun Lee, Yonsei University, South Korea
Junyoung Lee, Yonsei University, South Korea
Kyoungmi Lee, Yonsei University, South Korea
Hakkyun Kim, Concordia University, Canada

We find that lonely consumers prefer group-buying experiences to individual-buying experiences because they obtain feelings of consumer empowerment by participating in group-buying. This research provides insights for understanding how consumers cope with their feelings of loneliness in the marketplace, and how they restore better self-views.

52. The Identifiable In-Group: Group Status Moderates the Identifiable Victim Effect

Alixandra Barasch, University of Pennsylvania, USA
Rod Duclos, HKUST, Hong Kong
Emma Edelman, University of Pennsylvania, USA

We investigate an important moderator of the identifiable victim effect: victim group status. While most studies focus on the out-group (e.g.., victims of a foreign crisis), we build on previous work on identifiable vs. statistical victims by investigating the effectiveness of appeals that highlight in-group vs. out-group victims.

53. The Effect of Significant Others' Perceived States on the Evaluation of Relevant Products

Kiwan Park, Seoul National University, South Korea
Jiyoung Lee, Seoul National University, South Korea
Jerry Jisang Han, University of Texas-Austin, USA

The present research examines the effect of significant others' positive or negative states on the consumer's subsequent purchase intensions. We propose that individuals will exhibit compensatory attitudes toward certain products depending on their significant other's behavior, or on the situation prior to such a product assessment task.

54. Mark of Popularity or Distrust? The Role of "Peer Purchase Number" as a Cue Affecting Consumer Attitudes in the Web-Based Retail Context

Eun-Jung Lee, Kent State University, USA
Robert D. Jewell, Kent State University, USA

This study explores the role of peer purchase number (PPN) as a social cue affecting consumer attitudes online. In our experiment, increased PPN positively affected company/product evaluations, trust, and affirmation. Compared to the control condition where no PPN information was indicated, however, exposure of the small PPN negatively affected attitudes.

55. Network Coproduction: The Role of Self-Presentational Persona in Electronic Word-Of-Mouth

Shuling Liao, Yuan Ze University, Taiwan
Crystal Tzuying Lee, National Cheng-Chi University, Taiwan
Tzu Han Lin, Yuan Ze University, Taiwan

Consumers are regarded as active network co-producers to present their self-concepts though constructing eWOM. However, research that documents the link between self-presentational persona and eWOM is scant. We study show that consumers' self-presentational persona responds differently to their motives to post-eWOM.

56. Examining Consumer Response to Preferential Treatment Practices

Lan Xia, Bentley University, USA
Monika Kukar-Kinney, University of Richmond, USA

The practice of preferential treatment (i.e., treating and serving some customers better than other customers) is popular but involves both philosophical controversies and empirical inconsistencies. This research systematically examines characteristics of preferential treatment, its impacts on emotions and cognitions, and the underlying mechanisms of these effects.

57. Burger or Yogurt? The Effect of Private vs. Public Consumption Contexts on Indulgent Behavior

Shih-Chieh Chuang, National Chung Cheng University, Taiwan
Yin-Hui Cheng, National Taichung University of Education, Taiwan
Chien-Jung Huang, National Chung Cheng University, Taiwan
Yun Ken, National Yunlin University of Science and Technology, Taiwan

We conducted three studies and find that individuals tend to make choices other than those they favor privately when they anticipate that others will form impressions of them based on the decisions they make. Research findings support our basic prediction that people are more indulgent in private than in public.

58. Marketplace Metacognition in Consumer-to-Consumer Inferences: I Buy for Quality, You Buy for Status

Meghan Pierce, Pontificia Universidad Catolica de Chile, Chile
Kimberlee Weaver, VirginiaTech, USA
Kim Daniloski, University of Scranton, USA
Norbert Schwarz, University of Michigan, USA

Across three studies, participants identify quality reasons for their own and status reasons for others' purchases. These findings occur in recollected purchases (Study 1), when holding the products constant across condition, and when controlling for social desirability (Study 2). Consumers appear to be unaware of these consumer-to-consumer differences in metacognition (Study 3).

59. Dressed to Impress: When Images of Financial Success in Advertising Have an Inspirational vs. Detrimental Effect on Men

Abigail Schneider, University of Colorado, USA
Ethan Pew, Purdue University, USA
Susan Jung Grant, University of Colorado, USA

Although prior literature suggests that images of financial success in advertising are detrimental to men's self-esteem, the current paper posits a moderator of this condition: mating-motives. Specifically, we find that mate-seeking men desire to associate themselves with men who possess resources that aid in attracting members of the opposite sex.

60. Who Cares If It Is Deceptive, I Like It: The Effect of Social Exclusion on Advertising Deception

Hamed Aghakhani, University of Manitoba, Canada
Kelley J. Main, University of Manitoba, Canada

Research shows that advertising deception not only has a negative effect on subsequently encountered similar products and sources, but also has effects on people's attitudes towards advertising and marketing as an abstract concept. We show that social exclusion attenuates this carryover effect.

61. Speed and Social Connection

Melanie Thomas, University of Pennsylvania, USA
Cassie Mogilner, University of Pennsylvania, USA

This research examines the effect of speed on social connection. We examine how thinking about the benefits of time being slow, rather than the benefits of time being fast, increases desire for social connection and feelings of connectedness. We incorporate two different manipulations of speed and three measures of social connection.

62. Opening the Black Box: An Exploration of Consumer Production Influence on Marketplace Dynamics

Henri Weijo, Aalto University, Finland
Daiane Scaraboto, Pontificia Universidad Católica de Chile, Chile
Saara Könkkölä, Aalto University, Finland

Our study advances consumer researchers' understanding of consumer production. Through a meta-analysis of existing studies on consumers' value-creating activities, we identify three ways consumer production influences marketplace dynamics: through marketplace creation, actualization and reproduction of the marketplace, and marketplace destruction.

63. True Comeliness or Fake Beauty: Cosmetic Surgery as Mating Strategy

Sunyee Yoon, University of Wisconsin-Madison, USA
Nancy Wong, University of Wisconsin-Madison, USA

We explore the role of cosmetic surgery as a strategy to increase mating success from an evolutionary perspective. Cosmetic surgery is favored by females who are less sexually restricted and who possess stronger mating desires. However, men do not prefer women who have had cosmetic surgery because it does not improve reproductive values.

64. Classification of the Factors Influencing Ethical Consumer Choice: The Framework

Natalia Maehle, Institute for Research in Economics and Business Administration, Norway
Nina Iversen, Institute for Research in Economics and Business Administration, Norway
Leif Hem, Norwegian School of Economics, Norway

In the current study we explore the existing literature on ethical consumption and develop a framework classifying the main factors influencing ethical consumer choice. To our knowledge, this framework is the first one structuring the research in the field of ethical consumption and therefore represents an important theoretical contribution.

65. Whom to Trust? The Impact of Peer vs. Expert Opinions on Consumption Experiences

Travis Hancock, Brigham Young University, USA
Ryan Elder, Brigham Young University, USA

We demonstrate the differential impact of peer vs. expert reviews on pre-purchase attitudes and post-purchase consumption experience. We show that consumers use experts' opinions to a greater extent than peers', such that attitude change following a consumption experience is greater when consumers read peer (vs. expert) reviews.

66. The effect of Vertical Individualism on Status Consumption and Advertising Response

Michelle Nelson, University of Illinois at Urbana-Champaign, USA
Jing Zhang, San Jose State University, USA

Going beyond cultural differences in Individualism -Collectivism, we disentangle the Vertical (V) from Horizontal (H) aspects of Individualism (I) to illuminate its distinct effects in consumption and persuasion in three studies. We found that VI values affect consumers' brand consciousness, brand buying behavior, and their responses to status advertising appeals.

67. Emotional Intelligence, Giving, and Life Satisfaction: Some New Data and Conclusions

Rajani Ganesh Pillai, North Dakota State University, USA
Doug Rymph, North Dakota State University, USA
Sukumarakurup Krishnakumar, North Dakota State University, USA

In this paper we show that Emotional Intelligence (EI) may play a significant and unique role in the way people spend money on others (e.g., on gifts vs. donations). EI impacts the relationship between spending on others and life satisfaction differently, depending on whether individuals spend on gifts or donations.

68. It's All About Me: Effects on Product Samples for Self vs. Other

Chelsea Johnson, University of Illinois at Urbana-Champaign, USA
Brittany Duff, University of Illinois at Urbana-Champaign, USA

A promotional product sample high in incentive value may lead to general reward-seeking behavior. This study introduces the idea that reward seeking may be self-directed, with the effect driven by an increase in purchases for self. Implications for advertising and point-of-purchase incentives are discussed.

69. The Effect of Face Pressure on Chinese Consumer Decision-Making

Karthik Easwar, Ohio State University, USA
Robert Burnkrant, Ohio State University, USA

This research links two areas of research that suffer from minimal exploration, cross-cultural decision-making and face. We demonstrate that face is a crucial determinant of Chinese consumer behavior that explains behavior over and above the standard components of the TRA model.

70. Sense and Cents: Collective Consumer Sensemaking in an Online Investment Community

Andrew N. Smith, York University, Canada

Through an investigation of 241 blog posts, and all related comments in an online investment community, this study elaborates on the collective consumer sensemaking process. It finds that sensegiving plays an important role in shaping this process.

71. Consumer Creativity in Co-Creation: The Interaction between Default Product and Design Goal

Bo Chen, ESSEC Business School, France
Niek Althuizen, ESSEC Business School, France

Providing a default product in the co-creation process may influence the creativity of consumers' outcome, and this effect may be dependent on their design goal. This paper explores the interaction effect between the provided default product and the activated design goal on consumer creativity in co-creation.

72. Bidirectional Consumer Friends' Knowledge Calibration —Overestimated or Underestimated? A Two-Stage Model

Joicey Jie Wei, National University of Singapore, Singapore
Iris Hung, National University of Singapore, Singapore
Gita Johar, Columbia University, USA

The knowledge calibration process has been considered as a one-stage process in which people over-project their own self-knowledge to predict how much others know about them, leading to overestimation in friends' knowledge calibration. However, we suggest that the estimated accuracy should be a two-stage process.

73. What Drives Individual Purchase Decisions in a Network? A Consumer-Motivation Approach

Dongwoo Ko, University of Iowa, USA
Sanguk Jung, University of Auckland, New Zealand

Empirically, the center of the network has been regarded as a crucial component in marketing strategies; however, as the previous literature suggests, the center of network does not directly connect to revenue generation. This research pinpoints people who are more likely to follow others' opinions.

74. Assimilation and Contrast in Web Product Reviews: Devaluing the Recommendation of a Proficient but Dissimilar Reviewer

Michael Dorn, University of Bern, Switzerland
Claude Messner, University of Bern, Switzerland

Little is known about how the social information on the reviewer influences consumers' evaluation of the reviewed product. This experimental study applies the paradigm of social comparison and measures the product-evaluation. Contrasting the social information leads to a devaluation of the products recommended by a proficient but dissimilar reviewer.

75. A Typology of Crowdsourcing Participation Styles

Eric Martineau, Concordia University, Canada
Zeynep Arsel, Concordia University, Canada

What motivates individuals to participate in crowdsourcing, and what ends do they seek? We propose a typology of participation styles through a study of two prosumption communities: Threadless.com and Montreal Couture. We then provide guidelines for managers who wish to implement a crowdsourcing project.

76. Exploring Consumer Attitudes toward Social-Network Advertising

Cuauhtemoc Luna-Nevarez, New Mexico State University, USA
Jennifer Zarzosa, New Mexico State University, USA

Drawing upon the Theory of Reasoned Action, we develop a theoretical framework to explain the antecedents (perceived utility, attitude toward advertising, and advertisement intrusiveness) and consequences (intention to engage in online word-of-mouth and purchase intention) of social network advertising. A structural equation modeling analysis confirms the hypothesized causal relationships.

77. It's Not All About Coffee: A Netnography of the Starbucks Brand Page on Facebook

Heejin Lim, University of Tennessee, USA
Jewon Lyu, University of Tennessee, USA

This study aims to discover the nature and meanings of brand social networking on Facebook. A Netnography of the Starbucks Page on Facebook unveils a spatial meaning of the brand page, and the multifold meanings of the brand shared through the platform. Findings of this study support the postmodern consumption theory.

78. Changing Consumption Habits: Does Personalization Really Work?

Kirsikka Kaipainen, VTT Technical Research Centre, Finland
Brian Wansink, Cornell University, USA

Most dietary programs fail to produce sustainable behavior changes, since participants soon return to their old habits. Small changes based on simple behavioral heuristics have the best chance to be maintained. This study suggests that effectiveness of small habit changes is improved through personalization to circumstances and psychological needs.

79. Getting Lucky: When Loyalty Status Makes You Feel Lucky

Rebecca Walker Naylor, Ohio State University, USA
Kelly L. Haws, Texas A&M University, USA
Christopher Summers, Ohio State University, USA

Might loyalty status spillover into expectations about outcomes that should not be affected by membership (i.e. random events)? We suggest loyalty fosters a sense of deservingness that transfers to randomly determined outcomes, and propose that loyalty can lead consumers to feel lucky.

80. Feeling Lucky while Feeling Good: The Relative Impacts of Superstitious Beliefs and Affect on Consumer Judgment and Choice

Thomas Kramer, University of South Carolina, USA
Meredith David, University of South Carolina, USA

We examine the moderating role of superstitious beliefs on the established relationship between affect and preferences for a hedonic vs. utilitarian product. Two studies show that luck primes are more important than affect in influencing preferences, but they are less influential among consumers who have a high chronic belief-in-good-luck.

81. Shame on You! Motivating Consumer Behavior with Shame Appeals

Jennifer Jeffrey, University of Western Ontario, Canada
Juan Wang, University of Western Ontario, Canada
Dante M. Pirouz, University of Western Ontario, Canada
Matthew Thomson, University of Western Ontario, Canada

Social marketers use emotion-invoking appeals as a frequent persuasion technique but discount shame due to its association with avoidance behaviors and withdrawal. This research provides initial support that the intensity and self-focused nature of shame make it a helpful emotion to elicit in contexts aimed at changing a target's behavior.

82. Corporate Communications in Uncertain Times: Messages of Hope or Pride?

Anne Roggeveen, Babson College, USA
Anirban Mukhopadhyay, HKUST, Hong Kong
Dhruv Grewal, Babson College, USA

Hope and pride are two widely used positive emotions in corporate communications. Building on appraisal theory, four studies demonstrate that messages of pride result in more positive evaluations in situations of certainty, and messages of hope results in more positive evaluations in situations of uncertainty.

83. Affect and Consumer Behavior: A Meta-Analytic Review

Nancy M. Puccinelli, Oxford University, UK
Dhruv Grewal, Babson College, USA
Scott Motyka, Brandeis University, USA
Susan A. Andrzejewski, Franklin and Marshall College, USA

We report the results from a meta-analysis examining the influence of affect on evaluation and behavior, seeking to resolve discrepancies in findings by identifying mechanisms underlying affect-congruent vs. affect-incongruent outcomes (i.e., analytical bias and affect regulation). Conducted moderator analyses include involvement, transparency of affect manipulation, and social normative effects.

84. Hoarding and Consumer Anxiety: Understanding When Consumption Becomes Dysfunctional

Gail Leizerovici, University of Western Ontario, Canada
Dante M. Pirouz, University of Western Ontario, Canada
Samantha Cross, Iowa State University, USA

Hoarding is defined as the acquisition of and failure to discard large numbers of possessions and affects an estimated 6-15 million Americans. Our work shows that hoarding is related to OCD, anxiety and need for cognition. Future research will study what types of anxiety provoking events trigger hoarding.

85. All Kidding Aside: Humors Lowers Propensity to Remedy a Problem

A. Peter McGraw, University of Colorado, USA
Philip Fernbach, University of Colorado, USA
Julie Schiro, University of Colorado, USA

Although humor increases attention and liking, humorous appeals may lower people's propensity to remedy a problem because humor is associated with non-serious situations. Young adults viewed humorous and non-humorous PSAs that highlighted people's ignorance about birth control. We find the humorous PSA resulted in less search behavior for sexual health information.

86. Asymmetries in the Impact of Action and Inaction Regret: When and Why Do They Occur?

Atul Kulkarni, University of Missouri-Kansas City, USA
Rashmi Adaval, HKUST, Hong Kong

Through a set of three studies, we explore the conditions under which action vs. inaction regret may have an asymmetric effect on risk taking, and examines the underlying role of affective vs. cognitive drivers of the effect of regret on risk taking.

87. The Effect of Aging on Consumer Regret

Li Jiang, University of California Los Angeles, USA

This research investigates the moderating role of decision justifiability on age-related differences in the experience of regret. Older (vs. young) adults express more regret in response to a scenario in which a justifiable option is clearly defined, but not in the absence of a readily justifiable option.

88. Not Immediately Stupid: The Moderating Effects of Purchase Immediacy and the Mediating Effects of Regret on Self-Perceptions of Consumer Incompetence

Matthew Philp, Queen's University, Canada
Laurence Ashworth, Queen's University, Canada

Individuals feel like incompetent consumers after post-purchase discovery of a lower available price. This effect is attenuated when purchase immediacy is high, where the purchase was made out of immediate necessity. We present a model showing that consumer incompetence is moderated by purchase immediacy and mediated by regret.

89. Assessment of Heterogeneity of Compulsive Buyers Based on Affective States Preceding Buying Lapses

Sunghwan Yi, University of Guelph, Canada
Joowon Jung, Dongguk University, South Korea

We examine the heterogeneity of compulsive buyers based on the frequency of affective states preceding buying lapses. Contrary to the mood-repair view of compulsive buying, we identify two subtypes of compulsive buyers: one whose buying is mainly triggered by negative affect, and the other that is triggered by boredom.

90. Do Hedonic Benefits Always Create "Hedonic" Feeling? The Impact of Two Factors on Consumer's Response to Hedonic Rewards Design of Loyalty Program

Sidney Su Han, University of Guelph, Canada
Lefa Teng, University of Guelph, Canada
Yiqiu Wang, Northeastern University, China

Hedonic rewards do not always appeal to customers as marketers expect. Through two experiments, the authors propose that one scheme of loyalty program design (i.e. magnitude of rewards medium) and one consumer dispositional characteristic (i.e. self- regulatory concern) can influence consumers' affective and cognitive responses to the hedonic benefits of a loyalty program.

91. Compulsive Buyers Show an Attentional Bias in Shopping Situations

Oliver B. Büttner, University of Vienna, Austria
Matthew Paul, University of Vienna, Austria
Arnd Florack, University of Vienna, Austria
Helmut Leder, University of Vienna, Austria
Anna Maria Schulz, University of Vienna, Austria

This research used eye tracking to examine attentional processes that underlie compulsive buying. The results demonstrate an attentional bias. That is, compulsive (vs. noncompulsive) buyers are more likely to get distracted by products unrelated to their goal. The effect emerges only when the task is framed as a shopping situation.

92. Physical Temperature Effects on Consumer Decision Making

Tingting Wang, HKUST, Hong Kong
Rongrong Zhou, HKUST, Hong Kong

The present research explores the influence of temperature experiences on consumers' decision-making. The experiments reveal that physical coldness vs. hotness enhances consumers' tendency to buy, but decreases the inclination to sell products. These effects are moderated by the strength of belief in the association between temperature and abundance.

93. "It's Cold in Here. I Need a Bowl of Soup to Warm Me Up!" The Effects of Incidental Sensory Frames on Conflicting Sensory Inputs

Sydney Chinchanachokchai, University of Illinois at Urbana-Champaign, USA
Rashmi Adaval, HKUST, Hong Kong

Two studies show that sensory frames activate semantic concepts applied to judgment. However, when the attention is drawn to incidental cues, it triggers a motivation to think of the desirability of the focal object. The desirability increases only when there is a lack of it in the salient sensory frame.

94. "Size Matters!" The Effect of Floor Tile Size on Consumer Behavior in a Retail Environment

Nico Heuvinck, Ghent University and University College Ghent, Belgium
Iris Vermeir, Ghent University and University College Ghent, Belgium
Simon Quaschning, Ghent University and University College Ghent, Belgium

In this study, we show that although customers do not have the feeling of walking faster in small-tile aisles, they actually spent less time walking along small-tile aisles compared to big-tile/no-tile aisles, leading to lower brand recall and brand recognition.

95. Will People Express More or Less Conformity When They Feel Warm? The Moderating Role of Self-Construal

Xun (Irene) Huang, Chinese University of Hong Kong, Hong Kong
Meng Zhang, Chinese University of Hong Kong, Hong Kong
Michael K. Hui, Chinese University of Hong Kong, Hong Kong
Robert S. Wyer, Chinese University of Hong Kong, Hong Kong

We propose that high ambient temperature can either increase or decrease consumers' conformity tendency, depending on people's default level of perceived social closeness between self and others. Specifically, independent people conform more, and interdependent people conform less in the warm condition.

96. I Can Feel Your Pain: The Influences of Haptic Input on Donation Amount

Chun-Ming Yang, Ming Chuan University, Taiwan
Rong-Da Liang, National Kaohsiung University of Hospitality and Tourism, Taiwan

Three experiments test the influences of touch element on donation amount. The results showed that touching a victim's photo leads to higher donation amount, perceived sympathy mediates this effect, and seeing a victim's face is not a necessary condition, and this effect is stronger for high-NFT individuals.

97. Chi Ku: Bitter Taste Preferences and Responses to Unpleasant Experiences

Chun-Ming Yang, Ming Chuan University, Taiwan

"Eating bitterness" is a common Chinese metaphor but has received limited research attention. Five studies test the metaphorical link between bitter taste preference and responses to unpleasant experiences. Based on the embodied cognition literature, this research finds that individuals who prefer bitter taste reported higher distress tolerance and have different responses to unpleasant experiences.

98. Detaching the Ties of Ownership: The Effects of Hand Washing on the Exchange of Endowed Products

Arnd Florack, University of Vienna, Austria
Janet Kleber, University of Vienna, Austria
Romy Busch, University of Vienna, Austria
David Stoehr, University of Vienna, Austria

Research on the endowment effect shows owners usually exhibit more positive evaluations and a stronger preference for an object than non-owners. In three studies, we demonstrate that the action of hand washing can reduce these effects of endowment.

99. The Magic Touch: Psychological Drivers of the Discrepancy Between Traditional and Touchscreen Equipment

Ying Zhu, The University of British Columbia, Canada
Jeffrey Meyer, Bowling Green State University, USA

The research aims to advance knowledge in the touch literature to enable academic theory to keep up with the new technology. It builds on the literature of tactile functions and emotion, and incorporates new technology phenomena to predict consumer behavior on two devices: traditional and touchscreen equipment.

100. The Effect of Tangibility on Desire

Katrien Meert, Ghent University, Belgium
Mario Pandelaere, Ghent University, Belgium

This paper investigates the effect of tangibility on desire. Touching a product might increase product evaluations; however, consumers view items as appealing when they have to overcome obstacles to obtain them. Hence, we investigate whether displaying a product in a way that it cannot be touched might enhance desire.

101. Visceral Vigor: The Effects of Disgust on Goal Pursuit

Sachin Banker, MIT, USA
Joshua Ackerman, MIT, USA

Visceral states such as hunger, thirst, and sexual arousal are commonly shown to induce impulsive behaviors. We consider whether visceral states can instead result in long-term goal directed behavior. We present evidence that suggests induced-disgust states promote the pursuit of previously active goals.

102. Do We Judge a Book by its Cover? Unwrapping the Role of Visually-Appealing Packaging in Product Evaluation

Tanuka Ghoshal, Indian School of Business, India
Peter Boatwright, Carnegie Mellon University, USA
Jonathan Cagan, Carnegie Mellon University, USA

We find that aesthetically appealing packaging (AAP) positively impacts product attitudes and valuations for hedonic products but not for utilitarian products. We propose that evaluating a hedonic (utilitarian) product puts consumers in a promotion (prevention) orientation, making them more (less) likely to place weight on attractiveness factors like AAP.

103. Implied Sensory Experiences in Product Designs Makes People Think Global

Christophe Labyt, Ghent University, Belgium
Mario Pandelaere, Ghent University, Belgium

This paper examines the influence of exposure to products with an implied sensory design on a person's cognitive processing mode. Two studies indicate that exposure to sensory design triggers global processing. This finding is particularly true for participants who attach greater value than average to a product's appearance.

104. We're Gonna Need a Bigger Spoon: Spoon Size Effects on Product Perception

Aner Tal, Cornell University, USA
Brian Wansink, Cornell University, USA

Spoon size has been shown to lead to increased consumption. The current study examines whether this may be due to a distortion of product quantity where people see less food when holding a bigger spoon. We discuss potential explanations for this phenomenon.

105. The Effects of Physical Constraints on Creativity

Ke (Christy) Tu, University of Alberta, Canada
Jennifer A. Argo, University of Alberta, Canada

We investigate the effects of physical constraints on creativity in this paper. The results from one study show that when wearing a tight hat (vs. a loose hat), males are more creative, while females are less creative. We will test the theoretical framework in a serious of follow-up studies.

106. Multi-sensory Perception in Servicescapes: A Typology and Avenues for Future Research

Bernd Frederik Reitsamer, University of Innsbruck, Austria
Nicola Stokburger-Sauer, University of Innsbruck, Austria

The aim of this paper is to provide a conceptual framework that classifies existing research on environmental stimulus processing in management and marketing into four major dimensions. We highlight ample opportunities for further research in the multi-sensory realm.

107. The Sweet Taste of Charity: Cause Branding Affects Product Experience

Alyssa Niman, Cornell University, USA
Aner Tal, Cornell University, USA

Cause-branding is a wide and spreading marketing strategy. We demonstrate that part of the efficacy of cause-branding may lie in its alteration of product experience: products that do good taste good. We also explore possible underlying mechanisms such as conceptual consumption, the "halo" effect, and evolutionary psychology.

108. The Perils of an Expansive Posture: The Effect of Everyday, Incidental Posture on Stealing, Cheating and Parking Violations

Andy Yap, Columbia University, USA
Abbie Wazlawek, Columbia University, USA
Brian Lucas, Northwestern University, USA
Amy Cuddy, Harvard Business School, USA
Dana Carney, University of California Berkeley, USA

Three studies test the hypothesis that expansive postures lead to unethicality. A field experiment demonstrates that expansive postures induce stealing. Experiment 2 finds that incidentally expanded postures (e.g. forced upon by one's workspace) increase cheating. A third observational study finds that vehicles with larger cockpit-sizes are more likely to violate parking laws.

109. Hormones and Prosocial Behavior: The Influence of the Menstrual Cycle on Gift-Giving Propensity

Eric Stenstrom, Concordia University, Canada
Gad Saad, Concordia University, Canada

Can the menstrual cycle influence not only what women buy, but also for whom? Utilizing a 35-day panel study, we find that women allocate significantly more money towards gift-giving during the luteal phase than during the fertile phase. Our findings suggest that women's affiliative goals fluctuate across the menstrual cycle.

110. What Are Consumers Afraid Of? Perceived Risk toward Environmentally Sustainable Consumption

Jiyun Kang, Texas State University, USA
Sang-Hoon Kim, Seoul National University, South Korea

In this research, we investigate perceived risk in consumers' decision making specifically related to environmentally sustainable products, considering the multi-dimensional nature of perceived risk. This research provides marketers with implications to promote the adoption of socially-desirable products and further enables the broader diffusion of such products in the marketplace.

111. Sustainable Luxury: Oxymoron or Pleonasm? How Scarcity and Ephemerality Affect Consumers' Perceptions of Fit between Luxury and Sustainability

Catherine Janssen, Université Catholique de Louvain, Belgium
Joëlle Vanhamme, EDHEC Business School, France
Adam Lindgreen, University of Cardiff, UK
Cécile Lefebvre, IESEG School of Management, France

Sustainability may be key to luxury. Through a field experiment, we investigate the influence of two defining characteristics of luxury products—scarcity and ephemerality—on the perceived fit between luxury and sustainability, as well as how this perceived fit affects consumers' attitudes toward luxury products.

112. Born Out There: The Discursive Creation of Harmony between Humans and Nature

Joachim Scholz, Queen's University, Canada
Jay M. Handelman, Queen's University, Canada

This paper analyzes how the myth of living in harmony with nature is discursively constructed via the representation of nature in ads. Differentiating between Arcadian and Dynamic images of nature, we explore the complexities of the harmony myth, and how this myth relates to divergent meanings of "sustainable consumption."

113. Doing Good While Looking Good: Consumer Perceptions of Sustainability in the Fashion Industry

Rishtee Batra, Indian School of Business, India
Tonya Boone, College of William and Mary, USA

The present study uses the ZMET technique to examine consumers' general perceptions about sustainably manufactured products and also focuses more specifically on consumer perceptions of sustainably manufactured fashion items.

114. The Greening of Consumers: An Assimilation-Contrast Perspective for Product Sustainability Labeling

Yoon-Na Cho, University of Arkansas, USA
Scot Burton, University of Arkansas, USA

Despite an increase in consumers' interest in sustainable products, few studies focus on disclosures of sustainability levels for consumer packaged goods. We find that the type and amount of sustainability information disclosed interacts with the sustainability levels in influencing product evaluations.

115. Going Green, Going Feminism: Stereotype about Green Consumption and Social General Role

Yunhui Huang, Nanjing University, China
Echo Wen Wan, University of Hong Kong, Hong Kong

Green consumption is perceived to be related to the feminine gender role both implicitly (Study 1, through Implicit Association Test) and explicitly (Study 2). And engaging in green consumption will improve the judgment about the social status of male consumers but not for female consumers (Study 3).

116. Consumer Emotional Intelligence: Exploring Shades of Green and Grey

Sukumarakurup Krishnakumar, North Dakota State University, USA
Sonakshi Garg, North Dakota State University, USA
Christopher Neck, Arizona State University, USA

The role of consumer emotional intelligence (EI), or the ability to deal with emotions, has been much ignored in ethical and green consumer behaviors. We study the associations between EI, Machiavellianism, and ethical and recycling beliefs. Findings indicate that EI predicts ethical and environmental beliefs positively, even after controlling for Machiavellianism.

117. The Moderating Role of Situational Consumer Skepticism towards Sustainability Claims in the Effectiveness of Credibility Signals

Bonnie Simpson, University of Calgary, Canada
Scott Radford, University of Calgary, Canada
Mehdi Mourali, University of Calgary, Canada

This research explores boundary conditions of credibility signals in skeptical environments. The impact of situational skepticism is examined on the credibility of information source and message origin. We show that when the message originates internally, situational skepticism moderates source credibility and attitude certainty, resulting in less certainty in product attitudes.

118. The Moderating Role of Perceived Consumer Effectiveness and Consumer Involvement on the Effect of Message-Framing on Intention to Purchase Organic Food Products

Courtney Briggs, Purdue University, USA
Sejin Ha, Purdue University, USA
Richard Feinberg, Purdue University, USA

This study examines the effects of different label-message formats (positively- vs. negatively-framed message) on intention to purchase organic food, and the influence of two individual-difference moderators (involvement and perceived consumer effectiveness) on the performance. Using a Web-based experimental method, hierarchical moderated regression analyses confirmed the hypotheses.

119. From General vs. From Specific: Effects of Overestimating Future Engagement in General vs. Specific Green Behavior on Immediate Within-Domain and Across-Domain Green Behaviors

Kiju Jung, University of Illinois at Urbana-Champaign, USA
Dolores Albarracin, University of Pennsylvania, USA
Madhu Viswanathan, University of Illinois at Urbana-Champaign, USA

In two experiments, we find that consumers are more likely to immediately engage in various green behaviors after they are asked to engage in a general green behavior (green product purchase) in the distant future (vs. tomorrow). However, this is not case if they are requested to engage in a specific green behavior (e.g., compact fluorescent lamp purchase).

120. Mitigating Climate Change: The Role of Reasoning Errors, Ecological Knowledge, and Moral Positions

Christian Weibel, University of Bern, Switzerland
Ralph Hertwig, University of Basel, Switzerland
Sidonia Widmer, University of Basel, Switzerland

To explain inter-individual differences in pro-environmental behavior, we pitted the following predictors against each other: reasoning errors, environmental knowledge, and moral positions. We find little evidence that reasoning errors or environmental knowledge is strongly related to environmentally unfriendly behavior. Moral positions were far more predictive of pro-environmental behavior.

121. In the Name of Environmental Friendliness: Effects on Attitudes toward the Service

Ronnie (Chuang Rang) Gao, Drexel University, USA
Rajneesh Suri, Drexel University, USA

Environmental friendliness does not always offer consumers immediate benefits. For instance, many hotels no longer replace guest-bed linens daily. We empirically demonstrate that consumers high in environmental concern react more favorably towards reduced services, and more favorably when provided with a choice. We also found no effects when such consumers were merely exposed to environmental messages.

122. The Restorative Nature of Nature: Improving Consumer Decision Making

Merrie Brucks, University of Arizona, USA
Kevin Newman, University of Arizona, USA
Caitlin Nitta, University of Arizona, USA

This study provides evidence that natural environments improve self-regulation abilities, translating into healthier food choices and fewer items ordered. Given statistics related to the overconsumption of food, this research holds public policy implications affecting millions of Americans and provides them with a self-regulation resource that is free, safe, and plentiful - nature.

123. Risky Decisions: Citing Sources in Print Advertisement Claims

Catherine Armstrong Soule, University of Oregon, USA
Leslie Koppenhafer, University of Oregon, USA

The research investigates whether source citation of print advertisement claims can be beneficial to consumers by providing information that aids in accurate deception detection. Studies in different risk domains find the type and level of risk leads to differential processing of the presence or absence of advertising claim source information.

124. "Is it Risky or Beneficial?" Analysis of Supplement-Type and Dosage Preferences in Terms of Risk-Benefit Tradeoffs and Epistemological Beliefs

Zoe Rogers, Baruch College/CUNY USA
Stephen J. Gould, Baruch College/CUNY, USA

This research considers the effect of risk and benefit assessments on evaluations of health supplements. Familiar supplements lead to more thoughts about benefits and more positive evaluations, while unfamiliar supplements lead to more thoughts about risks and less positive evaluations. Epistemic beliefs are shown to underpin these assessments.

125. Personal Death-Thought Accessibility: A Mediating Mechanism between Self-Esteem and Risky Consumer Behaviors?

Sandor Czellar, University of Lausanne, Switzerland
Charles Lebar, HEC Paris, France
Christian Martin, University of Lausanne, Switzerland
Russell H. Fazio, Ohio State University, USA

Research investigating the relationship between self-esteem and mortality salience provides initial evidence that self-threats increase accessibility of death-related thoughts. We focus on the nature of those thoughts and investigate whether self-threats enhance accessibility of thoughts related to one's own death or death in general, bearing important implications for marketing communications.

126. Optimizing Targeting Effectiveness: The Reversed U-Shape Relationship between Target Market and Consumer Attitude

Shuoyang Zhang, Colorado State University, USA
Ishani Banerji, Indiana University, USA
Eliot Smith, Indiana University, USA

In the current research we propose a reversed U-shape effect of targeting strategy. Our findings show that compared with mass marketing and personal targeting, optimal consumer attitude is achieved when product recommendations are provided to a small group of similar people. This implies that extreme personalization can actually backfire.

127. Vice vs. Virtue: How Compromise Phantom Alternatives Can Increase Indulgence

Yuanyuan Liu, ESSEC Business School, France
Timothy B. Heath, HEC Paris, France
Ayse Önçüler, ESSEC Business School, France

The current study proposes that a compromise-but-unavailable "phantom" alternative can increase indulgence in vices. Three experiments examine this effect as well as the mediating roles of anticipatory guilt/regret and the moderating role of preference strength.

128. Scare an Optimist and Reassure a Pessimist: Message Frames Adjusted to Individual Coping Styles Enhance Breast Cancer Screening Participation

Laure Weckx, Katholieke University Leuven, Belgium
Anouk Festjens, Katholieke University Leuven, Belgium
Sabrina Bruyneel, Katholieke University Leuven, Belgium

We study (1) the relationship between individual coping styles and breast-cancer screening participation, and (2) the impact of message frames adjusted to these coping styles on participation intentions. Women who are optimistic about the outcome of the screening benefit from scaring invitations, whereas anxious women benefit from reassuring invitations.

129. To Trade or Not? Removing Trading Motivation Eliminates the Endowment Effect

Laurence Ashworth, Queens University, Canada
Lindsay McShane, Queens University, Canada
Tiffany Vu, Queens University, Canada

The current work suggests that owner/non-owner discrepancies can exist because consumers typically are required to specify prices at which they would trade. Consequently, we predict that owners/non-owners likely set prices sufficiently above/below perceived worth, to motivate trade. When ownership and trading are separated we find that the endowment effect disappears.

130. Why Preference Stability of Certain Product Attributes are More Than Others: Disaggregating Stability (Instability) into Core and Supplementary Attributes

Fangzhou Xu, University of Guelph, Canada
Juan Wang, Western University, Canada
Towhidul Ialam, University of Guelph, Canada

To reconcile the debate between stable and constructed preferences, we suggest an alternative view of decomposing product preference into attribute preference. Specifically, we argue that consumer preferences for core attributes of a product should be largely stable across time, while supplementary attributes should be largely unstable.

131. The Effect of the Change-Matching Heuristic on Consumer Purchase Decision Making

Yin-Hui Cheng, National Taichung University of Education, Taiwan
Chia-Jung Chang, National Chung Cheng University, Taiwan
Shih-Chieh Chuang, National Chung Cheng University, Taiwan
Che-Hung Lin, Cheng Shiu University, Taiwan

Based on the perspective of processing fluency, this study demonstrates the "change-matching heuristic," whereby people select a choice option that matches the amount of change in their wallets with the price of a product. We find that the compromise effect and the attraction effect will weaken the influence of the change-matching heuristic.

132. The Effects of Consumption Goals and Assortment on Cross-Price Sensitivity

Kiwan Park, Seoul National University, South Korea
Joonkyung Kim, Seoul National University, South Korea

We propose that activating a consumption goal makes people more sensitive to the price discounts of competing products in the same goal-derived category as the target product. Also, we propose that when one of two products is on sale, including a third option that highlights the similarity of the first two options would make people more sensitive to the price discount.

133. The Effect of Price Discounts and Quantity Restrictions on Consumption Enjoyment

Zhenfeng Ma, Wilfrid Laurier University, Canada
Guanfu Wang, University of International Business and Economics, China

Two experimental studies investigate the joint effect of price discounts and quantity restriction on consumption enjoyment. Findings suggest that price promotion can either enhance or dampen consumption enjoyment of the promoted product, depending on the form of quantity restriction (e.g., quantity ceiling vs. quantity flooring).

134. Letting Go of Meaningful Goods: How the Voluntary vs. Involuntary Nature of Disposition Impacts Seller Pricing

Kapitan Sommer, University of Texas at San Antonio, USA
David H. Silvera, University of Texas at San Antonio, USA

In this research, we show that voluntary sellers demand non-significantly different prices than buyers. However, involuntary sellers of prized goods, such as those selling in the face of foreclosure, layoff, divorce or death, demand higher prices than both involuntary sellers of non-prized goods and voluntary sellers of prized goods.

135. The Effects of Stackable Discounts on Consumers' Retail Price Image Perception

Shan Feng, William Paterson University, USA
Jane Cai, Independent, USA

This paper examines the impact of stackable discounts on retailers' price image. We compare stackable discounts to a single discount format in terms of the value perceived by consumers, and find that stackable discounts are superior in creating a more favorable retail image.

136. Presentation of Comparative Prices: Role of Working Memory

Rajneesh Suri, Drexel University, USA
Shan Feng, William Patterson University, USA
Rajesh Chandrashekran, Farleigh Dickinson University, USA

Comparative price promotions produce favorable consumer value perceptions and stimulate sales. This research suggests that the mental effort required when deciding about a price affects perceptions of discounts presented in vertical and horizontal formats. Three studies show that constraints on working memory resources favors computation of vertically vs. horizontally presented prices.

137. Virtual Endowment: How Location and Duration of Virtual Ownership Influence Valuation

Elisa K. Chan, Cornell University, USA
Aner Tal, Cornell University, USA

We examine the endowment theory in an online context and with virtual ownership. We find that simply placing an online product on a webpage vs. in an online shopping cart triggers a different willingness to pay. Our study suggests that general and personal virtual shopping carts elicit different perceived values.

138. The Effects of Scarcity Claims on Consumers' Willingness to Pay

Doreen Pick, Freie Universität, Germany
Peter Kenning, Zeppelin Universität, Germany
Felix Eggers, Zeppelin Universität, Germany

According to scarcity theory, time-limited offers can have positive effects on consumers' purchase intentions. We examine the impact of several scarcity claims on consumers' willingness to pay. Our results show mixed findings regarding different claims and product categories, which provides a basis for further investigation.

139. Don't Think Twice: The Effects of Decision Confidence on the Experienced Utility of Incidental Rewards

Aaron Snyder, Stanford University, USA
Maya Shankar, Stanford University, USA
Baba Shiv, Stanford University, USA

Research has shown that confidence in one's choice can increase satisfaction with the chosen outcome. We extend these findings to show that decision confidence can have downstream consequences on perceptions of incidentally-acquired rewards as well.

140. Your Cheating Heart: The Negative Impact of Sales Promotions on Loyalty

Olga (Olya) Bullard, University of Manitoba, Canada
Kelley J. Main, University of Manitoba, Canada
Jennifer J. Argo, University of Alberta, Canada

We examine the impact of consumers' use of sales promotions on service providers. Study1 reveals that service providers see consumers who redeem coupons and free gifts/service as disloyal. Study 2 identifies two moderators: size of sales promotion and existence of the relationship between consumer and service provider.

141. My Brand and I, and Others between Us: The Influence of Interpersonal Relationships on Consumer-Brand Relationships

Marina Carnevale, Fordham University, USA
Lauren G. Block, Baruch College/CUNY, USA

Despite their contextual nature, consumer-brand relationships are assumed to be independent of external interpersonal relationships (e.g., significant others). Across three studies, we show that when a product symbolizes an external relationship (e.g., it was a gift), changes in that relationship may impact consumers' feelings of self-brand connection and consequently their brand evaluations.

142. Revelatory Experiences: The Brand Backstory and its Impact on Consumers' Experience of Brand Narratives

Vanisha Narsey, University of Auckland, New Zealand
Cristel Russell, University of Auckland, New Zealand
Hope Jensen Schau, University of Arizona, USA

The "making-of" or "behind the scenes" activities of media brands are increasingly made available to consumers, often revealing the artifices of a brand. We explore consumers' experience of the brand backstory and the impact this experience has on personal brand narratives.

143. Who is the Brand Creator? The Effect of Different Brand Biographies on the Perception of Brand Personality

Marc Linzmajer, Zeppelin University, Germany
Jana Hauck, Zeppelin University, Germany
Marco Hubert, Zeppelin University, Germany
Reinhard Prügl, Zeppelin University, Germany

Based on the relationship model, this paper investigates the role of different brand biographies and hypothesizes that they lead to different consumer perceptions of brand personality. The results of our exploratory experimental study show there are significant differences between both brand creators and the perception of brand personality dimensions.

144. Consumer Persuasion Knowledge in Non-Conventional Marketplaces: The Case of Branded Prescription Drugs

Marjorie Delbaere, University of Saskatchewan, Canada
Mei-Ling Wei, Saint Mary's University, Canada

We argue that consumers are beginning to recognize the physician-prescribing situation as a potential persuasion attempt and that the onslaught of Direct-to-Consumer (DTC) advertising has brought about this change in meaning. We investigate the prescribing situation as a mixed-motive situation with high levels of ambiguity; in other words, as persuasion within a non-persuasion environment.

145. The Magic of Numbers and Letters in Alphanumeric Brand Names

Selcan Kara, University of Connecticut, USA
Kunter Gunasti, University of Connecticut, USA

This research explores the effect of number and letter changes in alphanumeric brand names (ABs) on consumers' reactions to brand extensions. Based on two experiments, we show that processing of number vs. letter changes in ABs lead to a variance in the perceived differences between the new and existing brands.

146. What is Brand Authenticity? An Exploration of the Concept

Amélie Guèvremont, Concordia University, Canada
Bianca Grohmann, Concordia University, Canada

This research focuses on understanding the concept of brand authenticity from a consumer perspective, a topic characterized by a lack of consensus in the literature. Following fifteen individual interviews, we identify eight common characteristics of authentic brands, revealing that some form of objectivity is found in consumers' authenticity perceptions.

147. Brand Happiness: Scale Development and Validation

Sunmyoung Cho, Yonsei University, South Korea
Ae-Ran Koh, Yonsei University, South Korea

This study develops a scale to measure the brand happiness construct and demonstrates that it captures consumers' feelings of happiness with their selves and lives as their happiness is related to brands. Through four different phases, we establish internal and nomological validity and explore various predictions.

148. Primacy of Acculturation Categories over Demographic Variables as Differentiators of Brand Preference

Rohini Vijaygopal, University of Bedfordshire, UK
Sally Dibb, Open University, UK
Maureen Meadows, Open University, UK

The literature highlights the importance of demographic variables and acculturation categories in consumer behavior involving ethnic minorities. This paper considers the primary differentiators of consumer behavior among British Indians by examining the relationships between acculturation categories, demographic variables and preferences for a range of ethnic and host brands.

149. Why Are Consumers Fans of Counterfeit Branded Products? Consumers' Psychological Motivations in Counterfeit Consumption

Xuemei Bian, University of Nottingham, UK
Natalia Yannopoulou, University of Newcastle, UK
Kai-Yu Wang, University of Brock, Canada
Shu Liu, University of Nottingham, UK

This research examines the psychological motivations of different consumer categories when counterfeits are consumed, while considering different quality levels of such products. Our findings reveal consumers' enjoyment during the shopping experience and satisfaction of securing a good deal as the main psychological motivations of such purchases. We offer guidelines to practitioners.

150. Is Social Responsibility Beneficial for Private-Label Brands?

Maryam Tofighi, Concordia University, Canada
H. Onur. Bodur, Concordia University, Canada

Integrating two research streams of corporate social responsibility in marketing and retail branding, this paper suggests that social responsibility initiatives are more beneficial for both national (or manufacturer) brands and high-quality private-label brands (i.e., brands owned, controlled and sold exclusively by a retailer), whereas social responsibility initiatives are detrimental for low-quality private-label brands.

151. The Impact of Luxury Brand-Retailer Co-Branding Strategy on Consumers' Evaluation of Luxury Brand Image: The Case of the U.S. vs. Taiwan

Shih-Ching Wang, Temple University, USA
Primidya K. Soesilo, Temple University, USA
Dan Zhang, City University of New York, USA
C. Anthony Di Benedetto, Temple University, USA

This study investigates whether co-branding of luxury brands and retailers negatively affects attitudes toward the luxury brands, and whether solutions can mitigate the negative effect. We empirically test our hypotheses using samples of consumers from Taiwan and the U.S.

152. My Brand and I: The Influence of Personal Pronouns on Brand Name Preference

Nicole Palermo, Fordham University, USA
Luke Kachersky, Fordham University, USA

In recent years, brand names that include the personal pronouns "I" and "my" have established a unique prevalence in consumer culture. The present research examines if, how, and under which circumstances the usage of "I" and "my" in brand names influences brand perceptions.

153. The Influence of Logo Design Elements on Perceptions of Brand Personality

Aditi Bajaj, Georgia Tech, USA
Samuel Bond, Georgia Tech, USA

Addressing a void in research on logos in consumer behavior, our research focuses on the connections between logo design elements and brand personality inferences. Basing our ideas in literature on branding and design, we suggest that specific logo design elements can be utilized to convey specific brand personality traits.

154. The Impact of Phonetic Symbolism on Stock Performance: Stocks with Stop-Consonant Ticker Symbols Perform Better Than Stocks with Fricative-Consonant Ticker Symbols during First Year of Trading

L.J. Shrum, University of Texas at San Antonio, USA
Tina M. Lowrey, University of Texas at San Antonio, USA
Sarah Roche, University of Texas at San Antonio, USA

The current research extends the notion of phonetic symbolism to stock performance. Because stop (vs. fricative) consonants and back (vs. front) vowels are associated with larger and stronger concepts, we expected that tickers with stop consonants would outperform those with fricatives, and so too would back vs. front vowel tickers. The hypotheses were supported for consonant effects but not vowel effects.

155. Phonetic Symbolism and Children's Brand Name and Brand Logo Preference

Stacey Baxter, University of Newcastle, Australia
Tina M. Lowrey, University of Texas at San Antonio, USA
Min Liu, University of Texas at San Antonio, USA

Phonemes can provide a cue for brand attributes with consumers preferring congruency between a brand's name-logo and attributes. However, because children do not possess adult-level language skills, they may not attach similar meaning to phonemes. In three experiments, we examine the meanings children draw from phonemes and the implications for branding.

156. Should Firms Apologize After a Crisis? The Moderating Role of Negative Publicity

Zack Mendenhall, McGill University, Canada
Ashesh Mukherjee, McGill University, Canada

Firms often apologize to consumers after product crises. Prior work suggests apologies improve customers' attitudes towards the firm. The present research shows apologies only work when negative publicity surrounding the crisis is low. When negative publicity is high, firm apologies do not improve attitude towards the firm.

157. Does Identifying Ambushers as Non-Sponsors Help or Hurt Legitimate Sponsors? Memory and Attitudinal Consequences

Clinton S. Weeks, Queensland University of Technology, Australia

Two experiments examine outcomes for sponsor and ambusher brands within sponsorship settings. It is demonstrated that although making consumers aware of the presence of ambusher brands can reduce subsequent event recall to competitor cues, recall to sponsor cues can also suffer. Attitudinal effects are also considered.

158. The Bad Side of Good: When More Experience Hurts Brands and Marketplace Agents

Jungim Mun, State University of New York Buffalo, USA
Charles Lindsey, State University of New York Buffalo, USA
Mike Wiles, Arizona State University, USA

Our framework asserts that for an omission error, observers penalize experienced brands/agents (in the form of decreased trust perceptions) more severely than inexperienced brands/agents. The mechanism responsible for this effect is that such errors are more likely to be viewed as intentional attempts to deceive when committed by experienced brands/agents.

159. Hot Brands, Hot Cognition: The Effects of Incumbency and Negative Advertising on Brand Preference and Choice—A Longitudinal Field Experiment

Joan Phillips, Loyola University Chicago, USA
Joel Urbany, University of Notre Dame, USA

The World Cup and the battle between Nike and Adidas to secure leadership of the world soccer market presented an opportunity to examine the impact of negative advertising in a natural setting, to identify the conditions under which an attack-brand might use negative advertising to capture leadership from the incumbent-brand.

160. The Company or the Crowd? The Impact of Customer-Led Service Recovery on Satisfaction

Lan Jiang, University of Oregon, USA
Matt O'Hern, University of Oregon, USA
Sara Bahnson, University of Oregon, USA

This research explores the impact of identity on service recovery satisfaction. Study 1 shows that when recovery fails, consumers prefer customer-provided solutions. Community connectedness mediates this effect. Study 2 shows that consumers' pursuit of individualistic goals attenuates this effect. Study 3 proposes that increasing participants' effort mitigates the community- connectedness effect.

161. Don't Care about Service Recovery—Inertia Effects Buffer the Impact of Complaint Satisfaction

Christian Brock, Zeppelin University, Germany
Markus Blut, University of Dortmund, Germany
Heiner Evanschitzky, Aston University, UK
Peter Kenning, Zeppelin University, Germany
Marco Hubert, Zeppelin University, Germany

Service recovery has received considerable attention in the marketing literature. The impact on purchase behavior has been largely neglected. However, intentions and purchase behavior are not necessarily highly correlated. We contribute to research analyzing service recovery effects on purchase behavior after recovery, as well as research assessing the role of inertia during service recovery.

162. Doing Worse and Feeling Better: Why Low Performance Can Increase Satisfaction

Dilney Goncalves, IE Business School, Spain
Antonios Stamatogiannakis, IE Business School, Spain
Jonathan Luffarelli, IE Business School, Spain

When average performance is low, high social-comparison orientation individuals infer that the task at hand is difficult. Subsequently, if relative performance is constant, they are more satisfied with a lower (vs. a higher) individual performance level, because they think that they outperformed more people in a difficult (vs. an easy) task.

163. New Insights on the Moderating Role of Switching Costs on the Satisfaction-Loyalty Link

Thomas Rudolph, University of St. Gallen, Switzerland
Liane Nagengast, University of St. Gallen, Switzerland
Heiner Evanschitzky, Aston University, UK
Markus Blut, TU Dortmund, Germany

Existing studies on the moderating role of switching costs on the satisfaction-loyalty relationship are inconclusive. Based on a meta-analysis and two studies, we show that switching costs moderate this relationship in a nonlinear (inverted u-shaped) way. Explaining existing inconsistencies, our results contribute to a better understanding of the satisfaction-loyalty link.

164. An Interruption Effect on Service Recovery

Fan Liu, University of Central Florida, USA

This paper attempts to advance the model of customer satisfaction in service-failure contexts and integrates interruption as a moderator and an enhancement on customer satisfaction.

165. Customer Satisfaction and Overall Rating: The Influence of Judgment Certainty

Eugene Sivadas, University of Washington, Tacoma, USA
John Kim, Oakland University, USA
Norman Bruvold, University of Cincinnati, USA

The objective of this research is to understand how rating magnitude and rating uncertainty and its interplay with satisfaction affects stated customer experience. We utilize the Judgment Uncertainty and Magnitude Parameters (JUMP) model to empirically examine consumer judgments of their overall experience.

166. Investigating the Positive Impact of Unexpected CSR

H. Onur Bodur, Concordia University, Canada
Bianca Grohmann, Concordia University, Canada
Ali Tezer, Concordia University, Canada

In this research, we investigate particular conditions in which consumers' elaborations of a CSR activity leads to more favorable motivations regarding the firm's involvement and more favorable brand evaluations.

167. A Research Paper on Process of Complaint Behavior Towards Social Commerce, Based on Attribution Theory

Yaeeun Kim, Korea Advanced Institute of Science and Technology, South Korea
Younghoon Chang, Korea Advanced Institute of Science and Technology, South Korea
Myeong-Cheol Park, Korea Advanced Institute of Science and Technology, South Korea

Through surveys, we find that the attributions consumers find themselves affect their post-purchase behavior. This study has implications in the social commerce area, because social commerce is based on the social network in which the consumers who are dissatisfied tend to complain.

168. The Difference of Satisfaction with the Second-Best Choice between Hedonic and Utilitarian Consumption

Yoonji Shim, University of British Columbia, Canada
Jinhyung Kim, Texas A&M University, USA
Incheol Choi, Seoul National University, South Korea

Two studies were conducted to investigate the difference of satisfaction with the second-best choice between hedonic and utilitarian consumption. Our results demonstrate that the gap of satisfaction between the best and the second-best choices is greater when the consumption goal is hedonic rather than utilitarian.

169. The Role of Self-Congruence in Consumers' Responses to Service Failures

Shuqin Wei, Southern Illinois University Carbondale, USA
Tyson Ang, Southern Illinois University Carbondale, USA

Using an experiment, we investigate an overlooked factor, consumers' self-congruence, in understanding consumers' emotional responses to service failures. Self-conscious emotions (e.g., embarrassment) and basic emotions (e.g., betrayal) are studied. Since distinct emotions require different service recovery strategies, distinguishing between different emotions is important. A moderator, service failure type, is explored.

170. Does Complaining Really Ruin a Relationship? Effects of the Propensity to Complain on Positive Consumer-Brand Relationships

Hongmin Ahn, West Virginia University, USA
Yongjun Sung, University of Texas at Austin, USA
Minette Drumwright, University of Texas at Austin, USA

This study suggests that when encountering relationship conflicts, consumers characterized by a high propensity to complain (PTC) are more likely to response destructively than are those with a low PTC. It further demonstrates that appraisals of a company's intention in regard to conflicts mediate such positive association between PTC and destructive responses.

171. Grotesque Imagery in Fashion Advertising

Jennifer Zarzosa, New Mexico State University, USA
Cuauhtemoc Luna-Nevarez, New Mexico State University, USA

The study investigates the grotesque genre of representation in luxury fashion advertising. In doing so, both the art and marketing literature is synthesized in order to identify distinct types of grotesque. In particular, we examine advertisements for Marc Jacobs. As such, the study further expands the theoretical parameters of the grotesque.

172. A Meta-Analysis of Nonverbal Accuracy Outcomes in Consumer Research Settings

Susan A. Andrzejewski, Franklin & Marshall College, USA

This meta-analysis quantitatively summarizes the literature on the relationship between nonverbal accuracy and consumer response in retail and service settings. In addition, this meta-analysis explores several potential moderators of the relationship between nonverbal accuracy and consumer response (i.e., domain, type of nonverbal cue decoded, channel of nonverbal cue).

173. (Illusory) Distance of Exposure as a Moderator of the Mere Exposure Effect

Anneleen Van Kerckhove, Ghent University, Belgium
Maggie Geuens, Ghent University, Belgium

Two studies demonstrate that (illusory) distance of exposure moderates the mere exposure effect, such that distant rather than nearby stimuli are more likely to generate liking after initial exposure. This advantage for distant stimuli levels off after multiple exposures; both distant and nearby stimuli then generate liking.

174. The Effects of Perceived Product-Association Incongruity on Consumption Experiences

Sarah Clemente, Brock University, Canada
Eric Dolansky, Brock University, Canada
Antonia Mantonakis, Brock University, Canada
Katherine White, University of British Columbia, Canada

The level of congruity between an object and its attribute is determined by the degree of match. Products with moderately incongruent associations enhance evaluations–this is the moderate schema incongruity effect. We investigate the influence of (in)congruity between an extrinsic cue (sponsor) and a product (wine) on consumers' product evaluations.

175. The Effect of Menu Presentation Characteristics on Consumer Food Choices

Jing Lei, University of Melbourne, Australia
Ying Jiang, University of Ontario Institute of Technology, Canada
Catharinna Cao, Mars Australia, Australia

This research examines how menu presentation characteristics such as the number of healthy vs. unhealthy options, separate vs. mixed presentation of healthy and unhealthy options, and text vs. picture presentation format influence consumers' food choices. We discuss the results from an experimental study and its implications.

176. The Impact of Category Labels on Perceived Variety

Tamara Ansons, University of Michigan, USA
Aradhna Krishna, University of Michigan, USA
Norbert Schwarz, University of Michigan, USA

We examine how different category labels influence viewers' perceptions of variety of a set by impacting visual imagery. Perceptions of variety increase when category labels sponsored the generation of mental imagery specifically related to the attributes of the set, but not when the labels merely increase imagery.

177. Illusion of Variety: The Effect of Metacognitive Difficulty on Variety Judgment

Zhongqiang (Tak) Huang, Chinese University of Hong Kong, Hong Kong
Y.Y., Jessica Kwong, Chinese University of Hong Kong, Hong Kong

In this research, we study variety judgment from a metacognitive perspective. Based on prior research on variety judgment, choice difficulty and metacognitive experience, we predict that higher-variety judgment in an assortment can result from metacognitive difficulty. We offer experimental evidence for this prediction.

178. Coffee without Overchoice

Claude Messner, University of Bern, Switzerland
Michaela Wänke, University of Mannheim, Germany

After choosing from simultaneously presented options, a coffee tastes less chosen from a large assortment than a small one. However, this effect reverses when consumers decide among attributes sequentially. Apparently, sequential choice is an effective strategy to retain the benefits of a large assortment without suffering from the costs.

179. Hmm…What Did Those Ads Say? Reducing the Continued Influence Effect in Political Comparison Ads

Rebecca E. Dingus, Kent State University, USA
Robert D. Jewell, Kent State University, USA
Jennifer Wiggins Johnson, Kent State University, USA

Comparative ads provide contradictory information and corrections. The impact this finding has on consumers' decisions is unknown because it is difficult to know what will be recalled. The continued influence effect (CIE) occurs when original information prevails in memory, although a correction is acknowledged. This paper aims to reduce the CIE.

180. Holistic vs. Analytic Thinkers in the West: Differential Reliance on Logos in Cognition- and Feelings-Based Product Evaluations

Alexander Jakubanecs, Institute for Research in Economics and Business Administration, Norway
Magne Supphellen, Norwegian School of Economics and Business Administration, Norway

Our research focuses on the effects of analytic-holistic information processing and product logos on cognitive and feelings-based product evaluations in France. One finding is that for lesser-known products, logos have effects on cognitive evaluations only for holistic thinkers. The research offers several contributions to the extant studies of processing styles.

181. The Relative Importance of Advertising Elements and the Roles of Sex (Gender) and Involvement

Even J. Lanseng, Norwegian Business School, BI, Norway
Maarten L. Majoor, Norwegian Business School, BI, Norway and University of Groningen, The Netherlands

This study examines men and women's reactions to models, number of product arguments, and claim type in advertising. We find that men process models as cues and hence prefer female models, whereas women process models as product arguments and hence prefer female or couple models. Sex differences are moderated by involvement.

182. Trivial Gets Central

Charan Bagga, Western University, Canada
Niraj Dawar, Western University, Canada

Our paper studies whether exemplar (non-exemplar) brands gain choice share and improve evaluations by differentiating on the basis of trivial attributes (TA). We focus on scenarios that disclose (do not disclose) the irrelevance of TAs. Finally, we investigate if the first-mover TA strategy of exemplars (non-exemplars) is sustainable.

183. Deception in Marketing: How the Source Influences Consumers' Responses to Deception and Its Contagious Effect on Unrelated Immoral Behavior

Marijke Leliveld, University of Groningen, The Netherlands
Laetitia Mulder, University of Groningen, The Netherlands

This study shows that perceptions of deceptive marketing strategies can be influenced by situational factors, like the source of the deception. Moreover, deception can be contagious to other (im)moral behavior, both related to the source, as well as unrelated to a consumer context.

184. Compassion for Evil but Apathy for Angels: The Interactive Effects of Mortality Salience and Just-World Beliefs on Donation Behavior

Fengyan Cai, Shanghai Jiao Tong University, China
Robert S. Wyer Jr., Chinese University of Hong Kong, Hong Kong

The present research examines the interplay of mortality salience and just-world beliefs in helping behavior. When mortality is not salient, individuals are more willing to help victims for whom they have much sympathy (little sympathy) when the need for help is low (great). Mortality salience qualifies these effects, however.

185. All Types of Mortality Salience Are Not Equal: The Effect of Contemplating Natural vs. Unnatural Death on Materialism Behavior

Zhi Wang, Chinese University of Hong Kong, Hong Kong

While previous research on Terror Management Theory (TMT) argues that Mortality Salience drives individuals to behave differently than they would otherwise, the literature has not differentiated behaviors caused by contemplations of death in different ways (e.g., unnatural vs. natural). This research aims to fulfill this gap by synthesizing TMT and Just-World Theory.

186. How Product Information Shapes Purchase Decisions: Behavioral and Functional Magnetic Resonance Imaging Studies

Sargent Shriver, Temple University, USA
Uma Karmarkar, Harvard University, USA
Michael I. Norton, Harvard University, USA
Angelika Dimoka, Temple University, USA

The authors use behavioral and functional neuroimaging methods to explore the mechanisms that underlie the evaluation of product information, and how this evaluation impacts purchasing behavior.

187. New Notion of Nostalgia

Keiko Makino, Seijo University, Japan

This study proposes a new notion of nostalgia and offers propositions by critically reviewing the previous literature. The propositions concern positive/ negative feelings evoked by nostalgic experiences, continuity/ discontinuity between the past and the present, and warmth as emotion/ aesthetic quality.

188. Constructing the Citizen-Consumer through Political Discourse in the U.S.

Gokcen Coskuner-Balli, Chapman University, USA
Gulnur Tumbat, San Francisco State University, USA

As political discourses denote a profound way that consumer subjectivities are constructed in the marketplace, this study explores the conceptualization of consumerism through political discourse in the US. Through historical analysis of American presidential speeches, we explore the myths that underlie the construction of consumer-citizens and their relations with the government.

189. When Nothing Means Everything: Consumer Evaluations of Specialized and Unspecialized Products

Gabriela Tonietto, Washington University in St. Louis, USA
Brittney Dalton, Washington University in St. Louis, USA
Stephen M. Nowlis, Washington University in St. Louis, USA

There are a number of strategies that companies can use when positioning products. This research focuses on three such strategies that vary in their degree of specialization. We propose that consumers infer that unspecialized products will fulfill all of their specific needs, leading to greater preferences for unspecialized than specialized products.

190. Can't Finish What You Started? Consumption Following Climactic Interruption

Daniella Kupor, Stanford University, USA
Taly Reich, Stanford University, USA
Baba Shiv, Stanford University, USA

We examine the important unanswered question of whether interruptions engender a quest for a resolution through the pursuit of closure-associated behaviors. We explore and demonstrate the possibility that interruptions trigger a need for a resolution that emerges in the choice of behaviors, even in totally unrelated domains. This is the case when the interruption disrupts an activity or task at its climactic moments (e.g., just before delivery of the punch line of a comedy act) rather than at non-climactic moments. We demonstrate that resolution-inducing behaviors will occur even if associated with a personal cost.

191. Monotonous Forests and Colorful Trees

Hyojin Lee, Ohio State University, USA
Xiaoyan Deng, Ohio State University, USA
Rao Unnava, Ohio State University, USA

We examine the effects of color on information processing style. We find that color makes people focus more on the details presented in a picture, while black and white makes people focus more on the overall meaning of the picture. The differential focus is then shown to affect product choice.
