Preface

The ACR North American conference held in Vancouver, B.C. from October 4-7 2012 marked the 43rd consecutive year the association gathered in North America. Furthermore, it was the second meeting in Vancouver – with the 2012 conference occurring almost 20 years to the day since the last time it was held there.

This year, the conference theme was "Appreciating Diversity." Everyone who helped plan and execute the conference took this theme to heart. Sharon Shavitt, Past President, and Angela Lee, President-Elect, organized the plenary session on professional ethics that featured a variety of renowned scholars adopting different perspectives from which ethical issues needed to be considered. Likewise, the Conference co-chairs, as well as Executive Director Rajiv Vaidyanathan, Conference Manager Paula Rigling, Doctoral symposium co-chairs Jennifer Argo and Amna Kirmani, Poster Track co-chairs Maureen (Mimi) Morrin and Vanessa Patrick, Roundtable co-chairs Zeynep Arsel and Hope Jensen Schau, Film Festival co-chairs Marylouise Caldwell and Paul Henry, Meet the Editors Breakfast organizers Susan Dobscha and Katherine (Kay) Lemon and the hundreds of volunteer reviewers, worked to create a conference program that reflected the breadth and depth of our discipline. Specifically, several innovations at the 2012 conference were designed to reflect the myriad methodological, theoretical and topical approaches that exist within the consumer behavior discipline. These included:

*Increasing the number of concurrent sessions to 15, allowing almost 300 competitive papers to be presented, even as a record 773 were submitted due to the first-time shift to 1000 word-abstract submissions versus past requests for papers that could be a maximum of 20 pages.

*Including nine roundtables on the program, which represent highly innovative research topics, and/or methodological approaches to these topics.

*Making a balanced program our goal; e.g., by making sure certain topics did not dominate. At the same time, we offered "micro-tracks" so attendees could enjoy back-to-back sessions within similar research realms.

*Retaining not only the Thursday plenary session, but also including a "Meet the Editors" breakfast on Sunday, that featured representatives from a broader spectrum of journals than in the past.

Whether all of these innovations pleased each individual member, it was the case that attendance at this conference set an all-time high just shy of 1100. Furthermore, 239 were newcomers. We hope our choice of a Newcomers' Chocolate Dessert Buffet, (although perhaps contradicting all of the sessions on moderation and food consumption), as well as the many opportunities to socialize at the receptions and the Gala at the Vancouver Aquarium, made the newcomers—and all members – feel welcome.

We would like to take this opportunity to thank ACR President J. Jeffrey Inman for trusting us with the responsibility of organizing and executing ACR (although we had a lot of help from those mentioned above, to whom we express our deepest thanks). It was an honor and a privilege to strategize this event, and we enjoyed working on this "diverse" team (we are on three continents, were born in three different decades and work in three different areas of consumer behavior). However, we are of one mind that the experience was highly rewarding—and we hope those who attended ACR found the conference to be so as well.

We are also happy that on the following pages, we are able to formally acknowledge everyone who helped from the "global village" that comprises ACR. We hope you enjoy this volume and that it will prove useful in research and in creating lasting collaborations.

2012 ACR Presidential Address

The Elephant Not in The Room:
The Need for Useful, Actionable Insights in Behavioral Research

J. Jeffrey Inman, ACR President, University of Pittsburgh

INTRODUCTION

I am honored and humbled to serve as president of ACR. When I attended my first ACR conference as a doctoral student and didn't know a soul, it never occurred to me that someday I might be standing up here. And I have to tell you that looking out at over 1000 of you is a pretty intimidating sight! Now I wish I had practiced my talk more.

As I considered potential topics for this address, I tried to generate ones that (1) are important, (2) that I am passionate about, and (3) that I know something about. Due in particular to that third objective, finding this combination proved to be a little more difficult than I had hoped, but the epiphany finally struck.

Today, I want to talk to you about a topic that I suspect 1/3 of you will have strong feelings against, 1/3 of you will resonate with, and 1/3 of you may not realize that there was even an issue. I want to talk about the increasing need for useful insights in our work. I've heard many friends and colleagues increasingly lament the lack of contribution of our work to actual problems faced by public policy makers, industry, and consumers. A quick scan of the implications section of a lot of consumer behavior articles reveals that the implications offered there are often rather far removed from the findings.

This brings us to the title of my address, "The Elephant NOT in the Room." Since some of you may not be familiar with the metaphor I used in the title of my talk, I'll briefly define it. My favorite source of metaphorical definitions, Wikipedia, defines this term as "An obvious truth that is either being ignored or going unaddressed. The expression also applies to an obvious problem or risk no one wants to discuss." I think it will soon become clear why I slightly adapted this metaphor for the title of this address.

I'll use the venerable ACR logo to make my point. But first, I want you all to take a pop quiz. Consider the following four options describing what the three characters in the ACR logo stand for. If you didn't know that they represent something, just guess.

A) Theoretical, Methodological, and Empirical contributions
B) Academia, Government, and Industry
C) Ann McGill, Mary Frances Luce, and Laura Peracchio
D) Consumers, Academics, and Practitioners

The correct answer is B) Academia, government, and industry. I suspect that many of us did not know that.

Over a period of many years, ACR has become increasingly focused on research topics that are of interest primarily to the academic constituency, with lip service often paid to the potential implications to public policy makers and practitioners. To illustrate where this rather insular focus has led, I culled through the registrations for this year's ACR conference. As you know, this year's ACR has set a new record for attendance. Unfortunately, attendance across the three constituencies has grown quite lopsided, with attendance by academics dwarfing those from government and industry. In fact, academics comprise over 99% of this year's conference attendance. I don't know about you, but I find this alarming.

THE LYNCH ET AL. (2012) TYPOLOGY

In the October issue of *JCP*, John Lynch, Joe Alba, Aradhna Krishna, Vicki Morwitz, and Zeynep Gurhan-Canli (when she wasn't busy co-chairing this year's ACR conference) co-authored a very thought-provoking article discussing multiple paths by which consumer research can create knowledge. They present a 2x2 typology broken out by the intended contribution of the research (conceptual vs. substantive) and the focus on concepts vs. findings. They discuss each combination in turn and provide guidelines for reviewers based on the core criterion that the research results in a shift in beliefs about something deemed important. This is a very interesting paper and I encourage you to read it.

My take on the four cells of this typology is that our field has become overly fixated on theory building or nomological network construction, such that the lion's share of research being presented at ACR and being published in the top consumer behavior journals falls in the upper left-hand cell. Regarding the right-hand column (findings-focused research), while there are notable exceptions, including an article in the most recent issue of *JCR*, research of this type tends to face a strong headwind in the review process. Pejorative comments such as "atheoretical," "ad hoc," and "applied" often greet the author who submits such a paper. Given the decidedly daunting task of pursuing findings-focused research in the right-hand column, my hope today is that I can convince you or at least a substantial proportion of you to pursue more research of the bottom left-hand type that seeks to generate theory-based, useful insights.

EVALUATING SUBSTANTIVE CONTRIBUTION:
THE US PATENT OFFICE APPROACH

This begs the following question: what qualifies as a substantive contribution? "Substantive" is a rather vague term, so I searched for a more concrete set of criteria for evaluating theory-based substantive research. As is so often the case, the answer came from an unexpected source – in this case the United States government. More specifically, from the US Patent and Trademark Office.

It turns out that the US Patent and Trademark Office considers three criteria when evaluating a potential patent: the concept or invention needs to be novel, non-obvious, and USEFUL. Fortunate for me given the time constraints, the criteria of novelty and non-obviousness were the focus of last year's presidential address by Sharon Shavitt, so I will refer you to Sharon's fascinating discussion of those topics and spend my remaining time on the third criteria - usefulness.

Our behavioral colleagues in management and OB are also struggling with the issue of evaluating research. In a recent article in the *Academy of Management Review,* Corley and Gioia (2011) discuss what constitutes a theoretical contribution and argue a similar point: "Our synthesis reveals two dimensions – originality and utility – that currently dominate considerations of theoretical contribution." While I don't think that we in consumer research are ready to claim that useful insights necessarily constitute a theoretical contribution, this is consistent with the notion that useful insights increase the overall contribution of a research manuscript.

The idea of generating useful insights may seem appealing, but how can we judge whether our findings are useful? Let's return to the US Patent and Trademark Office. Its position is that in order to be useful, an invention must work and serve some type of purpose.

More specifically, the US Patent and Trademark Office Manual of Patent Examining Procedure, says that, "The claimed invention as a whole must be <u>useful</u> (emphasis added). The purpose of this requirement is to limit patent protection to inventions that possess a certain level of "real world" value, as opposed to subject matter that represents nothing more than an idea or concept, or is simply a starting point for future investigation or research."

THE GROWING CALL FOR USEFUL INSIGHTS

Lest you think that I am alone in calling for more useful insights in our research, I wanted to cite some examples that suggest there is a growing sense that change is needed.

First, 40% of the respondents to last year's ACR membership survey said that more substantive research is needed. Second, there are several efforts underway in marketing to reconnect academic research with the real world. For example, our modeling colleagues are struggling with their own demons. They have found that the arms race of increasing model complexity has diminished the actionability (and usefulness) of their work. To help counter this trend, they launched the ISMS practice prize a few years ago to recognize and reward research that makes a difference to practice. Of course, our field is fortunate to have MSI to help fund useful research with implications for practice, so I would be remiss not to mention them. The TCR initiative begun by David Mick has motivated researchers to examine important consumer-centric topics such as over-eating and financial decision making. Finally, in 2011, marketing faculty members from Columbia and Harvard held the inaugural Theory and Practice in Marketing conference at Columbia. The deans from Harvard, Columbia, and Wharton participated along with the editors of *JCR*, *JMR*, and *Marketing Science* and academics from several universities. I wasn't able to attend because of a conflict, but I did see the attendance list and I was happy to see that several other behavioral researchers attended, suggesting that others are concerned about this issue.

But how do we translate this notion of usefulness to consumer research? Useful research moves beyond nomological insights that are often the sole focus of theory development research. But I'll come back to that later. The findings should pass the "so what?" or "who cares?" test and offer useful insights to other constituencies: public policy makers, industry, and yes, consumers as well. Importantly, relevance to other constituencies should not be a stretch. We should all think carefully about how our findings offer useful, actionable insights to non-researchers rather than just adding this to the discussion as an afterthought or ignoring it altogether.

WHY CHANGE?

You may be sitting there wondering, this is all well and good, but why should I change what I'm doing? As an associate dean for research and faculty, I've learned that getting faculty to row in a different direction is often a huge undertaking. After all, most of us get into this field because we are attracted by the idea of studying what interests us.

Returning to the Lynch et al (2012) 2x2 typology, there are at least three good reasons that you should consider pursuing more research of the bottom left-hand type. First, there is a growing need for research that provides generalizable explanations for real world phenomena. Witness the conversion of market research departments at many profit and non-profit firms to "consumer insights" depart-

ments. There is growing agreement that an increased understanding of the consumer should be a central focus of the organization.

Second, research of this type is often easier to get published. Editors, AEs, and reviewers who are tired of reading the 100th submission seeking to extend a popular theory-of-the-moment that relies exclusively on self-report lab studies to test the authors' hypotheses may well be more positively disposed to a paper that uses theory in a novel, non-obvious way to inform a substantive topic and generate useful insights. Am I arguing that we should abandon research focused on theory-building? NO. In fact, I just had a paper accepted last week that is of this type. I am suggesting, in the theme of this year's ACR conference, that we embrace the need for diversity in terms of the mix of research that we pursue.

Third, as we are all painfully aware, acceptance rates at our top journals are about 10% and are not going up. So even if your manuscript is twice as good as average, you have an 80% chance of having it rejected. If you are in a marketing department at a business school, and my random sample of the ACR registrations indicates that most of us are, then you might be motivated to submit your manuscript to another marketing journal. Based on my experience as an author and as an AE at JMR and JM, your chances are better if your paper is of the lower left-hand type and generates useful, actionable insights.

DIFFERENCES IN MANUSCRIPTS PURSUING USEFUL INSIGHTS

So, how does the pursuit of useful insights change the way we go about conducting and writing up our research? In my experience, I have noticed three main differences. One is in the way we test our predictions, one is in the topics that we choose for research to begin with, and one is in the way we craft the introduction and discussion sections of our manuscripts. I will briefly discuss each of these.

Consequential Dependent Variables.

The first difference is that total reliance on self-reports just won't cut it anymore for substantive research. In my role as an associate editor at JMR and JM, I tend to receive mainly consumer behavior manuscripts. I have seen a trend over the past few years by reviewers to ask for at least one study with what I will call a consequential dependent variable. What's that?

A consequential dependent variable is one where the study participant invests a resource and/or experiences a consequence. That is, they put some skin in the game such as Money, Time, Choice, or Effort. The strength of a consequential dependent variable is that it increases confidence in the substantive usefulness of the research by demonstrating generalizability of the findings to a believable context. In short, a consequential dependent variable makes your research more compelling and much more difficult to dismiss.

The most obvious context for a study with a consequential dependent variable is a field test. A field test demonstrates that your thesis obtains in an actual setting. That is, beyond the obvious advantage of increased external validity, it demonstrates generalizability and shows that the effects make a difference. While field tests are great, I feel that a lab or online context is often suitable as well, depending on the particular research focus. I'll also note that field tests are not a panacea for useful insights.

Should every paper include a study with a consequential dependent variable? Of course not. The focal construct may not lend itself to operationalization as a consequential dependent variable. That said, a lot of theory-building research could benefit from the inclusion of at least one study with a consequential dependent variable in order to demonstrate the pertinence of the theory to manifested consumer behavior.

Topic Selection.

A second change in research toward theory-driven useful insights is topic selection. The consumer shouldn't just be a convenient context. I'll briefly overview two examples where I see great opportunity for theory-driven consumer research with potentially game-changing useful insights. The first is Mobile Consumer Research. The second is…Mobile Consumer Research! Actually, this is a double entendre.

One meaning of mobile consumer research is consumer research in the mobile domain. There is already a lot of interesting work underway on digital consumer research, but the increasing penetration of smartphones offers particularly interesting and theoretically rich research problems such as the role of social media in an "always on" environment, the effect of smartphones and apps on consumer choice, and mobile shopping.

The other meaning of mobile consumer research focuses on mobile as the method, either as a data collection medium or as a way to deliver theory-based interventions, such as gamification and consumer self-monitoring. By self-monitoring I mean contexts where consumers are motivated to track their own behavior in pursuit of a goal such as weight loss. For example, there is a consumer movement called "The Quantified Self". This movement began several years ago in the United States but now there are Quantified Self groups throughout the world, including one here in Vancouver. Consumers join clubs in their city and attend monthly meetings to learn about various ways of tracking their behavior. Several apps and stand-along products such as biometric monitoring equipment and sleep monitors have been developed to assist consumers in this endeavor. The apps run the gamut from mood tracking to calorie burn trackers. This context is hungry for behavioral interventions to aid consumers in achieving their goals. This is just a sampling and I could have devoted my entire address to this topic.

Manuscript Construction.

The third difference is in manuscript construction. These differences are most notable in terms of the introduction and the discussion. The introduction lays out the importance of the consumer-related problem being addressed, along with the theory base being brought to bear on it. The discussion then circles back to the theoretical take-aways and the actionable insights from the research.

One drawback of a 2x2 typology like that proposed by Lynch et al. (2012) is that it implies that a given research can only fall into a single cell. I would argue that nomologically-focused research can also generate useful insights and that substantively-focused research can generate theoretical insights. In fact, if you look at the award-winning consumer research articles, you will find that many of them tend to provide a combination of nomological and useful insights. Thus, I urge us to not be confined to one of these cells but, rather, to think about how our research speaks to both theory and substance. I firmly believe that this is not necessarily a case of either-or and that we can often have our cake and eat it too.

So what is ACR doing to help?, you might ask.

AN ACR JOURNAL

As a follow on to the 2011 Task Force on ACR Strategic Direction that was appointed by Sharon Shavitt, I appointed the 2012 ACR Task Force to study the question of whether ACR should launch its own journal. Many people think of JCR as the ACR journal but this is not the case. ACR is only one of 11 organizations that sponsor JCR. I want to thank all of the task force members who donated significant amounts of time to this effort.

The journal task force applied three main principles in generating a recommended positioning for a potential ACR journal. First, it should avoid duplication with existing journals, particularly *JCR*. Second, they sought a positioning that would enable the journal to achieve a premier standing viewed by promotion and tenure committees as comparable to current premier journals such as *JCR*. And third, it should focus on "real problems" and encourage external validity. This is a familiar theme!

The task force also considered several alternative positionings and generated three key recommendations. First, the journal should focus on substance vs. theory or method as the primary contribution. To quote, "These include issues of consumer welfare, public policy, as well as for-profit and not-for-profit businesses." Second, it should encourage thematic work. That is, issues focused on a particular topic. Third, the new journal should encourage the use of field studies and/or secondary data.

Yesterday, the ACR Board discussed the task force's report and unanimously approved their recommendations. The next step is to develop an implementation plan for launching an ACR journal. This work will continue into 2013 and your feedback and suggestions are of course welcome.

ACR'S POSITIONING

Speaking of positioning, I wanted to use a stylized positioning map to make my final point. Over the years, I've heard some ACR opinion leaders caution against research that is too closely tied to practice, lest we become so-called "Handmaidens of Business." I've never been exactly sure what they meant by that, but they make it sound like a really bad thing. Plus, this strikes me as a rather brassy comment if you work in a marketing department in a business school. Besides, based on the statistics I reported earlier in this talk, we aren't at risk of becoming handmaidens of business anytime soon. In fact, if anything, one could argue that much of our work has taken ACR in the opposite direction and moved us toward psychology. My caution is that we need to be careful not to become handmaidens of a different sort.

Actually, it seems to me that ACR is uniquely positioned between the social science disciplines and practice. We have an opportunity and, I would argue, an obligation, to play a critical role in not only contributing to the "mother disciplines" but also to provide useful insights to practice.

CONCLUSIONS

In closing, the ACR logo captures the central guiding principle of ACR: the need to form linkages – linkages with other disciplines and sub-disciplines, linkages between these disciplines and practice, and linkages between nomological insights and useful insights. The bad news is that, like Elvis, the elephant of practice has left the building. The good news is that it is not too late to re-engage. However, in order for that to happen, as authors, we need to submit manuscripts that generate useful insights. Especially for those of us in business schools – we fail to heed this call at our peril. Amidst the present environment of state budget cuts for higher education, concerns about research ethics, and growing calls for faculty research accountability by alumni, students, and taxpayers, the ball is in our court to demonstrate the value of our research. Useful insights and implications for practice will go a long way in that regard.

Am I saying that we should shift all our focus to research that generates useful insights? Absolutely not. I AM saying today that we need to achieve a sustainable equilibrium between research that builds theory and research that applies theory to substantive issues to generate useful insights. Through this, we can form touchpoints be-

yond our academic colleagues and truly make a difference to practice and to society. Thank you.

SESSION OVERVIEW

This session will present research on the importance of rituals in consumption. The study of rituals have a long and rich history, with the use of rituals traced back to early humans – as well as other animals that use rituals in consumption acts (e.g., eating, attracting a mate). The papers in this session highlight the prevalence and power of rituals in consumer behavior. All data or materials have already been collected, and no work has been published.

This session speaks to the theme of diversity in the 2012 ACR conference in several ways. First is the diversity in the populations under study. Some work tested college and MBA students, whereas others studied community adults in Europe and Arab States.

Second, the methodology used in this work spans the breadth of approaches that consumer behavior scholars use. These presentations feature experimental, survey, and qualitative research.

Third, the way that rituals are conceptualized in these papers varies. Norton and Gino had consumers use their own personalized forms of rituals, whereas Risen et al. made use of popular rituals already known in the culture. Vohs et al. created novel rituals for consumers to use, whereas Sobh and colleagues observed naturalistic rituals being carried out.

Fourth, the breadth of the work on rituals and consumption is exceptionally diverse. Vohs and colleagues focus on the sensations and perceptions that accompany consumption under rituals, providing more of a bottom-up approach to understanding the effects of consumption rituals. Sobh and colleagues provide a top-down approach, focusing on cultural and religious identities as intertwined with rituals. In contrast still, Norton and Gino's as well as Risen et al focus on how people feel when events in life turn – or could turn – for the worse. Norton and Gino investigate how the use of rituals can soothe people's negative emotional state after a loss (from lotteries to lovers). Risen et al found that performing ritual actions provides a sense of psychological insurance that bad events will be kept at bay.

In summary, this is a session that consumer behavior scholars will want to see. It offers indepth, empirical, and theoretical advances featuring perceptual, cognitive, emotional, behavioral, and identity outcomes. To show that grieving, eating, hosting, and protecting are all made better by rituals illustrates why rituals are so common and, as the proposed session will highlight, so powerful.

Rituals Enhance the Experience of Consumption

EXTENDED ABSTRACT

Rituals mark many life events, big and small. From the sequences of activities around Thanksgiving dinner to the activities involved in opening a bottle of wine, people use systematized sequences of behaviors in order to signify an event, and quite often those are consumption experiences. We hypothesized that one reason that rituals are so tightly tied to consumption is that they amplify experiences. Four experiments tested and found support for this hypothesis.

In experiment 1, participants tasted a chocolate bar, before which they either performed or did not perform a ritual. In the *ritual* condition, participants were told that, "Before a consumption experience, people often engage in simple rituals (e.g., when opening a bottle of wine at a restaurant). Please follow these specific steps in unwrapping the chocolate: 1. Without unwrapping the chocolate bar, break it in half. 2. Unwrap one half of the chocolate bar and eat it. 3. Then, unwrap the other half and eat it." In the *no-ritual* condition, participants were told that, "Before you taste the chocolate, please spend a couple of minutes relaxing." We measured how much they savored the chocolate, as surreptitiously measured by duration spent consuming it. We also measured how much participants reported enjoying the chocolate, and how potent was its taste. We predicted and found that participants in the ritual condition spent longer eating the chocolate (i.e., savored it more), found the chocolate's taste to be more potent, and enjoyed the chocolate more than participants in the non-ritual condition.

Experiment 2 tested the hypothesis that rituals are effective in boosting consumption enjoyment and potency only when performed by the individual who is about to do the consuming. Experiment 2 tested whether rituals must be performed by the self in order to aid the consumption experience. Experiment 2 also included a measure of mood to examine whether engaging in rituals influences emotional state during the consumption experience. In the *self-ritual condition*, participants were given a series of steps that formed the ritual of making a glass of lemonade. They were told to pour half of a packet of lemonade powder and half glass of water into a glass, then to stir the mixture, and then wait for 30 seconds. After 30 seconds, they were told to pour the remainder of the lemonade mix and water into the glass, stir, and wait for 30 seconds. In the *other-ritual condition*, participants observed the experimenter perform the same steps as described above. The results demonstrated that rituals before consumption increase the potency of the consumption experience when performed by the individual who is about to consume rather than another person. We also ruled out mood, as there were no differences in positive or negative affect as a function of condition.

Experiment 3 compared ritualistic behaviors involving systematic movements to a control condition where participants engage in similar movements that are random and therefore not systematic. Second, the experiment included a control condition where no ritual was performed. Third, we measured both anticipated enjoyment before consumption and actual enjoyment. Last, we used an international sample of community adults. Participants were told that their task would involve consuming a specific beverage (of their choice), one that they drank at least five days a week in a typical week. They were given instructions to carry with them and perform wherever they consumed the drink. Participants assigned to the *ritual condition* were instructed to perform a distinct set of gestures before the first sip of the beverage. Then they rated their anticipated enjoyment of the beverage and willingness to pay, which occurred immediately before the first sip of the beverage that day. Participants assigned to the *non-ritual gesturing condition* performed hand gestures before consumption, but the gestures were randomized such that there was no consistent pattern. Participants assigned to the *no-ritual condition* were not given a ritual to perform before consuming the beverage. Results showed, as predicted, that anticipated enjoyment rose throughout each consumption experience for participants in the ritual condition but not so for participants in the other conditions. A similar pattern was found with actual enjoyment, and mediation analyses confirmed that the heightened anticipation of consumption led to heightened enjoyment upon consuming.

We designed a last study to further examine the relationship between potency, enjoyment and savoring in consumers' consumption experience, and test the role of fluency and intrinsic interest in explaining the beneficial effects of rituals. The study used the same product and procedure as in experiment 1. Participants were informed that they would be asked to taste a chocolate bar. The measures, as in Experiment 1, were enjoyment, and time spent savoring. In addition, we included measures of 5-item measure of fluency. The results showed that ritual condition participants enjoyed the chocolate more and spent more time savoring it, in a replication of experiment 1. Moreover, we found the same evidence for mediation through fluency for both enjoyment ratings and time spent savoring as dependent measures.

In summary, this work provides robust evidence that performing ritualized behaviors prior to consumption enhances the consumption experience. People who were randomly assigned to perform a ritual enjoyed that which they consumed more so than others. Meditational evidence suggested that anticipating the act of consumption is key, as is fluency. This work will be of interest to scholars who study motivated behavior, the regulation of intake (e.g., calories), as well as those interested in satiation. Because rituals are a lubricant for consumption, intervention implications are also suggested by this work.

"Home and Commercial Hospitality Rituals in Arab Gulf Countries"

EXTENDED ABSTRACT

Hospitality is so much a part of Arab Gulf heritage that a number of ethnographies of the region have titles like "'Ever a Guest in our House'" (Shryock and Howell 2001), "Guests of the Sheik (Fernea 1969), and "Culture-Middle East: Arab Hospitality Runs Deep" (Janardhan 2002). Arab hospitality is viewed as an expression of the high value placed by Arabs on generosity (Karam). Arab hospitality or karam al-arab is a traditional virtue of which Arabs are deliberately proud (Shryock 2004). There is a general consensus among Muslim scholars that hospitality and generosity towards guests are an integral part of faith in Islam. Many verses in the Q'uran as well as a significant number of ahadith (prophet Muhammad's sayings) provide such evidence.

The importance of hospitality to social relations in different regions of the Arab world has been documented by anthropologists (e.g., Young 2007). In the Gulf region hospitality rituals are attributed both to their traditional necessity in the harsh desert environment of the region's Bedouins and to their moral centrality in Islam. Hospitality in Arab Gulf countries is expressive of culture and an important part of the presentation of national identity. Yet, such rituals have been little studied in the social sciences either generally or in the Gulf region in particular. The concept of hospitality remains largely un-specified and un-examined. We believe that hospitality is a critical concept in a globalizing world and that the insights gained in the Gulf region can help inform theory and practice in other parts of the world. Due to petrowealth, Qatar and the UAE are the two wealthiest nations on earth and both are changing rapidly and dramatically. Despite such changes the society still requires strong adherence to traditional norms of hospitality. Urbanization has not eliminated these rituals and, if anything, may have increased their importance as a means for citizens who have become a minority in their own countries to assert their cultural identity in the face of broad immigration and visitation by guest workers, foreign business people, and tourists to the Gulf region.

Using depth-interviews and observations of hospitality rituals in Qatari households, we explore culturally constructed meanings of hospitality rituals in Gulf Arab States and examine associated performative constructions of ethnic identity as well as the multifaceted exchange of material and symbolic possessions (especially foods, perfumes, and incense) that take place between the host and guests. We also study commercial hospitality in high end hotels, restaurants and similar touristic sites in the Gulf region, focusing on the capitals of Doha in Qatar and Dubai in the UAE. Both commercial and home hospitality are forms of what Goffman (1959) called the presentation of self. That is, both are self-conscious acts performed for the guest in order to create a particular impression of the self, whether the self of relevance is the family or the culture. We show how contemporary hospitality rituals can help us better understand the concept of hospitality itself and how it differs from the hospitality of the Bedouin past, as well as what the possible futures of hospitality are between these minority hosts and majority guests. Ironically, this may be a future dependent more on commercial hospitality, inasmuch as few non-Qataris and non-Emiratis are visitors in Qatari and Emirati homes.

In the process, we discuss the process of commoditizing culture and its impact on both hosts and guests. Within the more public realm of paying guests, many of these rituals are transformed. The gracious hosts are now more like servants to the paying guests. This can occur, for example, from the moment of entering Qatar at the Doha airport. For a fee (often arranged by local hosts), rather than stand in lines to get a visa and have passports inspected and stamped, the visitor will be escorted to a lounge and asked to relax while a young woman takes the passport and does all required processing. When she returns, she delivers the passport and escorts the guest through the airport to transportation or another local contact person. Because service workers in Qatar are almost inevitably foreigners themselves, this is one of the first evident differences from hospitality within Qatari homes. Even at Bedouin and Arabian themed hotels, restaurants, oases, and other representations of local culture, the workers and performers are not likely to be Qataris. This may raise issues of authenticity (Bruner 2005), but authenticity is a socially constructed concept and as with going to the theater, the guests seem willing to either suspend disbelief or adopt a questioning gaze rather

than a more critical rejection of the representation (Kasfir 1999). After all, the tourist, business visitor, or non-Arab local has chosen this place rather than another that is part of the indistinguishable global chains that Augé (1995) calls non-places and Ritzer (2004) calls nothingness. And rather than being impartial observers of their experiences in the Gulf states, these visitors are likely to be affected by lingering Orientalism (De Botton 2002; Said 1978). At least to a certain degree, we see what we expect to see, even if this means reinforcing stereotypes. In addition, as with tourists in Dubai (Junemo 2004), tourists in Doha have a liminal attitude toward what they see and experience that is more playful than analytic. They likely take their role as guests quite differently than guest workers who have come to Qatar in order to remit money to their families in their original cultures.

We believe that there are potential lessons for the hospitality industry in terms of the specific meanings of the concept in the Gulf region. The transition, which has been described by some as, Arabs moving from the camel to the Cadillac, has transformed the region into a globally recognised hub of activity, ranging from finance, sports, and tourism to art, architecture, and education -- each of which has been infused with the imagery of hospitality and pluralism. Symbols of hospitality rituals and Bedouin generosity become attractive sources of ethnic identity and are prominently displayed in the public domain and in sites of commercial hospitality such has restaurants and hotels. Simply put, hospitality plays a major role in publicly marketing Qatar and the UAE as nations on the world stage.

Rituals Alleviate Grieving for Loved Ones, Lovers, and Lotteries

EXTENDED ABSTRACT

Rituals of mourning in the face of loss – from the death of loved ones to the end of meaningful relationships to losses in wars and competitions – are ubiquitous across time and cultures (Ashenburg, 2004; Durkheim, 1912; Stroebe, Hansson, Stroebe, & Schut, 2001). The most frequently studied rituals are those surrounding religion; people turn to prayer after negative life events such as September 11th, for example, and prayer has been associated with improved coping (Ai, Tice, Peterson, & Huang, 2005; Pargament, 1997; Sherkat & Reed, 1992). So common is this instinct to devise rituals in the face of negative events that the wide variety of known mourning rituals can even be contradictory: crying near the dying is viewed as disruptive by Tibetan Buddhists but as a sign of respect by Catholic Latinos; Hindu rituals stress the removal of hair when mourning while growing hair (a beard) is the preferred ritual for Jewish males (Clements, 2003; Kemp & Bhungalia, 2002). Ritualistic behavior manifests not just in religious practice, but is ubiquitous across domains of human life, providing order and stability while marking change – especially in times of chaos and disorder (Romanoff, 1998; Turner, 1969).

Why are rituals so ubiquitous, and why do they seem to improve coping? Despite the variance in the form that rituals take, we propose that a common psychological mechanism underlies their effectiveness: a restoration of feelings of control that losses impair. Indeed, people who suffer losses often report feeling "out of control" (Low, 1994) and actively try to regain control when they feel it slipping away (Brehm, 1966); feeling in control in turn is associated with increased well-being, physical health, and coping ability (Glass & Singer, 1972; Klein, Fencil-Morse, & Seligman, 1976; Rodin & Langer, 1977). Some qualitative data offer initial evidence for the link between rituals and control; for example, the extent to which athletes and fisherman engage in rituals is related to the unpredict-

ability of their jobs (Gmelch, 1971; Malinowski & Redfield, 1948; see Whitson & Galinsky, 2008). We suggest that the use of rituals serves as a compensatory mechanism designed to restore feelings of control after losses, and that this increased feeling of control contributes to improved coping.

We propose that people turn to rituals after diverse kinds of losses – in the experiments below, of loved ones, lovers, and lotteries – in order to reestablish their feelings of control and mitigate their general negative feelings, such that the feelings of control brought about by rituals will mediate the relationship between ritual use and reduced grief. Although we recognize the many differences in the rituals people use after experiencing a loss and the diversity of emotions that accompany different types of losses, we propose that a common psychological mechanism – perceived control – underlies the effectiveness of rituals. Engaging in rituals mitigates grief by restoring the feelings of control that are impaired by both life-changing (the death of loved ones) and more mundane (losing lotteries) losses, and rituals are particularly effective when participants are convinced of the efficacy of those rituals.

We tested our hypotheses in two experiments in which we explored the impact of mourning rituals after losses – of loved ones, lovers, and lotteries – on mitigating grief. Participants who were directed to reflect on past rituals (Experiment 1) or who were assigned to complete novel rituals after experiencing losses (Experiment 2) reported lower levels of grief. Increased feelings of control after rituals mediated the link between use of rituals and reduced grief after losses, and a belief in the effectiveness of rituals enhanced their positive effects.

In Experiment 1, we relied on participants' self-definitions of what constitutes a "ritual" – as a result, our investigation encompasses a broad definition of the term, including both actions prescribed by a religion or a community of reference as well as behaviors chosen arbitrarily by participants (and the experimenters). This choice is consistent with evidence that mourning rituals across cultures and religious are often contradictory, suggesting that the effectiveness of rituals on grief and coping after a loss is driven primarily by the act of engaging in a ritual and not by the specific actions involved in the ritual. Future research, however, is needed to explore at a more granular level the impact of specific types of rituals on mourning.

Finally, we note that our participants were drawn from non-clinical samples, and our conclusions therefore must be qualified in light of research suggesting that overly ritualistic behavior can negatively impair psychological functions, as in the case of obsessive-compulsive disorder (Tolin, Abramowitz, Przeworski, & Foa, 2002). Clearly, further research is needed to understand which rituals benefit which individuals. Still, our results offer initial support for Durkheim's contention that "mourning is left behind, thanks to mourning itself" (Durkheim, 1912, p. 299); the rituals of mourning in which our participants engage hasten the decline of the feeling of mourning that accompanies loss.

Rituals for Reversing One's Fortune

EXTENDED ABSTRACT

Across cultures, people try to "undo" bad luck with superstitious rituals such as knocking on wood, spitting, or throwing salt. We suggest that these superstitious rituals have more in common than just being actions that offer a sense of control. Instead, these superstitious rituals for reversing one's fortune all seem to involve avoidant motor movements that exert force away from the self. Thus, even though at first glance these rituals may appear to be unrelated cultural traditions, we suggest that these particular rituals

may have developed and been passed on, in part, because these avoidant actions create a sense that bad luck is being pushed away from the self.

This hypothesis is based on two streams of embodied cognition research. First, recent work suggests that people use bodily movements to understand and simulate their experience with abstract concepts (Barsalou, 2008; Niedenthal et al., 2005). Second, research has shown that pulling something towards one's representation of self is associated with approaching desired stimuli, and pushing something away from the represented self is associated with avoiding undesired stimuli (Cacioppo, Priester, & Bernston, 1993; Chen & Bargh, 1999; Markman & Brendl, 2005). We suggest that, because avoidant motor actions help avoid negative objects and reduce risk, engaging in an avoidant action may simulate the experience of avoiding bad luck. Consequently, after engaging in an avoidant action, people may feel less pessimistic about the likelihood of anticipated negative outcomes.

Four experiments test this hypothesis by having participants tempt fate and then engage in avoidant actions. In all four studies, participants were lead to tempt fate by having a scripted conversation with the experimenter. The experimenter asked questions and participants were provided with three answers that had the same meaning, but were phrased differently. They were asked to choose the one that sounded the most like them. For example, in Study 1, the experimenter said, "A friend of mine recently got into a car accident… it got me thinking about how dangerous it can be on the road, especially when the snow starts to fall. Do you think that there is a possibility that you or someone close to you will get into a horrible car accident this winter?" Participants in the control condition selected from one of three neutral options (e.g., "I can't believe it's going to start snowing soon"). Participants in the tempting fate condition chose from one of three options designed to express presumptuousness (e.g., "No way. Nobody I know would get into a bad car accident. It's just not possible"). Participants in Study 2a tempted fate about getting the swine flu and participants in Study 2b and 3 tempted fate about being mugged.

Based on previous findings (Risen & Gilovich, 2008), we expected that negative outcomes would seem especially likely after people tempted fate. We predicted, however, that the effect of the jinx would be reduced if people engaged in avoidant actions that exerted force away from the self. Critically, according to our hypothesis, even non-superstitious avoidant actions should be effective for reversing the effect of a jinx. Thus, we tested our prediction with a superstitious action (Study 1, knocking on wood) and a non-superstitious action (Studies 2a, 2b, and 3, throwing a ball).

In Study 1, after the conversation, the experimenter told participants that they should clear their thoughts before continuing to the next part of the study. To help, he would slowly count to 5. In the knocking-down condition, participants were instructed to knock down on the table with each number (away from themselves). In the knocking-up condition, participants were told to knock up on the underside of the table (towards themselves). In the no-knocking condition, the experimenter counted to five with no instructions to knock. Participants then rated how likely they believed it was that they or someone close to them would get into a horrible car accident. As predicted, participants who tempted fate were more pessimistic in the no-knocking and knocking-up conditions than those who did not tempt fate, but the effect of the jinx was eliminated when participants knocked down on the table and away from themselves.

Study 2 tested whether other movements that exert force away from self–even those that are not ingrained as superstitious rituals–also reduce the subjective likelihood of a bad outcome after people tempt fate. After the conversation with the experimenter, participants in Singapore (2a) and the United States (2b) were asked to either hold a ball in their hand or toss it away. After doing so, they rated the likelihood of becoming seriously ill or being mugged, respectively. We found that after tempting fate, participants who tossed the ball away were less concerned about getting sick and getting mugged than those who held the ball in hand.

Finally, in Study 3, we distinguished between exerting force away from the self and creating physical distance from an object in one's environment, and tested whether each was sufficient for undoing the effect of the jinx. All participants tempted fate and then engaged in an action that either created distance or not and either exerted force or not. We found that pretending to throw a ball (an action that does not create distance, but does simulate pushing something away) was as effective for reducing the effect of the jinx as actually throwing the ball.

The present research suggests that knocking (down) on wood is a successful strategy for reducing the heightened concern that typically follows a tempting fate behavior. Moreover, our results suggest that the success is due, at least in part, to the avoidant nature of the act. After tempting fate, avoidant actions—even those that are not part of a superstitious belief system—effectively undo the effect of the jinx. Although superstitions are often culturally defined, our results suggest that the underlying psychological processes that give rise to them may be shared across cultures.

Deepening our Understanding of Depletion: New Causes, Boundaries, and Processes

Paper #4: A Reexamination of the Role of Negative Affect in Resource Depletion Effects

Yael Zemack-Rugar, Virginia Tech, USA

SESSION OVERVIEW

Resource depletion theory has been a prominent theory of self-regulation since its inception, and has been a source of great interest and much research in both the psychology and consumer behavior fields. Resource depletion theory argues that the resources that underlie self-regulation are limited and that using these resources for an initial self-regulation task leaves less of them available for use at a later time. Moreover, such resource depletion causes decrements in self-regulation performance. Much of existing research has focused on demonstrating the wide variety of self-regulation tasks that can be depleting, and the wide variety of subsequent tasks that can be affected.

The four papers in this session provide new insights into the causes, boundaries, and processes underlying self-regulatory resource depletion. The first two papers demonstrate that initial exertion of self-regulation efforts is not required in order for depletion effects to arise; instead, the authors identify two new causes of self-regulatory depletion.

In the first paper, Alquist, Baumeister, and Tice show that uncertainty is depleting. The authors show that individuals need not exert self-control in an initial task in order for depletion effects to emerge. Instead, the authors either measure or manipulate uncertainty, and show that when an initial task brings about a state of high uncertainty, later performance on self-regulation tasks suffers. Five experiments demonstrate this effect. For example, the authors show that when participants were uncertain (certain) as to whether they were providing correct responses on an initial task, they persisted less (more) at a subsequent puzzle task. Similarly, participants who were unsure as to whether they would be asked to give a speech at the end of the study solved fewer anagrams than participants who knew whether or not they would be required to give a speech. In fact, even participants who knew they were going to give a speech (an unpleasant outcome) persisted longer at the anagrams than participants who were uncertain about whether they would have to give a speech. The authors further show that these effects are not driven by construal level or time orientation, and that the effects can be erased by the consumption of glucose.

This research demonstrates the inherent difficulty underlying self-regulation under uncertainty. This is a central point for a wide range of decisions and their implications, such as how much to gamble on a risky prospect, whether to buy shares of a stock with variable performance, and how a consumer regulates her consumption behavior in days when she awaits the results of an important health test.

The second paper by Dzhogleva, Lamberton, and Haws describes how recalling past acts of self-regulation can be depleting, depending on both the nature of the previous self-regulation and the ease of recall. This paper extends existing work which shows that depletion can occur vicariously (that is, without actually exerting effort; Ackerman et al., 2009) in several ways. First, previous research suggests that thinking about exerting self-regulation, that is, imagining successful self-regulation is depleting; the paper presented here shows that imagining *unsuccessful* self-regulation is also depleting, sometimes more so than thinking about successful regulation.

Dzhogleva et al. report three studies that show that participants who recalled instances of prior self-control failure were more likely to fail at a subsequent task than participants who recalled instances of prior self-control success. The authors found evidence for depletion, as self-reports of subjective fatigue mediated the results (Finkel et al. 2006). Moreover, the authors show that when self-control success is recalled, this is helpful (hurtful) for subsequent self-regulation when the recall process itself is easy (difficult). For example, the authors show that when participants were either under cognitive load or under no load (varying the difficulty of recall), recalling past failure was always depleting, leading to subsequent decrements in self-control. However, recalling past success was only depleting under load, such that when recall of success was difficult it lead to more depletion (and less subsequent self-control) than when recall of success was easy.

This research shows the power of mental simulation to impel consumers to fail at self-control, while also demonstrating that simulating self-control exertion can sometimes lead to self-control success. Moreover, this research identifies two new moderators of depletion: the valence of previous self-regulation efforts (i.e., success or failure) and the ease of retrieval of these past events.

The third paper in this session pushes forward our understanding of depletion effects by re-examining previously identified boundary conditions. Specifically, previous research has shown that intrinsic motivation can undo the effects of depletion (Muraven and Slessareva, 2003), as can the belief that self-control resources are unlimited (Job, Dweck, and Walton, 2010). Some have interpreted these findings as suggesting that depletion is "all in one's head." To examine this claim Vohs, Baumeister, and Schmeichel look at the effects of belief and motivations following either no depletion, mild depletion, or severe depletion.

Across two studies the authors found that when depletion is absent or mild, intrinsic motivation and beliefs in unlimited resources can overcome depletion hold. However, when depletion is severe, motivation and beliefs do not help mitigate the effects of depletion on behavior. For example, the authors show that when participants believed self-regulation resources were unlimited, they performed similarly well on a self-regulation task following no depletion or mild depletion, but significantly worse following severe depletion. This findings show that depletion is not simply "in one's head", but rather is a real phenomenon.

This research more clearly delineates the boundaries of depletion effects, bringing together existing research under one parsimonious umbrella, while extending our understanding of how and when depletion operates. This research demonstrates that beliefs about willpower and motivation sometimes moderate depletion effects and sometimes do not.

The final paper in this session provides a look at a possible process underlying depletion. In this paper, Zemack-Rugar shows that, contrary to previous theory and findings, depletion procedures can increase negative affect. Specifically, previous research has repeatedly shown a null effect of depletion conditions on both the PANAS and BMIS affect measures. Instead of these measures, the author uses a more sensitive measure of affect: stimuli evaluations. Previous research shows that negative affect leads to reduced stimuli evaluations. Accordingly, the author predicts that depletion will lead to reduced stimuli evaluations/increased negative affect.

Across two studies the data shows that depletion increased negative affect. Moreover, as predicted, this effect is moderated by trait self-control, such that it is stronger (weaker) for individuals low (high) on trait self-control. Most importantly, as predicted, the data shows that measured negative affect significantly mediates the effects of depletion on subsequent behavior.

This research furthers our understanding of how depletion might operate to impact such a wide variety of behaviors. This research is unique in that it examines the process underlying depletion, and is novel, in that, contrary to a wide stream of findings, it demonstrates that depletion does lead to an increase in negative affect, and that this increase is at least partially responsible for post-depletion behavior.

In sum, across four papers and 12 studies, this session provides new insights into the causes, boundaries, moderators, and processes underlying depletion. The presenters will report novel findings showing that initial exertion of self-regulation is not required for depletion; instead, the experience of uncertainty and the recall of past self-regulation failures (i.e., of a lack of self-regulation exertion) are also depleting. Moreover, this session shows that depletion is real, and that when it is severe, it cannot be overcome simply through beliefs or motivation. Finally, the session provides novel insight into on possible process underlying depletion – negative affect.

All papers included in this session contribute to the diversity theme of the conference as they present a variety of research methods, manipulations, and measures. The studies involve correlational data, measured and manipulated independent variables, a variety of dependent variables, as well as process measures. Based on the prominence of this theory and the vast interest in self-regulation, we the authors expect this session will appeal to a wide variety of audiences – most specifically scholars interested in self-control, ego depletion, goal pursuit, motivation, executive functioning, self and identity, and emotion regulation.

What You Don't Know Can Hurt You: Uncertainty Depletes Self-Regulatory Resources

EXTENDED ABSTRACT

The present research tested the hypothesis that uncertainty impairs self-control performance on unrelated tasks. Previous research has shown that people think more and remember more about situations that are uncertain than about situations that are certain (Wilson, Centerbar, Kermer, & Gilbert, 2005). Other research shows that certain kinds of mental effort, such as logical reasoning and decision-making can also deplete self-regulatory resources (Schmeichel, Vohs, & Baumeister, 2003; Vohs, Baumeister, Schmeichel, Twenge, Nelson, & Tice, 2008). Given these findings, we predicted that the extra mental effort uncertainty requires will lead to impairment in self-control.

We tested this hypothesis across 5 studies. In study 1 we asked participants to report how uncertain their job, social relationships, financial situation, and life overall had been over the past week. We then asked participants to report how often, over the past week, they engaged in a variety of behaviors that commonly require self-control (Oaten & Cheng, 2005). We found that participants who reported having more uncertain weeks did less housework, did less personal grooming, controlled their emotions less, managed their time less well, smoked more cigarettes, and drank more alcohol than less uncertain participants.

In study 2, we manipulated uncertainty by varying how uncertain/certain participants were about whether they were responding correctly. We then measured the amount of time spent and number of tries made on unsolvable puzzles. We found that participants in the uncertain condition made significantly fewer attempts and spent marginally less time working on the puzzle than participants in the certain condition. We also found that participants' self-reported uncertainty mediated the relationship between condition and persistence on the unsolvable puzzles.

In study 3 participants were either told whether or not they would be giving a speech or told that their experimenter had misplaced their condition sheet and would have to tell them their assigned condition later in the study. We then measured participants' self-regulation by asking them to solve as many anagrams as possible in ten minutes (Muraven et al., 1998). We found that participants in the uncertain condition attempted and solved significantly fewer anagrams than participants who were certain they wouldn't have to give a speech. This was true even for participants who were certain they *would* have to give a speech. Uncertainty resulted in less self-control than being certain of an undesirable outcome.

Study 4 was designed to rule out explanations based on construal level (Trope & Liberman, 2003) or time orientation (Mischel, Shoda, & Rodriguez, 1989; Twenge, Catanese, & Baumeister, 2003). We used the same manipulation as in study 3 and measured self-control using the game Operation (DeWall, Baumeister, & Vohs, 2008); construal level and time orientation were also measured. Participants in the uncertain condition made significantly more errors than participants in the speech and no speech conditions. However, there were no differences between conditions on construal level or time orientation.

Study 5 sought to test a moderator for our effects. Previous research has shown that glucose plays an important role in the limited resource model of self-control (Gailliot et al., 2007). People's glucose levels are lowered after engaging in self-control and when glucose is low, people's self-control performance suffers. An infusion of glucose can restore people's ability to exercise self-control after a previous act of self-control. After the uncertainty manipulation (from Study 3), we gave participants lemonade that was sweetened with either real sugar or a sugar substitute. We then measured participants' self-control using solvable anagrams. We found that among participants in the uncertain condition, participants who were given real sugar (restoring glucose) performed significantly better than participants who were given Splenda (not restoring glucose). In the control condition, there were no differences between participants who were given real sugar and participants who were given Splenda. Sugar improved the performance of participants whose self-control resources had previously been depleted by uncertainty but did not improve the performance of participants who had not been uncertain. This provides evidence that uncertainty impairs self-control by reducing self-control resources (mainly glucose).

The present research provides evidence that uncertainty can impair individuals' ability to exercise self-control. Uncertainty impaired self-control whether participants were uncertain about what they were doing (Study 2) or what would happen to them (Studies 3-5) and glucose restored participants' self-control performance (Study 5).

Haunts or Helps from the Past: How Does Recalling Past Self-Control Acts Affect Current Self-Control?

EXTENDED ABSTRACT

Recollections of one's past can be an invaluable source of information for future decisions (Aarts and Dijksterhuis 1999). Across three studies, we explore two dimensions of consumers' recall of past self-regulation behaviors: (1) the valence of the recalled acts (past successes or failures at self-control) and (2) the metacognitive experience accompanying the recall (subjective ease or difficulty of retrieval). We show that recalling failures prompts consumers toward indulgence no matter how difficult the recall of the past behavior is. However, when recalling successes, metacognitive information matters: easily-recalled successes prompt consumers to demonstrate increased self-restraint, but difficult recall of past successes leads to reduced self-control.

We argue that the interplay of valence of recalled acts and subjective difficulty of retrieval creates different levels of depletion, which, in turn, influences consumers' likelihood to indulge in the present. We argue that the interplay of the valence of recalled acts and subjective difficulty of retrieval creates different levels of depletion. We demonstrate that consumers are likely to be most depleted by one of two experiences: the recall of failures, whether easy or difficult, or the recall of successes, when doing so is particularly hard for them. The momentary sense of depletion felt in such recall situations is integrated into consumers' self-perceptions, such that these more depleted consumers feel they are worse at self-control and behave accordingly. However, when consumers find that recalling successes is easy, doing so does not create depletion. Therefore, they are able to use the recall of successes to bolster their own faith in their self-control ability and to restrain themselves in the present.

In Experiment 1, we used cognitive load (number memorization task: 7-digit vs. 2-digit number) to create different levels of subjective difficulty of retrieval. Participants were asked to retrieve either past self-control successes or failures within the spending domain. Then, participants completed a monthly household budgeting task, in which they allocated $2,500 among three categories: necessities, luxuries, and savings. Our results reveal that when participants reflected on their past self-control successes, those in the difficult recall condition allocated more money to luxuries in comparison to necessities than those in the easy recall condition ($p = 0.01$). In contrast, when participants recalled their past self-control failures, there was no significant difference between the recall conditions ($p = 0.96$).

In Experiment 2, participants were presented with one of two advertisements designed to cue recall of either past self-control failures or successes in the spending domain. The subjective difficulty of retrieval was measured. Subsequently, participants were asked to indicate their likelihood of contributing to a 401(k) program. We find that when recalling past self-control success is easy, consumers were more likely to contribute to their 401k than when recall was difficult ($p < .001$) or when failure was recalled; the effects of failure recall were the same regardless of difficulty ($p = 0.49$).

In Experiment 3, we used a range of the number of self-control acts (1 to 7 acts) to manipulate the subjective difficulty of the recall task with higher number of acts expected to induce greater perceived difficulty. Participants were randomly asked to retrieve either past

self-control successes or failures within the spending domain. They were then asked to indicate how much debt they were willing to incur to purchase an attractive item. We found a significant interaction ($p = .02$) between difficulty and valence such that when consumers recall their past self-control successes, the greater difficulty of the retrieval task led to increased indulgence ($p < .001$), whereas when recalling failures, task difficulty did not impact amount of indulgence ($p = .42$). Furthermore, participants indicated their level of depletion by responding to two established measures (Finkel et al. 2006). Results indicated that reported depletion fully mediated these effects (Sobel test $z = -2.52$, $p = .01$).

The present work contributes new insights to the self-regulation literature. Our research suggests that recall of self-regulation acts alone can deplete consumers and inhibit their ability to restrain themselves in the present. This occurs even (or more so) when the recall is of past failure, that is, the recalled event involves no exertion of self-control. Furthermore, our work reveals that recalling failures is more detrimental to present self-control than is recalling successes: in the domain of self-control, thinking positively may be a better strategy than is dwelling on past failures. However, this advice should be given with a caveat: recalling success is only beneficial for long-term goal pursuit when the retrieval of those acts is subjectively easy.

Motivation, Personal Beliefs, and Limited Resources All Contribute to Self-Control

EXTENDED ABSTRACT

Is self-control a matter of managing a limited energy supply or does it depend more on subjective beliefs and motivations? Contrary to the findings of depletion theory (Baumeister, Vohs, & Tice, 2007; Vohs & Heatherton, 2000) some research suggests self-control might be caused more by beliefs, motivation, or mindsets than limited resources. For example, Muraven and Slessareva (2003) showed that offering incentives can overcome depletion. Job, Dweck, and Walton (2010) showed that people who believed in unlimited willpower were immune to ego depletion. They provocatively proposed that ego depletion is "all in your head."

The present research integrates the findings of Job et al. (2010) and Muraven and Slessareva (2003) with the broader set of ego depletion findings. We hypothesized that personal beliefs and motivations can have significant effects on self-regulation under conditions of moderate depletion, but not at more profound levels of depletion.

Experiment 1 was a 2 (belief: willpower limited/unlimited) by 3 (depletion: none, moderate, severe) between subjects design. The first task comprised the manipulation of willpower beliefs and consisted of having participants rate their agreement with biased questionnaire items that either promoted belief in unlimited willpower or promoted belief in limited willpower (Job et al., 2010).

For the depletion manipulation the no depletion condition participants viewed products on a computer screen for four minutes and wrote phrases or words that occurred to them. They were told that in the end, they would receive one of the products they viewed. In the moderate depletion condition, participants viewed the same products as in the zero-task condition but made choices. Making such choices has been shown to cause ego depletion (Vohs et al., 2008). They also performed the Stroop task for two minutes.

In severe depletion condition, participants first completed the choice and Stroop tasks as in the two-task condition. Next, they watched an excerpt from a comedy video and told to stifle their facial and emotional reactions (Gross, 1998; Schmeichel et al., 2003). Last, they were given two pages of text and challenging instructions on when to cross out appearances of the letter *e*.

We assessed two dependent measures of self-control. First, participants made six intertemporal choices. These started with the choice between $10 now and $10 a week hence, ending with the choice of $10 now versus $15 in a week. Second came the Cognitive Estimation Test (CET), which is comprised of 20 questions that require active, logical thinking to generate plausible estimates (e.g., How much do a dozen apples weigh?; Schmeichel, Vohs, and Baumeister 2003).

Results revealed the predicted interaction between extent of depletion and willpower belief. On both outcomes, performance was unaltered by willpower theory condition when participants had performed no initial self-control tasks. Under mild depletion (two self-control tasks), participants' self-regulation was improved when they regarded willpower as unlimited rather than limited. However, as predicted, the effect of willpower belief disappeared among the severely depleted participants. In fact, in the case of CET scores, we found a significant reversal such that participants who were severely depleted and were induced to believe in unlimited willpower performed worse than their counterparts who were induced to believe in limited willpower.

Experiment 2 used a similar design, manipulating motivation rather than beliefs. The 3 depletion manipulations were similar to those in experiment 1. The motivation manipulation was similar to Muraven & Slessereva (2003). Participants in the high motivation condition read that their participation would help improve the well-being of consumers. Participants in the neutral motivation condition were not told that this experiment had special implications. The dependent measures were the same as in experiment 1.

The results were replicated. Participants in the no-depletion condition were unaffected by the motivation condition. Performance by participants in the mild depletion condition was benefited by extra motivational, relative to participants in the neutral-motivation condition. However, at extreme levels of depletion, extra motivation did not boost performance, which was equivalent between motivated and neutral-motivated participants.

In summary, ego depletion is a real, potentially powerful condition, but that at mild and moderate levels its impact competes with other variables such as subjective beliefs and motivations. However, as the extent of energy depletion increases, the scope for influence by other variables diminishes too. By analogy, a slightly tired person could perform well when bolstered by subjective motivation or self-confidence — but severe exhaustion would take its toll regardless of such factors.

A Reexamination of the Role of Negative Affect in Resource Depletion Effects

EXTENDED ABSTRACT

Depletion and negative affect are both deleterious to self-regulation. However, depletion theory posits that negative affect plays no role in depletion effects (Baumeister, Bratslavsky, Muraven, & Tice, 1998). Empirics largely support this stance. In a literature review 73 studies showed a null effect of depletion on negative affect. Yet, 5 studies showed that depletion increases negative affect, and a meta-analysis (of 36 studies) found a small but significant effect (Hagger et al. 2010).

We propose that this inconsistency occurs not because depletion does not influence negative affect, but because of measurement issues. Specifically, affect has been measured using either the BMIS (Mayer & Gaschke, 1988) or the PANAS (Watson, Clark, & Tellegen, 1988). Instead, we use more sensitive measures: stimuli evaluations. We argue stimuli evaluations will more consistently capture the effects of depletion on negative affect, showing reduced stimuli

evaluations (i.e., increased negative affect; Winkielman & Berridge, 2004) for depleted individuals.

This prediction is supported by various parallels between depletion and negative affect. Both have similar effects on self-regulation (Baumeister et al., 1994; Tice et al., 2001) and time perception (Droit-Volet & Meck, 2007; Vohs & Schmeichel, 2003). Both have similar causes, for example, difficult tradeoffs (Luce, Payne, & Bettman, 1999; Wang, Novemsky, Dhar, & Baumeister, 2010), and both have similar moderators such as positive affect (Tice, Baumeister, Shmueli, & Muraven, 2007), glucose (Benton 2002; Gailliot et al. 2007), and cash incentives (DeWall, Baumeister, & Vohs, 2008; Meloy, Russo, & Miller, 2006). Finally, because depletion tasks are effortful and tiring (Hagger et al., 2010) they may increase negative affect.

Given these similarities we predict that depletion will increase negative affect. We expect this increase will not be detectable when using the BMIS or PANAS, however, it will be detectable using stimuli evaluations. We further predict that trait self-control will moderate this effect. Trait self-control operates like a muscle, where "stronger" individuals are more resistant to the effects of depletion (Baumeister et al., 2006). Thus, individuals will be more (less) likely to reduce stimuli evaluations when they are low (high) on trait self-control. We also examine the mediating role of negative affect in post-depletion behavior, predicting that negative affect will be a significant mediator of depletion's effects on behavior.

Across two studies participants were depleted using established depletion tasks (study 1: Stroop, Wallace & Baumeister, 2002; study 2: text typing, Muraven et al., 2008) followed by either the established affect scales (PANAS, BMIS) or stimuli evaluations (study 1: music, study 2: Chinese ideographs, Winkielman, Zajonc, & Schwartz, 1997). Participants then completed an established self-regulation task (study 1: time spent on open ended math problems, Schmeichel, Vohs, & Baumeister, 2003; study 2: time spent on unsolvable anagrams, Baumeister et al., 1998) and the self-control scale (Tangney, Baumeister, & Boone, 2004).

In both studies depletion, self-control, and their interaction did not affect any of the PANAS or BMIS subscales; PANAS and BMIS also did not predict behavior (p's .11-.85). In contrast, in both studies, depletion and depletion by self-control significantly predicted behavior ($ps< .05$; consistent with prior research) and also predicted music evaluations (consistent with our predictions; $ps< .05$). Simple effects were such that depletion had no effect on evaluations when self-control was high (+1 SD; $ps > .50$), and a significant effect when it was low (-1 SD; $ps < .05$), reducing music evaluations for depleted participants low in self-control.

Also as predicted (in both studies) music evaluations significantly predicted behavior ($ps < .05$). Most importantly, when both depletion by self-control and music evaluations were included in the models, both remained significant (study 1: music evaluation: $t(145) = 2.18$, $p < .05$; depletion by self-control: $t(145) = 2.04$, $p < .05$; study 2: evaluations: $t(52) = 4.75$, $p < .0001$; depletion by self-control: $t(52) = 2.24$, $p < .05$). In both cases, evaluations were a significant mediator of the effects of depletion on behavior (Study 1: $Z = -2.16$, $p < .05$; Study 2: $Z = 4.55$, $p < .05$; Sobel, 1982).

These findings explore and identify the role of negative affect in depletion. It appears that the similarities in causes, moderators, and effects of depletion and negative affect arise because negative affect partially explains depletion effects. Negative affect provides a parsimonious explanation for previously unrelated depletion moderators and provides some insight into the processes underlying depletion. Importantly, we do not argue that negative affect is the sole explanation for depletion. Instead, our findings suggest that other mechanisms are also at play.

SESSION OVERVIEW

Charitable giving is a $290 billion industry in the United States (Giving USA Foundation 2011). With over 800,000 charitable organizations in the United States alone, charities must compete for limited donation dollars (Small and Verrochi 2009). As a result of this competition, nonprofit organizations claim that encouraging donations is their single most important challenge (West 2004). For this reason, charities have begun to spend significant amounts of money on marketing (Watson 2006). In addition to helping charities increase their donation rates, understanding what makes people likely to donate is important for consumer welfare as giving has been tied to increases in happiness and life satisfaction (Lyubomirsky, Tkach and Sheldon 2004, Meier and Stutzer 2008) as well as decreases in anxiety and depression (Field, Hernandez-Reif, Quintino, Schanberg and Kuhn 1998). This raises the important question: Why do people give and under what conditions are they more likely to do so?

With four papers, this session addresses this question as it integrates various research perspectives to identify factors that lead to charitable giving. Garbinsky and Aaker examine the effectiveness of emotional donation appeals over time. While past research has shown that inducing a negative emotion (sadness) results in greater willingness to give immediately following advertisement exposure, they show that inducing a positive emotion (happiness) results in greater donation amounts if solicitation occurs at a later point in time. Herzenstein and Small focus on how situational factors affect willingness to give by examining the effects of scarcity, showing that when financial resources are scarce, people are more likely to give to charities concentrated on local as opposed to global causes. This outcome is a result of social myopia whereby financial scarcity causes

them to more heavily discount the lives of distant others relative to close others. Vohs and Fennis investigate how reminders of money affect donation behavior depending upon the frame. Interestingly, they find that when appeals are framed in terms of others, people reminded of money are less generous than others, but when appeals are framed in terms of the self, people reminded of money are more generous than others. Finally, Norton et al. focus on the positive consequences of giving by providing the first evidence for a psychological universal: people around the world experience emotional rewards from using their financial resources to benefit others. This emotional benefit was observed not only in countries with plentiful resources, but also in impoverished nations.

Make Them Smile:
The Temporal Effect of Emotions on Giving

EXTENDED ABSTRACT

Charity advertisements often display a picture of a victim in order to obtain prosocial responses. These advertisements are effective because the victim's facial expression has the power to elicit the same emotion in the observer by means of emotional contagion (Hatfield, Cacioppo and Rapson 1992, 1994, Neumann and Strack 2000). For this reason, the emotional response that is elicited by the charity appeal depends heavily on the nature of the accompanying picture. Past research has shown that advertisements evoking sadness are more effective than advertisements evoking happiness if the donation is solicited immediately after exposure (Small and Verrochi 2009). However, it remains unclear if the same pattern holds over time.

Knowing that positive emotions are better remembered than negative ones (Walker, Vogl and Thompson 1997), we hypothesize that the immediate advantage of sadness-inducing advertisements will fade over time, and as a result, if a donation is solicited long after advertisement exposure, happiness-inducing advertisements will result in greater giving. Furthermore, we hypothesize that individuals' reasons for donating differ depending on whether the donation is solicited immediately after advertisement exposure vs. a later point in time and that these differential reasons also play an important role in the amount of money that people ultimately decide to give.

To test the first hypothesis, experiment 1 examined whether manipulating the emotion evoked while reading an advertisement would affect donation rates at a later point in time. Thus, participants were asked to evaluate an advertisement for St. Jude Children's Research Hospital that depicted a child with a happy or sad facial expression and then asked two weeks later about their likelihood of donating to this organization if they were to win a $50 lottery. Thus, experiment 1 utilized a single-factor between-subjects design where the emotion evoked while reading an advertisement was manipulated (advertisement: happy vs. sad) and where the donation rate two weeks later was the key dependent variable.

Follow-up survey results revealed no significant differences in the propensity to donate if the $50 lottery was won ($\chi^2 = .54, p = .46$). However, there were significant differences in the amount of money participants would be willing to donate if they won ($t(30) = -2.36, p = .025$). Participants that viewed the happy advertisement two weeks ago indicated that they would be willing to donate a greater portion of their $50 winnings ($M = 20.67, SD = 14.25$) than participants that viewed the sad advertisement ($M = 10.65, SD = 9.60$). While

sadness-inducing advertisements cause increased giving in the short-term, these results reveal that this pattern reverses over time.

To test the second hypothesis, experiment 2 examined the differential reasons for why individuals donate immediately after advertisement exposure or at a later point in time when sadness vs. happiness was induced while viewing the advertisement. After rating their current emotional state, participants were exposed to an advertisement for St. Jude Children's Research Hospital that depicted either a happy-faced child or a sad-faced child. Then, half of the participants were asked whether they would donate money to St. Jude if they were to win a $50 lottery while they were viewing the ad while the other half were asked whether they would donate money to St. Jude one week later. Those who indicated that they would donate were asked to provide an amount in addition to reasons why they would donate. Thus, experiment 2 utilized a 2 (ad: happy vs. sad) x 2 (donate: now vs. later) between-subjects design.

Follow-up survey results revealed no significant differences in the propensity to give for the donate now ($\chi^2 = 1.045$, $p = .307$) vs. donate one week later conditions ($\chi^2 = .436$, $p = .509$). However, there were significant differences in the amount of money participants would be willing to donate if they won. In the donate now condition, participants that viewed the sad advertisement indicated that they would be willing to donate a greater portion of their $50 winnings ($M = 30.23$, $SD = 14.92$) than participants that viewed the happy advertisement ($M = 20.00$, $SD = 14.83$), $t(46) = 2.37$, $p = .022$. Conversely, in the donate later condition, participants that viewed the happy advertisement indicated that they would be willing to donate a greater portion of their $50 winnings ($M = 25.00$, $SD = 13.96$) than participants that viewed the sad advertisement ($M = 15.79$, $SD = 8.04$), $t(38) = -2.52$, $p = .016$.

These temporal effects of donation solicitation then translated into differential reasons for giving based on the emotion that was evoked while viewing the advertisement. Participants were provided with a list of 8 statements and asked to indicate the extent to which the statement would be true for them if they were to win the lottery and donate. In the donate now conditions, one's current emotions (the emotions evoked by the ad) seemed to play a critical role in the decision to donate. Those in the sad ad condition indicated greater agreement with the statement that they would donate in order to feel happy than those in the happy ad condition, $t(46) = 2.054$, $p = .046$. In the donate later conditions, one's current emotions do not seem to play a large role, with participants in the happy ad condition indicating greater agreement with the statement that they would donate to feel important than those in the sad ad condition, $t(38) = -2.318$, $p = .026$. Furthermore, this desire to feel important mediates the relationship between ad condition and amount donated for the donate later participants, with a 95% confidence interval excluding zero (.488, 9.743).

Our studies are one of the first to integrate a temporal perspective on donating, with the results suggesting that the reasons why people give differ across time. Furthermore, the findings illustrate that eliciting negative emotions (sadness) may not always be advantageous and it is important to consider when donations will be solicited when designing charity advertisements. In follow-up investigations, we hope to shed more light on why time differentially affects emotions that were elicited during appeals and how charities can effectively use these mechanisms to increase their donation rates.

Donating in Recessionary Times: Resource Scarcity, Social Distance, and Charitable Giving

EXTENDED ABSTRACT

We examine whether perceptions of financial scarcity affect the allocation of resources to charity. A common sense assumption is that donations will decrease when resources are scarce. Indeed, charitable giving in the U.S. declined by seven percent during the global economic crisis in 2008. Interestingly, however, during that time, donations to national charities decreased more than to local ones (Rosenblum 2010). Thus, in addition to any main effect decrease in financial giving when resources are scarce, it appears that people choose differently—directing resources toward different causes. The present research examines this phenomenon in the laboratory with tighter controls and attempts to understand the psychology behind resource scarcity and donation choices.

Our main hypothesis is that people direct resources toward more socially proximate causes when resources are scarce than when they are abundant. In general, people are more empathic and helpful when they feel closer to others. Research on intergroup relations consistently finds that people care more about others in their in-group than in the out-group (e.g., Dovidio et al. 1997) and are less caring as anonymity between people increases (Bohnet and Frey 1999).

We expect that this tendency is amplified under conditions of resource scarcity and diminished under conditions of resource abundance. Why? From an evolutionary perspective, when resources are scarce, shifting focus to one's own group is necessary for survival. However, when financial resources are abundant, people may feel less concerned about in-group protection and more empowered to help others, regardless of their psychological distance.

In a recent paper, Shah, Shafir, and Mullainathan (2011) find that people behave more myopically when resources are scarce—heavily discounting the future. These findings help explain why the poor, compared with other populations, are more likely to take short-term high-interest loans, which help in the short run but are clearly damaging in the long run. People may likewise be *socially* myopic under conditions of scarcity—more heavily discounting the lives of distant others relative to close others. Indeed, Jones and Rachlin (2006) found that generosity declines with social distance in a "hyperbolic" pattern that resembled the hyperbolic function observed in studies of time discounting. Thus, there are fundamental similarities between temporal and social distance and that may translate to corresponding patterns under conditions of scarcity.

To test this hypothesis, we conducted three experiments involving actual monetary donations. In all experiments participants arrived at a lab, were seated in private cubicles, and received $5 compensation for their participation. In all experiments we induced feelings of financial scarcity or abundance by asking participants to estimate how much money they have in their combined bank accounts (following Nelson and Morrison (2005)). In the scarce resource condition, the scale for this question ranged from $0 to over $50,000 with increments of $5,000. Almost all participants checked the first tier of this scale. In the abundant resource condition, the scale ranged from $0 to over $500 with increments of $50, and almost all participants checked the last tier of the scale. In an ostensibly unrelated experiment participants read about a "great way to help children" and a description of UNICEF followed.

In the first two experiments, the donation targets were UNICEF in the U.S. ("helping children in our local community") and Africa ("helping children in a faraway community"). In experiment 1 (n = 107) we employed a within-participant design such that all participants could donate to UNICEF U.S., UNICEF Africa, or not

donate at all. They could also decide the amount to be donated. Donations were made in private to reduce any social pressure. We calculated the difference between the donation each participant allocated to the U.S. and Africa and subjected this variable to an ordered logit. Results show that resource scarcity significantly impacts where the money was donated: as resources become scarce, donations to the U.S. fund increased compared with Africa.

In experiment 2 (n = 158) we used a between-participants design such that roughly half of the participants read about UNICEF U.S. and the other half about UNICEF African. A 2(scarcity) × 2(donation target) ANOVA revealed only a significant interaction such that donations to the U.S. fund are higher than to the Africa fund when resources are perceived as scarce, but when resources are abundant there is no significant difference between the amounts donated to each country.

In experiment 3 (n = 131) we attempted to generalize our finding to another natural in-group/out-group dichotomy. Half of participants were asked to donate to "help improve the living conditions of business students like you" and the other half was asked to donate to "help improve the living conditions of agriculture students". A 2(scarcity) × 2(donation target) ANOVA revealed a significant interaction. Donations to business students are higher than to agriculture students when resources are perceived as scarce, but when resources are abundant there is no significant difference between the amounts donated to each group.

In sum, three experiments show that resource scarcity leads to socially-myopic donation choices. The results have important implications for understanding public aid in recessionary times. They suggest that beyond a simple decrease in generosity when financial resources are tight, there is also a shift in *where* people donate.

Are the Rich or Poor the More Generous Ones? It Depends on the Way the Appeal is Framed

EXTENDED ABSTRACT

Are the rich or poor the more generous ones? Confusingly, there are supportive findings on both sides. Two studies investigated how money reminders produce differential donation behavior. Our results in fact suggest that both states can lead people to donate more (or less), depending on the way that the appeal is framed.

Research has documented that having money can result in more and less donation behavior. Longitudinal research by Schervish and Havens (2001) has found that the wealthiest 7% of U.S. households contribute over 50% of the money to charitable causes. Experimental studies demonstrated the existence of a "noblesse oblige" social norm that prompts high status individuals, and not their low status counterparts, to behave prosocially (Fiddick and Cummins 2007). But the reverse also seems to be true, in that people without much money tend to donate more than their richer counterparts. For instance, household incomes of greater than $100,000 donate a lower proportion of their incomes than those of less than $25,000 (Gardyn 2003).

Because people who possess many or few financial resources might be inherently different types of people and, accordingly, such individual differences might be driving differences in donation behavior, we first sought to study the effects of mere exposure to the idea of money on donation behavior. In study 1, participants were brought into the laboratory and given 8 quarters ($.25) for their participation, a device that also allowed us to be sure that participants possessed money for the donation opportunity to follow. Next came a manipulation of the idea of money: Participants were either reminded of money or nonmoney (neutral) concepts via a phrase de-

scrambling task. After completing filler questionnaires, participants were told that the experiment was over and given a false debriefing. While participants gathered their belongings, the experimenter pointed to a covered box in the back of the room and commented that the lab was taking donations for the University Student Fund if the participant wished to donate. Participants were given a private opportunity to donate, which was the dependent measure.

The results showed that money-reminded participants donated less than participants in the neutral condition. In fact, money reminded participants donated on average 57% of what others did.

Study 1's results indicated that people reminded of money were less generous than others. A broader conclusion from this and other work is that people reminded of having money appear to be driven by a focus on the self (Vohs et al. 2006). Yet most donation appeals focus explicitly on others, not the self. We hypothesized that when an appeal for donations is framed in terms of others, people reminded of money would be less generous than others, as in study 1. Yet when framed in terms of the self, people reminded of money were predicted to be more generous than others.

We predicted the opposite effect for people reminded of lacking money. Recent work has depicted low socioeconomic individuals as more generous, charitable, trusting, and helpful compared to their high social class counterparts (Piff et al. 2010). By implication, we predicted that when in a mindset of lacking money, donations would rise if participants were reminded of others and fall if they were reminded of the self.

We tested our hypotheses using a field experiment assessing actual monetary donations to an existing charitable cause. The design was a 2 (prime: having money vs. lacking money) x 2 (reminder: own behavior vs. others' behavior) between-subjects factorial design. Participants first performed a descramble task designed to prime the sense of either having versus lacking money.

Then the experimenter indicated that she was soliciting monetary donations for the World Wildlife Fund (WWF). Participants in the self condition were asked if they agreed that thought the WWF was a worthy organization (all agreed). Then the experimenter reminded them of their support of the WWF and asked for a donation. In the other condition, participants were told that many other people had already supported the WWF by donating. Then the experimenter asked for a donation.

Results showed the expected pattern, that prime and reminder conditions interacted to predict donation behavior. In support of hypotheses, participants primed with the idea of having money donated more when the call for charity reminded them of their own behavior than when it highlighted the behaviors of others. Among participants who had been primed with the idea of lacking money, the pattern reversed — these participants donated more of their own money when the charitable request reminded them not of themselves but of the behavior of others.

Previous work has shown that people who have money display more charitable giving than do people lacking money — but, perturbingly, the reverse also has ample support. The present research shows that both outcomes depend on the way the appeal for generosity is framed.

Prosocial Spending and Well-Being: Cross-Cultural Evidence for a Psychological Universal

EXTENDED ABSTRACT

Warren Buffett, one of the richest people in the world, recently pledged to give away 99% of his wealth, saying that he "couldn't be happier with that decision" (Buffet 2010). Consistent with Buffett's claim, recent research suggests that financial generosity may indeed

promote happiness (e.g., Dunn, Aknin and Norton 2008). For Buffett, this striking act of generosity necessitated little self-sacrifice; he noted that "my family and I will give up nothing we need or want by fulfilling this 99% pledge," whereas for other people, "the dollars [they] drop into a collection plate or give to United Way mean forgone movies, dinners out, or other personal pleasures" (Buffett 2010). Of course, in many parts of the world, spending one's limited financial resources on others may mean sacrificing more than just movies and dinners out. Does spending money on others promote happiness even in relatively impoverished areas of the world?

To examine the correlation between prosocial spending and subjective well-being within a large number of countries, we use data collected from 136 countries between 2006-2008 as part of the Gallup World Poll (GWP; total $N = 234,917$, $M_{age} = 38$, $SD = 17$; 49% male). The sample represents over 95% of the world's adult population (aged 15 and older) and provides an exceptionally large and diverse snapshot. The data are collected using randomly selected, nationally representative samples with a mean size of 1321 individuals per country ($SD = 730$, range = 141- 4437). The relationship between prosocial spending and SWB is positive in 120 out of 136 countries included in the Gallup World Poll, with this relationship reaching traditional levels of significance ($p < .05$) in some 59% of these 120 countries. In a pooled global estimate, the prosocial spending coefficient, b = .27, $p < .03$, exceeds half the coefficient of log income, b = .41, $p < .03$. Thus donating to charity has a similar relationship to SWB as a doubling of household income. Importantly, although rates of prosocial spending are higher in wealthier countries, $r(134) = 0.54$, $p < .001$, the size of the relationship between prosocial spending and SWB that emerges within countries is unrelated to rates of donation, $r(134) = -.10$, $p = .23$, or to the countries' mean incomes, $r(134) = -.09$, $p = .31$, suggesting that generous financial behavior is linked to well-being in poor and rich countries alike.

In Study 2a, we tested the causal impact of prosocial spending on happiness, randomly assigning participants in Canada (N = 140) and Uganda (N = 680) to write about a time they had spent money on themselves (*personal spending*) or others (*prosocial spending*). As predicted, there was a significant main effect of spending type, whereby participants randomly assigned to recall a purchase made for someone else ($M = .09$, SD = 1.00) reported significantly higher happiness than participants assigned to recall a purchase made for themselves ($M = -.09$, SD = 0.99), $F(1, 784) = 8.21$, $p = .004$. The interaction of spending type and country was not significant, $F(1, 784) = 1.88$, $p = .17$. Thus, participants in Canada and Uganda reported higher levels of happiness when they thought about spending money on others rather than themselves. In Study 2b, participants in India (N = 101) were assigned to recall a recent purchase in which they spent money on themselves (personal spending condition) or someone else (prosocial spending condition); those in the control condition proceeded directly to our happiness measures without recalling a past spending experience. A one-way ANOVA revealed significant between-group differences in positive affect, $F(2, 96) = 3.44$, $p < .04$. Using LSD contrasts, we found that positive affect levels reported by participants in the control condition ($M = 3.72$, $SD = .72$) and personal spending condition ($M = 3.64$, $SD = .49$) were not significantly different from each other, $p > .65$; most importantly, participants in the prosocial spending condition reported higher levels of PA ($M = 4.11$, $SD = .54$) than participants in either of the other conditions, p's < .04.

In Study 3, participants in both Canada (N = 60) and Uganda (N = 95) engaged in a version of the "dictator game," a widely-used economic paradigm in which generous financial behavior can be observed in a controlled setting. We entered trait happiness, donation

amount, country, and a donation amount X country interaction term into a linear regression equation predicting post-task positive affect. Supporting our hypothesis, donation size was the only significant predictor of post-task PA, such that larger donations were associated with higher levels of positive affect ($\beta = .27$, $p < .001$). The interaction of donation amount and country ($\beta = -.06$, $p > .45$) did not approach significance, such that donation amount predicted dictators' post-task positive affect in both the Ugandan ($\beta = .19$, $p < .04$) and Canadian ($\beta = .35$, $p < .005$) samples.

Taken together, the present studies provide the first evidence for a possible psychological universal: human beings around the world experience emotional rewards from using their financial resources to benefit others. From an evolutionary perspective, the emotional rewards that people experience when they help others may serve as a proximate mechanism that evolved to facilitate prosocial behavior, which may have carried short-term costs but long-term benefits for survival over human evolutionary history. The robustness of this mechanism is supported by our finding that people experience emotional benefits from sharing their financial resources with others not only in countries where such resources are plentiful, but also in impoverished countries where scarcity might seem to limit the possibilities to reap the gains from giving to others. In highlighting the potential universality of emotional benefits stemming from prosocial spending, the present work adds to the chorus of recent interdisciplinary research on the importance of generosity for human well-being.

SESSION OVERVIEW

This special session is unified by a focus on women managing significant life transitions. Each of the four papers examines how women struggle across diverse life stages, the successful and unsuccessful use of goods and services during this transition, and how gendered roles constrain action as women negotiate to create spaces in which they can maneuver and thrive. The papers traverse across the life stages of virginity, motherhood, and middle age (van Gennep 1960).

Linda Scott examines the problem of retaining girls in secondary education in economically developing countries. In three field studies, she explores the viability of providing girls sanitary menstrual products to increase their attendance. Feminist discourses have traditionally argued that the same social structures oppressing women also dominate nature (Plumwood 1993). Thus, ecofeminists argue that researchers should align to dismantle the underlying dualisms (e.g., masculine/culture/developed vs. feminine/nature/developing). Ironically, global discourses in this context force a false choice between either protecting at-risk young women or the environment, all the while ignoring the environmental contradictions of Western women's practices.

Shifting to the challenges of motherhood, Amber Epp and Sunaina Velagaleti explore how Western women who have an abundance of opportunities manage motherhood through outsourcing. Mothers face new services aimed at families that extend beyond the traditional dilemma of selecting childcare to more nontraditional services. Mothers create assemblages of care that seek to balance control, intimacy, and substitutability as they explore the boundaries between private family life and public marketplace exchanges.

The final two papers explore later life stages as women transition through menopause and into the life stage of old age. Given the negative stereotypes and stigmas associated with being an older woman, these stages are associated with the assertion of new positive identities. Canan Corus and Bige Saatcioglu explore how menopausal women construct the meaning of womanhood and beauty as they go through this transitional life stage. Highlighting the relationship between women's consumption practices and these constructed meanings, they find that women evolve new identities aided by consumption practices in the domains of beauty, health care, and leisure.

Emily Moscato and Julie Ozanne examine the brand community of the Red Hat Society, which is a group of women over fifty who meet socially for friendship, fun, and laughter. The 'red hatters' are best known for their outlandish costumes of red hats, purple dresses, and dazzling accessories, as well as their penchant for shopping and dining out. Yet a deeper analysis suggests that, consistent with situated learning and theories on communities of practice (Wenger 2000), these women use this social support to learn and practice the skills needed for aging.

This session highlights diversity by examining the negotiation of gender both across life stages as well as across developing and developed economies. This session should be of relevant to researchers interested in consumer socialization, aging, rites of passage, feminist theory, gender, and issues of discrimination and social justice.

Red Flag: Inadequate Sanitary Care Derails the Transition to Secondary School in Africa

EXTENDED ABSTRACT

Retaining girls in secondary school is thought to be key to solving problems that block economic prosperity in poor nations: high fertility rates, high infant and maternal mortality, and rapid spread of disease, for instance (Hausmann et al. 2007). Yet drops in female enrollment after puberty continue to be dramatic and often prove intractable in the face of NGO and government efforts to encourage girls' education (World Bank 2011).

Local custom often takes a "coercive pronatalist" stance (Folbre 2009), even where official exhortations discourage early marriage and large families. Among other practices, habits and attitudes surrounding the onset of menstruation, such as unhygienic care and limited personal privacy, push girls into early motherhood even when they wish to continue in school. At the same time, menstrual taboos inhibit frank discussion of the problem, while rites of passage trumpet the sexual "ripeness" of even very young post-pubescent girls (Buckley and Gottlieb 1988; van de Walle et al. 2001).

This talk will focus on three studies, two completed and one ongoing, in east and west Africa, that investigate sanitary pads provision in educational settings, within the context of girls' transition into adulthood. However, sources and experiences from other developing nations will also be brought to bear on what is believed to be a widespread problem (for instance, El-Gilany et al. 2005; Mahon and Fernandes 2010; Nabar et al. 2006).

Two completed investigations of the impact of free sanitary pads provision will be described, one in Ghana and one in Uganda. Initial data, collected in Ghana, show that providing ordinary disposable sanitary pads increases not only attendance in school, but the ability to concentrate, levels of confidence, and engagement in activities from sports to household chores. An extension of this work, among a larger sample and with a longer time horizon, is now underway in Uganda.

After years of silence, menstrual provision has now emerged as a topic of keen interest in Africa, with nations such as Ghana and Kenya leading initiatives to guarantee adequate sanitary care, in order to protect girls' rights to equal education (for instance, Cherono 2011). Yet this welcome attention to a long-neglected problem has brought new challenges: toilet facilities are woefully inadequate and disposable pads may cause costly backups. At the same time, West-

ern environmental activists, who are often unaware of the nature of the material constraints, are pushing against the provision of disposable pads, arguing instead for menstrual cups and cloth pads (see, for instance, "Danish Company Gets Sida Grant to Sell Menstrual Cups in Kenya" 2011; Oster and Thompson 2007).

Thus, the third study, expected to conclude in July 2012, looks into the acceptability of various eco-preferable alternatives in the secondary and primary schools of a remote community in Uganda. Three locally sourced cloth pads are being tested alongside a paper pad made from papyrus in local cottage factories. In addition, an innovative incinerator for disposables (including the papyrus pad) is being tested. This incinerator burns without fuel at medical waste temperatures and can be attached directly to a latrine closet. The reasons for omitting menstrual cups, which pose a substantial public health threat, will also be outlined.

Distributing free sanitary pads may help improve girls' attendance and, perhaps, their performance and retention. But the world community also balks at giving girls these consumer products, particularly because of environmental concerns surrounding disposal of pads. Thus, this talk will end by describing the conflicting agendas of women's rights activists and environmental advocates in the context of puberty and education in the developing world.

Outsourcing Motherhood:
Managing Assemblages of Care

EXTENDED ABSTRACT

Increasingly, mothers are choosing to outsource some of their most intimate parental practices to the marketplace. Outsourcing refers to "the transfer of intimate tasks historically or normatively seen as being performed within the family and by family members to formal commercial establishments located outside of the family" (Lair 2007, p. 32-33). Although questions about whether to enroll children in daycare or place an elderly parent in a nursing home have long been at the center of public and academic debates, examples of outsourcing everyday family life have begun to proliferate in the media. Services exist for everything from teaching your child to ride a bike to taking your kids on college tours (Leider 2009). These emergent services blur the boundaries between family and the marketplace, and prompt new questions about what is acceptable to outsource and how families make these sometimes contentious decisions.

Family life incorporates a range of everyday practices of care, which range from daily rhythms to our most sacred milestones (Epp and Price 2008, 2010). Beyond acknowledging that "consumption is a moment in every practice" (Warde 2005), some scholars argue that the marketplace has become *too* close to family life. Prior research sets up an oppositional dichotomy between the realms of love/family/sacred and money/market/profane (Hochschild 2003). This strict dichotomy positions the marketplace as an intrusion in family life, propagated by overbooked lifestyles that force families to substitute paid care for family-produced practices (Hochschild 2003). Rather than accept this dichotomy as given, we allow families to reveal their own assumptions about how the marketplace should or should not be integrated into family life. This alternate perspective examines how intimacy and the marketplace coexist and draw upon one another in both conflict and partnership (Thompson 1996; Zelizer 2005).

Consumer researchers have only recently entered the academic debate on outsourcing and they tend to focus on major family decision contexts such as daycare or eldercare (Bradford and Sullivan 2010; Huff and Cotte 2011). Our study extends this research by investigating how mothers make choices about outsourcing everyday practices, where boundaries about what is acceptable to outsource

are challenged. Practices of care are not limited to major life decisions, but rather manifest in a range of everyday activities such as grocery shopping and preparing dinner, often heralded as sites for the expression of love and sacrifice (Miller 1998; Thompson 1996). Mothers express guilt and anxiety over outsourcing certain activities to make time for others (Daly 2001; Leider 2009), especially when there is fear of missing milestones or questions about whether the market can provide the same personalization of care (Hochschild 2003). Other mothers express pride in being able to provide their children with rewarding experiences delivered by professionals (Thompson 1996), but perhaps all practices are not equally up for negotiation. The potential for tension exists as practices considered sacred to some might be traded off for other practices (Epp and Price 2010, 2011).

We adopted a grounded theory approach based on in-depth interviews with 25 couples with children. Participants varied in their views, practices, and constraints related to outsourcing based on factors such as income or social class, availability of kin networks, and family structure. In order to ensure diversity with regard to access to outsourcing services, we interviewed families in multiple cities.

Our primary contribution is a framework for how mothers make decisions about outsourcing everyday practices of care. Specifically, mothers generate complex assemblages of care that incorporate heterogeneous resources to assert control, preserve intimacy, and approximate substitutability. Clear tensions exist around how and when to enlist outside resources that move beyond considerations of expertise. For example, following Hochschild (2003), mothers often expressed desires for service providers to customize care for their children to mirror the care she would provide herself. This might include sharing details about birthday traditions or rewards given during potty training. However, despite the sense of control and peace of mind gained from being able to customize, it also presented drawbacks. Facilitating perfect substitution engendered feelings of irrelevance: "if it could be substituted by any other adult, then what sets you apart as a parent?" (Lorna, Mother). Instead, care assemblages must include at least some practices that are "just ours," even if the meanings of practices or what these accomplish shift from some practices to others. That is, mothers weigh the entire assemblage of care when making outsourcing decisions, rather than thinking about a particular service in isolation. Further, attempts to substitute focus mostly on the child's experience, but mothers find it difficult to miss out: "Tara [care provider] has those memories [firsts], and I won't" (Allison, Mother). In addition to customization tensions, many service providers attempt to preserve intimacy by making children's experiences more accessible. Examples such as texting updates, online video feeds, or reports on the child's activities were prevalent. Tensions also surfaced with this strategy, as mothers who missed milestones attempted to redefine them ("it'll be a first time for *us* when we see her walk, too... *that* will be our first… We'll count that one, not the other one"—Allison, Mother). Mothers found it more difficult to reframe the milestone when providers tried to include them ("She [care provider] caught her steps with her camera"—Allison, Mother). Across families, we observed variation in the extent to which mothers' assemblages of care were intentional or emergent, but considering questions of control, intimacy, and substitutability often shaped which resources mothers incorporated.

The Social Construction of Womanhood in Middle Age: Menopause as a Rite of Passage

EXTENDED ABSTRACT

Middle age is considered a prominent rite of passage in a person's life whereby physical appearances change, new roles are adapted, and identities are negotiated (van Gennep 1960). Much of consumer research on aging focuses on the elderly (Price, Arnould, and Curasi 2000; Bonsu and Belk 2003; Schau, Gilly, and Wolfinbarger 2009), even though middle age is a major life transition that poses multiple physical, psychological, and social challenges (Hollis 1993). Middle age is experienced very differently by women than by men since the physiological change of menopause marks the beginning of midlife. As they become middle-aged, women not only undergo bodily and emotional changes but they also are at times subject to negative stereotypes related to aging, beauty, and their sexual attractiveness.

Middle-aged women are an understudied population in consumer research (see, for exceptions, Hill 1991; Thompson 2004; Ustuner and Holt 2007). Understanding women better and exploring their changing marketplace practices as they enter midlife is important for several reasons. First, women constitute a fairly large consumer segment with diverse needs and expectations (Huddleston and Minahan 2011). Second, women take an active role when it comes to consumption; for example, they are often the primary decision makers in much of the familial consumption practices (McIntosh and Zey 1989). In addition, exploring the depth and richness of the female world would contribute to the research on diversity and marketplace inclusion (Williams and Henderson 2012).

The purpose of this study is to explore middle-aged women's social construction of womanhood as they go through menopause. We study menopause as a transition that triggers changing definitions of self and womanhood. We seek to address questions regarding women's identity construction as they experience this transition: How are women's experiences of menopause colored by specific cultural and contextual constructions? What are the roles of social others (e.g., family, healthcare staff) in women's construction of their experiences? How do women's interpretations of their bodily changes shape their identity negotiations? We explore the ways menopausal women construct the meaning of womanhood and beauty as they go through this transitional life stage. Further, we try to understand the nature of the relationship between women's consumption practices and these constructed meanings.

Menopause is a rich context to explore the shaping and negotiation of womanhood in midlife for several reasons. First, menopause is a unique transition in that it is "strictly a female passage" that marks the beginning of several changes, challenges, and transitions in women's lives (Coulbrooke 2002, p. 170). As compared to men, women's bodies are more central to their social interactions, negotiations of power, and self-definitions. As such, there is much to learn through examining transitions in the way women's bodies are treated and imagined. Second, women who enter the menopausal period experience bodily changes that trigger different health and self-care consumption practices (Herrick, Douglas, and Carlson 1996; Lyons and Griffin 2003). Finally, menopause is often viewed as a woman's loss of her attractiveness and sexual appeal; in a society that worships youth and beauty, these perceptions highlight the challenges faced by midlife women (Martin 2001).

Although menopause is a natural hormonal transformation, it is sometimes treated as a "process of breakdown, failure, and decline" (Martin 2001, p. 43). In this definition of menopause, the female body is seen as a system that breaks down and loses its reproductive capabilities (Martin 2001, p. 42). Within this narrow and largely negative depiction of the female body in transition, menopause is described as a problem of hormone deficiency, a pathological state, which needs to be treated (i.e., the medicalization of menopause) [Conrad 2007]. In opposition to the medical discourse, feminist discourse constructs menopause as a natural physiological transformation that brings along new roles and freedoms in women's lives (Kaufert 1983).

Preliminary findings based on in-depth interviews with women across menopausal phases hint at multiple distinct constructions of menopause and middle age. For example, while few of our informants perceive menopause as a medical condition that needs to be cured via medical procedures (e.g., hormone replacement therapy) and thus, adhering to the medical discourse, others see it as a positive transition that motivates new beginnings (i.e., engaging in new hobbies, negotiating roles, and challenging societal norms about womanhood). Consistent with van Gennep's (1960) and Schouten's (1991) descriptions of rites of passage, we find that our informants go through the "separation" phase during which they distance from their previous social construction of womanhood. Menopause becomes the triggering event to start this separation phase. However, our initial findings highlight more complex versions of the two subsequent phases of rites of passage (i.e., transition and incorporation) than the ones conceptualized by van Gennep (1960) and Schouten (1991). Furthermore, our findings point to a variety of coping strategies with menopause and midlife transitions as well as newly acquired consumption practices in various domains such as beauty, healthcare, and hobbies. As such, our data highlights the diversity in both individual and social identities of women going through midlife.

Crones, Hags, and Biddies: How I Became a Burlesque Queen at Seventy

EXTENDED ABSTRACT

The stigmas of aging–unattractiveness, frailty, and dependency–are often amplified by gender expectations for women. For instance, looks are traditionally a source of social capital for women and, thus, women are judged harshly as their "looks fade." Women grow old while men become distinguished; men are seldom accused of "sagging" (Calasanti 2005). Against this backdrop, the members of the Red Hat Society (RHS) perform gender by parodying traditional expectations that women look pretty and act demurely. The RHS encourages its members to wear gaudy attire, buy branded merchandise, and consume loudly and hedonistically. The Red Hat community provides an opportunity to enhance our understanding of how older women negotiate culturally embedded standards of aging and beauty.

The Red Hat Society is an organization for women fifty years and older dedicated to celebrating aging through "fun, friendship, and freedom." The RHS boasts 80,000 registered members embracing the advice from Jenny Joseph's poem, *Warning*: "When I am an old woman, I shall wear purple, with a red hat that doesn't go…" They attend local chapter meetings at restaurants wearing their regalia of red and purple and accessorizing with feathers, flowers, beads, and sparkles. RHS members are known for their loud laughter, spontaneous singing, and frequent playing of red and purple kazoos. RHS is a brand community heavily focused on buying and consuming from their outlandish costumes to their monthly feasting rituals in which cocktails and desserts are consumed before the main meal.

Corporate headquarters states that "the official sport of Red Hat Society is shopping."

Emergent findings, based on interviews and fieldwork, suggest that beneath the surface silliness, these women both support and challenge traditional notions of what it means to be an older woman. The RHS highlights the dynamic tensions between conformity and resistance in consumption communities of marginalized individuals seeking mainstream recognition without assimilation. The RHS members coalesce around consumption of the RHS brand, sharing rituals, traditions, and a sense of responsibility to community members and potential members (Muniz and O'Guinn 2001). RHS prides itself on contradicting traditional gender roles. Publically, members are loud and boisterous and they focus on themselves and pleasure (rather than attending to family or social obligations). They support other gendered roles such as shopping, gift giving, and being beautiful. Yet, ironically, their performance of beauty is over-the-top like the garishness of burlesque queens as they don feathered boas, velvet dresses, and plenty of bling. "I saw this hat and I was just flabbergasted by it... it was so great I just had to have that hat so I bought it... and immediately wore that one and it was a hoot. Everybody just oohed and awed over it and it was great. I loved it" (Dana, 12/17/11).

Their focus on having fun and drawing attention is also a direct challenge of societal norms about appropriate behavior and appearance of older women, who are expected to "fade into the woodwork" (Stalp, Williams, Lynch, and Radina 2008, 247). Violating social expectations introduces RHS members to a new type of social performance, as one informant stated, "it's okay to laugh and be silly and make noise in a restaurant and do things that I've been socialized and condition not to do all these years" (Macey 10/24/11). Consistent with situated learning and theories on communities of practice (Lave 1991; Wenger 2000), RHS members acquire knowledge and skills for coping with the aging process through their community involvement. Through sharing, laughter, and community these women reframe their discomfort over growing old and affirm their worth and entitlement in a culture focused on youth, speed, and independence.

SESSION OVERVIEW

Understanding moral judgments is critical for society at large as well as businesses given an increasing level of moral uneasiness (Mills 2000) and growing dissention regarding judgments of right and wrong (or moral versus immoral) among political ideologies as well as religion and culture (Haidt and Joseph 2004). In seeking to understand moral judgments, a growing body of research has started to examine the role of various antecedents to moral judgments. For example, to date, research has examined how moral judgments are influenced by emotions and moral intuitions (Pizarro, Inbar, and Helion 2011; Ugazio, Lamm, and Singer 2012), individual differences such as sensitivity to bodily sensations and disgust (Inbar et al. 2009; Schnall, Haidt, Clore, and Jordan 2008), sensory experiences such as taste and physical cleanliness (Eskine, Kacinik, and Prinz 2011; Inbar et al. 2009), and even hypnotism (Wheatley and Haidt 2005). Nonetheless, the discord surrounding morality and moral judgments in society suggests that there is much yet to be understood.

The goal of this session is to gain better understanding of the various antecedents of consumers' moral judgments. Each of the four papers examines a different factor and thereby takes an integrative approach to understanding the precursors of the consumer moral judgment process. In doing so, this session draws on several different fields of study, addressing the conference mission of appreciating diversity to the extent that the series of papers offers interdisciplinary insights into moral judgments.

The first paper by Winterich, Morales, and Mittal presents four studies examining nuances of the extensive findings on affective antecedents of the moral judgment process. The authors explore how specific emotions (disgust, happiness, sadness) affect the severity of consumers' moral judgments. An important insight offered in this paper is the role of transgression magnitude in reversing the effect of emotions on moral judgments with both positively and negatively valenced emotion having similar effects on the severity of moral judgments based on other cognitions associated with the specific emotion.

Moving from the affective antecedents to the sensory determinants of the moral judgment process, the second paper by Nenkov et al. features six studies. The authors show that sensory input (i.e., seeing, touching, smelling, or hearing a product) lowers consumers' level of construal, which leads to less harsh moral judgments, less sophisticated moral reasoning, and more motivated moral reasoning.

The third paper by Hershfield, Cohen, and Thompson explores the cognitive determinants of moral judgment. In a series of five studies, this paper establishes consumers' ability to project one's self into the future as an important determinant of moral decision making. Specifically, whether measured or manipulated, similarity to one's future self not only decreases the severity of moral judgments, but also increases the likelihood of engaging in immoral behaviors such as lying and cheating.

Finally, after considering nuances of the affective, sensory, and cognitive antecedents of moral judgments, the fourth paper by Mazar et al. employs a large-scale twin study to explore the genetic determinants of the consistency of consumers' moral judgments. Their findings suggest that genetic structure can predict consistency in moral judgments, but, notably, genetics do not seem to underlie consistency in other judgments such as religious or economic decisions.

This set of papers not only considers a diverse set of antecedents to moral judgments ranging from heritable genetics to situational factors such as sensory inputs, but also offers insights from a total of 16 studies, some of which are field studies and others examining actual immoral behavior in addition to judgments. All four projects included in this session are at a very advanced stage of completion, and the manuscripts for all four of the papers, as well as the cited references, will be available upon request.

By studying various determinants (i.e., emotional, sensory, cognitive, and genetic aspects) of the moral judgment process, which includes the harshness and consistency of moral judgments, the sophistication of moral reasoning, as well as consumers' (un)ethical conduct, this symposium brings together diverse perspectives on the moral judgment process and is a model of "appreciating diversity" in keeping with the 2012 ACR conference theme. The projects presented in this session span multiple scholarly domains, various methodological approaches, as well as sample characteristics. Data were gathered from multiple countries around the globe (USA, France, Singapore, Sweden) such that diverse populations are represented and findings are not limited to potential cultural differences in moral judgments (Haidt and Joseph 2004). Moreover, the diversity of this session suggests it will be of interest to a wide range of scholars, with the following audiences finding this work to be of particular interest: scholars of moral judgment, researchers examining the nuances of

specific emotions, academics interested in sensory and genetic influences on consumer behavior, along with scientists interested in understanding influences of future-oriented thinking.

In short, the findings being presented embody a wide range of approaches, and we believe offer an integrative study of the diverse factors that affect the consumer moral judgment process. In doing so, this session not only offers theoretical insights, but also provides important considerations for individuals, business, and society facing increasing levels of moral unrest.

All Sins Are Not Equal:
The Moderating Role of Transgression Magnitude on the Effect of Disgust on Moral judgments

EXTENDED ABSTRACT

We do not judge all sins equally: most would consider stealing a laser printer to be a more severe transgression (i.e., more wrong) than stealing a few sheets of printer paper. How do people make such judgments and how do they vary based on emotions? Disgust has been found to influence judgments of immoral behaviors (Horberg, Oveis, Keltner, and Cohen 2009; Schnall, Haidt, Clore, and Jordan 2008; Wheatley and Haidt 2005), but the mechanism responsible for the impact of disgust on moral judgments is underdeveloped. Interestingly, a careful investigation reveals the positive relationship between disgust and moral judgments may be stronger when the magnitude of the transgression is high whereas the association may be weaker when the transgression is of low magnitude (Schnall et al. 2008; Wheatley and Haidt 2005). Why would this be the case?

We propose disgust and its corresponding cognitive appraisals of rejection (Rozin et al. 2000; Smith and Ellsworth 1985) may influence construal level (Trope and Liberman 2003 2010; Vallacher and Wegner 1987) such that perceived transgression magnitude moderates the association between disgust and moral judgments. Specifically, the abstract construal from disgust motivates people to examine the "why" of the behavior being evaluated. When judging high magnitude transgressions, disgusted individuals consider why one would engage in such a behavior and find it relatively harder to provide justifications for such high magnitude transgressions and judge the transgression more severely. In contrast, disgusted individuals

considering why one would engage in low magnitude transgressions are able to think of numerous justifications, resulting in less severe judgments than those not making an evaluation based on "why" (i.e., neutral state). This pattern results in divergent effects of disgust on moral judgments depending on transgression magnitude.

The first study is a 2 (emotion: disgust vs. neutral) x 2 (transgression magnitude: high vs. low) mixed design with emotion manipulated between-subjects and transgression magnitude within-subjects. Disgust was induced with a product evaluation task, and then participants evaluated a subset of high and low magnitude immoral behaviors used in past research (Detert et al. 2008; Eyal et al. 2008; Horberg et al. 2009; Schnall et al. 2008). A pretest confirmed that participants perceived the four high transgression magnitude scenarios to be of higher magnitude than the low transgression magnitude scenarios. Participants judged the wrongness and immorality of each scenario. Repeated-measures analysis revealed a two-way interaction of disgust and transgression magnitude. For the high (low) magnitude transgressions, disgusted participants evaluated the immoral behavior more (less) severely than the neutral participants. Thus, disgust *increases* the perceived severity of judgments when the behavior is of high magnitude, whereas disgust *decreases* perceived severity of judgments when the transgression is of low magnitude. A second study replicated this effect when the high and low magnitude immoral financial scenarios were identical except for the monetary value of the immoral behavior (i.e., embezzling $10 million vs. $100).

Next, we examine whether differences in construal level underlies this moderating effect. We propose that in an abstract construal the "why" processing that occurs results in more severe judgments for high magnitude behaviors (Eyal et al. 2008), but for low magnitude behaviors, justifications occur such that behaviors are not immoral in the "big picture." First, we demonstrate the disgust does indeed elicit an abstract construal. Study 3A elicits disgust through a video clip and finds participants in the disgust condition construed activities more abstractly than those in the neutral condition (Vallacher and Wegner 1989). Study 3B elicited disgust through a writing task and found disgust condition participants created fewer (i.e., broader) categories than those in the neutral condition (Liberman, Sagristano, and Trope 2002; Smith and Trope 2006), again indicating disgust results in a more abstract construal than a neutral state.

Study 4 adds two additional features to the experimental design. First, we examine sadness and happiness in addition to disgust. We include these additional emotional states to demonstrate that the effect of disgust on moral judgments is distinct from other negative emotions (Chapman et al. 2009; Lerner et al. 2004) and the process is driven by construal level since happiness is opposite of disgust in valence, but is characterized by the same abstract construal level (Labroo and Patrick 2009). Thus, the abstract construal resulting from both disgust and happiness should lead to similar effects on moral judgments. We also examine participants' thoughts regarding their moral judgments to determine the level of abstract processing (Malkoc, Zauberman, and Bettman 2010).

Participants were randomly assigned to one cell in a 4 (emotion: happy, sad, disgusted, neutral) x 2 (transgression magnitude: high vs. low) between-subjects design. Disgust was elicited through a writing task, and then participants evaluated either the four low magnitude or four high magnitude immoral financial behaviors used in study 2. Participants also listed their thoughts when making the evaluations, which were coded for justification of why one would engage in the behavior. The interaction of emotion and transgression magnitude was significant such that for high transgression magnitude behaviors, disgusted and happy participants made more severe moral judgments

than neutral or sad participants. The opposite pattern occurred for low transgression magnitude behaviors, such that disgust and happiness reduced the perceived severity of low magnitude immoral behaviors relative to neutral and sadness participants. Bootstrapping analysis revealed that justification thoughts mediated the relationship between emotion and transgression magnitude and severity of moral judgments. These results suggest that the effect of disgust on moral judgments is not accounted for by "gut feelings." Rather, it is the abstract construal associated with the affective state that influences moral judgments, allowing for disgust to both increase and decrease the perceived severity of the behavior depending on the transgression magnitude.

These results provide important insights into the nuances of the relationship between disgust and moral judgments, enhance our understanding of the affect and construal level relationship, and indicate how justifications may reduce the perceived severity of immoral behaviors, which has important societal implications.

Sense and Sensibility:
The Impact of Sensory Input on Moral Judgments

EXTENDED ABSTRACT

Prior research has not examined how individuals associate their concrete sensory experiences of sound, color, touch, or odor with higher-level abstract concepts such as morality. The purpose of the current research is to explore the effects of sensory input on several aspects of the moral judgment processes. We propose and subsequently show that sensory modality inputs (i.e., seeing, touching, smelling, or hearing a product) lower consumers' level of construal, which then leads to less harsh moral judgments, less sophisticated moral reasoning, and more motivated moral reasoning.

A product is more directly experienced when consumers can see, feel, hear, or smell it. We argue that products experienced with fewer sensory modality inputs (i.e., products described verbally) will be mentally construed at a more abstract level because they are less directly perceived in terms of the constellation of their sensory properties (Kardes, Cronley, and Kim 2006; Stephan, Liberman, and Trope 2010). No prior research we are aware of has directly tested whether the various modalities of sensory input alone or in combination reduce the level at which objects such as consumer products are mentally construed.

We further predict that sensory input, by reducing mental construal level, would lead individuals who encounter moral dilemmas to mentally represent these dilemmas at a more concrete level, with more specific, contextual details. As such, consumers' moral judgments would be more likely to reflect context-specific considerations, rather than simply follow general moral principles (e.g., it is wrong to steal).

We explore the effects of sensory input on several aspects of the moral judgment process. First, we show that sensory input reduces the level of moral reasoning, leading consumers to use lower-level moral intuition, which is more automatic, concrete, and context-dependent, as opposed to higher-level moral reasoning, which is more controlled, abstract, and context-independent (Haidt 2001). Second, sensory input is shown to lead consumers to take into consideration the context in which a moral violation occurs, reducing the harshness of their moral judgments (Agerstrom and Bjorklund 2009; Eyal, Liberman, and Trope 2008). Third, sensory input makes consumers more likely to engage in motivated moral reasoning by ignoring or selectively applying general moral principles depending on the context in which a moral transgression occurs (Ditto, Pizarro, and Tannenbaum 2009). We further explore the underlying process and show that the effects of sensory input on the moral judgment process are driven by changes in consumers' level of mental construal.

We test our predictions in six studies (total n = 918). We conduct three studies that demonstrate the effect of sensory input (visual, haptic, and olfactory) on construal level and three studies that

explore the effects of sensory input (visual, olfactory, and auditory) on the moral judgment process and demonstrate the mediating role of construal level. In all six studies we utilize sandpaper as the focal object, as it provides the opportunity to manipulate all of the sensory modalities except for taste (i.e., vision, audition, olfaction, and touch), but has a generally low level of familiarity among the target (manipulation checks confirmed generally low levels of category and brand awareness). We avoided products involving taste (i.e., the gustatory sense) due to the interactive effects of olfaction and taste and to avoid potentially strong differences in taste preferences.

Overall, our predicted effects of sensory experiences on morality emerge consistently when: using different measures of construals level used in past literature (Fujita et al. 2006; Semin and Fiedler 1988; Trope and Liberman 2003); manipulating different modalities of sensory input (visual, haptic, olfactory, and auditory); and examining different aspects of the moral judgment process (level of moral reasoning, the harshness of moral judgments, and the likelihood of engaging in motivated moral reasoning).

The current research shows that sensory input affects several aspects of the moral judgment processes by lowering consumers' mental construal level. In doing so, this research makes several important contributions to the literature. First, it sheds light on the effects of individuals' sensory experiences on the moral judgment process, contributing to recent literature on embodied cognition, which has largely focused on motor-driven rather than sensory-driven processes (Reimann et al. 2012). Second, it provides evidence for the effects of construal level on moral judgments, adding to recent research that has started to explore this issue (Agerstrom and Bjorklund, 2009; Eyal, et al., 2008). Third, it makes important contributions to construal level theory (Trope and Liberman 2003), as it broadens the conceptualization of psychological distance by demonstrating the effect of sensory input on construal level.

Short Horizons and Tempting Situations: Lack of Continuity to Our Future Selves Leads to Unethical Decision Making and Behavior

EXTENDED ABSTRACT

In this paper, we suggest that one underlying cause of unethical conduct is a fundamental inability to project one's self into the future. Our thesis is that feeling disconnected from one's future self is intimately linked to unethical decision making. Just as sense of shared connection with another person can lead to shared emotional and physiological states (Cwir, Carr, Walton, and Spencer 2011), feeling continuity with the future self may provide better access to that future self's feelings. If I am about to act in a potentially unethical way, but I can access the feelings that my future self will feel (e.g., guilty, ashamed) – because I maintain a sense of continuity with that self – I will recognize that I will be better off in the long run if I do not act in such a way. On the contrary, if my future self feels like a stranger to me – if I lack continuity with it and I do not have a good sense of how my self will feel in the future – then I might be more tempted to act in an unethical way in the present.

In five studies, we tested this hypothesis by exploring whether perceived continuity with one's future self is associated with unethical judgments and decision making. Studies 1a and 1b show that individual differences in future self-continuity predict unethical decision making in business contexts (as measured by the Unethical Business Decisions Scale), and rule out potential alternative accounts. Namely, we show that future self-continuity has a distinct effect on unethical decision making independent of relationships other types of selves (e.g., the ideal self, the past self) may have on unethical decision making. Study 2 extends this finding to attitudes toward inappropriate negotiation strategies (using the Self-reported Inappropriate Negotiation Strategies Scale) and establishes the mediating role of consideration of future consequences.

Study 3 extends the first two studies by showing that individual differences in future self-continuity are related to two different types of unethical behavior: lies and false promises. Study 3 was a two-part study. In the first phase, we administered the future self-continuity scale. In the second phase, we invited participants who scored in the upper and lower quartile of the future self-continuity scale to attend a lab session in which we directly examined the relationship between future self-continuity and lying. We administered Cohen, Gunia, Kim-Jun, and Murnighan's (2009) modified version of Gneezy's (2005) deception game—a "sender-receiver" decision making task in which participants have a monetary incentive to lie

(see also Cohen et al., 2011). The design of Study 3 also allowed us to assess the relationship between future self-continuity and the propensity to make false promises. By signing up for the voluntary lab session, participants were, in effect, making a promise to attend it. Given that almost no research study has perfect attendance rates, we were able to determine whether participants high in future self-continuity were more likely to attend the lab session, and thus, uphold a promise they had made. Here, we find that individuals who are low in future self-continuity are significantly more likely to lie on the deception game, and also less likely to follow through on their promise to attend the laboratory session.

In Study 4, we sought to replicate and extend the results of Study 3. First, we employed a different behavioral measure of unethical behavior: cheating. Second, although in Study 1b we ruled out one set of alternative explanations for our finding (i.e., different types of relationships between selves), in Study 4 we wanted to control for another alternative explanation. Namely, it is possible the unethical intentions and behaviors we observed in Studies 1-3 were not necessarily a function of continuity with the future self per se, but rather, were a result of a general lack of self-control. Indeed, recent research has shown that individuals whose self-control resources are depleted are more likely to engage in unethical behavior (Barnes et al. 2011; Gino et al. 2011; Mead et al. 2009). To what extent, then, are future self-continuity and self-control distinct constructs, and to what extent does each of these constructs independently explain unethical behavior? To address these questions, in Study 4 we assessed the relationships among self-control, future self-continuity, and the propensity to cheat on a laboratory task. Results indicated a negative correlation between future self-continuity and the propensity to cheat, even when controlling for trait levels of self-control, as well as the other Big 5 personality traits.

Results from Studies 1 through 4 demonstrate a robust significant relationship between low future self-continuity and unethical choices, even when controlling for a host of potentially relevant personality variables. These studies, however, rely on correlational evidence and thus, cannot necessarily speak to the causal relationship between low future self-continuity and unethical behavior. Thus, in Study 5, we examined whether a direct experimental manipulation of future self-continuity would affect subsequent endorsement of unethical behavior (measured by the SINS II scale, as in Study 2). In the experimental condition, we instructed participants to write about how they would remain similar over time—specifically, in ten years' time. We compared their behavior to those in a control condition in which participants wrote about what the world would be like in ten years. Given that both the experimental and control condition involved thinking about the future, this comparison is a stringent test of our hypothesis that feeling similar to one's future self, rather than just the future per se, leads to disapproval of unethical behavior. In line with our main hypothesis, participants in the experimental condition were significantly less likely to advocate inappropriate negotiation strategies than were participants in the control condition.

The Genetic Contribution to Preference Consistency in Moral Judgments

EXTENDED ABSTRACT

Human behavior is guided not only by self-interest but also by social motivations as manifested in our moral intuitions and capacity for moral reasoning. While morality may be universal, many social and political controversies in which harm is inevitable invoke a conflict between individual rights and the greater good, and it is known that there is heterogeneity in how such tradeoffs are resolved. For example, a focus on the cost-benefit analysis of the ends of an action and the goal to promote the greater good is more likely to result in utilitarian moral judgments. Putting more weight on the means rather than the ends of an action and striving to respect the inherent rights of all individuals is more likely to result in deontological moral judgments. Interestingly, however, individuals do not always show consistent preferences for one goal over the other. That is, they sometimes display inconsistent patterns of moral judgment (or "preference reversals"), and little is known about why some individuals' ethical convictions appear more stringent than others'.

The prototypical example-pair for a preference reversal in moral judgments are the trolley and footbridge dilemma. In the trolley dilemma, a runaway trolley is headed for five people, who will be killed if it proceeds on its present track. The only way to save them is to hit a switch that will turn the trolley onto an alternate set of tracks where it will kill one person instead. The question is whether it is morally right to sacrifice one person to save five others by hitting the switch. Most people faced with this dilemma say yes, it is morally right. That is, they give a utilitarian answer. In the similar footbridge dilemma, the runaway trolley again threatens to kill five people. In this scenario, however, the only way to save the five people is to push a stranger that is standing on a footbridge onto the tracks below. The stranger will die if this is done, but his body will stop the trolley from reaching the others. The question in this dilemma is whether it is morally right to sacrifice one person to save five others by pushing the stranger. Most people in this dilemma say no, it is not morally right.

The reason for these different outcomes has been suggested to lie in the extent to which a moral dilemma engages automatic emotional processing versus deliberate cognitive processing (Greene et al. 2001). What is not sufficiently understood, however, are the individual differences underlying the degree to which individuals exhibit stable preferences in moral judgments and the sources of that variation. In particular, individuals can either exhibit consistency across the trolley and footbridge dilemmas or appear sensitive to the dif-

ferences in those dilemmas' emotional content and switch between utilitarian and deontological responses, exhibiting a preference reversal. Based on a classic twin study-design with Swedish twins (the largest twin-registry in the world) this paper shows that almost 40% of the individual differences can be explained by genetic variation. In addition, recent studies suggest that gender, religiosity, and cognitive reflection play a role in explaining individual-level variation in type of moral judgments (Banerjee, Heubner, and Hauser 2010; Paxton, Ungar, and Greene 2011); and indeed we find that women and people low on cognitive reflection are more likely to give consistent responses (Lee, Amir, Ariely 2009). Thus, we also examine whether there is a shared genetic architecture between those factors and the tendency to make consistent moral judgments but find no statistical evidence for that.

The findings reported in this paper contribute to our understanding of individual differences in moral judgments. While the heritable variation of a trait should not be considered rigid across age and environmental conditions, similar to uncovering the forces of more economic behavioral anomalies such as loss aversion or procrastination (Cesarini, Johannesson, Magnusson, and Wallace 2011), the knowledge of the forces that generate perhaps undesirable patterns in the consistency of moral judgments may provide cues for policy on how to reduce them. Furthermore, our findings might motivate the search for reliable biological predictors of these individual differences such as genetic markers or hormone levels. For example, genetic variation in candidate genes that has shown to account for phenotypic variation in related behaviors could be tested for association to the consistency of moral judgments. This, in turn, may shed light on deeper biological processes (e.g., particular hormone regulations and other neurological processes). In addition, our findings about the consistency in moral judgments do not seem to generalize to consistency in any types of judgments. In particular, the survey asked respondents two questions to capture the fungibility of money across different frames. While the monetary outcomes described in the two scenarios are objectively the same, people tend to give inconsistent answers due to psychological accounting (Tversky and Kahneman 1981). Interestingly, we found no significant correlation between the consistency in those monetary judgments and the consistency in the moral judgments. Together our results underline the importance of genetic differences as a source of variation in the stability of preferences in moral judgments.

SESSION OVERVIEW

Physical spaces become places when we ascribe meanings to them (Williams et al 1992). Following Sherry's (2000) call to researchers to further investigate the issue, we propose to bring together a session that explores how a sense of place is constructed. The ways consumers attach meanings to their environment has primarily been studied in branded servicescapes such as malls (Haytko and Baker 2004; Maclaran and Brown 2005; Sandikci and Holt 1998) or flagship stores (Borghini et al. 2009; Kozinets et al. 2002), or extraordinary retail spectacles (Hollenbeck, Peters, and Zinkhan 2008; Kozinets et al. 2004). Yet, we argue that these studies focus more on how consumers interact with these settings than the act of place making. In other words the ways spaces become places, via sensemaking by marketers and sensegiving by consumers, has been relatively understudied. We suggest that consumer researchers need to better explore these processes.

Our session aims to contribute to consumer research by looking at how marketplace practices imprint a setting with a sense of place. Ranging from the experience of atmosphere in homes Linnet), to the establishment of a sense of place in servicescapes (Linnet; Larsen and Bean; Arsel, Debenedetti, and Mérigot), or constructing interiority via outdoor rituals (Sherry and Bradford), all four presentations in the session aim to unpack how places are constructed in marketplace and how consumers make sense of these places. All presentations also deal with the stability and dynamics of sensegiving and sensemaking activities in the marketplace. Whether a sense of place is built with a specific cosmopolitan ideology in mind (Larsen and Bean), or is imbued with a culturally specific sense of atmosphere (Linnet), or interrupted with servicescape discontinuities (Arsel, Debenedetti, and Mérigot), or even just temporally constituted through encampments (Sherry and Bradford), places are dynamic entities that are contextualized into a network of marketplace activities.

Linnet will start the session with a broader discussion of interiority in the marketplace and how marketplace sensemaking enables the subjective experience of *hygge*—the Danish equivalent of cosiness. Larsen and Bean will follow up this with their study of the commercial emplacement of cosmopolitanism in two New York restaurants. Arsel, Debenedetti and Mérigot will then discuss interruption and change by their work on a defunct Parisian restaurant

and its two spatially, symbolically and socially connected spinoffs. Finally, Sherry and Bradford will discuss the case of a transient place through their analysis of tailgating.

This session will appeal to a broad range of ACR members. The presentations should attract those scholars that are interested in culturally grounded and interpretivist work in general. However, we also aim to attract an interdisciplinary set of researchers investigating retail and retail atmospherics, rituals, domestic consumption, and food. The session also aims to contribute to the conference mission of *appreciating diversity* in multiple ways. First of all, we explore the diversity in the ways the sense of place can be constructed, emphasizing the role of mundane marketplace experiences: rituals, strategic emplacements, atmospherics, and social connections. Second, our researchers investigate a diverse range of cultural and geographical contexts: Small college towns, metropolitan cities, USA, Denmark, and France. Third we incorporate a diverse range of scholars: consumer researchers, sociologists, anthropologists and design scholars. Fourth, we study places where diverse people gather and share experiences.

All four projects are at the advanced stage, with complete data sets and substantial theoretical development. However, none of the papers have been accepted for publication elsewhere.

The Value of Atmosphere

EXTENDED ABSTRACT

Providing consumers with a sense of atmosphere is regarded as a competitive advantage in marketing. An added value that distinguishes, in the experience of consumers, a provider from competitors, even if products or services are in themselves quite similar. Atmosphere is seen as a subjective consumer experience that arises through a network-effect among a wide range of factors: Sensory, interactional and symbolic (Kotler 1973). In these two ways, atmosphere as it was first described in marketing research bears a close resemblance to another concept that has later received a great deal of attention in attempts to analyze and control the complex field of factors that constitute consumer experience: The brand. In spite of these conceptual similarities, at the level of everyday experience atmosphere differs from brand in being inherently site-bound.

The value of atmosphere is undeniable, but seems to figure in marketing literature on atmosphere as a commonplace observation in need of no further explanation; a black box assumption unopened by theory. Yet the constitution of perceived atmosphere is, from a theoretical viewpoint, a contested issue that invites very different and mutually contradictory explanations which ultimately rest on different ontological assumptions about how man relates to his surrounding world. Can material settings be seen as having inherent qualities that afford a certain experience, or should the factors that constitute the latter be sought in human subjectivity? On the side of subjectivity, should we look to culture and social group for an explanation, or to the human species´ sensory apparatus and neurological wiring? This paper brings those discussions into the arena of consumer research, asking *why* the experience of atmosphere is valuable. Suggesting an answer demands connecting atmosphere to what we know both about human faculties of sensory appreciation, ways of cultural interpretation, and existential needs. The paper presents empirical examples

of how atmosphere comes about, drawn from several years of ethnographic research into the Danish cultural phenomenon of *hygge*, a form of atmosphere that will be referred to here as simply coziness.

The perception of atmosphere arises through a subtle interaction between subject and object (Böhme 1992). In a consumption perspective "subject" refer to those subjective psychological and cultural factors that prime the consumer for seeking, perceiving and appreciating a certain type of atmosphere. "Object" refers to those material and symbolic conditions that impinges upon the consumer´s experience of a specific site, mainly those experienced there, which marketers try to control, although memories or anticipations of factors not immediately present (e.g. a stressful working day) can also exert influence. This perspective resonates with Kotler´s (1973) classic on the subject. Using the subject – object distinction, this paper presents empirical examples of how atmosphere arises in both homes and commercial venues like 3rd places and retail sites. The analytical goal is to isolate certain principles, across these different realms, for the creation of atmosphere, hereby shedding light on the issue of *why* the experience of atmosphere is valuable.

Based on empirical findings the discussion revolves around two main principles: Interiority and authenticity. Interiority concerns the experience of being sheltered, of being allowed to turn one´s back on discipline, sharing the here and now with others co-present (McCarthy 2005). It has to do with concrete arrangements of spaces, light, sounds etc. as well as symbols that communicate to people what this scene is about, what it allows and what kind of behavior it suggests. Authenticity concerns the singularity and rootedness of products or services that defies serial production and purely economic transactions. The paper argues that atmosphere essentially denotes the experience of being present at a site, through an awareness of its boundaries and of balanced interactions across those boundaries with the social and material world that surrounds the site. Such aspects are characteristic of the concept of interiority, of which atmosphere can be seen as an example, and which is useful in conceptualizing the fact that while atmosphere constitutes an inward-turning dynamic, it also relies upon a subjective awareness of spatial, temporal and symbolic contrasts to external realms, at least when we consider pleasurable forms of atmosphere like coziness. The subjective awareness of a spatial, temporal or symbolic contrast to the outside world facilitates the experience of pausing in a pleasurable, safe and invigorating environment. Authenticity is part and parcel of this dynamic since it further effects a localization of the experience, a rooting in the biographies of the site and the people present, including owners and those delivering the service.

The value of atmosphere then is predicated upon the symbolic needs of modern men and women who seek a temporary refuge from the control and discipline of work and gym, as well as the encounter with authenticity. However it also speaks to the preference of our neurological system for spaces that offer symbols of prospect and refuge, and amounts of visual information that can be decoded with a speed that pleases the brain, as neuro-architectural research shows (Rostrup 2011).

In the final instance of the interpretation offered in this paper, the value that is created for the subject (e.g. a consumer) of atmosphere is that in social and cultural terms it facilitates a focus on the here and now. This experience is shared with other people and relies for its effect upon their co-presence, but to a balanced extent, or else the atmosphere becomes claustrophobic. This interpretation may suggest what propels consumers to seek 3rd place sociality in places like cafés as a repetitive, ritual consumption act e.g. on Friday afternoon. The atmospheric immersion into a here and now is effective as a marker of transition, e.g. from the working week to the weekend.

Atmospheric establishments therefore afford the successful execution of certain consumer rituals (Rook 1985).

The Atmosphere of Cosmopolitanism: Mono- or Multi-cultural?

EXTENDED ABSTRACT

In this paper we analyze two new restaurants in New York City: The Red Rooster, Harlem, and Aamanns Copenhagen, located in Tribeca. The Red Rooster, owned by celebrity chef Marcus Samuelsson, is post-national, while Aamanns, backed by Sanne Ytting, a Dane residing in New York, strongly references Denmark. These restaurants were chosen for their opposing approach to cosmopolitanism. Both are trying to transcend the category of mere eateries by positioning their spaces as "community centers." We develop the concept of consumer-friendly cosmopolitanism by referencing the way this type of enterprise unproblematically serves up ideas of culture, ethnicity, and heritage. Through interviews, participant observation, and visual analysis of these two spaces, we develop the idea that cosmopolitanism can be expressed in the commercial sphere in at least two ways: either through mono- or multi-culturalism.

Restaurants are a constituent part of the genre of servicescapes (Bittner 1992, Sherry 1998) and are loaded with meanings useful to the study of place (Sherry 2000). They are valuable sites for research because they function as the nexus for sociality. As Kirschenblatt-Gimblett notes, "entire scenes form around a particular food… or beverage…. These scenes are distinguished by their architecture, décor, ambience, social style, equipage, schedule, music, fashion, and cuisine, and by the close attention paid to the details of the provisioning, preparation, presentation, and consumption of the defining food or drink" (2007: 78). Furthermore, in the US, food often becomes the medium used to engage with one's cultural roots or those of others while providing a way to gloss over differences. This mode of ethnicity is connected with middleclass North America, a segment of society to whom engagement with ethnic identity tends to be voluntary and associated with positive connotations (Alba 1990, Waters 1990). By disconnecting ethnicity from discrimination, it becomes a mode of enjoyment for the privileged (Larsen and Österlund-Pötzsch forthcoming). In addition to these ideas, the concept of American Plus is a useful way to underline the element of flexibility in the context in which this ethnic identity is performed. American Plus includes all the advantages (and disadvantages) of American identity, plus the potential advantages presented by the ethnic identity. This particular approach to ethnic identity emphasizes the aspect of choice and suppresses many problematic aspects connected with ethnicity. (Österlund-Pötzsch 2003).

We build on the idea of American Plus to suggest that restaurants such as the two we study are primary spaces in which people partake in consumable cosmopolitanism. Cosmopolitanism, as defined by Hannertz, is "a stance towards diversity itself, toward the coexistence of cultures in the individual experience… cosmopolitanism is first of all an orientation, a willingness to engage with the Other. It is an intellectual and aesthetic stance of openness toward divergent cultural experiences, a search for contrasts rather than uniformity" (1990, 237). Whereas Thompson and Tambyah (1999) highlight the tension between cosmopolitan identity and local culture, our work illuminates the construction of a local culture designed to make cosmopolitians feel at home. Recent work builts on Hannertz's thesis and theoretical tools from actor-network theory to distinguish different kinds of cosmopolitanism and to better understand the role objects play in cosmopolitanism (Saito 2011).

In our case studies we detect two very different kinds of consumable cosmopolitanism, namely that of mono- and and multi-culturalism, which are differentiated by the consumption of only one other culture or by an assemblage of many others. Samuelsson's approach is multi-cultural. A business writer attributes Samuelsson's success to his multi-ethnic background, claiming that "Samuelsson's background hits on almost every point of cultural diversification researchers say helps open a person to unusual associations" (Johansson 2006). Upon the opening of the Red Rooster Harlem the New York Times reviewer nodded to the food but effused about the cosmopolitan scene:

> *The racial and ethnic variety in the vast bar and loft-like dining room are virtually unrivaled. The restaurant may not be the best to open in New York City this year (though the food is good). But it will surely be counted as among the most important. It is that rarest of cultural enterprises, one that supports not just the idea or promise of diversity, but diversity itself. (Sifton 2011)*

This review and other similar media representations of Samuelsson and his restaurant raise the question of how an atmosphere catering to a cosmopolitan audience is consciously constructed. Samuelsson weaves his own identity and multi-ethnic background into the environment of the restaurant, which includes a bar made of three colors of wood meant to denote skin color, a series of curated, but anonymous vintage photos of multicultural families, and wallpaper custom-printed with family recipes illustrating his culinary heritage.

In contrast, Sanne Ytting, the Danish entrepreneur opening a franchise of Aamanns Copenhagen in New York, has chosen to include only the Danish reference. In her mono-cultural project everything from food to utensils needs to be Danish. The chef explained the decision to stick with *rugbrød,* the Danish word for the restaurant's signature dish, because he thinks something gets lost in the translation to "open faced sandwiches," and stands behind this decision to keep an "unpronounceable word unpronounceable" (Eater 2011). The all-white interior of Aamanns, designed by a Danish designer living in Denmark, is filled with potent symbols of Danish culture that have been provided by leading Danish design interests, including Anne Black ceramics, Bang and Olufsen speakers, and Arne Jacobsen chairs (Øllgaard 2001).

These two examples illuminate two different kinds of cosmopolitanism. At Aamanns established ideas of Danishness are being retold through place and the composition of this particular consumer narrative is kept tight. The Red Rooster reflects only Samuelsson's ideas about multiculturalism, wheras Ytting's role is akin to a curator organizing an exhibition of all things Danish. One is expansive and multicultural. It draws others in and refigures them into a new and coherent total experience. The other is exclusive and monocultural. It draws only one kind of other in and re-configures an existing category of atmosphere in a new place. This work contributes to knowledge on the relationship between cosmopolitanism and consumption within the field of consumer research.

The Dynamics and Continuity of Place Attachment: Cues from a Parisian Wine Bar

EXTENDED ABSTRACT

Place attachment corresponds to the emotional aspect of a sense of place (Hummon 1992; Jorgensen and Stedman 2001) which includes meaning systems, experiences, and social interactions with a spatial setting. Existing research on place attachment mainly focuses on either residential settings (e.g. Fried 1963) or outdoor recreation places (e.g. Williams and al. 1992) but not commercial spaces. While research on retail frequently touch on the notion of place, these scholars either treat one dimension of retailscapes, such as the social (e.g. Price and Arnould 1999; Rosenbaum et al. 2007), as the central point of investigation, or consider place holistically (e.g. Maclaran and Brown 2005) without explicating how these different elements come together. Building on Altman and Low (1992) who suggest that a combination of different elements contributes to establishing an emotional sense of place, we argue that it is important for researchers to better explicate the dynamics between these elements.

Furthermore, existing consumer research hasn't looked at the continuity of attachment through time and space. Kleine and Baker (2004) show the similarities between attachment to possessions and place attachment, yet acknowledge that material possessions are portable whereas places are immovable due to the unique characteristics of spatial settings. Places are embedded in a geographical landscape: moving an establishment disconnects it from its original spatial context. Yet, in the context of multi-outlet stores—where the original setting may contain specific meanings (for example brand history and legacy)—successful continuity of a brand across new branches seems to prove that place attachment could be transferred to some extent. Understanding the elements of continuity is also crucial to manage transitions such as moves, transfers of ownership, or dissolutions that are recurrent in small business servicescapes. We argue that constraining place to one specific dimension, considering it only as a non-separable entity, or ignoring the changes in these elements through time and space oversimplify the complex retail dynamics and the attachment processes.

With this paper, we aim to unpack two issues: 1. What are the servicescape elements that contribute to the attachment that consumers develop towards a commercial setting? 2. To what extent this attachment is maintained in case any of these elements change?

We address these questions using a longitudinal ethnographic approach, based on the investigation of one defunct Parisian wine bar—Le Coin de Verre—and the two interrelated institutions that emerged after the bar's closure. The first one, Café Epicerie, has only kept the physical envelope of the original wine bar even though the new owners claim the legacy of Le Coin de Verre on their website. The location, as well as the path that leads to the setting (address and phone number), remain the same, but the place has been physically (through rebuilding, decoration) and socially (managers, employees, new customer profile) changed. Furthermore symbolic activities and rituals (e.g. ringing a bell to get access to the setting) as well as differentiating offerings (e.g. recipes) that once made the place special are no longer present. The second spinoff is Coin de Table, which opened one block away from original setting. It is managed by a former waitress of Le Coin de Verre and claims the heritage of the original setting through the consultancy and recurrent presence of former manager of the original place. In contrast to Le Café Epicerie, this setting has tried to keep the spirit of Le Coin de Verre through atmosphere, social elements and activities, while many physical elements changed.

We conducted 20 interviews with customers of Le Coin de Verre, some of which now frequent the spinoff establishments. We also conducted three interviews with managers of these institutions. The interview data amounts to a total of 26 hours of recordings. In addition, we made extended participant observation recording diaries, fieldnotes and photos. These were supplemented by secondary data from gastronomy chronicles in newspapers and customer reviews gathered from the Internet.

In our findings, we discuss three main servicescape dimensions that establish place attachment: social, physical and activity-based. Social elements are the staff, other customers, and the relationships

consumers build within these spaces. Physical elements relate to the aesthetics of the place as well as the spatial belongingness such as terroir and locale. We also argue the physical trajectory, the geographic path that a consumer takes to reach the place is relevant. Lastly, activity based elements include product and service assortment, and specific procedures—rituals, scripts and norms—that are embedded in these activities.

Our next set of findings concerns the transfer and continuity of place attachment. Our informants, who were originally attached to Le Coin de Verre, indicate a sense of detachment from Café Epicerie, claiming that "the soul has been lost" because of many reasons: the spatial environment has been altered through rebuilding, and the commercial proposal is quite different from Le Coin de Verre where only artisanal products were sold. Most importantly, the social relationship has been altered and customers of the original setting lost their social connections. Conversely, in Coin de Table, even though the spatial setting is not be the same (new locale, new trajectory to reach the place, new decor), some key differentiating elements have been kept: the social atmosphere (the waitress, the bell, the special welcome, the lack of table settings); the service concept and the commercial proposal are also similar to those of Le Coin de Verre. As a result, loyal Coin de Verre customers feel like they have found their home again.

Preserving the emotional attachment to a service establishment goes beyond claiming the same heritage, and needs to be orchestrated using multiple servicescape dimensions. Even though physical elements are easier to preserve (location, trajectories, or elements like the fireplace in the case of Café Epicerie), this does not result in the same sense of place. On the contrary, while places are theoretically impossible to move, when spatial elements are altered but social elements and activities are kept, consumers experience the same sense of place in a different setting. Thus we argue that while it is impossible to completely replicate places due to their ontology, place attachment can be preserved with careful management of servicescapes.

Creating Home and Community in Public Spaces: Vestaval in Tailgating

EXTENDED ABSTRACT

Consumption encampments are ephemeral phenomena of varying duration and composition, whose closest commercial analogs are periodic markets such as swap meets (Belk, Sherry, and Wallendorf 1988; Sherry 1990), farmers' markets (McGrath, Sherry, and Heisley 1993), and art fairs. Consumption encampments have been the focus of previous inquiry into dwelling sites such as Wrigley Field (Holt 1995), Burning Man (Kozinets 2002), and Mountain Man Rendezvouses (Belk and Costa 1998). Tailgates are consumption encampments that occur in conjunction with sporting events or music concerts, and provide a stage for the convergence of such American cynosures as automobility, overindulgence and voluntary association. Tailgates, with one notable exception (St. John 2005), have gone largely unexamined, and are the context we explore to explain public enactments of consumer chorography.

Consumption encampments share a "dwelling" aspect that is different from the simpler "visiting" aspect attaching to most of their commercial cousins. Themed flagship brandstores (Diamond et al. 2009), coffee shops (Simon 2009) and brandfests (McAlexander and Schouten 1998; McAlexander, Schouten, and Koenig 2002) have occasionally sought to tap the dwelling ethos. However, a sense of dwelling is largely confined to populist constructions unfolding at a site of consumption, whether private or public, where managerial intention may guide rather than direct consumer agency. In a very tangible sense, in the duration of a tailgate, a city is raised (and ultimately razed), replete with ersatz homes, a grid of streets with ingenious address coordinates, playing fields, and channels of information exchange.

Place making at the tailgate begins with the deployment of material culture. The stuff of tailgating is distributed in a way that defines macro and micro zones of consumption. Discrete places are constructed for the performance of particular activities and the enactment of the genres of tailgating. Generally speaking, we find three kinds of place established by tailgaters in their deployment of material objects: personal, tribal, and commercial. The most common and deeply appreciated place is close and personal. Nomads establish a minimalist home on the grounds of the larger encampment. This is a domestic place, configured like its counterparts in the everyday world. Within this place, we can discern kitchens, dining rooms, family rooms, and living rooms. Bars and patios are also in evidence. Yards are a figurative presence, detectable n the play spaces between tailgates. It is as if the walls of the domicile have been removed, leaving many of the household's everyday practices exposed to the surrounding world. This public performance of domesticity is a hallmark of the tailgate.

The structure and dynamics of tailgating reveal an interesting interaction between the hestial and hermetic dimensions of experience (Sherry 2001; Sherry et al. 2001) . The quintessentially domestic activities of the household are put on public display, giving the polity a collective opportunity to examine the interior world of the household, even as that display contributes to the emergence of that polity in real time. A community of tailgaters arises through the many public performances of domestic practice which encourage interaction within and across individual tailgates. This performance in plain sight of thousands of individual acts of hospitality, the public enactment of generosity (as well as such dark side behaviors as invidious comparison and theft), and the forging of community through the sacred-celebratory vehicle of the party (Kozinets 2003) brings hestial and hermetic into intimate association. As household dramas unfold in the agora of lots and fields, against the backdrop of the gridiron drama staged in the agon of the stadium, the ethos of tailgating is manifested. On the one hand, even if males do not completely appropriate quintessentially female space, their vigorous participation is blessed by women. On the other, to the extent that tailgating is construed as "extreme picnicking" or "camping lite," women are welcomed onto the masculine terrain of living rough. Either way, males are domesticated, and publicly valorize their taming.

Tailgating is a ritual act of eversion that turns the household inside out, putting its interior workings on public display. While it shares elements of the carnivalesque, carnival is more properly a ritual act of inversion, which turns social conventions upside down. Similarly, tailgating incorporates elements of the festal, but festival is more clearly a ritual act of obversion, which reveals a ludic dimension to quotidian life, turning the outside in. Finally, tailgating enjoys some contiguity with the spectacular, but spectacle is better considered a ritual of subversion, which saps authentic participatory agency in the service of political pacification, and structures social relations hegemonically, right-side up. Carnival, festival and spectacle are recognized social forms to which we would add "vestaval," (Vesta + levāre), after the goddess of the hearth. To the literature, we contribute a description of how a vestaval celebrates household values, dramatizing them in hermetic space, publicly proclaiming the importance of a shared sense of domesticity to the life of a culture. In terms of the semiotic square, the vestaval is in a relation of contradiction to spectacle, of contrariety to carnival, and complementary to festival.

The Paradox of Memory

Priyali Rajagopal, Southern Methodist University, USA

SESSION OVERVIEW

On one hand most Americans believe that "memory works like a video camera" (Simons & Chabris, 2011, p. 1) laying down representations of events that are accurate and accessible. Consumers value these memories enormously, and yet we know as consumer researchers that these memories to be highly malleable and subject to distortion. Broadly this session will be about this memory paradox. This session will contribute to the diversity call of the conference through these different views of memory and the role memory plays in consumer decision making. Marketers need to understand why consumers value memories if they want to build on them with their communication efforts as well as to what degree they can frame memories and at what point should they expect "push back" if their influence attempts become too apparent.

In my own research I have studied the two extremes of this paradox-- how early childhood memories frame current preferences (Braun-LaTour, LaTour and Zinkhan 2007), and the fragility of these memories (Braun, Ellis and Loftus 2001). This session is designed to dig deeper into that memory paradox. While these papers were selected to highlight one side over the other (value vs. distortion), the paradox is implicit in all the work because if we didn't value the memories, then having them distorted wouldn't be important, nor would we value the memories as much if we thought they would never be forgotten.

The session will start off with Patrick Vargas highlighting the extreme value consumers place on their memory experiences. He will discuss research he has done asking people to provide dollar values to certain memories and the astronomical numbers they attach to even negative experiences. Then Altaf Merchant will discuss some research we have done on nostalgic advertising and developing a nostalgic advertising scale. These studies look at how marketers can bank on the value of consumer memories but there are aspects, like icons, that they shouldn't messed with when trying to appeal to the past, such as PBS' move to promoting Cookie Monster as Veggie Monster.

Then we move to the malleability side of things—Rajesh Bhargave will present his work looking at under what conditions memories are more positively recalled. This research identifies a basic factor that can distort memories—the act of recollecting an episode provides information on how memorable the experience was, which in turn can influence evaluations. Thus, while people value memories and seek to recollect past events, they may distort these memories each time they recall them in great detail.

Nicole Votolato Montgomery will end by presenting her paper on the moderating role of brand commitment on false product experience memories. Hence, while the first two papers focus on the value attached to memories by consumers, the latter two papers focus on the malleability of these memories. The paper on brand commitment and false memories further highlights this paradox by demonstrating that consumers can be motivated through brand commitment to distort their memories.

On The Often Outrageous Value of Memories

EXTENDED ABSTRACT

Try to recall your first kiss, or the time you bought your first car and drove it home. Now imagine that I am both willing and able to buy those memories from you. If you agree to sell me those specific, episodic memories those events will no longer exist in your mind; however, you will have cash money that I pay you, and you can do whatever you like with the cash. If a memory is particularly valuable to you, you would place a high price on it; if it is not valuable to you, you would place a low price on it. If it is a painful memory (e.g., your first heartbreak) perhaps you would even be willing to pay me to extract that memory.

People asked to value their memories via this thought experiment placed astronomically high dollar values on their memories. In one study people averaged $1x10^36 per memory. To put this into perspective, the wealthiest man in the world, Carlos Slim Helú, is estimated to be worth $74 billion, or 74x10^9. The number of atoms in the observable universe is estimated at 10^80. Values in the neighborhood of $10^36 are most likely symbolic, to be interpreted as "this memory is exceptionally important to me."

In a second study I asked people to constrain themselves, and I reminded them of Carlos Slim's net worth. Even then, the mean dollar values for individual memories were around $5 million. By eliminating some of the ultra-high values I still ended up with mean values ranging from $11,000 to $1.9 million per memory.

From these two simple studies I arrived at several tentative conclusions. First, people value their memories a lot. Second, there is remarkable variability in the extent to which people value their memories. The values placed on "memory of first heartbreak," for example, ranged from $-1 million (i.e., willingness to pay me a million to remove the memory) to $100 million. Third, for negative memories, such as first heartbreak, there was a nearly symmetrical distribution of values around zero, suggesting that some people really value negative life events and others would much rather get rid of negative memories.

This is an investigation of the extent to which, and reasons why, people feel that their memories of specific life events are valuable. What makes some memories more valuable than others? Inspired by Katz's (1960) work on attitude functions, I propose several possible reasons why memories are so valuable. First, the commonly held illusion that our memories are accurate, like a video recorder (Simons & Chabris, 2011), probably accounts for some of the value people place on their memories. Memory is not like a video camera, it is

not accurate. Memory is reconstructive, and easily manipulated; our memories for life events are most likely full of large errors (Braun, Ellis & Loftus, 2002; Talarico & Rubin, 2003). If people learn that their memories are inaccurate, they should place lower values on them. People are not rational, and this prediction – that people would devalue their memories if they learned about the frailty of human memory – requires further empirical testing.

Second, the valence of the memory matters; presumably happy memories would be worth more, on average, than aversive memories. So memories might be valuable to the extent that they help us to regulate our emotions. One surprising example of the importance of memory for emotion regulation is in a study of amnesiac patients v. "normal" controls. Both groups were shown a sad movie. Amnesiacs showed poorer recall of the film than controls; however amnesiacs showed greater persistence of sad feelings than controls because only the "normal" group was able to recall the sad film and attribute their sadness to the film (Feinstein, Duff, & Tranel, 2010).

Third, some negative memoires might be valuable, if the memory represents some kind of lesson learned. If I no longer had the memory of getting food poisoning, I wouldn't know to avoid eating Maryland crabs that had been sitting out in the sun all afternoon. Memories might be valuable because they serve a knowledge function (Katz, 1960; Shavitt, 1990).

Fourth, and perhaps most importantly, people may feel that losing a valuable memory might somehow fundamentally change them. Our intuition is that our memories make us who we are; with a different set of memories, or minus a few critical memories, you or I might be a very different person. So memories might be valuable because they serve an essential, existential function. Related to this idea, people's willingness to take enhancing drugs is inversely related to the extent to which that drug will affect a trait perceived as fundamental. For example, most everyone would benefit from being kinder, but only nine to ten percent of people would be willing to take a drug that improves kindness because kindness is perceived as a fundamental trait. On the other hand, 45-51 percent of people would be willing to take a drug that improves rote memory, because rote memory is not perceived as a fundamental trait (Riis, Simmons, & Goodwin, 2008). There may be other reasons we value memories, as well. This project will help us understand the psychology of self-perception and self-knowledge.

Nostalgic Charity Appeals: Moderating Effect of Memory Processing, Beneficiary, and Childhood Icons

EXTENDED ABSTRACT

Individuals donated about $217.8 Billion to charity in 2011. This represented about three quarters of all philanthropic giving (Giving U.S.A., 2012). Charitable organizations have increasingly realized that their fundraising communications need to have a credible and engaging message. Appeals to donate are often designed to emotionally stir consumers, attempting to influence their donations (Basil, Ridgway & Basil, 2008; Dillard & Peck, 2000). Some of the emotions that have been studied in the context of appeals for charities are sadness, anger, fear and guilt. Recently, Merchant, Ford and Rose (2011) found that nostalgia could be one of the reasons why people donate to charity. Moreover, Ford and Merchant (2010) and Zhou, Wildschut, Sedikides, Shi and Feng (2011) posit that nostalgia based fundraising appeals promotes charitable giving.

Nostalgia has been found to influence preferences for certain products and services (Braun-LaTour, LaTour & Zinkhan, 2007). In a content analysis of a thousand U.S. television advertisements, Unger, McConocha and Faier (1991) found that nostalgia was used via theme, copy or music in ten percent of all of the U.S. advertisements analyzed. This reuniting of the individual with a longed-for past (Bassin, 1993) can be seen in the use of the songs of the 1960s and 1970s to evoke strong emotional connections with such products as automobiles, foods and beverages. It is a particularly promising mechanism for companies that claim a long and storied history since it is possible that multiple generations of consumers have past experiences that can be connected to happy periods in their lives which would potentially enhance their emotional orientation towards the company involved.

In the current inquiry we add to the emerging research (Ford & Merchant, 2010; Merchant et al., 2011; Zhou et al., 2011) on the influence of nostalgia on charitable donations, by examining three boundary conditions of this effect. First, we argue that the effect of nostalgic charity appeals is moderated by the consumer's memory processing. Next, we posit that they are more efficacious when consumers feel communal connections with the beneficiary of the charity. Lastly, we contend that nostalgic appeals work better when they evoke important consumer memories using childhood icons.

In the first study we employed a 2X2 experimental design among 201 consumers. Attitude towards the ad (Aad) was the dependent variable; memory processing (personal/generic) and type of charity appeal (nostalgic/non-nostalgic) were the independent variables. The findings reveal that nostalgic appeals for charity work especially well when the consumer is primed with generic childhood memories. It appears than when the consumer is primed for personal childhood memories, he/she is any way emotionally engaged and hence even non-nostalgic ads perform as well.

Belk (2010) postulates that when someone shares with family or the extended family, the act of sharing expands the sense of self for the individual; sustaining feelings of community with the receiver. Thus, past research has found that donors are more likely to donate to people with whom they can relate to and feel they have a communal relationship with (Small and Simonsohn, 2008). In study two we employed a 2X2 experimental design among 65 consumers. The dependent variable was Aad; the independent variables were communal connections with beneficiary of the donation (manipulat-

ed – high or low) and nostalgic memories evoked (measured-high or low). The findings reveal that when consumers feel that they have communal connections with the beneficiary of the charity, increasing nostalgic memories would result in higher attitudes towards the ad.

Lastly, in study three, we argue that nonprofits can depend on the consumer's nostalgic memories for raising donations but there are aspects, like icons, that they shouldn't messed with when trying to appeal to the past, such as PBS' move to promoting Cookie Monster as Veggie Monster. Here we employed a 2X2 experimental design among 67 consumers. The dependent variable was nostalgic memories evoked and the independent variables were ad character (manipulated – familiar or changed) and need to belong (measured-high or low) (Loveland, Smeesters and Mandel, 2010). The results from study three indicate that changing iconic characters of nonprofits may have an effect on how consumers process charitable appeals. This especially has an effect in the high need to belong consumers and tends to deflate the ability of the ad to evoke nostalgic memories.

In summary, we build on recent research on the influence of nostalgia on charitable donations by suggesting more nuances to these effects.

Memorability and Retrospective Evaluations: The Social Function of Autobiographical Memory in Evaluations of Experiences

EXTENDED ABSTRACT

Consumers are often prompted to remember details from past hedonic experiences. A patron may recollect a dish she ate at a restaurant in order to write a recipe. Alternatively, she may remember such details to share a story with a friend. We suggest that such reminiscence can impact the episode's retrospective evaluations; if the event seems very memorable, it is evaluated at higher intensity. In our work, we also explore how the function of memory moderates the relationship between remembering the episode and its evaluations.

Recently evoked information can contaminate consumers' memories of past experiences through reconstructive processes. For instance, consumers incorporate information from post-experience advertising in their experiential memories (Braun, 1999). Imagery-evoking ads can also produce false memories, whereby consumers mistakenly believe that they have experienced the advertised brand (Rajagopal & Montgomery, 2011). These results suggest that consumers' memories are malleable, shaped by lay theories and inferences.

We argue that people may form their inferences about past experiences on memorability itself. When a past event is recalled, the act of reminiscence provides new information: the subjective experience of ease or difficulty of remembering the event (Schwarz et al, 1991). Given that more intense experiences generally produce more vivid memories (Talarcio, LaBar, & Rubin 2004), consumers may learn the positive association between memorability and intensity across various experiential domains. As such, we predict that consumers will infer that if they can vividly recall the sensory details of a past experience, it was more intense. Thus, this inference is based on a lay theory concerning how memory operates. Importantly, although intense experiences are typically more memorable, other factors can influence the ability to remember a past episode, thereby dissociating this relationship.

We further argue that this effect—inferring intensity from memorability—will be more pronounced when the memory is generated for social purposes—to communicate with others—and less pronounced for directive purposes—when using the past experience to guide one's own future behavior (Bluck et al., 2005). The ability to recall an episode with vivid sensory details is more diagnostic for social uses of memory than directive uses, because describing the event to others requires concrete information to ensure a smooth and fluent interaction (Schlosser & Shavitt, 1999). Indeed, one of Grice's (1975) conversational maxims is that speakers must be clear, avoiding obscurity—a principle served by retrieving specific sensory details when recalling a hedonic episode.

We tested these predictions in three studies. In study 1, student participants (N = 69) engaged in a blind taste test of a wine through a series of sips. After a filler task, participants were asked to think about serving the wine at a future social gathering. Next, as a between-subjects manipulation of ease-of-retrieval for sensory details, they were asked to recall and write about either two sensory aspects about the wine—an easy task, or six such aspects—a more difficult task. The study also had a control condition in which participants did not recall any sensory aspects. They were then asked how interested and likely they would be in serving the wine at a social gathering and how successful and memorable it would be with guests. As predicted, ratings of intensity were higher when few sensory aspects (M = 5.64) were recalled versus no (M = 5.22) or many sensory aspects (M

= 5.22). Participants in the few sensory aspects condition also valued the wine $3 per bottle higher than the other two conditions. Notably, recalling six aspects was perceived to be more difficult than recalling two sensory aspects, consistent with an ease-of-retrieval effect.

In study 2, mTurk participants (N = 133) were asked to retrieve a past autobiographical dining experience that took place between two weeks and two months ago. First, they wrote basic information about the experience: where they ate and who accompanied them on the meal. Next, they were asked to recall two, six, or no sensory aspects from the experience in a similar between-subjects manipulation of ease-of-retrieval as in study 1. They were then asked to rate the experience on its overall positivity, how much they enjoyed it, and how likely they would be to return to the restaurant. Ratings were higher in the few aspects condition (M = 6.32) than the many (M = 5.75) or no sensory aspects (M = 5.9) condition. Follow-up analyses revealed that the types of sensory aspects listed in the few and many conditions did not differ in their valence. However, writing more sensory aspects was perceived as more difficult.

In study 3, we examined the role of memory function. We propose that the emphasis on either social versus directive functions of autobiographical memory can differ incidentally according to how people perceive themselves in relation to others when recalling a past episode. Study 3 (N = 166 mTurk participants) primed whether participants would construe themselves as primarily independent from others or interdependent with others after writing about the target experience (Trafimow et al, 1991). Examining our key dependent measures of perceived intensity, we found a significant ease-of-retrieval X self-construal interaction (p < .01); greater memorability enhanced perceived intensity in the interdependent self-construal condition, but not the independent self-construal condition. Taken together, our work offers new insights on the role of memorability in consumers' evaluations and the functions of autobiographical memory.

Remembering the Best of Times or the Worst of Times? The Moderating Role of Brand Commitment on False Product Experience Memories

EXTENDED ABSTRACT

According to the reconstructive view of memory (Braun, 1999; Braun-LaTour et al, 2004), people may inadvertently recreate a recent experience (e.g., a visit to a favorite restaurant) by integrating information obtained from multiple sources, both internal (e.g., past experiences dining at the restaurant) and external (e.g. reviews of the restaurant, word of mouth from friends). Thus, consumers may erroneously recall entire experiences or details about experiences that did not occur. Such mistaken beliefs about an event are termed as *false memories (*Loftus 1997, 2003*)*.

We extend the literature on false memory by suggesting that consumers' commitment to a brand moderates their false memories about that brand. Specifically, we show that brand commitment can both increase as well decrease the incidence of false memories, depending on the valence of the experience. Thus, highly committed consumers are less susceptible to the creation of negative false memories, but are *more* susceptible to the creation of positive false memories about prior brand experience. This is because negative experiences are likely to be atypical for high commitment consumers, thus lowering the plausibility of a false negative experience for these consumers. On the other hand, we suggest that positive and negative experiences are likely to be equally typical and hence, equally plausible for low commitment consumers. Therefore, low commitment consumers will not differ in their susceptibility to positive versus negative false memories. We find these effects of brand commitment across two different communication routes: advertising (study 1) and word of mouth (studies 2 and 3). Exposure to vivid experiential information either through marketing communications like advertising or exposure to vicarious experiences appear to result in memory distortion.

In our first study we found that a significantly larger proportion of consumers who were highly committed to Pizza Hut (48.3%) reported having tried a fictitious brand variant (Pizza Hut "Naturals" pizza) than consumers who were not as committed to Pizza Hut (17.8%, $\chi^2(1)$ = 6.12, p < .05). Further the highly committed consumers were also more confident in their false memories (3.97) than the low commitment consumers (2.36, t (102)= 2.93, p < .05). Thus, when the product experience was neutral/positive, highly committed consumers were more susceptible to the creation of false memories.

In our second study, we found that consumers who were not highly committed to Subway reported higher negative false memories (2.2 on a 4-point scale) after exposure to vivid, negative online experience reviews, as compared to exposure to vivid and positive online reviews (1.6, t = 2.12, p < .05). Thus, low commitment consumers' false memories varied with the valence of the reviews. On the other hand, consumers who were highly committed to Subway did not exhibit any significant difference in their incidence of false negative memories across exposure to negative (1.44) or positive reviews (1.77, t < 1). We also found that false memories impacted brand attitudes such that negative (positive) false memories lowered (increased) brand attitudes for the low commitment consumers, but not for the high commitment consumers. Thus, in addition to strategically using memories as a defense mechanism against vivid negative information, high commitment consumers are also unlikely to allow memories to change their favorable brand evaluations. Finally, a mediation analysis revealed that false memories mediated the effect of review valence on brand attitudes.

In our final study, we extend these findings from study 2 by documenting a similar pattern of results when the target brand varies across respondents (respondents selected the brand of athletic shoes they most preferred and were committed to) and a fictitious variant of the target brand is advertised (e.g., Nike Altra athletic shoes). Further, we examine the effect of commitment across several additional dependent measures including brand experience recall, the likelihood of other consumers' negative experiences with the brand variant, brand variant quality assessment and brand variant purchase intentions, and find similar results across all these measures.

We contribute to the false memory literature in several ways. First, we document a new moderator of false memory effects – brand commitment and show that brand commitment interacts with experience valence to affect the incidence of false memories. Second, we add to the emerging research on false memories in marketing (Lakshmanan and Krishnan 2009; Schlosser 2006) by exploring a previously unexamined route by which false beliefs about product experience may arise – word of mouth. Finally, we explore how the valence of presented information affects the nature of the false beliefs about past product experience and, hence, product evaluations.

We also contribute to the literature on brand commitment by demonstrating that memory can be used as a strategic defense by highly committed brand consumers. Previous research has shown that highly committed consumers refute negative information through the generation of counterarguments and limiting the spillover of negative information to unrelated attributes (e.g. Ahluwalia et al. 2001). Our research suggests that highly committed consumers may also indulge in memory distortion to reduce the effect of negative brand information.

SESSION OVERVIEW

Prior research has examined social and interpersonal influences in the food environment (Herman, Roth, & Polivy 2003). This session advances existing research by exploring a wide range of different types of social influences in the food domain. Specifically, through these four papers, we examine: 1) how the societal normalization of being overweight affects people's food choices and consumption [paper 1], 2) how the body type of social others affects people's choices for themselves and for social others [paper 2], 3) how people make food choices for themselves in social settings in which social others' food choices are not easily observable [paper 3], and 4) how people judge low-income versus non-low income consumers as a function of their food choices (paper 4).

In the first paper, Lin and McFerran show that exposing women to societal images that normalize being overweight leads them to engage in more unhealthy behavior. The paper was inspired by actual large-scale advertising campaigns such as Dove's "Real Beauty" campaign, which feature images of normal weight and overweight women. The authors conducted two studies that exposed participants to ads featuring an overweight model in which being overweight was either normalized (through the addition of an ad tagline "For Normal Women" or "For Real Women") or not normalized (with the ad tagline "For Plus-Size Women"). They found that exposure to an ad normalizing being overweight led participants to consume more of an unhealthy snack (study 1), to choose higher calorie meals (study 2), and to be less motivated to live a healthier lifestyle (study 2). In sum, Lin and McFerran show that the social normalization of being overweight leads to an increase in unhealthy food choices and consumption.

In the second paper, Liu et al. examine how consumers choose foods for themselves and for social others, as a function of the social other's body type. In four studies, the authors show that people are more likely to choose the same foods for themselves and an over-

weight recipient than they are for themselves and a normal weight recipient. Furthermore, they show that this effect is driven by people's desire to minimize negative inferences that overweight recipients might make if different foods were selected. Specifically, they find that people choose the same foods more for themselves and an overweight recipient, but only when choosing different foods might lead the recipient to make negative inferences (such as if the different foods differed on the dimension of healthiness). In addition, they find that the effect of the recipient's weight on choosing the same foods is mediated by a desire to avoid making the recipient feel bad about her weight, but only for an overweight recipient. Therefore, unlike past research showing contrast from dissociative group members, such as the overweight (Berger and Heath 2007), the authors find that in social consumption settings, people are more likely to choose the same foods for themselves and an overweight other when different foods could lead to negative inferences being drawn.

In the third paper, Davis et al. show that how much people base their food choices on the contextual positioning of the dining venue is a function of whether the food choices of their dining companions are initially observable or ambiguous. In five studies, including a field study, the authors find that when individuals are dining with friends (versus alone), they make healthier choices at venues positioned as healthy and unhealthier choices at venues positioned as unhealthy. This reliance on contextual cues does not occur when the venue is ambiguous in its health positioning or when dining companions send clear cues about the healthiness of their food choices. Furthermore, the authors show that when making consumption choices, people elaborate on thoughts that reflect the venue's health positioning when they eat with friends versus alone; these positioning-related thoughts mediate the relationship between contextual positioning and social context on choice. In sum, the authors find that in the absence of cues regarding peers' foods choices, individual choices become overly biased by contextual cues as a means of reducing social risk.

In the fourth paper, Olson et al. examine how an individual's personal income level and food choices jointly shape others consumers' moral judgments of the individual. In four studies, the authors find that whereas people perceive non-low income consumers to be more moral when they purchase organic foods, they perceive low-income consumers to be *less* moral when they purchase organic foods. These effects are driven by people's perceptions that organic foods are an unnecessary indulgence when purchased by low-income consumers. Accordingly, the authors find that lower-income consumers' morality can be partially repaired when they purchase organic food (1) on sale rather than at regular, premium prices or (2) for children. In sum, Olson et al. show that food choices and income status are important determinants of people's judgments of other consumers.

Across four papers and 15 studies, this session investigates both social influences on people's food choices and consumption for themselves and others as well as the effects of food choices on others' impressions of them. This session is expected to appeal to a wide audience including those interested in social influences on consumer choice, food choices, choices for others, and moral judgments. This work relates to the conference theme of "appreciating diversity" both because the four papers explore a breadth of different types of social influences in the food domain and because two of the papers address an often-overlooked group of consumers that is becoming more prevalent (the overweight and obese). The (Ironic) Dove Effect: How Normalizing Overweight Body Types Increases Unhealthy Food Consumption and Lowers Motivation to Engage in Healthy Behaviors

EXTENDED ABSTRACT

In 2004, Dove introduced the "Real Beauty" campaign, which featured overweight models with the tagline, "Real women with real curves." Similarly, The Body Shop's "Love Your Body" campaign featured the image of an overweight Barbie doll and the tagline, "There are 3 billion women who don't look like supermodels and only 8 who do." Although these campaigns set out to enhance women's body-esteem and have been both commercially successful and widely applauded, they also suggest that an overweight or obese body is normal, prevalent, and acceptable. Promoting healthy body-esteem is an important goal; however, given the rise in obesity rates, it is equally important to examine whether "normalizing" larger body types might also be detrimental to people's health and wellness.

Overweight or obese individuals are at a heightened risk for serious health problems such as heart disease, diabetes, and cancer (Bianchini, Kaaks, & Vainio, 2002). Over two-thirds of adults and one-third of preschoolers in the U.S. are either overweight or obese (NHANES, 2004), which validates a report entitled, "Is Overweight the New Normal Weight?" (Gray, 2011). Normalizing a behavior or concept can decrease the stigma or negativity associated with it, which in turn can have detrimental consequences. For example, normalizing personal debt (because "everyone does it") enhances people's justification to make poorer financial decisions (Peñaloza & Barnhart, 2011). Similarly, we suggest that a belief that overweight bodies are the norm reduces people's desire to (1) lower their caloric consumption and (2) be in better shape. Past research has examined how different body types (thin vs. overweight) affect self-perceptions (Mills, Herman, & Tiggemann, 2002) and food consumption (McFerran et al., 2010). We diverge from this research by asking how—holding body type constant—normalizing an overweight body type affects people's consumption of an unhealthy food item (study 1), the calorie counts of their meals (study 2), and motivation to live a healthier lifestyle (study 2).

Study 1

The study had a one-way between-subjects design with three conditions (advertisement: normalization vs. plus size vs. control), and 80 participants (M_{age} = 19.90). All participants were female students because females are especially susceptible to the influences of stimuli related to body image (Häfner, 2009; Halliwell & Dittmar, 2005). Upon arriving for the experiment, all participants were given an opaque cup containing seven individually-wrapped chocolates, purportedly "left over from a prior experiment" and told that they were free to snack on as many or as few as they wished. Participants next viewed an ad for a fictitious female clothing store. The ad contained a photo of an overweight female model, accompanied by the tagline "*For Normal Women*" (normalization condition), "*For Plus Size Women*" (plus size condition), or "*For Women*" (control condition). The model was removed in the control ad. (A pretest confirmed that exposure to the normalization (vs. plus size) ad resulted in more agreement that being obese or overweight was "normal.") Before leaving the study, participants also completed several unrelated measures designed to mask the purpose of the research. The dependent measure of the study was the number of chocolates consumed during the session (approximately 45 minutes).

An ANOVA revealed a significant effect of advertisement condition, $F(2, 79)$ = 6.44, p = .003. Participants in the normalization condition consumed more chocolates (M = 4.59) than participants in

the plus size (vs. M = 3.05, $t(77)$ = -1.98, p = .05), and control (vs. M = 2.03, $t(77)$ = -3.58, p = .001) conditions. The latter two conditions did not differ ($t(77)$ = -1.34, *ns*), thus supporting our postulation that normalizing the overweight body type *increased* consumption of an unhealthy food item.

Study 2

Participants of both genders (N = 162) were recruited from a national online survey panel (M_{age} = 32.99; females = 60.6%). The manipulation was similar to study 1, but we removed the tagline completely in the control condition and changed the tagline from "*For Normal Women*" to "*For Real Women*" in the normalization condition. This manipulation is subtler and is consistent with the message promoted in Dove's "Real Beauty" campaign. Pretesting again confirmed the efficacy of the advertisement manipulation.

After viewing the advertisement and answering filler questions, participants created their ideal meal from a list of 15 food items. Pictures and calorie counts were given for each item, and the total calorie count for the meal was summed. Participants also rated the extent to which they "want to be in better shape" (-3 = not at all, +3 = very much). Significant effects were found for calorie count ($M_{normalization}$ = 625.00 vs. $M_{plus size}$ = 448.21 vs. $M_{control}$ = 503.46, $F(2, 161)$ = 4.25, p = .01) and motivation ($M_{normalization}$ = 1.53 vs. $M_{plus size}$ = 2.02 vs. $M_{control}$ = 2.16, $F(2, 161)$ = 3.77, p = .03). The pattern of results replicated those observed in study 1, suggesting that normalizing an overweight body *increased* the selection of foods with higher calories, and *decreased* people's motivation to be in better shape.

Discussion

The present research demonstrates that a mere media suggestion regarding the normality of overweight body types has adverse consequences for healthy intentions and behaviors. Our experimental paradigm suggests one reason why obesity has been shown to be socially contagious (Christakis & Fowler, 2007). The prevalence of a condition is associated with its normality and in many cultures today, being overweight places one in the majority. As being overweight or obese becomes normalized (in a literal sense or simply via manipulations such as ours), individuals subsequently make poorer health choices.

Matching Choices to Minimize Offense: Avoiding Offending Stigmatized Group Members by Making Similar Choices for Them and for Us

EXTENDED ABSTRACT

Consumption situations in which people choose products both for themselves and for others to consume together are common. For instance, people may find themselves responsible for buying drinks at the bar for themselves and another, picking up take-out dinner entrees for themselves and a colleague, or packing snacks for a social event. What happens when people need to choose products for themselves and stigmatized others? Given that we are increasingly encountering consumers who are members of stigmatized groups, we examine the interpersonal challenges that arise in such communal consumption scenarios in which people choose for and consume together with stigmatized group members. Specifically, we focus on overweight others as a special case of a stigmatized group.

Past research suggests that we may choose different products for ourselves versus for members of stigmatized groups (Berger & Heath, 2007). However, this and other related research examined choices in isolation (i.e., when one is choosing to consume alone) (Berger & Heath, 2007; McFerran et al., 2010). However, there are

often situations in which people choose for both themselves and a stigmatized group member and consume together with them. In such situations, we propose that a new factor comes into play: the potential for the stigmatized group member to make negative inferences about different choices. We argue that people may worry about the inferences the other person would make about differing choices and that this concern would therefore influence them to make more similar choices for themselves and a stigmatized group member.

We examine this phenomenon of making the same choice for yourself and a stigmatized group member in the context of choosing foods for yourself and an overweight person. We predict that people have the intuition that choosing non-matching foods for an overweight recipient can lead to the recipient making negative inferences. Furthermore, we predict that people act on this intuition by being more likely to choose the same foods for themselves and for a recipient when the recipient is overweight than when the recipient is normal weight. Results from four studies supported our hypotheses.

In the first study, which had a within-subjects design, participants predicted the inferences that an overweight versus normal weight recipient would make if the selector made matching choices (the same unhealthy or healthy option for both persons) versus non-matching choices (a healthy option for one person and an unhealthy option for the other). Participants predicted that recipients would make more negative inferences if the selector made non-matching choices for an overweight recipient. This study suggests people believe they can prevent overweight recipients from forming negative inferences by matching choices.

The second study tested this intuition with a between-subjects design in which half of participants chose salad or fries for an overweight recipient and themselves, and half made selections for a normal weight recipient and themselves. We confirmed the intuition, finding that people chose matching foods more often with an overweight recipient than a normal weight recipient.

The third study tested whether the second study's findings were due to a strategy to avoid the recipient making negative inferences, rather than a tendency to always select matching options for themselves and an overweight other. Specifically, we used a 2x2 between-subjects design in which participants chose between fries and salad or fries and onion rings, for themselves and either an overweight or normal weight recipient. We found that when dining with an overweight recipient, increased matching occurred when choosing different food options might lead to negative inferences (i.e., when the items differed in healthiness: salad/fries), but not when choosing different food options would not readily lead to negative inferences (i.e., when the items were of the same healthiness: onion rings/fries).

Finally, the fourth study tested our hypothesis that increased matching occurred when eating with an overweight recipient because people did not want the overweight recipient to feel bad. Specifically, we used a between-subjects design similar to that used in study 2, in which half of participants chose a healthy or unhealthy food for an overweight recipient and themselves and half of participants chose between a healthy or unhealthy food for normal weight recipient and themselves. Participants were then asked to indicate to what extent they chose the foods to make the recipient feel positive (not negative) about her weight. We hypothesized and found that there was moderated mediation, such that for an overweight recipient but not a normal weight recipient, the effect of the recipient's weight on matching was mediated by whether the participant chose the options to make the recipient feel positive, not negative, about her weight.

The present research therefore examined the choices that selectors make for themselves and for overweight versus normal weight recipients in scenarios in which recipients are aware of both choices. First, we found that people think that making non-matching choices that differ in healthiness will lead an overweight person to make more negative inferences than a normal weight person (study 1). In line with these beliefs, we found that people are more likely to choose the same choices for themselves and a recipient if the recipient is overweight than if the recipient is normal weight (studies 2-4). Importantly, we found that people are only more likely to choose the same choices for themselves and an overweight recipient than a normal weight recipient if the non-matching choices differ in healthiness (study 3). Finally, we found that people make matching choices to make an overweight recipient feel positive (not negative) about her weight (study 4).

Thus, in four studies, we identify a novel choice strategy of matching to avoid offending others. Unlike past research that shows divergence from the choices of undesirable groups, we found that in communal consumption scenarios, people select the same products when choosing for oneself and a member of a stigmatized group. More broadly, we argue that people may use a general matching strategy when choosing for oneself and for others if non-matching choices could lead the recipient to make negative inferences.

Using Contextual Positioning to Bias Healthier Social Behavior

EXTENDED ABSTRACT

Consumers tend to model their own behavior on observations of their peers' behavior (Feunekes, de Graaf, & Van Staveren, 1995; Herman, Roth, & Polivy, 2003; Kulviwat, Bruner, & Al-Shuridah, 2009), such as selecting an alcoholic beverage at a lunch outing after observing others doing the same or choosing food based on what others are eating. Yet there are situations in which the behavior of others is not observable or predictable, such as placing a food or beverage order before all others in a group. In these situations, individuals would often like to avoid eating a salad when everyone else has chosen a burger or drinking beer when everyone else has selected water,

In this research, we explore the cues to which consumers turn in social settings when the behavior of others is not easily inferred. We focus on food-related consumption decisions because they often are associated with social risk. Social risk could arise in the form of embarrassment for consuming an unhealthy product among those who typically consume healthily, or judgment from others who observe a loss of willpower when breaking a promise of abstinence (e.g., a pledge to avoid alcoholic beverages or fattening foods). Conversely, social risk could also arise in the form of embarrassment for consuming a healthy product among those who consume unhealthily or appearing to be prudish or judgmental while everyone else is letting loose. In the absence of information about others, we propose that consumers use cues in the external environment to serve as standards for consumption and infer social behavior. Past research has demonstrated that environmental cues have a wide-ranging influence on consumption behavior (Wansink, 2004). This research investigates instances in which individuals use such environmental cues to compensate for the lack of explicit information about social behavior. Specifically, we investigate how consumer choice and consumption are impacted by contextual positioning (e.g., healthy versus unhealthy restaurants) and social context (e.g., consuming with friends versus alone). When friends' behavior is unobservable, people may be likely to eat healthfully at a restaurant positioned as healthy or to eat unhealthfully at a restaurant positioned as unhealthy. When eating alone, however, individuals are free from the evaluative concerns that drive them to behave in line with social behavior and therefore

are less likely to rely on contextual cues. In this situation, food preferences may be more important than the restaurant's positioning.

To explore the role of contextual positioning in a social context, this paper includes a field study and a series of lab experiments. In Studies 1 and 2, we find that individuals dining with friends make more healthful choices at venues positioned as healthy (e.g., Chipotle) than individuals dining alone. Conversely, individuals make less healthful choices when they dine with friends at venues positioned as unhealthy (e.g., Taco Bell) than individuals dining alone. These results suggest that individuals dining alone do not model their choices on a venue's positioning. Furthermore, when a venue's positioning is ambiguous, there is no observed difference between choices made while eating with friends versus alone (Study 3). In this situation, there are no environmental cues from which individuals are able to infer relevant information about the expected behavior of others. In addition, Study 4 demonstrates that, when dining with friends whose food choices are unambiguously healthy or unhealthy, individuals do not model the healthfulness of their food choices on a restaurant's health positioning. In this case, individuals use the behavior of their friends to gauge their own consumption. Finally, in Study 5 we show that when eating with friends, people make consumption choices and elaborate on thoughts that reflect the venue's health positioning. These positioning-related thoughts mediate the relationship between contextual positioning and social context on choice.

In sum, our findings illustrate that people look to venue positioning in a social context when actual social behavior is not observable. This finding carries important implications for food manufacturers and retailers, because it demonstrates the importance of positioning for consumption of healthy foods. To illustrate, although many "unhealthy" restaurants have added more nutritious selections to their menus (e.g., salads at McDonald's) and many food manufacturers have created healthier versions of snack foods (e.g., 100 calorie packs), prior research has shown that these efforts do not always lead consumers to engage in more healthful eating behaviors (e.g., Scott et al., 2008; Wilcox et al., 2009). Based on our research, we propose that consumers may select these healthy options more frequently if the producers' positioning is more healthful. However, the role of contextual positioning in a social consumption setting reaches far beyond the food domain to include various consumption behaviors and scenarios. Given the joint impact of social context and contextual positioning on consumption, parties involved in marketing exchanges will be well-served to investigate the outcomes associated with these effects.

Created Equal?
The Morality of Food and the People Who Eat It

EXTENDED ABSTRACT

In light of growing environmental concerns, food safety issues, and rising obesity rates, many consumers are seeking out healthier, more sustainable alternatives to conventional agriculture. A trip to one's local grocery store will highlight the increasing availability of products possessing organic, fair-trade, and green-friendly labels. The organic industry alone has experienced tremendous growth in recent years. For example, in 2010, U.S. sales grew to nearly $29 billion, with 78% of families reporting that they have purchased organic foods in the past (Organic Trade Association, 2011a, 2011b). However, foods possessing these ethical attributes (such as organic food) tend to come with a higher price tag, which makes purchasing them less feasible for low-income segments of the population. If low-income consumers purchase these items, others may view these consumers as being wasteful or overly indulgent. The present research explores how an individual's personal income level and food choices jointly shape how other consumers judge his/her morality.

Beginning with Haire's (1950) seminal grocery list study, prior literature reveals that individuals judge others based upon their food choices. More recently, Stein and Nemeroff (1995) demonstrated that individuals judge others who consume unhealthy, fattening foods as more immoral than those who eat healthy, noncaloric foods. In addition to ascribing social meanings and values to specific food choices (Barker, Tandy, & Stookey, 1997), individuals also attribute specific qualities to members of different social classes. Low-income groups are often perceived as "other" and lesser in moral values, character, work ethic, and motivation (Bullock, Wyche, & Williams, 2001; Cozzarelli, Wilkinson, & Tagler, 2001; Lott, 2002). We propose that consumers also hold strong associations between "moral" and choosing "organic" but that this association may not be present or even reverse when the target shopper is low in socioeconomic status. That is, when purchased by low-income shoppers, organic food may be perceived as an unnecessary indulgence.

Study 1 utilized a 2(organic label: yes, no) × 3(annual income: $85,000, $25,000, welfare) between-subjects design. Participants were presented with a grocery list featuring eight items that belonged to a target individual where three of the foods (i.e., carrots, 2% milk, and cereal) were labeled organic or not. The remaining five foods were held constant across conditions. An overall morality index was created by averaging responses from four items: unethical/ethical, cruel/kindhearted, immoral/moral, and uncaring/caring (α = .90). As expected, analysis revealed a significant interaction between income and organic labeling (p = .016). Specifically, individuals earning $85,000 were perceived as significantly *more* moral when they choose organic foods versus conventional equivalents, whereas those receiving welfare benefits were perceived as significantly *less* moral. Moderated mediation tests demonstrated that the effects of organic labelling on moral judgment were mediated by differences in perceptions of the grocery shopper's Puritan work ethic, but only when the shopper was described as receiving welfare benefits or earning $25,000. It appears purchasing organic food is viewed as selfish and irresponsible among lower-income groups, which results in perceptions of immorality.

Study 2 builds upon these findings by manipulating health value directly, rather than controlling for its effect. Study 2 used a 2(organic label: yes, no) × 2(health: healthy, unhealthy) × 2(annual income: $85,000, welfare) between-subjects design. A similar 8-item grocery list paradigm was used with either three healthy items [i.e., extra-lean (3% fat) beef, whole wheat bread, and skim milk cheese] or three unhealthy items [i.e., regular (30% fat) beef, white bread, and whole milk cheese]. These same three items either contained the organic label or not, while the remaining five filler items were held constant across conditions. Participants completed the same series of measures as in Study 1. A significant three-way interaction was found on the morality index (p = .046). Higher-income consumers were seen as more moral when purchasing healthy and organic food versus unhealthy and conventional food. In contrast, low-income consumers were seen as immoral when purchasing organic food. However, they were not seen as more immoral when the food was merely healthy but not organic.

To address the potential role of price, Study 3 utilized a 2(price: premium, discount) × 2(annual income: $85,000, welfare) between-subjects design. In the discounted pricing condition, organic items appeared with prices that were 30% lower than the prices appearing in the premium condition. Again, a significant interaction was found on the morality index (p = .026). Whereas wealthy consumers were not judged differently depending upon whether or not the organic

items were on sale, perceptions of lower-income consumers' morality were significantly higher when they purchased organic items for a discount. This pattern suggests that lower-income consumers' morality can be partially repaired when they purchase organic food on sale rather than at regular, premium price points.

Study 4 manipulated who the food was to be consumed by, adults versus children, and featured a 2(label: child, no label) × 2(household income: $140,000, welfare) between-subjects design. All participants viewed a portion of a grocery list belonging to a family consisting of two children and two adults. Three items were always organic, but half of the participants were presented these items with a children's label [e.g., (kids') organic yogurt; (children's) organic crackers]. Results showed two significant main effects (both p's < .001). Individuals were perceived as more moral when the organic food was for children (vs. not) and when purchased by wealthy (vs. poor) individuals. Interestingly, a family receiving welfare buying organic food for children was viewed as equally moral compared to a wealthy family buying organic food for adults. These findings suggest that the negative stigma that comes from buying organic food when one is low-income can be eliminated if the organic food is purchased for children.

In conclusion, results from four studies demonstrate for the first time that consumers not only make moral judgments of each other based merely on food choice, but that these judgments are based on a sliding scale depending on the target's income.

The Effects of Temperature on Consumers Cognitive and Affective Decisions

SESSION OVERVIEW

Consumers are continuously exposed to fluctuations in temperature. Some fluctuations happen gradually (e.g. changing seasons), while others happen more suddenly (e.g. stepping inside an air-conditioned store). While previous research documents that consumers' physical surroundings significantly affect their decisions (Belk 1975), temperature remains an understudied atmospheric variable. Despite widespread agreement that temperature influences consumer behavior, the literature is rife with mixed results, partly driven by a lack of consensus on the theoretical mechanism by which temperature exerts its effects. This session addresses the gap in our understanding and reconciles mixed findings by examining in more detail why, when, and how temperature impacts consumer decision-making.

We bring together four papers that explore the impact of ambient temperature on different outcome variables and behaviors: task performance, complex decision-making, social conformity, and processing strategy. Importantly, each paper relies on diverse theoretical bases to investigate the temperature conundrum. Tong and colleagues explore the impact of ambient temperature on task performance using a thermal stress account. While previous literature reported mixed findings regarding the effect of temperature on cognitive task performance, they reconcile the inconsistent findings by showing that the nature of the task interacts with temperature to jointly determine performance level.

Building on the thermal stress paradigm, Cheema and Patrick narrow the theoretical underpinnings by proposing a resource-depletion explanation: warm temperatures increase thermal load, resulting in resource depletion. The authors extend the effects to a different behavioral domain: complex decisions; and postulate boundary conditions under which warm (vs. cool) temperatures lead to System 1 vs. System 2 processing. The next paper continues exploring the effects of warmer/cooler temperatures on processing style by introducing the notion of "mental thermoregulation." Using a regulatory lens, Hadi, Block and King examine the effect of experienced temperature on individuals' use of cognitive versus affective processing. They find that reliance on emotions/cognitions can function as warming/cooling mechanisms, and thus individuals may alter their decision-making style according to their thermoregulatory objectives. Finally, Huang and colleagues complete the session by exploring the social consequences of ambient temperature independent of affect. Applying a social distance paradigm to the study of ambient temperature, Huang and colleagues explore the effect of ambient temperature on consumers' preferences for popularity (vs. uniqueness). All the papers in this session are in advanced stages of completion, with multiple studies and full papers available.

All these papers explore the impact of temperature on consumer behavior. However, consistent with the conference's theme of appreciating diversity, they draw from various theoretical underpinnings and come to results that may seem conflicting on the surface. We plan to discuss the systematic differences across papers to reconcile these findings. Due to this interesting juxtaposition and general interest in the burgeoning area of temperature, we expect this symposium to stimulate much discussion and appeal to a large group of conference attendees.

Warmer or Cooler: Exploring the Influence of Ambient Temperature on Cognitive Task Performance

EXTENDED ABSTRACT

Although both practitioners and academics agree that temperature affects human cognition in important ways (Hancock, Ross, and Szalma 2007; Williams and Bargh 2008), there is no consensus in terms of how temperature exerts its effect. In fact, mixed results have been observed in the literature (Hancock and Vasmatzidis 1998). While some research suggests that warmer temperatures enhance cognitive task performance (Ramsey 1995; Wyon, Anderson, and Lundqvist 1979), other studies suggest just the opposite (Givoni and Rim 1962; Hancock 1981). We aim to reconcile this discrepancy in the literature by suggesting that task complexity moderates the impact of temperature on task performance. While for simple tasks, cool (vs. warm) temperatures help, the opposite is true for complex tasks. Support for our hypothesis comes from three lines of research.

First, prior research on temperature suggests that heat, which can induce thermal stress, competes for cognitive resource and consequently hurts task performance (Hancock and Warm 1989). Thus, compared to individuals in a cool temperature condition, those in a warm temperature condition should have limited cognitive resource towards the focal task (Ramsey et al. 1983).

Second, a separate line of research suggests that different levels of cognitive resources can prompt alternative information processing modes. When individuals have limited cognitive resource for the focal task, they are likely to engage in less systematic and more heuristic processing (Todorov et al 2002). Thus, we expect that those in the warm (cool) temperature condition, due to their limited (abundant) cognitive resources, are likely to engage in primarily heuristic (systematic) processing (Cheema and Patrick 2011).

Finally, past research has shown that while systematic processing benefits simple tasks (Frisch and Clemen 1994), heuristic processing is more beneficial for complex tasks (Rieskamp and Hoffrage 1999). Systematic processing is extensive and compensatory, whereas heuristic processing involves limited and selective information processing. The comprehensive nature of systematic processing makes it particularly suited to simple tasks (i.e., tasks that require individuals to process a small amount of information). However, a different pattern of results is expected for complex tasks. Decision makers have limited information-processing capacity. Thus, as task complexity increases (i.e., as the task requires individuals to process a larger amount of information), systematic processing suffers from computational errors and limited memory capacity (Bettman, Luce, and Payne 1998), leading to worse decisions. Heuristic processing, because it relies on less information and is less subject to computational errors, does not lead to worse decisions as task complexity increases. Relatively speaking, then, heuristic (vs. systematic) processing should lead to better performance on complex tasks. Summarizing our theorizing so far, we hypothesize that cool (vs. warm) temperature should prompt greater systematic processing, and consequently lead to better performance on simple tasks; and that, in contrast, warm (vs. cool) temperature activates primarily heuristic processing, and thus leads to better performance on complex tasks.

Our first two studies (1A & 1B) test the above hypothesis. Study 1A used 3 (temperature: warm vs. moderate vs. cool) * 2 (task complexity: simple vs. complex) between-subject design. The focal task was a classic choice task, which requires participants to select their preferred lottery from four different options (Payne et al., 2008). Options were defined by payoffs for 12 equiprobable events defined by drawing 1 of 4 numbered balls (simple condition) or 1 of 12 numbered balls (complex condition) from a bingo cage. Among the four options, one option had the highest expected value, which represents the correct answer. The study was run with no more than four people per session. The same lab was used, but the temperature was set to be warm (25-26 Celsius), moderate (21-22 Celsius), or cool (16-17 Celsius). Results confirmed our hypothesis, such that when the task was complex, a significantly higher percentage of individuals in the warm temperature condition chose the correct option than that in the cool or moderate temperature condition. However, when the task was simple, participants in the cool (vs. warm) temperature performed better. Study 1B was a theoretical replication of study1A by using a different task.

Study 2 aims to shed light on the underlying mechanism. If, as we argue, heuristic processing underlies the beneficial effects of warm temperature on complex task performance, then we should observe equally good performance from those in the cool temperature condition if we prompt them to engage in heuristic processing. To induce heuristic processing, we manipulated participants' available cognitive resource by having them remember either a 2-digit or an 8-digit number (Gilbert and Hixon 1991). In line with prior research, we expect that those being asked to remember the short (long) number would have ample (limited) cognitive resources for the focal task, and thus engage in primarily systematic (heuristic) processing (Chen and Chaiken 1999). The study employed a 2 (temperature: warm vs. cool) * 2 (available resources: high vs. low) between subject design. The focal task was always the complex lottery task as used in study 1A. As anticipated, when participants had ample resources for the focal task, we replicated prior result such that those in the warm (vs. cool) temperature performed better on the complex lottery task. However, for those with low available resources, they performed equally well regardless of whether they were in the warm or cool temperature condition, presumably.

Study 3 extends our theorizing to the domain of creative cognition. We theorize that warm temperatures, due to its activation of heuristic processing, can enhance creativity. Prior research suggests that the carefree nature of heuristic processing prompts individuals to think freely and thus facilitate creative cognition (Friedman and Förster 2000). In three separate tasks (studies 3A, 3B, and 3C), we found support to this hypothesis.

Influence of Warm (versus Cool) Temperatures on Consumer Choice: A Resource Depletion Account

EXTENDED ABSTRACT

Across four studies, we find that relative to people who are cool, people who are warm are (1) less likely to gamble, especially for difficult gambles, (2) less likely to purchase an innovative product, (3) more likely to rely on System 1 processing, and, (4) more likely to perform poorly on complex cognitive tasks.

OVERVIEW OF STUDIES

Pilot Study

This study provided preliminary evidence that warm temperatures can impact lottery sales, but only for difficult lotteries. We used daily lottery sales over a one-year period from a large metropolitan county in the USA. Pre-tests revealed that multiple-option lotteries were judged to be more complex relative to single-option lotteries. We find that temperature has a significant negative effect on lottery sales, but only for complex (difficult) lotteries.

Study 1

replicate in the laboratory the basic effect found in the pilot study. We manipulate the temperature to be either warm (77 degrees Fahrenheit) or cool (67 degrees). Participants are asked how likely they will be to make a series of gambles. We manipulate gamble difficulty by either providing (easy) or not providing (difficult) the expected values of gambles. We find that for difficult gambles, warm (versus cool) individuals are less likely to gamble. However, temperature does not affect likelihood of making easy gambles.

Study 2

This study implicates resource depletion as the process underlying the effect of temperature. We manipulate temperature to be warm or cool. We manipulate depletion with a procedure used by Baumeister et al. (1998). Participants see a silent video clip of a woman being interviewed. The video also includes common words that appear on one side of the screen. Participants in the depleted condition are told to ignore the words and, if their attention is drawn to the words, to consciously focus it back on the interviewee. Participants in the non-depleted condition are not provided these instructions. The dependent measure is participants' proof-reading performance. We find that for non-depleted individuals, warm participants have lower cognitive performance (the number of correctly identified typos) than cool participants. However, temperature doesn't affect depleted individuals' performance.

Study 3

This study has two objectives. First, it shows that warm (versus cool) temperatures are depleting. Second, it demonstrates the moderating role of task complexity: warm temperatures lower willingness to adopt an innovative new product, but don't influence adoption of an established product. As before, we manipulate temperature to be warm or cool. We use a complex estimation task to measure performance. The cognitive estimation task requires participants to provide

10 estimates that are typically difficult to generate (for example, one item asks participants to estimate the height of the empire state building, in feet). Each estimate is scored in terms of its variation from a norm determined on the basis of typical responses. More extreme estimates, that are too high or too low, get a higher score (1 or 2) while estimates within the norm are scored as a zero. A higher score on this task has previously been used as evidence of decreased System 2 processing, being inhibited by depletion (Schmeichel et al. 2003). We find that warm participants perform worse (score higher) relative to cool participants. As a control, performance on a 10-item general knowledge task (such as asking people about the capital of a country) is not affected by temperature. As general knowledge responses are likely retrieved from memory rather than constructed, System 2 inhibition doesn't affect performance on this task.

Following the cognitive estimation and general knowledge tasks, participants see a product purchase opportunity. All participants read that they have been looking for an affordable voice recorder to take notes. Half the participants saw an established product (a box-shaped voice recorder) while the remaining saw a new, innovative product (a voice recorder in a pen). We find that among participants who saw the innovative recorder, cool (versus warm) participants were more likely to buy. However, among participants who saw the regular voice recorder, warm (versus cool) participants were more likely to buy.

Study 4

This study juxtaposes the effects of depletion and temperature to show that warm temperatures hamper performance on complex tasks because of an increased reliance on System 1 (heuristic) processing. We manipulate temperature to be warm or cool. We manipulate depletion using the video attention task from study 2 (Baumeister 1998). We use the complex estimation task from study 3 to test for the effects of depletion on cognitive performance. We find that for non-depleted participants, warm (vs. cool) temperatures lead to poorer performance with more varied answers. However, the effect of temperature is attenuated for depleted participants. Similar to study 3, neither temperature nor depletion affects performance on the general knowledge task.

We measure propensity for System 1 processing using a task from Mishra et al. (2007), with participants choosing between two cell phone plans (A and B). A cursory examination of the charges associated with above-plan usage suggests Plan A (which is actually the more expensive plan) is superior to Plan B (the frugal plan). However, closer examination reveals that Plan B is more frugal because it gives the user more free in-plan minutes. Mishra et al. (2007) demonstrate that individuals using System 1 are more likely to choose the expensive plan compared to individuals using System 2. We find that among non-depleted participants, warm (versus cool) participants are more likely to choose the expensive plan. By contrast, temperature doesn't affect plan choice among depleted participants.

Mental Thermoregulation: Affective and Cognitive Pathways for Non-physical Temperature Regulation

EXTENDED ABSTRACT

In the behavioral sciences, the term "cool" processing typically refers to those processes which involve cognitions and critical analysis, while "warm" processing alludes to those systems involving feelings, desires, and emotions (Metcalfe & Mischel 1999). This terminology suggests that at least semantically, each of these processes encompasses a distinct thermoregulatory tone. However, if reliance on emotions can indeed function as a psychologically warming process and reliance on cognitions functions as a psychologically cooling process, individuals may alter their decision-making style according to their thermoregulatory objectives, without conscious awareness. It is precisely this notion that we address in the current research.

The mammalian tendency to physically thermoregulate is well documented in the biological sciences (Kirkes 1899, Alberts & Brunjes 1978). Mammals seek warm stimuli when their body temperature drops below normal, and seek cooling stimuli when their body temperature rises above normal. For humans, however, physical thermoregulation may not be the only way in which regulation can occur. Thermoregulation might be possible via non-physical mechanisms. For example, some research suggests individuals may consume stimulating products and partake in interpersonal activities in response to physical cold (Parker & Tavassoli 2000, Tavassoli 2000, Zhang & Risen 2010). Collectively, such research seems to imply that humans can engage in thermoregulation through non-physical and largely mental means, a process we term "mental thermoregulation." We assume this is indeed the case, and further propose that the use of a particular decision-making style (using either an affective or cognitive pathway) can also serve as a thermoregulatory mechanism.

Thus, we propose that an individual may embody a particular decision-making process that is metaphorically consistent with his or her thermoregulatory *objective* (and thus inconsistent with his or her thermoregulatory *state*), whenever the current state is non-optimal. Our specific hypotheses are as follows:

Hypothesis 1a: *Cooler temperatures lead individuals to rely more on emotions when making decisions.*

Hypothesis 1b: *Warmer temperatures lead individuals to rely less on emotions when making decisions.*

In study 1, participants were assigned to either a cold or warm temperature condition, and were given a binary choice task in which one alternative, chocolate cake, was superior on the affective dimension but inferior on the cognitive dimension compared to the other alternative, fruit salad (procedure borrowed from Shiv & Fedorikhin 1999). Results confirmed a significant main effect of temperature on choice in the hypothesized direction: the cake was chosen more often in the cold temperature condition than in the warm temperature condition. A 4-item decision basis scale ($\alpha = .84$) measured whether decisions across different conditions were based on respondents' affective reactions or cognitions. Specifying a confidence interval of 98%, with 5000 bootstrap resamples, the indirect effect of temperature on choice through decision basis was significant, with a confidence interval excluding zero, suggesting that reliance on emotions mediated the relationship of temperature on choice of cake.

Study 2 was a 2 (temperature: cold vs. warm) x 2 (object description: low sentiment vs. high sentiment) between-subjects design, and examined the degree to which individuals were relying on affect by measuring their WTP for insurance for an object (an antique clock). Presumably, if one is not relying on emotions, there should be no difference between WTP under the two object descriptions. However, if one *is* relying on emotions, we expect WTP to be higher for the object with a high sentiment description. Results revealed a significant temperature by object description interaction. In the cold temperature condition, the difference between the low sentiment and high sentiment conditions was indeed significant, with individuals' WTP higher in the high sentiment condition than in the low sentiment condition. In the warm temperature condition how-

ever, the difference between the two object description conditions was not significantly different.

The third study was a 2 (temperature simulation: cold vs. warm) x 2 (number of pandas: one vs. four) between subjects design. We adapted our procedure from Hsee and Rottenstreich (2004), who argue that when individuals rely on affect in making decisions, they become insensitive to scale. Thus, individuals relying on their emotions are willing to donate as much money to save one panda as to save four pandas, but those using cognitive processing are willing to donate more to save more pandas. Results revealed a significant temperature x number of pandas interaction. In the warm condition, the difference between the one-panda and four-pandas conditions was indeed significant- participants were more likely to donate when there were four pandas in the scenario than when there was only one panda in the scenario). In the cold temperature condition however, subjects appeared to indeed be insensitive to scale- the difference between the one-panda and four-pandas conditions was not significant.

The purpose of our fourth study was to support the thermoregulation explanation by suggesting that the mere use of cognitive versus affective pathways can indeed alter an individual's perception of physical temperature. After the temperature manipulation, participants were given explicit instructions to use either their feelings or evaluative thoughts in assessing a series of scenarios (adapted from Pham 2001), and then asked to indicate how cold/warm they felt, as well as how comfortable they felt temperature-wise. Results indicated that participants in the affective pathway condition felt warmer than those individuals in the cognitive pathway condition, regardless of their initial temperature condition. Further, results produced a significant temperature x processing interaction on comfort: in the cold condition, affective respondents were more comfortable than cognitive respondents, but the reverse was true in the warm condition, supporting our mental thermoregulation account.

Our research suggests that instead of merely reacting to the physical temperature in a metaphorically consistent manner, physical sensations might instead activate a thermoregulatory goal, thus motivating individuals to embody a process with a metaphorically-opposite thermoregulatory tone. This research encourages more research to explore instances in which physical sensations may lead to goal-driven behavior in a pattern that is metaphorically inconsistent with one's current physical state.

Physical Warmth and Following the Crowd: The Effect of Ambient Temperature on Preference for Popularity

EXTENDED ABSTRACT

The effect of ambient temperature on consumer behavior has seldom been investigated. Furthermore, most prior research has focused on the adverse effects of uncomfortable (very hot or very cold) temperatures (e.g., Anderson et al., 2000). We argue, however, that temperatures within a comfortable range can influence consumers' preferences and behaviors independently of the affect that the temperatures elicit. This possibility is especially relevant to marketing, as most retail stores set the ambient temperature within this range (Baker and Cameron 1996).

We propose that warm ambient temperatures increase consumers' preferences for choice alternatives that are preferred by others. Other research indicates that ambient warmth increases perceptions of social proximity (IJzerman and Semin 2009). We show that these perceptions influence the propensity to follow others' decisions in two different ways.

First, people who experience warm temperatures tend to perceive others as friendlier (Williams and Bargh 2008). When people view themselves as close to others, they experience a sense of "we-ness." As a consequence, they may consider conformity to others' decisions to be more socially desirable independently of the validity of these decisions (Gardner, Gabriel and Hochschild 2002). Such social approval-based conformity may facilitate people's fulfillment of their need for affiliation (Baumeister and Leary 1995, Martin, Hewstone and Martin 2003). This motive generally holds for decisions that reflect primarily the decision maker's personal values and lifestyle.

Second, relative to socially distant others, socially close others are also believed to hold more reliable and accurate opinions (Naylor, Lamberton and Norton 2011). To this extent, the adoption of others' views and decisions may occur not only when individuals' primary goal is to gain social approval but also when their financial well-being is at stake (Cialdini 2001, Castelli, Vanzetto, Sherman and Arcuri 2001, Quinn and Schlenker 2002).

We tested the above predictions in four laboratory experiments and a field study of the betting behavior at the racetrack. In the laboratory experiments, participants were seated in a room in which the temperature was either warm (75-77°F) or cool (61-63°F), but in each case was within the comfortable range (Anderson et al. 2000; Baker & Cameron, 1996; Baron & Bell, 1976; IJzerman & Semin, 2009). Experiment 1 examined conformity when decisions were a matter of personal taste. Participants were shown an ad for a museum and asked to report their attitude towards it. In some cases, the ad emphasized popularity ("Visited by Over a Million People Each Year") and in other cases, it stressed uniqueness ("Stand Out from the Crowd"). Participants evaluated the first ad more favorably, but evaluated the second ad less favorably, when they were in a warm room than when they were in a cool room.

Experiment 2 replicated these findings and, in addition, confirmed that the effects were mediated by the impact of ambient temperature on perceptions of social closeness. However, participants' affective reactions did not differ as a function of temperature, indicating that differences in affect were not a contributor to the effects we observed.

The next three studies extended our findings to decisions in which the primary consideration was financial. In Experiment 3, participants were given six graphs, each depicting changes in the price of a stock, and were asked in each case whether they would buy the stock or sell it. In some conditions, participants were shown the predictions that the majority of previous participants in the experiment had made. In control conditions, this information was not provided. Participants who received information about others' predictions were more likely to conform to them when the temperature was high than when it was low. In the control conditions, participants' choices did not depend on temperature.

Experiment 4 further examined the mediation of perceived social closeness in the domain of financial decisions. Participants in both warm and cool temperature conditions were told to imagine they were at the race track and had an opportunity to place bets on each of seven races. For each race, the distribution of "winning odds" (a function of the amount of money that was bet on each horse) was provided. Participants were more likely to bet on the favorite (i.e. the horse with lowest odds) when the temperature was warm than when it was cool. These effects were mediated by the effects of ambient temperature on participants' perceptions of their social closeness to other betters. However, the positive and negative affect that participants reported experiencing, their risk propensity, involvement, arousal, relaxation and tiredness, did not depend on temperature.

A field study was then conducted in the context of horse racing data in Hong Kong over a period of three consecutive years

(2007 - 2009). Horse races are only held in seasons during which the temperature is comfortable. The extent to which bets on each race converged on the favorite over the hour before each race was averaged over the races run on each day and correlated with the average temperature on that day. This correlation was significantly positive ($r = .20$; $n = 204$). Furthermore the mean standard deviation of the odds associated with the horses in each race (a second indication of the convergence of bets on the favorite) was also significantly correlated with temperature ($r = .11$, $n = 224$). Thus, these data confirm the effects we observed in the laboratory and indicate that the impact of ambient temperature on the adoption of others' opinions is motivated by a desire to make money and is not restricted to conditions in which conformity is motivated by social desirability concerns.

SESSION OVERVIEW

Individuals use brands to construct their self-concepts and their identities. Once individuals have incorporated their brands into their self-image, individuals often use these brands as signals to others. These signals often function as status symbols. However, the use of brands as signals may also function as self-verification or self-enhancement tools (Escalas and Bettman 2003). In this session we explore beyond the many ways individuals use brands as signals to others. We examine ways in which individuals use brands as signals to themselves, and by doing so fulfill needs, including relational, functional, and identity relevant. In the first part of the session we examine how individuals use brands commonly thought of as status symbols to fulfill other, more basic needs. We then examine the ways in which individuals, who have fulfilled identity needs by incorporating brands into their self-image, react to a threat to the brand. Taken together, these papers present a novel, multicultural picture of the antecedents and consequences of the selective use of brands as a means of need fulfillment.

In the first part of the session, we examine situations in which many would expect brands to be used merely as status signals to others and yet, instead, are also being used to fulfill other, basic needs. In the first paper, Brick, Fitzsimons and Chartrand explore how wealthy individuals are using their favorite brands not to demonstrate their wealth, but rather to serve as relationship partners. Although many individuals often associate high-end, luxurious brands with the wealthy, they find that wealthy individuals report stronger brand relationships with brands that are less expensive, less publically consumed and more likely to be consumer packaged goods.

They also find that it is connection with these brands that contributes to the strong brand relationships.

In the second paper, Sarial-Abi and Gürhan-Canli examine another, related area in their examination of who purchases high-end counterfeits. Intuitively, one might think that high-end counterfeits are only used as self-enhancement signals. However, Sarial-Abi and Gürhan-Canli find that this is not always the case, and that high-end counterfeits can fulfill other, practical needs. They examine how the functional and symbolic benefits offered by high-end counterfeits influence purchasing intentions, and that self-presentation goals determine on which aspects of the product individuals will place the most value.

Next, we move to consequences of the use of brands as a signal, particularly once those brands have been used to fulfill an identity-relevant need. Once individuals have incorporated brands into their identity, threats to the brand, including brand failure or changes in brand image, may be felt as a threat to the self. Xu, Cheng, and White support this theory in the third paper by their examination of the consequences of brand failure on self-esteem and subsequent attempts to restore the "shaken" self-view. They show that after a brand threat, consumers with high (but not low) self-brand connections are more motivated to pursue salient goals in an effort to correct the threat to their self-esteem.

Finally, Gaustad, Samuelsen, Warlop, and Fitzsimons expound upon the role that a change in the brand image can have on one's esteem in their paper. In particular, they show that highly connected consumers experience brand, and self-identity threat, not only as a result of the introduction of new traits to a brand image, but also, counter intuitively, as a result of reinforcement of current traits. The threat response is contingent upon the degree to which the brand primarily relates to consumers' actual or ideal self.

Besides offering an in-depth view, through the examination of antecedents and consequences, of the selective use of brands, this session also offers a broad view of this topic through the inclusion of multi-cultural studies. Submitters represent schools from a variety of nations, and this variety creates a large, diverse sampling population. As a result, this session presents a number of theoretical and practical contributions appealing to a broad audience, and should attract researchers with interests in topics as far ranging as consumer-brand relationships, goal pursuit, social identity, behavioral predictions (including charitable giving), and life satisfaction. In sum, this session has implications for a large, multicultural audience, and will further the conference's mission of appreciating diversity.

All speakers (Brick, Sarial-Abi, White, and Gaustad) have agreed to participate if the proposal is accepted. Of note, all papers in this session are advanced and extensive data collection, including multiple studies for each paper, has been completed. We anticipate allowing 15 minutes for each presentation and 15-20 minutes of discussion regarding the session topic and individual presentations.

As Income Level Rises,
So Too Does Our Connection with "Tide"

EXTENDED ABSTRACT

Individuals use brands to signal identity and self-concept; individuals also use brands as self-verification and self-enhancement tools (Escalas and Bettman 2003). As such, one might think wealthy individuals would be most loyal to high-end, luxury brands that, in effect, serve as status verification and self-enhancement signals to the self and others. However, we find this is not the case. Instead, we argue, that wealthier individuals are using brands for another reason – to serve as relationship partners. Instead of signaling status to others or even to themselves, wealthier individuals are choosing and using brands that fulfill basic relationship needs. As a result, wealthier individuals form stronger brand relationships, the strength of which is mediated by self-brand connection.

Why might wealthier individuals form stronger brand relationships? Past research has demonstrated that having money makes people more self-sufficient, less likely to turn to others for support (Vohs, Meade and Goode 2006), and that the mere presence of money can make people more distant, cold, and less willing to help others (Vohs, Meade and Goode 2008). These effects extend beyond the immediate context; higher socioeconomic status has been associated with signs of weaker social connections (Kraus and Keltner 2009). As the need for social relationships is fundamental to human psychology (Baumeister and Leary 1995), we argue that instead of turning to others, wealthier individuals are turning to their brands to fulfill this need. They are developing stronger brand relationships than less wealthy individuals, who are more likely to form stronger interpersonal relationships (Kraus, Côtè and Keltner 2010).

In a first study, we examined whether wealthier individuals form stronger brand relationships and the types of brands they are forming these relationships with. Although there have been a few scales designed to measure relationship quality (e.g., Park, Kim and Kim 2009), some of these scales are relatively long and most do not contain all of the characteristics commonly found in interpersonal relationships we intended to study. Therefore, in order to test brand relationship strength we devised a Brand Relationship Measure for this study. The seven-item measure ($\alpha=0.87$) was rated on a 1 (not at all) to 7 (very much) scale. In order to evaluate the brands individuals were reporting on, two independent coders rated each of the brands reported on several characteristics (interrater reliability $\alpha=.98$). If they are fulfilling an intrinsically-motivated, fundamental relationship need, we hypothesized the brands to which wealthier individuals are reporting as being most loyal would not be expensive, "keeping up with the Joneses" brands, often associated with social jockeying (Christen and Morgan 2005) or status signals. Instead, we hypothesized these brands would be less expensive, more privately consumed, and more likely to be consumer packaged goods (CPGs) than the brands to which less wealthy individuals are reporting as being most loyal.

One hundred six individuals (N=71 females, Mage=41.2 years, SDage=13.5) from an online source participated in this study. In line with our hypothesis, we found that wealthier individuals, as characterized by income, report a significantly stronger brand relationship with their brands. Providing additional support that wealthier individuals are forming relationships with brands that are not serving as a status signal, the brands wealthier individuals reported were significantly less expensive, less publically consumed, and more CPGs than less wealthy individuals.

Study 2 sought to replicate the findings from study 1 that wealthier individuals form stronger brand relationships, and also to explore our prediction that connection with the brand mediates the effect. One hundred one individuals were recruited and participated in this study from an online source (N=68 females, Mage=35.7 years, SDage=13.8). We used the same Brand Relationship Measure from study 1, and in order to test connection with the brand, we used Escalas and Bettman's (2003) self-brand connection scale.

Replicating our initial findings, individuals with greater wealth, as measured by income level, reported significantly stronger brand relationships. Next, we examined our contention that connection with the brands mediates the effects of wealth on brand relationships. In line with our hypothesis, wealth significantly and positively predicted self-brand connection. Furthermore, brand connection positively predicted relationship strength. When self-brand connection is added to the model predicting wealth on the brand relationship measure, self-brand connection remains a significant predictor, but wealth is no longer significant. In order to test whether connection with the brand mediates the effect of wealth on brand relationship strength, we used a 5,000 resamples bootstrapping approach (Preacher and Hayes 2008). The bootstrapping technique did not contain zero, suggesting connection with the brand mediates the relationship between wealth and brand relationship strength.

Study 3 enhances the above findings by manipulating perceptions of wealth, and then asking participants to report on their brand relationships and connection with their brands. Supporting our hypothesis we find that individuals who feel wealthier report significantly stronger brand relationships, and that this is again mediated by connection with the brand. In study 4, we provide further evidence that wealthier individuals are not using their brands just to signal status to others or themselves. We again manipulate perceptions of wealth, but in this study we introduce a new set of brands and measure strength of the brand relationship and connection with the new brand. In addition, we expand upon the prior studies by evaluating the effects of the prior findings on consumer behavior outcomes. The theoretical and practical implications are discussed.

Benefits Offered by High-End Counterfeits Influence Intentions to Purchase Counterfeits–The Role of Self-Presentation

EXTENDED ABSTRACT

In today's economy, counterfeits are estimated to account for 7% of the whole world trade (World Customs Organization 2004). Previous research mainly investigates why consumers buy cheap knockoffs of the genuine brands (Wilcox et al. 2009). However, with increased technology, a new generation of counterfeits is emerging that is often more convincing than the cheap knockoffs with much higher prices (Holmes 2011). In this research, we investigate who would buy these high-end counterfeits and why.

Counterfeiting: Demographic factors influence intentions to purchase counterfeits. For example, females are more likely to be heavy buyers of counterfeit clothing and accessories (Cheung and Prendergast 2006). Social factors such as the presence of a friend buying a counterfeit influence one's intention to buy counterfeits (Penz and Stöttinger 2005). Product and brand-related factors such as the selling price also enhances willingness to buy counterfeits (Lau 2006).

Functional Versus Symbolic Benefits: Individuals buy things for what they can do with them and for what those things mean to them (Keller 1993). Brand features or brand associations refer to attributes or benefits that consumers link to a brand and that, in their

minds, differentiate it from competitors (Dillon et al. 2001). Extant literature has focused on functional benefits (Domzal and Kernan 1992), as well as symbolic benefits offered by brands (Drolet and Aaker 2002).

Functional benefits are related to the more intrinsic aspects of product consumption and usually correspond to product attributes. High-end counterfeits offer high functional benefits. For example, they are made of high-quality materials, which increase their durability (Holmes 2011). On the other hand, symbolic benefits are related to the extrinsic advantages of product consumption. They usually correspond to non-product-related attributes and relate to underlying needs for social approval and personal expression (Park et al. 1986). Because symbolic benefits relate to underlying needs for social approval and personal expression, individuals who have high need for self-presentation should be more likely to purchase high-end counterfeits. However, are individuals who have low need for self-presentation ever likely to purchase high-end counterfeits?

Self-Presentation: Self-presentation is the goal-directed process of people controlling information about the self to influence the impression others form of them (Schlenker et al. 1996). Social actions required for self-presentation are consumption-oriented and depend upon individuals' brands (Williams and Bendelow 1998). Consumers may self-present by purchasing high-end counterfeits because counterfeits help them create identities and impress others (Hoe et al. 2003). This suggests that individuals who have high need for self-presentation should be more likely to purchase high-end counterfeits when these counterfeits offer them symbolic benefits. However, they should be less likely to purchase high-end counterfeits if these counterfeits offer them high functional benefits (e.g., quality) but low symbolic benefits (e.g., no logo).

Individuals who have low need for self-presentation are less concerned with impressing other people. Because they are less concerned with impressing others, what they expect from a brand is more likely to be related to the functional benefits. Given the possibility that some high-end counterfeits may offer as many functional benefits as the original brands, these individuals who need low self-presentation should be more likely to purchase high-end counterfeits when these counterfeits offer them high functional benefits. However, they should be less likely to purchase high-end counterfeits if these counterfeits offer them high symbolic benefits, but low functional benefits.

Study 1(N=100): Participants first received the self-presentation manipulation. Afterwards, they randomly received the functional and symbolic benefits manipulations. Dependent variables and control variables were then measured.

An ANOVA on intentions to purchase counterfeits yielded a significant self-presentation by benefits interaction ($F(1, 96) = 13.26$, $p < .001$). Participants who have high (vs. low) need for self-presentation have higher intentions to purchase counterfeits when they think about symbolic brand benefits (3.76 vs. 2.43; $F(1, 96) = 7.9$, $p < .05$). On the other hand, participants who have low (vs. high) need for self-presentation have higher intentions to purchase counterfeits when they think about functional brand benefits (3.22 vs. 1.89; $F(1, 96) = 7.82$, $p < .05$).

Study 2 (N=200): Participants first received the self-presentation manipulation. Afterwards, they randomly received the functional and symbolic benefits manipulations. The order of the benefits manipulations was counterbalanced. Dependent variables and control variables were then measured.

An ANOVA on intentions to purchase counterfeits revealed a significant three-way interaction of self-presentation, functional benefits, and symbolic benefits ($F(1, 192) = 5.56$, $p < 0.05$). When func-

tional benefits are high, individuals who have low (vs. high) need for self-presentation are more likely to purchase high-end counterfeits if these counterfeits offer low symbolic benefits (3.96 vs. 2.89, $F(1, 192) = 7.24$, $p < .05$). However, intentions to purchase high-end counterfeits did not vary as a function of low (vs. high) need for self-presentation when high-end counterfeits offer high functional and symbolic benefits (3.74 vs. 3.82, $F(1, 192) = .13$, $p > .72$).

Moreover, when functional benefits of high-end counterfeits are low, individuals who have low (vs. high) need for self-presentation are less likely to purchase high-end counterfeits if these products offer high symbolic benefits (2.72 vs. 3.86, $F(1, 192) = 7.69$, $p < .05$). However, intentions to purchase high-end counterfeits did not vary as a function of low (vs. high) need for self-presentation when high-end counterfeits offer low functional and symbolic benefits (2.61 vs. 2.53, $F(1, 192) = .12$, $p > .73$).

General Discussion: In this research, we extend the literature on intentions to purchase counterfeits by examining high-end counterfeits specifically. Second, we extend the literature by demonstrating that functional and symbolic benefits offered by high-end counterfeits influence purchase intentions. Finally, we demonstrate that those individuals who have low need for self-presentation are also likely to purchase high-end counterfeits when these counterfeits offer them functional benefits. Focusing on how improvements in functional (vs. symbolic) benefits offered by high-end counterfeits influences brands' long-term profitability would be an important research focus. More research with different methodologies is required to understand the impact of counterfeit consumption on consumers.

Taking More Money and Donating More Money: The Influence of Self-Threat on Goal-Pursuit

EXTENDED ABSTRACT

Believing that the self is a capable and lovable person is a basic human need (Branden 1969) and is essential to individuals' subjective wellbeing (Taylor and Brown 1988). However, it seems inevitable for us to encounter incidents that threaten this belief, even in consumption contexts. For example, consumers may feel shame about their appearance when they view an ad featuring attractive models (Gulas and McKeage 2000) or feel incompetent when they realize that they paid more than others for an identical item (Argo, White, and Dahl 2006). Having a favorite brand could also be a source of self-threat when the beloved brand fails (Cheng, White, and Chaplin 2012). For those who want to be unique, realizing one's favorite brand is also liked by a large number of consumers could also pose a threat (Imak, Vallen, and Sen 2010).

Of course, human beings are not passive victims of various threats. In response to these threatening incidents, individuals are often motivated to restore a positive self-view through biased information processing or biased attributions (for a review, see Sherman and Cohen 2006). Unfortunately, many of these defensive responses are maladaptive because they promote an inaccurate understanding of the self and the world. We propose and test a beneficial consequence of experiencing self-threat. Specially, we suggest that self-threat can elicit a general motivation that urges people to pursue salient goals that they consider to be important. Moreover, pursuing important goals can boost individuals' threatened self-esteem.

Experiment 1 was a 2 (*Self Threat:* Threat vs. No-Threat) x 2 (*Salient Goals:* Help Others vs. Pursue Self-Interest) between-participant design. Self-threat was manipulated using a RAT task and the salient goal was manipulated through participating in either a "Buyer-Seller Game" (the "self-interest" condition) or a "Doner-Donee Game" (the "help others" condition). The results of Experi-

ment 1 are consistent with our hypothesis that self-threat motivates individuals to pursue the goal that was made salient by the context (significant goal by self-threat interaction, $F(1, 75) = 6.06, p < .02$). Significant planned contrasts revealed that when the goal to pursue self-interest was made salient in the Seller-Buyer Game, self-threat increased the amount of money that participants decided to keep for themselves ($M_{threat} = 9.00$ vs. $M_{no-threat} = 7.96$). However, when the goal to help others was made salient by the Doner-Donee Game, self-threat increased the amount of money that participants decided to give to others themselves ($M_{no-threat} = 4.73$ vs. $M_{threat} = 6.06$). Moreover, even though the manipulation of self-threat decreased participants' self-esteem, this effect was completely eliminated following successful goal pursuit.

Experiment 2 used a 2 (*Self Threat:* Threat vs. No threat) x 3 (*Salient Goals:* Saving Money vs. Spending Money on Luxurious Products vs. control) between-subjects design. Participants were given an opportunity to pursue a more important goal (i.e., saving money; $M_{importance} = 6.06$) or a less important goal (i.e., spending money on luxury products; $M_{importance} = 3.93$). When the goal was [not] important, threatened participants [did not] save[d] a greater amount of money than did control participants (threat x goal importance interaction $= F(1, 201) = 4.40, p < .04$). Moreover, only pursuing important an goal was self-affirming.

In Experiments 4 and 5, we induced self-threat exposing participants to negative brand information for brands with for which they had a high vs. low self brand connection (SBC). Cheng, White, and Chaplin (2012) found that consumers with high self-brand connections to certain brands experienced a threat to their positive self-view upon receiving negative brand information. Extending these findings, we suggest that negative brand information should motivate high SBC consumers to pursue irrelevant goals (e.g., helping others) that are made salient by the situation. To test this possibility, we used the brand Adidas, which was one of the major business sponsors of 2008 Beijing Olympic Games. After getting information about Adidas' sponsorship, participants read either a negative commentary or a neutral commentary on this sponsorship. In Experiment 4, we found a significant brand information x SBC interaction ($\beta = .49, t = 2.46; p < .02$). Simple slope analysis revealed that when participants received negative information about Adidas, those who felt highly connected with the brand took more money for themselves ($\beta = .30; t = 2.01; p = .05$). However, when participants received neutral information about Adidas, the effects of SBC on the amount money that participants took was not significant ($\beta = -.26; t = -1.54; p > .10$). In Experiment 5, we manipulated self-threat by providing negative brand information about Blackberry to high vs. low SBC respondents and measured their willingness to donate to UNICEF. As expected, the effect of SBC on the amount of donation was significant ($\beta = .51, t = 2.86, p < .02$), indicating that when participants received negative information about Blackberry, those who were highly connected to the brand donated more money to UNICEF. We also measured self-esteem in this study. As expected, receiving negative information about Blackberry decreased participants' self-esteem when they were highly connected to the brand Blackberry. Moreover, it appears that this self-threat motivated participants to donate more to charity, which, in turn, boosted (restored) their self-esteem.

Conclusion. Individuals often take actions to self-affirm following threats to their positive-self view. We propose that: 1) self-threat can cultivate a general motivation to pursue salient goals; 2) this tendency could lead to behaviors with divergent implications when opposing goals are activated; and 3) goal importance moderates this effect. We tested the implications of this framework in the context of self-brand connections; we show that negative brand information

poses a self-threat to consumers with a high self-brand connection (but not to those with a low self-brand connection) and motivates them to pursue the goals highlighted in the subsequent situation. In particular, following exposure to negative brand information, high SBC consumers donated more money when the goal to help was made salient, yet took more money when the salient goal was to pursue self-interest.

Identity Change: The Effects of Actual and Ideal Self-Brand Connections on Consumers' Response to Brand Image Change

EXTENDED ABSTRACT

In contrast to the extant literature (MacInnis et al. 2009), we investigate a potential disadvantage of strong of consumer-brand bonds. Consumers sometimes incorporate brands into their self-concept to construct and/or signal identity (self-brand connection, Escalas and Bettman 2003). We argue that for those consumers who have incorporated the brand into their self-concept, change in brand image can represent an identity-threat. Consumers cope with this threat, not only by reacting negatively to the change, but also by reducing their felt brand connection.

Study 1 applies brand acquisitions as the context. We propose that consumers' reactions to an acquisition are contingent on whether or not it changes target brand image. Further, we expect self-brand connection to moderate this effect. Since strongly connected consumers incorporate the brand in their self-concept, a change in brand image is a forced change in the self and represents an identity-threat. Thus, we expect these consumers to reduce their connection if brand image change.

Seventy undergraduate students participated in a 2 (no change/change) × self-brand connection (measured) mixed design experiment. First, we measured attitude and self-brand connection to Nike and other filler brands. Then (one hour later), participants read a newspaper article about the acquisition of Nike. The acquirer was a fictitious venture capital company. Statements in the article manipulated no change/change in brand personality due to the acquisition (the change condition entailed Nike becoming more glamorous, sophisticated and upper class). Last, we measured the dependent variables and manipulation checks.

We conducted multiple regressions with the experimental conditions (no change/change), self-brand connection (continuous), and their interaction as independent variables.

The results showed an interaction between the experimental conditions and self-brand connection on attitude to the acquisition ($\beta = -.40$, $t = -2.44$, $p < .02$) and, more interestingly, also on both change in attitude ($\beta = -.38$, $t = -2.03$, $p < .05$) and change in self-brand connection ($\beta = -.26$, $t = -.194$, $p = .057$) to the target brand. Investigations of the interactions confirmed the predicted significance of slopes, as well as contrasts between no change/change at high levels of self-brand connection.

The results indicate that consumers react more negatively to change in brand image the greater connection they have with the brand. Further, strongly connected consumers experience brand image change as a threat to their self and withdraw from the brand relationship.

The first experiment investigated brand imagechange through the introduction of new traits. However, brand image can also change by reinforcement of existing traits. There is some evidence that consumers are reluctant to enhance existing traits that are fundamental to their self-concept (Riis et al. 2008). Hence, we expect consumers with strong self-brand connection to react negatively to every devia-

tion from the existing brand image, even to reinforcement of existing salient traits.

Based on pretests, we chose 'Diesel' as the target brand for study 2. The traits most strongly associated with Diesel were rugged, tough, masculine and daring (pretest). We therefore used these strongly associated traits to examine reactions to change through reinforcement of established traits. Except for the use of established (vs. new) traits, the procedure was similar to study 1. Thirty-six undergraduate students completed the study.

Multiple regression revealed an interaction between the experimental conditions and self-brand connection on attitude to the acquisition ($\beta=-.71$, $t=-2.70$, $p<.02$), as well as on change in attitude ($\beta=-.68$, $t=-2.05$, $p<.05$) and change in self-brand connection ($\beta=-.37$, $t=-2.51$, $p<.02$). Investigations of the interactions confirmed the predicted significance of slopes, as well as contrasts at low and high levels of self-brand connection.

The results indicate that strongly connected consumers react negatively and show threat response, not only to introduction of new traits, but also to change through reinforcement of existing brand associations. Next, we investigate whether this effect is valid for all brand connections or whether it depends on which part of the self-concept the brand primarily connects (actual or ideal self).

In study 3, we investigate the hypothesis that whether the brand is primarily connected to consumers' actual or ideal self influences reactions to brand image change. We hypothesize that for consumers' feeling congruence between their actual self and the brand, all brand image changes are negative because they decrease the felt congruence between the self and the brand. However, for consumers feeling congruence between their ideal self and the brand, reinforcement of the existing brand image can be positive as it increases the brands ability to signal an ideal identity.

One hundred and seventy-two participants completed a survey on an online web panel (American participants $age_{mean} = 35.1$, 56 % females). First, we measured brand attitude, actual and ideal self-brand congruity, as well as brand personality. After some filler tasks, participants read a hypothetical scenario about the re-positioning and change in Nike's brand image. Lastly, we measured participants' attitudes to change in different personality traits of Nike.

We conducted multiple regressions with an index of attitude to change in the five most descriptive traits (based on the personality evaluation in the first part of the survey: successful, leader, winner, confident, and up-to-date) as a dependent measure, with degree of actual self-brand congruity (continuous) and degree of ideal self-brand congruity (continuous) as independent variables.

The results revealed a negative effect of actual self-brand congruency ($\beta=-.15$, $t=-2.16$, $p<.04$) and a positive effect of ideal self-brand congruency ($\beta=.26$, $t=4.65$, $p<.01$).The results indicate that consumers' response to reinforcement of existing salient traits depends on whether the brand is connected to the consumers' actual self or ideal self.

Overall, we find support for the hypothesis that consumers who use the brand to construct and/or signal their identity demonstrate identity-threat responses to brand image change. They are more negative to brand image change (than those who are less connected to the brand) and react by withdrawing from the relationship. We also demonstrate that if the connection is based on congruence between the actual self and the brand, all changes in brand image are perceived as negative. However, if the brand connection is based on congruence between the ideal self and the brand, changes through reinforcement of existing brand traits are perceived as positive.

SESSION OVERVIEW

Consumers are increasingly acting as co-creators of value, rather than as just passive recipients of it (e.g. Prahalad and Ramaswamy 2002; Vargo and Lusch 2004). Numerous companies have emerged that allow customers to design their own products, both through mass-customization toolkits and crowdsourcing sites. Moreover, firms continue to expand the involvement of customers in the promotion of their products, by encouraging them to create and distribute brand related content. This trend has lead to an unprecedented amount of labor being outsourced to the firms' costumers. In this session we present diverse perspectives on the costs and benefits of consumer labor for both the firms, and the consumers themselves.

The first paper examines some of its costs, by showing that people may be insensitive to their earning rate, and thus work to the point where they are tired, rather than when they have maximized their overall utility. As such, constraints on the amount people can earn can lead to higher well-being. The second paper looks at the effect of constraints in creative tasks. It shows that constraints can influence the evaluation of self-created products and the effort devoted to these, and that this is moderated by the identity primed. The third paper shows how labor not only affects the evaluation of the product created, but also how it can affect the overall relationship with the brand. Finally, the last paper examines the mechanism behind the value customers derive from their own labor, and shows how this can be used to increase the involvement of customers in co-creation. As a whole, this session provides novel and varied views on the consequences of consumer labor.

Labor or Leisure?

EXTENDED ABSTRACT

This research studies how people allocate their time between labor and leisure, a question that is relevant to every consumer who needs to work in order to earn what she/he wants to consume. Do people ever overwork – endure unpleasant labor to earn more than what they believe they can possibly consume?

Although these questions are apparently important, they are hardly answerable in the real world, because the real world is too complex for researchers to determine what the right amount of work

or the right amount of earning is; hence to define what overworking or over-earning is.

Instead of studying overworking or over-earning in the real world, the current research seeks to achieve the following more modest and specific objectives: to introduce a minimalistic paradigm that allows researchers to define and study overworking and over-earning in a controlled laboratory setting, and to use this paradigm to demonstrate when and why people overwork and over-earn.

The Paradigm

Participants are run individually using a personal computer, and each participant is required to wear a set of headphones. The experiment consists of two consecutive phases, each lasting five minutes. During phase I, the participant can either listen to music and earn nothing (leisure) or listen to noises and earn chocolates (work). The default is listening to music. At any time she can press a dedicated key on the computer keyboard to disrupt the music and listen to a short, 0.2 sec, beep-like noise, and for every certain number of times she listens to the noise, she will earn one piece of chocolate. The noise is pretested as less pleasant than the music. Throughout phase I, the computer screen displays the number of chocolates earned and the time elapsed. The participant may not eat the earned chocolates in phase I.

Once phase I ends, phase II commences. The computer instructs the participant to take the number of chocolates she has earned in phase I from a jar on the table and start to eat them. She does not have to eat all the earned chocolates, and if there are any remaining ones, she has to leave them on the table and cannot bring them home. The participant may not listen to more noises or earn more chocolates in this phase.

Every aspect of the procedure is explained to the participant before the experiment starts; she knows what type of chocolate she will earn and what type of noise she will hear. In addition, the participant is told that it is entirely up to her how many chocolates to earn in phase I and how many to eat in phase II, and that her only objective is to make herself as happy as possible in the entire experiment. The main dependent variables are how many chocolates she earns in phase I and how many she eats in phase II.

We define *overworking* as forgoing leisure (music) to earn more chocolates in phase I than the predicted optimal amount. (In this paradigm, overworking and overearning are the same, and we will use these terms interchangeably.) We define *predicted optimal amount* as the number of chocolates the participant herself or somebody in the same situation as the participant *predicts* that she will eat in order to make her most satisfied, and we empirically establish this level in pretests.

Findings

Using this method, we have conducted a series of studies to explore when and why participants overwork (or underwork). Because we already introduced the method above and also because of the space limit, we will not elaborate on each study. Instead, we will summarize the main empirical findings below:

- When the earning rate was low (e.g., earning 1 chocolate every 10 times one listened to the noise), participants underworked, i.e., stopped working and earning before they earned the predicted optimal amount. When the earning rate was high (e.g., earning 1 chocolate every time one listened to the noise), participants over-

worked, i.e., continued to work and earn after they had earned the predicted optimal amount. These results imply that low-income people tend to underwork relative to what they need and high-income people tend to overwork relative to what they need

- The above effects occurred, because participants were insensitive to the earning rate or to the utility of their earning; they worked until they felt tired, rather than until they had enough.
- Predicted optimal amount was quite accurate, that is, quite similar to the actual consumption amount. Note that this similarity was not due to participants' desire to be consistent between prediction and behavior, because the predicted optimal amount was elicited from a separate group of participants and the main participants were not aware.
- Participants who overworked were less happy than participants who did not. It suggested that people overworked, not because they enjoyed working.
- Finally, we tested a paternalistic intervention method – not allowing participants to earn more chocolates after a certain point, though still allowing them to work (listen to noise) if they wished. This method produced two effects: First (less interesting), it curtained overworking. Second (more interesting), it increased participants' happiness. It suggested that (high-income) people lack the self control to stop working and stop earning after they have already earned more than what they can possibly consume and not allowing them to make excessive earning can reduce their tendency to overwork and, more importantly, can make them happier.

The Influence of Identity on Creative Outcomes

EXTENDED ABSTRACT

While much of creative consumption involves creating a product for personal use, the bulk of work on consumer creativity focuses on "objective" evaluations of an outcome by someone other than the individual who created it. When creating for oneself, we propose that identity motives interact with constraints provided at the time of design to influence consumers evaluations of their own creative outcomes.

Prior literature has shown that constraints both enhance and inhibit creativity (e.g., Dahl and Moreau 2007; Moreau and Dahl 2005; Sellier and Dahl 2012). Through three studies all involving actual creative tasks, we show that identity motives influence the relationship between constraints and evaluations of self-created outputs. Importantly, this relationship also depends on the structured nature of the creative task itself (i.e., an unstructured drawing task vs. customization via a structured toolkit).

Identity, what comes to mind when we think of ourselves, includes two major components: a personal identity related to the independent self and a social identity related to the interdependent self (Kirmani 2009; Oyserman 2009). Cheng et al. (2008) suggest that activating an identity makes related knowledge structures accessible for creative tasks. This knowledge structure accessibility may make creative tasks easier, but it can also lead to more habitual and less objectively creative outcomes (e.g., Aarts and Dijksterhuis 2000). Across three studies, we examine how priming identity-related knowledge influences both effort expended and evaluations of one's own creative outcomes.

In Study 1 all participants (N =97) receive a blank piece of paper along with colored pencils (high constraint = 6 colors, low constraint = 12 colors) and are asked to draw a picture that could be used on a customized product. Those in the "identity" condition are told to draw something that represents something interesting or important to them (participants in the "no identity" condition are simply asked to think about products that could have customized designs). We find a significant interaction of the two manipulated factors on evaluations ($F(1,96) = 3.81$, $p = .05$). When identity is primed, participants with high constraints evaluate their drawings more positively than those with low constraints ($M_{Identity, Low Constraints} = 4.08$ vs. $M_{Identity, High Constraints} = 4.96$; $F(1, 96) = 4.87$, $p < .03$). When identity is not primed, input constraints do not have a significant influence on evaluations ($M_{No Identity, Low Constraints} = 4.29$ vs. $M_{No Identity, High Constraints} = 4.19$; $F(1, 96) = .06$, n/s). We find that effort expended mediates design evaluations such that when participants are not primed with identity, they exert more effort when constraints are low. However, when primed with identity, they report exerting more effort when constraints are high. From this study, we conclude that in an unstructured task environment, when identity motives are not active, participants prefer low constraints. But when motivated by identity, participants prefer higher constraints.

In the following studies, we examine the interaction between constraints and identity motives using online customization toolkits. Like other constraints, we propose that the structured nature of these task environments make participants less reliant on their own memories and accessible knowledge structures, leading them off the Path of Least Resistance (e.g., Fink et al. 1992; Moreau and Dahl 2005; Ward et al. 2002). To test this theory in our next two studies, all participants engage in creative tasks using online customization toolkits. We capture product evaluations both at the time of design and several weeks later at delivery.

In Study 2, all participants (N = 89) design a "skin" cover for a cell phone or MP3 player. Again we manipulate identity motive (absent vs. present) and input constraints (low = option to upload images or use library, high = library images only). We find that consumers evaluate their designs more favorably when constraints are low ($M_{Low Constraints} = 5.41$ vs. $M_{High Constraints} = 4.37$; $F(1, 88) = 13.57$ $p < .001$). This difference is enhanced when an identity goal has been activated and the interaction is significant ($F(1, 88) = 3.92$, $p = .05$). This pattern holds 10 days later when we deliver the product. As in Study 1, we find that effort (captured as time taken) mediates the effect of the manipulated factors on evaluations at the time of design.

Study 2 demonstrates that in a structured task environment, consumers given greater design freedom evaluate their designs higher and are more satisfied at delivery than those given less design leeway. In our next study, rather than broadly motivating identity, we independently motivate two competing identity-based motivations: personal identity and social identity (e.g., Oyserman 2009).

In Study 3, all participants (N = 82) design a customized travel mug (all participants actually receive the product they design, allowing us to capture satisfaction measures 6 weeks later at delivery). Two factors are manipulated across participants: input constraints (high vs. low, as in Study 2) and identity motives (social vs. personal). A two-way ANOVA reveals a significant interaction ($F(1,81) = 3.70$, $p = .05$). Participants reported higher evaluations of their designs when constraints were low (vs. high). This effect was more pronounced for those primed with personal identity motivations ($M_{Personal, Low Constraints} = 5.43$ vs. $M_{Personal, High Constraints} = 4.23$; $F(1,81) = 10.14$, $p < .01$) than with social identity motivations ($M_{Social, Low Constraints} = 5.15$ vs. $M_{Social, High Constraints} = 4.93$; $F(1, 81) = .38$, n/s). These results hold 6 weeks later at delivery.

By engaging participants in real creativity tasks, these three studies examine the influence that identity-related motivations have on consumers' evaluations of their own creations. These studies demonstrate that simply making salient an identity motivation prior to design can significantly influence design evaluations, product satisfaction and the effectiveness of the input constraints.

Self-Customization Effects on Brand Extensions

EXTENDED ABSTRACT

Mass customization (i.e., letting consumers customize their own products) is considered central to current marketing strategies and is gaining growing popularity in practice. So far, the main finding in the literature has been that self-customized products deliver superior value to customers (Franke et al. 2010; Norton et al. 2012; Randall et al. 2005). Four studies in the current research demonstrate that self-customization also positively affect the more general customer-brand relationship, conceptualized as brand attachment (Fedorikhin et al. 2008; Thomson et al. 2005; Park et al. 2010). The resulted brand attachment affects customers' intention to buy and willingness to pay for a *noncustomized* brand extension.

Study 1 was a scenario-based experiment to test effects of self-customization on brand attachment. We used scenarios to control for the most common reported outcome of self-customization, namely preference fit (defined as the fit between customer preferences and product characteristics). Following scholars like Bendapudi and Leone (2003), we developed two graphic scenarios to portray different purchasing situations. To allow participants to identify easily, we used a hypothetical figure named Pat. 159 participants were randomly assigned to one of the following conditions: (1) self-customization group, in which Pat was designing an individual PC with a mass-customization toolkit, and (2) the standard choice condition, in which Pat chose one option. All participants were informed that Pat was very satisfied with the self-customized (chosen) PC. The brand attachment measure focused on participants' connection to the brand (Thomson et al. 2005). We also included questions assessing preference fit and reactions to the graphic scenarios. Manipulation checks suggest that, as intended, preference fit was perceived to be constant (i.e. high) across conditions. Our results indicate that, as hypothesized, self-customization has a significant effect on brand attachment.

In Study 2 and 3 we show that feelings of autonomy and competence that result from self-customization mediate the processes leading to higher brand attachment. This effect is also found to depend on the design freedom granted to consumers: in case of a large (small) solution space the effects are amplified (attenuated) (Study 2). Study 2 was a one-way between subject random design with three conditions. 259 students were randomly assigned to either the standard condition or one of the two self-customization conditions. Those in the standard choice condition were asked to select a pair of casual shoes; participants in the self-customization groups were asked to design their own pair of shoes in a real customization task. In the high solution space condition, participants had a great deal of options; in the low solution space condition, the number of available options was much more limited. The collection of standard shoes and also the modules and options in the customization tool were pre-tested and developed by a professional designer. Following executing the task, respondents rated items measuring the main variables: brand attachment, autonomy and competence. Autonomy is defined as people's need to believe that their activities are self-chosen, self-governed, self-determined, and self-organized. Competence is the need to feel capable and effective and to have a sense of achievement. It refers to the anticipated satisfaction derived from completing a creative task successfully. We also measured preference fit and some other control variables (perceived effort of the design / choice tasks and product category involvement).

Manipulation checks suggest that actual solution space significantly affected perceived solution space. An Anova model applied to the brand attachment measure resulted in a significant effect of

customization. In particular, mass-customization in the high solution space resulted in a significantly higher brand attachment than in the other conditions. There is no significant difference, however, between the standard choice and the low customization conditions (i.e. effects are attenuated in the customization low solution space condition). Bootstrapping results suggest that feelings of autonomy and competence mediate this effect. Results are robust when including our control variables.

We designed another scenario-based study (Study 3; n = 444) to deepen our understanding of psychological processes and would contribute to the understanding of processes that underlie the formation of brand attachment. Method and procedure was very similar to Study 1. In a 2 (self-customization vs. standard condition) x 2 (preference fit high vs. average) factorial design, we show that both self-customization and preference fit have an independent and positive impact on brand attachment. We again show that feelings of autonomy and competence mediate the main effect of customization on attachment.

Finally, Study 4 demonstrates the mediating role of brand attachment on the effect of mass customization on the acceptance of brand extension of a *noncustomized* product – highlighting the importance of incorporating brand attachment in the theory and practice of mass customization and brand extensions. We conducted between-subject experiment that involved a real customization (choice) task. Participants (n = 126) were randomly assigned to one of the following two conditions: (1) The self-customization group was asked to design its own muesli mix (using the mass-customization toolkit of the company Mymuesli [www.mymuesli.com]) and (2) the standard choice condition was given the task of choosing one of 10 ready-made mixes. To add realism, participants were delivered the exact breakfast cereal mix they had self-customized (chosen). After product delivery – and after some time allowing for product trial – we measured preference fit, brand attachment, and willingness to pay (WTP) for a moderately dissimilar brand extension (muesli bars). In order to avoid any "cheap talk", we conducted an incentive-compatible BDM lottery to assess WTP for a brand extension. In line with our previous studies, we find that self-customization positively affects brand attachment. The effect of self-customization on WTP for a noncustomized brand extension is also significant and positive. Customers are willing to pay, on average, 35% more for the brand extension (package of muesli bar). We conducted a product-of-coefficients test to establish our proposed mediation.

In sum, our contributions are as follows: First, we extend the literature on brand attachment to mass customization research; second, we demonstrate the mediating role of brand attachment on the effect of mass customization on the acceptance of brand extension of a *noncustomized* product. Theoretical implications for mass-customization, brand attachment and brand extension along with managerial implications are discussed.

The IKEA Effect:
Signaling and Restoring Feelings of Competence

EXTENDED ABSTRACT

Prior work has shown that consumers are willing to pay more for self-made products than for identical products made by someone else (Franke, Schreier, and Kaiser 2010; Norton, Mochon, and Ariely 2012), an effect labeled the IKEA effect (Norton et al. 2012). In the current work we examine the underlying process behind this effect. We suggest that this premium is due to the role that self-created products have in fulfilling two deep identity-related desires of consumers: their desire to signal to themselves an identity that they

are competent and have effectance, and their desire to display that identity to others. Self-assembly of products fulfills both of these needs: by building things myself I am controlling and shaping my environment, proving my own competence, and by displaying my creations I am demonstrating my competence to others. In support of this theory, we demonstrate that feelings of competence mediate the premium attached to self-made products (Study 1); that allowing consumers to affirm their competence another way reduces the magnitude of this effect (Study 2); and that threatening people's sense of competence in one domain, increases their desire to assemble goods, and thus reestablish their competent self-view (Study 3).

In study 1 we examine whether feelings of competence mediate the IKEA effect. In this study participants were presented with a Lego car. *Builders* were given the pieces for the car with the instructions that come with the product, and were asked to assemble it accordingly. *Non-Builders* were given the car already assembled, and were asked to examine it. Participants were then asked to give their maximum willingness to pay using an incentive compatible BDM procedure. We then measured the feelings of competence associated with the product, as well as participants' overall mood. Replicating prior work on the IKEA effect, the builders were willing to pay more for their car ($M = \$1.20$, $SD = 1.35$) than the non-builders ($M = \$0.57$, $SD = .76$; $p < .05$). Builders also associated higher feelings of competence with their creations ($M = 4.39$, $SD = 1.48$) than non-builders ($M = 2.81$, $SD = 1.34$; $p < .001$). Importantly, the feelings of competence associated with the product fully mediated the effect of build condition on WTP (Sobel $Z = 2.08$, $p < .05$). Moreover, while builders ended up with a more positive mood than non-builders, mood did not mediate the IKEA effect.

In study 2, we test our account by both measuring, and also directly manipulating participants' need to feel competent. If our theory is correct, participants who are allowed to affirm the self another way (Aronson, Cohen, and Nail 1999; Steele 1988) may no longer need to signal competence through the products they create, and therefore should not show the IKEA effect. Participants in this study were randomly assigned to one of four conditions of a 2 self-affirmation condition (no affirmation vs. self-affirmation) x 2 build condition (pre-built vs. build) between-subjects design. Participants were first presented with a manipulation where they either did or did not affirm their values (Sherman, Nelson, and Steele 2000). Following the self-affirmation manipulation, participants were presented with an IKEA Kassett storage box. *Builders* were given the parts necessary to assemble the box, as well as the instructions from IKEA to assemble it, and assembled the box. *Non-Builders* were presented with a box that was already built, and were asked to examine it. We then measured participants maximum WTP using an incentive compatible procedure as well as the feelings of competence associated with the product.

The results showed no significant main effect of the self-affirmation or build conditions. However, we found the predicted significant interaction between these two factors ($F(1,115) = 3.90$, $p = .05$). In the no affirmation condition, we replicated the standard IKEA effect: builders ($M = \$0.72$, $SD = .45$) were willing to pay significantly more than those who received a box pre-built ($M = \$0.46$, $SD = .50$; $p = .05$). This effect was eliminated for participants in the self-affirmation condition, where there was no significant difference between builders ($M = \$0.49$, $SD = .46$) and those who received a pre-built box ($M = \$0.58$, $SD = .46$; $p = .48$). Thus, providing participants with an opportunity to affirm the self eliminated the IKEA effect. We further tested a model of moderated mediation to examine whether the indirect effect of competence on WTP depends on self-affirmation (Preacher, Rucker, and Hayes 2007). The results suggest

that, as in the previous study, competence acts as a mediator of the effect of building on WTP, but that this effect was moderated by the self-affirmation manipulation. Indeed, the analyses revealed a significant conditional indirect effect of the competence mediator in the no affirmation condition ($Z = 2.80$, $p < .01$), and a non-significant conditional indirect effect of the mediator in the self-affirmation condition ($Z = 1.34$, $p = .18$).

In study 3 we examined whether threatening people's sense of competence would increase their propensity to want to create their own products. In this study participants were first presented with a short math test which was either very difficult (*Low Competence Condition*) or easy (*Control Condition*). Participants were then asked to imagine that they had just bought a bookcase from IKEA, and were asked whether they would prefer to assemble it themselves, or would prefer for it to come pre-assembled. While only 33% of participants in the control condition said that they would prefer to assemble the bookcase themselves, 58% of participants in the low competence condition indicated that they would prefer to do so ($p < .05$).

The above results provide convergent evidence that the IKEA effect is driven by consumer's desire to signal competence to themselves and others. Moreover, these results suggest important practical implications for firms, by demonstrating that customers can be encouraged to participate in co-creation by appealing to their desire to signal competence.

SESSION CONCLUSION

This session helps further the conference's mission of diversity by drawing attention to a growing area in consumer research that views consumers in a novel way: rather than just being passive recipients of goods, under the perspective of this session, consumers are active creators of value. The diverse perspectives presented here should offer a good starting point for the discussion of the advantages and costs of this new model of consumer behavior.

SESSION OVERVIEW

In order to survive, consumers depend on a several key resources, including food and money. Yet in any given day, these resources can be seen as threatened (e.g., short-term financial crisis) or experienced as lacking (e.g., chronic poverty). Despite the centrality of resources in daily human life, relatively little research has investigated how actual or perceived scarcity can shape consumer mindsets, product preferences, and daily decisions, such as tradeoffs between time and money. The proposed session aims to highlight the newest research from around the globe that tackles these questions and more using a diverse range of methods, population samples, and measures. Broadly, the first two papers examine how resource scarcity (compared to resource abundance) changes consumers' mindsets and product preferences, whereas the final two papers examine resource scarcity among different populations. Specifically, Mehta will begin by showing that resource scarcity changes the way that people approach problems in a way that leads them to think outside in the box, thereby heightening consumer creativity. Van Horen will continue by examining how consumers use products with specific haptic sensations to restore a sense of comfort when resources are perceived as uncertain. Mead will then focus on how scarcity affects monetary trust decisions, showing that scarcity differentially impacts men and women's trust. Hall will close the session by demonstrating and discussing how and why low-income consumers differ in everyday financial decisions from high-income consumers. Taken together, the diverse approaches, methods, and populations represented in the four papers provide a broad yet deep view into emerging research on the implications of resource scarcity and abundance for consumer behavior. Particularly in the current climate of economic and political uncertainty, the novelty of the topic and diversity of the research will surely draw a large audience and stimulate a lively dialogue among these researchers.

Do the Worst of Times Increase Creativity?: Scarcity vs. Abundance Psychology and Creativity

EXTENDED ABSTRACT

The face of human society is constantly changing. As humans moved into the late modern era as an industrialized society, consumerism and over-acquisition of resources started to become the way of living (Côté 1993, 1996; Riesman 1950). Abundance started to supplant scarcity, especially in first world societies. Simultaneously, creativity has taken on a relatively more central and important role in consumption environments. On the demand side of the equation, consumers engage in everyday creative behavior such as home décor and fashion (Burroughs and Mick 2004; Burroughs, Moreau and Mick 2008). On the supply side of the equation, many businesses thrive on consumers' ability and desire to be creative.

One question that arises, then, is whether and how perceived availability of resources affects creativity in consumption environments. Or more specifically, how might a scarcity (vs. abundance) mindset influence consumers' creativity? In the current work, we conceptualize scarcity as the perception of an insufficient supply of resources, and abundance as the perception of an excessive supply of resources (Zhu and Kalra 2012). Past research has shown that the existence of constraints induces novel problem solving (Moreau and Dahl 2005). That is, constraints make people move away from the path of least resistance (POLR), thereby increasing their creativity. Hence, we argue that perceptions of scarcity will cause consumers to approach problems from multiple perspectives. That is, when scarcity cues are salient, individuals will overcome functional fixedness (Ward, Smith, & Finke, 1999) and explore solutions more broadly, leading to heightened creativity. However, when abundance cues are salient, individuals may not have sufficient motivation to move away from the POLR. Thus, among abundance participants, we predict a higher degree of functional fixedness, narrower exploration of solutions, and relatively lower creativity.

Experiment 1 tested our basic hypothesis that inducing a scarcity (vs. abundance) mindset will lead to higher creativity. To manipulate mindset, we had some participants write a paragraph about "Growing up in a society with scarce resources" (scarce condition), and other participants write a paragraph about "Growing up in a society with abundant resources" (abundance condition). Then all participants were presented with 10 Remote Associate Test items; their responses were assessed as a measure of creativity (Mednick 1962). As expected, participants primed with abundance cues demonstrated lower creativity as compared to participants primed with scarcity cues and participants in the control condition.

In experiment 2, we examined the mechanism through which perceived resource availability affected creativity. Specifically, we assessed whether abundance (vs. scarcity) mindset led to lower creativity because it increased functional fixedness. To induce perceptions of abundance and scarcity, we used the same manipulation used in experiment 1. All participants were then asked to generate creative uses of a brick (Friedman and Forster 2001). To assess the creativity of the uses generated, a panel of 12 judges rated the creativity of participants' responses. A second independent panel of 12 judges rated each of the uses on functional fixedness (i.e., how different the idea

was from the usual use of a brick). As predicted, uses for the brick generated by scarcity participants were judged to be more creative as compared to those generated by abundance participants. Also, we observed that functional fixedness mediated the effect, such that a scarcity mindset led to lower functional fixedness, which in turn led to more creative uses for the brick.

Experiment 3 provided further support for functional fixedness as the underlying mechanism. In this experiment, we manipulated functional fixedness salience in addition to manipulating perceived resource scarcity. To manipulate functional fixedness, participants were asked to generate ideas for a new kind of a computer keyboard. Those in the functional fixedness salient condition were told specifically to generate ideas for a new type of a "computer keyboard (the one you are using to type now)," whereas those in the control condition were simply asked to generate ideas for a new type of "computer keyboard." A two-way analysis of variance (ANOVA) revealed an interaction between functional fixedness and scarcity. Participants in the control condition demonstrated the same pattern of results observed in experiments 1 and 2: an abundance (vs. scarcity) mindset lowered creativity. However, when functional fixedness was induced experimentally, the effect disappeared: creativity did not differ between abundance and scarcity participants.

In summary, three experiments indicate perceived availability of resources has important consequences for consumer creativity and problem solving. Whereas a scarcity mindset induces the psychological processes necessary to stimulate creativity, an abundance mindset causes people to engage in a narrow exploration of solutions, thereby impairing creativity. Implications for consumer behavior and managerial practices will be discussed.

Dealing with Uncertainty Through Haptic Sensations

EXTENDED ABSTRACT

How do consumers adapt to a world that is fundamentally uncertain? For example, how do consumers react and cope with the prospect of financial scarcity during a financial crisis or after job loss? Or, how do consumers respond to profound shifts in a country's political climate?

Much research has focused on uncertainty regarding people's preferences or choices, which may be reduced by active information search (Kohn-Berning and Jacoby 1974; Urbany, Dickson, and Wilkie 1989). Uncertainty, however, is often externally rather than internally imposed (Kahneman and Tversky 1982). Uncertainty is thus a characteristic inherent in the environment and hence out of people's control, making it nearly impossible to reduce uncertainty by simply searching for information (Smithson 2008). Some research has suggested that people combat such external uncertainty by reestablishing a sense of order and structure, for instance through perceiving meaningful patterns among random stimuli (Whitson and Galinsky 2008) or by increasing faith in governmental institutions or in God (Kay, Gaucher, Napier, Callan, and Laurin 2008). In the current work, we suggest that people may deal with such uncertainty on a more basic experiential level – through seeking specific haptic sensations.

Touch is the first sense to develop and is critical in understanding and dealing with the world. Early haptic sensations importantly shape our memories and drive our future behavior (Gallace and Spence 2010). Interpersonal touch forms the foundation for beliefs about caring and comfort. Research shows that such learned beliefs can affect our behavior. For instance, in one study a simple pat on the back increased people's sense of security and led them to make riskier financial decisions (Levav and Argo 2010). Even touching non-personal objects, such as a teddy bear, influenced people's behavior and affective experiences by making them act more prosocially after social exclusion (Tai, Zheng, and Narayanan 2011) or by reducing their negative mood (King and Janiszewski 2011).

As touch is associated with comfort, we hypothesize that simply touching, holding, or feeling something soft may be an effective way to deal with uncertainty. More specifically, we propose that, when feeling uncertain, consumers will seek such haptic sensations and choose products with softer as compared to harder properties. In addition, we predict that softness is functional and that it reduces feelings of uncertainty. Three experimental studies tested these hypotheses.

In experiment 1, participants read and wrote about life events that were characterized by either high levels of uncertainty (e.g., financial scarcity, job loss) or high levels of certainty (e.g., financial stability, good health services). Subsequently, participants unobtrusively experienced softness by drawing two pictures with two pens – one with a soft-grip and one with a hard-grip (counterbalanced). As a token of appreciation, participants were then asked to choose one of these pens. The results showed that participants who had earlier read about certainty were no more likely to choose the soft or hard pen (18, 18). Uncertain consumers, however, chose the soft-grip pen more often (27) than the hard-grip pen (9). There were no differences in mood between conditions. Hence, the effect of certainty on preference for softness cannot be attributed to mood.

In experiment 2, we conceptually replicated the results of experiment 1 using a different behavioral measure – namely, the choice between a hard and soft sweet. Additionally, we incentivized choice of the hard candy by making the hard candy more attractive than the soft one. (Pre-test results confirmed that the hard candy was indeed more attractive than the soft candy.) Thus, not surprisingly, certain participants chose the soft candy much less often (2) than the hard candy (21). Uncertain participants, however, chose the soft candy about as often (9) as the hard candy (11). Thus, across two experiments, uncertain consumers deviated from certain consumers by switching towards a softer commodity.

In the last experiment, we demonstrate that consumers do not only deal with uncertainty through touching something soft, but that softness also has the capability to *restore* certainty. After uncertainty/certainty was induced, participants were asked to write down the objects they believed were hidden in a Snowy Picture Task (SPT, Ekstrom, French, Harman, and Dermen 1976) while writing either with a soft-grip pen or with a hard-grip pen. Importantly, for each object they were asked to indicate how uncertain/certain they felt about their answers. In addition, participants were asked right after the manipulation (time point 1) and right after the SPT (time point 2) how uncertain/certain they felt at the time. As expected, uncertain consumers felt more certain about their answers on the SPT after writing with a soft-grip pen than after writing with a hard-grip pen, whereas there were no differences between conditions for certain consumers. Furthermore, uncertain consumers felt, as predicted, more certain at time point 2 than at time point 1 after using a pen with a soft-grip, whereas using a pen with a hard-grip did not change feelings of uncertainty. For certain consumers, on the other hand, using a soft-grip pen induced uncertainty, whereas using a hard-grip pen kept their level of certainty equally high over time.

Across three experiments, using two different behavioral measures, results indicate that feelings of uncertainty induce a preference for soft products. Furthermore, we found that softness can mollify feelings of uncertainty. This finding indicates that, in the face of uncertainty (e.g., prospect of financial scarcity), solace can be found

and uncertainty can be reduced through the experience of soft haptic sensations.

Perceived Resource Scarcity Reduces Trust among Men but Increases Trust among Women

EXTENDED ABSTRACT

Trust plays a crucial role in both economic and social transactions (Fehr 2009). In this research, we examined whether merely altering people's perception of available resources can affect their trust, and whether perceived resource scarcity has different effects among men and women. From an evolutionary perspective, times of resource scarcity should have differentially affected men and women. In particular, when resources were relatively scarce, competition for dominance might have increased among men (Daly and Wilson 1988), but attempts to affiliate with others for social support might have increased among women (Taylor 2002). We therefore predicted that perceived resource scarcity would decrease trust among men, but increase trust among women. We tested this prediction in two experiments by manipulating the amount of two separate resources (food and money) that participants felt were available to them and measuring their trusting attitudes and actual trusting behavior.

In experiment 1, forty-seven undergraduate students read a scenario in which they were asked to imagine traveling to a new country they had never visited before. We manipulated the perceived scarcity of food by telling some participants to imagine that, upon arriving in a small village, they discovered that it was a national holiday and all the stores and restaurants were closed until the next morning. They were further told that they only had a small amount of food with them, which would have to last until the stores reopen in the morning. Participants in the abundance condition read the same story but were told that they had more than enough food in with them to last until the morning. As a manipulation check, we asked all participants the extent to which they felt they had enough food to last until the next day. This measure confirmed that participants in the scarcity condition reported having less than enough food to last them until the next day, relative to the abundance condition; the manipulation was equally successful for men and women (i.e., the interaction was not significant).

After reading this scenario, participants completed the Interpersonal Trust Scale (Rotter 1967), which is designed to measure an individual's propensity to trust other people (e.g., "Most people can be counted on to do what they say they will do.") A 2 (resources: scarcity vs. abundance) X 2 (gender: male vs. female) ANOVA on the Interpersonal Trust Scale revealed no main effects. However, there was a significant Resources X Gender interaction, whereby women in the scarcity condition trusted significantly more than women in the abundance condition, whereas men in the scarcity condition trusted relatively (but not significantly) less than men in the abundance condition.

In experiment 2, sixty-six undergraduate students participated in a "trust game" for real money (Berg, Dickhaut, and McCabe 1995). All participants played the role of sender, in which they had the option of keeping a €5 endowment for themselves (not trust) or sending it all to an anonymous partner (trust). If sent, the money would be quadrupled to €20 and the receiver then had the option of returning half the money to the sender or keeping it all for him/herself. We induced feelings of financial scarcity or abundance by changing the categories on a scale asking participants how much money they had in their checking and savings account, such that most respondents either placed themselves in the lowest (scarcity condition) or highest (abundance condition) category (for a similar manipulation, see

Nelson and Morrison 2005). We then measured their decision to trust and their beliefs about the trustworthiness of their partner.

We regressed the decision to trust on resources condition, gender, and the interaction between resources and gender. The only significant effect that emerged from this model was a Resources X Gender interaction. Men in the scarcity condition trusted less than men in the abundance condition, whereas women in the scarcity condition trusted more than women in the abundance condition. We also found a Resources X Gender interaction on perceived trustworthiness of their partner. Mirroring the pattern from the decision to trust data, scarce men thought that their partner would be less likely to split the money evenly with them compared to abundant men, whereas scarce women thought that their partner would be relatively more likely to split the money evenly with them compared to abundant women.

Taken together, the results of two experiments suggest that the perceived availability of critical resources such as food and money can have different effects on trust beliefs and behavior among men and women. These findings suggest that changes in macroeconomic conditions—such as the recent global financial crisis—might lead men and women to adopt different strategies for coping with the resulting threat to their personal resources.

Mental Accounting in the Context of Poverty

EXTENDED ABSTRACT

While the mental accounting literature has contributed to the understanding of general consumer behavior, no work to date has examined these phenomena with respect to low-income consumers. In terms of simple, everyday decisions regarding buying and saving, low- and high-income decision makers make many of the same choices. Deciding whether to spend more time to save a certain amount of money is a common choice for both groups, but these choices might be more consequential for lower-income individuals. In addition, low-income individuals might be more used to focusing on smaller amounts, amounts that may carry less meaning for those with greater incomes. Saving a modest amount on a pair of shoes might seem appealing to both groups, but the lack of a financial buffer experienced by low-income individuals might make them more sensitive to the absolute amount saved rather than the proportion of the total amount saved.

We hypothesize that low-income individuals might not replicate the traditional topical accounting pattern observed in previous experiments that examine the willingness to travel to save a fixed amount of money on either a large or a small purchase (Tversky and Kahneman 1981). Specifically, because they live in a context where modest sums of money matter more, low-income individuals may not be as sensitive to different proportional amounts to be saved. The scenarios presented represent reasonable choices that both groups may face, but the context of poverty may cause low-income individuals to be more sensitive to absolute amounts. Overall, the main goal is to argue that, for some mental accounting scenarios, generalizing from findings demonstrated with high-income groups does not accurately describe the behavior of low-income decision makers. Low-income individuals do not show the same pattern of preference for relative over absolute savings (for modest amounts), resulting in a different pattern of results than what has traditionally been described by the literature.

In these surveys, we show that low-income individuals do not replicate the traditional pattern of topical accounting results. Study 1 uses adapted versions of Tversky and Kahneman's (1981) stimuli, examining willingness to travel to save money. Study 2 more rigorously extends this using a novel, within-subjects design which forces

participants to choose between saving scenarios. In study 3, explore the relationship between numeracy and these effects.

In Study 1, low-income participants did not replicate the usual findings consistent with a strong preference for proportional saving. High-income participants demonstrate the expected preference reversal, while low-income participants seem more concerned with the absolute amount in these cases. In Study 2, this finding is supported using a novel, within-subjects design. When asked to decide between two saving options, high-income participants prefer the savings option that reflects the greater proportion. When the amount saved is not identical, high-income participants still choose the greater proportion, even when it is a lower absolute amount. Low-income participants do not replicate this; instead, they appear to rely more on absolute values. These findings may suggest that low-income individuals are more sensitive to modest amounts; without the buffer enjoyed by individuals in a higher-income context, low-income individuals may be more sensitive to absolute amounts, even under similar types of choice scenarios. The third study examines the rela-tionship between numeracy and willingness to save. Previous studies have shown that individuals higher in numeracy are more likely to show the preference for a higher amount of proportional savings. This study replicates this pattern for the high-income consumers, but does not hold for the low-income participants. Lower-class consumers show the same pattern as in the previous studies, regardless of their level of numeracy.

Across this set of studies, the results for high-income individuals are consistent with previous findings in the literature. Of greater interest are the responses by low-income individuals. The data suggest that, relative to the high-income respondents, low-income respondents are more sensitive to absolute savings. Low-income participants do not show a clear preference for saving the greater absolute amount. They appear to be influenced by smaller relative sums that generate greater proportional savings. In contrast, high-income individuals appear to focus on the absolute amount at these moderate levels of saving.

How Corporate Social Responsibility Influences Consumers

Paper #4: Is Less More When Communicating Sustainability? Consumer Response to Ambiguous versus Detailed Sustainability Product Labels
> Rebecca Walker Naylor, The Ohio State University, USA
> Remi Trudel, Boston University, USA

SESSION OVERVIEW

A recent survey shows that when marketers invest in corporate social responsibility (CSR) initiatives, enhancing relationships between consumers and brands is the number one objective (BCG/MIT Sloan Management Review). Consumers report higher intentions to purchase goods and services from companies known for CSR, and willingness to pay higher price for those goods and services (e.g., Cotte and Trudel 2009). However, market data suggests that these intentions do not materialize in consumer behavior, since many products marketed by firms with strong CSR reputations remain niche products. Recent research suggests that the relationship between CSR and consumer behavior is complex, and CSR initiatives sometimes lead to *decreased* consumer preference (e.g., Luchs et al., 2010). The objective of the proposed session is to more deeply examine how, when and why CSR initiatives influence consumer behavior. The research presented here addresses calls from previous researchers to "unpack" the causal mechanisms by which CSR can lead to enhanced business performance and/or social and environmental outcomes (e.g., Margolis, Elfenbein, and Walsh 2009; Peloza 2009).

The proposed session includes four papers that are completed works, or all in advanced stages of completion including data collection in multiple studies. Across four papers, CSR's impact on consumer behavior is examined in new ways. For example, the session will provide important insights into the conditions under which consumers support or resist CSR (all presentations), the equivocal role of perceived corporate intentions (presentations 1 and 3), how consumer behavior can lead to improved firm financial performance (presentation 2), and how the means by which CSR is communicated to consumers influences their support (presentations 1 and 4). In particular, Presentation 1 demonstrates that a reputation for CSR at a corporate-level leads consumers to overestimate the ability for the firms products to provide health and safety benefits. Presentation 2 suggests that firms benefit from increased consumer support when philanthropy is focused among a small portfolio of charitable causes. Presentation 3 examines how consumers attribute blame for corporate crises, with the counterintuitive finding that perceptions of

social (versus financial) motivations by the firm increase attributed blame. Finally, Presentation 4 examines how marketers can use either ambiguous or detailed product labels to more effectively gain consumer support for environmental initiatives. Although these four papers highlight different aspects of CSR and its ability to shape consumer attitudes and behaviors, they provide an integration of current research in a topic area that is of critical importance to the field of consumer behavior. In order to accommodate four papers in 75 minutes, we intend to allocate 15 minutes of presentation time for each paper with a 15-minute group Q&A session at the end.

Each of these papers make a strong contribution in its own right, and the collection of these papers in a special session allows for a highly focused discussion of the relationship between CSR and consumer behavior. However, although highly focused, the papers in this session represent a diverse range of perspective on CSR, and include a focus on both consumer and corporate outcomes, positive and negative aspects of CSR, a variety of forms of CSR, examined using a diverse set of theoretical bases. We therefore expect relatively broad interest from researchers interested in transformative consumer research, CSR, sustainability, prosocial behavior, consumer well-being, public policy and branding to name a few. We believe that our understanding of how CSR impacts consumer behavior is in its infancy, and this session will serve as a catalyst for future research initiatives and a basis for valuable discussion at the conference.

Is Corporate Social Responsibility Good For You? How Corporate-Level CSR Impacts Consumer Perceptions of Product-Level Attributes

EXTENDED ABSTRACT

Early research in corporate social responsibility (CSR) demonstrated that it leads to benefits for marketers through corporate level, as opposed to product level, effects. For example, activities such as charity donations lead to enhanced consumer-company identification (e.g., Bhattacharya and Sen 2003). Brown and Dacin (1997, p. 70) argue that a positioning based on CSR "offers consumers little information that is directly associated with the products and services it provides." More recently, researchers have examined the potential for CSR to directly influence perceptions of product performance. For example, Luchs et al. (2010) find that when products are positioned with attributes that make environmental sensitivity a priority (e.g., detergents and soaps made from eco-friendly ingredients), consumers may infer product performance trade-offs. In this more recent stream of research, although CSR impacts consumers' product performance evaluations, CSR is conceived in a fashion that makes it highly salient to product performance (e.g., source ingredients).

The current research posits a third route to consumer influence through CSR, and bridges the gap between these two literatures by examining the potential for corporate-level CSR initiatives such as philanthropy to impact perceptions of product attributes and performance. Specifically, this research posits that when companies position themselves as compassionate and caring through activities such corporate philanthropy, it leads consumers to over-estimate product attributes related to their own well-being (e.g., healthiness, calorie content, etc.). The theory behind this effect is derived from the literature on consumer inference-making. Kardes, Posavac, and Cronley (2004) demonstrate that consumers form inferences about missing information by making connections between the missing informa-

tion and other available information. This research proposes that perceptions of product attributes related to consumer well-being are influenced by consumer inferences of stakeholder stewardship by the firm.

We demonstrate these effects across four studies. In Study 1, participants estimated a lower number of calories, saturated fat and trans fat in granola bars marketed from a company described as highly involved in corporate level CSR activities (e.g., donations to charity, treatment of employees) than a company with a neutral CSR reputation. Triangulating these nutrition estimates were concurrent estimates of better taste of the product marketed by the firm with a neutral CSR reputation (i.e., unhealthy=tasty, Raghunathan et al. 2006). Study 2 examines the role of firm intentions behind the CSR and finds that when firms engaged in CSR activities are viewed as motivated by community concern versus public image management, their products are perceived as healthier. This effect is consistent across calories, saturated and trans fat and sodium, as well as a general measure of product healthiness. We again find that perceptions of taste are higher for the firm not motivated by community concern.

In Study 3 we demonstrate that products marketed by firms with strong corporate level CSR reputations are particularly attractive to health conscious consumers, who state higher purchase intentions for such products compared to consumers low in health consciousness. Further, we find that health conscious consumers demonstrate higher purchase intentions to products advertised using CSR appeals versus more direct health appeals. We show that skepticism toward the more informational approach of health appeals is behind these effects. Finally, in Study 4 we replicate our findings with a parent sample examining perceived sunscreen safety. We demonstrate that parents are more likely to purchase sunscreen marketed by a firm with a strong (versus weak) corporate level CSR reputation, and that this effect is mediated through perceived product safety.

This research extends previous studies that examine the perceived trade-off between product performance and ethics (e.g., Sen and Bhattacharya 2001), and contributes to the literature examining the business case for CSR (e.g., Peloza 2009). The research also extends prior research examining inference-making with product-level attributes (e.g., how perceptions of taste are altered by labeling (Allison and Uhl 1964) or product color (Hoegg and Alba 2007)). Elder and Krishna (2009, p. 755) note that impacts of heuristic-based cognition on perception is a "fruitful area for future research" and that "thoughts generated by other extrinsic cues could be equally as intriguing." The proposed corporate-level examination represents an extension on this basis.

Managing Charitable Giving: Cause Portfolio Dimensions And Their Impact on Stakeholder Evaluations

EXTENDED ABSTRACT

Firms donate a substantial amount of their profit to non-profit organizations. According to the Foundation Center (2010), giving of corporate foundations rose by 3.9 percent in 2008 to $4.6 billion. As charitable giving increases, firms shift their focus to the profitable management of these activities. Recent studies have highlighted the complexity of the charitable giving – performance relationship (Wang, Choi, and Li 2008; Lev, Petrovits, and Radhakrishnan 2010) and the objective of this research is to understand whether and when a firm's giving activities create value for the firm. To date, most studies focus on the impact of the *amount of giving* on firm value but little is known about the impact of the *allocation of giving*.

To investigate how allocation decisions create value for the firm, we develop the concept of cause portfolios which we define as all relationships a firm builds with non-profits as part of its day-to-day business activities. The size and diversification of the cause portfolio should be guided by brand and market considerations (Varadarajan and Menon 1988) and take into consideration the different stakeholder groups of the firm (e.g., consumers). A firm can promote the varying interests of these stakeholder groups through their charitable giving activities (Drumwright 1996) which can result in improved performance, such as higher perceptions about the firm and its brands, higher satisfaction, stronger identification with the firm, and higher purchase intentions (Brown and Dacin 1997; Creyer and Ross 1997; Luo and Bhattacharya 2006; Marin and Ruiz 2007; Sen and Bhattacharya 2001). To obtain these benefits from its cause portfolio investments, firms have to manage the relationships within the cause portfolio properly. Depending on how portfolio characteristics, such as size and diversification, are managed, firms may or may not be able to attain the same level of return.

We base our predictions on relationship management theory to propose a mechanism that explains why these cause portfolio characteristics (e.g., size and diversification) have a differential impact on stakeholder evaluations and thus firm value. We propose that diverse cause portfolios are more strongly associated with positive outcomes for the firm when the portfolio is small rather than large. Stakeholders make assessments about the firm's motivation to give to charities and non-profits. If a cause portfolio appears to be stretched too far in both size and scope, then stakeholders should have lower perceptions of the firm. As firms donate to a large number of non-profits associated with various causes, it should become more difficult for the stakeholders to identify the focus of the firm's giving activities. This, in turn, should lower the perceptions that the firm is committed to the causes in the cause portfolio. Furthermore we propose that perceived commitment mediates the relationship between cause portfolio characteristics and performance outcomes.

In Study 1, we address our hypotheses using an experimental setting. Participants (n=86) were asked to read about Company Y, a bath company that makes shampoos, hand and face soaps, and lotions. Participants were told that Company Y was selling a new body wash and were provided a brief description of it. Further, participants were told that Company Y is helping the community through its support of certain causes. Participants were shown one of four conditions in a 2 (Size: Small [5 charities] vs. Large [20 charities]) X 2 (Diversification: Diverse vs. Focused) between-subjects design. After reading the scenario, participants rated the body wash on the following variables of interest: purchase likelihood and perceived commitment of the company to the causes. The results showed a significant interactive effect of size and diversification ($F(1, 85) = 3.99, p < .05$). The results show that for a diverse portfolio, purchase likelihood is greater when it only includes five charities compared to twenty charities ($p < .05$). We do not see such a difference in perceptions for a focused portfolio. Therefore, the findings of the experiment confirm our prediction that diverse portfolios are more likely to lead to better performance when they are small as compared to large. Furthermore, we tested for mediated moderation and in line with our prediction we find that perceived commitment of the firm to the cause portfolio mediates the relationship between cause portfolio characteristics and performance.

Data from secondary sources confirm our findings from our experimental study and show that both a large and a diverse cause portfolio that targets different giving areas, such as education, health, or the environment, can be beneficial but the simultaneous pursuit of a large and diverse cause portfolio is not rewarded by the firm's

stakeholders. We find that this pattern of results holds for different stakeholder groups evaluating a firm's charitable giving activities including both consumers and investors. Finally, we examine whether a stakeholder's perception of the firm's charitable engagement is in line with the actual social impact of the firm. Using information on the firm's community social performance, we also find evidence that firms with diverse portfolios are not better at meeting stakeholder expectations regarding community impact when the portfolio is large compared to a diverse and small portfolio.

This present paper provides some initial insights into the structural management of charitable giving. We show that, besides the overall amount of giving, characteristics of the cause portfolio, such as size and diversification, matter to consumers (and other stakeholder groups) and thus influence the likelihood that firms receive a return on their charitable giving. In summary, our results show that in order to appeal to consumers, cause portfolios have to be properly managed.

Can Social Responsibility Backfire? The Role of Intentions in Times of Corporate Crisis

EXTENDED ABSTRACT

The purpose of the current research is to examine the impact of a corporate crisis on consumer perceptions of a firm involved in the crisis. We advance prior research on corporate crises (Brown and Dacin, 1997; Gorn, Jiang and Johar, 2008; Luchs et al., 2010; Palmatier et al., 2009; Sen and Bhattacharya, 2001; Yoon, Gurhan-Canli and Schwarz, 2006) by incorporating the role of counterfactual thinking. Specifically, in this paper, we theorize how consumer perceptions of a firm embroiled in a crisis are driven not only by thoughts about what the firm has done wrong but also by thoughts about what the firm could have done differently to prevent the crisis. We theorize that such processing is affected by the intentions that a firm states for actions taken preceding the crisis. In this research, we focus on two different types of intentions that firms state for corporate decisions (socially-motivated versus profit-driven) and find evidence to support the counter-intuitive notion that a socially-motivated as opposed to a profit-driven intention leads consumers to think more about what the firm could have done differently to prevent the crisis and as a result to deem the firm more blameworthy for the crisis. In this paper, we also identify factors surrounding corporate crises (i.e., outcome of a default event and emotions) that not only amplify the degree of blame that consumers bestow on a firm but also isolate the process through which consumer perceptions of a firm are formed in times of crisis.

In Study 1, we asked a total of 135 undergraduate students to participate in a 2 (stated intention for a focal corporate decision: socially-motivated versus profit-driven) x 2 (outcome of the default event: different versus similar) between-subject study for course credit. The study involved participants reading an article about the financial bailout of *General Motors (GM)*. Thus, information about our two factors as well as information about a corporate crisis involving *GM* was communicated to participants via the article. For clarity, we believe that it is important to define the term default event. In the counterfactual thinking literature, a default event is defined as "a highly available counterfactual mutation to the factual event; it is the event that readily comes to mind as an alternative to the factual event that preceded some to-be explained outcome" (Wells and Gavanski 1989, p.162). Notably, the outcome of a default event is commonly used in the counterfactual thinking literature as a way to either accentuate or attenuate the degree of counterfactual thought processing. For example, prior research has shown that more

(less) counterfactual thinking occurs when the outcome of a default is different (similar) than that of the actual event. Thus, in Study 1, we posit and show a significant interaction between stated corporate intentions and the outcome of a default event. Specifically, we find that when consumers read about *GM*'s corporate crisis and learn that a default event existed which would have yielded a different (versus similar) outcome than the actual event, knowledge that *GM* had a socially-motivated as opposed to a profit-driven intention leads to more counterfactual thoughts implicating *GM* and as a result to more negative consumer perceptions of *GM* (i.e., mediation supported). Thus, these results support the proposed theorizing.

Next, we garner additional support for our counterfactual thinking perspective by examining the role of emotions, which is another factor shown to produce counterfactual thinking (Meyers-Levy and Maheswaran, 1992). While a number of negative emotions exist, we focus on the effects of two - anger and sadness - because they are relevant to the context of corporate crises and appraisal theory suggests differential implications for counterfactual thinking. Specifically, anger tends to arise out of an attribution that others are responsible for the situation, whereas sadness tends to be associated with the attribution that events are beyond anyone's control (Han, Lerner and Keltner, 2007). Also, anger (sadness) increases (decreases) the tendency to blame others, as consumers have been shown to direct attributions outward as they attempt to resolve a violation (Maheswaran and Chen, 2006). Thus, we theorize anger (sadness) will accentuate (attenuate) Study 1 effects.

To test this notion, we asked a total of 209 undergraduate students to participate in a 2 (emotion: anger versus sadness) x 2 (stated intention for focal corporate decision: socially-motivated versus profit-driven) x 2 (outcome of the default event: different versus similar) between-subject study for course credit. The procedure was identical to that used in Study 1 except for the following: prior to presenting an article about *GM*, participants in the *anger (sadness)* condition were asked to recall an event that made them angry (sad) and to describe their emotions in a personal essay (Maheswaran and Chen, 2006). As expected, we found a significant three-way interaction. Specifically, we find that when consumers feel angry, read information about *GM*'s corporate crisis, and learn that a default event existed which would have yielded a different (versus similar) outcome than the actual event, knowledge that *GM* had a socially-motivated as opposed to a profit-driven intention leads to more negative consumer perceptions of *GM*. Notably, sadness did not exhibit this pattern of results.

This research contributes to the literature on product and service failure, social responsibility, emotions and counterfactual thinking. The findings suggest firms stating socially responsible intentions expose themselves to additional risk once crises occur. This hypothesis differs from predictions made using attribution theory perspectives to corporate crises. This research accounts for this divergence by providing evidence of an additional mechanism through which assessments of blame arise via counterfactual thinking. The research also conjoins emotions and counterfactual thinking to reveal theoretical linkages between these important consequences of corporate crises.

Is Less More When Communicating Sustainability? Consumer Response to Ambiguous versus Detailed Sustainability Product Labels

EXTENDED ABSTRACT

As more sustainable products flood the marketplace each year (Luchs et al. 2010), consumers are faced with the increasing chal-

lenge of trying to discern which products positioned as "sustainable" actually deliver on this promise. To do so, an increasing number of consumers are turning to various on-product labels designed to communicate sustainability. Although ample past research in marketing has explored how consumers respond to product labels, much of this research has focused on consumer response to nutrition labels (e.g., Block and Perrachio 2006). Unlike nutrition labels, which are mandated by the Nutritional Labeling and Education Act (NLEA), labels designed to communicate sustainability can take almost any form. New standards for water use, packaging, recyclability, and carbon impact are competing for attention and space, and multiple versions of the same label are in use (e.g., detailed vs. ambiguous versions of the Carbon Reduction Label). This situation creates a challenge for marketers since it is an open question how best to communicate sustainability to a broad audience that varies in their interest in sustainability.

Our research seeks to provide guidance on this issue, focusing specifically on how consumers respond to different variations in detail on sustainability labels. We hypothesize that the consumer response to sustainable products will depend both on the level of detail in labeling and on consumers' level of concern for the environment. Specifically, we hypothesize that consumers with relatively low levels of concern for the environment will respond more positively to ambiguous than to detailed sustainability labels. Ambiguous labels that do not provide detail about a sustainable product's characteristics are more appealing to these consumers because they do not lead the consumer to think in-depth about the environmental issue behind the label (e.g., the consequences of global warming when reading a Carbon Reduction Label). More detailed labels can lead consumers who would not normally think about environmental issues to do so in greater detail than they wish to, making them feel less hopeful about the issue, resulting in negative affect that transfers to the product itself. Conversely, specific labels do not negatively impact consumers who care a great deal about environmental issues because these consumers are already inclined to think about these issues in detail regardless of the amount of information featured on a label.

To test this hypothesis, we conducted two studies using the Carbon Reduction Label, an on-pack sustainability label that consumers can use to check whether products are working with the Carbon Trust to reduce their carbon emissions. The label exists in multiple versions, all with a footprint graphic; in addition to this graphic, the ambiguous version reads "Reducing with the Carbon Trust," while the detailed version includes this wording plus specific information about the carbon footprint. Our studies used t-shirts as stimuli, so the detailed version of the label showed the carbon footprint (in kg) per garment.

Study 1 employed a 2 (label type: ambiguous vs. detailed) x green personal identity design where green personal identity was a measured variable (GREEN scale; Haws, Winterich, and Naylor 2012). All participants viewed a webpage about a brand of sustainable t-shirts called "Green Label T's" that was purportedly working with the Carbon Trust to reduce carbon emissions. The label shown was either ambiguous or detailed, depending on condition. After viewing the t-shirts and label, all participants then indicated how much they liked the t-shirts. Participants subsequently completed a questionnaire that included the GREEN scale. The results support our hypothesis with a significant interaction between label condition and score on the GREEN scale ($F(1, 62) = 9.86$, $p < .01$). Follow-up analyses indicated that participants with low scores on the GREEN scale liked the product more when the sustainability label was ambiguous ($F(1, 62) = 3.71$, $p = .06$), while participants with high scores on the GREEN scale liked the product more when the sustainability label was more detailed ($F(1, 62) = 6.43$, $p < .05$).

Study 2 employed a 2 (label type) x 2 (prime: green vs. neutral) design where level of environmental concern was manipulated by a sentence unscramble task designed to prime a "green" mindset. Participants once again indicated how much they liked the t-shirts after viewing the shirts and label. After doing so, all participants completed a follow-up questionnaire. One of the questionnaire items measured our hypothesized mediator, "When you think about the problem of carbon emissions negatively impacting the environment, how *hopeful* do you feel about the chance of correcting this issue". Results revealed a significant label x prime interaction ($F(1, 212) = 3.65$, $p = .06$). Participants in the neutral prime condition (i.e., participants not primed to have high levels of environmental concern) liked the shirts better when they saw the ambiguous (vs. detailed) label ($F(1, 212) = 6.50$, $p < .05$). Label condition did not impact liking for participants primed to have a high environmental concern ($F(1, 212) = 0.13$, NS). To provide support that label and environmental concern influence how much consumers like the t-shirt through hopeful, we conducted a moderated mediation analysis (Preacher, Rucker, and Hayes 2007; model 2). The first, mediator model revealed a significant main effect of label ($\beta = -.54$, $p < .05$) and a significant environmental concern x label interaction ($\beta = .79$, $p < .05$) on hopeful. The second, dependent variable model examined the effects of label, environmental concern, hopeful, and the interaction between label and environmental concern on how much participants liked the t-shirts. The dependent variable model showed a significant effect of hopeful ($\beta = .15$ $p < .05$), and label ($\beta = -.67$ $p < .05$) on how much participants liked the t-shirt while all other effects proved to be non-significant (ps > .10). Bootstrapping techniques employed to test conditional indirect effects confirmed the mediating role of hopeful for consumers low in environmental concern (95% confidence intervals excluding zero; -.25 to -. 01) but not for consumers high in environmental concern (95% confidence interval includes zero; -.02 to .18) (Preacher et al., 2007; Zhao et al., 2010).

Construal Levels: New Antecedents, Insights and Implications

SESSION OVERVIEW

Since the publication of Liberman and Trope (1998), considerable work has been devoted to the theme of construal level theory. Despite the large amount of research in this area, some critical gaps remain. The objective of this session is to address these underexplored questions. Below, we briefly describe these gaps and how each paper seeks to bridge them.

First, while it is now well established that psychological distance influences construal levels, the fundamental question of why this is so has received limited attention. The paper by Yan et al. suggests one possible mechanism, arguing for an intervening role of mode of processing (visual vs. verbal). Consistent with this argument, their studies reveal that people tend to process psychologically near events visually by forming mental images, while processing distant events verbally. In turn, visual (vs. verbal) processing leads to more concrete, lower level construals, thus explaining the oft-observed impact of psychological distance.

Second, extant research on the antecedents of construal level has primarily focused on the four dimensions of psychological distance (e.g., temporal, social, etc.). Surprisingly little attention has been devoted to identify other possible drivers (for exceptions, see Labroo and Patrick 2009; Lee, Keller, and Sternthal 2010). Drawing on perspectives on grounded cognition, the paper by Aggarwal and Zhao identifies a novel antecedent: the physical height at which people are currently imagining themselves to be. This paper proposes and shows that locations higher up (e.g., a hot-air balloon ride) are associated with a big-picture perspective and induce a higher level of construal, while locations lower down (e.g., a deep-sea diving trip) are associated with a detail-oriented perspective, inducing lower levels of construal.

Third, research on the antecedents of construal level has typically adopted a cognitive perspective, arguing in terms of existing, overgeneralized associations between antecedent factors such as psychological distance, and the evoked level of construal (Trope and Liberman 2003); indeed, the paper by Aggarwal and Zhao above, while it identifies a novel antecedent, also draws on an association-based perspective. Much less is known, however, about motivational factors underlying the activation of construal levels. The paper by Fujita and MacGregor, to our knowledge, is among the first to examine this possibility. Specifically, the authors propose and find that in order to resist proximal temptations (which break down defenses by activating low-level construals), people deliberately activate high-level construals, which in turn facilitates self-control.

Finally, in addition to exploring novel questions regarding the antecedents of construal level, this session also provides new insights into the consequences end of the spectrum. A large body of empirical studies in psychology and marketing has shown a negative impact of regulatory depletion: performing a prior self-control task impairs performance on a subsequent task. In contrast, the paper by Wan and Agrawal draws on construal level theory to predict and demonstrate the reverse: experiencing regulatory depletion shifts individuals' construals to lower levels, and therefore enhances performance on subsequent tasks that require attending to lower-level, contextual details.

Why Does Psychological Distance Influence Construal Level? The Role of Processing Mode

EXTENDED ABSTRACT

Construal level theory proposes that people tend to construe psychologically distant (proximal) events at higher (lower) levels. Much empirical evidence has since been obtained for the proposition (Trope and Liberman 2010). Surprisingly little, however, is known about the mechanisms underlying the effect of psychological distance on construal levels. The objective of the present research is to fill this gap by proposing and testing such a mechanism.

Our argument conjoins two premises: a) proximal (vs. distal) events are more likely to induce imagery-based (vs. verbal) processing; b) visual (verbal) processing leads to relatively concrete, low-level construals (vs. abstract, high-level construals). The paper on which this abstract is based reviews several lines of thought supporting each premise; here, we report one such supportive argument for each. The first premise is consistent with research showing that when an event is temporally closer or more likely to happen (vs. distant or less likely to happen), people are more likely to form implementation intentions (Trope and Liberman 2003); in turn, forming implementation intentions usually involves mentally imagining the steps that must be taken to achieve a goal (Gollwitzer 1999). The second premise is consistent with definitions of "concrete", which comprise ideas such as "capable of being perceived by the senses", "real", "actual", etc. Because visualized information (as opposed to verbal information) can be directly perceived by the senses, it should induce a more concrete construal. Relatedly, much research suggests that imagining an event makes it more "real" (Carroll 1978; Rajagopal and Montgomery 2011) – again, this argues for a link between visual/verbal processing on the one hand, and concrete/abstract construals on the other.

We tested our proposition in four studies. Study 1 used a 2 (task orientation: visual vs. verbal) x 2 (temporal distance: proximal vs. distant) design. Participants were first asked to write a short essay about "this weekend" or "a weekend in 2020". They then tried to solve a puzzle that involved either a hidden figure or a hidden word. Consistent with the premise that near (far) events induce visual (verbal) processing, participants in the proximal condition performed better in the hidden figure task ($M_{proximal} = 6.68$ vs. $M_{distant} = 5.27$; $t = 2.80$, $p < .01$), but worse in the hidden word task ($M_{proximal} = 2.09$ vs.

$M_{distant}$ = 3.06; t = 1.94, p = .06; 2-way interaction $F(1, 125)$ = 11.23, p = .001).

In study 2, participants were first asked to imagine that a friend was visiting Hong Kong either tomorrow or a year from now and they were to show her around. Then they were shown a list of 40 tourist attractions in Hong Kong and asked to categorize them into groups. Participants also responded to two items that measure their extent of mental imagery while completing the categorization task. Participants generated more categories ($M_{proximal}$ = 5.59 vs. $M_{distant}$ = 4.17; $F(1, 65)$ = 10.43, p < .01) and were more likely to form mental imagery when the event was proximal vs. distant ($M_{proximal}$ = 3.72 vs. $M_{distant}$ = 2.64; $F(1, 65)$ = 128.37, p < .001). Importantly, a mediation analysis showed that the extent of mental imagery mediated the effect of temporal distance on construal level.

Study 3 tested our proposition by examining theoretically-derived boundary conditions for the impact of psychological distance. If processing mode indeed mediates the effect of distance on construal level, this effect should attenuate both for chronic visualizers and verbalizers. That is, visualizers (verbalizers) should construe *both* distant and proximal events at a lower (higher) level. Hypothetical distance was used to operationalize psychological distance. Participants were asked to imagine that their friend was planning to visit Hong Kong, with a likelihood of either 95% or 5%. They then completed the same categorization task as in study 2, before filling out the Style of Processing Scale (SOP; Childers, Houston & Heckler 1985), which assesses the chronic tendency to form visual images. As expected, lower hypothetical distance (t = 2.80, p < .01) and higher scores on SOP (t = 6.92, p < .001) both led to more categories being formed. More importantly, spotlight analyses revealed that the effects of hypothetical distance on construal level became non-significant for chronic verbalizers, and also for chronic visualizers (p's > .10).

Study 4 replicated these findings while manipulating processing mode and examining the social dimension of psychological distance. A 2 (social distance) x 3 (visualizing vs. verbalizing vs. control) between-subject design was employed. Participants first completed either a hidden figure or word puzzle (visualizing vs. verbalizing conditions). Those in the control condition did not perform any task. Afterwards, participants received information about a target person, described as being very similar or very dissimilar to them. All respondents then completed the BIF measure (Behavioral Identification Form; Vallacher and Wegner 1989), which is a standard assessment of activated construal level; higher means indicate more abstraction. The control condition obtained the usual effect of social distance on construal level: distance produced more abstract construals ($M_{proximal}$ = 14.77 vs. $M_{distant}$ = 16.59; $F(1, 187)$ = 3.45, p = .07). Further, those in the visualizing condition reported more concrete construals than those in the verbalizing condition ($M_{visualizing}$ = 14.73 vs. $M_{verbalizing}$ = 16.32; $F(2, 187)$ = 2.97, p = .05). Most importantly, the visualizing condition led to relatively concrete construals irrespective of social distance (Ms = 14.52 vs. 14.94, t < 1, p > .60), while the verbalizing condition produced abstract construals irrespective of distance (Ms = 15.95 vs. 16.79, t < 1, p > .30). These findings are consistent with the proposition that the effect of social distance on construal level was indeed driven by the processing mode.

Our paper contributes to the construal level literature by identifying one possible mechanism that underlies the effects of psychological distance on construal level. We also add to the mental imagery literature by identifying a new factor (psychological distance) that can influence the tendency to engage in visual versus verbal processing.

Do Lilliputians See the Big Picture? The Effect of Physical Level on the Level of Construal

EXTENDED ABSTRACT

We often use terms like big-picture view or broad perspective to suggest a higher level of thinking, and limited vision or narrow view to describe a lower level of thinking. Clearly, vision is associated not just with the physical act of seeing but also with perspective in the metaphorical sense, that is, how one thinks. Is it possible that these two meanings of vision are linked to each other such that a person's physical location could influence the way in which that person thinks?

In this research, we draw upon prior work on grounded cognition (Barsalou 1999, 2008) and construal-level theory (Liberman and Trope 1998) to examine the interesting proposition that the physical level at which people imagine themselves to be affects their level of thinking. Specifically, locations higher up lead to a higher level of thinking, with a big-picture perspective, while locations lower down lead to a lower level of thinking, with a detail-oriented perspective. Recent work on grounded cognition suggests that people tend to associate their physical experiences, whether bodily or simulated, with more abstract conceptual meanings, and that changes in one tend to be associated with changes in the other (Barsalou 2008). For example, people who are primed with the physical experience of warm temperature (holding a warm cup of coffee) judge an unknown person as more likeable and friendly (socially warm) than do people who hold a cold cup of coffee (Williams and Bargh 2008). The key premise underlying these findings is that bodily states can be used to generate cognitive activity (Barsalou 2008). These findings are also consistent with prior work on metaphorical representations, which suggests that metaphors reflect something deeper about our ability to represent knowledge (Lakoff and Johnson 1980), and that the representation of abstract concepts might function in a similar manner, with metaphors being a manifestation of how we ground abstract thought (Barsalou 2008). For example, height is associated with affect (Meier and Robinson 2004), power (Meier and Dionne 2009), divine (Meier et al. 2007) and prosocial behavior (Sanna et al. 2011).

Extending this stream of research, we propose that physical level can affect people's construal level since physical view and mental view are metaphorically related. Because being physically higher up gives people a broad view of a situation, we believe that this physical experience is linked to the metaphorical meaning of taking a big-picture view, that is, a high level of construal, with greater focus on the central aspect of a decision. Thus, a higher physical level gives people the ability to see the forest without being distracted by the trees. Similarly, a physically lower level gives people a more detail-oriented view, which is linked metaphorically to a low level of construal, resulting in a greater focus on the peripheral aspects—resulting in the classic situation of not being able to see the forest for the trees. Put more formally, the main proposition is that physical level will influence level of construal such that a physically higher level leads to a high-level construal and a physically lower level will lead to a low-level construal. And this effect of level on construal occurs because individuals on a physically higher level are more likely to have big-picture orientation compared to those on a physically lower level.

We test our predictions through four studies using different manipulations of physical level and different dependent variables to assess level of construal. In Study 1 we compare people imagining a ride in a hot-air balloon with those imagining a deep-sea diving trip. Consistent with our hypothesis, participants in the high (hot-air balloon) condition were more likely to choose the LL (larger-later)

rewards over the SS (smaller-sooner) rewards compared to those in the low (scuba diving) condition (Ms = 86% vs. 63%, $\chi2$ (1) = 7.92, $p < .01$). Study 2 adapts a scenario from the children's classic Gulliver's Travels (Swift 2001) to demonstrate that participants who put themselves in the shoes of Gulliver (a tall person) indicate a greater preference for a higher-payoff, lower-odds gamble than are those who take the view of the Lilliputians (tiny people) (M = 6.77 vs. 5.69, $F(1, 91) = 5.24$, $p < .05$), and use more abstract terms to describe what they imagine seeing (Ms = 3.61 vs. 3.03, $F(1, 91) = 9.19$, $p < .01$). Further, participants' big-picture orientation score mediates the effect of height on the level of construal. Study 3 extends these findings to a real behavioral measure using a lottery. Physical level was manipulated by displaying locations on a map north and south of a city representing higher and lower physical levels (Meier et al. 2011). Results showed that those in the high condition (north) prefer receiving LL (larger later) rewards relative to those in the low condition (south) (Ms = 6.69 vs. 4.63, $F(1, 40) = 4.37$, $p < .05$). Finally, in Study 4, we take a more direct measure of the underlying process and find that those located on the upper level of a building prefer a job requiring a big-picture orientation relative to those on the lower level of the building (Ms = 5.32 vs. 7.39, $F(1, 44) = 4.58$, $p < .05$). Across the four studies, we rule out alternative explanations, including affect, perceived power, and physical distance.

This research contributes theoretically to growing research on embodied cognition, metaphorical representation and construal level theory. It also suggests itself to future investigation linking physical height (across gender, cultures, etc.) to their perspectives. In addition, the findings provide some very interesting managerial implications for industries such as real estate, airlines and subways.

When Proximity Prompts Abstraction: High-Level Construal as a Means of Counteractive Control

EXTENDED ABSTRACT

The allure of salient concrete and immediate rewards frequently tempts people to forgo the attainment of abstract and delayed goals. Research on counteractive control theory has revealed a number of cognitive and behavioral means by which people counteract the negative impact of proximal temptations on goal pursuit (e.g., Fishbach and Trope 2007). The present research proposes that high-level construal can serve a counteractive control function to promote self-control.

Construal level theory (CLT) suggests that one way that proximal temptations undermine self-control is by prompting low-level construal. CLT proposes that psychological distance impacts the way people subjectively represent or construe events (Liberman and Trope 2008; Trope and Liberman 2003; 2010). Psychological distance refers to the removal of an event from direct experience of the here-and-now. People often lack detailed information about distant events. To prepare and plan for such events, people engage in high-level construal, using cognitive abstraction to extract the central, primary, and goal-relevant features likely to be present in all possible manifestations of the events. As detailed specifics become increasingly available and reliable with greater proximity, people are able to engage in low-level construal, incorporating this information into concrete representations that highlight those secondary features that render a particular event unique. This association between distance and construal is over-generalized, apparent even when equivalent information about psychologically near and distant events is available.

Research indicates that the low-level construal that the proximity of temptations triggers is deleterious to self-control (e.g., Fujita 2008). The focus on concrete and idiosyncratic features promoted by low-level construal may distract one from one's abstract and distal goals. Supporting this assertion, for example, female undergraduate students, a population generally concerned about their weight, are more likely to prefer candy bars over apples as a snack when engaged in low-level rather than high-level construal (Fujita and Han 2009). This and other research suggests that proximal temptations promote self-control failure by prompting low-level construal (Fujita 2008).

The present research proposes that people have mechanisms that allow them to counteract the tendency for proximal temptations to trigger low-level construal, and to engage instead in high-level construal. If indeed high-level construal serves as a means of counteractive self-control, it should be evident when people anticipate temptations will undermine valued goals (Study 1) and have no alternative means of control available (Study 2). Engaging in counteractive high-level construal should promote successful self-control (Study 3).

Study 1 tested the hypothesis that people engage in high-level construal when they anticipate temptations will undermine valued long-term goals. Undergraduate students were recruited a week prior to a midterm examination. Those in the high threat salience condition were asked to list upcoming exams along with temptations that interfere with exam, whereas those in the low threat condition were not. Participants then reported which of two paired abstract and concrete descriptions of studying best corresponded to their own thoughts as an assessment of construal (e.g., "reading chapters in my textbook" vs. "mastering course material"). Participants also reported their academic achievement motivation. Threat salience condition had no effect on academic achievement motivation, $t(86) = .67$, $p = .51$. As predicted, however, threat salience and goal motivation interacted to predict construal level, $b = .32$, $SE = .15$, $p = .04$. Salient threats led undergraduates to prefer more abstract descriptions of studying as their academic goal motivation increased, $b = .57$, $SE= .21$, $p = .01$. By contrast, academic goal motivation was not related to construal when threats were not made salient. People thus appear to engage in counteractive high-level construal to the extent that they anticipate temptations will undermine valued goals.

The availability of alternative means of control should reduce the need to engage in counteractive high-level construal (Fishbach & Trope, 2005). To test this, participants were led to believe that they would be sampling a new cookie product that was tasty yet unhealthy and fattening. Half were told that it was up to them to decide how many cookies they desired to eat (self-control condition), whereas the other half were told that the experimenter would decide how many cookies they could eat (other-control condition). As an assessment of construal, participants were asked to what extent their thoughts about the upcoming cookie taste test took the form of words versus pictures. Research indicates that whereas words are associated with high-level construal, pictures are associated with low-level construal (Amit, Trope, and Algom 2009; Yan, Sengupta, and Hong, this symposium). As predicted, those in the self-control condition reported using words more than pictures, as compared to those in the other-control conditions, $F(1, 106) = 3.86$, $p = .05$. People appear to engage in counteractive high-level construal, then, to the extent that they have no alternative means of control.

Study 3 sought to demonstrate that counteractive high-level construal promotes successful self-control behavior. Undergraduate students were recruited a week prior to their final exam. All participants were asked to list their exams and temptations that interfered with exam preparation. They then reported whether their thoughts about studying took the form of words versus pictures as an assessment of construal. Students also reported their academic goal mo-

tivation. We used students' grade improvement between their midterms and final exams as an indicator of successful self-control in their final exam preparations. As predicted, increasing goal motivation was associated with greater use of words over pictures, $\beta = .56$, $SE = .28$, $t(39) = 1.98$, $p = .05$, suggesting high-level construal. The use of words over pictures, in turn, predicted greater grade improvement from the midterm to the final, $\beta = .02$, $SE = .01$, $t(38) = 2.39$, $p = .02$. The 95% confidence interval for the indirect path through word over picture representation, as predicted, did not include zero (.0009 to .03), indicating a significant indirect effect of goal motivation on grade improvement through high-level construal. Thus, counteractive high-level construal appears to promote successful self-control behavior.

When Feeling Depleted Helps: The Positive Effect of Regulatory Depletion

EXTENDED ABSTRACT

Past research on regulatory depletion theory posits that exerting self-control consumes regulatory resource (Muraven and Baumeister 2000), and predicts a negative impact of regulatory depletion: performing a prior self-control task impairs the performance on a subsequent task that also involves volitional action, a phenomena termed as the depletion effect (Baumeister et al. 1998; Muraven and Baumeister 2000). A large body of empirical studies in psychology and marketing has demonstrated the depletion effect in diverse domains. For example, Baumeister et al. (1998) found that participants who exerted regulatory resources to resist the temptation of food, compared with those who did not engage in this self-control act, were less persistent on trying to solve a challenging puzzle subsequently. Likewise, suppressing thoughts undermines individuals' control on impulse purchases (Vohs and Faber 2007). Other studies have documented this effect in the contexts such as alcohol consumption (Muraven, Collins, and Nienhaus 2002), processing health-risk information (Agrawal and Wan 2009), and making deliberative choices (Vohs et al. 2008; Wang et al. 2010).

The current paper bridges the research on regulatory depletion and the literature on construal level theory to propose a new case in which depletion might exert a positive effect on task performance. Recent research on self-control has suggested that exerting self-control alters the way in which individuals construe information. Wan and Agrawal (2011) suggest that engaging in self-control systematically shifts individuals' construals to lower levels. Their studies showed that highly depleted (vs. less depleted) participants relied on feasibility (vs. desirability) attributes, favored secondary (vs. primary) features, and chose products framed in a proximal (vs. distal) perspective. Similarly, Bruyneel and Dewitte (2006) showed that depletion leads to a narrow attention span and breadth of categorization which are consistent with the mental representations at lower-level construals.

The literature on construal levels suggests that construal levels influence individuals' cognitive style and information processing (e.g., Liberman and Trope 1998; Trope and Liberman 2003). At lower-level construals, individuals are likely to attend to subordinate, incidental features, and concrete and contextual details, whereas being at higher-level construals emphasize superordinate features, and abstract and global pictures. If experiencing depletion shifts individuals' construals to lower levels, we predict that regulatory depletion will enhance the performance on tasks that require attending to low-level and contextual details.

Three experiments tested our proposition. In experiment 1, participants first completed a cross-off-letter task adopted from past research to manipulate regulatory depletion (Baumeister et al. 1998). Then participant performed the picture completion subtest of the Wechsler task (Wechsler 1991), a task used to examine people's ability to observe contextual details (Wakslak and Trope 2009). Specifically, all participants were presented with thirty pictures, each of which contains a missing part. Their task was to identify the missing parts within three minutes. Our results showed that highly depleted participants identified more missing objects than did less depleted participants ($p < .05$), supporting our prediction that depletion enhances the performance on tasks that require the attention to details.

In experiment 2, participants first performed the same cross-off-letter task that manipulated depletion, followed by an Embedded Figure Test (Witkin et al. 1971) in which eleven objects are embedded within a more complex big figure. Participants' task was to identify the embedded objects. Past research has shown that, to identify the embedded objects, people need to focus on the contextual details and ignore the big picture. Participants were given five minutes to perform the task. The results showed that highly depleted participants identified more embedded objects than did less depleted participants ($p < .05$), replicating the finding in experiment 1 and again supporting our prediction.

Experiment 3 tested our prediction in a product evaluation context with a 2 (high vs. low depletion) x 3 (information omission with cue vs. information omission without cue vs. full information) between-subject design. Participants first performed a thought suppression task adopted from past research (Vohs and Faber 2007) to manipulate depletion, followed by reading the message about a laptop computer. In the full information condition, the message described the computer on five major attributes. In the information omission without cue condition, the important attribute of memory size was omitted from the attribute list. In information omission with cue condition, the memory size information was omitted but was listed as "information unavailable to customer." Participants evaluated the computer, and recalled if any attributes were missing from the message. A 2 x 3 ANOVA on product attitudes indicated a significant interaction ($p < .05$). When there was a missing attribute without the omission cue, highly depleted participants evaluated the product less favorably than did less depleted participants ($p < .01$). However, participants in the full information did not differ in their attitudes whether they were highly or less depleted ($F < 1$). Similarly, in the omission with cue condition highly depleted and less depleted participants did not differ in their attitudes ($F < 1$). We also found the same pattern on the number of recalled missing attributes. Moreover, in the information omission conditions the number of recalled missing attributes mediated the effect of depletion on product evaluation. These results suggest that depletion enhances performance on detecting details, which has influenced their evaluation of the target products.

The current research contributes to the literature by identifying novel effects of regulatory depletion through the lens of variations in construals, and enhances the understanding the psychological processes underlying self-control.

The Good, the Bad, and the Ugly of Consumer Spending within Close Relationships

SESSION OVERVIEW

It begins with dinner and a movie. With any luck, an engagement ring follows. Before we know it we are buying our first home, deciding on vacation destinations, saving for our children's college tuition, and eventually retirement. Spending decisions permeate our close relationships and often form the basis for their long-term success or ultimate failure. However, little is known about the factors that can impact (for better or for worse) the financial decisions we make in our dating, marriage, and family life and how those decisions affect the overall health of our close relationships.

The four papers in this session all present emerging research on spending behavior within close relationships – from dating partners and marriage partners to parents and children – and the critical factors that shape the financial decisions that we make within them. The first paper uses both archival and experimental methods to investigate the environmental factors that shift parental consumer choice. The next two papers examine spending behavior within the context of initial attraction and dating – including when and why spending behavior influences the mate attraction dynamics of potential dating and marriage partners. The final paper focuses on critical factors linking materialism to marital discord and divorce.

Durante and colleagues draw on theory and research in animal behavior to investigate how the economic climate can influence whether parents spend more money on daughters versus sons. Consistent with the effects of resource scarcity on parental investment across species, they find – in a series of experiments – that economic recessions lead parents to spend more on daughters than on sons.

Lens and colleagues examined conditions under which men conspicuously consume to attract dating partners. They use both real and experimentally-induced dating situations to investigate materialism's influence on men's conspicuous consumption. Materialism predicts the extent to which men consider their wealth a tool to at-

tract a romantic partner, as well as the type of partner these men desire.

Olson and Rick examined whether and why construal level influences how savers and spenders are viewed as potential dating partners. While lavish spending is sometimes used to attract romantic partners, they find that people induced to have a concrete mindset are more attracted to savers than to spender. The reverse is true for those evaluating dating partners under an abstract mindset.

Sundie, Burroughs, and Beal investigated the factors that lead materialism to erode a marriage. Using survey data from married couples collected at multiple time points, they find a three-pathway model that links materialism to divorce. Additional findings reveal important mediators of materialism's influence on marital discord.

Overall, this session focuses on the factors that influence our spending behavior within the context of close relationships and how these spending patterns can impact attraction and relationship maintenance. This session aims to celebrate diversity by introducing research lines that have received little to no empirical attention to date and by presenting novel avenues for future consumer research. As such, the session would be of interest to a breadth of consumer researchers, including those interested in family spending, motivation, social perception, nonconscious processes, romantic relationships, and biological and evolutionary approaches to consumer behavior.

I Love You Both Equally, But…Parental Spending on Girls versus Boys in Economic Recessions

EXTENDED ABSTRACT

Do economic conditions influence how parents spend money on their children? While past research has revealed important insights into children's consumer behavior and the consumption patterns of spouses (e.g., Rick, Small, and Finkel 2011), much less is known about how parents make spending decisions regarding sons versus daughters. Drawing on theory in animal behavior, we use both archival and experimental methods to examine how spending on boys versus girls is influenced by economic recessions.

Theory and research in animal behavior shows that parental investment in male versus female offspring depends on environmental conditions (Clutton-Brock 1991; Trivers and Willard 1973). When conditions are favorable, parents invest relatively more in male offspring. By contrast, when conditions are bad, parents invest more in female offspring. This gender-specific difference stems from the difference in reproductive variance between males and females. Across the animal kingdom, males have *higher* reproductive variance: Whereas some high-status males attract a large number of females and, as a result, produce high numbers of offspring, a substantial portion of lower-status males attract no mates and produce zero offspring (Dittus 1998). By contrast, females have *low* reproductive variance: As long as a female is healthy enough for reproduction, almost all females are able to attract a mate and tend to produce some moderate number of offspring.

Environmental conditions alter how parents invest in male versus female offspring because an offspring's likelihood of reproduction depends on their status and health. However, whereas under good conditions parental investment is focused on achieving a *maximum amount of status* (e.g., large size and dominance) for offspring, in bad conditions parental investment is focused on maintaining a *minimum*

level of health needed for reproduction. When conditions are good, investing in male offspring has higher reproductive benefits because a high-status male will out-reproduce any female. When conditions are bad, however, this pattern reverses. In bad conditions, investing in a female ensures that there will be at least some offspring. Accordingly, animal research shows that when environmental conditions are favorable (e.g., abundant food resources), parents invest more in male offspring. But when environmental conditions are poor (e.g., scarce food resources), parents invest more in female offspring (Krist 2006).

In the current research, we examine whether humans might show similar types of patterns by examining how economic recessions influence investment in daughers versus sons. Based on theory and research in animal behavior , we hypothesized that economic recessions should be associated with higher spending on girls versus boys.

Study 1 examined how household spending on girls' versus boys' apparel in the US relates to fluctuation in the US Gross Domestic Product (GDP) from 1984 to 2010. We focused on apparel because it is a child consumer product category that is clearly separated by gender. Consistent with predictions, findings showed that GDP growth was negatively related to the ratio of spending on apparel for girls relative to boys (r=-.55, p=.003). This means that downturns in GDP over the last 26 years are associated with spending more money on girls' relative to boys' clothing.

Study 2 used experimental methods. Participants (both parents and non-parents) first read a news story either about an economic recession, an economic upswing, or a neutral story. Participants then imagined that they have two school-aged children (a boy and a girl) and answered questions about allocating resources to either their son or daughter. For example, "You have the funds to put one child in a special healthy lunch program at school. Which child will get the lunch program?" Responses were provided on 8-point scales (no midpoint) with "Definitely Son" and "Definitely Daughter" at the endpoints. Participants also indicated how they would divide their assets to bequeth either to their son or daughter. Consistent with predictions, people invested more resources in daughters in the economic recession condition (p=.011). Economic recessions also led people to bequeth more assets to daughters than to sons (p=.036).

Both studies thus far find that economic recessions are associated with increased allocation of resources to daughters versus sons. Study 3 investigated whether mothers and fathers might invest different types of resources in their children. Because "resources" include both money and time, we examined whether economic conditions influence how fathers and mothers invest time versus money in their children.

In Study 3, participants again read a news story either about an economic recession or an economic boom. They then answered a question about allocating money ($100) and a question about allocating time (10 hours) between a son and a daughter. As in the first two studies, people invested more in daughters than sons in the economic recession condition (p=.01). However, the specific nature of the investment – time or money – depended on the gender of the parent. Economic conditions altered *monetary investment* primarily for fathers. Fathers allocated 8% more money to daughters in recessions (p=.037). However, economic conditions altered *time investment* primarily for mothers. Mothers allocated 7% more time to daughters in recessions (p=.032).

These findings highlight how theory and research in animal behavior can provide insight into consumer behavior. Just as resource scarcity leads animals to invest more in female offspring, we find

that the resource scarcity (as indexed by economic recessions) leads people to invest more resources in daughters relative to sons.

Romantic Motives and Men's Conspicuous Consumption: The Role of Materialism

EXTENDED ABSTRACT

Men's conspicuous consumption may fulfil an important communicative function in a mating context (Griskevicius et al. 2007). Indeed, in response to women's preference for men with status, men in a mating mindset show an increased interest in status-signaling products (Griskevicius et al. 2007). However, little research has investigated the consequences of materialism for (men's) mating goals and partner preferences. The current research examines links between men's reliance on conspicuous consumption to attract women and materialistic values.

Research suggests that materialistic men may desire partners who are sexy or highly attractive, characteristics which are especially important in a short-term mating context rather than long-term, mating interest. Indeed, the fact that materialists tend to display little empathy and to experience poor interpersonal relationships could be interpreted as signals of low ability or willingness to commit. Materialism is related to extrinsic goal pursuit. As such, materialistic men may place greater emphasis on characteristics (e.g., attractiveness) that afford social approval.

Three studies examined materialism's influence on conspicuous consumption in mating contexts. Studies 1 and 2 investigated whether materialistic men particularly rely on conspicuous consumption to attract mates. Study 3 explores a) whether materialism predicts a preference for socially visible and attractive partners, and b) whether extrinsic goal pursuit (e.g., striving for the approval of others) mediates materialistic men's partner preferences.

In Study 1, 40 men indicated to what extent they relied on eight characteristics (wealth, humor, intelligence, attractiveness, masculinity, caretaking abilities, faithfulness, status) to attract women. Materialism (Richins 2004) was positively correlated with reliance on wealth and status to attract women, and negatively correlated with promoting one's caretaking abilities.

Study 2 assessed more explicitly whether the activation of men's mating motives, induced by a real-life encounter with an attractive woman, increased materialistic men's interest in *products* which *signal status*. 117 men were welcomed in the lab by a female experiment leader who was either plainly (control) or sexily dressed (mating condition). Next, participants rated the attractiveness of 5 status-signaling gadgets and 5 inconspicuous products (all pretested), then completed the materialism measure. GLM analysis yielded a significant interaction between Materialism, Condition, and Product Type (within subjects), p=.048. Mating goal activation increased interest in status-related products (but not in functional products) among more materialistic men.

In study 3, 150 men read descriptions of two hypothetical romantic partners. Description A depicted a woman who scored high on characteristics related to social visibility (attractive, admired by others), but low on characteristics typically valuable in the long run (responsible, faithful); vice versa for description B. Participants indicated which type (A or B) corresponded best to their ideal partner. They completed a measure of extrinsic goal pursuit (Kasser and Sheldon 2000) assessing their motivation to gain social approval, and the materialism measure.

Logistic regression analyses revealed that the probability of preferring partner B (over A) decreased with increasing levels of materialism, p=.03. Extrinsic goal pursuit significantly mediated

the relationship between materialism and partner preference, *p*=.81. Hence, a need for social approval underlies materialistic men's pursuit of socially visible, attractive partners.

In sum, this paper investigated the role of materialistic values play in mating-relevant behaviors such as conspicuous consumption, and advanced our understanding of the consequences of materialism for romantic partner choice. Materialistic men prioritized socially desirable, surface partner characteristics (e.g., attractiveness), even when those qualities come at the expense of faithfulness and conscientiousness in a forced choice scenario. Materialistic men's partner preferences appear to be more in line with short-term (as opposed to long-term) mating criteria. Interestingly, men's conspicuous consumption may draw women's attention, in particular when women are ovulating and ovulation temporarily increases women's short-term mating interests (Lens et al. 2012). Hence, ovulating women may be most receptive to the conspicuous consumption displays of materialistic men. In addition, ovulating women may more strongly resemble materialists' ideal partners. Together, this seems to imply that materialism, from a short-term mating perspective, could be considered as a beneficial trait. This idea is novel given the abundance of research documenting the negative consequences of materialism, yet requires further testing.

When is Saving Sexy? The Role of Construal Level in Shaping the Appeal of Savers and Spenders as Romantic Relationship Partners

EXTENDED ABSTRACT

Among all the possible sources of conflict in romantic relationships, financial disagreements are some of the most prevalent (e.g., Amato and Rogers 1997). Different attitudes toward spending money among spouses can be a common source of such arguments (Rick, Small, and Finkel 2011). Are some spending habits initially more appealing than others in prospective mates? Lavish spending can signal desirable information about one's resources, and thus help to attract mates (Griskevicius et al. 2007). But are there situations in which chronic savers are initially more appealing than spenders?

Given that "saver" and "spender" labels could bring to mind abstract or more concrete outcomes (e.g., retiring comfortably vs. avoiding daily indulgences), we considered this question from a construal level theory (CLT) perspective (Trope and Liberman 2003). CLT suggests that the same event, behavior, or individual can be represented at multiple levels. High-level construals are relatively simple, abstract representations that capture the primary essence of available information. Low-level construals, by contrast, are more concrete and detail-oriented.

Competing predictions based on CLT are plausible. On the one hand, recent work suggests that priming a high-level (versus low-level) construal leads to better self-control, which reduces preference for immediate gratification and encourages a focus on long-term benefits (Fujita et al. 2006). Because birds of a feather flock together in relationships (e.g., Watson et al. 2004), these results suggest that a high-level construal might increase the appeal of potential mates who are also responsible. On the other hand, Kivetz and Keinan (2006) find that virtuous choices also lead to stronger regret over time. From this perspective, people who take a global, more abstract perspective may seek spenders to avoid a future filled with regret over missed opportunities. Savers, who potentially miss out on many expensive but fulfilling experiences, may be considerably less attractive to people thinking abstractly.

We conducted two studies to examine whether and why construal level influences how desirable chronic savers and spenders are

as relationship partners. In Study 1, participants were first induced to have either a high-level or low-level construal mindset using a word categorization task validated by Fujita et al. (2006). Following manipulation checks, a second, seemingly unrelated study examining perceptions of local singles was introduced. Participants were presented an opposite-sex target who was either a self-described saver or spender. Targets were rated for their attractiveness as both short-term and long-term relationship partners.

Because the attractiveness items correlated highly and previous research points to a single dimension underlying mating strategies (Simpson and Gangestad 1991), we averaged the two items to form an overall index of attractiveness. Analyses revealed a significant interaction between construal level and the target's spending habits. When participants were thinking concretely, savers were significantly more appealing as relationship partners than spenders. When participants were thinking abstractly, the attraction "gap" between savers and spenders disappeared.

Thus, the initial evidence is consistent with the regret-avoidance hypothesis. Of course, many questions about the underlying process remain unanswered. For example, does one's construal level change the inferences made based upon the saver/spender label? It is possible that a saver is viewed as especially practical by low-level construers, while a spender is viewed as especially idealistic? Another possibility is that priorities change as construal level is varied, with low-level construers valuing responsibility more than high-level construers.

Study 2 sought to replicate the initial findings and gain insight into how construal level shapes the information conveyed by the monetary labels. Participants were randomly assigned to have either a high-level or low-level construal mindset before evaluating a potential mate (a "saver" or "spender"). Targets were again rated on the attractiveness index, but also in terms of various personality traits. Two indices were formed by averaging responses to five items each: an excitement index (adventurous, fun, exciting, confident, and outgoing) and a responsibility index (timid, careful, cautious, practical, and responsible). Results again revealed an interaction on the attractiveness index, suggesting that savers are especially appealing to low-level construers but not to high-level construers. More importantly, we found that responsibility was a significant predictor of attractiveness among low-level construers, but excitement was not. Conversely, excitement was a significant predictor of attractiveness among high-level construers, but responsibility was not. Construal level did not influence the inferences drawn from the saver/spender label (e.g., spenders were always viewed as more exciting than savers, by both low-level and high-level construers).

In conclusion, results from two studies demonstrate that the effect of a potential partner's monetary habits on attractiveness depends upon construal level. Because savers are viewed as more responsible than spenders, and low-construal increases the extent to which responsibility is valued, low-construers prefer savers to spenders. High-construers value excitement more than responsibility, and thus do not show a preference for savers. Thus, saving can be sexy, as long as the search for love is accompanied by a concrete mindset.

Why is Materialism Bad for Marriage? Testing Pathways Linking Materialism to Divorce

EXTENDED ABSTRACT

In 2009, Jamie McCourt filed for divorce from her former business partner and husband of thirty years, L.A. Dodgers owner Frank McCourt. Amid rumors the McCourts misused Dodgers assets to

fund their posh billionaire lifestyle, the team was taken over by Major League Baseball. In a May 2011 ABC News interview, Frank McCourt accepted blame for the "unhealthy" and "unsustainable" lifestyle he felt contributed to the demise of his marriage. Stories such as that of the McCourt's highlight a downside of "living the high life"—rampant materialism may undermine the viability of close relationships. Surprisingly little research has sought to understand how institutions of social connection, such as marriage, are influenced by materialistic values and the rise of consumer culture. Prior research shows materialism correlates with poor individual-level outcomes. Materialists report lower personal well-being, and people who emphasize extrinsic goals (e.g., financial success) report having shorter, more negative friendships and romantic partnerships (Kasser and Ryan 2001). We examined how materialism influences marital viability, investigating three pathways by which material values may negatively influence marital dynamics:

Household Finances. As a predictor of marital quality, household money management is surprisingly under-studied despite ample popular press claiming its leading role in divorce. Materialism is linked to poor money management (Richins 2011). Rick and colleagues (2011) did not investigate materialism's role in marital finances, but did find that larger *differences* between spouses in tight versus loose spending tendencies predicted financial conflict and lower marital satisfaction. We examined whether poor outcomes on key household financial benchmarks (retirement savings, emergency savings, credit card debt, and credit rating) mediate the relation between couples' materialism and divorce intentions.

Relationship Investment. Materialists may invest more in things than they do relationships. People prioritizing extrinsic goals characterize their relationships in more negative terms (e.g., more emotional extremes and jealousy, less trust; Kasser and Ryan 2001). Reasons for the correlation between materialism and poor relationships are not well understood. A person's developmental environment may play a role--young adults rating financial success as an important life goal also reported experiencing low maternal nurturance (Kasser et al. 1995). Attachment theorists suggest that people developing avoidant attachment styles–deactivation of the need to rely on close others for support–may turn to money and the acquisition of objects to foster identity and self-worth (Mikulincer and Shaver 2008). Furthermore, materialistic pursuits are linked to other traits emphasizing a lack of interest in others' well-being, such as Machiavellianism (McHoskey 1999). These factors may lead materialists to invest less in close relationships. We examined whether relationship investment mediates the relation between materialism and divorce intentions.

Coping with Marital Conflict. Disagreements occur routinely within even healthy partnerships, and the way partners handle conflicts can serve to resolve (or magnify) the problems, and solidify (or harm) the relationship over time. Two forms of problematic coping seem likely for materialists: hostile/argumentative, and depressive/self-blaming. Several findings suggest that materialism is connected to hostile reactions to social problems. Materialism is linked to disagreeable and ungracious reactions to others (McCullough et al. 2002). Materialists exhibit narcissism and avoidance, which manifests in manipulative, defensive, and aggressive conflict coping

Table 1. Standardized path coefficients for Couple-Level Model of the marital outcomes of happiness and success materialism

Predictors	Income	Credit Score	Relationship Investment	Self-Blame	Conflict Coping
Happiness Materialism	-.27*	-.38*	-.23*	.43*	.29*
Success Materialism	-.05	.07	.21*	-.07	.19
Outcome					
Divorce Intentions		-.10	-.24*	-.03	.46*

Note: Income was specified as an exogenous variable (correlating with materialism) that influenced credit score. *$p < .05$.

Table 2. Standardized path coefficients for Actor-Partner Interdependence Model of the marital outcomes of happiness and success materialism

Predictors	Husband's RI	Wife's RI	Husband's Conflict Coping	Wife's Conflict Coping
Husband's Happiness Materialism	-.34*	-.35*	.00	.12
Wife's Happiness Materialism	.05	.06	.36*	.13
Husband's Success Materialism	.21	.45*	.24	.22
Wife's Success Materialism	.00	-.16	-.12	.09
Outcomes				
Husband's Divorce Intentions	-.25*	-.07	.32*	.18*
Wife's Divorce Intentions	-.18*	-.10	.23*	.23*

Note: Income was specified as an exogenous variable (correlating with materialism) that influenced credit score.
RI = Relationship Investment. *$p < .05$.

(e.g., Bushman and Baumeister 1998). Regarding the self-blaming response, Wachtel and Blatt (1990) found that materialists scored higher on the self-criticality dimension of a depression inventory. This tendency for materialists to focus inwardly and negatively suggests that they may self-blame during disagreements. Since neither coping style is considered constructive in resolving conflicts, these poor coping mechanisms may erode relationships. We examined whether poor coping with conflict mediates the materialism--divorce intentions link.

180 socioeconomically and demographically diverse married couples participated. Two surveys were administered at least 5 days apart to separate constructs that could contaminate one another or produce common method bias. Concerns of method bias were further alleviated by having spouses rate the materialism (Richins 2004) of their partner.

Given previous findings of divergent validities between the happiness and success facets of materialism and well-being outcomes (e.g., Deckop et al. 2005), we examined separate models for the overall materialism construct and these two facets. We also examined separate models for couple-level effects (scores on materialism, financial health, relationship investment, coping styles, and divorce intentions, averaged across husband and wife) and intracouple effects (Actor-Partner Interdependence Models). All of these models provided good fit to the data (CFIs ranged from .93-.96). A close examination revealed several interesting findings. First, the model collapsing across materialism facets revealed small to moderate effects through the financial and hostile coping pathways, but did not support self-blame or relationship investment pathways. Once success and happiness facets of materialism were split out, an interesting pattern emerged revealing support primarily for the relationship investment and hostile coping pathways, as these were the only predictors of divorce intentions (Table 1). Happiness materialism predicted unfavorable outcomes across the board, whereas success materialism predicted increases in relationship investment.

We expanded the final model to include husband and wife paths (allowing for separate influences, and cross-partner effects), but focused on the relationship investment and conflict coping mediators. Model 2 bore both similarities and differences to the above effects. First, though husbands' materialism affected wives' relationship investment (happiness decreased it, and success increased it), wives' relationship investment did not predict divorce intentions (Table 2). A similar pattern was found for husbands, but their relationship investment *did* predict divorce intentions. A final path linked wives' happiness materialism to both husband and wife divorce intentions by increasing husbands' hostile coping. Happiness materialism increased divorce intentions of both husbands and wives, but did so primarily through a decrease in husbands' relationship investment and an increase in husbands' hostile coping. In addition, some evidence supports a positive role for success materialism by increasing perceptions of relationship investment.

Paper #4: When 'Your Brand' Changes the Terms of the Relationship: Vicarious Dissonance in the Context of Brand Attachment

Eda Sayin, Koc University, Turkey

Nilufer Aydinoglu, Koc University, Turkey

Zeynep Gürhan-Canli, Koc University, Turkey

SESSION OVERVIEW

Consumers use symbolic products and brands to express who they are and to make inferences about the identities of others (Escalas and Bettman 2005). Symbolic brands are markers of in-group identity and signal membership to a specific brand community. The dynamic group of users of the brand shapes the associations and attitudes that consumers hold with respect to their symbolic brands (Berger and Heath 2007; White and Dahl 2006). The papers in this session examine the roles of brands as symbols and means of self-expression for consumers, as individuals and as members of specific in-groups.

Besides contributing to the main conference theme of appreciating diversity by providing novel theoretical insights into the particular domain of symbolic brands, the proposed session contributes to the understanding of several topics that are of great interest to ACR conference attendees, including conspicuous consumption, brand attachment, brand extensions and dilution, and in-group and out-group dynamics.

In the first paper, Escalas and Bettman propose that consumers appropriate brand symbolism that comes from celebrity endorsement to construct and communicate their self-concepts and that consumers with compromised identities look to celebrities to a greater extent than those with less insecurity. Across three studies, the authors demonstrate that consumers are more likely to look to celebrities for meaning when their self-esteem is threatened (1), have low levels of social complexity (2), and are under high life stress (3).

The second paper by Bellezza and Keinan examines how current users of symbolic brands react to new lower-status users of the brand. Contrary to the shared notion that lower-status consumers are by definition a threat to the brand, five lab and field studies demonstrate the conditions under which lower-status consumers enhance rather than dilute the brand image. This research shows that positive brand enhancement is mediated by the impact on the pride of current users and moderated by self-brand connection level.

In the third paper, Amaral and Loken investigate brand dilution for prestige brands and the moderating role of the users' group

social class. In four studies, the authors examine the effects of using counterfeit luxury products on the perceptions of observers regarding the genuine brand. Results show more favorable beliefs toward and attitudes regarding prestige when the counterfeit product is used by an in-group (versus an out-group) social class member.

Finally, the fourth paper by Sayin, Aydinoglu and Gurhan-Canli examines how consumers' evaluations of incongruent brand extensions differ depending on the level of attachment to the symbolic brand. Building on vicarious dissonance theory in social psychology, this research shows in a series of studies employing symbolic brands that strong consumer-brand attachment leads to vicarious dissonance and can positively affect consumer attitudes toward the brand extension and the product category.

All speakers (Escalas, Bellezza, Amaral, Sayin; indicated by asterisk below) have agreed to serve if the proposal is accepted.

Connecting with Celebrities: The Therapeutic Function of Celebrity Endorsement

EXTENDED ABSTRACT

With the rise of social media and reality television, some refer to our times as the social era of celebrity (adly.com). Given the prevalence of celebrity endorsements, it is important to understand their effects. We propose that consumers appropriate brand symbolism that comes from celebrity endorsement to construct and communicate their self-concepts and that consumers with compromised identities look to celebrities to a greater extent than those with less insecurity. Three studies show that consumers whose identities are compromised are more likely to look to celebrities for meaning: the effect of celebrity endorsement on self-brand connections is augmented when consumers' self-esteem is threatened (study 1), for consumers with low levels of social complexity (study 2), and for consumers who are experiencing life stress (study 3).

McCracken (1986) asserts that brand meaning originates in the culturally constituted world, moving into goods via the fashion system, word of mouth, reference groups, and, importantly for our purposes, celebrities. A celebrity endorser may provide a bundle of cultural meanings that becomes associated with the brands s/he endorses. Meaning moves to consumers as they construct their identities through brand choices based on congruency between brand meaning and desired self-image. Thus, the meaning and value of a brand is not just its ability to express the self, but also its role in helping consumers create and build their self-identities (McCracken 1986). Additionally, research has shown that source congruence, that is, the match between the celebrity's image and the brand's image, is an important influence on brand beliefs and attitudes under conditions of high involvement/elaboration (Kirmani and Shiv 1998).

In our research, we examine the therapeutic function of celebrity as a source of meaning in modern consumer culture. We propose that celebrities play the role of modern heroes, where heroes have historically helped people make sense of their lives and form connections with others (Campbell [1949] 2008). Although this may be true for society in general, it is particularly relevant for individuals with compromised identities. When consumers' have a compromised identity, in response to stressful events, life changes, lack of a complex social network, or some other self-esteem threat, they are motivated to repair their self-identity (Leary et al. 1995). We argue that

these vulnerable consumers are more likely to look to modern heroes (celebrities) to make sense of who they are and their role in society.

Our assertion that consumers with compromised identities seek meaning from celebrities is supported by research into why some people become more obsessive about celebrities in general. Some social psychological analyses link celebrity worship with shyness, loneliness, lack of cognitive flexibility, fantasy proneness, and substandard mental health (e.g., Maltby et al. 2006). A compromised identity also may lead to obsession with celebrities that enables such individuals to establish an identity and sense of fulfillment. In this research tradition, celebrities have a therapeutic function; people look to celebrities to repair their compromised identity. Thus, we expect to find that consumers with greater active self-concept concerns or insecurities (i.e., more compromised identities) will be more likely to look to celebrities for meaning in the consumption domain, augmenting the effects of celebrity endorsement.

In study 1, we found that a compromised identity augments the influence of celebrity endorsement on self-brand connections by threatening self-esteem. We presented participants with an article criticizing the US, which threatened the self-esteem of those participants who had a high US national identity. We found a significant interaction of self-esteem threat by celebrity aspiration level ($F (1, 277) = 4.07$, $p < .05$). People whose self-esteem had been threatened formed connections to brands that were endorsed by celebrities that they aspired to be like. They also rejected brands that were endorsed by celebrities with images that did not match their desired self-image. Participants whose self-esteem was not threatened did not form differential self-brand connections based on celebrity aspiration level.

Study 2 examined a second source of compromised identity, social complexity, defined as joining and maintaining membership in diverse groups. By providing social support, social complexity provides a buffering effect against stress and loneliness and enhances personal and collective self-esteem. In this study, we found a significant three-way interaction of social complexity, source congruency, and participant congruence on self-brand connections ($F(1, 109) = 5.47, p < .05$). Consumers who were not socially complex (thus, have compromised identities) looked to celebrities for meaning more than consumers who had highly complex social networks. This effect was augmented by source congruence (that is, the celebrity image matches the brand image, Kirmani and Shiv 1998) and consumer congruence (the consumer's self-image matches the brand image – in this study, athletic watches).

Study 3 examined yet a third vulnerability for consumers' personal identity: life stressors. As people deal with loss of a spouse, a job, or go through other periods of stress, they are often in a transitional or liminal state with regards to their self-identity. Here, we found a significant three way interaction of life stressors, source congruence, and participant congruence on self-brand connections ($F(1, 335) = 6.09, p = .01$): consumers whose identities are compromised by dealing with stress in their lives look to celebrities for meaning more than consumers who have fewer life stressors. This effect is also augmented by source congruence and consumer congruence (in this study – a Syrah wine).

In sum, our studies show celebrity plays a therapeutic function for consumers in our culture, with consumers with compromised identities being more likely to look to celebrity endorsers as a source of meaning. We find this effect whether we threaten self-esteem, measure social complexity, or measure the number of life stressors present in consumers' lives. In all three cases, the effect of celebrity endorsement on self-brand connections is stronger, compared to consumers who do not have similarly compromised identities.

Brand-Tourists or Brand-Immigrants? How New Lower-Status Consumers Dilute or Enhance the Image of Symbolic Brands

EXTENDED ABSTRACT

There is an inherent trade-off in managing symbolic and luxury brands. Brand managers need to generate growth by extending the customer base to new segments and new markets; yet, this increased popularity and prevalence can paradoxically hurt the brand and threaten its symbolic value. Indeed, marketing research warns managers of brand dilution risks (Loken and Roedder John 2009). Contrary to the shared view that new lower-status consumers are a threat to symbolic brands, we investigate the conditions under which new lower-status users and downward brand extensions can enhance rather than dilute the image of the brand.

We introduce a distinction between two types of new consumers based on how they are perceived by current brand users. We define "*brand immigrants*" as those who are perceived by current brand users to claim "in-group status" they do not fully deserve (i.e., consider themselves as part of the in-group of brand users), and define "*brand tourists*" as those who buy the new branded products but do not claim any in-group membership (i.e., do not claim to be part of the brand users' in-group). We propose that new consumers who are perceived by the current users as claiming but not fully deserving in-group status (brand immigrants) will have a negative impact on the brand. However, when these new consumers are not perceived to claim membership status, but just show their admiration for the brand (brand tourists), they will not dilute the image but rather enhance the symbolic value of the brand.

These predictions build on research examining attitudes toward out-groups (Berger and Heath 2007; White and Dahl 2006) and immigration (Lee and Fiske 2006). Immigrants are often treated with hostility by national residents due to economic and symbolic threats. Similarly, in the context of symbolic brands, we predict that brand immigrants can threaten the exclusivity of the brand. In contrast, tourists, who do not demand any privileges or citizenship rights, are often welcomed and encouraged to visit host countries. In a pilot study with 210 American citizens, we confirm that citizens hold more favorable attitudes towards tourists than towards immigrants. Tourists boost the pride of citizens. Likewise, brand tourists, as fans of the brand, are expected to have a positive effect on the symbolic value of the brand and the pride of current customers.

Five lab and field studies explore the responses of current symbolic and luxury brand consumers to new customers and new brand extensions. To ensure high external validity of our findings, all our studies examine the reactions of real consumers to brands they actually own or use, and are based on real branding dilemmas and brand extension scenarios. We explore diverse consumer populations and symbolic brands representing a wide variety of ways to obtain in-group status, such as monetary investment and product knowledge (owners of Ferrari cars or luxury bags), passing admission tests (students at Harvard University), or even training for an activity (yoga practitioners who wear Lululemon, or participants of the "Tough Mudder" race).

We demonstrate that the negative responses to brand immigrants and positive responses to brand tourists are mediated by feelings of pride and moderated by brand ownership and level of self-brand connection (Escalas and Bettman 2005).

Study 1a examines the responses of Harvard Undergraduates to a Harvard part-time online undergraduate program. We manipulate the description of the part-time students between-subjects in three conditions by providing testimonials claiming in-group status (brand

immigrants), testimonials not claiming membership (brand tourists), or no testimonials at all (control condition). We find that Harvard students have positive reactions when part-time students are perceived as brand tourists and that pride mediates the reactions.

In Study 1b, we recruited owners of Prada and Marc Jacobs's products and followed the same experimental paradigm of study 1a (i.e. description of new lower-status consumers of the brand). We find that the prestige image of the brand is significantly higher in the brand tourist condition than in the control and brand immigrant conditions.

Study 2 examines the responses of participants of the endurance run "Tough Mudder." We test how participants react to offering non-participants the opportunity to buy a ticket to watch the run and take part in the festivities. We describe these non-participants as brand tourists or immigrants. We find that while brand immigrants are perceived as a threat to the symbolic value of the brand, tourists reinforce and enhance the brand's desirability and status. This effect is mediated by the impact on pride and it moderated by level of self-brand connection.

Study 3 investigates how and where the product is being used by examining Ferrari car owners' reactions to Ferrari car renters. We find that owners react negatively when renters intend to drive the car on the streets of Miami and could be mistaken for real owners, but react positively when the renters' intention is to experience the car on a Miami racing track.

Study 4 identifies boundary conditions for the brand tourism effect by comparing the responses of owners of a symbolic (Lululemon) vs. non-symbolic (Gap) brand and investigate yet another way of depicting brand tourists and immigrants by manipulating the ability and the potential of the new consumer to claim in-group status (i.e., a toddler vs. an adult). We demonstrate that while Lululemon owners are very sensitive to non-members' ability to claim in-group status, Gap owners are less sensitive to these concerns.

Finally, we discuss theoretical and managerial implications, including additional studies and demonstrations of how some of our findings have been applied in the field.

Brand Dilution: The Impact of the User of Counterfeits on Genuine Brand Perceptions and the Moderating Role of Social Class

EXTENDED ABSTRACT

Traditionally, brands of luxury goods or status goods are defined as those for which the mere use or display of the branded product brings prestige on the owner, apart from any functional utility. Many firms spend significant portions of their revenue, and top management's time, on building such strong brands by communicating positive and unique identities to consumers. These efforts, however, can be undermined by the unauthorized use of trademarks through counterfeit products, offering consumers some of the symbolism of the brand for a fraction of the cost of the genuine name brands ($20 Rolex watches or $40 Prada bags). Despite the magnitude of the problem, little attention has been devoted to counterfeits in the literature (for exceptions see Wilcox, Min Kim and Sen 2009). Specifically, research on the effects of counterfeit goods on perceptions of the brands they imitate is lacking (Loken and John 2009). We examine the nature of people's inferences about others using counterfeit brands and how these perceptions interact with social class in affecting a brand's equity.

People compare themselves to both in-group and out-group members to maintain in-group distinctiveness. Consumers aspire to buy products of their associative reference groups, and presti-

gious brands, in particular, come to symbolize an individual's social class position (Martineau 1968). Research on dissociative reference groups suggests that people avoid or even abandon brands that are linked to disliked groups (White and Dahl 2006, Berger and Heath 2007).

The consumer's use of a counterfeit product, such as a counterfeit "Louis Vuitton" bag, could change the symbolism of that brand, depending on the social class of the counterfeit user and the social class of the observer. Specifically, persons should be more likely to accept counterfeit product usage by persons from a similar than a different social class as them. Perceptions of the genuine brand should be negatively (positively) affected when a counterfeit product is used by a member of one's out (in)-group social class. We investigate this hypothesis through four experiments in which this match between social classes is either implied (studies 1 and 2) or manipulated (studies 3 and 4).

Experiments were conducted in a variety of settings. In studies 1 and 3 experiments were conducted in a laboratory setting with female undergraduates at a large University in the Midwest. Study 2 data were collected from inner-city high-school aged females in local community centers. Study 4 was conducted using a popular online survey provider. In studies 1 and 2, participants viewed a photo of a consumer using a luxury handbag and subsequently reported their prestige beliefs and attitudes about the genuine brand. The luxury handbag shown in the photo was described as either a counterfeit luxury brand or a real luxury brand, and the woman in the photo (using the handbag) was described in terms that reflected either a higher or a lower social class. In Studies 3 and 4, we provided a more direct investigation of the role of social group similarity on brand beliefs. In study 3 we manipulated the class of both the consumer and the observer (i.e. the participants) and in study 4 we manipulated the perceived similarity between the consumer and the observer.

The results from the first two studies suggest that, for prestige products, the use of counterfeit products can change people's perceptions of the genuine brand but that this effect is limited by the match between the social class of the observer (i.e. participant) and the perceived social class of the consumer. Specifically, study 1 participants, drawn from a relatively high-class population, rated Prada and Louis Vuitton as more prestigious and more likeable when the counterfeit was being used by a higher than a lower class consumer . For study 2 participants, drawn from a relatively lower social class, the reverse effect occurred. The genuine brands were rated as more prestigious and less likeable when the counterfeit was used by a *lower* than a *higher* social class consumer.

Study 3 manipulated participants' perceptions of their own social class by framing questions about income and education with relatively high or low choice options. Results demonstrated that a match in the social classes of the observer and the consumer resulted in higher beliefs and attitudes towards the original brand than a mis-match between the social classes, for both high and low class observers.

Study 4 manipulated participants' perceptions of overall similarity between the user of the counterfeit and the observer by asking participants to imagine someone who was very much un/like them and then to imagine that person using a counterfeit prestige product. Corroborating our hypothesis, the brand was rated as more prestigious and likeable when the user of the counterfeit was similar rather than dissimilar to the participant.

Together, these studies provide compelling empirical evidence for the effects of counterfeit usage by social class in-groups and out-groups on perceptions of the genuine brand. That is, the effects of observing counterfeit use on beliefs of prestige and overall brand

attitudes depend significantly on the social class of the observer and the consumer. Importantly, the perceptions of people who observe the use of counterfeits of luxury brands are more positively (negatively) disposed to liking the genuine brand when the counterfeit product is used by an in-group (out-group) member.

When 'Your Brand' Changes the Terms of the Relationship: Vicarious Dissonance in the Context of Brand Attachment

EXTENDED ABSTRACT

Consumers see brands as legitimate relationship partners (Fournier 1998). When consumers have strong personal connection (attachment) with a brand, they incorporate the brand into their own sense of self (Park et al. 2009). Attachment to a particular brand influences one's allocation of emotional, cognitive and behavioral resources towards the object of attachment and induces a readiness to evaluate it positively. Consumers follow the brands that they feel attached to, know them very well and have expectations from them. They have a tendency to see these brands as extensions of self and members of their in-groups.

Consumers rely on their relationships with a brand when they are evaluating brand extensions (Aaker and Keller 1990). Consumers evaluate brand extensions according to their established perceptions of a family brand and the similarity with the extension categories. Such evaluations build on the terms of the brand-self relationship (i.e., characteristics of the brand perceived by the individual as part of self-concept). Accordingly, consumers might experience dissonance when these brands do not behave in line with their expectations.

Vicarious dissonance theory in social psychology suggests that when people witness a discrepant behavior (contradictory to already established expectations) from a person that they have a bond with and regard as a member of their in-group, they experience a dissonance. As the behavior cannot be undone, individuals have a tendency to change their own attitudes toward the discrepant behavior in order to reduce the dissonance. Applying the vicarious dissonance theory to the marketing context, we suggest that people who feel connected to specific brands will have certain expectations regarding how these brands should behave. When these brands do not behave in line with expectations, specifically within the context of brand extensions, consumers will experience vicarious dissonance and then change their attitudes towards the unexpected behavior. In order words, consumer attitudes toward the brand extension and its product category will become more positive compared to their first reaction due to the vicarious dissonance felt.

For example, a person who identifies himself with the Porsche brand may associate the brand personality (young, exciting sports cars) of Porsche with himself, and therefore feel vicarious dissonance when Porsche decides to produce an SUV, a product category that is incongruent with the established brand personality of Porsche. In an effort to reduce the dissonance, the consumer may amend his own attitude towards the SUV product category. Hence, a person who has a bond with the Porsche brand may develop a positive attitude toward SUVs as a product category (not only to the Porsche SUV) after Porsche's decision to produce SUVs. To sum up, we suggest that strong consumer-brand attachment will lead to vicarious dissonance and affect the attitudes toward the brand extension and the product category.

Additionally, we suggest that not only different attachment levels, but also the different functions of the brands may impact the attitudes of consumers. Park and his colleagues (2009) specify three functions that brands serve; entertaining the self, enabling the self and enriching the self. In order to create consumer-brand attachment, brands need to serve all three of these resources. However, the prominence of each of these resources may be different for various brands. We assume that consumers identify themselves more with brands that have more enriching resources. Hence, we believe that different resources of brands such as enriching, enabling and entertaining the individuals, affect the level of brand-self-identification and impact the vicarious dissonance felt by the consumers when an incongruent behavior occurs. Thus, we expect that the prominence of different functions of brands will moderate the vicarious dissonance felt by the consumers. Negative impact of incongruent brand extensions on consumer attitudes toward the brand will be lower for brands with enriching resources in comparison to brands with entertaining and enabling resources.

Three pretests were conducted to choose the brands to be studied, to identify the congruent and incongruent brand extensions that these brands have, the type of attachment consumers feel for these brands and the baseline evaluations for the product categories of incongruent brand extensions. Based on these pretests, we selected two well-known brands; one luxury car brand and one fashion clothing brand.

In the first laboratory experiment, we demonstrated that participants felt vicarious dissonance when a brand that they were highly attached to introduced an incongruent brand extension. We first measured the evaluations for the unbranded product categories. Participants' evaluations for these unbranded product categories were significantly increased after they were informed that brands that they were highly attached to launched them. In contrast, there was no change in the evaluations of the participants who did not feel attached to the brands. These findings are replicated for both brands and product categories.

In the second study, we have examined the same effects using hypothetical scenarios with fictitious brands. Hence, attachment levels were manipulated. Consistent with study 1, we found that participants' evaluations increased for the unbranded product categories, even though they found them incongruent with the brands explained in the scenarios. In the third study that we are currently conducting, we are collecting data to measure the effect of different attachment types on vicarious dissonance and product evaluations.

Our research contributes to the work on attitudes toward atypical brand extensions. We extend the vicarious dissonance literature by demonstrating its effect on the incongruent extensions of brands that consumers feel attached to.

SESSION OVERVIEW

For decades, the topic of how consumers influence other consumers has been of vital interest to consumer behavior and marketing strategy scholars. They have explored it through studies of word of mouth (e.g. de Matos & Rossie 2008; Dichter 1966), of the flow of product information through networks (e.g. Lee, Cotte, and Nosworthy 2010), of opinion leaders and opinion followers (e.g. Silk 1966; Coulter et al 2002), of market mavens (e.g Feick and Price 1987), of leader users (e.g. Kratzer and Lettl 2009; Schreier, Oberhauser, Prugl 2007) and of peer influence (e.g. Watts and Dodds 2007). Indeed, more than 190 consumer and marketing research studies have been published in the 28 peer-reviewed journals and conference proceedings reviewed for this session. Not surprisingly, a considerable amount of knowledge has accumulated. Relatively little attention has been paid, however, to understanding the diverse ways in which influence is (co) produced, especially within different kinds of consumption communities. Moreover, we lack understanding of the diverse ways that consumers come to have and to maintain influence and what the effects of their influence practices may be. This oversight is particularly problematic given the explosive growth in online communities in which consumers with shared consumption interests may congregate. Our objective in this session is to shed new light on the very nature of consumer influence and on factors and processes that make some consumers more influential than others in online contexts.

The general orientation of this session is toward seeing influence as a contextually embedded and collectively co-constructed phenomenon. We anticipate some similarity across contexts, but we seek to understand the diversity, both in what influence means, and in what makes consumers influential in online communities that have differing norms and practices, that interact on different kinds of platforms and that share interests in products, practices, and problems with differing characteristics.

Likely audience

Scholars interested in word of mouth, opinion leaders and followers, peer influence, and consumption communities will all find fresh insights in this session.

Issues and topics to be covered

In the first two papers of the session, a primary issue of concern is how influential consumers produce and maintain their influence. Savignac, Parmentier, and Marcoux, study the authenticity management tactics of lead bloggers in a somewhat countercultural community focused on skateboards and the street-wear that skateboarders favor. Dolbec and Fischer highlight how curatorial practices are crucial in an aesthetic community. The latter study, as well as the final two in the session, illuminate the diverse means by which influence can be co-created. Dolbec and Fischer highlight the emergence of an alternative taste structure that deviates from that of mainstream fashion, Smith focuses on how opinion leaders in an online investing community provide antenarratives with which followers engage to help make sense of unstable markets, and Schau, Dang and Zhang analyze "code switching" in the influence process in a community populated by migrants seeking to understand US markets and marketing practices.

Why the session is likely to make an important contribution

The session will make an important contribution because it complements and moves beyond previous work that has studied influence in the form of encouraging or discouraging new product acceptance, or general psychological, demographic and socio-graphic characteristics of those whose transmit word of mouth or who are regarded as lead users, influencers or opinion leaders. It does so by focusing on contextually situated and materially shaped practices within diverse communities, where new product adoption is but one of many issues relevant to participants. Together the papers in this session will broaden and deepen our understanding of the concept of influence, of the ways in which consumers can come to be influential, and of how influence is sustained.

Furthering the conference mission of appreciating diversity

This session furthers the mission of appreciating diversity first by focusing on online communities that involve consumers from diverse countries, ranging from China (in the community studied by Schau et al) to French Canada (in that studied by Savignac et al) to regions as disparate as the Philippines, France, the UK, and Japan (in that studied by Dolbec and Fischer). The session also furthers the conference mission by involving researchers who originate in multiple countries: Canada, China, and the United States. Diversity is also represented in the mix of scholars, from masters and doctoral students, to junior faculty, to senior faculty. Finally, diversity is reflected in the mix of quantitative (see Schau et al) and qualitative methods and in the varied theories used across the papers.

Stage of Completion of Each Paper

All data has been collected and analyzed for each paper, and working versions of each have been drafted.

Consumer-Bloggers Mobilized in Marketing Campaigns: A Study of Opinion Leaders' Authenticity Management in a Streetwear Community

EXTENDED ABSTRACT

Recent research (Thompson 2006; Kozinets et al. 2010) has shown that consumer-bloggers, acting as opinion leaders in online communities, can have a substantial influence on their audience. Prior research efforts have been concerned with identifying optimal narrative strategies that can be used by bloggers when participating in a WOM campaign (Kozinets et al. 2010), and with the perceived credibility of bloggers as information sources (Kumkale et al. 2010; Eisend 2010). In contrast, our research focuses on how influential bloggers manage their authenticity through their online presentation of self as they participate in marketing campaigns. We ask: Do influential consumer-bloggers feel their authenticity threatened by the commercial pressures they face? And if so, what practices do they engage in to build and maintain authenticity, with what effect?

We know from previous research efforts that the concept of authenticity relies on perception of others (Beverland 2006; Rose et Wood 2005). More precisely, an individual may be perceived as authentic if his or her actions reveal his "real" self (Arnould and Price 2000). We argue that the literature has yet to address how influential consumers perceive the social construction of their influence within a community and, as a consequence, how they build and manage an authentic self. We find, in particular, a paucity of research about the processes and practices of authenticity management online. We are particularly interested in the context of consumer-bloggers acting as opinion leaders in their virtual community of consumption as they increasingly face potential communal-commercial tensions when getting involved in marketing campaigns (Kozinets et al. 2010). Our paper addresses these gaps by focusing on consumer-bloggers' perspectives on online authenticity and their strategies to maintain an authentic self.

The qualitative methodology used for this research project follows Kozinets (2010) recommendations about the netnographic approach. Specifically, data was collected through combining a netnography of six influential blogs with offline in-depth interviews with each consumer behind these blogs. The participants were all members of Montreal's streetwear community, i.e. an on- and off-line community formed around a common interest in streetwear fashion (e.g., sneakers), urban art, and skateboarding. The first author, a member of the community, engaged in offline observation of the community as well. Our netnography was concerned with these opinion leaders' approaches in discussing products and brands on their blogs (both sponsored and non-sponsored products) and their presentation of self as influential members of the community. Through the in-depth interviews, the first author investigated further the relationships between these consumer-bloggers and their audience, made of community members, outsider-consumers and marketers.

Schau and Gilly (2003) argue that the Internet offers the opportunity for web users to plan, refine and even rebuild their presentation of self. Our results show that consumers acting as opinion leaders are greatly preoccupied with conveying an authentic self to their audience. To that effect, our research findings show five main practices mobilized by consumer-bloggers in order to construct an authentic self. First, by adopting an informal tone (1) in the writing process of their blog entries, and thus remaining true to the communal norms, our bloggers felt they improved the authenticity of their online self. Also, by publishing original content as opposed to simply sharing existing content (2) and contextualizing in detail the subjects of their blog entries (3), our bloggers perceived that they were

strengthening the authenticity of their self-presentation. Publishing blog entries that reflected their offline reality (4) was also perceived by bloggers as instrumental to the construction of an authentic self, as was displaying field-specific capital and expertise around the subjects discussed on their blogs (5). These strategies seem to be effective considering the increase attention these influencers received from both consumer and marketing manager audiences. In conclusion, this research extends consumer behavior knowledge by demonstrating that consumer-bloggers evolving in a virtual community of consumption are not only concerned with the perception of their readers, but also attempt to maintain their influence by actively managing what they perceive as their authentic self.

Institutional Dynamics when Consumers Coalesce in Aestheticized Product Markets

EXTENDED ABSTRACT

Consumer researchers are increasingly interested in marketplace dynamics – understanding what leads to the creation of new markets (Ansari and Philips 2010; Humphreys 2010a, 2010b) or to significant changes in existing markets (Giesler 2008, 2012; Scaraboto and Fischer forthcoming; Thompson and Coskuner-Bali 2007). Prior market level research has examined the role of consumers to a limited extent, often emphasizing marketers as the main agents of market dynamics (e.g. Giesler 2012; Humphreys 2010a). Research that has looked at consumers' roles in market dynamics has largely focused on those who want to challenge the market, either based on ideology or unmet needs (e.g., Coskuner-Bali 2007; Scaraboto and Fischer forthcoming). Little attention has been paid to the unintended consequences for markets that may ensue when 'contented' consumers, not seeking any particular form of market change, interconnect with one another because of their shared interests in and enthusiasm for a product category. Interconnected consumers have been presented as value creators for particular brands (Schau, Jensen and Muniz 2009) and as brand co-producers (Fuller et al. 2008), but no prior research has examined the market-level implications of interactions by avid, interconnected consumers. We aim to fill this gap, focusing on an aestheticized market, where aesthetics *are* the products (Entwistle 2002), and inquiring about the processes by which the actions and interactions of interconnected consumers leads to institutional level changes in the market.

The context of this study is the fashion industry. We used a multi-method qualitative approach. Our data set is composed of field notes and observation following an 18-month long netnography on an outfit sharing website, lookbook.nu, combined with interviews with 13 fashion bloggers and participants in lookbook.nu, journal articles from major fashion magazines and websites, leading world journals and interviews with industry actors, and data gathered from leading online fashion forums and fashion bloggers. We employed institutional theory (e.g., Greenwood et al. 2008) as our theoretical lens to facilitate a market-level analysis, which we combined with field theory (Bourdieu 1984; 1991). We draw on concepts such as institutional logics, institutional work, mimetic isomorphism and concepts of symbolic capital derived from Bourdieu's perspective to make sense of the marketplace dynamics and sources of changes we observed. Our findings provide a process-oriented analysis which identifies different, inter-related processes and institutional impacts for each.

First, consumers need an easily accessible platform through which they can connect and share their passion for products in a category. Platforms such as online forums, sharing and curating websites, and easily self-publishable discussion sites (e.g., blogs), are

first created by enthusiasts. When multiple such platforms have been created and are widely embraced by consumers who share their tastes and opinions, a new type of institution can be said to have emerged in the field. These institutions allow consumers to emulatw practices engaged in by other categories of actors in the institutional field,(e.g. consumer-produced photo shoots), ultimately re-distributing the locus of institutional work. Second, some consumers, through their creative contributions in such forms as fashion critiques, fashion creations, street photography, and outfit photo shoots, and through the "fans" they accrue, gain greater symbolic capital in the eyes of other actors in the field. Such consumers may convert their existing capital to enter the field of fashion in producerly roles. Others may develop "bridging" capital, combining high and low fashion, acting as facilitators between those two subfields by translating high fashion looks into everyday fashion. Third, platforms where consumers congregate can become important institutional players,as a growing range of institutional actors, such as designers, model agencies and industry publications, are influenced by what is being said and done on those platforms, and, in the case of publications, citing the interventions of consumers on those platforms. More, companies begin to mimic the platforms created by consumers to appropriate the latter under their own brand. Fourth, powerful market actors further contribute to the legitimation of consumer-created trends by sponsoring those who started them, emulating the platforms consumers created, using consumer-generated pictures to sell their own products, inviting influential consumers to industry events, featuring influential consumers in mainstream fashion publications, and citing them as inspiration. Fifth, a niche economy develops around the new tastes represented by interconnected consumers. A growing number of online retailers are now catering to those, answering to the rapid changes for new tastes and emerging trends. Ultimately, some of these trends get diffused in mainstream fashion.

Our research shows the unintended consequences which can alter an aesthecized market when interconnected consumers increase the level and the visibility of their participation in the market. While consumers cannot escape markets when they wish to do so (Kozinets 2001) they can profoundly alter those they wish to participate in.

Never-Ending Stories: Opinion Leadership and Antenarratives in an Online Investment Community

EXTENDED ABSTRACT

Consumer researchers have studied opinion leadership for decades (c.f. Silk 1966), investigating aspects including characteristics and dimensions of the concept (e.g. King and Summers 1970; Flynn, Goldsmith, and Eastman 1996), its relationship with network structure (e.g. Kratzer and Lettl 2009; Lee, Cotte, and Noseworthy 2010) motivations and antecedents (e.g. Feick, Price, and Higie 1986; Stokburger-Sauer and Hoyer 2009) and its effects, especially on the diffusion of innovations (e.g. Leonard-Barton 1985; Iyengar, Van den Bulte and Valente 2011). Researchers have also identified activities in which opinion leaders engage: the acquisition of knowledge about categories of interest, word-of-mouth behavior, and advice-giving on product search, purchase, and use. However, few studies actually observe opinion leaders in action; one exception is Kozinets et al. (2010), who focus on word of mouth involving online product seeding. The dearth of research that observes how opinion leaders interact with others suggests there is an opportunity to refine our understanding on what opinion leaders actually do.

This study seeks to broaden our understanding of what opinion leadership entails.

It does so by investigating opinion leaders and other participants in an online investment community, Seeking Alpha. Investing is an increasingly important consumer research topic (c.f. Morrin et al. 2002; Hirsto 2011). Seeking Alpha positions itself as "the premier website for actionable stock market opinion and analysis, and vibrant, intelligent finance discussion." It hosts more than 300,000 blog posts, written by more than 4,000 contributing investors. The site tracks and publicizes "opinion leaders," deemed as such based on how many page views their posts received during the preceding 90-day period. This study draws on more than 3,000 blog posts, and all ensuing discussion, from 26 contributing investors posted over the 90-day period of November 28, 2011 to February 26, 2012. These investors were the "opinion leaders" over this time period for the most read category in the community, "Long & Short Ideas." This category includes 7 subcategories (e.g. long ideas, IPO analysis, options, etc.). All "opinion leaders" in the sample ranked in the top 5 most read authors in at least one of these 7 subcategories.

Based on my analysis, I offer some novel answers to the question '*what do opinion leaders do?*' Specifically, I find that they construct and facilitate the evolution of "antenarratives." Antenarratives are "non-linear, incoherent, collective, unplotted, and pre-narrative speculations, a bet, that a proper narrative can be constituted" (Boje 2001: 1)." They differ from traditional narratives, possessing neither plot nor coherence, and being inherently speculative since they arise in the flow of experience that occurs before narrative closure (Boje 2001; Barge 2004). Collectively drafted, antenarratives emerge in a variety of contexts (e.g. organizations (Vaara and Tienari 2011); advertising campaigns (Grow 2008)). Investing appears to be a context in which antenarratives that help to make sense of unfolding events are particularly welcome, perhaps because 'the market' is constantly evolving, presenting itself as a "continuous knowledge project for consumers" (Zwick and Dholakia 2006) and because one purpose of investing is to speculate on 'the market', and make a bet on one's mastery of its logic. In an online community context, these bets are proposed – and sometimes taken up – as well as collectively debated, refined, reformed, discarded and resuscitated with the next analyst upgrade, quarterly report, management shake-up, economic forecast, rate cut, etc.

My analysis also indicates that opinion leadership is not strictly about influencing product decisions, but also about influencing others' participation in marketplace storytelling, a phenomena that is important both to those who are interested in value co-creation and those who are interested in the movement of the stock market, which rises and descends with the information and stories that envelop it. My analysis reveals that participants in Seeking Alpha – who only infrequently admit to being influenced in terms of stock buying or selling – are regularly enticed by the "opinion leaders" to participate in the authoring of antenarratives through commenting and unique posts. The factors that appear to be associated with this type of influence (revealed through higher reader participation) in this context include a content focus on "cult stocks" (e.g. Apple, Sirus XM, Annaly Capital Management) within the community, the use of inter-textual referencing, and the inclusion of personal investing anecdotes and positions.

My paper offers a significant complement to the extant literature on opinion leaders and the ways in which they exert influence over others. It elaborates on antenarrative storytelling as one key behavior of online opinion leaders and discusses how influence pertains to activities like storytelling and not just purchase decisions. It also explains how opinion leaders in such a community exert influence. It thus enhances our understanding of online consumer influence and influencers.

Learning the Language of the Market: Contextual Influence and the Use of Code Switching in Online Consumer Acculturation Platforms

EXTENDED ABSTRACT

The US marketplace is governed by a host of contradictory situational norms that can, at times, confuse even the savviest American consumers. For example, in some circumstances you pay full asking price (i.e., groceries, clothing, and department stores), haggle (i.e., automobiles, second hand goods, and domiciles), bid (i.e., antiques and eBay), barter (i.e., co-operatives), donate (i.e., Goodwill and Toys for Tots), and tip (i.e., hair salons, restaurants, and cabs). You may pay in advance, pay at the time of purchase or service, pay in installments, pay a third party over time, or even lease. A consumer is unlikely to have perfect market information, therefore, the most favorable price or "best deal" on a given product or service across stores is virtually unknown (Urbany et al. 2000). Consumers less familiar with the rules and norms of the American marketplace (i.e., immigrants, temporary residents and tourists) are at a severe disadvantage.

Immigration is a cornerstone of American society. In 2010, 1,042,625 people were granted legal permanent residency in the United States (Monger and Yankay 2011), 619,913 became naturalized citizens (Lee 2011), 73,293 were given refugee status, and 21,113 were granted asylum (Martin 2011). Homeland Security reports 160 million nonimmigrant admissions to the United States in 2010 (Monger and Mathews 2011). And these figures only reflect legal, documented entrants. Nearly 11 million "unauthorized immigrants" were estimated to reside in the US in 2010 (Hoefer et al. 2011). Regardless of formal status, these immigrants, refugees and foreign nationals must all learn to navigate American marketplaces.

Peñaloza (1994) provides a complex model of immigrant consumer acculturation, demonstrating that the process requires specific types of influential consumer acculturation agents, who know both the culture of origin and the culture of immigration (Peñaloza 1994, 36, 48). Part of this influence is language facility that enables the transmission of complex cultural logics from one culture to another. Consumer acculturation agents are highly influential because their dual language competencies can help them impart the requisite cultural logics to new consumers, thus teaching consumers to navigate new marketplaces. Drawing from sociolinguistics, we demonstrate that code switching is a common consumer acculturation strategy. Influencing agents educate new migrants through thick descriptions of market practices in the language of origin and directly import terms from the host language as labels for the practices.

Codes are defined in the sociolinguistics literature as community-level communication systems (Gumperz 1982) and code switching as a communicator's systematic and deliberate shifting between codes during a single communicative episode (Coulmas 2005; Heller 1988). The most common community-level communication system is a language and code switching occurs between languages. For example, immigrants from China may switch between speaking Chinese and speaking English in a single communication event such as a face-to-face conversation in a grocery store. We show that code switching allows the cultural entrant to both understand market phenomenon of the host locale and recognize it when it appears in host language communications. Interestingly, we also find that code switching may persist beyond the initial learning stages to become the manner in which influential communications about brands, price discounts and bundling promotions are conveyed.

Our study is situated in an online forum, MITBBS (http://www.mitbbs.com/) which serves as an influential acculturation platform where Chinese immigrants and foreign nationals interact to discuss the rules and norms of the American marketplace.

We combine netnography, a qualitative method of manual thematic forum analysis (Kozinets 2009) with an established computational linguistics method to trace the discourse on the acculturation platform MITBBS specifically, the market-oriented sub-board, "PennySaver." The netnographic method is used to obtain the general patterns in the data; the computational linguistics method is used to generate quantitative analysis results to determine the magnitude of the phenomenon. The data reveal that the message board is an influential acculturation tool. We demonstrate that one specific linguistic strategy dominates the process of learning the market: code switching. Code switching behavior occurs at the language-level and at a subcultural level with a shared code developed among participants on the acculturation platform regarding American retail protocols and marketing promotions. This discovery of a shared code on the acculturation platform echoes a recent study that discovered language, dialect and brand level codes operating in quick service restaurants and beverage bars (Schau et al. 2007). We illustrate the manner in which code switching is used by contextually embedded influentials to teach market rules and collaboratively strategize ways of extracting maximum value in market transactions. We also show that code switching, while expected in early learning stages, becomes a robust norm for these influentials to communicate market-level phenomenon to susceptible novice consumers.

Encouraging Healthier Food Consumption: The Role of Product Package Cues

Christopher L. Newman, University of Mississippi, USA
Elizabeth Howlett, University of Arkansas, USA
Scot Burton, University of Arkansas, USA
J. Craig Andrews, Marquette University, USA

SESSION OVERVIEW

This session brings together four papers that explore an influential element of marketing communications, a product's packaging, on consumer health and well-being. Because a product's packaging is the final aspect of the marketing communications mix that consumers are confronted with (at point of sale), the influence of packaging on judgment and decision making has important implications. In particular, because overweight and obesity are widespread public health problems, effects of packaging elements on nutrition judgments and food choices are particularly important from a practical perspective.

The first two papers in the session (Leonard, Manning, and Campbell; Connell, Brucks, and Nielsen) investigate the role of visual packaging elements such as licensed characters and spokescharacters from a developmental perspective. Leonard et al. investigate how the presence of licensed characters on packaging influence children's food preferences and the amount of food consumed. Building on this theme, Connell et al. investigate how children's cognitive constraints in recognizing and defending against product packaging and advertising elements lead to a blurred distinction between commercial and entertainment content that persists into adulthood and potentially leads to biased judgments of associated food products.

The second two papers in the session (Debevec, Andonova, and Miller; Newman, Howlett, Burton, and Andrews) investigate how the portrayal of nutrition packaging information enhances or thwarts consumers' ability to process this information. Debevec et al. investigate how placement and portrayal of nutrition information on a product's package influences the extent to which consumers recall and process this information. Newman et al. demonstrate that the combination of nutrition facts disclosures available to consumers impacts their ability to process this information.

Thus, as a whole, these papers provide new insights into how different packaging elements influence consumers' food judgments and decisions. They investigate this question from a variety of perspectives – examining influences on both children (Leonard et al.) and adults (Debevec et al., Newman et al.) as well as how these influences vary over time (Connell et al.). They also consider the impact of both health (Debevec et al., Newman et al.) and non-health related information (Leonard et al., Connell et al.) and have important implications for improving consumers' food choices.

The findings should be of interest to diverse constituencies at ACR, including researchers interested in information processing, judgment and decision making, child development, and consumer health and well-being. The four papers represent work at advanced stages of conceptual development and data collection. This session contributes to the ACR conference's theme of diversity by integrating a diverse set of perspectives (developmental, information processing, and judgment and decision making) under one overarching theme (product packaging's effects on consumer health). In addition, these papers present data from both children (an important at-risk group) as well as adult participants. (Note: * denotes speaking author. Each speaker has agreed to present at the ACR conference in the event the session is accepted.)

The Impact of Licensed Cartoon Characters on Children's Eating Choices

EXTENDED ABSTRACT

The incidence of overweight and obesity among children in the U.S. has shown a dramatic increase over the past 40 years. For instance, obesity rates among preschool-aged children have more than doubled since the 1970s, and have more than tripled among 6-11 year old children. During this period, food and beverage companies have increased the amount spent on marketing to children. Including licensed characters on packaging is a prevalent part of marketing to children, with licensed characters and tie-ins with children's entertainment accounting for 13% ($208 million) of all youth marketing, and up to 50% of youth marketing in some food categories, such as restaurant foods and fruits and vegetables (Kovacic et al 2008). While advertising to children has declined, the incidence of cross-promotions such as licensed characters increased by 78% between 2006 and 2008 (Harris et al 2009). Some advocates have argued that companies should not use characters to promote food products to children, and some companies have agreed to only use licensed characters to promote food products that meet a minimum nutritional standard. However, several questions about the impact of package-based licensed characters on children's preferences, choices, and consumption behavior remain unanswered.

Recently, studies have shown that the presence of brands and licensed characters on food product packaging can affect the perceived taste of the foods among young children. When children were asked to taste pairs of identical foods presented in packaging that differed only in terms of whether it was branded as McDonald's (Robinson and Matheson 2007) or included a sticker of a licensed character (Roberto et al 2010), children indicated that the food from the branded/stickered package tasted better than the food from the plain package, and that they would prefer food in the branded/stickered package as a snack. In a between-subjects design, children indicated that an ostensibly healthy cereal tasted better when it came from a package with a licensed character than without, but there was no perceived taste

difference when the cereal was purportedly unhealthy (Lapierre et al 2011). While these studies find that the presence of licensed characters or branding elements on the food product package improved the perceived taste of the food among young children, none of the studies gave the children the opportunity to actually choose a snack or to consume as much as they wanted. Based on research showing that positive arousal leads to increased consumption in adults (Macht et al 2002; Kenardy et al 2003), we propose that the presence of a licensed character will, among children, increase positive arousal and thereby influence product selection and the amount consumed. The subsequently described studies extend existing research by examining whether the inclusion of popular licensed characters on packaging affects (1) the choices children make, and (2) the amount that children choose to consume and/or what foods they choose to consume. In a yet to be completed study, we will also seek to understand why the presence of a licensed character on a food package affects choice and consumption.

The goal of Studies 1a and 1b was to confirm the common belief that children are more likely to choose food in packaging that includes a licensed character over packaging that does not. For both studies, children between 4 and 10 years old were approached in public spaces and offered a choice between a free sample of two fruit gummy snacks, one with a licensed character, and one without. Study 1a (n=26), used the same brand of fruit gummy snacks, one with a sticker of a Spongebob character attached. Study 1b (n=26) used two different brands of fruit gummy snacks, one that included Scooby Doo characters on the package, and the other with pictures of fruit, but no character. Children were significantly more likely to choose the option with the licensed character than expected by chance in both Study 1a (77%; (χ^2= 7.54, *p*=.006) and 1b (69%; χ^2 = 3.85, *p*=.05).

Considering that children choose food packages that include a licensed character over food packages that do not, the goal of study 2 was to examine the effects of a licensed character on consumption amount of healthy and unhealthy foods. Eighty children aged 4 to 7 were asked to participate in a taste test. They saw a package of either cookies or dried apricots that either included an image of Scooby Doo or the same package, but without Scooby Doo. They were offered a bowl of the cookies or dried apricots, purportedly from that package, and asked to taste at least one and to complete a survey. Afterwards, the amount of the food the child consumed during the survey was measured. Results show a main effect of character, controlling for hunger, such that for both healthy and unhealthy foods, children consume more when Scooby Doo is on the package ($M_{Character}$ = 0.68, $M_{No\ Character}$ = 0.54, p=.05). There were no other significant effects.

Overall, this set of studies contributes to the literature on the effects of marketing techniques on children by examining the effects of including popular licensed characters on food packaging. We find that children are more likely to choose food with licensed characters on the package and importantly, to consume more of both healthy and unhealthy foods when the package includes a licensed character. A fourth study examines why these effects occur, specifically examining the role of arousal.

Exposure to Advertising and Packaging Cues in Early Childhood Leads to Blurred Distinction Between Commercial and Entertainment Media That Persists into Adulthood

EXTENDED ABSTRACT

Previous research has found that children incrementally learn how to recognize and cope with marketing communications as they age. It is now well-established that children first learn how to distinguish commercial from entertainment content (Butter et al. 1981), then later recognize the persuasive intent of marketing communications (Ward, Wackman, and Wartella 1977), and finally learn to utilize cognitive defenses against marketing communications (Brucks, Armstrong, and Goldberg 1986). However, the question remains as to whether these developmental constraints lead to effects that persist into adulthood. Across four studies, we demonstrate that distinction between commercial and entertainment stimuli from early childhood is blurred. In contrast, we do not observe this blurred distinction for stimuli that is initially encountered later in life, after full development of marketing communications knowledge. This blurred distinction, along with hedonic associations with early childhood advertising stimuli, results in subsequent judgment biases favoring associated products on unrelated utilitarian (e.g., nutrition) attributes that can persist into adulthood. These biases are likely to be activated by advertising/product packaging elements (e.g., spokescharacters), are difficult to correct, and can even extend to brand extensions supported by the same advertising/packaging elements (Bousch and Loken 1991).

The purpose of study 1 was to provide evidence that memory representation of commercial stimuli experienced first in early childhood remain influenced by the initial encoding as entertainment. Fifty-one U.S.-born and raised participants completed an Implicit Association Test (IAT; Greenwald 2008), where they classified stimuli as either entertainment or advertising. We selected eight entertainment (four "earlier" and four "later") and eight advertising/packaging characters (four "earlier" and four "later") to be used as visual stimuli. The "earlier" stimuli had all been widely used for decades, thus ensuring that participants likely would have been exposed to them initially in early childhood. "Later" stimuli were chosen so that they were nonexistent in early childhood for older participants, but were extant and commonplace in early childhood for younger participants. Participants were classified as "older" or "younger" based on the age the participant would have been at the time the later stimuli were introduced so that "older" participants could have experienced only half the stimuli in early childhood. In contrast, "younger" participants would have likely experienced all of the stimuli in early childhood, before advertising knowledge would have been fully developed. Results supported the predicted interaction between participant age group, stimulus chronology, and stimulus type ($F(1,50)$=3.81,*p*=.056). Exploring the older group of participants further revealed a two-way interaction of stimuli type by stimuli chronology ($F(1, 50)$=3.78, *p*=.056) which, as predicted, is driven by an enhanced ability to categorize advertising stimuli where initial exposure came after full development of advertising knowledge ($M_{Earlier}$=1078.64, M_{Later}= 942.45, $F(1,50$=17.34), *p*<.001). In contrast, there were no differences in this age group in their ability to categorize the stimuli ($F(1,50)$=1.83, *p* = .18). Importantly, this two-way interaction did not replicate for younger participants ($F(1,50)$<1).

The purpose of study 2 was to provide evidence to show that the blurred distinction documented in study 1 can lead to biased nutrition judgments for products associated with the advertising, due to

the hedonic nature of children's advertising. As a visual stimulus, we selected a well-recognized mascot used for advertising and packaging since its associated pre-sweetened cereal's launch in 1979. One hundred and fifteen participants from the United States were recruited from Amazon mTurk. As in study 1, participants were divided into younger and older groups based upon the age they would have been when this product was launched. After viewing the stimulus, the associated product was rated on health-related items embedded among other measures on 7-point scales. As expected, the younger group rated the product as healthier than the older group ($M_{Younger}$=4.31, M_{Older}=4.00, $F(1,112)$=2.61, p=.05).

The purpose of studies 3 and 4 was to demonstrate that nutrition-related biases for early childhood products are resilient and difficult to correct, and can be done so only when both motivation and ability to correct bias are high (Wegener and Petty 1985) and when highly positive affect does not serve as a motivational deterrent to attend to negative attributes (e.g., high sugar) in a product (Ahluwalia, Burnkrant, and Unnava 1998). In both studies, we selected a visual stimulus that has been heavily and continuously used in advertising and packaging since 1951, making it highly likely that U.S.-born participants would have been exposed to this mascot at a very early age. In study 3, 150 U.S.-born undergraduate participants were randomly assigned to a between-subjects design where motivation (prime:health/control per Bargh et al. 2001) and ability (source of bias made salient/not salient) were manipulated and affect toward the stimulus image was measured. The presweetened cereal product endorsed by the relevant stimulus was then rated on health-related items embedded among other measures, as in study 1, on 7-point scales. We observed the hypothesized interaction between motivation, ability, and positive affect ($F(1,141)$=4.23, p<.05). When both ability and motivation to correct were enhanced, there was a significant linear relationship, with the effect of a decreasing likelihood to correct bias as positive affect toward the relevant stimulus increased (t=3.14, β=.46, p <.01). Judgments did not change regardless of level of felt affect in the other three conditions (all t < |1|). In study 4, we replicated this pattern of results on a product extension with different ability manipulation (passage read on advertising's effects on children/elderly) and with motivation measured by assessing how interested participants were with the information in the ability manipulation with 78 U.S.-born participants ($F(1,69)$ =5.10, p< .05). As in study 3, higher levels of positive affect interfered with bias correction when ability to correct was enhanced and participants were motivated to attend to the message (t = 2.94, β = .55, p < .01). Also replicating the pattern in study 3, judgments did not change regardless of level of felt affect in the other three conditions (all t < |1|).

This research provides evidence that early exposure to advertising and packaging elements can lead to effects that persist for years, even decades, into adulthood. Furthermore, these effects have the potential to adversely impact consumer health and well-being.

Is That Healthy? The Influence of Information Type and Location on Nutritional Information Processing

EXTENDED ABSTRACT

Rising obesity rates and a resulting increase in health consciousness has led to increased interest in how to better communicate nutritional information on packaging. Several systems (e.g., traffic light, Facts Up Front, NuVal, Smart Choices) have been introduced. In this paper, we focus on two such systems – Facts Up Front (FF), which typically places icons with calorie, total fat, sodium and sugar information in the top corner of the package, and NuVal, which rates products on a 1-100 scale based on 30-plus nutrients and nutrition factors. Although NuVal has not been used on packages to date (they provide information on shelf tags and at their website), we selected it for study due to its summary nature, in contrast to FF's inclusion of more specific information about individual nutrients.

We examine how the type of information (FF, NuVal) and its location influence consumer awareness of the information as well as the degree to which they prompt self-referencing (i.e., whether consumers process this information relative to their own experiences). Self-referencing was chosen as a key focus of our investigation because self-referencing has been shown to lead to greater learning and recall of information (e.g., Klein and Loftus 1988), increased message elaboration and persuasion when message arguments are strong (Burnkrant and Unnava 1995), more favorable attitudes toward ads and products, and increased purchase intention (Debevec and Iyer 1988). Further, given research reporting that females tend to be more health-focused than men, we also sought to understand how the effectiveness of the nutritional information varied by gender. Specifically, we examine: (1) whether consumers are more likely to pay attention to the nutritional labels when they are overlapping the product, in close proximity to the product, or at the top right corner; (2) whether consumer self-referencing varies based on the location and type of the nutritional information; and (3) whether gender moderates these effects.

To examine these questions, we conducted a 3 (location: top, overlapping, proximal) x 2 (type of information: FF, NuVal) x 2 (gender) between-subjects experiment with an additional control group; 247 students (42.5% female) participated for course credit. Participants were presented with a picture of the front of a box of WhoNu cookies which contained the product name, image of the cookies, and four health-related manufacturer claims (e.g., "as much fiber as a bowl of oatmeal"). In the NuVal and FF conditions, the box also contained the NuVal logo and score or the 4 FF boxes in one of three different locations on the package – overlapping the cookies, above the cookies (proximal), or in the top right corner of the package. After viewing the package, participants were asked questions to assess their recall and processing of the nutritional information.

As expected, location influenced the degree to which consumers paid attention to the nutritional information. We expected recall to be highest for information overlapping the product image since information in this location would be more likely to fall within the consumers' focal view when examining the product. Consistent with this hypothesis, NuVal information yielded the highest recall when it overlapped the cookies (54% correct vs. 15% in top right (p = .02) and 11% when proximal (p = .01)). However, results suggest that the optimal location of information may vary by information type. Recall was highest for FF when it was placed in the top right corner (68% correct compared to 54% and 30% when it was overlapping and proximal to the cookies, respectively). There were no differences in recall by gender.

Also, as expected, location, type of information, and gender influenced the degree to which consumers engaged in self-referencing. A 3 (location) x 2 (type of information) x 2 (gender) ANOVA on self-referencing revealed a main effect of location (F(2, 199) = 3.14, p < .05) and a main effect for gender (F(1, 199) = 6.08, p < .02). Nutritional information placed on the top right resulted in marginally higher self-referencing (M = 4.45) than when the information was overlapping (M = 3.74, p = .06), but did not differ from when it was proximal to the cookies (M = 4.10, p > .4). As expected, females had higher levels of self-referencing than males (M_f = 4.45, M_m = 3.84, p < .01). There was also a significant three-way interaction among location, type of information, and gender (F(2, 199) = 3.22, p < .05). This interaction appeared to be driven by differences in how men and

women responded to the information when it overlapped the cookies. Men were significantly more likely to self-reference the NuVal information (M = 3.86) than the FF information (M = 2.94, p < .05), while women were (directionally) more likely to self-reference the FF information (M = 4.52) than the NuVal information (M = 3.61, p = .1).

Our research contributes to the literature on consumer processing of nutrition information by identifying the optimal placement of different types of nutritional information (specifically, FF and NuVal). Follow-up studies will seek to enrich our understanding of these findings by exploring why males and females differ in the type of information seen as most relevant to them and why the optimal location varies by information type. Further, our research contributes to an understanding of how consumers use front-of-package nutritional information. Despite grocery store efforts to promote the NuVal measure, consumers' knowledge of this system is still limited. Eighty percent of our respondents indicated they were not familiar with the NuVal scoring system, even though 59% shop at a store that displays the information. Overall recall of nutritional information on packages (regardless of information type) was also low, suggesting efforts should be directed at raising consumer awareness of these systems if they are to be effective. In addition, marketers and policy makers should consider where the information is placed on the package and how its placement relates to other information on the package if they want to maximize the likelihood that consumers perceive the information and use it in their choices.

Confronting the U.S. Obesity Conundrum: Assessing Front-of- Package Evaluative vs. Reductive Nutrition Information Disclosure Systems

EXTENDED ABSTRACT

Some two-thirds of all U.S. adults are overweight and 33% are considered "obese." It has been estimated that by 2015, 75% of all U.S. adults will be overweight and 41% will be obese (Wang and Beydoun 2007). Obesity, largely driven by food and beverage consumption, is a major cause of heart disease (CDC 2012) – a disease that accounts for approximately 29% of all U.S. deaths. While consumers may be bombarded with considerable nutrition information in facts panels and with claims on the front of packages, in today's retail environment, consumers are faced with literally thousands of choices that they make in a very restricted amount of time. While many consumers are interested in making healthier food choices at the retail shelf, each package presents various types of information, and this package and product category 'clutter' makes decisions more difficult for consumers.

To help address consumer welfare and health issues by simplifying the task consumers face at the shelf, a number of initiatives have been implemented recently. These include 'reductive' systems that present some subset of calorie and nutrient information found in the Nutrition Facts panel (e.g., the GMA/FMI Facts Up Front labeling system with calories, saturated fat, sodium, and sugar), as well as evaluative systems that integrate nutrient information (e.g., Walmart's Great For You icon, the Institute of Medicine's (IOM) multiple 'stars' rating system).While there is a common goal of for these various approaches (i.e., to help consumers more easily determine if a particular food item is a healthful choice), each system has certain potential strengths and weaknesses (Andrews, Burton, and Kees 2011; IOM 2011; Cooper 2012). While much of the research on FOP provision supports the basic premise that *some form* of simplified or summarized FOP nutrition information can be useful, the literature is unclear with regard to what *specific* information or format will be most effective (IOM 2011).

In this research, we employ a processing fluency theoretical framework to develop and test hypotheses concerning effects of different FOP labeling approaches (Winkielman and Cacioppo 2001; Schwarz 2004; Winkielman et al. 2003). Of particular interest is the influence of package disclosures on consumer evaluations of perceived package and category retail shelf processing fluency, consumer evaluations (healthfulness, purchase intentions), and choice when FOP information is presented in isolation and when it is combined. Data have been collected from a series of four experiments that are a mix of retail lab studies and internet-based experiments. The first two studies are internet-based between subject experiments (with 300+ adult consumers). Results show that the presence of a FOP interpretive icon moderates the effect of a Facts Up Front reductive (multi-nutrient) disclosure on both perceived fluency (F (3,355) = 9.53, p <.01) and trustworthiness (F (3,355) = 11.41, p <.01) of FOP health information. Additional results reveal a moderating effect of consumer skepticism toward FOP labeling on perceived organization trustworthiness (F (3,355) = 4.74, p <.05). The pattern of results across the two studies shows how alternative FOP disclosure systems can potentially complement one another by compensating for weaknesses of the individual systems (Andrews et al. 2011).

Studies 3 and 4 are retail lab experiments where participants are exposed to FOP information on packages for different categories with multiple brands on retail store shelving. Experiment 3 is a 2 (interpretive FOP system: (IOM stars vs. control) x 2 (reductive system: Facts Up Front vs. control) x 2 (healthfulness: more healthful vs. less healthful product options) across two product categories: soup and granola bars. The first two factors are between subjects and the latter is a within subjects (i.e., participants are exposed to multiple products and categories). Results indicate that a FOP interpretive icon (IOM 'stars') moderates the effect of objective product healthfulness on purchase intentions in both the granola category (F (1,96) = 15.59, p < .001) and the soup category (F (1,96) = 11.85, p < .01). Addition of the IOM 'stars' strengthen effects of product healthfulness on purchase intentions. Results also reveal that the FOP interpretive icon (IOM 'stars') moderates objective product healthfulness on perceptions of product nutritiousness for both the granola category (F (1,96) = 17.88, p < .001) and the soup category (F (1,96) = 17.25, p < .001), as well. The fourth experiment replicates the design for Study 3 but varies the product categories (to include granola bars and macaroni and cheese) and uses 121 adult consumers with children living at home as participants. Analysis suggests that a FOP interpretive icon moderates objective product healthfulness on product attitudes in both the granola category (F (1,110) = 21.66, p < .001) and the macaroni and cheese category (F (1,110) = 25.15, p < .001). In addition, inclusion of the FOP icon strengthens parents' intentions to purchase the more healthful food product for their children in both the granola category (F (1,110) = 13.68 p < .001) and the macaroni and cheese category (F (1,112) = 7.01, p < .01).

An additional study will use a large internet-based experiment (n=600) to further address adult consumers with children at home. The between subjects experiment assesses the effect of two recently announced evaluative FOP systems (IOM 'stars' vs. Walmart 'Great for You' vs. FOP control), in conjunction with a reductive FOP system (Facts Up Front vs. control) across brands and product healthfulness levels.

From a conceptual perspective, findings extend our knowledge and understanding of conceptual fluency in a packaging context, and they demonstrate how the fluency conceptualization can be extended to a full product category retail shelf context. These findings, taken cumulatively, have important theoretical implications as well as practical implications relevant to policy makers and promotion and brand managers.

The Control Dilemma: Pros and Cons of Perceived Control on Self-Regulation

Chair: Jaideep Sengupta, HKUST, Hong Kong

Paper #1: Environmental Disorder Leads to Self-Regulatory Failure

SESSION OVERVIEW

Objectives and Overview

A greater sense of control over one's decisions and choices is usually viewed to be desirable (Kelly 1963; Ryan and Frederick 1997). Thus, consumers in general appreciate making their own decisions (Markus and Kitayama 2003), and companies strive to offer as many alternatives as possible in order to enhance perceptions of choice freedom (Levav and Zhu 2009). There is, however, relatively scant research on the possible downsides of perceived control and autonomy (for an exception, see Botti, Orfali, and Iyengar 2009). The papers in this session offer new insights into the nature and effects of perceived control, with a particular emphasis on how it may exert either a positive or negative influence on self-regulation, depending on aspects of the context and the task. In putting together this work, we hope to spark an interest in new directions of inquiry into perceived control and its effects.

Topics

The first two papers in the proposed session identify, respectively, a negative and a positive influence of perceived control on self-regulation. The next two papers then use the goal pursuit context to identify moderating factors for when either a positive or a negative effect may be obtained.

First, Chae and Zhu, while documenting the negative impact of low perceived control, identify an entirely novel antecedent of such perceptions. The authors examine the impact of environmental orderliness on consumers' self-regulation. Across four studies, they propose and find that a disorganized (vs. organized) environment threatens individuals' sense of personal control, causing them to spend substantial cognitive resources to cope with this threat. Consequently, people are resource depleted and exhibit more self-regulatory failures in a disorganized (vs. organized) environment. In the second paper, Chen and Sengupta demonstrate the beneficial effects of consuming vices, and in so doing, identify a context in which lower perceived control actually produces a positive influence on self-regulation. Across four studies, they find that giving in to temptations (e.g., eating indulgent food, or impulsively buying hedonic products) increases subjective vitality – defined as the positive energy available

to oneself. Increased vitality, in turn, produces better self-regulation. Of importance, these effects only obtain when vice consumption can be justified – such as when it can be explained away on the grounds of relatively low personal control. For example, greater vitality and improved self-regulation obtain when eating an unhealthy but tasty snack is perceived as complying with the experimenter's instructions, rather than resulting from one's own free choice. Thus, in the specific context of vice consumption, lower perceived control actually produces beneficial effects. The next two papers focus on how perceived control in the sense of choice freedom influences self-regulation, as manifested in goal pursuit. Etkin and Laran propose that freedom (vs. restricted freedom) in an initial goal-consistent choice can increase or decrease goal-directed motivation, depending on the level of goal activation prior to choice. Across three studies, they show that when a goal is highly active at the time of choice, increased (vs. restricted) freedom in making a goal-consistent choice leads to that choice being interpreted as having fulfilled the goal. Ironically, this then hinders subsequent goal pursuit. For example, having the freedom to choose between several healthy products (vs. having to pick the only available product) in pursuit of an active self-control goal induces the inference that one has at least partly satisfied the goal, lessening the motivation to engage further in it. On the other hand, when the goal is less active at the time of choice, free (vs. restricted) choice simply increases goal activation, which then increases subsequent goal pursuit. Finally, Huang and Zhang also propose both positive and negative effects on goal pursuit as a result of increased choice freedom, operationalized in their work as the number of reward options available upon task completion (e.g., having the freedom to choose between many different rewards after completing a certain number of frequent flyer miles, as opposed to having just one possible reward). The critical moderator identified in their work is stage of goal pursuit. At an early stage, the multiple available rewards are construed as substitutable for one another; these substitutes, combined, create a greater perceived likelihood that one will eventually get something desirable. Therefore, freedom of choice increases goal pursuit motivation. On the other hand, when nearing goal attainment, multiple available rewards (vs. an assigned reward) are conversely construed as competitive against one another – the consumer now has to decide which one to pick. Because it highlights the fact that some attractive rewards will have to be foregone, this produces a demotivating effect on goal pursuit.

General Orientation and Likely audience

Together, the four papers in this proposed session enhance our understanding of the nature of personal control, and also of how it may influence self-regulation. We believe that this session, if accepted, will attract scholars interested in the diverse yet related areas of motivation, goals, vitality, and self-regulation. Given the overlap as well as the distinctions between the four papers, we hope that they will, as a set, provoke illuminating discussion and debate.

Fit with Conference Theme

Finally, we believe that this session proposal fits with the theme of this year's ACR – appreciating diversity – along two aspects. First, while all the presentations will touch upon two common themes (perceived control, and self-regulation) each of them offers distinct insights on a diverse set of topics, such as vitality, environmental disorder, option availability, and reward programs. Second, the authors

involved in the different papers represent schools across Canada, Hong Kong and the US; thus, this session, if accepted, would serve to further facilitate interaction among a far-flung group of scholars.

Environmental Disorder Leads to
Self-Regulatory Failure

EXTENDED ABSTRACT

A common theme in many popular home organizations TV shows is that environmental disorganization is associated with a number of negative outcomes, such as deteriorating health and self-regulatory failures. As such, better organization or de-cluttering can improve life quality. Despite these beliefs in practice, our theoretical understanding of how environmental organization or orderliness can affect cognition and behavior remains limited (Keizer, Lindenberg, and Steg 2008). We address this question in this research by focusing on the impact of environmental orderliness on self-regulation.

Research on personal control (Kelly 1963) suggest that humans have a fundamental need to control their environment (Kelly 1963; White 1959). Among various factors such as choice freedom and predictability of outcomes that are known to affect personal control, we focused on the impact of characteristic of physical environment on personal control and consequently self-regulation. Previous literature documents that characteristics of a physical environment, such as physical confinement, can threaten individuals' sense of freedom, a very important component for people to maintain their sense of personal control (Baum, Singer, and Baum 1981; Edney and Buda 1976; Levav and Zhu 2009). For instance, Levav and Zhu (2009) showed that, just like restriction on choice freedom, physical confinement also increases reactance behaviors. Extending on this line of research, we suggest that environmental orderliness can threaten individuals' sense of personal control, because people in messy homes often feel that their lives are also out of control (Belk, Seo, and Li 2007; Cwerner and Metcalfe 2003) and people tend to attribute a messy home to the person's lack of ability to manage her time and life (Bitner 1990). Furthermore, research on resource depletion theory suggests that coping with a threat demands cognitive resources, and subsequently increases self-regulatory failures (Glass, Singer, and Friedman 1969; Inzlicht and Kang 2010). Combining the above theorizing, we propose that a disorganized environment threatens individuals' sense of personal control, causing them to spend substantial cognitive resources to cope with this threat. As a result, these people are resource depleted and exhibit more self-regulatory failures in subsequent tasks.

Across four studies, we show that individuals who were exposed to a disorganized (vs. organized) environment exhibited more self-regulatory failures in subsequent tasks, such as impulsive buying, less persistence on challenging tasks, and unhealthy eating. We also validate our process explanation by showing that: (1) the negative impact of environmental disorder on self-regulation is more acute for people who are highly sensitive to control threats (study 2), (2) the control motivation mediates the relationship between environmental orderliness and self-regulation (study 3), and (3) self-affirmation, which helps recoup cognitive resources, moderates the relationship between environmental orderliness and self-regulation (study 4a and 4b).

Study 1 showed that a disorganized (vs. organized) environment leads to poorer performance on a challenging task. The study was run with one participant at a time. Upon arrival, the participant was guided to the room where environmental orderliness was manipulated. Specifically, she was exposed to either an organized or a disorganized environment. In the disorganized environment condi-

tion, office supplies (e.g., paper, file folders, and paper cups) were scattered all over the place in a cluttered manner. In contrast, in the organized environment condition, the same amount of items was placed in a very structured and ordered manner. Then, the participant was escorted to the second room where no orderliness manipulation was present and was asked to complete an unsolvable puzzle (Baumeister et al. 1998). We found that participants who were exposed to the disorganized (vs. organized) environment earlier gave up sooner on the unsolvable puzzle.

Study 2 provided a theoretical replication in an impulsive buying context, and illuminated the process by showing that this effect is more salient among individuals who are chronically motivated to react to control threats. The environmental orderliness manipulation and the procedure were similar to those in the study 1. After exposure to either an organized environment or a disorganized environment, participants were asked to indicate Willingness-To-Pay (WTP) for a number of products (Vohs and Faber 2007). Individuals' chronic reactance were assessed via the Hong Psychological Reactance Scale (Hong and Faedda 1996). The result provided the replication on impulsive buying: participants in the disorganized environment indicated higher WTP than those in the organized environment. Furthermore, the impact of environmental orderliness on WTP was only salient among participants who were chronically high in reactance.

Study 3 tested the proposed process explanation by demonstrating that the control motivation mediates the effect of environmental orderliness on unhealthy eating behavior. Adopting a lexical decision task to assess the implicit activation of control motivation, we showed that people in a disorganized (vs. organized) environment responded faster to control-related words, indicating the increased activation of control motivation (as measured by response time to control-related words) mediated the effect of environmental orderliness on chocolate consumption.

Finally, Study 4 provided further evidence for the underlying process. Based on the finding that self-affirmation counteracts resource depletion and facilitates subsequent self-control behaviors (Schmeichel and Vohs 2009), we expected that self-affirmation will counteract the resource depletion induced by a disorganized environment, and thus attenuate self-regulatory failures in subsequent tasks. Results from two studies (4A and 4B) supported our hypothesis.

What's the Point of Temptation if You Don't Give in
to It? The Positive Impact of Vice Consumption on
Consumer Vitality

EXTENDED ABSTRACT

Vice consumptions are characterized by immediate pleasures, which have negative later consequences (Rook 1987). Therefore, such behaviors, e.g., eating a rich but fattening piece of cake, or buying an expensive sweater that one can't quite afford – are typically viewed as being normatively "bad". This research takes a different tack: we examine how vice consumption can actually have beneficial effects – specifically, by increasing vitality – as long as the consumption can be explained away on grounds of relatively low perceived control.

Arising from self-determination theory (SDT; Deci and Ryan 1991), subjective vitality refers to the positive experience of having energy and feeling alive (Christianson et al. 2005; Nix et al., 1999). Vitality arises from the feeling of behaving in fulfillment of intrinsic motivations rather than norm-based rewards and punishments (Deci and Ryan 1991). Thus, tasks that are inherently enjoyable (e.g., jogging for the sheer pleasure of it) typically produce more vitality than tasks that are performed as a means to an end (e.g., jogging in order

to lose weight; Ryan and Deci 2000). Viewed from this perspective, since vices are associated with immediate hedonic pleasure, yielding to the temptation to consume a vice (vs. a virtue) should produce enhanced subjective vitality.

Vice consumption should also exert a countervailing force on vitality, however. Given its negative normative connotations, consuming a vice typically produces guilt. Because vitality is characterized by the absence of conflict (Ryan and Frederick 1997), the tension produced by these feelings of guilt should dampen the vitality that would otherwise be induced by vice consumption. We argue, therefore, that vice consumption will enhance vitality only when the accompanying guilt can be reduced by justifying the behavior. For example, if eating a chocolate cake can be justified on the grounds of complying with instructions (as opposed to freely choosing to do so), it should improve vitality. Support for this argument would inform SDT, which posits that autonomous (i.e., freely-chosen) behaviors produce more vitality than behaviors that are externally mandated. While this positive effect of autonomy has received wide support in the context of regulatory behaviors (Muraven, Gagne, and Rosman, 2008; Nix et al. 1999), we argue that the vice consumption context is qualitatively different: here lower autonomy actually leads to increased vitality. Finally, our research also examines downstream consequences of the increased vitality produced by vice consumption. Drawing on the idea of vitality as an enabling resource (e.g., Muraven et al. 2008), we propose that as long as accompanying guilt can be attenuated, the increase in vitality produced by consuming a vice should lead to enhanced creativity, as well as improved self-control.

Results from four studies provide convergent support for these arguments. Experiment 1 required participants to sample either a chocolate cake (vice) or baby carrots (virtue), and vitality was measured using a standard scale (Ryan and Frederick, 1997). Higher vitality obtained for the former ($M_{chocolate}$ = 4.46 vs. M_{carrot} = 3.74, F (1, 82) = 11.92, p < .01). A corresponding effect was obtained on creativity as measured on an alien-drawing task (8.73 vs. 6.96, respectively, F = 38.78, p < .01); vitality fully mediated this effect.

Experiment 2 provided a more complete picture by examining the interaction between type of behavior and external justification. Participants were either explicitly instructed to sample the snack they were exposed to (either chocolates or carrots) as part of the experiment, or were asked to choose between eating the snack and writing an aversively long essay – eating the snack was more under one's control and accordingly less "justified" in this condition. The vitality benefit accruing from eating a chocolate (vs. a carrot) was greater in the justified condition (M's: 4.78 vs. 3.79, F (1, 76) = 13.71, p < .01) than in the not-justified condition (M's: 3.95 vs. 3.78, F (1, 76) = 0.57, p > .50). Note that these results argue against a simple physiological account (eating chocolates increases vitality because of higher sugar/calorific intake); this argument would not explain the effect of justification. Results from a control condition (M = 3.88) showed that the vitality difference observed in the justified conditions was due to increased vitality obtaining in the chocolate condition, rather than a dampening in the carrots condition. Guilt was also measured in this study, and as expected, indulgent behavior led to higher guilt in the no-justification condition ($M_{chocolate}$ = 5.22 vs. M_{carrot} = 2.62, F (1, 76) = 7.23, p < .01), but not in the justification condition (M's: 2.96 vs. 2.89). This study included a new measure of creativity, as manifested in advertising slogans generated by participants, and adjudged by independent observers. The creativity of these slogans was greater given justified (vs. not-justified) vice consumption (M's: 7.16 vs. 5.24, F (1, 76) = 32.46, p < .01); inter-

estingly, justification had the reverse effect for virtue consumption (M's: 5.15 vs. 6.07, F (1, 32) = 7.08, p = .01).

Experiment 3 used the same design as Experiment 2 and found evidence for another downstream consequence of the vitality induced by consuming vices: i.e., self-control performance, as measured in a concentration task. Individuals who consumed a vice performed significantly better at this task when the vice was justified (vs. not); no such difference obtained for virtue consumption. Experiment 4 replicated these results using a different operationalization of vice vs. virtue behaviors (impulsively buying a hedonic product vs. deliberatively buying a utilitarian product), and also of justification (mentally accounting the purchase as a gift from another person). Exactly the same significant pattern of results on vitality, guilt, and self-control was obtained as in previous studies (not detailed here for reasons of space).

Thus, in opposition to the view that one should not give in to the temptation of consuming a vice, we find evidence for its beneficial effects – vice consumption heightens a resource, vitality, which then benefits consumers' creativity and self-control performance. We also inform self-determination theory: contrary to extant findings in this literature, in the vice-consumption context, lower autonomy may actually benefit vitality.

Let Freedom Ring?
Divergent Effects of Free Choice on Goal Pursuit

EXTENDED ABSTRACT

There is a generalized belief that freedom of choice is beneficial to consumers. Companies strive to offer as many product lines as possible, shopping malls are popular for having many different stores available, and consumers appreciate making their own decisions, without the influence of others. The current research looks at freedom of choice from a goal pursuit perspective. Our focus is on understanding the conditions under which perceiving freedom in an initial goal-consistent choice (e.g., being able to choose without any restrictions, making decisions without the influence of others) helps versus hinders subsequent goal pursuit. For example, when will healthy grocery-shoppers feel more motivated to be healthy? After making healthy snack choices with freedom, or after their freedom to choose has been restricted?

We propose that the impact of freedom in an initial goal-consistent choice on subsequent goal pursuit will depend on the level of activation of the goal at the time of choice. Specifically, we predict that having freedom in goal-consistent choice when a goal is highly active at the time of choice will reduce subsequent goal pursuit, whereas having freedom in goal-consistent choice when a goal is not highly active at the time of choice will increase subsequent goal pursuit. We base our predictions on the following reasoning. When people have freedom in choosing products associated with a goal, we expect that they will perceive their behavior as pursuing their goal to a greater degree relative to when they do not have as much freedom. For instance, going to the supermarket and being free to choose several different healthy items is perceived to be a stronger exertion of self-control than when one is able to choose only one type of item (the number of options is restricted), even if in the same quantity.

The impact of this perceived stronger act of goal pursuit on subsequent motivation will depend on the level of goal activation prior to choice. When the goal is highly active, for example, if people have been exposed to environmental cues associated with the goal (Chartrand et al. 2008), a strong act of goal pursuit will satisfy the goal to a greater degree. As a result, the goal will be less active following freedom versus restricted goal-consistent choice (Bargh and Ferguson

2004), decreasing subsequent goal pursuit. In contrast, when the goal is not highly active prior to choice, a strong act of goal pursuit will not satisfy the goal, but increase the activation of the goal (Bargh 2006; Laran and Janiszewski 2009; Shah and Kruglanski 2002). As a result, having freedom versus restricted freedom in initial goal-consistent choice should increase subsequent goal pursuit in this case.

Across three studies we find support for our propositions. In each study, we invite participants to make several healthy snack choices, varying whether a health goal is highly active (vs. not active) prior to choice, as well as whether participants have freedom (vs. restricted freedom) in choosing snacks. Having participants choose among healthy snacks ensures that they all have the opportunity to pursue a health goal, with or without freedom. Study 1 provides an initial test of our reasoning regarding the effect of freedom versus restricted freedom in goal-consistent choice on goal activation. Consistent with our argument, when a health goal was not activated prior to choice, free (vs. restricted) choice increased the level of goal activation, as measured by a word-stem completion task ($M_{freedom}$ = 3.52, $M_{restricted}$ = 2.28; F (1, 121) = 15.77, p < .001). In contrast, when a health goal was activated prior to the snack choice task, free (vs. restricted) choice satisfied the goal, decreasing its level of activation as measured by a word-stem completion task ($M_{freedom}$ = 3.03, $M_{restricted}$ = 3.67; F (1, 121) = 3.84, p = .05).

Study 2 demonstrates the divergent effects of choice freedom on goal pursuit following an initial goal-consistent choice. Supporting our predictions, when a health goal was not activated prior to choice, free (vs. restricted) choice among the healthy snacks increased participants' subsequent likelihood of engaging in a healthy behavior, as measured by their propensity to participate in an unrelated study involving eating raisins (health goal-consistent) versus M&Ms (health goal-inconsistent; $M_{freedom}$ = 58.3%, $M_{restricted}$ = 23.1%; χ^2 (1) = 9.70, p < .01). In contrast, when a health goal was activated prior to choice, free (vs. restricted) choice decreased participants' subsequent likelihood of engaging in a healthy behavior ($M_{freedom}$ = 38.9%, $M_{restricted}$ = 71.1%; χ^2 (1) = 7.74, p < .01). Finally, study 3 provides another demonstration of these effects, with different goal activation and choice freedom manipulations. Again supporting our predictions, when a health goal was not activated prior to choice, free (vs. restricted) choice among the healthy snacks increased participants' subsequent likelihood of making a healthy choice, as measured by their propensity to choose an apple (health goal-consistent) versus a candy bar (health goal-inconsistent) as a thank you for participating in the study ($M_{freedom}$ = 63.3%, $M_{restricted}$ = 31.8%; χ^2(1) = 4.46, p < .05). In contrast, when a health goal was activated prior to choice, free (vs. restricted) choice decreased participants' subsequent likelihood of making a healthy choice ($M_{freedom}$ = 26.9%, $M_{restricted}$ = 56.0%; χ^2 (1) = 4.45, p < .05).

In sum, this research demonstrates divergent effects of experiencing freedom in goal-consistent on subsequent goal pursuit; freedom (vs. restricted freedom) can increase or decrease goal-directed motivation, depending on the level of goal activation prior to choice. As such, our findings contribute to the literature on goal pursuit by showing that motivation to pursue a goal is not simply dependent on whether consumers make a goal-consistent choice or not, but on the degree of freedom associated with this choice. In addition, we contribute to the literature on the benefits of offering consumers freedom by showing that freedom of choice is not always beneficial and may in fact be detrimental to people's motivation to pursue a goal.

Kids in the Candy Store:
The Motivational Consequences of Multiple Goals

EXTENDED ABSTRACT

A goal is the mental representation of a desirable end state, and could influence not only the direction of people's behavior, but also the intensity of such behavior (Locke & Latham, 1990; Pieters et al., 1995). While prior research has mainly focused on the pursuit of a goal in isolation, recent efforts have been made to extend our understanding toward "goal structure" that comprises a network of interrelated goals (Kruglanski et al., 2002). In practice, marketers often offer multiple goals for customers to choose from (e.g., offering multiple rewards for customers who have accumulated 10,000 miles in a frequent flyer program), under the assumption that such freedom of choice would lead to greater motivation and participation. In this research, we ask the question: Is the offering of multiple goals always more motivating? For companies that try to encourage repeat purchases, should they design a loyalty program that allows consumers to choose a prize from multiple options? Also, should companies use the same reward structure to motivate customers who just joined a loyalty program as those who are getting close to redemption?

We posit that people view the relations among multiple goals that can be served by a single means differently as they move from earlier stages to later stages of the pursuit, and thus the freedom of choice could either be motivating or demotivating, depending on one's current stage in the pursuit. Specifically, when people first begin the pursuit and are still far away from the end-point at which they would need to make a decision on the final reward, the freedom of choice among multiple goals (vs. an assigned goal) elicits greater motivation. This is because, at this early stage, multiple goals are construed as *substitutable* for one another; therefore, these potential substitutes, combined, create a greater perceived likelihood that one would eventually attain something one desires, which leads to greater motivation in the pursuit.

However, when people have made substantial progress and are approaching the end of the pursuit, the need to make a decision on the reward becomes imminent and people begin to compare among options; at this advanced stage of pursuit, the freedom of choice among multiple goals (vs. an assigned goal) conversely becomes demotivating. This is because, when people begin to contemplate and compare among options, multiple goals would conversely be construed as *competitive* against one another (i.e., one would have to let go some equally attractive options), which leads to lower perceived value in the pursuit and thus lower motivation.

Two studies provided supportive evidence for the proposed hypothesis and the underlying mechanisms. In Study 1, we asked participants to memorize price information of products in different categories, and to type down these prices in question sections to earn points for the reward. We provided participants either one assigned reward or four different rewards (of equal market value) to choose from, and tracked how their motivation naturally progressed throughout the pursuit. This study allowed us to obtain the trend of participants' motivation when given the freedom of choice among multiple goals. We found that when there was only one assigned reward offered for attaining the target number of points, participants' motivation constituted a linearly increasing trend as they accumulated more progress. In contrast, when given the freedom to choose from multiple rewards, participants' motivation instead fitted a cubit trend; further analyses showed that, although participants who had the freedom of choice among multiple rewards became slightly more motivated from stage1 to stage 2, their motivation did not increase as they moved across the mid-point of the pursuit (i.e., as they ad-

vanced into the later stage and started comparing among different options).

In Study 2, we provided prospective customers of a school-based debit-card loyalty program either one assigned reward or four different rewards to choose from, and directly manipulated the loyalty points they have accumulated so far in the semester (based on their accumulated expenditure on campus and school-related businesses) as their progress level in the program when they joined. We measured these prospective customers' thoughts about the loyalty program and the reward system (e.g., the perceived goal competitiveness, goal attainability, and goal value) to capture the underlying mechanisms, and we also measured their sign-up rate for the loyalty program as a proxy for their motivation to continue the pursuit of the reward. Three moderated mediation models provided supportive evidence for the proposed mechanisms. We found that when people were at the initial stage of the pursuit, having the freedom to choose among multiple goals led to higher perceived likelihood to attain something one desired, which elicited greater motivation to sign up for the loyalty program (conditional indirect effect: $\beta = .07$, $z = 2.74$, $p < .01$); however, when people were at the advanced stage of the pursuit, the freedom to choose among multiple goals conversely led to lower perceived value of the program, which led to lower motivation to sign up (conditional indirect effect: $\beta = - .04$, $z = - 1.65$, $p < .10$); this is because the perceived goal competitiveness (i.e., the perception that some options were more attractive than others) led to lower perceived value for people at this advanced stage of pursuit (conditional indirect effect: $\beta = - .05$, $z = - 2.88$, $p < .01$).

Brands as a Means of Self-Expression:
Threatened, Unexpressed, Omnivorous, and Flexible Self

SESSION OVERVIEW

The goal of the proposed session is to build on the existing literature to further the understanding how self-identity affects consumers' brand preferences. Research papers to be presented investigate this topic from multiple theoretical perspectives, offering a broader view of the role of brands in self-expression. Given the relevance of the topic to central issues in consumer behavior, this session is likely to have significant effect on future identity research and, in particular, the role of brands as a means of self-expression. Apart from providing theoretical insights into how identity influences brand preferences, the proposed session will contribute to the understanding of several content areas of great interest to ACR conference attendees, including brand extension, attitudes, self-concept, and compensatory consumption. Specifically, this special session will address the following issues:

Research presented by Ward and Dahl explores the effect of threats to self on brand preferences. They extend past research which has established that when one's self-concept is threatened, s/he is more likely to acquire objects to reaffirm the self. Ward and Dahl investigate this proposition in a luxury retail context and examine how a rejection from the sales staff impact consumers' brand perceptions. The authors show that, contrary to conventional wisdom that a welcoming sales staff will attract consumers, rejecting consumers may actually enhance retailers' appeal to some consumers. Specifically, they conclude that when an individual is rejected by a salesperson from brand that is relevant to his/her ideal (vs. actual) self, s/he is likely to increase (decrease) his/her assessments of the brand and willingness to consume in ways that enable him/her to affiliate (disassociate) with the rejecting brand.

Research by Ma, Hamilton, and Chernev examines how restricting self-expression in the social and political domains (e.g., being forbidden to comment on political leaders; inability to express feelings toward others) impacts consumers' brand preferences. They

show that the unexpressed self in the social domain leads to an increased need for self-expression and conspicuous consumption, strengthening individuals' preferences for self-expressive brands. They attribute this effect to the compensatory nature of self-expression, whereby restricting self-expressive means in one domain leads to a greater desire to self-express in an unrelated domain.

Adding to the counterintuitive findings that the threatened self and unexpressed self can lead to increased brand preferences, research by Gosline and Lee examines another counterintuitive hypothesis that omnivores (consumers who mix high and low status brands) find interstatus brand collaborations less appealing than univores (owners of only the high or the low status brands). They test this hypothesis using various experiments that feature hypothetical and actual interstatus co-branding collaborations. They find that the greatest damage to brand prestige is actually amongst current owners of both the high and lower status brands. These findings contribute to the longstanding brand extension literature, particularly the literature that addresses symbolic status brands, which suggests that these brands could dilute their image and reputation when engaging in some form of downward extension.

Lastly, Ding, Xu, and Wan examine the impact of identity framing on motivation and self-control. They show that consumers with a broad identity (vs. a narrow identity) perceive themselves as having more social resources, which in turn enhances motivation for social tasks and improves their self-control. They further demonstrate that this effect is apparent in communal relationships but attenuated in exchange relationships. Moreover, the findings confirm that perceived social resource mediate the effect of identity framing on consumers' motivation and self-control.

Our proposed session can contribute substantively to the theme of ACR 2012—appreciating diversity. The research papers in this session investigate the relationship between self-identity and brand preference in diverse range of contexts, such as in-store purchasing, restricted social and political environment, co-branding collaborations, and social tasks. These research projects involved a wide array of consumers, including those from both East and West, and in the lab and the field. This session will contribute both to basic theory development in the realm of identity and branding, and as well will suggest implications for marketing strategy.

Each presenter will be given 15 minutes to present. This will leave 15 minutes for discussions between the presenters and audience. The discussion will aim at facilitating a broader understanding of the role of brands as a means of self-expression and the implications of this understanding on expanding the field of consumer behavior.

Being Mean to Keep 'Em Keen:
Retail Rejection Increases Aspiring Consumers' Desire for the Rejecting Brand

EXTENDED ABSTRACT

Consumers often feel intimidated by unfriendly sales staff at luxury retailers and cite this as a reason they avoid shopping in these venues. Indeed, a former employee of Yves Saint Laurent admits that sales people size up a customer by looking at his watch and his shoes and 'if the accessories are not expensive, the customer is not worth

the effort of even a simple hello' (Wilson 2009). However, as luxury sales have declined in recent years, retailers endeavor to become approachable in an effort to attract new consumers and increase sales (Odell 2009).

Yet, contrary to conventional wisdom that a welcoming sales staff will attract consumers, we demonstrate that rejecting consumers may actually enhance retailers' appeal to some consumers. The extant research supports this conjecture: individuals who have been rejected have been found to endeavor to ingratiate themselves with the rejecter (Romero-Caynas et al. 2010). Indeed, when aspects of the self-concept are threatened, people become more materialistic (Chang and Arkin 2002), are subsequently more likely to acquire objects that make a good impression on the rejecting party (Meade et al 2010) and bolster the threatened the self (Rucker and Galinsky 2008)

Building on the prior research on social rejection, we contend that people differentially respond to rejection. Individuals' sense of who they currently are and who they want to be is largely dependent on and reinforced by the groups they belong to. While one's actual self is fairly stable, one's ideal self is less certain and thus more vulnerable to threat (Swann1983). Consequently, our prediction is that when we an individual is rejected by a brand that is relevant to his/her ideal (vs. actual) self, s/he is likely to increase (decrease) his/her assessments of the brand and willingness to consume in ways that enable him/her to re-affiliate (disassociate) with the rejecting brand. Luxury brands are a domain that consumers are likely turn to when they are seeking affirmation and self-expression and as such, provide an excellent context to examine our hypotheses.

In the first study we investigate how consumers' self-concepts affect their brand assessments and desire to purchase from brands to which they aspire but feel rejected by. In a 2 (brand: Gucci vs.. Louis Vuitton) x 2 (salesperson behavior: rejecting vs. neutral greeting) experiment, participants first indicate their level of identification with and degree to which they aspire toward the brand. Next, they read a scenario describing a hypothetical shopping experience in which they are directed to some clothing items in a store by a rejecting (vs. neutral) salesperson.

After reading the scenario participants answered a series of questions about their brand perceptions and desire to buy and wear the clothing from the brand.

We examined how the rejecting (vs. control) salesperson affected participants' assessments of the products from that brand. We observe an self-concept X salesperson behavior interaction (F(1, 100) = 4.78, p < .03) indicating that when consumers who possess ideal vs. (actual) identities relative to the brand, are rejected (vs. control) by the brand representative, they evaluate the products sold by the brand more positively.

The results show that not all rejection causes consumers to ingratiate via consumption but rather these behaviors are most likely when the rejection is threatening to the individual's tenuous ideal self. In the next study, we further investigate how self-control affects consumers' responses to rejection by manipulating their self-concept rather than measuring it.

In our second study we controlled self-views by priming participants' ideal vs. actual identity with a sentence rearranging technique in which participants rearranged words relevant to one's aspiration (vs. actual) identity. Next, participants completed an ostensibly unrelated study using the same scenario as the prior study. Finally, participants answered the same questions described in study 1.

We replicated the self-concept x salesperson behavior interaction (F(1, 121) = 4.28, p < .05) indicating that when consumers who aspire toward (versus identify with) the brand, are rejected by (vs

have a neutral interaction) with the brand representative, they evaluate the products sold by the brand more positively.

In study 3, we created a situation that mimics the experience of rejection in a retail environment. Participants participated in a 2 (brand: Gucci vs. Louis Vuitton) x 2 (salesperson behavior: rejecting vs. neutral) x 2 (prime self-concept: ideal vs. actual identity) x 2 (pre-experimental self-verification: self-verify vs. control) "product assessment study" in which participants interacted with a brand representative. Prior to the study half of the participants participated in a fashion knowledge tool (vs. neutral questions) enabling participants to express their fashion expertise enabling them to preemptively self-verify their fashion identity. Next, half of the participants were primed with an ideal vs. actual identity prime (see study 2). Finally, participants interacted with brand representatives who followed either a rejecting or neutral script. In rejecting conditions brand representatives appeared skeptical of the participant's knowledge of the brand, and disapproving of his/her appearance (versus neutral). Participants then rated bags from the brand on how variables from prior studies. Two weeks after the study, participants again rated their views about of the brand.

The data reveal a salesperson behavior x prime self-concept x pre-experimental self-verification interaction (F(2, 172) = 6.61, p < .01) indicating that consumers who aspire towards (vs. feel affiliated with) the brand and have not (vs. have) been allowed to self-verify prior to interacting with a rejecting (vs. control) brand representative evaluate the products sold by the brand more positively.

Finally, we show that participants who had a rejecting (vs. neutral) interaction with the brand representative had significantly less positive perceptions of the brand two weeks after the interaction (M Rejecting= 4.82 vs. M Neutral = 5.60, F(1, 121) = 4.09, p < .04).

The findings from three studies show that retailer rejection may drive consumers to prefer products that enable them to ingratiate themselves to the rejecting group when the group is one which they aspire to belong. However, these effects can be mitigated if they are able to self-verify prior to rejection.

The Unexpressed Self: The Impact of Restricting Freedom of Self-Expression on Brand Preferences

EXTENDED ABSTRACT

Individuals frequently have a desire to express aspects of the self. This desire to self-express stems from one of the most basic human needs—the need to belong and to be accepted and valued by others (Baumeister and Leary 1995; Fiske 2010; Maslow 1970). Despite the fundamental nature of self-expression, individuals are not always free to express their values, opinions, and beliefs. The limits to self-expression can be caused by a variety of factors. One is the restriction on free expression imposed by various government and regulatory entities. Such suppression of one's ability to express views typically involves the domains of politics and public policy, often extending to related domains that include religion, communications, the media, and use of the Internet. In addition to being restricted by government, individuals' self-expression also can be limited by social context, such as an imbalance of power in interpersonal relationships (e.g., an employee arguing with the boss). One's need for self-expression can further be curbed by social norms, such as restrictions imposed by traditions (e.g., not speaking ill of the dead), as well as by norms of politeness (e.g., not telling a friend how she really looks in skinny jeans). On many occasions, individuals' ability to express their views can be limited by a variety of factors that physically restrict one's ability to reach an audience (e.g., when access to one's social network is temporarily disrupted).

The ubiquity of possible impediments to self-expression raises the question of how restricting one's ability to express values, opinions, and beliefs influences subsequent behavior. Because of its importance, the topic of restricting self-expression has been the focus of numerous studies that for the most part have focused primarily on the implications of restricting self-expression in social or political domains. In this context, it has been shown that suppressing social or political self-expression is likely to produce perceptions of injustice (Stevens 1992), as well as trigger oppositional social movements (Andersen 2006; Fetner 2008; Polletta 2004).

Building on prior research, we take a different approach and examine whether and how restricting one's ability to express opinions in socio-political domains influences individuals' preferences and behaviors in domains unrelated to the views being suppressed, in particular, the domain of product consumption. In this context, we investigate how the impact of restricting individuals' ability to express their socio-political views influences their brand preferences.

We argue that restricting individuals' ability to express their socio-political views can have a significant impact on brand preferences and that this impact tends to strengthen their need for self-expression through brands. This proposition builds on previous findings in the goal literature suggesting that when the means of pursuing a goal or fulfilling a need are restricted, people frequently experience a rebound effect, such that the restriction leads to a subsequent increase in need-related behavior (Lewin 1951). For example, suppressing thoughts about colors (Liberman and Förster 2000), stereotypes (Macrae et al. 1994) or white bears (Wegner et al. 1987) leads to increased thoughts of these constructs relative to a condition in which these thoughts were not suppressed. Likewise, when the means to fulfill a goal are removed, the desire to complete the goal becomes stronger (Förster and Liberman 2001; Förster, Liberman, and Higgins 2005). This is consistent with Lewin's (1926) tension system theory of goals, which states that when a goal has been activated, the person feels a tension until the goal is completed.

Applied to self-expression, these findings imply that restricting the means to self-express can increase people's motivation to express themselves. Since brands can serve as a non-restricted means of self-expression when other avenues are closed off, we propose that restricting one's ability to express in social or political domains can strengthen one's preference for self-expressive brands. Thus, we predict that curbing one's ability to share their views of a major political or social event—such as opining about the performance of the president, commenting on major world news events, even sharing opinions about celebrities—will strengthen individuals' preferences for ostensibly unrelated brands such as Nike, Oakley, or Levi's. We propose that individuals' need for self-expression is compensatory in nature and that consumers tend to offset their inability to self-express in one domain by seeking opportunities to express in other, unrelated domains.

We test this prediction in a series of five empirical studies. Experiment 1 shows that restricting self-expression in various social domains (opinions about celebrities, countries, universities, pop stars, etc.) strengthens consumer preferences for self-expressive brands. Experiment 2 further shows that restricting freedom of speech (commenting on a newsworthy current event) strengthens consumer preferences for self-expressive brands. Building on the findings of the first two studies, Experiment 3 further documents the compensatory nature of self-expression in cases when the restriction of self-expression is internally imposed (e.g. voluntarily controlling one's feelings toward others). Experiments 4 and 5 aim to shed more light on the compensatory nature of self-expression. Specifically, Experiment 4 shows that the effects observed in the first three studies are attenuated when consumers have a channel other than brand evaluation in which to express themselves. Experiment 5 provides further support for our account by showing that conspicuous consumption, such as choosing a self-expressive brand, decreases individuals' need for self-expression in the original, restricted domain (e.g. inability to comment on Obama's performance).

In sum, this research investigates how curbing one's ability to express an opinion in non-consumption domains subsequently increases one's preferences for self-relevant brands. We show that this effect is due to the compensatory nature of self-expression—the unexpressed self in one domain can be expressed by self-expressive means from other domains, such as brands. This research adds to the literature on self-expression by demonstrating the compensatory nature of self-expression. It also adds to the literature on branding by documenting that brands can help consumers express the unexpressed self in non-consumption domains.

Breaking Status Boundaries:
When Interstatus Brand Collaborations Undermine Self-Expression by Omnivorous Consumers

EXTENDED ABSTRACT

Past research has shown that symbolic brands serve as a means for consumers to express their identities and social status, and to differentiate from dissociative outgroups (Chernev, Hamilton, Hal 2011; Berger and Heath 2007; White and Dahl 2006, 2007; Holt 1998; Shavitt 1990; Belk 1981; Veblen 1899). It may be quite surprising then that, recently, fashion brands have witnessed a growing phenomenon: co-branding partnerships between high and lower status brands. High status luxury brands (such as Jimmy Choo, Karl Lagerfeld, Stella McCartney, Roberto Cavalli, and Vera Wang), have entered into collaborations with lower status companies like Target, Kohls, J.C. Penney, Wal-Mart, and Payless Shoes. These status boundary violations (Lamont 1996) support recent research that has shown that many high status persons are not cultural snobs, but in fact eclectic and "omnivorous," in their tastes (Erickson Peterson and Kern 1996; Erickson 1996; Peterson and Simkus 1992). Previous literature has explained this as a generational shift, due to cohort replacement and changes in social structure, values, and art-world dynamics. We introduce a new perspective on this phenomenon: that omnivorous status boundary-violating behavior is based on a need for self-expression. This leads us to a counterintuitive hypothesis that omnivores (consumers who mix high and low status brands) should find interstatus brand collaborations less appealing than univores (owners of only the high or the low status brands). We test this hypothesis using various experiments that feature hypothetical and actual interstatus co-branding collaborations. We find that the greatest damage to brand prestige is actually amongst current owners of both the high and lower status brands. These findings contribute

to the longstanding brand extension literature, particularly the literature that addresses symbolic status brands, which suggests that these brands could dilute their image and reputation when engaging in some form of downward extension.

Our first study focuses on univores, and shows that owners of either the high status brand or the low status brand penalize their brands for collaboration. We recruited undergraduate students at Harvard to complete an online survey on a potential co-branding effort between Harvard and the University of Phoenix, and to browse the beta-website of the Harvard-Phoenix Online University to "get a sense of what the joint initiative would look like." This collaboration was seen as an affront to owners of the high status brands (Harvard undergraduates), as the Harvard brand was deemed highly symbolic and used as a means of identity expression. We show that these subjects feel that their Harvard brand suffers lowered status (t(29) = -10.770, p < 0.001) and prestige points (t(29) = -7.324, p < 0.001), due to this collaboration. For non-Harvard subjects, who did not use the brands as self-expressive symbols, we saw no such penalty for the interstatus collaboration. Additionally, our Study 1 shows that Harvard subjects believed that the lower status school's brand would increase in status and prestige due to the inter-status co-branding initiative with their school (t(29) = 12.245, p < 0.001). This indicates that the high status consumers are not merely trying to dissociate from or punish the lower status consumers.

Study 2 shows that, surprisingly, that the greatest damage to the collaborating brands is amongst consumers who currently own both the high status and lower status brands. These types of consumers, called omnivores, consume high and lower status brands simultaneously – this mixing behavior is a means of self-expression that is undermined by interstatus brand collaborations. Study 2 demonstrates this with an experiment featuring a hypothetical collaboration between the high-status Prada brand and the lower-status Banana Republic brand. We find that actual univore owners of Prada and actual univore owners of Banana Republic are quite similar to non-owners, in that their ratings of the prestige level of their respective brands experience little to no change. However, we find that actual omnivore owners of both Prada and Banana Republic penalize the high status brand (t(83) = -1.73, p = 0.087). These omnivores also rate the prestige of the collaboration significantly lower (t(84) = -2.22, p = 0.029), while univore owners of either the high status or the lower status brand are not significantly different from non-owners in their prestige ratings of the collaboration. We find that omnivores seek to make self-expressive statements with their status boundary violations. Despite the fact that these omnivore consumers currently own both the high and lower status brands simultaneously in their wardrobes, they also have a significantly lower rating of the fit of these same brands for a co-branding collaboration (t(84) = -3.254, p = 0.002). We argue that these consumers are motivated by a need for self-expression, and that omnivore behavior conveys a boundary spanning behavior that speaks to distinctive taste (Bourdieu 1984). As a result, when high and lower-status brands collaborate, they obviate the self-expressive nature of omnivore consumption.

In Study 3, we test whether interstatus collaborating brands may escape penalty if self-expression is aided by a "moral alibi" -- an alternative explanation provided by the manufacturer that allows omnivore consumers to impute a moral meaning, like a charity or goodwill effort, to their consumption behavior. This moral alibi may create a means for self-expression for the brand owners that could defray the perceived negative consequences of the co-branding on the higher-status brand. However, though we find that it can significantly reduce the prestige or status lost compared to when a moral

alibi is not proffered, the higher-status brand in the co-branding collaboration still suffers a penalty (t(32) = -3.922, p < 0.001).

The results of these three studies indicate the importance of preserving opportunities for self-expression amongst consumers of symbolic products. Interstatus collaborations may seem most appropriate for people who already mix brands of differing status, but pre-fabricated omnivrous brand offerings undermine the ability of consumers to express themselves via omnivorous consumption.

Will Broad Identity Make People Feel Stronger: The Impact of Identity Framing on Motivation and Self-Control Behavior

EXTENDED ABSTRACT

Prior research has suggested that identities are situation-sensitive and that a shift in identities can lead to differences in information processing and actual behavior (Oyserman 2009). For example, Mandel (2003) finds that individuals primed with the interdependent (vs. independent) self-identity were more likely to take financial risks. Shih et al. (1999) found that Asian-American women performed better on a mathematics test when their ethnic identity was activated, but worse when their gender identity was made accessible.

Although a sizable research has examined the effect of different types of social identities on judgment and behavior (Aaker and Lee 2001), so far little research has examined the impact of different levels of social identity on behavior. According to self-categorization theory (Turner et al. 1987), people have multiple social identities with multiple levels of inclusiveness: the superordinate level based on similarities among human beings, the intermediate level emphasizing interdependence, and the subordinate level emphasizing independence. Based on this theory, we posit that social identities can be defined either broadly or narrowly. A broad identity defines a member in a superordinate group (e.g., an employee in P&G China), which combines heterogeneous features, and focuses on the similarities among subgroups. Conversely, a narrow identity defines a member in a subgroup (e.g., an employee in the Beijing Center in the R&D Department of P&G China), which constrains individuals to a specific domain, and focuses on the differences among subgroups. We further hypothesize that making the broad or narrow identity accessible to individuals will alter their cognitions and behaviors accordingly. Specifically, we propose that individuals with a more accessible broad identity (vs. narrow identity) will perceive belonging to a bigger group and having more social resources to spare, which in turn increase their motivation in social tasks. Moreover, prior literature has indicated that social support could attenuate job-stress and enhance self-efficacy (Viswesvaran et al. 1999). So we posit that a broad identity will enhance individuals' perception about their self-regulation strength and improve self-control.

We also examine the boundary condition for the effects of identity framing on motivation and self-control. Building on the differences between communal and exchange interpersonal relationship (Aggarwal 2004), we hypothesize that a broad identity (vs. a narrow identity) will increase individuals' motivation and self-control in subsequent tasks only when people perceive the interpersonal relationship as communal but not when they perceive it as exchange,

and that this moderation effect would be mediated by the perceived social resources.

To tests the proposed hypotheses, we conducted three experiments. In Experiment 1, the identity framing was manipulated by presenting either the whole organization chart of HP (broad condition) or the same chart but with the highlight that they belong to the "Engineering Management" subdivision (narrow condition). Following this task, participants responded to the perceived social resource scale adopted from Zimet et al. (1988). Afterwards, they were instructed to read the description of environmental protection campaign which required them to collect signatures among their friends to support the campaign. Then participants estimated how many signatures they could get, and returned the collected signatures one week later. The results indicated that participants primed with a broad identity (vs. a narrow identity) reported having more social resources, estimated that they could collect more signatures, and actually returned more signatures. These results provided initial evidences for our proposed effect of the identity framing on self-perception and motivation.

Experiment 2 tested the moderation effect of interpersonal relationship on the impact of identity framing. The manipulation of identity framing was similar to that used in experiment 1. The interpersonal relationship was manipulated in the form of an idiom understanding task. In the communal condition, participants read the idiom as "Between friends all is common" which implied that people should care about others and show a genuine concern. Conversely, in the exchange condition, "Even reckoning makes long friends" was presented which emphasized that interpersonal relationship should be quid-pro-quo and that people should try to keep things even with others. We then measured participants' motivation in social tasks by estimating how many signatures they could get to protect endangered animals. The performance on self-control was measured using a task of processing useful but threatening health message (Agrawal and Wan 2009). The findings demonstrated that among the participants in the communal condition, those primed with broad identity estimated they could get more signatures than those primed with narrow identity. However, for the participants in the exchange condition, the estimation of signature numbers did not differ between participants primed with broad identity and those primed with narrow identity. A similar pattern was found on the amount of time spent on reading the health message which reflected the participants' self-control.

Experiment 3 explored the process underlying the moderating effect of interpersonal relationship on the impact of identity framing. We also aimed to replicate the results of experiment 2 in a marketing relevant context. Specifically, the identity framing was manipulated by priming participants as members of one parent brand fans club (broad identity) or one sub-brand fans group (narrow identity). Then participants moved on to the idiom task which manipulated the interpersonal relationship. Next, participants read the brochure of one new product trial campaign, and estimated the number of friends they could invite to join the campaign. Afterwards, participants proceeded to a product evaluation survey involving a series of binary choice, a task adopted from Vohs et al. (2008) to assess self-control. They were told to do as many as they could, with the understanding that they could stop anytime when they "want to quit." The amount of time spent on doing the survey served as the dependent measure of self-control. Consistent with our predictions, the positive effect of broad identity on performance for both social and self-control tasks were only replicated in the communal relationship condition. Furthermore, we found that this moderation effect was mediated by perceived social resource.

This research contributes to the literature of social identity, prosocial behavior, and self-control. In addition, our findings provide insightful implications for marketing practice and organization behavior.

Paper #4: Vulnerable Consumers: Ethnography of the Consumption of French Farmers Facing Impoverishment

Françoise Passerard, HEC Paris, France
Kristine De Valck, HEC Paris, France
Romain Laufer, HEC Paris, France

SESSION OVERVIEW

Douglas (2007) defines poverty as the inability to maintain the exchanges that define one as a member of the society. Such exchanges are not however limited to economic domains, and as such the effects of poverty on consumers – as well as the mechanisms that impoverished individuals employ to countervail the hardships in their lives – are multifaceted. This special session draws inspiration from the TCR agenda to address substantive issues facing consumers around the world and synthesizes four studies that explore the effects of poverty and impoverished consumers' efforts to improve their lives.

Each of the papers to be presented relates to completed research projects, and fits with the conference mission of appreciating diversity as they not only explore the effects of poverty from different situational contexts (rural farmers in France, the homeless in the US and UK, slum-dwellers in Kenya, and single mothers in the UK), but also utilize different units of analysis (individual, family, and their broader networks). The papers draw on discussions within the poverty track at a recent TCR dialogical conference, in which the scholars identified five research streams with implications for impoverished consumption including: consumption choice amidst the burdens of poverty, product and service experiences, the effects of consumer culture, adverse marketplace forces, and consumption capabilities (Blocker et al 2011, 2012).

Kathy Hamilton (University of Strathclyde) explores consumption paradoxes of stigma avoidance with single mothers living in poverty in the UK. Fredah Mwiti, Maria Piacentini, (Lancaster University) and Andrew Pressey (Birmingham University) use ethnography to examine the integration of resources within subsistence consumer networks in Kenya. Andres Barrios (Lancaster University) and Chris Blocker (Baylor University) explore the consumption practices that homeless individuals use to countervail the experience of stigma and transform their self-identity in the UK and US. Françoise Passerard investigates the consumption vulnerability of French farmers. Beyond the implications that each individual study poses for

poverty-related TCR, together these four studies contribute to dialogue on consumer surprise, irony, and ambivalence. In particular, a 2011 JCR editorial highlights the idea that research could explore ways that consumers are made better or worse off when they experience and act upon surprising thoughts or behaviors (Hsee et al. 2003). The studies in this proposed session make salient consumers' varying strategies for countervailing the effects poverty, and in doing so, the collective findings reveal paradoxical tensions and feelings of ambivalence. Thus, we anticipate interesting dialogue as to how consumer strategies may ultimately help mitigate their vulnerabilities or exacerbate them. Speakers will have a maximum of 15 minutes each to present their papers. This will ensure that sufficient time is allocated for general audience engagement and discussion.

In sum the session provides a platform for those interested in the intersection of poverty and transformative consumer research to discuss and gain major understanding over the 4 billion plus consumers who live in impoverished conditions. Beyond this, the session will appeal to a wide audience including those who have a theoretical interest in consumer vulnerability, consumer disadvantage, social exclusion, consumer coping, stigma and emerging markets.

Single Mothers in Poverty: Consumption Paradoxes of Stigma Avoidance

EXTENDED ABSTRACT

This presentation will focus on single mothers in poverty and the paradoxical nature of their quest to avoid stigmatization and social disapproval. At previous ACR conferences, I have concluded that single mothers can improve their situations and develop self-esteem through initiating various creative strategies to respond to their family's demands (Hamilton and Catterall 2007, 2008). A re-interpretation of this research reveals that coping strategies which seem functional and effective at the micro level may have unanticipated outcomes if considered within the wider societal context. Thus the coping strategies employed to disguise poverty and aid the portrayal of a socially acceptable image can actually create further stigmatization. This highlights the importance of moving beyond only focusing on the stigma management strategies employed by consumers to also incorporate sociocultural understandings.

This study consists of 24 in-depth interviews in single mother households. A family approach was adopted for the study meaning that children aged 11 and over also participated in interviews. Therefore in 9 households, a family interview was conducted with the mother and her child(ren) and in 16 households the mother was interviewed alone. Interviews were conducted in respondents' homes and interview topics included everyday life, budgetary strategies, hopes for the future, family background information and financial circumstances. Hermeneutics was used to interpret the data. In this paper, the data interpretation is advanced by using macro social discourse to gain a deeper and more complete understanding of individual experiences. To do so, the lived experience of low-income consumers is considered within the context of exclusion and single mother discourse.

Poor consumers are often defined in relation to marketplace exclusion. For example, Bauman (2005, 38, 112-113) argued that 'a "normal life" is the life of consumers' with the poor described as

'inadequate,' 'unwanted,' 'abnormal,' 'blemished, defective, faulty and deficient,' 'flawed consumers' and 'non-consumers.' However, recent popular discussion "focuses not on the inability to consume, but on the *excessive* participation in forms of market-oriented consumption which are deemed *aesthetically* impoverished" (Hayward and Yar 2006, 14).

Coping through consumption is a strategy that extends to almost all the families in the study, and there is emphasis placed on ensuring children have access to the 'right' brands to facilitate identity construction. Many strategies focused on minimizing expenditure are strictly followed to ensure budget allocation towards more conspicuous forms of consumption including clothing, footwear, jewellery, home decor and gifts for others. The purchase and display of brand names is viewed as a way of avoiding stigma and could be considered as a disconfirmation of the stereotype (Miller & Major, 2000) aimed at disguising restricted class positions. By attempting to contest and resist the stigmatizing regime, low-income consumers seek consumer normalcy (Baker, 2006) through their marketplace transactions. According to Bourdieu (1984, 56) the 'refusal of tastes' plays a key role in consumer choice as people avoid the purchase of goods and services that may be detrimental to their social self-concept. Within the current context, this includes the rejection of low-cost clothing in favour of visible brand names and logos. Evidence suggests that coping efforts may be empowering for lone mothers and can result in higher self-esteem. This interpretation provides an optimistic image of the low-income consumer as an active individual coping victoriously within the challenging context of consumer culture to improve the standard of living for themselves and their family.

However, by interpreting such consumption activity in relation to "a new vocabulary of social class" (Tyler 2008) it becomes apparent that those who follow a strategy of conspicuous consumption in efforts to mask poverty ultimately encounter the very stigmatization that they set out to avoid in the first instance. In recent years, exclusion discourse in the UK has focused on 'chav' culture (alongside regional variations in semantics). Often believed to stand for 'Council Housed and Violent,' popular media representations and discourse surrounding chav culture is overwhelmingly negative. The stigmatisation of single mothers is particularly prevalent in chav discourse as articulated in Tyler's (2008) article entitled 'Chav Mum Chav Scum.' As Tyler (2008, 26) suggests "whilst young unwed working-class mothers have always been a target of social stigma, hatred and anxiety, the fetishisation of the chav mum within popular culture has a contemporary specificity and marks a new outpouring of sexist class disgust." The chav single mother is heavily criticised for vulgar consumption choices, in particular dressing her children "with expensive and thus apparently wholly inappropriate designer clothing and jewellery" (Hayward and Yar 2006, 22). In a cruel irony, some of the brand names that low income consumers purchase to escape stigmatization are the same brands that have particular negative user stereotypes associated with them.

Research on stigma is often based on either micro-individual or macro-social analysis. However, as Campbell & Deacon (2006, p. 412) suggested, there are problems with both these approaches because stigma is both a psychological and a social process. By focusing on the stigmatized individual, 'existing social relations are usually taken as given' and by focusing on macro-social analysis, one risks overlooking the 'individual psychological dimensions of stigma.' The current research contributes by combining both approaches. By highlighting individual lived experiences of poverty and coping with stigma in relation to discourse on chav culture and single mothers, this study has highlighted the paradoxical nature of consumption.

Integrating Resources via Practices within Consumer Networks: Subsistence Consumers Participating in 'Chama' Networks in Kenya

EXTENDED ABSTRACT

Subsistence consumers are portrayed as being characterized by a scarcity of economic resources, but rich in social ties formed through networks (Viswanathan et al., 2008). Such networks give them opportunities to interact with one another and generate various forms of resources which enable them to enact their life projects and meet their goals (Arnould, Price and Malshe 2006; Sewell, 1992). The kinds of resources generated and employed vary, as do the terms used to categorize them. Bourdieu's (1986) categorizes resources in terms of capital, including economic, social, cultural and symbolic capital. More recent studies using the service dominant logic categorize resources as either operand (tangible resources such as material objects) or operant (intangible resources such as social resources) (Arnould, Price and Malshe 2006). A number of other classifications exist, but despite the different terminologies used, resources constitute accumulative assets that consumers can use to achieve their goals and basically to satisfy their needs (Bristow and Mowen, 1998: 2). Within consumer research there have been calls for researchers to consider the resources that the poor have and not just deficits (Moser 1998). This paper explores how subsistence consumers in Kenya integrate and (re) configure their resources by engaging in consumer collectives (Chama), and concludes that through the practices enacted within such collectives the integration of resources is perpetuated with varying outcomes.

The term 'Chama' is used to refer to collectives very similar to the Rotating Savings and Credit Associations (ROSCAs), and is the term to be used in this paper to refer to ROSCAs and other similar collectives. The emergence of such groups in Kenya started in the 1970s and 1980s (Johnson, 2004), predominantly organized and run by women. The prevalence of women participants has been attributed to the patrilineal nature of the communities they live in, where inheritance and ownership arrangements are often biased against them (Kimuyu, 1999). This makes it hard to access lump-sum financial resources offered by banks and other lenders who usually require collateral in form of property rights to extend such credit to them (Johnson, 2004). Consequently, many of them form Chama to access informal credit easily in order to meet their consumption goals. Given the view that Chamas are formed primarily for purposes of accessing credit and for saving, Chamas have largely been studied within economic disciplines, where they are depicted as forms of informal financial markets that fill in gaps left by formal financial markets (Siamwalla et al., 1990; Bouman, 1995). However, they also serve non-financial roles as they are avenues in which societal roles are enacted (Johnson, 2004). This implies that other non-financial resources may be activated, accumulated and shared there as well. Furthermore, Chamas also play important consumption–related roles, as they enable participants to pool funds together in order to meet consumption goals (Kimuyu, 1999). In this paper therefore, Chamas are considered as consumer-constituted collectives which enable various forms of resources to be employed and integrated with various outcomes for the participating consumers.

Methodology and Findings

The study employed an ethnographic approach and was carried out in two slums in the capital city of Kenya (Nairobi) over a period

of 5 months. Living in the slum is characterized by what has been conceptualized as "poor living" (Sen 2000) where consumers face a shortage of income, insecurity, limited social amenities, poor infrastructure among others. In order to experience the lived worlds of these consumers, the first author spent a significant amount of time in the slums with the participants as they went on with their daily activities such as shopping and attending Chama meetings. Six different Chamas, each consisting of an average of 15 women were visited on several occasions. The researcher would sit in during their meetings and take notes, and whenever consent was given the proceedings would be audio-recorded and photographs taken. Group interviews were conducted during these meetings, and individual interviews also followed on different dates with at least 3 different people from each of the Chama. Other data collection methods were also employed such as observations, document analysis as well visits to the sites (like markets) that these participants frequented within the slum.

Findings from the study reveal that subsistence consumers do indeed possess various resources which they employ within their contexts. Consistent with other studies focusing on impoverished communities (e.g. Lee, Ozanne and Hill 1999), social capital was found to be prevalent within the Chamas, and engendered norms like mutual support, reciprocity and trust. Drawing on these norms, the participants were able to leverage this capital and achieve certain goals such as assisting one another to educate their children or acquiring consumer durables that they would not otherwise afford individually. Chama hence endows them with capabilities that enable them to perform their consumer (as well as other societal) roles.

The findings further reveal that consumers engaged in several practices in Chama, and were consequently able to accrue various forms of resources, as well as convert them to other forms through these practices. In one of the main practices named 'merry-go-round' for instance, participants meet in one of their homes primarily to pool financial resources together for various consumption purposes (integration of economic capital). Such meetings are in some instances characterized by feasting, providing participants opportunities for social interaction (accruing social capital) as well as enabling the hosts to demonstrate their hospitality skills, gaining respect through their adroit performances (demonstration of cultural capital and possible accumulation symbolic capital). For these women, the ability to perform this 'merry-go-round' practice effectively (e.g. by consistently providing the funds to be pooled, cooking the 'right' foods) demonstrates possession of context-specific cultural capital, and women who do not demonstrate this capability may sometimes find themselves excluded from engaging in future Chama activities. So important is it to be part of Chama that some of the participants consider women who do not belong to Chama 'abnormal'. As such, exclusion from Chama would marginalize them socially, further exacerbating the vulnerabilities they face.

Literature on resource integration has been presented largely within consumer-supplier exchange contexts (e.g. McGrath and Otnes 1995), and even when done outside such contexts, the emphasis has been on financial resources (e.g. Ruth and Hsiung, 2007). This current research makes contributions by focusing on a variety of resources integrated by consumers collectively outside the market exchange interface. It is envisaged that much can be learnt about resource integration outside such contexts especially amongst impoverished consumers whose resource constraints have wider implications beyond those experienced within the consumer-supplier exchange interface. This research also addresses recent calls to focus on the practices involved in integrating resources (e.g. Klein-altenkamp, 2012) and highlights how collective practices act as the catalysts that determine how resources are integrated, accumulated and even lost.

Using Consumption Practices to Countervail Stigma Experiences and Transform Self-Identity among the Homeless

EXTENDED ABSTRACT

Becoming homeless is a stressful event that society stigmatizes (Phelan et al. 1997). Homeless individuals experience a threat to their self as a result of not only stress-inducing events such as loss of their economic resources, but also the stigma experience and social disapproval of their social identity (Dovidio et al. 2000). Link and Phelan (2001) reviewed various definitions and conceptualized stigma as a convergence of components that develop with the co-occurrence of social labelling, stereotyping, separation, status loss and discrimination, as well as the existence of an adverse power structure that allows these factors to facilitate stigmatization. In short, "it takes power to stigmatize" (Link and Phelan 2001, p. 375). This implies that the social production of stigma on an individual or group depends on social, economic, political, and cultural power to activate stereotypes, stimulate discrimination, and link them to undesirable characteristics in society.

Beyond the presence of power structures, scholars argue that the effects of stigma on individuals are shaped by the extent to which those individuals internalize the stigma (Veer, 2009, Alonzo and Reynolds, 1995). In particular, Miller and Major (2000, p.247) suggest that stigmatized individuals will not necessarily "suffer from reduced well being if they use coping strategies that are effective at managing the internal or external demands posed by the appraised threat." Individuals can use coping strategies to protect the threatened individual self, and generate cognitive and behavioral efforts to countervail the stigma threat. In other words, the stigma threat perceived by individuals depends on not only the socio-culturally produced stigma prevalent in society, but also how they manage the stigmatization.

One critical realm for coping with the experience of stigma threat is community. According to Swanson (1985), stigmatized individuals that live in a supportive community can draw vital material and spiritual support from other community members to help them adapt to the social world. Part of this adaption involves challenging the legitimacy of social stigma and re-appropriating cultural meanings that bring harm. An example from a consumer behavior perspective is found in Scaraboto and Fischer (2010), who investigated the "Fat Acceptance Movement" and demonstrated how the action of collectives helps consumers fight stigma and promote social change.

Goffman (1963) posits that stigma is developed through social interaction, and the marketplace is one of the social spaces in which individuals perform and develop their social identities. In recent years, studies have focused on analyzing different groups that suffer from discrimination in the marketplace. Scholars have identified the way individual and collective practices can become instruments that consumers use to not only cope with a stigmatized experience, but also promote a positive self-conception (Adkins and Ozzane 2005, Crosby and Otnes 2010, Hamilton and Catterall 2008, Hamilton and Hassan 2008). However, most studies focus on stigma and coping strategies when people are already stigmatized. Few studies have explored how a stigmatized characteristic is developed and its trajectory over time (e.g Sandikci and Ger 2010), or have used a process-oriented approach to analyze individuals' response strategies while the stigma characteristic is being constructed (see Alonzo

and Reynols, 1995 for an exception in the medical literature, who described the stigma trajectory on HIV patients).

The present study analyzes different consumption-related strategies that homeless individuals, and communities related to them, use to alter the power relationship that influences their stigma experience (Link and Phelan 2001). To do so, the study draws upon ethnographic methods including observation, immersion experiences, and depth interviews in two contexts: a shelter dedicated to offer different services to the homeless individuals in the UK, and a US organization that seeks to develop community among homeless people through weekly religious services.

In the first context, the inquiries focus on identifying the different types of stigma that UK and US individuals experience and the consumption-related coping strategies they employ along their pathways to homelessness (Clapham, 2003). Findings reflect how individuals experience different types of stigma during their path into homelessness, as well as the different coping strategies they develop and modify during the time they spend on the streets. We find that informants initially fight their stigma, however, they embrace it during periods of chronic homelessness. Interestingly, we find that some individuals learn to use stigma to their own benefit (e.g. Hiding or highlighting the their stigmatized label to obtain money by begging). Participants range from passive victims to active challengers, and individuals found alternatives in their everyday lives to change the power dynamics and resist the experience of stigmatization

In the second scenario, inquiries are directed to explore the role that collective action and the sense of community with people who do not share the stereotyped characteristic plays in the stigma experience. Findings in this scenario reveal that collective action and the sense of community become the individual's authoritative performances (Arnould and Price 2000), in which the community creates and sustains shared collective traditions that enable individuals to gain power and agency to face the difficult situation they are experiencing. The participation of non-stigmatized individuals within the community experience (i.e. religious service) brings a legitimating view from outsiders that re-orients the social sphere and minimizes focus on stereotypes/status (i.e. "*I don't care if you're homeless or a CEO, in this place all are children of God*").

In conclusion, the study reflects an overlap between manifestations of consumer resistance and coping strategies employed to reduce disadvantages in the marketplace. This phenomenon is consistent with Firat and Venkatesh's (1995) view that in postmodernity, consumption processes have an emancipatory potential.

Vulnerable consumers: Ethnography of the Consumption of French Farmers Facing Impoverishment

EXTENDED ABSTRACT

When Time magazine has a cover title about "France's Rural Revolution: Traditional French farms are dying", we can read between the lines and ask ourselves about the farmers whose farms are dying. Who are those farmers? How does this context impact their life, their family life? How are they facing this transition, this "revolution"? A closer look at this specific population of smallholding farmers (a total of 328.000 families) gives striking figures for the year 2011 showing that more than 39.000 impoverished families of farmers are eligible for welfare assistance such as income support and food bank. The paradoxical phenomenon is such that farmers, who are supposed to feed the people, can no longer feed themselves.

The current research consists of an ethnography of the consumption culture of vulnerable and impoverished consumers. The originality of this study lies in the singularity of farmers as a community, and as a professional group, that is facing a multi-level crisis (international, European, national, regional, departmental, professional, familial, individual).

Within the domain of consumer vulnerability, we have identified calls for research to study unique and specific populations to develop the field of consumer vulnerability (Baker, Gentry, Rittenburg, 2005), and to study impoverished vulnerable consumers in rural areas of developed countries (Hill 2008). Our literature review is three-fold: Marketing and poverty researchers (Townsend 1962, Caplovitz 1962, Andreasen 1993, Alwitt 1995, Adkins and Ozanne 2005, Hill 2008) have first looked at what poor people consume, before looking at the behavior and culture of consumption of those impoverished consumers. Social scientists see poverty as an issue related to the lack of social links and to the inability to express oneself through consumption goods and rites (Douglas 2007). Transformative Consumer Researchers take the approach that research should shed light on consumer issues, and help to improve consumers' lives (Mick 2006).

We propose two research questions. First, how can we characterize and describe the notion of consumer vulnerability in the context of the rural and agricultural space? Second, if we consider that one function of consumer goods is to make culture tangible, then how can we characterize poor farmers' culture of consumption? More specifically, we look at how the experience of vulnerability shapes consumers' response and adaptation to the consumption context. Mary Douglas (2007) describes the cultural theory of apathy as a long-lasting state that emerges when the freedom to choose is suppressed, when socialization networks are destroyed, when despair is stronger than hope. We hypothesize that a way out of this dead end occurs when vulnerable consumers engage in a project of creating new social links through consumption practices.

To follow the tradition inherent to the stream of research on poverty and vulnerability issues, we rely on ethnographic methods such as interviews and observation: individual in-depth unstructured and semi-structured follow-up interviews, group interviews, (Arnould and Wallendorf, 1994); participant observation and analysis of documents (diaries, blogs, forums). Our unit of analysis is the family, i.e three generations (the farmer, the farmer's parents, and the farmer's children). In order to integrate farmers' children, we use children's drawing (Chan, 2006) as a support for the interview.

A French association, dedicated to help farmers facing difficulties, helped us get in touch with their members and access our field of research. During the year 2011, fifteen interviews were conducted, resulting in a focus on three families. We met each family in their farm, and we spent full days with them. Thus, we could observe and share several moments of their daily life in order to develop an in-depth understanding of the material and social world in which our informants live.

From the findings, we have established a typology of farmers that allows us to identify their different reactions and adaptation to vulnerability as consumers. For example, farmers who see themselves as "entrepreneurs" initiate networks of barter economy. Those who continuously redirect their production also experience a lack of stability in their daily consumption. Farmers who remain on the fringe of development inevitably adopt a way of life similar to voluntary simplicity. Over-indebted farmers tend to deny their state of impoverishment and refuse to ask for resources allowances or to go to the food bank.

"Before the mad cow disease, our life was a life of constraints, for sure, and it was ok for us. Being a farmer means having a life of constraints. But today, we suffer from new constraints which we haven't chosen and we drown. We don't know when this will end.

Every day we wake up for work but we lose more money than what we earn. We have given up some habits. We go back to former practices; we live next to nothing, like our grandparents did."

Considering poor farmers' culture of consumption, this quote highlights how families experience vulnerability as a specific period of time which is remembered as a strong event. Then, any single tool or good represents a memory of the family's former and more elaborate material culture: an old coffee mill, the reuse of old sheets to sew up curtains or dresses, the familial hair scissors to avoid the cost of a hairdresser. Staying in touch with their familial roots help those farmers keep the faith in their future. Their motto is henceforth: "*If everyone took care of the little they have, the world would feel bet-*

ter." This peasant common sense par excellence introduces a sensitizing theoretical framework for how families elaborate a system of values underlying their world of consumption.

The findings of this ethnography have the potential to inform social marketing and social business by elaborating a specific knowledge of one kind of hidden poverty. We portray a typology of consumption processes within a vulnerable population, and enhance knowledge of the role of consumption goods in their strategies of identity survival. We also help social marketing actors better target this population of impoverished farmers when preventing bankruptcy, social isolation or suicide.

SESSION OVERVIEW

The pursuit of happiness is a fundamental goal consumers have. However, the relationship between consumption and happiness is not well understood (e.g., Mick et al. 2011). In this proposed session, we present four research projects that shed light on the complex and surprising effects of consumption on consumer well-being. These four research projects not only offer different theoretical perspectives on the drivers of happiness but also explore a diverse range of consumption contexts. In the first paper, Carter, Rosenzweig, and Gilovich show that consumers can take advantage of the ambiguous nature of the boundary between material and experiential purchases to increase their happiness. That is, happiness is a function of how an acquisition is subjectively categorized by consumers. The second paper by Yang, Carmon, and Dhar challenges the widespread belief that having more material possessions necessarily makes consumers happier. They show that owning multiple goods in the same product category can ironically dampen satisfaction when important attributes of the goods are negatively correlated. Further, the third paper by Ma and Roese shows that fewer material rewards may produce the same amount of happiness as more material rewards. This effect occurs when the reward format involves less easily counted units. In the fourth presentation, Pyone and Isen explore how affect impacts materialistic tendencies. They show that under positive affect, people are less likely to pursue material goods as means to achieve happiness. Each presenter will have 15 minutes to present their paper, leaving 15 minutes for discussions between the presenters and audience.

Our proposed session can contribute substantively to the theme of ACR 2012—appreciating diversity. The research papers in this session investigate the relationship between consumption and happiness in a diverse range of consumption contexts such as consumer choice, post-choice consumption, pre-choice decisions, and responses to reward distributions. These research projects involved a wide array of consumers, including those from the East and West, and in the lab and the field. This session will contribute to theoretical development in the areas of well-being and consumption, and yield important implications for consumers and firms. Further, this session will appeal to a large segment of ACR members interested in judgment and decision making, happiness, and consumer well-being, qualities of lives, materialism, affect, and value sensitivity. This session will also foster discussions of diverse range of topics relating to consumption and happiness, sparking new future research directions.

Taking Advantage of Real and Perceived Differences Between Material and Experiential Purchases

EXTENDED ABSTRACT

A growing body of work suggests that there are genuine benefits to purchasing experiences, intangible purchases such as vacations and concerts, instead of purchasing material possessions, tangible goods such as clothes, trinkets, and electronics (Carter & Gilovich, 2010, 2012; Howell, Pchelin, & Iyer, in press; Nicolao, Irwin, & Goodman, 2009; Rosenzweig & Gilovich, 2011; Van Boven & Gilovich, 2003). Experiences, compared with possessions, appear to be ultimately more satisfying because they are less likely to suffer from invidious comparisons to unchosen options or new information (Carter & Gilovich, 2010), and are more central to one's self-concept (Carter & Gilovich, 2012). What's more, the general tendency to choose experiences over possessions is associated with well-being and life satisfaction (Howell et al., in press). However, as all of this work acknowledges, the categories are not very clearly defined. What makes an experience an experience? What makes a possession a possession? While there are certainly purchases that are clearly experiential (e.g. concerts) or material (e.g. clothes), there are also quite a few that cannot be so easily categorized. An mp3 player is a tangible object, but it also allows one to enjoy the experience of listening to music. How do these ambiguous purchases fit into the overall pattern of findings? What's more, what does such ambiguity say about the underlying properties that define the categories?

To start, we endeavored to examine the types of purchases that participants generated when prompted to recall a material or an experiential purchase. In Study 1, we found that independent raters were easily able to guess, based on the description provided by the participant, which type of purchase they had been assigned to recall. This suggests that, regardless of any fuzziness in the categories, most participants seemed to have little trouble using them. There were some purchases, however, that fell somewhere in the middle, and also appeared to be somewhat middling in terms of their satisfaction. Would it be possible to take advantage of that ambiguity, to take those same purchases and emphasize aspects of one category or the other, to produce the same psychological effects?

In Study 2, we again had participants recall either a material or an experiential purchase, and again found that participants in the experiential condition were more satisfied with their purchases. However, we also asked a third group of participants to recall a material purchase, but we asked them to take a moment to think about

its experiential qualities. As expected, we found that this group was just as satisfied as participants in the experiential condition. While the previous study suggested that there are real differences between the categories, this finding indicates that there is a certain amount of latitude in how one thinks about a given purchase.

In the next three studies, we examined that very latitude. We took the same purchase, one that was smack in the middle of that fuzzy boundary between the two types of purchases, and emphasized either its material or its experiential qualities. Participants in Study 3 were asked to think about a boxed set of music either as part of a music collection, something one puts on a shelf, or as an experience, something one listens to. Participants who had been led to think of it as an experience were less bothered by negative comparative information (learning it was now available for a lower price), and thought it would be more satisfying than participants who framed it as a possession.

In Study 4, participants were asked to think about a new 3-D TV as either a possession, emphasizing where it would go in their home and fit in with their other possessions, or as an experience, emphasizing experiencing television in a whole new way and how it would fit with their other activities. We then showed participants several sets of overlapping circles, as in the Inclusion of the Other in the Self scale (Aron, Aron, & Smollan, 1992), and asked them to choose which matched how much they thought the TV would be a part of their self-concept. As predicted, participants in the experiential framing condition chose circles that overlapped to a greater degree, thinking that the more experiential television would be more closely associated with their self-concept.

In Study 5, we looked at the flip side of satisfaction: regret. People tend to feel regrets of inaction about their experiences (i.e. missed opportunities) and regrets of action about their possessions (i.e. buyer's remorse). Would framing a purchase as an experience or possession produce similar patterns of regret? When a 3-D TV was described as an experience, participants felt that the regret of a missed opportunity would be stronger than the regret of buyer's remorse, but not when it was framed as a possession.

It's worth noting that reframing ambiguity may be asymmetric. That is, it may be fairly easy to think of a tangible object in terms of the experiences it affords, but rather difficult, if not impossible, to think about an intangible experience in terms of its material qualities. Fortunately, turning possessions into experiences appears to be the reframing that is most psychologically beneficial.

These studies taken together suggest the differences between the categories appear to have something to do with real, tangible differences between possessions and experiences, but also with certain psychological processes, such as comparison and regret, and perhaps it is those psychological processes that underlie what makes an experience an experience. What's more, the ambiguity in category definitions can actually be taken advantage of – producing greater satisfaction and reduced susceptibility to negative comparative information. In sum, although it's possible that the categories are largely in the mind, it may be the mind that matters.

More Possessions can Make You Less Happy

EXTENDED ABSTRACT

A fundamental tenet of consumerism is that owning more is more desirable than owning less. The yearning for additional possessions is reflected in such impressive statistics as American women on average owning 27 pairs of shoes, and men, 12 pairs (TIME 2006), and average households having 2.9 TV's—more TV's than people (Neilsen 2009). In this research, we challenge that belief, identifying a common condition under which owning more can dampen rather than boost consumption satisfaction.

While prior research sheds important light on how judgments and choices are affected by options being viewed jointly or in isolation (e.g., Botti and Iyengar 2006; Bazerman et al. 1992; Brenner et al. 1999; Hsee and Leclerc 1998; Nowlis and Simonson 1997; Schwartz 2004), the effect of owning multiple goods on consumer satisfaction is not well understood. The current research advances the notion of competing advantages—each good in a set being perceived as better than others on some dimensions yet worse on other dimensions. When the set is consumed, differences between the attributes (e.g., one TV has USB ports; the other, 3D graphics) and attribute values (e.g., one TV has a larger screen but inferior sound quality than the other) become salient. This induces an upward shift of the comparison standard for assessing satisfaction, making each good in the set appear deficient on some dimensions. Because deficiencies tend to be more salient and attention-grabbing (e.g., Pratto and John 1991) and weighted more heavily in evaluations (e.g., Fiske 1980; Mittal et al.1998) than positive attributes, the deficiencies loom larger than sufficiencies. Thus, compared with owning just one good where a comparison standard naturally present in consumers' mind (e.g., the expected consumption experience) is applied to assess satisfaction, owning multiple goods can, ironically, be less satisfying.

The degree to which competing advantages alters comparison standards should depend on the extent to which consumers' standards are developed and stable. Those with high need-to-evaluate (NTE) chronically make more judgments (Jarvis and Petty 1996), possess more developed and stable internal standards (Federico 2004), and are less likely to alter their established views when they encounter additional information pertaining to those views (Albarracín et al. 2004). Consumers with low-NTE are thus likely to be more affected

by competing advantages, as their comparison standards for satisfaction assessment are more malleable.

We tested our propositions in the lab and field. In Study 1, participants were randomly assigned one of three consumption sets (Set$_{TV1}$, Set$_{TV1\&2}$, and Set$_{TV1\&3}$) and asked to imagine owning the good(s). Set$_{TV1\&2}$ had competing advantages—TV1 had both better and worse attributes than TV2. Set$_{TV1\&3}$ did not—TV1 dominated TV3 on all dimensions. Though a pretest established that participants strongly preferred Set$_{TV1\&2}$ over the alternatives in a choice task, those who had this set were significantly less satisfied than those had Set$_{TV1}$ or Set$_{TV1\&3}$. That owning Set$_{TV1\&3}$ was more satisfying than owning the superior Set$_{TV1\&2}$ nicely illustrates the detrimental impact of competing advantages, as TV3 was, by design, objectively inferior to TV2. Further, as an indirect measure of the comparison standard used to assess satisfaction, participants were asked rate the extent to which they thought their TV(s) were imperfect.

As predicted, participants with Set$_{TV1\&2}$ were less satisfied than those who had Set$_{TV1}$. This negative effect of owning more disappeared when the competing advantages were removed by downgrading the attributes of one of the TV's (downgrading from TV2 to TV3). This suggests that the competing advantages were a cause of the lowered satisfaction, and that the negative effect of owning more could not be accounted for by an averaging mechanism—participants simply averaged their satisfaction with each TV when assessing their overall satisfaction with two TV's. If averaging were driving the effect, those who with an inferior set of two TV's (Set$_{TV1\&3}$) should have been less satisfied than those who with the superior set (Set$_{TV1\&2}$). Finally, the changes in participants' comparison standards mediated the differences in satisfaction.

Study 2 investigated the negative impact of owning more in the field. Consumers took home either multiple framed pictures with competing advantages, or just one. After owning the product(s) for a few days, they responded to measures similar to those in Study 1. They also answered an open-ended question about an ideal framed photo, another measure of changes in the comparison standard. Although a pretest revealed that owning more was clearly preferred in a choice task, participants who owned more were significantly less satisfied. Further, compared to participants who had one good, those who owned multiple goods described significantly more product attributes on the ideal-product measure, and perceived their goods as significantly more imperfect. These changes in comparison standards mediated the effect of owning more on satisfaction.

Study 3 examined whether dispositional differences in Need-to-Evaluate (NTE) moderate the negative effect of owning more, and whether competing advantages reduce satisfaction with individual goods in the consumption set. Accordingly, the Set$_{TV1}$ and Set$_{TV1\&2}$ conditions were identical to those of Study 1, and, in a third condition (Set$_{TV1|TV1\&2}$), participants were given TV1 and TV2 but asked to assess their satisfaction with only TV1. In addition to responding to measures used in Study 1, participants also completed the NTE scale (Jarvis and Petty 1996). As expected, those with low NTE were significantly more affected by competing advantages—they altered their comparison standard more and reported lower satisfaction than those with high NTE. Further, compared to participants with Set$_{TV1}$, those who received Set$_{TV1|TV1\&2}$ reported significantly lower satisfaction with TV1. Finally, the satisfaction differences across the three conditions were mediated by the changes in comparison standards.

Altogether, our findings cast doubt on whether overflowing closets of clothes and shoes or multiple TV's, necessarily provide higher satisfaction than having fewer possessions. Contrary to popular belief, owning more can, in fact, be less gratifying. Further, our research advances the notion of competing advantages and explicates their impact on comparison standards used to assess satisfaction. Finally, our research yields transformative advice for consumers—owning and consuming less can help the environment and, in and of itself, be more satisfying.

The Countability Effect: Comparative versus Experiential Reactions to Reward Distributions

EXTENDED ABSTRACT

There is general agreement in the fairness literature that people who are under-benefitted are less satisfied than those who are over-benefitted (Adams 1963; Homans 1973; Walster et al. 1978). For example, when compensated for precisely the same work, an employee receiving $10 / hr will be less satisfied than another employee receiving $15 / hr. However, it has become increasingly clear that other factors may moderate the impact of inequity on satisfaction. A key perspective centers on value sensitivity, or evaluability, which reflects the extent to which the magnitude of subjective value is influenced by the magnitude of objective value (e.g., Hsee 1996; Hsee 1998; Hsee et al. 1999; Hsee et al. 2009). As summarized in the recent General Evaluability Theory, the construct of evaluability is defined as "the extent to which a person has relevant reference information to gauge the desirability of target values and map them onto evaluation" (Hsee and Zhang 2010, p. 344).

In the present research, we argue that countability feeds into evaluability, and as such will operate as a powerful moderator of the impact of inequity on satisfaction. When a reward can be easily counted in numerical terms, the effect of inequity on satisfaction is relatively straightforward: those who receive less than they ought to feel less satisfied than those who received more than they ought to. However, when rewards are not so easily counted, people cannot rely so easily on a simple numerical indicator of relative value. Instead, they focus on idiosyncratic aspects of how the reward might be enjoyed at a purely experiential level.

More generally, countability reflects the powerful role that numbers play in our lives. People associate numbers with cardinal values, such that numbers act as representations of internal magnitudes or quantitative values (e.g., Diester and Nieder 2007; Rubinsten et al. 2002). Once these associations are established in mind, they provide a foundation for estimation and comparison that is indispensible in people's lives (e.g. Girelli, Lucangeli, and Butterworth 2000). Research on numerical information processing (e.g., $32 dollars, 20 calories, 500 mg) consistently finds that numerical information is processed relatively rapidly and efficiently (Dehaene and Akhavein 1995; Girelli, Lucangeli, and Butterworth 2000; Tzelgov, Meyer, and Henik 1992; Viswanathan and Childers 1996). This literature thus provides support for our contention that when distributions can be counted in numerical terms, people are more likely to make comparisons and to be more sensitive to inequity than when distributions cannot be counted. Hence, we propose two main hypotheses:

Hypothesis 1: *Countability moderates the effect of inequity on satisfaction. Although an easily counted over-benefit will evoke greater satisfaction than an easily counted under-benefit, a less easily counted over-benefit and under-benefit will evoke similar degrees of satisfaction.*

Hypothesis 2: *The underlying mechanism for H1 is that countable rewards evoke comparisons within the reward distribution, whereas uncountable rewards evoke a focus on the experiential aspects of one's own reward.*

With a 2 (benefit: under-benefit vs. over-benefit) x 2 (countability: countable vs. uncountable) between-subjects design, six experiments consistently demonstrated that when rewards can be counted in numerical terms (e.g. two vs. three slices of cake), the under-benefited are less satisfied than the over-benefited, whereas when rewards cannot be counted in numerical terms (e.g. small vs. large cake), the under-benefited are just as satisfied as the over-benefited. This effect was demonstrated across different product categories, across different demographic groups, and across the East vs. West.

Moreover, we examined the underlying cognitive mechanism for the role of countability. Specifically, when participants were prompted to think comparatively (i.e., calculate the numerical amounts of rewards), those in the uncountable condition behaved as though they were in the unprompted countable condition, and when participants in the countable condition were prompted to focus on their consumption experience, they behaved as though they were in the unprompted uncountable condition. Thus, uncountable rewards mitigate the sting of unfair reward distributions in part because they push people to focus more on the experiential aspects of their own reward, while pulling them away from unfavorable upward comparisons to those who received more.

This research extends General Evaluability Theory (Hsee and Zhang 2010) by proposing a new powerful factor – countablility – influencing value sensitivity. It also adds to the literature on how information display influences people's perception by demonstrating that the numerical format of rewards can make people focus more on face value and ignore the possible emotional elements. Moreover, it proposes a new way to mitigate unfairness perception and unhappy feelings in unfair distributions. Making the world an objectively fair place is important, but when unfairness is unavoidable, we should be able to find a way to increase our subjective happiness in unfair situations. Unfair distributions do not necessarily lead to subjective perceptions of unfairness that affect our emotions and behaviors (Weiner 1995). We are a species that relies on emotions and perceptions as inputs into judgments and behaviors, we should learn to deal with potentially negative situations and nonetheless derive eventual happiness from them. This idea of subjective approaches to unfair situations is one contribution of this article. Although the cake distributions are objectively unfair, we may still enjoy our small cake if we do not count it!

When Happiness Doesn't Seem Contingent on Material Goods: The Influence of Positive Affect on Materialism and Conspicuous Consumption

EXTENDED ABSTRACT

Much of the previous research has investigated how materialism influences happiness (e.g., Belk 1984; Van Boven and Gilovich 2003). On the other hand, relatively little research has been conducted on the reverse, the influence of positive affect on materialism. In the present research, we examine how mild positive affect that people experience in everyday life influences materialistic and conspicuous consumption behavior.

Based on the affect literature suggesting that positive affect leads to more flexible thinking (Isen 2008) and broadened scope of attention and cognition (Fredrickson and Branigan 2005), we hypothesize that positive affect enables people to think about aspects of their life and their happiness more flexibly (i.e., they can think of various ways of pursuing happiness other than acquiring material goods), and thus they are less likely to rely on material goods as a primary source of happiness or self-worth, while neglecting its other sources.

First, in order to examine a lay theory of materialism, in a pilot study we asked participants to describe materialism in their own words. They defined materialism broadly in two ways: 1) valuing material goods over other, or abstract, values in life (e.g., family or friendship), and 2) engaging in consumption behavior in order to "show off" or signal status. In five studies, we tested the influence of positive affect on materialism as represented in prior research and the lay ideas generated above.

Study 1: What Makes You Happy? Participants were randomly assigned to either a positive or a neutral affect condition. Affect was manipulated using a video clip: a mildly amusing clip (showing a dancing hippo) or a neutral clip (showing moving color bars). After the affect induction task, materialism was measured in a way similar to that used by Chaplin and John (2007). Participants were asked to list things that make them happy using six categories: Hobbies, Material Things, Achievements, Sports, People, Other. A ratio index of materialism was obtained by dividing the number of material items by the total number of items, for each participant. The results revealed that people in positive affect reported lower materialism ratios than did those in neutral affect.

Study 2: Money Allocation II -Material vs. Experiential Purchase. In Study 3, following the research by Van Boven and Gilovich (2003), we measured materialism in terms of the type of purchases people pursue (material or experiential). After the affect induction task (as in Study 1), participants were asked what specific things they would like to buy or do with the $500, and to indicate the amount of money they allotted to each item. A materialism index was created for each subject, by subtracting the amount allocated to experiential purchases (e.g., going out to dinner with friends, skiing) from that to material purchases (e.g., new clothing, handbags). Results showed that people in positive affect allocated a smaller portion of the money to material purchases (relative to experiential purchases), than did the controls.

Study 3: Conspicuous Consumption I. In Studies 4 and 5, we measured materialism in terms of the underlying motive for buying material goods: the degree to which people want to signal wealth or social status. Participants (all female) were randomly assigned to a 2 (affect) x 2 (signal: high, low) between-subjects design. After the affect induction task, participants were told that they would evaluate a high-end product. Half of the participants saw an image of a Gucci handbag with a salient brand-logo (high signal), and the other half saw a Gucci bag with no logo (low signal). Results revealed that people in neutral (vs. positive) affect perceived the good with the salient logo as more attractive, wanted to own it more, and were willing to pay more for it.

Study 4: Conspicuous Consumption II. In Study 5, Conspicuous consumption was measured among male subjects. Participants (all male) read product descriptions about cars from two different brands: a Low-end model from BMW and a Premium model from Mazda. The BMW model was described so that participants could see that its performance (e.g., engine, fuel efficiency, horsepower, etc) was inferior to that of the Mazda, but as superior as a status symbol. Participants then were asked to make a choice between the two models. The results showed that positive-affect people were more likely to choose the high-end Mazda (performance) over the low-end BMW (status) than were controls.

In sum, results of four studies suggest that under mild positive (vs. neutral) affect, people are less likely to rely on material goods as a primary source of happiness, while neglecting its other sources, and also less likely to engage in conspicuous consumption (i.e., signal status through material goods).

SESSION OVERVIEW

Online labor markets allow "requesters" to recruit "workers" for the completion of computer-based tasks. One such market, Amazon Mechanical Turk (AMT), offers a convenient means of accessing a relatively diverse population. The speed and ease with which data can be collected on AMT has led to considerable interest in using it to collect experimental data, as indicated by the large and growing number of publications that rely on AMT data over the past few years (>400 in the social sciences alone) and self-reports by researchers subscribed to the major mailing lists in social psychology and decision-making (>50% have used AMT).

Initial evaluations of AMT as a source of data have emphasized its compelling strengths, notably the comparatively diversity of workers and the possibility of conducting research on a common population. In a nutshell, these studies have found that AMT workers produce quality data, and are more representative than other convenience samples.

Fewer efforts have been made to explore and quantify potential unique drawbacks and limitations of using AMT to collect social science data. This special session focuses on some of the issues that threaten experimental validity on AMT and on providing easily implementable solutions to avoid these problems.

The four papers included in the session deal with diverse issues. Joe Goodman discusses differences between AMT workers and more traditional subject populations that are of high relevance to consumer behavior research. Julie Downs discusses strategies for restricting data collection and data retention to attentive participants, together with their implications for the generalizability of AMT data. Dan Goldstein addresses issues of participant honesty, including the results of experiments designed to detect dishonest behaviors among AMT participants and identify some of their predictors. Gabriele Paolacci addresses the issue of non-naïvety among AMT workers by presenting studies about cross-talk and duplicate participation and provide simple remedies to attenuate this concern.

The special session contributes to the conference mission of appreciating diversity by focusing on a research method – web experimentation – that expands diversity in two important ways. First, it allows researchers to access a more representative, and certainly more heterogeneous population that traditional subject pools. Second, it democratizes science, by making these populations available to all researchers at a low cost and with minimal technical knowledge, eliminating geographic constraints and reducing financial constraints on research. Taken together, the four proposed contributions will provide attendees with a comprehensive view of how to make the best use of this resource, while avoiding common, but not widely discussed threats to data quality.

Data Collection in a Flat World: Strengths and Weaknesses of Mechanical Turk Samples

EXTENDED ABSTRACT

Mechanical Turk (AMT), an online labor system run by Amazon.com, provides quick, easy, and inexpensive access to online research participants. As use of AMT has grown, so have questions from behavioral researchers about its participants, reliability, and low compensation. A main concern about using AMT for research is that participants who are willing to participate in a study for well below the minimum wage must be unusual. And, most importantly, they might be unusual in ways that challenge the validity of research investigations. Researchers have verified that AMT demographic responses are accurate (Rand, 2012), validated the psychometric properties of AMT responses (Buhrmester, Kwang, & Gosling, 2011), and replicated some of the classic findings in behavioral economics (Horton, Rand, & Zeckhauser, 2011; Suri & Watts, 2010) and decision-making research (Paolacci. Chandler, & Ipeirotis, 2010). However, research has not thoroughly investigated differences between AMT participants and traditional samples on attention, personality, financial, and consumption dimensions. In this paper we review recent research on using AMT and compare AMT participants to community (Study 1) and student (Study 2) samples on several dimensions, finding many similarities between AMT participants and traditional samples, but also finding important differences that are relevant to consumer research.

In Study 1 we examine whether AMT participants are less attentive to study instructions than college student samples. We measured the rate at which participants pay attention by administering an attention test or Instructional Manipulation Check (IMC; Oppenheimer, Meyvis, & Davidenko, 2009) requiring careful reading of study materials. Similarly, we investigated whether AMT participants have different cognitive capabilities compared to non-AMT participants by administering the Cognitive Reflection Test (CRT; Frederick, 2005). Our results showed that AMT participants performed more poorly on the IMC and CRT compared to student participants. More importantly, we found that simply administering the attention test and filtering participants by whether they correctly answered the IMC or not reduced statistical noise; including participants who failed the IMC reduced the likelihood of finding statistically significant differences between groups on other dimensions. Though we found that IMC failure was correlated with a participant being from

outside the US or a non-native speaker of English, the results suggest the IMC was the most efficient filter as it both excluded fewer people and reduced Type II error.

For consumer behavior researchers, it is especially important to examine whether AMT participants differ in terms of how they value and spend money and time. Given that AMT participants are willing to complete tasks for little money, some have questioned their valuation of money and time. To address this issue, in Study 2 we compared AMT participants, college students and a community sample on their preferences for time and money (Cryder & Loewenstein, 2010), their material values (using the Material Values Scale; Richins, 2004), and how averse they are to spending money (using the Tightwad-Spendthrift scale; Rick, Cryder, & Loewenstein, 2008). We also compared AMT and non-AMT participants on the Big Five dimensions of personality (Gosling, Rentfrow, & Swann Jr., 2003) and global self-esteem (Robins, Hendin, & Trzesniewski, 2001).

Our results showed that compared to non-AMT participants, AMT participants were significantly (p's < .05) less extraverted, less emotionally stable, and had lower self-esteem. AMT participants also exhibited attitudes about money and time that were more similar to student participants than to community participants, valuing money more than time, reporting more materialistic values and feeling more averse to spending money (p's < .05) than the community sample. Compared to students, AMT participants were equivalent on all these dimensions. It seems that AMT participants may be similar to students in terms of their financial outlook.

Given the low compensation of AMT participants, AMT participants might also respond unusually to decision tasks involving money and risk. We explored this proposition by testing for present bias and discounting asymmetries (Loewenstein, 1988; Malkoc & Zauberman, 2006), risk aversion for gains, risk seeking for losses, and the certainty effect (Kahneman and Tversky, 1979). Our results showed that AMT participants exhibited the same effects as the student population. AMT participants were present-biased, showed delay/expedite asymmetries, were risk averse for gains, risk seeking for losses, and showed the certainty effect—but no more so than other samples.

Recent research about the use of AMT for behavioral research has concluded that AMT has many benefits, making it suitable for a wide range of behavioral research. We agree: We found that AMT participants generally produced reliable results that are consistent with previous decision making research and we found many commonalities between AMT participants and our traditional samples, contributing to this growing literature (Buhrmester et al., 2011; Paolacci et al., 2010; Rand, 2012). However, we also found important differences between AMT participants and community and student participants. To mitigate concerns that may arise from these differences, we discuss and recommend to researchers the use of screening procedures to measure participants' attention levels and acknowledge that AMT participants may vary from non-AMT participants on social and financial traits.

Screening Participants on Mechanical Turk: Techniques and Justifications

EXTENDED ABSTRACT

Concerns about the quality of Amazon Mechanical Turk (AMT) participants have led researchers to use a variety of screening techniques. Some researchers use screening data to disqualify participants in real time, punishing them for their poor performance, and some use it to omit suspicious data at the time of analysis. We assess several strategies for restricting data collection and data retention, evaluating them according to their discriminant power to identify observations contributing only noise.

We evaluated four categories of screening techniques: 1) meta-data from typical surveys, such as time on task, and depth of responses; 2) pre-screening of participants, such as limiting participation to those meeting a threshold of performance in the AMT system; 3) integral aspects of survey design, such as incentives and required responses; and 4) responses to questions included specifically to identify "poor" participants, such as gold standard questions (for which there is an objectively correct answer, unlike most survey responses). Some gold standard questions are unobtrusive, whereas others communicate their purpose to participants (e.g., by asking participants to give non-standard answers). The latter type, sometimes called Instructional Manipulation Checks (IMC; Oppenheimer, Meyvis, & Davidenko, 2009) has the potential to change participant responses in systematic ways. By randomizing whether these questions appeared at the beginning or end of the task, we created a measure of the impact of obtrusive gold standard questions on responses (conditional on passing). We included two types of criteria to assess the effectiveness of each screening technique: reliability of measures, and effect sizes of established psychological phenomena. For reliability, we used classic individual difference scales (e.g., Need for Cognition, with a Cronbach's alpha in the mid-90s; Cacioppo & Petty, 1982), as well as measures of internal consistency on behavioral tasks (e.g., choosing between lotteries that varied along dimensions of risk). For phenomenological effect sizes, we used classic demonstrations of cognitive performance and bias in judgment and decision making, such as the Stroop task and the framing effect. In addition to assessing the level of noise in the data between the screened-out and retained populations, we examined responses from these populations for evidence of systematic differences on our measures. Participants located in the US were recruited into five different surveys on AMT, each paying the equivalent of about $8 per hour, to approximate minimum wage, plus a possible bonus in some cases, to incentivize performance. For most surveys (except where noted) we required 500 or more completed AMT tasks and an approval rating of 95% or higher.

Each category of screening technique will be reviewed in turn. Simple meta-data did not prove to be useful in identifying noisy observations. The fastest 8% of respondents performed no worse than the population as a whole (N = 302, z = 0.08, p = .936), and the fastest 3% (10 of 302 participants, who performed remarkably fast with a slight discontinuity from the rest of the sample) performed only very slightly worse (z = 0.73, p = .465). The slowest 3% of the sample performed slightly better than the rest of the sample, although not significantly so. Although the faster and slower respondents did not produce notably noisier data than their more average peers, these respondents did differ along certain individual difference measures, with faster responders scoring lower in Need for Cognition and slower responders scoring higher. Removing standard pre-screening criteria did not reduce reliabilities compared to those who were required to have a large number of completed tasks and a high approval rating (N = 403; z = 0.58, p = .562). Requiring responses did not significantly improve reliabilities (N = 303; z = 1.18, p = .238). Reducing the payment rate to one-quarter of minimum wage (25¢ for an 8-minute task) had no notable effects on reliabilities (N = 346; z = 0.10, p = .920). Participants who failed gold standard questions did not perform any worse in reliabilities than those who passed (N = 178; z = 0.27, p = .787), although other differences in performance did emerge. Measures of bias did differ in some of the populations that would be omitted based on the various screeners, and obtrusive gold standard questions had moderate effects on some outcome mea-

sures, including changing the effect sizes of some measures of judgment bias. These effects will be discussed in more detail.

Consistent with other research, data quality in this sample was reasonable. Furthermore, screening strategies failed to identify meaningful subsets of the population who were contributing mere noise to the data. Although these findings cannot attest to full engagement of all participants in the tasks, they also cannot support the practice of omitting participants based on screener performance without concern about biasing the sample (at least in US populations). For example, although time stamps are a popular technique that can be used without adding to participant burden to omit people taking too little (or too much) time, these individuals' data did not warrant exclusion from analyses. Indeed, the systematic differences between high and low performance on many screening tools suggest that omitting participants based on these indicators would likely bias the sample rather than merely reduce noise. We suspect that the internal reputation system used by Amazon is effective in dissuading participants from attempting to game the system.

Under the Radar: Determinants of Honesty in an Online Labor Market

EXTENDED ABSTRACT

Many institutions and social systems depend upon some degree of honesty to function as intended. The legal system, for example, is predicated on honest testimony, and oaths are used with the goal of promoting truth-telling. Moreover, many economic transactions assume a truthful description of what is being sold or a promise that an agreement will result in a payment.

For online labor markets like AMT, honesty between the employers and employees helps the market to be efficient. Employers who trust the work of the employees, and employees who trust that payment will be rendered by the employer, both benefit from an environment in which honest dealing is the norm. Consumer behavior research, which relies heavily on self-report, is hard to verify, meaning that under prevalent dishonesty, such markets would be of limited interest to researchers.

Standard economic models capture the belief that people trade off the benefits of cheating with the costs of getting caught (Allingham & Sandmo, 1972; Becker, 1968). On AMT the costs of getting caught at any individual time are arguably low–a worker might only have their work rejected. However, consistently dishonest behavior can lead workers to be banned from the site. The frequency of cheating is an open question, determined both by the hassle of creating a new account, and recultivating the reputation necessary to complete much of the more lucrative work. Additionally, The pragmatic benefits of cheating sit in tension with people's intrinsic motivation to avoid feeling like they are dishonest (e.g., Mazar, Amir, & Ariely, 2008) and to maintain the appearance of honesty to others (Hao & Houser, 2011). Thus, it is not a priori clear how much dishonesty would be exhibited by workers in an online labor market.

The central focus of this work is measuring the degree to which workers on AMT are honest and determining which factors affect their honesty. Fischbacher and Heusi (2008) conducted a study which is the inspiration for this work. In a series of offline laboratory experiments, the authors had participants roll a die in private and report their roll. Participants were paid proportionally to the value they reported (with the exception of rolling six, which paid nothing). Since the experimenter could not see the roll, the participant could report any number. While each number would be expected 17% of the time, the subjects reported a roll of four 27% of the time and reported a roll of five 35% of the time. A roll of six, the lowest paying

roll, was only reported 6.4% of the time, suggesting dishonest reporting. In addition to this baseline treatment, the authors conducted additional treatments where they increased the stakes (by a factor of three), ensured the anonymity of the participants, and changed the victim of the lie from the experimenter to another subject. These treatments did not have a large impact on the distribution of reported rolls.

In this work, we seek to understand the determinants of dishonesty in experiments in which payment can be affected by lying. We asked participants on AMT to roll die (at home or using a randomizer website, as they wished) and to report the values of the rolls, which gave them both ample opportunities to lie and no chance of being caught lying on any single roll (since we, as experimenters, could not observe the participants).

In the first experiment, we replicate the basic effect. Participants report a die roll between one and six and are paid 25 cents per pip (spot on the die). The average roll, under honest reporting, would be 3.5. The average of the reported rolls was 3.91, significantly higher than chance (p < .0005), with the distribution of rolls heavily favoring fives and sixes.

The second experiment asked whether people would report more honestly if there were less to be gained by lying. In the first experiment, the ratio of payouts between the worst and best roll (taking the flat fee into account) was 3.5, giving a strong incentive to cheat. In the second study, this ratio was reduced to merely 1.24. However, despite having less to gain, participants cheated as much in this condition as in the baseline, showing surprising insensitivity to what can be gained through dishonesty. Furthermore, participants from India and the US cheated by the same amount, again suggesting that the stakes are not a key determinant of cheating.

Given that cheating seems relatively unrelated to the magnitude and variance of the payouts, the third and fourth experiments ask whether the probability of detection may drive the decision to cheat. In all studies reported above, including those by other researchers, participants rolled a die just one time before reporting their answer. In such a situation, a six is just as likely as a one. However, when reporting, for example 10 rolls, it is less likely that the sum of these rolls would equal 60 by chance as it would equal, say, 35. If participants have a grasp of intuitive statistics, they would realize the experimenter could reject the null of honest reporting over multiple rolls if the sum of the die exceeds a certain number (or if the distribution of values reported deviates significantly from uniformity). In a large randomized experiment, participants rolled a die either 2, 3, 5, 10, or 20 times and were paid proportional to the sum of the result. Consistent with the view of people as intuitive statisticians, participants continued to cheat in a way that was easily detectable at the aggregate level, but undetectable at the individual level.

Non-naïvety Among Experimental Participants on Amazon Mechanical Turk

EXTENDED ABSTRACT

Certain experimental paradigms strongly rely on participant naïvety, either as a precondition for an effect to emerge, or to prevent experimental demand effects. Prior knowledge about the purpose of an experiment, familiarity with an experimental manipulation, or reason to suspect deception, can influence participant responses. While traditional subject pools offer a continuous supply of naïve participants, this is less true of AMT, where workers can complete an unlimited number of experiments. Given the popularity of AMT among consumer researchers, it is important to know whether concerns of non- naïvety among AMT workers are negligible or not.

Further, if non- naïvety is prevalent, it is pressing to come up with solutions that can be implemented by single researchers or scientific communities to mitigate this problem. In this work, we discuss two potential sources of non-naivety on AMT.

One important phenomenon that affects participant naïvety is cross-talk between participants. Empirical research on college undergraduate populations has demonstrated that participants do share information with each other, at least when sufficiently motivated (e.g., when incentives are offered for a correct response; Edlund, et al., 2009). The web offers great opportunities for cross-talk: Indeed, AMT workers maintain online forums where they share information and opinions, which could potentially lead to foreknowledge in experimental participants.

A second concern is participation in experiments that share independent or dependent measures. AMT automatically prevents workers from completing a single task multiple times. However, it is still possible that participants are recruited for experiments that are conceptually or methodologically related to experiments they have previously completed. Our survey data (Study 1, N = 300) show that cross-talk is not a critical issue on AMT. Only 26% of participants reported knowing personally someone else who used AMT, and only 28% reported reading forums and blogs about AMT. Further, when asked to rank the reasons why they discuss or read about AMT, the actual purpose or contents of the tasks are far less important than pragmatic considerations such as the amount requesters pay or their reputation. Only half of the respondents who actually read blogs (about 13% of the overall sample) reported ever seeing a discussion about the contents of a social science research study online. Such low levels of reported cross-talk can hardly contribute substantially to participant non- naïvety. However, researchers should probably monitor discussion boards that refer a lot of respondents, and conclude their experiments by asking workers how they found the task. We also highlight the less tangible effects of workers discussing the reputations of individual experimenters and research institutions.

Duplicate participation is a more serious concern. 55% of our worker sample from Study 1 reported having a list of favorite requesters and monitoring their tasks (indeed, browser plug-ins are available that do this automatically), and 58% of the time this list included academic researchers. Data from a follow up conducted one year later showed that these percentages became 63% and 71% respectively, suggesting that this is a growing concern. Moreover, a substantial proportion of workers reported participating in some of the more common and easily describable experimental paradigms (e.g., 52% of Study 1 participants played an Ultimatum Game, becoming 83% one year later).

In order to obtain more reliable information about duplicate participation, we pooled the data from several researchers who had received a total of 16,408 completed submissions (Study 2). The tasks included in this sample had been completed by a total of 7,498 workers. The average worker completed more than two studies, with the most prolific 10% of the workers (N = 750) responsible for 41% (N = 5,864) of the completed submissions. Taken together, these results suggest that duplicate participation is a potential source of non-naïvety that cannot be neglected by researchers who use AMT. At a minimum, experimenters should ask participants whether they have completed similar experiments before and treat prior participation as an additional factor in their data analysis. We offer several practical solutions that allow duplicate workers to be filtered out before they participate, saving money, and eliminating the concern that excluding duplicate workers may contribute additional researcher degrees of freedom.

The very features that make online labor markets appealing to researchers, such as its accessibility, lead to some concerns about whether experimental participants are naïve enough to participate in all experiments. Whereas participant cross-talk seems not to constitute a problem, care is required to deal with duplicate participants.

SESSION OVERVIEW

This session brings together four papers that examine an important but neglected area in consumer research: gender roles and family identity. Because the growth of non-traditional families frequently violates traditional gender roles and norms as defined by society, investigating the interplay of gender identity and family identity is of crucial importance in understanding consumption in modern families. All of the papers in the session take a consumer culture theory (CCT) perspective and use ethnographic data, specifically interviews and observation, to examine these nuances of gender and family identity.

The first paper in the session (Schau, Russell, and Crockett) investigates how family and gender representations within television narratives are appropriated by consumers and linked to their consumption choices. The second and third papers in the session examine unique challenges to family identity for mothers (Huff and Cotte) and for fathers (Bettany, Kerrane, and Hogg). The final paper (Schau and Connell) investigates how gender roles within families influence intergenerational transfers between mothers and fathers and their children.

Collectively, the papers' findings should have broad appeal for attendees interested in consumer culture. The session will be of particular interest to researchers examining the roles family identity and gender identity play in consumption. In addition, given that several of the papers in the session examine constraints consumers face or conflicts within families, the session will also have appeal to members of the transformative consumer research community.

This session is particularly well-suited for the conference's mission on appreciating diversity. The research not only examines gender roles and unique identity challenges faced by both female and male consumers, but also includes changing family roles and nontraditional families. Furthermore, attendees to this session will be exposed to consumer perspectives from Canada, the United Kingdom, and the United States. The four papers in this session offer completed work by scholars who are esteemed for their work on family and gender identity

Gender and Family Identification in Television Narratives: Homophilization and Appropriation

EXTENDED ABSTRACT

We explore how family and gender representations within television narratives are appropriated by consumers and linked to their consumption choices. In contemporary culture, family and gender have multiple, highly contested meanings (Spigel 1992). Television instantiates reigning cultural logics; it is a prime medium for acculturation (Morley 1988), where consumers observe and adopt the cultural logics and consumption practices depicted in the narratives. Consumers must engage and reconcile polysemic texts as they construct and communicate their family and gender identities (McKinley 1997). We posit that television viewing is uniquely important in addressing questions about how family and gender take on meaning and impact consumption.

We asked 137 young adults (19-39 years) to create a collage centered on a TV-based character's consumption choices and to complete an online semi-structured questionnaire about their collage. A subset of these collage creators (N = 22) also participated in an interview about their collage: using the collage in a manner analogous to Heisley and Levy's (1991) autodriving, participants were asked to walk the researcher through their collages discussing the meanings they attributed to the brands, the significance of their inclusion and placement within the collage, and how the collages related to the participants' own consumption constellations (Solomon and Englis 1992) and identities.

Our data reveal that consumers identify with television narratives through a process we term "homophilization": they actively envision various features of television narratives as similar to their own lived experience, even if the similarities are not readily apparent to a casual observer. The data show that homophilization is enacted primarily by customizing the narrative, or textual poaching (Jenkins 1992), where consumers insert themselves into the narrative, at times bending both the narrative and their own lived experience to achieve resonance, and further that consumption choices serve as primary mechanisms for poaching. Interestingly, our data show that the consumers relate to the media text primarily through the lens of family of origin (their childhood family), rather than as a family of procreation (romantic partner and children), friends, colleagues, or neighbors. The consumers consistently draw on gendered roles within families of origin to anchor their identification.

Our informants describe the myriad narratives available in the mediascape and the lengths they go to identifying with the characters as members of their family of origin. This may best be shown using a specific data example. One informant described a void in the mediascape to explain her choice of a classic television program, *The Cosby Show* because, "I love the premise: a strong black upper middle class family talking about morals, education, ethics and music." When asked if she was like the characters in the show, she responded, "Well, no… I'm a 34 year old black woman… I'll never be a doctor like he was on the show, or a lawyer like Clair, his wife on the show. I'll just never be. My family was not middle class. We lived pay check to pay check. We still do… It kept me in school." She notes her gender difference from Bill Cosby, as well as a wide social class gulf between family life as she experiences it and as portrayed on *The Cosby Show*. Yet, she indicates that when she watches the

show she identifies Cosby as a father figure. She cites the exceptional nature of the depiction of middle class black family life as her main motivation for watching the show which she still accesses to fuel her identification. She credits the show's emphasis on education and Cosby's father figure depiction with encouraging her to remain in college, to consume higher education.

Consumers revise, or retrofit media narratives to coalesce with their own lives, seamlessly merging the depictions and their idiosyncratic lived experience. In the example, this occurs even though the defunct *The Cosby Show* narrative is quite different in family and gender depiction from her own family of origin which contained a single mother and a mostly absent father. Here, our informant, as a 34 year old woman with two children of her own could have identified with the narrative as a family of procreation (she in the role of mother). Instead she draws discrete comparisons between the media text and her life, and actively identifies with the television family the Huxtables as members of her family of origin.

At times the homophilization may be attributed to aspirations (as in the above) but need not be. For example, a 21 year old informant sees Monica of *Friends* as a "mother" to the rest of the group. As such, she references the brands that symbolize, based on her family experience, an inviting home. She imagines Monica would use Kitchen Aid, stating "One of my first memories regarding this product is when I was 10 years old and my father bought me my first mixer, it [the one in the Monica collage] was the one that he got me." The informant's own family experiences shape how she envisions both Monica and motherhood. Here, the homophilization occurs, consumption is implicated, and the textual poaching to make that happen bends both the narrative and her own experience of family: Monica is not a mother in the narrative and the informant's experience with the consumption object is actually through her father. The same informant also imagines Monica uses a specific brand of coffee, Maxwell House, though it is never depicted on the show because her parents served it to household guest.

Our data reveal consumers engaging in active homophilization through textual poaching that bends the narrative and/or their lived experience until there is a tenable perceived similarity and implicates consumption as a tangible signifier of identification. Consumers consistently opted to identify with the narrative through the lens of family of origin as opposed to a family of procreation, or no familial identification at all (friends, colleagues, neighbors) and cite gendered roles within the family as explicit points of connection.

Gender Norms, Family Identity, and the Performance of Motherhood Using Commercial Childcare

EXTENDED ABSTRACT

Gender and identity are heavily implicated in consumption. Prior research has established that consumption can facilitate gender performance and identity work by providing symbols and resources to enact gendered identity (e.g., Holt and Thompson 2004; Thompson 1996). More recent work has revealed that consumption can complicate gender performance and identity work, particularly for consumers in a period of transition; competing discourses, ideologies, and gender norms can create new tensions for consumers as they engage in identity projects (The VOICE Group 2010a, b; Zayer et al. 2012). Consumption can also be problematized by gender discourses that are no longer dominant (Fischer, Otnes, and Tuncay 2007), which raises questions about how traditional and contemporary gender roles shape and are shaped by consumption. Further, questions remain about how family identity – a family's subjective sense of itself – is influenced by individual members' identity work and consumption practices (Epp and Price 2008). In this research, we focus on mothers' experiences using commercial childcare as they pursue careers. Our goal is to understand how childcare consumption facilitates and problematizes mothers' identity work, influences how motherhood is performed in relationships between mother and children, and is co-constituative of collective family identity.

Much of the current consumer research on gender and family identity focuses on the consumption of products, particularly those of importance, such as the integration of a special heirloom into a family home (e.g., Epp and Price 2010; Thomsen and Sørensen 2006). We build on this body of research by exploring the consumption of a service in everyday life. In foregrounding the routine use of a service, we are able to examine the ways that motherhood is both produced and consumed, and the ways that the marketplace influences family identity at individual, relational, and collective levels (Epp and Price 2008; Hogg, Curasi, and Maclaran 2004).

Motherhood plays a prominent role in women's gender performance (Christopher 2012). We focus on mothers with careers because these women are likely to experience strong tensions between the dominant logic of the marketplace, which emphasizes productivity and self-interest, and the dominant logic of motherhood, which emphasizes selflessness (Friedan 1963/2001; Hays 1996; Zelizer 2005). On a daily basis, these women encounter competing gender norms, including norms for contemporary working women, and more traditional norms associated with motherhood (Collins 2009). Consequently, mothers need to reconceptualize how they perform motherhood, because the daily caregiving of their children is outsourced to a service provider (Christopher 2012).

To address our research goal, we conducted depth interviews with four women who have young children in childcare and who classify themselves as professional. The interviews were conducted face-to-face in informants' homes, and lasted approximately 90 minutes. We sampled purposively for mothers who were eager to return to work after taking maternity leave from their careers. Our data included 93 single-spaced pages of transcripts and field notes. We used a hermeneutic approach to analyze and interpret the data (Thompson, Pollio, and Locander 1994), and engaged in peer debriefing.

In our sample, each informant is married, a loving mother, and has a career that required post-secondary education and a professional designation. Informants are very pleased with the quality of childcare they are currently using, and note that their children enjoy going. Further, each informant reveals that they did not enjoy their maternity leaves (ranging from 1 to 12 months) as much as they had expected; they found themselves unfulfilled by the mundane tasks of full-time childcare, and sought the feelings of achievement and productivity that came from their careers.

Following the framework of family identity put forth by Epp and Price (2008), we examine the intersection of gender and family identity in the context of commercial childcare consumption. We begin by revealing how mothers' individual identity work is shaped by competing conceptions of fulfillment, which plays a prominent role in the lives of professional women. Our informants reveal that fulfillment can be conceptualized in traditional ways, wherein fulfillment is achieved through intensive mothering and domestic work, and in more contemporary ways, wherein fulfillment must include some degree of productivity in the marketplace. These opposing perspectives of fulfillment complicate women's gender performance (Tropp 2006; Zayer et al. 2012).

Next, we demonstrate that the use of commercial childcare reframes our informants' relationships with their children. This relational identity is reconstructed as mothers outsource daily childcare. Our informants demonstrate gender fluidity as they draw on

traditional and contemporary norms to perform motherhood in the time they do share with their children. Unscripted, child-focused leisure time takes precedence over domestic labour, and women reconceptualize motherhood to involve managing childcare rather than providing it (Christopher 2012; Epp and Price 2012; Johnston and Swanson 2006), which has implications for the identity enactments of this relational group.

Last, we uncover the ways that family identity is shaped by use of childcare. Our data are somewhat limited in this regard, but we sketch out how families enact collective identity when young children are in commercial care during regular working hours. Our informants contrast their own families' activities with those of families with stay-at-home mothers, and reveal that nonmaternal childcare challenges and reinforces the family's sense of itself (Epp and Price 2008).

This work contributes to our understanding of gender, family identity and consumption. We begin to tease apart the traditional and contemporary gender roles, and reveal how they influence mothers' identity, mothers' relationships with their children, and collective family identity. By foregrounding childcare consumption, we are able to shed some light on the ways that routine, everyday consumption facilitates and complicates gender performance and family identity.

Negotiating "The New Father": The Consumption of Technology Within the Contemporary Family

EXTENDED ABSTRACT

In consumer research, the negotiation of the relation between fatherhood and masculinity as expressed and reproduced through consumption practices and processes has been identified as a research area in need of further investigation (Gentry *et al.,* 2003; Davies *et al.,* 2009). In this research we undertake such an investigation using the specific case of fathers engaging in their first transition into fatherhood. We focus on the inextricably linked negotiation processes of first time fatherhood and masculinity around the choice, consumption, and use of technological consumption objects typically purchased during this period.

It has been documented in the wider social sciences and consumer research that the relation between masculinity and fatherhood is contested, complex and contentious (Davies *et al.,* 2009; Gentry *et al.,* 2003; Miller, 2011). Specifically, the discourses which frame men's transitions into first time fatherhood sit uneasily between more traditional expressions of hegemonic masculinity (Connell, 1995) (for example, father as breadwinner and economic provider), and more recent articulations of the involved and nurturing fatherhood (Gatrell, 2007; Wall and Arnold, 2007). Hegemonic masculinity, the ability of the dominant group to obtain consent from those being subjugated, frames fatherhood within certain conceptions of masculinity (Williams, 2008) as bound up in the breadwinner model. Such cultured stereotypes of masculinity are suggested to inhibit caregiving or nurturing behaviour (Russell, 1986) in favour of economic fatherhood alone (Townsend, 2002). Whilst some maintain that there has been relatively little change in the input of fathers into family life (see, for example, Demos and Acock, 1993; Jamieson, 1999), others argue that men *are* becoming more involved in family life, challenging traditional notions of hegemonic masculinity (O'Brien and Shemilt, 2003; Warin *et al.,* 1999). At the nexus of these conflicting discourses, the important contemporary cultural figure of "the new father" has emerged.

The new father emerges, it is argued, as an effect of a range of policy, economic, demographic and cultural shifts, rendering this figure as both responsible financially for his offspring (Townsend, 2002) and, in addition, as an important and (ideally) equal caregiver and nurturer within the family dynamic (Miller, 2011). Implicated and entwined in this emergence of "the new father" are both reproductions of, and challenges to, gender norms, including the negotiation of what masculinity and fatherhood means, reproductions of hegemonic masculinity and the emergence of new, competing masculinities (Connell, 1995).

Utilising Laclauian discourse analysis, we examine how "the new father" emerges as an "empty signifier" within the field of discursivity around the transition to fatherhood; and how chains of equivalence emerge and are maintained within the family setting which allow for the simultaneous challenging and reaffirmation of hegemonic masculinity within the negotiations of consumption (and other) family practices and processes during this transitional period.

Laclauian discourse analysis has been used to examine the intersections of culture, politics and cultural identity and to examine the formation of hegemonies within cultural and political settings. As such, we suggest, it is well positioned to provide a theoretical framework and toolkit to examine the multiple articulations of masculinity implied in this study (Carpentier and Spinoi, 2008). The power dynamics of familial relations at this specific time in family formation, and the implications for gendered identity formation, utilisation and reinforcement suggest the requirement for a theoretical framework that can not only explain identity formation but also expose the complex political machinations and power struggles within the family that ultimately conclude in the reproduction of common sense of "what it is to be a man" at this crucial transitional time.

Utilising ethnographic data, we examine how three "must have" technological consumption objects, "the baby buggy", "the baby monitor" and "the baby car seat" emerge as important nodal points around which power and gender relations within and around the family are negotiated, and hegemonic gender norms are simultaneously challenged and reaffirmed. We found key episodes around the consumption and use of these products where these processes of "gender trouble" are played out. We conclude that although the purchase and use of technological products provide a refuge for new fathers within this challenging transitional period, allowing expressions of hegemonic masculinity, that the figure of the new father allows the expression of newer discourses of caring masculinity and nurturance to be appropriated. We demonstrate how these technology-suffused products become symbols of masculine power and domination over women and nature within the family but, in addition, how they simultaneously become important nodes for contestation of patriarchal gender relations.

The Influence of Gendered Interfamily Coalitions on Intergenerational Transfer

EXTENDED ABSTRACT

Intergenerational transfer is a pervasive yet poorly understood consumer behavior. The small amount of research in the field has acknowledged and/or observed gendered patterns of intergenerational transfer. For example, Fournier (1998) finds evidence of brand preferences that are passed down from mother to daughter. Similarly, other research has observed disposition of special possessions to subsequent generations in gender-stereotypic ways, such as fishing poles to male family members and dishes to female family members (Curasi, Price, and Arnould 2004; Price, Arnould, and Curasi 2000). Perhaps recognizing the impact of gender in intergeneration transfer, Moore, Wilkie and Lutz (2002) conducted their study on intergenerational transfer entirely within the context of mother-daughter dyads.

However, gender roles have not been the focus of this research, leaving a major gap in understanding this widespread phenomenon.

Because one's gender is a culturally persistent part of one's identity, we believe it plays a profound role in how intergenerational transfers manifest themselves within families. Epp and Prices (2008) describe how family identity operates at individual (each person within the family), relational (interfamily coalitions), and collective (the entire family) levels. We believe that gender roles within the family are likely to particularly influence the nature of intrafamily coalitions as they relate to intergenerational transfers. Thus, in this research we specifically examine how coalitions within families are formed around identity-centered consumption that is passed down from one generation to the next.

In the spirit of discovery-oriented consumer research to develop new theories (Wells 1992), we used depth interviews to draw on key themes that emerge from the data (Glaser and Strauss 1967). Depth interviews allow us to gain emic understanding through detailed discussion and probing the informant about complex inspirations and experiences (McCracken 1988). To locate relevant field sites and recruit informants, we opted for theoretical sampling (Glaser and Strauss 1967; Miles and Huberman 1994). We interviewed 27 informants about practices they had either adopted from their parents or had passed along to their children. Sixteen of these informants belonged to one of five families where we interviewed multiple family members that represented different generations within the family. Three key patterns emerged from our data: (1) a parent tended to favor engaging in intergenerational transfers with same-sex child in gender-stereotypic ways that exclude opposite-sex children, (2) a parent tended to disengage from intrafamily identity projects that were aligned in gender-stereotypic ways with their opposite-sex family members, even if they supported these identity projects, and (3) a parent tended to engage in gender-neutral intergenerational transfer with opposite-sex children if same-sex children were not in the household.

We will first examine the instances in which a parent tended to favor engaging in intergenerational transfers with same-sex child in gender-stereotypic ways that exclude opposite-sex children. We observed this pattern in nearly all of our interviews that involved dyads or networks of individuals within families that belonged to the same sex. As gender is a pervasively salient part of one's identity in Western culture (Eagly and Wood 1999), it is not surprising that parents would seek to instill those aspects of their gender identity in their same-sexed children. When intergenerational transfer attempts were well-received by same-sex children, the frequent result was a synergistic relational family identity project involving the parent and his/her same sex child(ren). We observed that even with consumption that could be construed as gender-neutral (e.g., collecting Dis-

ney movies and merchandise or sports), this was often defined along gender lines (e.g., Disney "princesses" among mother and daughter or football among father and son). Thus, opposite-sex children were excluded from these intrafamily coalitions. We observed that these consumption coalitions, while facilitating relational family identity among same-sex family members, often created tension between the coalition and opposite-sex family members. Sadly, these tensions that often involved feelings of isolation, jealousy, and resentment were seldom recognized by members of the coalition. Interestingly, excluded family members seemed less concerned about their inability to participate in the consumption in question, but rather felt that it served as an impediment to building family identity with their opposite-sex family members. We did observe exceptions where opposite-sex children chose to engage in the coalitional practice any way (e.g., a daughter playing sports when it was clearly identified in the family as a male activity). When this was the case, it often resulted in open conflict among the parent and the opposite-sex child that potentially drove them farther apart.

Next, we will examine when a parent tended to disengage from intrafamily identity projects that were aligned in gender-stereotypic ways with their opposite-sex family members. In contrast to the situation when a child was excluded from gendered intergenerational transfers, we did not observe cases where a parent felt resentful or envious of such consumption in our data. Rather, the parent was often supportive of these identity projects if they felt it facilitated relational family identity-building among their spouse and opposite-sex child(ren). However, in cases where intergenerational transfer attempts strongly encouraged by the spouse but were met with resistance from the child(ren), then support for these intergenerational transfers among opposite-sex parents began to wane because they no longer viewed the consumption as facilitating family identity-building.

Finally, in many families a parent does not have any same-sex children, and is not content with merely playing supporting role to their spouse's gendered intergenerational transfers to the family's children. In this case, the parent tended to engage in what they viewed as gender-neutral intergenerational transfer with their opposite-sex children. For example, one informant described wanting to share his love of Lego building blocks with his daughter because "Legos are for everyone."

While intergenerational transfer is a pervasive behavior, and is clearly influenced by gender, research on this phenomenon has been practically nonexistent. When it has been addressed in the literature, it has typically been relegated to the sidelines. We hope that our research, as the first in-depth investigation into the influence of gender roles on intergenerational transfers within families, will spur additional inquiry into this important phenomenon.

The Mere Idea of Money Alters Consumer Welfare, Preferences, and Morality

SESSION OVERVIEW

Money is crucial to surviving and thriving in modern life. Most obviously is its use as a tool, but perhaps more intriguing is its far-ranging ramifications for the self, interpersonal relationships, and morality. This session features cutting-edge research on the psychology of money, showing how it not only affects spending (and how to aid consumer welfare in the process) but also how it affects moral judgments and interpersonal behavior.

The first talk by Mogilner will discuss three experiments demonstrating that reminders of money shift people's focus toward functionality. Prior work has shown that reminders of money harm interpersonal connectedness, but Mogilner's talk will discuss how to reverse that effect. People plan to socialize more and actually socialize better (as rated by their partners) after socializing is framed as a functional behavior – i.e., a networking opportunity. Even more telling is the additional finding that money reminders shift moral judgments in a classic "trolley problem" game, whereby money primed participants are more likely to say they would push one person off of a bridge to save five others. Money and functionality are tied together in a much more basic way, of course, namely through spending money to obtain desired goods and services. Yet spending situations in which the choice size is large can be stressful, leading people to exit the spending situation without purchasing. The second talk by Shah will discuss how to assuage consumer feelings during a spending situation with a large choice size, using several clever manipulations that reduce the pain of paying. In doing so, her findings show that not only does spending increase but consumers report feeling less decision conflict and being more satisfied than otherwise.

Spending is also a part of the story that the third talk, by Nelson, will discuss — but not spending in a traditional way. Nelson's work attempts to understand how people think about how much money to spend when it is completely up to them to price the product. Using a novel manipulation, consumers entering a museum are told that another customer already has paid for his or her entry and they are given the opportunity to pay for a future customer. The question is how much will consumers then pay when they are paying for a future customer in this Pay-It-Forward pricing scheme. The results show that in comparison with Pay-What-You-Wish pricing (which is economically identical), Pay-It-Forward pricing scheme yields higher revenue. Last, the interpersonal and moral dimensions of money are at the forefront of Vohs's presentation. In her work, money that is crisp, clean, banknotes or money that has been soiled in dirt for several days is used as a manipulation to activate notions of fairness or greed. Using these manipulations, she finds consistent evidence that clean money produces fair trade and honest responding, whereas dirty money elicits moral violations, greed, and dishonesty.

In summary, this session tackles some of the big questions about money's effects on consumer psychology. How do various forms of money affect spending, relating, and moral behavior? The answers to these questions and many more will be revealed in the current session. The issues examined in this session have important implications for policy and societal well-being, as well as basic scientific understandings of the psychology of money. As a result, this session will appeal to researchers interested in the self, interpersonal relationships, morality, judgment and decision making, as well as those interested in policy or managerial decision-making. This session speaks to the theme of diversity in several ways. First, the papers presented collectively embrace a diverse set of research methodologies, using field and laboratory experimental methods, as well as survey and qualitative methodologies. Second, the diverse population of those studied, undergraduate students, graduate students, and the general public. Finally, money is as close to a universal uniter as any contemporary cultural construction. As a consequence we expect that a diverse set of scientists, policymakers, and scholars will find value in the session.

Reminders of Money Focus People on What's Functional

EXTENDED ABSTRACT

A growing body of research has shown that thinking about money makes people less socially inclined. Reminders of money lead people to be less likely to help others, less likely to ask others for help, more likely to maintain physical distance from others (Vohs, Mead, and Goode 2006), more impervious to social rejection (Zhou, Vohs, and Bauemeister 2009), more threatened by affiliation attempts (Liu, Vohs, and Smeesters 2011), and less motivated to socialize (Mogilner 2010). These results have been explained by the observation that money serves as a supremely functional resource that allows individuals to be self-sufficient, not relying on others to obtain what they want and need (Lea and Webley 2006; Vohs et al. 2006). Here, we explore the possibility that, beyond money serving as a tool, merely focusing on money may increase people's own functionality. That is, reminders of money may lead individuals to behave more functionally. Furthermore, this functionality may result in individuals behaving more prosocially—when it serves a functional benefit.

Across three studies we test this hypothesis that money makes people functional. The results show that, compared to neutral primes,

money primes increase individuals' tendencies to choose behaviors that are more functional in nature. Furthermore, in instances where prosocial behaviors are functional, these findings demonstrate that thinking about money can make individuals *more* socially inclined, rather than less.

Experiment 1 tested whether participants primed with money would be better able to make a tough, emotionally-laden moral decision in order to benefit a greater number of people. First, participants were asked to complete a "guessing task" in which they were shown a series of eight magazine covers and were asked to guess the year and month that the particular cover appeared. For participants in the money prime condition, the magazine covers were from Money magazine and the word "money" appeared in large block letters on all of the covers. For participants in the control condition, the covers were all from Scientific American magazine.

Next, participants were asked to respond to an ostensibly unrelated dilemma – the moral dilemma posed by the Trolley Problem. Two common variants of the trolley problem were used. In the flip-the-switch variant, participants were told that there was a runaway trolley headed toward five people and the only way to save them was by flipping a switch, which would divert the trolley on to a second track that contained one person. In the push-the-man variant, participants were again told about a trolley headed toward five people. However, in this case the only way to save them was to push an overweight man onto the track. Participants were asked, "How likely would you be to flip the switch [push the man] in order to save 5 people?" The results showed that priming money increased participants' likelihood of diverting the trolley to save five people, particularly in a situation in which people are less likely to endorse this option (the push-the-man variant).

Previous research has shown that priming money makes people less motivated to socialize when it is solely for the sake of interpersonal connection (Mogilner 2010). Experiment 2 thus tested whether participants primed with money would be *more* motivated to socialize when socializing was framed as functional (i.e., good for one's health). First, participants read a short newspaper article and were told that they would subsequently be asked related questions. Participants were randomly assigned to read either an article that espoused the health benefits of spending time with friends or a control article about jellyfish. Then, half of the participants completed a sentence unscramble task that surreptitiously exposed them to money-related words. Participants who did not complete this task comprised the control condition. All participants then went on to complete a survey about how they planned to spend their day. The results showed that after reading the control article, participant primed with money planned to socialize less than the control participants; however, after reading the article that highlighted the functional health benefits of socializing, participants primed with money planned to socialize more.

Experiment 3 tested whether participants primed with money actually socialized better when socializing was framed as being functional (i.e., a networking opportunity). First, participants completed a sentence unscramble task that exposed them to money-related words or all neutral words. Then, participants were informed that they would have the opportunity to interact with another student for 10 minutes. For some, this interaction was framed as a networking opportunity, and for the rest it was simply framed as an opportunity to get to know someone. The participants were then paired up and given 10 minutes to talk. Following the interaction, participants rated their partner in terms of how much they would like to interact with them in the future, etc. We relied on each participant's partner's ratings to assess the quality of participants' socializing. The results revealed that in the normal social frame, participants primed with money were worse at socializing than those in the control condition; however, when the interaction was framed as a networking opportunity, participants primed with money were more charming.

Together, these results suggest that reminders of money make people behave more functionally and, in some cases, more prosocially—when doing so has serviceable benefits.

The Paradox of Payment: The Moderating Effect of Pain of Payment on Buying Behavior as the Number of Alternatives Increases

EXTENDED ABSTRACT

In an economy with increasing product variety and mounting financial debt, we ask how the number of alternatives affects consumer behavior and well-being and how the pain of payment influences this relationship. There is accumulating evidence that as the number of alternatives increases, buying initially increases and then decreases (Shah & Wolford, 2007). Two processes account for this function. First, as the number of alternatives increases, there is a positive monotonic effect of choice size on matching consumer preferences. However, as choice increases, there is a negative monotonic effect of choice size and cognitive load. As the number of alternatives increases, consumers are more likely to have two or more alternatives that meet their criteria and are close in subjective value, resulting in increased effort and search cost (Schwartz, 2000, 2004; Shugan, 1980), lower choice accuracy (Payne, 1976), lower decision satisfaction (Malhotra, 1982), increased post-decision regret (Schwartz, 2004), and greater choice avoidance (Dhar, 1997; Dhar and Simonson, 2003; Iyengar & Lepper, 2000). An U-shaped function describes how buying as the number of options increases as a result of these two forces. Across three studies, we examine whether attenuating the pain of payment through either payment mechanism (credit/debit card versus cash) or by reducing the price moderates the inverted-U finding. That is, reducing the pain of payment may lead to increased buying and higher post-decision satisfaction as the number of alternatives increases.

When people make purchases, the pain they feel from giving away a piece of their wealth reduces the pleasure they feel about purchasing a product (Prelec & Loewenstein, 1998). Furthermore, the 'pain of payment' varies for different payment mechanisms. Money in the form of legal tender conjures more thoughts of payment than other payment mechanisms (Raghubir & Srivastava, 2008). Attenuating the pain of payment associated with a purchase (e.g., paying with a credit or debit card versus cash) leads consumers to not think as much about the negative attributes of their purchase resulting in more positive evaluations overall (Chatterjee and Rose, 2011). We hypothesize that reducing the pain of payment through payment mechanism will increase buying and satisfaction as the number of alternatives increase by lowering the cognitive costs, affective costs, and decision conflict associated with purchase.

Experiment 1 tested whether reducing the pain of payment by paying with a credit or debit card increased buying as the number of alternatives increased. Experiment 1 had a 2 (mode of payment: cash, student 'plastic' card) X 10 (number of alternatives: 2, 4, 6, 8, 10, 12, 14, 16, 18, 20) between subjects design. The price for each pen varied from $0.70 to $1.50. In a field experiment, students were invited to purchase a pen from a given choice set using their own money in order to elicit true buying behavior. Half of the participants could only pay with cash while a different set of participants could only pay with a student debit/credit card commonly used on campus. As predicted, for cash consumers, buying behavior was a

curvilinear function of the number of alternatives, resulting in an inverted U-shape consistent with previous research (Shah and Wolford, 2007; Iyengar and Lepper, 2000). For card consumers, initially buying increased as a function of the number of alternatives. However, in contrast to cash consumers, buying did not significantly decrease for choice sets with more alternatives. For those who bought across conditions, consumers paying with plastic bought more pen units overall than consumers paying with cash.

Study 2 sought to replicate the findings of Experiment 1, gain greater insight into potential processes driving the effects, and also rule out an alterative explanation. Experiment 2 had a 2 (mode of payment: cash, student 'plastic' card) X 2 (purchase restriction: unlimited pen purchase, single pen purchase) X 5 (number of alternatives: 2, 6, 10, 14, 18) between-subjects design. Students passing through common areas were invited to purchase a pen from a set of alternatives using their own money and were restricted to purchasing only one pen if they so desired. We also sought to rule out an alternative explanation that budget constraint differences could be driving the effect by restricting consumers to purchasing at most one pen. Plastic card consumers may have responded to tradeoff difficulties between options by purchasing all suitable options because they were less constrained. With a purchase restriction, consumers could spend no more than $1.50 regardless of the payment mechanism. As predicted, pain of payment via payment mechanism moderated the effect of an increasing choice set on buying regardless of restriction level. Buying behavior as the number of alternatives increased was described by an inverted U-shape function for cash consumers, while plastic card consumers did not significantly decrease buying. In addition, plastic card consumers spent less time making a purchase decision (lowered cognitive costs) and reported higher levels of post-purchase satisfaction (lowered affective costs) than cash consumers.

In Study 3, we examined whether an alternative method for reducing the pain of payment, manipulating the cost of the items would moderate the choice overload effect. Study 3 had a 2 (mode of payment: cash, student 'plastic' card) X 3 (number of alternatives: 4, 10, 16) X 3 (price per pen: $0.25, $1.00, $2.00) between-subjects design. Again, students were restricted to one pen per purchase from a given choice set using their own money. Consistent with our theory, reducing the price of the pen to $0.25 moderated the inverted U-shape, with individuals buying more in higher choice sets. For plastic card consumers, increasing the price of the pen to $2.00 led to an inverted U-shape, with individuals buying less in the higher choice sets.

In summary, reducing the pain of payment associated with the purchase through payment mechanism or price moderates buying behavior as the number of alternatives increases. This research advances our understanding of choice overload. Furthermore, these results provide evidence that the pain of payment can significantly influence consumer decision-making and welfare.

People Pay More When They Pay-It-Forward

EXTENDED ABSTRACT

In daily economic transactions, people often follow the norms of market exchange: seeking the lowest possible prices in order to find the highest possible value. This narrative neglects the fundamental social forces at play in an exchange. Our research considers the consequences for a shift from market-determined fixed prices, to customer-dictated flexible prices. What happens when a company asks its customers to simply pay whatever price they want? That shift – from a pure market transaction to one steeped in fairness, donation, and giving – upends established knowledge about consumer behav-ior, and opens questions about how such a market could work, and when it could thrive.

Pay-what-you-want pricing has grown in popularity, and is most frequently seen in its basic format: a company offers a good or service and the customer can pay any price he or she would like (typically including $0). Past research highlighted how much small variants can influence the success of such a program. For example, in one large experiment, when people learned that half of their payment would go to charity, people paid six-times as much (Gneezy et al. 2010). That treatment offered a better product to the customer, was maximally profitable for the firm, and also yielded a substantial charitable surplus. This small pricing tweak uniformly increased total social welfare.

Our research considers an even more fundamental change to pay-what-you-want (PWYW) pricing. What if payments were all gifts? What happens when people have an option to pay for someone else (and are told that someone has already paid for them)? Such pay-it-forward (PIF) pricing has identical commercial features (e.g., the option to pay $0), but invokes a very different set of social norms. We predict that people's willingness-to-pay is higher when they pay forward than pay what they want. In three studies we test this prediction and investigate some of the factors that might explain higher payments in the PIF pricing model.

In our first study, museum visitors (N = 311) saw either PWYW or PIF admission prices. As we predicted, people paid a higher amount for their admission to the museum under PIF pricing than PWYW pricing (M = $3.12 vs. $1.89). This field study suggests that when people pay what they want, they pay more for someone else than they do for themselves.

Perhaps people paid more because they felt something of an obligation for the other customers? Consistent with this possibility, prior research has shown that social preferences are heavily influenced by knowledge of, and experience with, the givers and recipients of prosocial acts (Small & Loewenstein, 2003; Roth,1995; Hoffman et al., 1996; Bohnet & Frey, 1999; Xiao & Houser, 2005). In Study 2, we tested the role of social interaction in people's willingness-to-pay in PWYW and PIF pricing in a controlled lab setting. Perhaps increased social interaction would differentially influence PWYW and the comparatively socially-oriented PIF pricing schemes. Participants (N = 294) interacted with the previous participant (the gift giver in PIF conditions), the next participant (the gift receiver in the PIF conditions), or no one, immediately prior to the experiment. At the end of the session, participants were presented with a coffee mug and asked to either pay-what-they-want or pay-it-forward to the next participant.

People paid more for a coffee mug under pay-it-forward than under pay-what-you-want (M = $1.79 vs. $1.27). However, contrary to our predictions, social interaction did not influence payments in the PIF conditions. Interestingly, there was a persistent effect that across all conditions people thought that the previous participant and the next participant paid more than they did. Furthermore, those estimates of the payments of others were particularly heavily influenced by the payment manipulation: people think that others will pay more under PIF than PWYW.

These results suggested that PIF operated in two stages. Something about the manipulation led participants to believe that other people were paying more. Based on that assessment, participants raised their own payments to match their new perceived norms. If that is true, we reasoned, then we should be able to eliminate the influence of PIF by simply informing participants about the payments of others. We tested this prediction by telling approximately half

of the participants (N = 198) that the previous participant had paid $1.50, whereas the remainder were not told this.

Consistent with our prediction, and with the previous findings, when people did not know how much the previous participant had paid, they paid more under PIF than under PWYW (M = $2.48 vs. $1.19). When participants learned how much the previous person had paid this effect was eliminated and people paid about the same amount under PIF and PWYW (M = $1.21 vs. $1.23).

In summary, Pay-it-Forward leads to higher payments than does Pay-What-You-Want. This effect was not influenced by social interaction with the giver or the receiver of the gift. However, the effect was entirely eliminated when participants had a clear reference price of others' payments. People appear to believe that, because PIF must increase the payments of others, they should increase their own payments to match.

Clean Versus Dirty Money Produce Wildly Different Effects on Behavior

EXTENDED ABSTRACT

The present research began with the view that many people hold two distinct sets of associations about money. On one hand, money may evoke ideas of greed, exploitation, selfishness, corruption, and other unsavory, antisocial patterns, especially because many such antisocial actions have been performed throughout history in order to obtain money. Money may therefore elicit immoral sentiments and harmful behavior. Yet, money facilitates culture, fair trade, philanthropy, caring for loved ones, science and art, and many other social goods, and so it may be associated in people's minds with norms of fair exchange and positive treatment of others. Therefore, it may elicit morally commendable sentiments and prosocial actions.

We sought to evoke these different patterns of associations using clean and dirty money. We predicted that clean money would evoke the positive associations (and attendant behaviors) toward fair exchange, whereas dirty money would evoke the unsavory and antisocial associations. The prediction was that money and dirt would interact to influence how people treat others.

Experiment 1 was a field experiment designed to show the differential effects of clean versus dirty money on actual financial behavior. In a farmer's market, experimental confederates purchased vegetables and paid initially with either clean or dirty money. The confederates then ostensibly decided to purchase an additional vegetable, so they asked for the original money back. After collecting the (second) vegetables that constituted the main dependent measure, the experimenter actually paid for all their purchases with typical circulating money. Therefore, clean and dirty money acted as naturalistic primes. The dependent measure was the actual weight of the additional vegetable. In all cases, the customer ordered and paid for 500 grams of the last vegetables, and so fairness and reciprocity would dictate giving the customer precisely 500 grams.

We computed a fairness index for each sale by dividing the actual weight by the amount for which the vendor had charged (i.e., normally 500 grams but occasionally slightly more or less). As predicted, the dirty money prime caused vendors to short-change and thus cheat the customer by giving them less (in weight) than they paid for. In comparison, the clean money prime led to transactions that were in line with what consumers paid for.

Experiment 2 used a 2x2 between-participants design in which participants first performed a finger dexterity task. As a function of condition, they counted out dirty or clean money or dirty or clean sheets of paper. Then participants played the trust game, which has two distinct roles. The sender is given a certain stake of money and can send any part of it to the other person (the receiver), while keeping the rest. The sender is told that whatever money is sent will be tripled by the experimenter and given to the receiver, who then is free to divide the enriched amount between self and the sender. Thus, the receiver can keep all the (tripled) money that the sender donated.

All participants believed they were playing the role of receiver, and it was up to them to decide how to divide the money. Thus, someone else had trusted them, and they could decide whether to repay that trust or keep most of the money for themselves. We predicted an interaction effect, such that participants who had handled clean money would tend toward making a fair and even division of the money, whereas those who had handled dirty money would keep more money for themselves. We predicted an interaction effect, such that participants who had handled clean money would tend toward making a fair and even division of the money, whereas those who had handled dirty money would keep more money for themselves.

Results were in line with expectations. The clean money group returned significantly more money than the dirty money group. The paper conditions did not differ from one another.

Experiment 3 used the most basic of economic games, the dictator game. The participant is given a stake of money to divide between self and another person. The participant's decision is final, and both players get whatever that allocation is. The other person has no vote and no power. Hence it constitutes a relatively pure measure of how well the participant wishes to treat the other person.

This study also changed the manipulation. There were 3 conditions. All participants counted ordinary and thus not notably clean or dirty money (and no one counted paper). Control participants went to the next task. For dirty and clean money manipulations, participants read an ostensible news item about how clean or how dirty is the nation's money supply. Then they performed a lexical decision task in which they rated the positivity of words related to fairness and reciprocity. Last, they played the dictator game and allocated money to an anonymous partner.

Dictator game results: As expected, the clean money group was significantly more generous and fairer to the others than the clean paper group. Meanwhile, the dirty money group was less fair than the control group.

Word rating results: As predicted, the clean money group rated reciprocity words more positively than the control group. The dirty money group rated these words as worse than the control group. We found mediation on the part of word ratings to explain the relationship between the manipulation of dirty money vs clean money vs control on dictator game generosity. Participants in the dirty money condition evaluated fairness words less positively than participants in the control and clean money condition, who rated those words most positively. This accounted for their low and high generosity in the dictator game.

Money is a pervasive aspect of modern life, and the idea of money crosses the average person's mind many times every day. The present findings suggest that there may be more than one set of associations to money. In particular, we found that clean money and dirty money had radically different effects. Despite the negative associations that money can evoke, the idea of clean money can improve people's tendencies to behave in positive, prosocial, culturally beneficial ways.

Doing Well vs. Doing Good:
The Interplay of Morality and Performance in Consumer Judgments

Erik G. Helzer, Cornell University, USA
David Tannenbaum, University of California, Los Angeles
David A. Pizarro, Cornell University, USA

SESSION OVERVIEW

Moral beliefs are among the strongest beliefs that consumers hold, and are deeply tied to how individuals view themselves. However, in the real world, successful performance is not always associated with morally upstanding behavior. For example, individuals sometimes resort to immoral behavior in order to perform better and achieve success, and successful individuals sometimes behave as if they are exempt from certain moral standards. The present session seeks to examine the complex and fascinating interplay of morality and performance in consumer judgments. Specifically, the four papers presented here examine how consumers make moral judgments about others, and how these judgments influence subsequent purchase decisions and brand evaluations.

Virtually every week, new examples emerge of public figures that have been accused of immoral behaviors, and the first two papers concern the relation between performance and morality when evaluating these cases. First, Hamerman and Parker show that a public figure's good performance can be as redemptive as an apology for bad behavior. Next, Bhattacharjee, Berman and Reed investigate a new reasoning process that consumers use to support public figures that have transgressed. Similarly, the latter two papers broadly concern moral judgments of performance. Williams and Steffel show that consumers display an ethical double standard in judging their own versus others' use of products that enhance performance (e.g. sports drinks, medication). Finally, Critcher et al. propose a new model of moral judgment: instead of focusing on the performance of good or bad deeds per se, individuals instead focus on an actor's moral sentiments. The first three papers are currently in review process, and the fourth will be submitted for review shortly.

Together, these papers highlight various ways in which consumers combine and reconcile dimensions of performance and morality in their judgments. Given the breadth of these issues and the primacy of moral beliefs as a driver of consumer decision making (e.g., Brinkmann 2004; Smith 1990), we expect that the session will be well attended by researchers with interests in brand management,

motivated reasoning, social cognition, CSR, and morality and ethics to name a few. However, despite the pervasiveness of moral concerns in consumption contexts, it is striking to note the dearth of sessions dealing with moral judgments at recent ACR conferences. In the spirit of the conference theme of appreciating diversity, we hope that this session can offer a special opportunity to open the field to investigating the moral consumer.

Redemption through Success: When Good Things Happen to Bad People

EXTENDED ABSTRACT

Media reports are filled with instances of pop stars, athletes, and corporate executives being linked to immoral or illegal acts. However, these misdeeds seem to be ignored after the transgressors recapture professional success (e.g., by winning a big game). This paper demonstrates that because people infer the morality of others based on their professional performance, success can be as effective as an apology in redeeming one's reputation. Demonstrating that this is not merely a halo effect, three experiments show that seeing an immoral person achieve professional success is upsetting, which leads to a discounting of the immoral act in a manner consistent with cognitive dissonance. When participants were provided with the tools to cope with threatening information (via self-affirmation) or were no longer threatened by this information (such as when the actor was punished for his or her misdeed), they ceased to discount the transgression.

Experiments 1A and 1B investigated the influence of professional success on the evaluations that participants made about a real protagonist: Michael Vick, an NFL quarterback who served time in federal prison for running a dog-fighting ring. The good-play scenario described Vick's on-field success during the 2010 NFL regular season. The poor-play scenario described Vick's poor play during the 2010 NFL playoffs. Finally, the apology condition simply quoted the apology on his website and made no mention of his on-field performance. Participants indicated their general perceptions of Vick (1 = negative, 8 = positive), how trustworthy they perceived him to be (1 = not trustworthy at all, 7 = extremely trustworthy), and how likely they would be to purchase two products endorsed by Vick (Experiment 1A). The perception and trustworthiness items were combined into a single measure of participants' evaluations of Vick's moral character (the same measures were used in experiments 2 and 3).

As predicted, the evaluation of Vick in the apology condition (M = 3.73) did not differ from the good-play condition (M = 3.16). More importantly, evaluations in the apology and good-play conditions were significantly more positive than in the poor-play condition (M = 2.03; p < .05). Participants were also asked to evaluate Vick's on-field football performance. It is important to note that while perceptions of Vick's football performance in the apology condition were higher than those in the poor-play condition, they were also lower than those in the good-play condition. Thus, perceptions of Vick's performance did not map directly onto respondents' evaluations of Vick as a person. In other words, participants were not simply using Vick's professional success as a proxy for evaluating him as a person.

Experiment 1B used conditions identical to those in experiment 1. However, experiment 1A allowed participants to enter either: (i) a lottery for Michael Vick jersey, or (ii) a lottery for Kevin Kolb (described as being an "average" NFL quarterback) jersey. As expected,

participants were more likely to enter a lottery for a Michael Vick jersey (vs. a Kevin Kolb jersey) when Vick was successful (29/38 (76%)) versus unsuccessful (18/37 (49%)), p < .05. Further, those participants in the apology condition were just as likely to choose the Vick jersey (22/37 (59%)) as were those in the successful condition (29/38 (76%)), $\chi^2(2) < 1$.

To explore the process behind this finding, two additional experiments were conducted. We hypothesized that the results of experiments 1A and 1B were related to cognitive dissonance. Specifically, because people are upset by the idea of an immoral person achieving professional success (shown in a pretest), we hypothesized that individuals discount the severity of a moral transgression ascribed to someone who subsequently becomes successful, thereby leading to more positive evaluations of this actor. Accordingly, manipulations that either (i) increase participants' ability to handle such threatening information, or (ii) alleviate the upsetting nature of this apparent conflict should attenuate the documented effect.

In experiment 2, a subset of participants was given the tools to cope with threatening information via self-affirmation. After re-affirming core values, people are better able to handle threatening information without resorting to rationalizations seen in cognitive dissonance (Harris, Mayle, Mabbott, & Napper, 2007; Steele & Liu, 1983; Steele, Spencer, & Lynch, 1993). Accordingly, completing a self-affirmation exercise should reduce the need to rationalize or discount transgressions committed by successful individuals, reducing the influence of professional success (vs. failure) on evaluations of others. After completing either a self-affirmation or an unrelated control task, participants read a scenario describing a banker who was arrested for drunk driving and subsequently made successful or unsuccessful investments. We found a main effect of success for evaluations of the banker (p < .01), qualified by an interaction between success and self-affirmation (p < .01). As predicted, there was no effect of professional success in the self-affirmation condition ($M_{Successful} = 3.62$ vs. $M_{Unsuccessful} = 3.69$), F < 1, but the attitudes of the participants in the no-affirmation condition were strongly affected by the banker's level of professional success ($M_{Successful} = 4.17$ vs. $M_{Unsuccessful} = 2.99$), p < .001).

In experiment 3, we expected that punishing the banker would alleviate the threatening nature of his post-transgression success. Punishment ensures that transgressors receive their "just deserts" (Carlsmith, 2002; Darley & Pittman, 2003). Therefore, it should be less upsetting to discover that an immoral person has been successful after learning that he or she has (vs. has not) been punished. Using the same "drunk driving" story from experiment 2, we manipulated the banker's investment success and whether he was punished for his actions.

As expected, we found a main effect of success on participants' evaluations of the banker (p < .001), qualified by a significant interaction between success and punishment (p < .01). Participants' attitudes in the not-punished condition were strongly affected by professional success ($M_{Successful} = 5.13$ vs. $M_{Unsuccessful} = 2.92$), p < .001, while success played no role in the attitudes of those in the punished condition ($M_{Successful} = 3.84$ vs. $M_{Unsuccessful} = 3.50$), F < 1. Moreover, respondents' evaluation of the seriousness of the act (drunk driving) fully mediated their judgments of the banker's moral character.

Tip of the Hat, Wag of the Finger: How Moral Decoupling Enables Consumers to Admire and Admonish

EXTENDED ABSTRACT

Bill Clinton, Roman Polanski, Tiger Woods, and Martha Stewart all share something in common: they are public figures whose immoral actions have threatened their professional reputations. How do consumers reason to support public figures who have acted immorally? We propose that when motivated to support a public figure who has transgressed, consumers engage in *moral decoupling*, a psychological separation process by which they selectively dissociate judgments of morality from judgments of performance.

Though moral beliefs are among the strongest beliefs that people hold, they are particularly subject to motivational biases (Ditto, Pizarro and Tannenbaum 2009). Current research emphasizes moral rationalization processes, by which consumers reconstrue transgressions as less immoral when motivated to do so (e.g., Mazar, Amir and Ariely 2008; Paharia and Deshpande 2009). However, because rationalization requires people to implicitly condone an immoral behavior, and because such judgments are deeply tied to the self (Aquino and Reed 2002), this mechanism may threaten consumers' moral self-image. We propose that people also engage in moral decoupling, a distinct moral reasoning strategy that enables consumers to support a transgressor while still condemning the transgression. Moral decoupling works by altering an individual's view of the relevance of moral actions to performance in a given domain. By dissociating performance from morality, an individual can support an immoral actor without being subject to self-reproach for condoning immoral behavior.

Five studies demonstrate that, relative to moral rationalization, moral decoupling is psychologically distinct, easier to justify, and more predictive of consumer support in one real world context.

A pilot study provides initial evidence that moral decoupling is distinct from moral rationalization. After reading a scenario describing an Olympic gold medalist who has physically abused his wife, participants rated their agreement with moral decoupling and moral rationalization items and rated the player on performance and degree of immorality. Regression analysis found that only decoupling significantly positively predicted performance ratings ($t(95) = 7.59$, $p < .001$), while only rationalization significantly reduced judgments of immorality ($t(93) = -3.55$, $p < .001$), suggesting that these constructs are distinct.

In study 1, we sought to gain causal insight by priming specific moral reasoning strategies. Participants wrote statements related to moral decoupling, moral rationalization, or humor (as a control). In an ostensibly different study, they then read about a CEO of a consumer electronics firm who has supported discriminatory hiring policies. Participants primed with a moral decoupling or a moral rationalization reasoning strategy reported being more likely to purchase the company's products than those in a control condition ($F(2, 118) = 9.93$, p < .001). More importantly, participants in the moral decoupling condition rated the performance of the CEO higher than the moral rationalization and control conditions ($F(2, 118) = 9.87$, p < .001), while those in the moral rationalization condition rated the immorality of the CEO's actions to be less severe than the other two conditions ($F(2, 118) = 7.00$, p < .001), reinforcing the difference between these psychological pathways.

In study 2, we examined the process of moral decoupling by directly varying the relevance of a transgression to performance. Participants read a scenario in which either a baseball player or a governor was found to have either taken steroids or engaged in tax evasion. As expected, participants were more supportive when transgressions were less relevant ($F(1, 83) = 22.2$, p < .001). Multiple-step mediation analysis found that relevance directly influenced moral decoupling, which increased performance judgments, leading to greater consumer support (indirect effect = -0.82; 95% C.I. = [-1.25, -0.44]). However, relevance had no effect on the degree of moral

rationalization or the degree of immorality (ts < 1), clarifying our proposed process and better establishing discriminant validity.

Study 3 investigates consumers' choice of a moral reasoning strategy as well as the implications for the self. Participants read the above scenario involving a baseball player or governor, and selected a supportive statement (reflecting either moral rationalization or moral decoupling) that best reflected their own beliefs. They then wrote an argument justifying their beliefs. Consistent with our previous findings, participants were more likely to select a decoupling (vs. rationalization) statement when the transgression was low (vs. high) in relevance ($\chi^2(1) = 8.20, p = .004$). In addition, a two-way ANOVA revealed a main effect of strategy choice on ease of justification ($F(1, 58) = 7.60, p = .008$): regardless of relevance, participants who chose a moral decoupling felt that their argument was easier to justify than those who selected a moral rationalization argument.

Finally, we looked for field evidence of moral decoupling using a sample of online comments about Tiger Woods before his return to golf in April 2010. From a random subset of 400 comments posted on major news sites, we eliminated those that were irrelevant, retaining 124 comments for analysis. Three coders blind to hypotheses rated the degree to which each comment supported or opposed Tiger Woods. In addition, they rated each comment on the extent of moral rationalization, the extent to which participants separated performance and morality (i.e., moral decoupling). Regression analysis shows that the degree of moral decoupling ($t(120) = 6.18, p < .001$) was a strong significant predictor of expressed support, while the degree of moral rationalization was only marginally significant ($t(120) = -1.84, p = .067$). Further, both the degree of moral decoupling ($t(120) = -3.48, p < .001$) was a strong significant predictors of opposition, while the degree of moral rationalization did not significantly predict expressed opposition ($t(120) = -1.03, p = .30$).

Thus, we outline the existence and nature of a new psychological mechanism—moral decoupling—by which consumers selectively dissociate judgments of morality from judgments of performance in order to support public figures that have transgressed. Doing so allows consumers to admire immoral actors while still admonishing their immoral actions, simultaneously tipping their hats and wagging their fingers.

Double Standards in the Use of Enhancing Products by Self and Others

EXTENDED ABSTRACT

Products can improve their users' lives in many ways, allowing them access to experiences, traits, and abilities they would not be able to achieve on their own. These types of product benefits raise questions about such products' ethical use, and how their use is perceived. One factor that may determine perceptions of their ethicality is how the effect of such products is construed, whether they are seen as helping to enable a person to reveal their true abilities or enhance them beyond their true abilities; further, this construal may differ depending on who benefits from them.

We suggest that the same product will have different ethical implications depending on whether oneself or another person is using it. People think their own potential ability is a part of who they are but not a part of others (Williams, Gilovich, and Dunning 2012), and consequently, products that seem to enable the self appear to enhance others. Because people are less comfortable with products and interventions that enhance a consumer's standing than ones that enable it (Lowery, Chow, and Crosby 2009; Riis, Simmons, and Goodwin 2008), people may see the same product as morally acceptable for the self to use but less so for others.

To establish that people see the same product as enabling themselves but enhancing others, and to show this effect with actual product use, in study 1 we had participants consume Jelly Belly Sport Beans, which work like sports drinks do to improve performance. Participants were supposedly paired with another student on an intellectual task to examine the effects of the beans on performance. They completed a baseline round of the task, consumed the jellybeans, and then completed the second target round. Next, they received feedback about their own or the other participant's performance in both rounds; the feedback was identical for both, such that the player improved his/her ranking on the task after consuming the jellybeans. When asked to what extent the Sport Beans helped reveal the player's true abilities (= 0; an enablement interpretation) versus helped them perform above and beyond them (=100; an enhancement interpretation), participants indicated that the Sport Beans were more enhancing of the other participant (M = 30.4) than they were of the self (M = 22.5; t(147) = 2.22, p < .05). This suggests that people do have different interpretations of the effects of the same potentially enhancing product when it is used by the self or another person.

In study 2, we connected this difference to ethical double standards. Participants imagined an interview for a much-wanted job. Ideal candidates were to be easy-going and relaxed, capable of dealing calmly with issues on the job. Participants then imagined that the candidate on this interview believed they had the potential to be the ideal candidate, but were worried that the interview situation would make them appear more tense than they actually are. The candidate took an anti-anxiety medication, Zatex, for the interview, and they got the job. Importantly, half the participants imagined that they were the job candidate, and half imagined that they were the interviewer.

Participants indicated that Zatex helped the candidate's true abilities show (= 1; versus making them appear to have abilities they don't actually possess = 7) to a greater extent when they themselves were the candidate (M = 3.5) than when they were interviewing the candidate (M = 4.4; F(1,119) = 11.29, p = .001). They also believed that the use of Zatex was more acceptable when they used it (M = 4.4) than another person (M = 3.8; F(1,119) = 6.51, p = .01). Participants' interpretation of the effects of the drug significantly mediated how acceptable its use was perceived to be. Namely, the more enhancing the drug seemed, the less fair its use. And because the drug seemed more enhancing when another person took it than the self, people held double standards for the use of Zatex. Further, how acceptable the use of the drug seemed to be determined how deserving of the job the candidate seemed to be, and whether the candidate should have to disclose that they took Zatex.

Finally, in study 3, we tested some consequences of these interpretations for how participants would choose to regulate the marketplace for such products. Student participants considered a potential new policy at their university that would forbid students from using non-prescribed attention-enhancing drugs like Ritalin or Adderall. This policy was framed as something the participant would need to agree to, or something that students in general (of whom the participant is logically a part) would need to agree to. Participants considering the effects of such a policy on themselves, rather than students in general, were more likely to believe that the drugs enabled (= 1; versus enhanced = 7) their users (M_{self} = 3.8 vs. $M_{students}$ = 4.4; F(1,74) = 4.12, p < .05). They also believed that the policy was more fair when framed as affecting students (M = 5.1) rather than themselves (M = 3.9; F(1,74) = 4.38, p < .05). Participants' interpretation of the effects predicted how unfair they perceived the policy to be, suggesting that interpretations of a product's effects influence how consumers think the product should be regulated. Further, the fact that mere framing could lead to these differences suggests that this

goes beyond a simple self-favoring bias. The consequences for the self were constant between framing conditions; if participants were solely trying to give themselves flexibility to use the product, simply changing their focus from self to a group that still includes the self would be unlikely to bring about the difference in perceived fairness.

Our research thus indicates that who is using a potentially enhancing product, oneself or someone else, can alter how moral a person perceives the use of that product to be. This work suggests that marketers, organizations, and citizens in general should carefully consider who uses such products, who will know, and what that means.

Actions Speak Less Loud Than Sentiments: A New Model of Moral Judgment

EXTENDED ABSTRACT

Consumers frequently form moral evaluations of others. They may question whether a celebrity spokesperson is an upstanding role-model, ask themselves whether a company's executive has solid moral values, or assess the moral character of other consumers. One may think the simple answer to such questions lie in the target's deeds—after all, "Actions speak louder than words". In fact, a long tradition in moral psychology has asked what it is that makes an action praiseworthy or blameworthy (e.g., Kohlberg, 1969; Gilligan, 1982; Greene, 2009).

Previous research in social and moral psychology has noted one obvious caveat: People should not get credit for doing the "right thing" for the "wrong reason" (Malle, 2004). Consumers are known to be suspicious of the ulterior motives of others (Fein, 1997). For example, after reflecting on businessmen-philanthropists identified by *Slate* as among the most altruistic people in America, participants became increasingly cynical about the philanthropists' motives (Critcher & Dunning, 2011). In total, work in this tradition suggests that consumers are quick to decide that good actions do not merit praise.

Instead, we propose that this approach to moral judgment is fundamentally flawed. In assessing others' moral character, it is not the case that people give others credit for good actions as long as they cannot be explained away by ulterior motives. In fact, we contend that it may not even make sense to talk about certain actions as good or bad at all. Instead, consumers try to make sense of what moral sentiments others experience and judge them positively to the extent that they act consistently with them. As a concrete example, when people praise a consumer for returning an item that was accidentally shoplifted, people do not praise the consumer for the action, but for acting in accordance with a moral sentiment (here, an assumed tinge of guilt the consumer likely experienced when seeing the unpaid-for item). Without the sentiment, praise is not offered.

In the way that moral judgment has typically been studied, these two possibilities—praising others' for good actions versus for acting on moral sentiment—have not been distinguishable, in large part because of the decontextualized scenarios in which moral judgment effects are examined. This is particularly troubling for consumer behavior researchers who draw on moral psychology perspectives and theory in motivating our research. In this talk, we offer four studies that distinguish between these competing possibilities and find consistent support for our perspective (praise for acting on sentiments) instead of the typical perspective (praise for doing good)

or a motives perspective (praise for having good intentions). Our studies show the importance of perceived moral sentiments not as praiseworthy or blameworthy cues in themselves (as motives are), but as part of a sentiment—action chain on which moral evaluation is actually based.

In Studies 1a-1c, participants considered (different) moral dilemmas: the Nazi-baby dilemma, a moral quandary in which a Jewish townsperson must decide whether to smother a crying child to death so Nazi soldiers will not find Jewish villagers' hiding spot'; the sick Johnny scenario (Tetlock et al., 2000) in which a hospital director must decide whether to use hospital funds to save the life of a sick seven-year-old or instead update hospital infrastructure; and a novel moral dilemma in which an American military commander must decide whether or not to order a strike on a rural Ukrainian inn where high-level Al Qaeda terrorists as well as innocent civilians are staying. First, participants indicated to what extent the decision-maker was likely experiencing each of two competing moral sentiments (e.g., "finds it morally wrong to let the child die" vs. "realizes many more lives could be saved by diverting the funds elsewhere"). After then learning what the moral agent decided, participants judged his character. In all three studies, analogous meditational models showed that participants praised the moral agent to the extent he was assumed to appreciate the moral sentiment that would lead to the action. This provided initial support for the acting on sentiments perspective.

Our model makes the unique prediction that factors that change the likelihood that a decision-maker will appreciate one moral sentiment or another also change the praise that different actions will receive. Studies 2-4 used the earlier-described dilemmas but varied an action-unrelated feature that we assumed (and empirically confirmed) would change the moral sentiments a target would be assumed to appreciate: a neurological disorder the agent was said to have (Study 2); the time the agent had to make the decision (Study 3); and the arbitrary visual perspective of the agent (Study 4). In each case, these manipulations had the predicted effect: They changed the moral sentiments the target was assumed to appreciate, which changed the praise the agent received for each action. For example, in Study 3, participants assumed that if the Jewish townsperson was rushed, he would have an immediate impulse to not kill a child but would not fully appreciate the utilitarian justification for the opposite course of action. Only in this case did people praise the townsperson for not smothering the child. In Study 4, even though participants knew that the military commander was aware of who all was in the hotel, participants assumed his moral sentiments would shift depending on whether he happened to see an al Qaeda operative or an innocent civilian through a window. Thus, even though the decision-maker confronted the same moral dilemma, he was praised for ordering the strike when he could actually see the terrorist, but was praised for instead not ordering the strike when he could actually see the innocent civilian.

Behavioral researchers from consumer, social, and cognitive psychology have spent considerable effort asking what makes behavior morally (im)permissible. The present research suggests that such an approach may be misguided. We instead show the real question to be what moral sentiments people assume others will appreciate. By understanding how (frequently arbitrary) features of a decision-making context shift what sentiments are assumed to be salient to moral decision-makers, we can then predict when and why actions receive moral praise.

Expanding the Theoretical Understandings of the Place of Consumption in Market Formation and Transformation

SESSION OVERVIEW

The goal of this proposed session is to examine how markets are formed and transformed, and the ways in which markets constitute – and are constituted by – transformations in their environments. Embedded within dynamic social, cultural, legal, and historical environments (Giesler 2008; Ger and Karababa 2011), markets are constituted by – and constitutive of - internal and external actors, who have different roles in facilitating/hindering formation, legitimation (Humphreys 2010b), signification/valuation (Peñaloza and Mish 2011) and evolution (Giesler 2008) of the market. This session builds up on, and would like to push forward, an important stream of research on *market*s, and offers new perspectives by discussing multiple facets and transformative potentials of marketplace activities. Markets are conceptualized by the authors as actors attempting to create social change; mythmakers transforming contaminated space; signifying and value-creating enterprises; or consuming entities. What is common to these arguments is the potential of markets to transform norms, ideals, legislations, and socio-cultural dynamics. These discussions contribute to a further understanding of how market actors mobilize resources and discourses, engage in strategic alliances, create different types of values, and also shape academic discourse; in attempting to transforming and legitimating both themselves and their environments. We believe this session also provides valuable discussions for other research initiatives on the relationship(s) between consumers and markets.

The papers in this session extend, but also question and contest previous arguments on market creation, evolution and transformation; providing a diversity of perspectives on these important topics. The first two papers are perspectives on transformations of illicit/contaminated markets, with Kuruoglu's paper exploring market creation and transformation in a restricted environment and questions whether legitimation is sufficient in explaining the processes of formation and transformation. Veresiu on the other hand draws upon assemblage theory to theorize the transformation of a previously "contaminated" space into a thriving market via mythmaking. Venkatesh et al. contribute with a conceptual piece which argues that transformation can be understood through the conceptualization of value co-production. Giesler, on the other hand, challenges existing conceptualizations of markets, arguing that markets are consumers, and that strategical "mythmakers" not only effectively reshape so-

cial realities, but also influence the way researchers conceptualize markets. For all four studies in our session, data collection (when relevant), and analyses are complete. The last 15 minutes of the session will be devoted to discussions guided by Güliz Ger.

The Creation and Transformation of an Illegal Market: Kurdish Music in Turkey

EXTENDED ABSTRACT

Market creation has been described as a process of legitimation wherein social networks, financial resources, territorial structures, and legitimating discourses are mobilized by multiple actors (Humphreys 2010a), including "firms, consumers, policymakers, and financial stakeholders" (Peñaloza and Mish 2011: 26). The social and cultural structure within which these actors are embedded shapes the processes through which a market is created, but in turn, this larger structure is also prone to change through strategic actions of "coalitions of actors" that propote or oppose its legitimation (Humphreys 2010a: 14; cf. Ger and Karababa 2011; Peñaloza and Gilly 1999).

Marketplace interactions have been the context for the negotiation of illegal, immoral, stigmatized, or transgressive practices (Ger and Karababa 2011; Giesler 2008; Goulding et al 2009; Humphreys 2010 a,b). Competing ideologies frame these practices in different lights (Giesler 2008) – drinking coffee at the Ottoman coffeehouse, for instance, was deemed an immoral practice by orthodox Sunni Islam, whereas the heterodox Sufi sect, saw coffee as carrying health and moral benefits. Coffeehouse owners and the public were complicit in tactical resistance, and collaborated in effecting changes in legislations (Ger and Karababa 2011). Humphreys (2010a, b) also shows how different actors – including the state - come together in bringing about change in public opinions as well as legislations with regards to gambling at casinos in the USA. This paper seeks to extend previous research on the creation of a market that is initially illegitimate; and focuses on the marketplace performances of multiple actors in striving to attain legitimacy and effect social change, through practices with regards to both use and exchange (Venkatesh and Peñaloza 2006).

The legitimacy of the market for Kurdish music has been rendered problematic (and to this day remains so) in connection to a longstanding history of ethnic tension and armed conflict, particularly between the Turkish state and the Kurdish terrorist organization PKK (Marcus 2007), as well as prohibitive state policies and practices of social exclusion. Broadcasting and publishing in Kurdish were prohibited by constitution in Turkey until 1991; owning and playing music recordings in Kurdish language at the time could lead to several years of imprisonment. An amendment in 1991 legalized Kurdish music production, but an informal market for music had long existed. Cassettes were smuggled across borders, and home-made recordings of the live performances were exchanged among social networks, and transported to other cities. This circulation of cassettes formed an informal marketplace, and was instrumental in the creation of an imagined community (Anderson 1983) characterized by Kurdish ethnicity. The experience of listening to the music was heightened by a fear of getting caught as well as the aura of enacting a resistive performance of ethnicity.

Post-1991, many companies started producing music albums in Kurdish, but strict state-imposed surveillance and censorship pre-

vailed in the market throughout the 1990s. The firms and other actors, including artists, politicians, publishing houses and broadcasters engaged both legitimating discourses, and also other resistive and discursive acts in trying to attain a less restricted environment for Kurdish music production – framing the music as cultural heritage or as a part of Turkey's ethnic and cultural multiplicity; engaging in activities such as selling cassettes off the records, educating and engaging audience to join the Kurdish movement, drawing international attention to the legal restrictions, and joining illegal organizations (including the PKK). The 2000s have been characterized by a somewhat more relaxed atmosphere, with local and multinational companies producing many albums each year, but the legitimacy of the market for Kurdish music is still ambiguous, with celebratory accounts of music and performances coexisting with discriminatory practices such as lack of shelf space or opportunities for advertisement in mass media. Thus, despite having undergone a transformation from illegal and informal to a legal, institutionalized marketplace, with sophisticated production and distribution channels, the Kurdish music market has attained legitimacy only in the regulatory sense, but not in the normative or cultural-cognitive sense (Suchman 1995), when examined in the whole of Turkey.

This analysis is based on an ethnography of the market for Kurdish music in Turkey. Data that I gathered from interviews with producers, artists, cultural producers in other fields, and audience; participant observation at relevant events; as well as a survey of newspaper articles and other secondary texts have contributed to the emergent account I present here.

Myth Market Collaboration: Transforming a Culturally Contaminated Area into a Thriving Tourism Market

EXTENDED ABSTRACT

How can culturally contaminated areas be transformed into successful tourism markets? A dominant research stream unpacking the relationship between market creation and culture is the literature on myth markets. This research commonly conceptualizes the formation of myth markets – the markets for goods, services, or experiences created from culturally resonant, and thus consumer identity-enhancing stories – as a process of ideological and cultural competition and conflict among multiple stakeholders (e.g., Arsel and Thompson 2011; Giesler 2008; Holt 2004; Luedicke, Thompson, and Giesler 2010; Peñaloza 2001; Thompson 2004; Thompson and Tian 2008). Consequently, little theoretical attention has been devoted to the strategic alliances and symbiotic relationships that can form among stakeholders to shape a myth market's cultural meanings and consumer identity value.

This paper examines the collaborative mythmaking practices involved in transforming a culturally contaminated area into a thriving tourism myth market. Drawing on assemblage theory in sociology (De Landa 2006), I describe myth markets as assemblages of actors and develop a process model of myth market collaboration. According to De Landa (2006, 4), "[a]ssemblages are wholes whose properties emerge from the interaction between parts." In particular, De Landa (2006) characterizes assemblages along three dimensions: (1) defining the roles that an assemblage's parts may play, (2) defining the processes in which these parts become involved and, (3) defining processes in which specialized expressive media (genetic or linguistic) intervene to provide the assemblage with more flexibility or rigidity. Building on these characteristics, I theorize that an assemblage of actors (e.g., business owners, governments, the media, celebrities, consumers, etc.) can strategically coordinate their myth-

making activities to confine the negative cultural meanings associated with an area and establish their desired definitions of a market.

To illustrate myth market collaboration, I conducted a two-year ethnographic and netnographic (Kozinets 2002) investigation of the ongoing transformation project of a place popularly dubbed "Hitler's Hill" in the German Alps (Obersalzberg, Bavaria) that was historically associated with the Nazi Party. Since 2001, several actors including the Bavarian and German governments, the InterContinental hotel, the national media, historians, intellectuals, and celebrities, as well as local museums, restaurants, ski resorts, tourist promoters, and residents, have joined forces to establish a successful tourism market. I conducted up to three interviews with five international tourists, four InterContinental hotel staff, six local business owners, and three government officials, where we discussed topics ranging from the area's origins, to Hitler's domination, to current tourism business opportunities, challenges, and future directions. I analyzed the complete data-set, which includes 34 in-depth, semi-structured interviews ranging from 20 minutes to two hours in length, as well as 160 pages of online materials and historical data, using the established hermeneutical analysis mode of tacking back and forth between data and theory (Thompson 1997).

My findings reveal the decontamination strategies actors use to displace the negative cultural meanings associated with an area and to remythologize it as an idyllic touristic landscape. The collaborative mythmaking practices focus on creating and maintaining a clear distinction between the area's violent past and peaceful present. This idea is aptly summarized by German historian Volker Dahm (2005), who argues, "the best way to demystify places associated with the Nazis is to allow normal life to go on there." Thus, similar to assemblage theory, I find that each involved actor has specifically assigned roles and processes that stabilize the contemporary tourism myth market. As a few examples, two new touristic destinations (the InterContinental Hotel and the Documentation Centre) have been established on the very site where Hitler and his generals had their homes in order to create a strategic duality. The five-star hotel's role is to represent the relaxing and luxurious Alpine touristic experience, while the area's main museum is responsible for containing the only reminders of the past. Even the "Eagle's Nest," Hitler's 50th birthday present by the Nazi Party, has been transformed into a restaurant highlighting local cuisine. The Bavarian government, which owns the majority of the land, has the watchdog role to ensure that all tourism business initiatives follow the overarching mythic storyline of classy Alpine retreat with the past of an innocent mountain village.

Overall, these findings advance the growing research on myth markets, and the nascent literature on market system dynamics – the social processes involved in market creation and evolution (Giesler 2008; Humphreys 2010; Karababa and Ger 2011). Myth market collaboration can better help us understand the co-creative role of multiple evolving interests in shaping and transforming the cultural meanings and myths associated with tourism markets.

Beyond the Social System: Understanding Markets as Consumers

EXTENDED ABSTRACT

The worldwide soft drinks market consumes more than 1.4 trillion liters of fresh water to produce 392 billion liters of soft drinks per year (Chamberlain 2008). A rapidly growing global seafood market has led to an overexploitation of 25% of world fisheries to the point where their current biomass is less than the level that maximizes their sustainable yield (Grafton et al 2007). Each year, the global tourism market consumes nearly as much energy as Japan, produces the same amount

of solid waste as France, and consumes as much fresh water as is contained in Lake Superior (Krantz 2007).

Markets - not countries - are now the largest consumers of the world's energy, resources, and life. And yet surprisingly little theoretical attention has been devoted to understanding markets *as* consumers. Perhaps this oversight stems from the ways in which markets have been previously theorized. From within the marketing discipline, consumer researchers have referred to markets as "institutionalized arenas of conflict and compromise" (Giesler 2008), "performative stages" (Deighton 1992), or "concrete exchange structures" (Humphreys 2010).

The goal of this paper is to offer a theorization that conceptualizes markets as consumers. I argue that markets are successful to the extent to which they can mask their identity as consumers and instead position themselves at the center for the production of consensus, freedom, empowerment, creativity, and community.

In the first part of the analysis, I explore the relationship between consumer culture theory and a certain branch of economic thought referred to as neoliberalism to better understand the existing perspective on markets and consumers. I offer three methodological neoliberalisms that have prevented consumer researchers from approaching markets as consumers. First is the tendency to uncritically adopt rather than interrogate the traditional economic distinction between "consumer" and "market." Second is the tendency to understand markets as structural stage or spaces on/in which agents productively interact rather than as macro-actors who have the potential to reshape interests and identities. And third is the tendency to view the distribution of resources, their meanings (e.g., music, gambling, coffee), and their production and consumption as if they were naturally situated within the borders of individual market systems.

After that, I analyze the rhetorical masking practices involved in expanding what has been referred to as the "global market system" (Schiller 2000). To understand this market system, I conducted a multi-year ethnographic investigation of the World Economic Forum (WEF) in Davos, Switzerland. The WEF was founded in 1971 and includes the most prominent transnational corporations.

I conducted in-depth interviews with 14 WEF delegates to document how they tailored global, national, and regional, territories, resources, social and political problems, and the needs and wants of individuals in relation to their competitive and ideological consumption needs and to combat criticisms rendering the global market as an inequitable, volatile, ecologically wasteful, and all-consuming villain (George 2010; Klein 2009; Chomsky 2011; Vertovec 2009; Sassen 1998). To track changes in their evolving global market representations, each informant was interviewed up to four times between 2004 and 201. To analyze the data, I used an iterative, part-to-whole process of hermeneutic analysis (Thompson 1997; Giesler 2008). To contextualize the interview data, I also collected WEF communiqués and annual competitive reports published between 1987 and 2010, as well as other cultural materials available through mass media channels and on the Internet.

This research makes two contributions. First, it contributes to prior studies on market system dynamics (Humphreys 2010; Giesler 2008). This stream of research has studied how concrete exchange structures between producers and consumers are established and evolve. My analysis complements and extends this body of research by theoretically explicating the agency markets mobilize to reshape social realities and subjectivities in relation to their ideological and competitive goals as well as the resistance against this marketization process.

Second, I demonstrate how the import of rhetorical conventions from marketing and economics, while lending legitimacy to earlier

CCT generations, also brought in a number of neoliberal biases. These manifest in the tendency to either concentrate on an autonomous, entrepreneurial consumer-subject or the creation of a marketplace structure instead of asking how the latter reshaped the former so that the former can sustain the latter. In doing so, some of the worst volatilities, contradictions, and excesses of contemporary market consumption are erased from the analytical radar. Theorizing markets as consumers - how they systematically tailor societies, territories, resources, and living beings in relation to their economic and ideological agendas - may help address some of these theoretical blind spots.

Consumer Markets and Value Transformation in the Global Context

EXTENDED ABSTRACT

Recently, there has been a growing interest among consumer and marketing researchers in examining the study of "markets" as our disciplinary focus especially in the current global context (Humphreys 2010, Venkatesh and Peñaloza 2006, Domegan et. al Forthcoming). As noted by Sandıkcı and Rice (2011), one main shortcoming of contemporary consumer/marketing theories is that they are very US centric and are applied to various contexts without examining differing cultural conditions. In this study, we propose to study more broadly *markets as value creating enterprises* and examine their transformational characteristics in terms of their value creation potential.

Our focus in this proposal is on the constitution of particular subject positions within "consumer markets" as the social and economic institutional arrangements within which value is created by and for various constituencies which include customers, stakeholders and other agents/participants, and the society at large. In the global context where markets transcend national boundaries, truly global markets extend beyond such boundaries (Ger 1999) and give us an opportunity as researchers to examine and develop a value system appropriate for such a study.

As noted by Peñaloza and Mish (2011), the concept of value in consumer marketing has been viewed in terms of the material, instrumental and psychological benefits (e.g. satisfaction) derived by the customer through engagement with the product or service.

Typically, the field of consumer marketing has focused primarily on Exchange Value and Use Value as its primary focus. We broaden this binary conceptualization of value framework in working through four distinct types of value: Exchange Value, Use Value, Sign/Cultural Value and Societal Value. It is the integration of different value systems that presages global transformational possibilities.

Exchange Value

One fundamental notion of value discussed in our discipline is that there is a value producer and intended value recipient – the former creates value (i.e. confers value on an object or engages in an action that embodies value) and the recipient is the beneficiary (Bagozzi 1975). If the value recipient performs something in return, this is an example of exchange value.

Use Value

The concept of use value stems from the notion that the offering that has been produced through exchange is *useful* (and usable) and is therefore put to use by the customer (Holbrook 1999). Use value refers to the direct usefulness of an object or service. It can also be called the functional value and is inextricably tied to the tangible or intangible property of the offering. A use-value can be both subjec-

tive and objective. A major focus of the field of consumer research may be said to concentrate on use value.

Sign/Cultural Value

Broadly speaking, the concept of sign refers to the symbolism and meanings within the significatory system in which the product is embedded (Levy 1981). The meanings attributed to physical objects, or broadly, company offerings, are well documented in cultural and anthropological studies (Lash and Urry 1994). For example, Ger (1999) provided symbolic notions of glocalization (1999) in marketing practices, Holt (2004) detailed the incorporation of social trends and group language by firms in advertisements for "iconic" brands. Scott (2004) elaborated the intricate interrelations between cultural and economic development in tracing feminist consumption sensibilities to the changing place of women in the workforce. Venkatesh (1995) proposed the notion of ethnoconsumerism as incorporating sign systems in the global/cultural contexts. The implications of this for sign value are that in the global economy, signs are created, transferred, controlled, expressed and consumed in relation to other sets of signs that encompass consumers' identities in ways that negotiate their interests and relations with other constituencies.

Societal Value

Here the simple question is, when does the market system through its product offerings and activities benefit a society and when does it compromise the latter? Of interest here are the pragmatic and societal questions that have become very central in the contemporary environmentally conscious world.

In looking at the market as a value-based economy, the above framework t integrates the four systems of value: exchange value, use value, sign value and societal value into the market system.

Summary and Conclusions

The goal of this proposed session is to examine the transformational potential of markets and market formations. In this study, we have proposed a framework that examines consumer markets as value creating enterprises in a dynamic global context. Our framework integrates four systems of values in markets – exchange value, use value, sign/cultural value and societal value, with implications for consumption practices and theories.

SESSION OVERVIEW

Accurately predicting how and when consumers, peers, colleagues, and citizens will react to content (advertisements, gifts), share items (e.g. word of mouth), feel in situations (e.g. thirst, physical pain), and make decisions (e.g. investments, purchases) is a fundamental requirement for some of the most important consumer, social, and policy decisions. The research presented in these four papers demonstrates that often a person's state (e.g. experiences, construal) can threaten the accuracy of the social cognitions necessary for these important decisions.

In this special session we identify factors that influence when people are likely and unlikely to use their own perspectives and metacognitions to inform their predictions of others' preferences and reactions. Importantly, we also identify when reliance on these perspectives and metacognitions will facilitate accurate predictions and when the same reliance will lead to costly mispredictions. In addition to these theoretical contributions on choices and predictions for others, metacognition, and psychological distance, the session makes substantial contributions to the topics of word of mouth, gift giving, and investing, and demonstrates how a few popular lay beliefs (e.g. indulgent items are better gifts and more experience leads to wiser predictions) can lead consumers astray. In summary, each paper tells a piece of a larger narrative about how and when consumers (inaccurately) rely on their own perspectives and feelings when making predictions for similar and dissimilar others.

In the first paper, Baskin and colleagues examine a construal level (Trope & Liberman, 2010) mismatch between gift givers and gift receivers. The authors find that givers tend to conceptualize their gift choices abstractly due to their high distance from the consumption experience. Therefore, givers choose gifts higher on desirability attributes to the detriment of gifts higher on feasibility attributes. Gift recipients, in contrast, conceptualize received gifts more con-

cretely, and care more about feasibility aspects (how easy a game is to learn versus the quality of the game). This difference leads gift givers to mispredict how much a receiver will enjoy certain gifts and to mistakenly overpay for desirable items. Further, gift givers mistakenly expect giving an item high on desirability will increase social bonds with the receiver and will result in more social reciprocity. The findings of this paper contradict the popular lay belief that the best gift for someone is an indulgent, highly desirable gift. Instead the results suggest that givers may save a lot of money and trouble by putting themselves in the shoes of the receivers and that marketers who are motivated to encourage successful gift giving should try to bring gift givers down to a lower construal level.

One potential way to improve predictions of others' reactions to content is to acquire concrete experience with the content or to ask someone who has had a lot of concrete experience. However in the second paper, Campbell and colleagues find people can quickly gain too much experience. Individuals can rapidly become desensitized (Dijksterhuis & Smith, 2002) to content after repeated or extended exposure such that their current tastes and sensitivities to emotive content become vastly different from people who have not been as thoroughly exposed to the content. Importantly, the authors find that people are largely unaware of the effect that repeated exposure has had on their personal emotive reactions, even when prompted to consider the influence. Accordingly, they overweight their own current dulled sensitivities in their predictions for others' emotive reactions and preferences (e.g. for comedy, art, sports photography, painful noises). This leads consumers to mispredict others' reactions and at times to choose to share bad content that others will not enjoy. Finally, the authors find that when consumers are searching for quality emotive experiences, they tend to seek out a person who has had more versus less repeated experience. The authors experimentally demonstrate how this behavior can doom consumers to receive inappropriate recommendations and ultimately can lead consumers to have worse experiences.

Similarly to Campbell et al., Steffel and Shafir investigate how people use their own feelings to infer others' preferences. Specifically, the researchers examine how the metacognitive feeling of choice difficulty impacts estimated consensus. They find that participants' estimates of the proportion of other people who shared their preferences in a series of choices were correlated with their subjective ratings of choice difficulty. Further, they find in an initial study that subjective difficulty was a valid cue of actual consensus. However, even though choice difficulty can serve as a valid cue for consensus, the authors found that when choice difficulty is manipulated in a manner that does not actually influence consensus (e.g. font readability), reliance on choice difficulty can lead to systematic mispredictions of consensus. Similarly to Campbell et al. focus on repeated experience, Steffel and Shafir find that the common experience of repeated exposure to a choice can reduce the metacognitive feeling of difficulty and lead to increased predictions of consensus. In a final study, the authors identify a boundary condition to this phenomenon such that when one is dissimilar to the target population, one does not use subjective difficulty to judge consensus in the target population.

In the first three studies, the authors examined how people's experiences and perspectives influenced their judgments. In the last paper, similarly to the final study in Steffel et al., O'Brien and col-

leagues examine when people are likely to rely on their own state, particularly their metacognitive feelings, when making predictions for others. A wealth of research suggests that people use their own visceral states to inform their social judgments, such as predicting others are thirstier when oneself is dehydrated (Van Boven & Loewenstein, 2003). The authors find that these typical egocentric influences on social predictions (replicated in the prior papers in this session) are at times undermined by incidental knowledge of the target. Cold and thirsty participants judged others as more sensitive to cold and thirst, but only when those in question shared their ideological values (e.g. same stance on same sex marriage). This suggests that internal cues in general may simply be less (or not) influential when predicting the responses of dissimilar others. For instance, while at a hot baseball game one might not use their own feeling of thirst to determine whether a dissimilar other would enjoy a cold drink. In general, this is one of the first studies to find identify a boundary in embodied cognition.

Across four papers and 17 studies, this session investigates when people are likely to rely on their own states to predict others' preferences, and when reliance on their own states is likely to benefit or bias their predictions of others' preferences. Data has been collected for all reported studies and all papers are very advanced or complete. This session relates to the theme of "appreciating" diversity as it tells a narrative of consumer interaction interwoven between theoretical perspectives. The session should appeal to a wide audience including those with theoretical interests in choosing for others, metacognition, embodied cognition, perspective taking, psychological distance, outgroup perception, and social cognition in general. Additionally, the session will appeal to those with substantive interests in word of mouth, gift giving, and investment. This session also directly relates to the theme of "appreciating diversity" as all four papers deal with how people predict others' responses, and the latter three papers specifically examine how people predict the reactions of others who have explicitly different beliefs or have had explicitly different experiences. Why a Frying Pan is Better than Flowers: A Construal Level Approach to Gift Exchange

EXTENDED ABSTRACT

The tradition of gift giving is as old as culture itself. From the circular gift exchange formed by the Trobriand islanders (Malinowski, 1922) to today's frenzied holiday shopping, gift-giving rituals have played a central cultural role. Indeed, evolutionary psychologists have suggested that gifts are a natural way to establish, create and maintain order in a group of social beings (Cosmides & Tooby, 1992). Additionally, anthropologists have focused on the role of gift exchange in building and maintaining social bonds (Gouldner, 1960; Mauss, 1925). Thus, due to the importance of gifts, givers have a large stake in making sure their gifts are well received and then reciprocated in order to ensure the continuity of their social relationships.

The importance of gift-giving raises the question of how one decides on the perfect gift. In this research, we look at differences in giver/receiver gift evaluation using construal level theory (CLT) as a framework (Trope & Liberman, 2010). We propose that givers conceptualize their choices abstractly due to their high distance from the receiver and the eventual use of the gift. Therefore, they choose gifts higher on desirability attributes to the detriment of attributes higher on feasibility dimensions. Gift recipients, in contrast, conceptualize received gifts more concretely, and care more about feasibility aspects (e.g., how easy is the gift to use?). This difference in construal between givers and receivers creates an important asymmetry between what givers care about and what recipients care about that leads to a mismatch in the kinds of gifts the two parties prefer to give/receive and reciprocate. Our findings also stand in contrast to the typical folk wisdom that givers should always seek to maximize gifts' desirability.

We explored this asymmetry in a series of studies. In Study 1a, we asked participants to assume a gift giving or receiving mode by respectively writing about a time they gave or received a gift. Those in giving mode scored higher on the Behavioral Identification Form (Vallacher & Wegner, 1989), a measure of abstract orientation. This study establishes that a giving mode activates a more abstract orientation than a receiving mode. Study 1b corroborates the link to construal by showing that gift givers can be induced to give more feasible gifts by giving gifts to people in nearby locations while receivers show no effect based on distance from givers. This suggests that givers are imagining the receiver using the gift such that the psychological distance from the consumption experience decreases with the spatial distance. However, receivers imagine their own consumption, so they are unaffected by these changes in spatial distance.

Studies 2a and 2b examined tradeoffs people make when giving gifts. By using items that require tradeoffs between abstract/desirability and concrete/feasibility dimensions (e.g., a high resolution 3D videogame that takes 10 hours to learn vs. a poor looking videogame that one can pick up and play), we show that givers evaluated high desirability gifts as better than high feasibility gifts. However, receivers do not exhibit this preference. We assigned participants to either the giver or the receiver role and asked them to evaluate gifts in a variety of domains (e.g. restaurant gift certificates, newspaper subscriptions, etc.). Participants evaluated gifts using a scale consisting of the following questions: "How much did you like the item as a gift?", "How good is this gift?", "How appropriate is this gift?" and "How positive is this gift?" Study 2b extended these finding by eliciting participants' willingness to pay (WTP). Givers reported their WTP for the gift while receivers reported their WTP as if they were buying the item for themselves. While receivers were willing to pay significantly more for desirable gifts than feasible gifts, givers had a significantly higher WTP difference than receivers between high desirability and high feasibility gifts. From this study, we show that there is a mismatch in willingness to pay for desirable goods in that givers are willing to pay a comparatively higher price than receivers for highly desirable gifts. The results of Studies 2a and 2b combined show that givers place more value on desirability attributes over and above that placed by receivers, and literally pay for this error.

Study 3 examined implications of these differences for social bonds between exchange partners. Participants were told about two different movie offers, one of which was more desirable, but relatively inconvenient (access to view *Harry Potter and the Deathly Hallows (HP7): Part 2* online during an inconvenient five-hour window) and the other less desirable, but more convenient (access to view the less novel and widely available *HP7: Part 1* online during a convenient 30-day window). Participants believed they were either giving a gift to, or had received a gift from, another participant in the study. As predicted, givers preferred to give other participants in the study the more desirable/less convenient *HP7: Part 2*, but receivers preferred to receive the less desirable/more convenient *HP7: Part 1*. More importantly, givers thought that if they picked *HP7: Part 2*, receivers would be more likely to reciprocate their gift in the future. Receivers, on the other hand, were willing to reciprocate both gifts equally suggesting that their opinions of the giver were not affected

by the choice of gift. Instead, givers are mistaken in their prediction that desirable gifts will increase social bonds.

Since gift giving is primarily about relationships, we are conducting future research to examine how various gifts change the relationship between gift givers and gift receivers and how people's awareness of biases in selecting gifts may improve their relationship with the other person. Overall, the results of this current research suggest that givers may save a lot of trouble and at times money by putting themselves in the shoes of the receivers and think about the kind of gift they would prefer to receive. The findings further suggest that the conventional wisdom of always maximizing gift desirability, rather than other gift features, may be incorrect since givers generally underweight concrete/feasibility aspects of the gift as compared to receivers.

Too Much Experience:
Predicting Others' Emotive Reactions and Making Recommendations after Repeated Exposure

EXTENDED ABSTRACT

People often seek out individuals who are distinguished by their repeated experience with emotive content (e.g. art, comedy, freeway noise). Consumers seek out these individuals for recommendations, corporations hire these individuals to design products for the public, and governments employ these individuals to craft policy for the public. Additionally, when trying to predict others' reactions to emotive content, people often make an effort to become a well exposed person. For instance, a person may deliberately watch a YouTube video multiple times to decide whether it is funny or appropriate enough for sharing. Both lay intuition and empirical research suggest this gaining experience can help people predict others' emotive reactions by closing empathy gaps (Nordgren, McDonnell, & Loewenstein, 2011).

However, individuals can quickly gain too much experience and become desensitized to content after repeated or extended experiences (Dijksterhuis & Smith, 2002). Although much research has examined how desensitization affects judgments of one's own tastes and preferences (e.g., Loewenstein, O'Donoghue, & Rabin, 2003; Wilson & Gilbert, 2003), we examined downstream consequences for prediction of others' judgments.

We hypothesized that people will not only desensitize to an emotive experience after repeated exposure, but also incorrectly use their desensitized sensitivities to make predictions of how someone else would react to an emotive experience. Our framework is rooted in the dual judgment model of emotional perspective taking (Van Boven & Loewenstein, 2005). This model posits people predict others' emotions by first considering their own (simulated) emotions and often fail to adequately adjust for differences between self and other. Thus, rather than realizing that one's own current state (e.g., subjective desensitization) may be different from someone else who lacks a high level of exposure, people who desensitize to an emotive experience might falsely assume that the experience is less arousing for others. This should lead them to mispredict others' preferences and emotive reactions and lead them to error when they recommend and share content with others. We tested this desensitization bias in social judgment hypothesis across six studies using various emotive content ranging in valence, complexity, and repeated exposure method.

In the first study, we exposed participants to twenty images of a dramatic style of astrological art called "Digital Blasphemy." After the exposures, we asked participants to remember from a written description the first and last images they had seen and to indicate which image would be better for publically consumed Space Art media. We counterbalanced the first and last picture between subjects, and found that participants showed a bias to select the image that was presented at the start of the exposure (before they became desensitized) rather than the image at the end.

In study 2, after viewing a slideshow of motorcycle tricks, we presented participants with two images, each featuring a different thrilling stunt performed on a motorcycle. Participants were asked to select which image would be more impressive as a single promotional image to people viewing motorcycle stunts for the first time in their lives. We found that participants were more likely to choose the image of a specific stunt type if that stunt type had been featured *less often* in a slideshow that preceded the choice.

In study 3, people were repeatedly exposed to one of two shocking pictures of Lady Gaga.

We found participants were more likely to predict others previously unexposed to both images would be less shocked by the image participants themselves were repeatedly exposed to compare to the image participants were not repeatedly exposed to.

Additionally, a variety of indirect and direct probes in studies 2 and 3 found that participants were largely unaware of the desensitization bias and unable to retrospectively correct for the bias. In sum, the breadth of the first three studies distinguishes the desensitization bias as a unique phenomenon separate from related phenomena such as primacy effects (Carpenter & Nakamoto, 1989) and peak-end biases (Kahneman et. al, 1993).

In studies 4 and 5, we tested the underlying process and potential downstream consequences. In study 4, we found that repeated exposure to a joke (writing it five versus one time) lead participants to find the joke personally less humorous, predict the joke would be less humorous to others, and report lower likelihood to share the joke. As predicted, we found the effect of repeated exposure on one's own feelings fully mediated the effect of repeated exposure on predictions of others' feelings and likelihood to share. In study 5, we found that after extended versus shorter exposure to a painful noise, participants predicted an additional very short sound burst would be less painful for themselves, predicted it would be less painful for others never exposed to the sound, and reported they would feel less guilty using the sound burst to punish other participants in a game. Similar to study 4, the effect of exposure on the latter two other-regarding variables was fully mediated by predictions of how painful a short noise burst would be for oneself.

In the final study, we tested whether this desensitization-bias could lead high-exposure consumers to make very poor recommendations for unexposed others. Participants were given an objectively better joke and an objectively worse joke (based on pre-test ratings). We found that participants who were repeatedly exposed to the good joke (writing it down five times) were about 3x less likely to choose to share it with someone else compared to participants who were not repeatedly exposed (presumably because the extra exposure desensitized them to its funniness). Moreover, we described the study to a separate group of participants and asked them who they would rely on to choose them the funnier joke: a person in the control condition or a person in the repeated exposure condition? A majority chose the person in the repeated exposure condition, thus dooming themselves to a worse experience.

These studies suggest that repeated exposure can dramatically and negatively influence sharing, recommendations, and social behavior. The lay intuition to seek out those with more exposure and to acquire more exposure to better predict others' reactions may often steer consumers in the wrong direction. At times, high-exposure "ex-

perts" might be in the *worst* position to connect with someone who lacks any exposure at all.

From Personal Choices to Perceived Popularity: The Impact of Choice Difficulty On Estimated Consensus

EXTENDED ABSTRACT

Effective decision-making often depends on accurately gauging others' preferences. Manufacturers try to forecast consumer preferences, politicians try to gauge public opinion, and most people try to anticipate how their peers will react to what they say and do. Incorrect predictions of others' preferences can lead to detrimental behaviors, like investing in a product that fails to generate interest, or campaigning on an issue that triggers unexpected reactions.

Although psychologists have well documented the impact of choices – conceived as binary outcomes – on predictions of others' preferences (e.g., Ross, Greene, and House 1977), relatively little is known about the impact of the metacognitive experiences that accompany those choices. This research explores how the feeling of choice difficulty impacts people's predictions of others' preferences and how it impacts judgmental accuracy.

We hypothesize that people perceive greater consensus when choice feels easy than when it feels difficult. In a pretest, participants' estimates of the proportion of other people who shared their preferences in a series of choices between monetary lotteries were correlated with their subjective ratings of choice difficulty, (b = -0.91, t = 8.88, p < .001). Further, in these initial situations, subjective choice difficulty served as a valid cue for predicting consensus, as it was highly correlated with consensus (β = -0.77, t = 4.91, p < .001). Thus, at least in some cases, the metacognitive feeling of choice difficulty can guide people to correct estimates of consensus.

However, there are many cases in which choice difficulty may be misleading. Many factors that are not indicative of actual consensus can influence subjective choice difficulty. For example, factors such as font readability, mere exposure, reason listing, and brow furrowing, can all increase perceptions of choice difficulty (Alter and Oppenheimer 2009). We show that, when choice difficulty is manipulated independently from the relative attractiveness of the choice alternatives, reliance on choice difficulty can lead to systematic mispredictions of consensus.

We first tested when holding actual consensus constant, would manipulating choice difficulty influence estimated consensus? Participants were presented with a hypothetical choice about whether or not to tip a waitress who provided fast service (easy condition) or slow service (difficult condition). Although participants were equally likely to tip the waitress across conditions, participants estimated greater consensus in the easy condition (M = 81%) than in the hard condition (M = 74%; t(156) = 2.84, p = .005). Choice difficulty fully mediated the relationship between the manipulation and estimated consensus, (95% CI = -7.85 to -2.62).

Study 2 sought to isolate the feeling of choice difficulty as the mechanism underlying consensus estimates by holding constant the content of the choice options and manipulating choice difficulty via fluency. In this study, a target lottery was presented either several times (fluent condition) or only once (disfluent condition; for a review of repetition as a form of fluency, see Alter and Oppenheimer, 2009). As predicted, estimated consensus was greater when the choice was repeated (M = 62%) than when the choice was novel (M = 53%; t(123) = 4.28, p < .001), regardless of which option was chosen. Choice difficulty served as a significant partial mediator of the relationship between the fluency manipulation and estimated consensus, (95% CI = -4.90 to -.83). Within the repeated condition, there

was a linear trend such that participants estimated greater consensus with increased repetition (first presentation: M = 59%; second presentation: M = 60%; third presentation: M = 62%; F(1, 67) = 5.44, p = .02). The difference in choice difficulty between the first and final presentation mediated this effect, (β = -4.17, SE = .54, t = -7.78, p < .001).

An additional aim of study 2 was to illustrate a consequence of relying on choice difficulty to predict consensus: since estimated consensus should increase with repetition regardless of which lottery is chosen, then false consensus (as measured by the sum of estimated consensus for the lottery chosen by the majority and the lottery chosen by the minority) is more likely to emerge when choices are repeated than when choices are novel. Indeed, false consensus was 125.3% when the choice was repeated and 105.2% when the choice was novel. Within the repeated condition, the sum of estimated consensus for the lottery chosen by the majority and the lottery chosen by the minority increased with repetition (first presentation: 117%; second presentation: 120%; third presentation: 125%).

Study 3 explored whether perceived similarity moderates the extent to which people rely on choice difficulty to gauge consensus by priming participants to think of ways in which they were similar to or different from the target population. Indeed, there was a significant interaction between the priming condition and choice difficulty, (b = -0.20, t = 2.35, p = .02), such that participants who were primed to think of similarities relied on choice difficulty to predict consensus (b = -0.39, t = 4.51, p < .001) but those primed to think of dissimilarities did not (b = -0.11, t = 1.18, p = .24).

People gauge consensus, not just based on their own choices, but also based on the metacognitive experiences that accompany choosing. People infer greater consensus when choice feels easy than when it feels difficult. Although subjective choice difficulty can sometimes serve as a valid indicator of consensus, many factors that are not indicative of consensus can affect choice difficulty and lead to systematic mispredictions. We will discuss implications for real-world decisions: for example, an investor who has had greater exposure to the stocks in his portfolio may expect greater buy-in from other investors than is borne out in the stock market, or a politician who repeatedly reevaluates his platform may expect more unified support from his constituents than is borne out in the actual election. We will also discuss moderators of reliance on choice difficulty – e.g., perceived dissimilarity to the target population and attributions for choice difficulty – and directions for future research.

When My Pain is (Not) Your Pain: Self, Similarity, and Embodied Cognition in Social Predictions

EXTENDED ABSTRACT

Predictions of others' thoughts, feelings, and preferences do not occur in a bubble. Rather, people predict the internal states of others differently depending on whether those in question are perceived as similar or dissimilar to them on the surface.

People typically judge similar others egocentrically – they put themselves in the others' shoes by first thinking, "How would *I* feel in their situation?" (Dunning & Hayes, 1996; Epley et al., 2004). Thus, one's own states are often projected onto similar others. Obama-supporting Democrats might overconfidently assume that Obama likes the same wine that they do.

However, people are less likely to use their own experience as an anchor when judging others who seem very different from them (Ames, 2004; Robbins & Krueger, 2005). In these cases, the self becomes a poor proxy to figure out very dissimilar people. Obama-

supporting Democrats might have little reason to assume Sarah Palin shares their wine preference.

In our experiments, we examined how far the effect of dissimilarity extends. We focused on the influence of one's visceral states on how people perceive similar versus dissimilar others' feelings and preferences.

Visceral states refer to strong transient states of arousal (e.g., hunger, threat). These feelings are typically so strong that they assimilate with perceptions of others who may not even be experiencing the same state. For example, when people are dehydrated they perceive others as thirsty (Van Boven & Loewenstein, 2003), and when people are frightened they perceive others as afraid (Van Boven, Loewenstein, & Dunning, 2005). Might the effect of even these powerful states dissipate when judging others who seem very different?

In Experiment 1, we explored this question by assigning participants to read a story about a hiker who gets lost with no food, no water, and no extra clothes (adapted from Van Boven & Loewenstein, 2003). Participants rated the hiker's feelings and their own feelings. To manipulate similarity, the hiker was described as either a left-wing, pro-gay rights Democrat or a right-wing, anti-gay rights Republican, who went hiking on a break from a political campaign (a strong dissimilarity manipulation: Mitchell, Macrae, & Banaji, 2006). At the end of the study, participants answered a forced-choice item about whether they were similar or dissimilar to the hiker, confirmed by their own political values. We used this forced-choice to group participants into "similar" or "dissimilar" conditions. To manipulate visceral experience, all participants were recruited during winter in Michigan (M_{temp}=6° Fahrenheit). We tested people who were indoors in the university library ("warm" condition) or outdoors at a nearby bus stop ("cold" condition).

Did being in the freezing cold influence social judgment? Yes – but only when judging similar others. When asked whether hunger, thirst, or cold was most unpleasant for the hiker, a significant interaction was obtained between similarity and location (β=-2.75, p=.005). Participants who perceived the hiker as similar were more likely to choose "cold" when they were outdoors (94%) than indoors (57%), replicating standard assimilation effects. However, judgments of dissimilar hikers were uninfluenced by location (55% outdoors, 63% indoors). The same interactions were obtained for whether the hiker most regretted not packing food, water, or *extra clothes* (β=-2.05, p<.01), and for how cold the hiker felt on a continuous scale (β=2.21, p<.001). These patterns were further reflected by regression-based mediation: participants' coldness mediated judgments of how cold similar others felt (β=−0.71, p=.004)—but not how cold dissimilar others felt (β =0.06, p=.86).

In Experiment 2, participants were induced to feel thirsty by eating salty snacks either with or without water. The same patterns from Experiment 1 were observed. When asked whether hunger, thirst, or cold was most unpleasant for the hiker, a significant interaction was obtained between similarity and thirst (β =-1.81, p<.02). Participants who perceived the hiker as similar were more likely to choose "thirsty" when they were thirsty (71%) versus quenched (20%); judgments of dissimilar hikers were uninfluenced by participants' own thirst (37% thirsty, 26% quenched). The same interactions were obtained for whether the hiker most regretted not packing food, extra clothes, or *water* (β=-1.88, p<.03), and for how thirsty the hiker felt on a continuous scale (β=1.72, p<.01). Again, participants' thirstiness mediated judgments of how thirsty similar others felt (β=0.54, p=.02) – but not how dissimilar others felt (β=0.04, p=.89).

Although physical feelings powerfully shape our predictions of others' thoughts, feelings, and preferences, these findings suggest that their influence is eliminated when judging dissimilar others. This observation may have far-reaching consequences. In other studies, for example, people who held a warm cup of coffee judged a target person as more socially "warm" (Williams & Bargh, 2008), and those who held a resume on a heavy clipboard thought it was more "weighty" and "important" (Ackerman, Nocera, & Bargh, 2010). These embodiment effects may be inhibited by dissimilar targets; liberal undergraduates holding a warm drink may not think Republicans are nicer.

More importantly, predicting how others feel is vital for everyday interactions between bosses and employees, relationship partners, and sellers and consumers. One way to more accurately understand others' situations is to find one's self in their shoes. For example, actually catching a sickness or feeling pain can help people better empathize with others' needs (Loewenstein, 2005). But the success of this strategy might be inhibited if one perceives others as different, even on a superficial level. For instance, while shopping for Christmas gifts on a cold New York City night, a woman may be inspired by her own cold feelings to purchase a winter jacket if she was shopping for a close cousin, but *not* if she were shopping for a distant mother in-law.

In sum: egocentric processes underlying how people make predictions of others' states are undermined by incidental knowledge about those in question. Such knowledge appears to prevent environmental stimuli (e.g. a hot coffee cup, the weather, hunger) from influencing social predictions, which at times may inhibit people's ability to make optimal predictions of others' needs and preferences.

Socio-Historical Change and Representations of Consumers in Ads

SESSION OVERVIEW

Session objective

To bring together diverse yet similar papers examining change in advertising depictions over time employing a cultural lens to address the relation between socio-cultural change and advertising representations of various social categories of consumers.

General orientation

The session's orientation is socio-cultural rather than psychological and covers broad temporal change in representations of social categories in advertising.

Likely audience

The likely audience is consumer researchers with an interest in advertising and its relation to larger society. It will also draw CCT scholars and consumer researchers with social science interests outside psychology, particularly those with interests in historical analysis, sociological interpretation, and anthropological approaches. It will attract those with an interest in social class, gender, and ethnicity. And, given the focus of the Stephens paper, we anticipate that it will attract many Canadians at the conference.

Issues and topics to be covered

Advertising, cultural change, historical analysis, gender, race, class, immigration, and inequality.

Importance of contribution to CB

On average, biology grants us the opportunity to understand a time span of 78.49 years (81.48 years for Canadians) through direct experience. Historical analysis expands our range of understanding beyond that granted by biology, and deepens our understanding beyond what can be directly experienced.

The conference mission of appreciating diversity in approaches

The topics covered that are often not covered in ACR presentations are gender as a social category, social inequality, relations between immigrants and host culture, international relations through advertising, and most importantly, a broad historical perspective. The presenters include several first time ACR presenters, including an award winning senior scholar from sociology. The presentations draw from the perspectives of three different generations of consumer researchers, each of whom approaches these time periods in a different way.

Stage of completion

All projects are fully complete.

Making the Changing Scene

EXTENDED ABSTRACT

The basic goal of the presentation is to observe and analyze how advertising expresses a society's values. The themes to be discussed are these: Society moves generally from mass consumption to making increasingly individual choices serving subgroup and personal choices. There is the large development that starts with the struggle to feed, clothe, and house masses of poor people. I term this *obligatory marketing*. This mass consumption is accompanied by relative scarcity, the central role of commodities, problems of distribution, an emphasis on economics, and pressure toward low prices as well as the importance of commodity companies, non-profit agencies, and government.

Movement toward economic success increases opportunities for the expression of subgroup lifestyles and personal distinction; that is, both to belong and to stand out. I term this *permissive marketing*. Individualized and niche consumption goes with branding, higher prices, and the creation of distinction for products through artistic means. A key artistic achievement is the creation of brand images. Brand images are created by all marketing means, but especially by advertising. Planning and executing advertising is a rich, complex, and challenging activity. To do it well requires awareness of cultural changes in values. Sometimes advertising leads the way with innovation and anticipation of where society is going. Commonly it follows where the people are going.

Three JIF Peanut Butter commercials from three historical periods are used as exemplars of advertising's process of adaptation to changing values and roles in American life. The first commercial shows a traditional emphasis on being a good mother. It assumes the mother stays at home and takes care of the children. The second commercial is one in which JIF brand represents women as working women rather than "just mothers." However, despite their job related concerns, their concern with good food for the family is depicted as still being of primary importance. The third commercial includes the father of the family doing the shopping and being the one who chooses JIF while the woman is evidently off doing something else.

Taken across time, these advertisements point to important questions about the ways advertising reflects and/or provokes cultural change. As such, the presentation is intended as an opening to the discussion on this topic that the other papers take up.

Working Reality: Advertising Representations of Social Class and Race during a Time of Increasing Income Inequality, 1970-2010

EXTENDED ABSTRACT

We will present the results of a systematic analysis of American general interest magazine advertising, 1970-2010. We will focus on representations of the middle class, the working class, and race.

The ads are a subsample (n=213 for all general interest) of a larger data collection (n=1200) covering the period 1900 to 2010 and coded along multiple dimensions of stratification including age, race, gender, and social class by three trained coders (Krippendorff's alpha = 0.78). We focus on the 1970-2010 period due to its sociological and economic significance. It is during this period that the U.S. exits a post-World War II period of increasing equality, equitable income growth and economic wellbeing. From the mid 1970s forward the U.S. experiences increasing inequality on virtually every dimension, rending the class divide ever wider. This reversal of fortunes that occurred in the 1970s is widely known to sociologists as the Great U-Turn (Harrison and Bluestone 1988). The presentation will overlay our content analysis with other empirical social indicators, such as measures of income inequality and public opinion. We will investigate whether this trend holds only in general interest advertising or whether the same class message is conveyed differently to consumers occupying different social classes. We will also identify, describe, and report the frequency and nature of one common visual trope within each of the social class representations. In each case we examine how the trope deftly leverages social stratifications to sell products, and presents a world consistent with advertising's institutional goals.

The overwhelming majority of individuals who appear in general interest advertising are drawn from the middle class. The period begins in 1970 with 45.2 % of pictured individuals identified as middle class. They average 55.9% of the sub-sample. While this level over-represents the middle class compared to the 32% of the population that is objectively middle class, it is the astonishing growth of images of the middle class until 2000 that is particularly striking, at which point the middle class comprises 73.3 % of the individuals in our subsample. Advertising insists that the middle class is stable, secure, even growing. This trend becomes particularly interesting and counterintuitive when overlaid with popular press and public opinion data that suggest a significantly threatened, shrinking, or even disappearing middle class. The distance between advertising images and public perception is investigated along multiple dimensions: an artifact of the target market of mass advertising, a "safe" and desirable way to sell products, as part and parcel of the "egalitarian myth" that has been an ever present and defining theme in American politics (Pessen 1971), and the institutional environment in which a foreshortened class structure is present (Marchand 1985).

In examining the portrayal of the middle class in general circulation advertising, we go beyond numeric representations and investigate the common tropes or tableau in which the middle class is placed. We find that the middle class plays a unique role in advertising. The modal ad shows the middle class to be overworked and over-committed (Schor 1993). In this trope, which we label the "consumer drama," a simple narrative unfolds. These narratives are unbalanced and dramatic; women scramble up on chairs when they see a mouse, fall off clumsy step stools, and are escorted off beaches by police officers. All tell a simple narrative in which something goes wrong and a branded consumer good or service is used to solve the problem. The function of this style of trope and its relationship to the stratification of society is suggested.

The end of this counter-empirical reality comes in 2010. Abruptly, representations of the middle class fall from 73.3% to 36.6% in just ten years. Why? We propose a number of possible hypotheses. We examine alternative social stratifications and hierarchies as well as popular opinion and populist sentiment as potential drivers of this shift. By 2010 income inequality had become common a common media meme, a mid-term election issue, and part of several left and right populist movements.

In accounting for the decline of the middle class in the final decennial year, 2010, we expand our analysis to the intersections of social class with race and ethnicity. The proportion of Blacks, Latinos, and other minority ethnic groups portrayed in ads averages a combined 8.0% from 1970 to 2000, never exceeding 20%. However, in 2010 the number of non-whites portrayed in general interest advertising crescendos to a remarkable 47.5% of all individuals. Not only is the increase sharp, 2010 represents the first year when racial and ethnic minorities are overrepresented as compared to the actual population. We consider multiple causes of this dramatic shift including demographic shifts in the American populace, the powerful effect of Obama's presidency, and the emergence of a "post-racial America." Because class, race and ethnicity are often confounded, we also consider socioeconomic shifts such as the Great Recession. When these explanations are found lacking, we turn to the final crucial factor – the institutional environment. Our analysis reveals that the most compelling explanation for this shift is less about demography or ideology than the institutional environment. Many minorities pictured in 2010 appear in ads that emphasize a firm's corporate social responsibility and charitable activities across the world including China, India, and Africa.

A large body of empirical work has consistently shown that media representations significantly impact people's beliefs about the composition of the social world (Gerbner et al. 2002). Our world is increasingly mediated by social representations brought by advertising supported television, paid search, and entertainment. Advertising is the most explicit in its purpose: to get consumers to want and buy things. Yet, social class, inextricably tied to consumption, has remained largely unexamined. As theorists have argued, the information in ads is never random (Schudson 1984; Goffman 1976) or mundane, but rather goes well beyond copy and product demonstration to comment on the fabric of social life. Our investigation of class and stratification images reveals crucial processes of social representation and the interplay of forces such as institutions that have not been apparent in previous research.

"I am Canadian": The Rise of Canadian Identity in Canada's Censuses, 1981-2006

EXTENDED ABSTRACT

The "I am Canadian" commercial for Molson's *Canadian* beer, first aired in 2000, became an overnight phenomenon in Canada. In "The Rant," as it was known, an actor listed stereotypical characteristics of Canadians and ended with the emphatic declaration "I am Canadian." This ad was interpreted by many as an expression of national pride and an emblem of Canadian patriotism (MacGregor, 2003); its success quickly led to numerous spin-offs and spoofs, and increased beer sales for Molson's Beer Co. The campaign was perfectly timed: it occurred after two decades of change in how Canadians identified themselves. In 1981, less than 1% of the Canadian population identified their origins on the federal census as "Canadian" or "Canadien". By 2001, the number describing their origins as at least partly Canadian or Canadien had grown to 40%.

The rapid growth of the numbers and percentages of people in Canada identifying themselves as Canadian in response to the census questions on race and ethnic "origins" between 1981 and 2006 is the result of several different sets of processes. The first set consists of demographic processes: immigration, racial and ethnic intermarriage, and generational aging. Immigrant origins such as "Ukrainian" or "Italian" fade in salience by the third and later generations. As intermarriage between origin or ancestry groups increases, the complexity of origins of the next generation increases and the salience of any one ancestral thread decreases.

A second set of processes consists of methodological issues that helped shaped the conversation between the premier data-gathering organization of the country, Statistics Canada, and the nation's population. Details of the operationalization and design of the questions and the responses for racial and ethnic "origins" in the censuses, first discouraged, then allowed, then reacted to, and finally encouraged people to declare that their racial or ethnic origins were "Canadian" or "Canadien" or included a Canadian component. In this regard, both Statistics Canada and the respondents to the censuses worked in concert to produce an upswing in the numbers of people declaring themselves, at least in part, as Canadian.

A third set of issues concern the ambiguity and complexity of the concepts–nationality, race, ethnicity–that underlay ancestral origins and the phenomena that shape people's choice of a particular discourse describing their origins. Because these concepts are complex and overlapping, contemporaneous and extraneous phenomena such as advertising campaigns for beer or a clothing chain can bring a specific discourse to the forefront at a time when respondents must confront the need to choose a particular answer on a federal form.

Scholars have argued that the tenor of Canadian nationalism changed in the mid-1980s. During the 1980s and 1990s, several commercial enterprises became important actors in the expression of Canadian patriotism. These included Roots, a Canadian clothing store, Tim Horton's chain of coffee and donut shops, as well as Molson's beer company. The proclivity of Canadians to drape themselves in clothing branded with beavers, canoes and maple leaves, and to drink coffee in shops associated with a hockey player, blossomed during these two decades. Carstairs (2006) argues that these consumer purchases allowed Canadians the ability to be "proudly Canadian" while imagining an idealized life of wilderness parks and successful athletes. The success of Molson's nationalistic and forceful "I am Canadian" campaign, which was particularly evident at the very beginning of the 21st century, may well have helped produce the crest in the numbers of individuals who chose to opt for the response most evocative of a nationalistic stance in the 2001 census,

fielded only a year after the beginning of the campaign. It is also possible that the Canadian Government's extensive advertisements for the 1998 Winter Olympics in Nagano, Japan (Rose, 2003) fueled nationalistic responses on the 2001 census.

However, five years later, in 2006, the year of the next census, the percentage of respondents declaring themselves as Canadian/Canadien dropped back slightly to 35%. But by then the novelty and prominence of Molson's very forceful campaign had faded and so the other options, discourses centered on race or ethnic origins, may have moved back into the forefront for some individuals as they confronted the need to choose one or two words to describe their origins on the federal census form.

An Historical Analysis of Archetypical Shifts in Representations of Women in Luxury Product Advertising in the early 1960's

EXTENDED ABSTRACT

This study zooms in on a particularly noteworthy moment in U.S. history to closely examine how socio-historical events reverberate in advertising representations of social categories of consumers. It follows the work of Marchand (1985) and others focused on advertising's cultural meanings within a particular socio-historical context (Scott 1994; Stern 1989, 1996; O'Guinn, Pracejus, Olsen 2006). We examine the temporal relationship between political and social change and advertising representations of consumers. We began our research wanting to consider whether a single traumatic event in U.S. history could significantly alter advertising conventions for luxury products not directly connected to the event. That is, can changes in advertising representations of consumers be traced to distinct social disruptions, even in ads for luxury products that usually show little change over time?

Method. We examine a set of 800 magazine ads for women's perfume and cologne appearing from 1962 – 1965, a period that brackets the assassination of President John F. Kennedy on November 22, 1963. In this presentation we examine changes in representations of women in these ads. Our data is a comprehensive set of such ads contained in the J. Walter Thompson Competitive Advertisements Collection at the Hartman Center at Duke University. Our data set provides broad inclusion of perfume and cologne advertisements found in a structured sample of major distribution magazines including *Mademoiselle*, *The New Yorker*, *Harper's Bazaar*, *Seventeen*, *Good Housekeeping*, *Ladies' Home Journal*, and *Life*.

Perfume and cologne advertisements were chosen because they often utilize abstract messages to sell the product. Like automobile, soft drink, and cigarette advertisements, perfume ads seek to associate the product with culturally framed aspirations such as success, romance, youthfulness, or adventure (Zelman 1992). However, un-

like automobiles, soft drinks, and cigarettes, there is no commonly understood vocabulary to fully express the particular compositional qualities of fragrance. Consequently, perfume and cologne advertisements rely on abstract symbolism to sell the product and to link a particular scent to elements of an American dream (Zelman 1992). Because perfume and cologne advertisements employ symbolism rather than information about functional product attributes, their advertising conventions are perhaps more flexible in their ability to change with shifts in cultural meanings.

The advertisements in the data set were coded on many executional dimensions, but in this presentation we focus on the representations of women in the ad. By closely examining the implied viewer, surroundings, eye contact, clothing, and social setting, women appearing in the ads were coded as representing archetypal images. Eight archetypal images of women were frequently featured: Femme Fatale/Woman as Animal, the Girl-Next-Door, the Sophisticated Upper-Class Woman, the Bathing Beauty, the Young Lover, the Pretty Woman, the Passively Seductive Woman, and the Hand. Of the 500 ads that featured women rather than just product packaging, 438 of the women represented one of these eight archetypal images.

Results. The results focus on decreases in the prevalence of the Sophisticated Upper-Class woman after the assassination, increases in both the Femme Fatale/Woman as Animal and the Passively Seductive Woman, and a later-period resurgence in representations of the Girl-Next-Door.

In the analysis, these shifting representations of the social category of women are interpreted not just with respect to the assassination of JFK and the disappearance of Jackie Kennedy from the public eye (Perry 2004), but also with respect to other social disruptions that occurred in parallel during the time period under study. In particular, FDA approval of the birth control in 1960 (Watkins 1998), the publication of Betty Friedan's *The Feminine Mystique* in the spring of 1963, and the appearance of the Beatles on the Ed Sullivan television show in late 1963 all had important consequences for American culture's complex construction of the symbolic meanings of gender. Our analysis traces each of these social disruptions in the ongoing cultural conversation about gender that takes place even in the pages of magazines that feature advertisements for perfume and cologne.

Conclusion. Nuanced cultural analysis of shifting archetypical representations of women in perfume and cologne ads during this period point to the complex conversations that constitute cultural change, even when focusing simply on ads for luxury products. By identifying each strand in this conversation, our understanding of the moving collective consensus and conflict around gender is given dimensionality and dynamism.

Thus, the primary contribution of this research is not in its details about this particular time period or these particular ads. Instead, its contribution to consumer research is in highlighting the importance of moving beyond research that is insensitive to temporal change, and instead finding explanations of the microscopic, yet profound, steps in the processes of cultural change.

SESSION OVERVIEW

Record numbers of consumers found themselves at the bottom of the pyramid in the past few years. Job loss, foreclosures, and wage cuts in the recent economic recession drove countless middle-class families below the poverty line (Yen, 2011). In 2009 alone, more than 170,000 US families were pushed out of their homes and into the homeless shelters. At the same time, the amount of time spent at the shelters and the number of consumers moving into shared dwellings with other families soared compared to the preceding years (Pugh, 2010). In the midst of these alarming trends a question that is often raised is, what is the reality of being at the bottom of the distribution?

Previous research found that low-status individuals—those who are inferior to others on a socially relevant dimension (Ridgeway & Walker, 1995)—often feel shame, dissatisfaction, and envy towards others (Frank, 2007; Goffman, 1982). As a result, they save less (Dynan, Skinner, & Zeldes, 2004), spend more (Charles, Hurst, & Roussanov, 2007), eat more high-calorie foods (McLaren, 2007), and take more risks (Haisley, Mostafa, & Loewenstein, 2008) than high-status individuals. This limits their ability to accumulate wealth and to improve well-being in the long run (Bagwell & Bernheim, 1996). Such troubling patterns of behavior, paired with increasing numbers of low-status individuals in the population (Cohen, 2010), have made it critical for researchers and policy makers to understand how consumers experience and cope with low status. This session addresses these issues.

Four papers examine the strategies that consumers use to cope with low status and ways to mitigate their negative outcomes. Ivanic, Overbeck and Nunes start off by showing that African Americans, assumed to have lower endowed status than Caucasians, will pay more voluntarily for certain products in order to assert status. The saliency of race during the transaction and the strength of one's racial identification moderate this tendency. De Boer, Dewitte and Vanhouche continue by arguing that low-status consumers do not always give in to the temptation to spend money on high-status products. In fact, individuals, who have low status due to their restrained financial resources, may strategically reduce the attractiveness of unaffordable products after autonomously refraining from purchasing them.

Next, Dubois, Denton and Rucker find that a similar devaluation effect extends to consumers' valuations of *owned* possessions, leading low-status consumers to sell their possessions for less than their actual value. Finally, Ordabayeva and Chandon find that low-status individuals are motivated to improve their rank even if it means demoting others and hurting the welfare of the group, especially when equality is high. This effect disappears when the status gain is costly.

These findings advance our understanding of relative deprivation in several important ways. First, they demonstrate the diverse nature of behaviors that individuals adapt in response to low status (all papers). Second, they show that the effects of low status extend far beyond simple spending decisions (all papers) and consumers' individual welfare (all papers), but that they also impact the welfare of the group (papers 1 and 4) and efficiency of market transactions (papers 2 and 3). Third, the papers propose strategies to curb the negative outcomes of low-status responses (papers 3 and 4), and in doing so uncover surprising findings that suggest some effects established in the previous literature do not hold at the bottom of the pyramid (e.g., endowment effect and benefits of equality in papers 3 and 4).

The papers complement each other and respond to the call for diversity in many ways. First, the papers draw on diverse theories (status, stereotypes, self-determination theory, attitude change, behavioral decision theory, group processes). Second, they employ complementary views of status (perceived and actual availability of financial resources, the endowed status of race, relative position within a group), and consequently examine diverse samples of low-status individuals (those who actually experience low status due to their resource constraints or race as well as unsuspecting individuals who are put in a low status position in an experimental task). Finally, the papers demonstrate the effects of low status on a diverse set of outcomes (willingness to pay, product attitudes, purchase decisions, the endowment effect, other-directed behaviors within a social group). Needless to say, the session brings together scholars with diverse backgrounds in terms of geography as well as stage in the career.

Overall, the session offers novel insights on status processes and encourages a debate on the rationality of compensatory behaviors and their effectiveness as coping mechanisms. The session will appeal to a vast audience interested in consumer psychology, stereotypes, group processes, and behavioral economics.

Status, Race, and Money: The Impact of Racial Hierarchy on Willingness-to-Pay

EXTENDED ABSTRACT

Status affects one's opportunities, relationships, and self-concept. Regardless of whether people choose to acknowledge this, society is vertically stratified on several dimensions (e.g., income, education, race), and status hierarchies persist. Whether based on achievement (merit) or endowment (birth), status hierarchies are socially imposed, and manifested in the way certain groups are treated. Consequently, status perceptions affect how group members behave. We examined how the ingrained status hierarchy between African Americans and Caucasians affects individuals' spending behavior. Specifically, we explored whether, when, and why African Americans willingly pay more for products and services than they would otherwise, and more than Caucasians.

Historically, African Americans have had lower endowed status than Caucasians, which has led to persistent discrimination. African Americans are often stereotyped as being poor, lazy, and uneducated and thus treated as inferior (Wittenbrink, Judd, & Park, 1997). In the marketplace, African Americans feel categorized as "low value" customers because of the perception that they cannot afford purchases at upscale stores (Ainscough & Motley, 2000) and frequently report being skipped over by sales associates who serve Caucasian customers first.

Past work has demonstrated that members of racial minorities respond by consuming status-related goods as a way of asserting high status (Fontes & Fan, 2006). More generally, individuals purchase products that convey high status to restore a sense of power or to repair self-integrity (Rucker & Galinsky, 2008). Our work goes beyond high-status goods as we propose paying more money itself constitutes a strategy for asserting status.

The ability to spend money represents success, wealth, and high social status (Veblen, 1899). Spending money engenders feelings of equality because money begets respect (Goldberg & Lewis, 1978). In the early 1980s, the NAACP created "Black Dollar Days," encouraging African Americans to spend money to demonstrate the strength of African Americans' purchasing power (Boyer, 1985). By extension, we predict that African Americans would increase their WTP (for both status- and non-status-conveying products) in an attempt to assert high status. We expect this would be particularly true for African Americans who are concerned that their social standing is seen as inferior— a concern that may arise from a chronic sense of status disadvantage or from explicit awareness of race (and associated low-status stereotypes).

We also propose that the manner in which race, or endowed status, is made salient can affect African Americans' WTP. When a stereotype is implicitly activated, the automatic response is to confirm the stereotype (Bargh & Pietromonaco, 1982). With explicit activation, individuals become more mindful of the stereotype and may behave in stereotype-inconsistent ways (Wheeler & Petty, 2001). We argue, when race is explicitly activated, African Americans are reminded of the stereotype that they are poor and low status. Consequently, they elevate their WTP to fight against the stereotype and assert high status—particularly if they perceive themselves to be disadvantaged with regard to status. Conversely, implicit activation should lead African Americans to decrease their WTP, because implicit activation occurs outside awareness and thus does not prompt stereotype resistance. We anticipated that individual differences in racial identification might moderate the effect of identity salience: More highly identified African Americans who feel a greater sense of pride in group membership may counteract societally imposed status stereotyping reducing their need to pay more to assert status.

We tested our predictions in several studies. Study 1 examined the differential effect of race salience on WTP for African Americans versus Caucasians. The study used a 2 (race: African American, Caucasian) × 3 (race salience: explicit, implicit, control) between-subjects design. When the concept of race was not activated, the difference between African Americans' and Caucasians' WTP was not significant. When the concept of race was activated explicitly, African Americans were willing to pay significantly more than Caucasians as well as more than in the control condition. Conversely, African Americans were willing to pay less in the implicit activation condition than in the control condition.

The data suggest that when the concept of race is explicitly activated, African Americans become sensitized to stereotypes of being poor and inferior, and hence increase their WTP in what we argue is an attempt to assert their status. Conversely, these stereotypes and related behaviors are so ingrained that implicit activation of the concept of race leads African Americans to decrease their WTP, as they do not feel a need to assert their status.

Study 2 examined the role of two possible moderators of this effect: perceived status disadvantage (PSD) relative to others and racial identification. We reasoned that greater PSD should heighten WTP, given the greater experience of threatened status. Conversely, we expected that stronger racial identification would lower WTP. As predicted, PSD and racial identification yielded opposing effects on WTP. Greater feelings of status disadvantage resulted in a higher WTP as African Americans tried to assert high status when race was salient. In contrast, stronger racial identification resulted in a lower WTP among African Americans when race was salient.

In Study 3, we explored how differences in WTP result from feelings of threat, by introducing a common overt status threat and examining its interaction with race and race salience. Key findings include: African Americans who received inferior treatment in the marketplace and for whom race was made salient reported higher WTP than poorly treated African Americans whose race was not salient, and well-treated African Americans whose race was made explicitly salient. They also reported higher WTP than did Caucasians in any of the conditions in this study.

Findings from the three studies support our claim that African Americans who feel disadvantaged use payment behavior as a way to assert high status. Additional studies underway explore how racial diversity in the presence of others at the time of purchase impacts willingness to pay. Our work raises awareness that some individuals may sometimes support an unfair system through their own behavior. By underscoring how an entrenched status hierarchy can create internalized imperatives for African Americans to pay more, our studies provide insight into race-based status dynamics and how they affect consumption patterns.

When Diamonds are not the Poor's Best Friend: How the Poor Deal with Unaffordables

EXTENDED ABSTRACT

Governmental, judicial, and bank policies tend to reduce the poor's financial freedom by either giving them allowances for specific purchases or by limiting their credit options (Ruelens & Nicaise, 2002). The rational for the autonomy reducing approach is endorsed by research suggesting that the poor lack sufficient regulatory skills to control their expenses (Green et al., 1996), which might boost excess spending behavior as a way to attenuate their lower class status. We question if autonomy reducing measures help consumers to deal with, and resist, luxury products. We explore how the degree of autonomy shapes attitudes of luxurious products. The term "luxury" is taken to refer to the situation in which buying a certain good, although physically possible in some circumstances, would put undue strain on the buyer's budget.

A wide array of research suggest that (high) autonomy increases a consumer's ability to deal with challenging situations (Ryan & Deci, 2001), and one way to deal with the temptation of luxury products, is to downplay their value ("The grapes are too sour"). Importantly, research in the self-control domain suggests that self-control is exerted only when external control is absent (Fischbach & Trope, 2005), i.e. when autonomy is high. Findings in the food domain suggest that exposure to food without consumption leads to a reduced attractiveness of the tempting food items (Dewitte et al., 2009). Reduced attractiveness seems to be observed under high autonomy conditions. Hence, this evidence suggests that high autonomy can decrease the attractiveness of luxury products. But, as people are

motivated to regulate their behavior in function of the necessity of that behavior (Vohs et al., 2008), the effect should be specific to the poor or to people harboring another self-based motivation to refrain from buying the luxury product.

We distinguish three possible processes that may be responsible for attitude changes. Attitude reduction may be product specific, implying a devaluation that is limited to the currently encountered luxury product (Myrseth et al., 2009). Attitude reduction can also be attribute specific, implying that the attitude reduction of the luxury product spreads towards related products (e.g. from candies to M&Ms, Geyskens et al., 2008). Lastly, attitude reduction, may be driven by a generalized inhibition effect (Tuk et al., 2011), implying that after encountering a luxury product all attractive products devalue. We test these hypotheses in three studies.

In the first experiment we explored the influence of autonomy and financial scarcity (both manipulated) during restrained purchase of a luxury product (a concert ticket) on one's subsequent attitude toward that product. We asked participants about their finances by means of 3 questions on a 10-point scale and varied the scale anchor points to manipulate financial scarcity (Nelson & Morrison, 2005). Participants then read a scenario where they had the opportunity to buy a concert ticket of their favorite band. In the low autonomy condition, it was announced the concert tickets were sold out. Participants then rated the attractiveness of the concert ticket (4 items on a 7-point scale). The attitude towards the luxury product, the concert ticket, was significantly lower among the autonomous poor ($M = 3.48$) relative to non-autonomous poor ($M = 4.02$, $p < 0.05$). For the non-poor, no differences between the autonomous and the non-autonomous were obtained (respectively, $M = 3.87$ vs. 3.73, $p > .05$).

The second study aimed at testing whether devaluation is driven by a product specific, attribute specific, or generalized devaluation process. We pre-exposed participants (all in financial scarcity conditions) to a physically present gadget (a penguin fan) and either helped them decide not to buy it or made the "not buy" decision for them (high versus low autonomy). We then had them rate the gadget and products that varied in relatedness to the gadget (strong relation: ice bear headphone, an igloo tent, and refrigerator poetry; weak relation: an egg cup, an i-pod holder, and a small helicopter with remote control). We replicated the devaluation of the target product in the autonomous group ($M = 3.31$) relative to the non-autonomous ($M = 4.64$, $F(1, 60) = 11.87$, $p < .01$). Devaluation expanded only to products related to the non-purchased item: The related products were considered as significantly less attractive in the autonomous group ($M = 2.90$) relative to the non-autonomous group ($M = 3.58$, $p < .05$). For the unrelated products no significant differences emerged between the autonomous and non-autonomous ($M = 4.46$ vs. 4.35, $p > .05$). Both study 1 and study 2 demonstrated the causal relationship between autonomously refraining from the purchase of a luxury product, and its subsequent devaluation. Study 2 extends these findings by illustrating how this devaluation might be attribute specific.

To complement the internal validity of our lab study, we conducted a field study with actual poor consumers, who had either a history of high or low financial autonomy. We compared them to a matched sample of non-poor consumers. Assuming that pre-exposure is cumulative and that the devaluation operates via attribute attitudes, we predict that the autonomous poor will devalue luxury products more than non-autonomous poor. We don't expect this difference for the moderately expensive and cheap products. A significant interaction between poverty category and price level emerged ($F(4, 60) = 2.62$, $p < .05$), and was consistent with the predicted pattern. Attitudes towards the products did not vary much, except for

the attitude towards luxury products among the autonomous poor, which were significantly lower than the other attitudes.

Together, the results suggest that the poor, provided that they autonomously manage their budget, may develop a coping mechanism that helps them deal with products that are not within their budget. The findings suggest that if public policy wants to help the poor to resist luxury products, it may be unwise to deny poor consumers access to luxuries or to control their expenses for them.

I'll Sell That for a Dollar: How Social Status Threats Devalue One's Possessions

EXTENDED ABSTRACT

One feature of many unprivileged consumers' daily experience is their repeated encounter with psychological threats in social situations (Marmot, 2004). And, it is well documented that a variety of status threats to consumers have far-reaching effects on consumer behavior (for reviews see Lee & Shrum, in press). The majority of this literature, however, has focused solely on consumers as *buyers* and investigated how threats impact consumers' willingness to spend on products based on whether they have the potential to alleviate the threat or not.

This research investigates how status threats affect consumers as *sellers*. Specifically, we propose that experiencing a threat has the potential to spillover to the valuation of one's possessions. Past research has posited that one's possessions are often evaluated in relation to the self (Belk, 1988). For example, an individual for whom football is a large part of his identity is likely to value an autographed football more than an individual who has little passion for the game. Building on this idea, we propose that when the self is threatened, changes to the self may affect the value of one's possessions. Specifically, when threats diminish *social worth* or *status—one's value relative to others—* we hypothesize that the experienced loss in social worth might spillover onto their possessions. Consequently, although past research on the endowment effect has shown that owning an object increases its value (Kahneman, Knetsch, & Thaler, 1990), this work proposes that threatened sellers might price owned possessions as lower than objects they do not own.

Furthermore, we propose our devaluation effect should be moderated by whether people encounter a social status vs. personal threat. For example, an individual's intelligence might be under threat because she is focused on the fact she performed poorer than her classmates (i.e., a social status threat) or because she received a grade on a test that was below her own personal standard (i.e., a personal threat). Although each instance reflects a threat to one's intelligence, the loss in social worth, and subsequent devaluation of one's possessions should be greater when the threat is social in nature.

Finally, we predict that social status threats do not devalue every possession an individual owns. In particular, when possessions have the potential to help alleviate the threat, we hypothesize that its value to cope with the threat i*ncreases* the product's value in the eyes of the consumer. For example, an individual whose intelligence is threatened may part with their favorite science fiction novel for less, but sell their encyclopedia collection for even more.

We test these hypotheses across three experiments.

Experiment 1: Can Social Status Threats Devalue One's Possessions? Undergraduates were randomly assigned to a 2 (mug ownership: owned, non-owned) × 2 (threat condition: none, social) between-subject design. Participants were first given a mug to own or to use just for the session. Threat was manipulated by instructing participants to recall a time they went to the grocery store (no threat) or performed poorly relative to others (social status threat).

Subsequently, all subjects were asked at what price they would sell their mug. A significant interaction emerged, $p < .01$. In the no threat condition, participants owning the mug set a higher selling price than participants who did not own the mug, $p < .01$, consistent with findings from the endowment literature. Of greater novelty, threatened participants set a lower selling price when they owned the mug than when they did not own the mug, $p < .01$.

Experiment 2: Social Status Threats versus Personal Threats. Undergraduates were randomly assigned to a 2 (ownership of a pen: owned, non-owned) × 3 (threat condition: none, social, personal) between-subject design. Participants were given a pen to own or simply to use for the session. Threat was manipulated using a recall task, where participants were asked to recall a list of items they purchased the last time they were at a grocery store (no-threat), performed poorly relative to others (status threat), or performed worse than their personal standard (personal threat). Finally, participants had the opportunity to set the price of the pen. An ANOVA revealed a significant 2-way interaction, $p < .001$. Replicating Experiment 1, participants in the social threat condition set a lower selling price when they owned the pen compared to when they did not own the pen, $p < .05$. However, participants in the personal and no-threat conditions set higher prices when they owned the product compared to when they did not. Furthermore, participants' loss of social worth mediated the effect of social status threat on selling price.

Experiment 3: The Value of Possessions that Alleviate Threat. Undergraduates were assigned to a 2 (ownership: owned, non-owned) × 2 (threat condition: none, social) × 2 (product relevance: threat irrelevant, threat relevant) between-subject design. Participants were given a new pen to own or to use momentarily. The pen was described to participants as an opportunity to display one's intelligence to others in the threat relevant condition (i.e., it was capable of alleviating the threat), and as just a pen in the threat-irrelevant condition. Threat was subsequently manipulated using the recall task in former experiments. Finally, participants were asked to set the price they would sell the pen for. An ANOVA revealed a significant 3-way interaction, $p < .01$. When products were threat-irrelevant, threatened participants devalued products they owned. However when products were threat-relevant, there was a significant ownership × threat interaction, $p < .05$. Threatened participants owning the threat-relevant pen set an even higher selling price than threatened participants who did not own the pen, $p < .01$.

Conclusion and Contributions: Social status threats led consumers to set the selling price of an item they owned lower than non-threatened consumers. This effect was moderated by whether threats were personal versus social, and reversed when the owned product had the potential to alleviate the threat. Implications for the threat and endowment literatures, as well as for social policy as discussed.

When Improving Equality Promotes Selfish Behavior

EXTENDED ABSTRACT

Increasing equality is expected to bring a host of social benefits in a group (Frank, 1985). In particular, it is expected to reduce conspicuous consumption by people who feel threatened by their low status (Becker, Murphy & Werning, 2005). More generally, equality is expected to improve social cohesion and cooperation and to promote welfare-enhancing behaviors within a group (Zizzo, 2003).

However, recent research has demonstrated that increasing equality may not always be beneficial. Ordabayeva & Chandon (2011) showed that greater equality actually increases, rather than decreases, conspicuous consumption among people at the bottom of the hierarchy because it increases the status gains (the number of people that can be surpassed) provided by consumption. Interestingly, much of the previous literature focused on conspicuous consumption as a means to enhance status, thus overlooking other methods that individuals may use to improve their relative position. We propose that aside from conspicuous consumption, which improves one's rank by enhancing own performance, people may also improve their rank by pulling other people down. For example, they can "burn" other people's money (Zizzo, 2003) or sabotage others' performance in order to improve rank. Whereas conspicuous consumption directly affects only one's own well-being, demoting others hurts the well-being of others and the total welfare of the group.

This research therefore examines whether, counter to existing arguments (Wilkinson & Pickett, 2010), equality promotes selfish behaviors that low-status individuals use to cope with a status threat. We hypothesize that increasing equality will increase status-seeking among low-status individuals by encouraging behaviors that demote others and the group. Furthermore, the effect should be moderated by status level (low vs. high) and status desirability. We expect that equality effects should be stronger for low-status individuals than for high-status individuals (because for high-status individuals, increasing equality has the opposite effect of reducing position gains) and when status gain is positive (vs. negative). We tested our hypotheses in four studies, which measured selfish tendencies of low-ranked individuals in the context of salespeople. This context was chosen because salespeople are commonly assessed based on their ranking and low ranking poses tangible threats such as withheld commissions and job loss.

A pilot study examined whether a low-status individual was evaluated more negatively and hence had stronger reasons to engage in status-seeking behaviors when the distribution of performance was equal (vs. unequal). A group of MBAs read a scenario about managing 20 salespeople at an electronics store. They read that to evaluate the salespeople's performance they monitored the distribution of monthly sales. They saw an equal or an unequal distribution of previous month's sales and indicated how likely they would be to fire a salesperson with a low sales rank (19th out of 20). The results indicated that the low-ranked salesperson was evaluated more positively and faced a lower threat of being fired in the equal than in the unequal distribution.

In study 1, we examined whether equality would encourage selfish status-seeking behaviors among low-ranked individuals despite higher performance evaluation by managers. The participants read the same scenario as in the pilot study, except that they imagined that they were a salesperson (vs. a manager in study 1). The participants imagined having attained low rank (19th out of 20) or high rank (9th out of 20) in the equal or the unequal distribution of sales. They were then asked to indicate how likely they would be to help a new colleague, who could improve the store's overall sales, but reduce the performance of individual salespeople. The results revealed that the low-status salesperson was less likely to help a new colleague than the high-status salesperson. More importantly, equality reduced the likelihood of helping among low-status salespeople but not among high-status salespeople.

Study 2 examined the moderating role of individual selfish tendencies. The participants read the same scenario as in the low-status condition of study 1 and answered three questions about the low-ranked individual's selfish status-seeking behaviors. The first behavior involved refusing to train a new colleague (as in study 1). The second behavior involved directly sabotaging a colleague's sales, and the third behavior involved directing customers to the competing store in exchange for a higher commission from the competitor. We measured the individual propensity to endorse selfish, devious,

and manipulative behaviors using the Machiavellian attitudes scale (Christie & Geis, 1970). Whereas people with strong Machiavellian attitudes indicated high likelihood of engaging in selfish status-seeking behaviors regardless of equality, individuals with weak Machiavellian attitudes were more likely to engage in selfish behaviors when the distribution of performance was equal (vs. unequal).

Study 3 sought to replicate the findings in the context of real behaviors and tested the moderating role of status desirability. Throughout the experiment, the participants earned tickets for a lottery that was conducted at the end of each session for a €10 cash prize. In the first stage, the participants earned tickets in a general knowledge test. At the end of the test, everyone was assigned low performance rank (2 correct answers out of 10 = 10 tickets) and saw the distribution of everyone's test scores (high vs. low equality). In the second stage, the respondents participated in a public goods game (in which they could multiply everyone's tickets by initially contributing tickets to the common pool) and a burning game (in which they could spend some of their tickets to burn the tickets of others). Status desirability was manipulated by informing half of the participants that the winner would pay a tax on the lottery earnings and help a research assistant, which reduced the benefits of ticket accumulation. The results showed that high equality reduced contributions to the common pool and increased spending to burn others' tickets when the lottery earnings were free, but not when the lottery winnings were taxed.

Overall, our findings demonstrate that the effects of equality go beyond consumption decisions and may encourage status seeking so much that people resort to selfish behaviors that hurt others and the group. More generally, the results have implications for understanding the adverse effects of equality and the dark side of social comparisons.

Stereotypes, Memories and Nostalgia:
Contested States of Longing, Belonging, and Being Within Consumer Acculturation

Paper #4: 4. Social Status Implications of Transmigrants' Consumer Practices in Their Cultures of Origin
Mine Üçok Hughes, Woodbury University, USA

SESSION OVERVIEW

The theme of this year's ACR conference is "Appreciating Diversity". In congruence with this theme, this session explores various stages of consumer acculturation as they relate to the experience of immigrants both in the country of re-rooting and in their home country. Consumer acculturation then is viewed as a manifestation of wider interactions and power play between the dominant host society, the immigrant populations, and their ethnic networks in the home countries, as these groups negotiate inevitable cultural and societal changes. Extant acculturation research has tended to be either American centric favouring comparative studies of assimilation amongst different ethnic groups (Waters 2005) or focuses mostly on the way immigrants confront the consumption practices of the host nation (Wamwara-Mbugua, Cornwell, and Boller 2007). The four presentations together address these criticisms through illustrating the varying stages in the consumer acculturation process, ranging from initial immigrant contact, through to negotiating feelings of loss and dislocation, culminating in consumer acculturation problems related to the migrants' return to their original home country. By drawing upon research from a European centric perspective we illustrate the complex roles that consumption undertakes in how immigrants negotiate and construct their sense of identity, self-esteem and place in the world.

The first paper explores the role of consumption in stereotyping and stigmatising amongst Russian immigrants living in Sweden. To handle the stereotypes ascribed to them the Russian informants seemed inclined to conform to the stereotypes they ascribed to the Swedes and to thus consume accordingly. The sense of dislocation inferred in this paper is continued in the next paper, which explores the role of real and re-created memories amongst immigrants. Negative acculturation experiences lead to migrants recalling and re-creating pre-migration memories and making these memories real through consumption cues. In doing so immigrants tended to split their memories distinctly between pre- and post-migration, recreating pre-migration consumption memories as a defence mechanism against acculturation stress. The third paper continues the theme of dislocation and recreating pre-migration through understanding the role of nostalgia within consumer acculturation. In particular, this paper deconstructs the nostalgia of Turkish immigrants living in France into four categories indicative of their acculturation processes, including a nostalgia based around the desire to identify with the country of their ancestral origin. Nostalgia and the desire to return to Turkey by Turkish immigrants are discussed in our final paper, which also touches upon stereotypes and stigma among those who do return to visit Turkey. Exposure to Western European culture and consumer acculturation renders these returning Turks as foreigners in a country that they feel a close connection with. The four papers in this session thus firmly locate the migrant not as a welcomed, integrated embodiment of wider society, but forever a group in transition and constantly adapting, recreating and reconstructing a sense of identity. Notably, migrant identity practices implicate consumption to simultaneously integrate into the dominant culture, while yielding protection from the wider pressures of acculturation.

Three of the session papers are completed projects, with one representing an ongoing project, and all present differing theoretical perspectives. Methodologically, the papers adhere to the interpretivist approach and provide empirical knowledge based on ethnographic data. This special session is then expected to appeal to an audience interested in the interactions between culture, ethnicity, identity and consumption, whilst being of interest to those academics with an interest in memories and nostalgia.

Finally, the focus of the proposed session on immigrants and the role of consumer acculturation from a European centric perspective addresses the diverse audience of ACR and resonates with Vancouver's diverse population.

"Russians always wear red lipstick": Acculturation, Identity and Stereotypes

EXTENDED ABSTRACT

During the last few decades the world has experienced migration on a global scale resulting in a growing number of consumers with a foreign background living in Sweden; something which has put acculturation on the political agenda. Immigrants both forge and are subjected to various processes of acculturation and previous consumer acculturation research has documented the play of multiple cultures: the host, the migrant, and the transnational.

Since the acculturation process is a mutual adjustment where the parties are learning to co-exist, it is important to study the ways in which migrants and hosts develop understandings of each other. Both the migrant and the host are often a subject of mutual stereotyping where particular traits and values are ascribed to them. Those stereotypes can be positive but are more often biased and oversimplified. The stereotyping has to do with normative expectations regarding conduct or character of people "who are passing strangers to us" (Goffman 1963, p. 68). The concept of stereotyping has been well developed in other disciplines but not in literature dealing with acculturation through consumption (i.e. Askegaard et al. 2005, Luedicke 2011). This study intends to fill this literature gap by exploring how stereotyping affects the process of acculturation through consumption. The analysis will be based on the multi-disciplinary literature on stereotypes (e.g., Hinton 2000), as well as on stigma (Goffman 1963).

We have chosen to study Russian immigrants in Sweden and conducted a pilot study consisting of three in-depth interviews with young Russian females living in Stockholm. The informants were asked about why they came to Sweden, what they do now and what

their everyday life looks like. In the course of these "oral stories" the goal was to identify stereotypes as well as the coping practices. The main study consists of 20 interviews with Russians of diverse ages and backgrounds. Complimenting this, a critical review was undertaken of Swedish media portrayals of Swedish stereotypes of Russians connected to historic-political developments. From the data, three main stereotypes are highlighted:

- A cultivated culture: refined, formed through literature, music, theater: pre-revolutionary Russia;
- A feared culture: characterized by strong 'bullying' power, military domination: a Communist ideological stronghold throughout, especially during the cold war;
- A materialist culture: non-sophisticated consumption, nouveau rich: post-Communism.

When summarizing the interviews we found that, remarkably, only negative stereotypes, similar to those propagated by Swedish popular culture, were identified by the interviewees:

"Russians can always be identified as Russians. [They] *always* [wear] *red lipstick and too much eye make-up, stiletto heels. The colors* [of their dress and make-up] *are always standing out"* (interview with A). The same woman was eager to point out that she did not belong to this category and was similar to a Swede who dressed more "low key."

The preliminary analysis of the interviews show that the emerging stereotypes are "the extreme materialist" (Russian stereotype of Russians) and "the rational functionalist" (Russian stereotype of Swedes). These stereotypes could be partially explained by the power dynamics between the groups, where Swedishness holds the dominating position and Russianness is perceived an abnormality, a deviant expression, and a stigma (Goffman 1963). Stigma is a mark of distinction and articulation of distinctions and is a social construct, not an inherent quality (ibid). As an ascribed way of behavior and appearance it renders Russians to be socially inferior. All three interviewees, both verbally and in their appearance, were inclined to conform to the Swedish cultural ideology of "lagom" or "just enough". "Lagom" propagates moderation which seems to diametrically oppose the Russian materialist stereotype – the garishness and the tendency to "show off". We hope to develop this finding further at a later research stage.

Our preliminary research also demonstrates that although created externally, stereotypes are internalized by those subjected to them, so a Russian can always recognize another Russian. Furthermore, Russians also seem to use stereotyping as part of a power play. For example, "*It is easy to recognize a Russian… In Russia … we dress on our best when* [going out]. *Swedes can show up in a pajama, it is considered normal"* (interview with N).

The stereotypes presented here can be seen as subject positions mutually constructed by Swedes and Russians; positions that operate as a reference points from which people compare/distinguish themselves. The analysis shows that these stereotypes seem to play a major part in the acculturation process and mostly manifest themselves through consumption.

Memories of pre- and post-migration consumption: Better times or embodiments of a defensive mental state?

EXTENDED ABSTRACT

Previous migration studies tend to draw an implicit line between the place and time of migration (past) and the current place and time (present). Yet this approach fails to address how pre-migration memories emerge and appear in migrants' daily lives. In particular, research has not addressed: (i) how migrants present lives evoke memories of their past, or how consumption may reproduce pre-migration routines and knowledge, and (ii) how consumption is used in recalling past memories into the present, even if this leads to conflict between what is remembered and what is experienced. We explore these questions through migrants' pre- and post-migration memories, and how they manifest through consumption. In doing so we address research calls to understand how people encode and retrieve memories (Hastie and Dawes, 2001) and identity-based consumer memories (Mercurio and Forehand (2011).

The concept of memories and consumption, extensively addressed within consumer literature, offers interesting insights into the relationship between migration memories and consumption. For example, migrants' consumption of products indicative of pre-migration, such as food, may reinforce positive memories (Schlosser, 2006), yet such consumption acts may be undertaken to create false pre-migration memories. Indeed, Schlosser (2006, p. 377) notes that object interactivity may lead to "the creation of vivid, internally generated recollections that pose as real memories". Real experiences of a pre-migration life subsequently may become modified based around autobiographical events into false memories (Loftus and Pickerell, 1995) or be induced by product consumption that the individual has not previously used (Rajagopal and Montgomery, 2011). Hence, Aaker, Drolet and Griffin (2008), drawing upon the psychological theory of memory, argue that memories are not a direct copy of the individual's past but instead are reconstructed and re-imagined, brought alive through a variety of cues that assist individuals in making inferences about their past. The extent then that acculturation produces stress and this stress is managed through positive real and re-imagined memories of a pre-migration through consumption cues forms the basis of this research.

A sample group (n=8) of first generation Indian immigrants living in Britain were repeatedly interviewed to gather their pre- and post-migration experiences, lived lives, memories and consumption behaviors. Interviews were recorded, transcribed and analysed.

Data analysis revealed a clear splitting in participants' memories between their pre- and post-migration experiences, and consequently their memories. Of interest was how consumption featured in these memories and the sensory aspects of these memories differed.

Migration memories for participants were vividly recalled in terms of colours, smells and textures. For example, Margey describes her childhood memories of life in India as '*...bright and warm and very real almost...the colours are more vivid and alive, the smells I can recall are like I am actually there* [in India]'. References are made to cultural symbolisms such as brightly coloured bracelets and cloth being purchased to make clothes. In contrast, Margey's post-migration life in Britain, one where acculturation stress manifested in family tensions, is described as feeling '*...a bit cold because it's wintery quite a lot. Maybe I felt the cold more because I was from a warm place, but it felt cold … and me wearing ...a grey duffle coat I used to have...so it feels like a black and white film.*' The association of memories of life in Britain in black and white terms is later associated with consumption experiences, such as collecting the coal for the lounge fire, the brown lino floor covering and so on. Similar findings were shared with other participants.

The recall of memories in sensory terms is somewhat similar to Aaker, Drolet and Griffin's (2008) and Loftus and Pickerell's (1995) work on reconstruction of memories. The focussing on pre-migration memories predominantly represented happier times for participants, when issues of identity difference and related stresses were less pronounced. Consequently, participants appear to be engaging in a process of re-imagining pre-migration memories and related experiences, as suggested by Rajagopal and Montgomery (2011). Par-

ticipants achieved these re-imagining symbolic consumption experiences, such as their mother's cooking, indicative of pre-migration. Whilst clothing and religious artifacts, to some extent supported these memory recalls, food production and consumption was seen as central to memory recall. For instance, Tracey commented how she recreates childhood pre-migration memories through consuming potato poratas (a potato-bread dish): '*When my older sister makes it* [potato poratas]*, it does take you back. You remember her* [participant's sister) *making it for you and putting it on your plate, you used to think, 'Oh, I remember this, eating this on* [this pre-migration date]*', call it the baby turn...reminds you of old times'.* These consumption experiences tended to occur during moments of heightened stress levels.

The question then arises why do participants split their pre- and post-migration memories so distinctly? We suggest that the answer may lie in the psychodynamic term 'splitting', where traumatic events are separated and compartmentalised by the individual between good and bad events. In this instance, participants effectively were splitting their migration memories between pre-migration (colourful and positive) and post-migration (black and white, and negative). This act of splitting then represents a psychological defence mechanism to protect the individual's self-identity. Participants' pre-migration memories tended to be provoked during stressful experiences (feelings surrounding acculturation stress, such as ethnic difference) or illness (comforting). In the former, consumption was actively used to recall pre-migration memories to relieve symptoms of acculturation stress, whilst in the latter consumption invoked positive, comforting, pre-migration memories.

For those migrants who migrated as children, post-migration is reflected in various acculturation stresses, suggesting a wider sense of disempowerment arising from migration. Recreating consumption experiences based on pre-migration memories offered a means of relieving acculturation stresses, offering a sense of empowerment. For example, Peter watching old Bollywood films remembered from his childhood in India. The extent that these memories are re-imagined is inferred by the participants themselves, which may explain the contrasting colours used in memory recall. In contrast, only one participant differed in her memory narratives. A woman who actively sought out and chosen migration to emancipate herself from Indian cultural patriarchy.

Home Sweet Home: The Role of Home Country Nostalgia on Immigrants' Acculturation and Consumption

EXTENDED ABSTRACT

Nostalgia has been defined as a psychological obsession "to be back", that is, "a sentimental longing for the past", which people may develop with reference to things, significant-others, places or experiences that are no longer existing or at direct reach.

Acculturation studies and nostalgia research have developed quite independently. While extant works on nostalgia have largely advanced, and identified various facets of this emotion and its implications on consumption, acculturation studies have only marginally addressed nostalgia. Within the body of works investigating nostalgia, it has been argued that nostalgia can be either a state of *personal* (Holbrook and Schindler 1991) or *social* emotion (Zauberman, Ratner, and Kim 2009). Also, it has been proved that nostalgia can be activated from: (i) an idealization of direct memories (*true or real nostalgia*), (ii) from an indirect experience via the memories of the people close to us (*simulated nostalgia*) and, (iii) from the collective evocation of some pretended origins (*collective nostalgia*) (Baker and Kennedy 1994). Finally, (iv) time orientation marks the distinc-tion between retrospective (*"if only" fantasies*) versus prospective forms of nostalgia (*"someday" fantasies*) (Akhtar 1996).

Whilst nostalgia recurs within acculturation studies this is mostly as a side-effect. Immigrants developing new cultural competences in the host culture are described as nostalgic individuals who indulge in the consumption of artifacts (food, media, novels, clothes, etc.). These artifacts are dense in memories of their "other life" and, for many of them, of the "dreamed future life" once back to the country of origin (i.e., the myth of return) (Akhtar 1996). As such, nostalgia is seen as an effect or an implication of acculturation.

Our work argues that nostalgia is not only an *outcome* of immigration and the related pains of integrating in a frequently hostile, resisting, culture, but also plays a major role in the way immigrants acculturate to the host culture. Nostalgia then may be a *constituent* of the acculturation process that extant research has undervalued. In detail, this paper aims at answering to two main research questions: (i) what is the role of home country nostalgia in the processes of immigrants' acculturation? and (ii) what is the connection between immigrants' nostalgia for their home country and their consumption behaviors?

This study is based on an ethnographic research, conducted in France, on 18 Turkish immigrants (seven first generation and 11 second generation participants) followed during a period of 18 months. Data were mainly collected by means of in-depth interviews and participant observation, and complemented by factual data on the narrators, indirect indicators (e.g., social capital indicators captured during the interviews), and photography, in order to increase the richness of the data set. During the semi-structured interviews, questions covered the interviewees' life histories, their feelings about their host and the home society, their food and media consumption habits, and more. Data were analyzed iteratively consistently with interpretive research logics and through a circular theory-field process.

Our findings are two-fold. First, we detect four main nostalgia consumption strategies deployed by immigrants' along their process of acculturation: shelter, tribute, solidarity, and reculturation. More expectedly, when immigrants are dissatisfied with their extant life due to isolation, negative stereotypes or marginality (cfr. Tolstikova and Molander's, Lindridge's, and Ucok Hugh's papers in this session), they may indulge in nostalgic consumption — typically of food, given its pervasive capability of activating various senses and Turkish soap operas — so to build a *shelter* in which to escape the arduousness of their life. More notably, nostalgic consumption can be used as a *tribute* to the home country. The largest majority of Turkish immigrants in France, including our informants, migrated for economic reasons looking for better job opportunities. As a consequence, many of these migrants later developed a sense of guilt because they felt they had abandoned their country for personal financial gain. Paradoxically, the perceived betrayal of a beloved Turkey, due to personal materialistic reasons, is emended through materialistic purchase and consumption of nostalgic goods (cultural products as DVDs, albums, decoration objects, etc.). These purchases then become a tribute to their home country where their achieved economic capital is transformed into symbolic and cultural capital (cfr. Üçok Hughes' paper in the session).

Nostalgic consumption may also serve at a social level, and notably within the local ethnic community, as an expression of *solidarity*. Our data shows that Turkish immigrants are evaluated and sanctioned by relatives and other Turkish acquaintances living in France. As such, the decision of indulging in nostalgic consumptions (folklore, food, narratives, etc), as a form of reciprocal support, testifies to their common belongingness; the celebration of an "ideal us", as opposed to the dominating French society. Finally, and especially

for second generations, nostalgic consumptions serve as means of *reculturation*. Food, Turkish art, media, and ethnic retailing shops respond to the quest of yearning and understanding of Turkish culture for Turks living in France, who have grown up in a different cultural context. Reculturation applies also to first generation immigrants, but in this case nostalgic consumptions are used to revisit, revise, and groom their pristine cultural background.

A second order of findings illustrates the nature of the connection between home country, nostalgia and consumption. Empirical evidence demonstrates a *circular, self-feeding process* through either the exposure of Turkish immigrants to nostalgic consumptions activates nostalgic feelings, or the search for nostalgic consumptions is guided by a pre-existing nostalgic emotion for the home country.

This work helps advance acculturation research by locating immigrant's nostalgia for the home country in the middle of the acculturation process. Nostalgic consumption then is not only an effect of acculturation but also a powerful part of it. A part that is capable of increasing/reducing immigrants' chances to succeed in their double integration into the host culture and the local ethnic community.

Social Status Implications of Transmigrants' Consumer Practices in Their Cultures of Origin

EXTENDED ABSTRACT

While substantial research focuses on the consumption practices and identity projects of immigrants in their cultures of settlement, this phenomenon is largely ignored with regards to transmigrants' cultures of origin. Rooted in ethnographic empirical research, this paper explores the consumption practices, experiences, perceptions and identity negotiations of Turkish transmigrants, living in Denmark, during their annual visits to Turkey and the subsequent implications on their social status.

Research literature abounds with studies of acculturation patterns of people moving into a new culture, including patterns of immigrant consumer acculturation from one extreme (hyper identification) to the other (rejection). Recently, integration of transmigrant studies (Basch et al., 1994) have analyzed immigrants as being global, transnational, consumers whose lives and consumption practices are affected not only by interactions with their cultures of migration, but also with their cultures of origin (Üçok and Kjeldgaard 2005). These transmigrants are described as immigrants who continue to forge and sustain ties with their home/host cultures, implying connections to their countries of origin (Basch et al. 1994).

Transmigrants often acquire several identities, as their social status and class varies across social and national contexts. Many carry their possessions with them, often as status symbols. Yet, these possessions may connote different meanings in different contexts. For example, Caglar (2002) found that the decoration and organization of Turkish immigrants' homes, in Germany and Turkey differed strikingly, due to German Turks' quest for recognition. Being stigmatized in Germany as a foreign, non-European group, they suffer from a lack of social recognition. In contrast to their low status in Germany, working class German Turks find themselves economically closer to the middle class in Turkey. However, because Turkey is a class structured society, with invisible barriers to class mobility, transmigrants experience resistance from the Turkish middle class who find German Turks' symbolic capital to be insufficient for inclusion.

Beginning in the early 1960s, Turkey has witnessed major migratory movements, domestically and internationally. Üstüner and Holt (2007) researched the social status struggles of domestic migrants and their descendants who settled in big city squatters, and found that their efforts at social mobility were restricted by their lack of capital.

Turkish immigrants in Denmark constitute a heterogeneous group with regards to age, gender, education level, and occupation. For example, Üçok and Kjeldgaard (2005) found that within one group, savings accumulated in Denmark are transferred to Turkey to buy status-symbol goods, whilst in another group, economic capital is transferred, within Denmark, into social and cultural capital to facilitate successful integration. Typically, first-generation immigrants are likely to invest in Turkey by accumulating houses, land and shops in their hometown, and summer houses in coastal towns. They continue to support their relatives financially and contribute to the local community by donating towards the building of mosques or other communal buildings. Vacationing at five star holiday resorts on the Turkish Riviera also is popular, especially among the descendants (ibid).

Data for the current research were collected in Turkey and Denmark, amongst Turkish transmigrants, in five towns, over a period of two years. Semi-structured and in-depth interviews were conducted with members of Turkish immigrant communities in Denmark, as well as with their families living in Turkey. The author also participated in several cultural events in both countries and documented her observations via a research journal. Photographs were taken to document immigrants' homes (inside and outside), personal possessions and their cultural functions. Secondary data was also collected, mainly, through Turkish and Danish print media. All immigrants interviewed still held strong ties with their friends and families living in Turkey. This paper focuses then on the consumption practices of the immigrants during their annual visits to Turkey.

Vedat, a male, first generation immigrant informant, is typical of participants when he spoke about the *stigmatization* Turks living in Denmark encounter in their "home" town/country: "*When we go to Turkey they say we are tourists, they don't look at us. We have become strangers. The villagers . . . they look at us and call us gavur-cusun* [you are a foreigner] … *everywhere! Once you are in Turkey, everywhere*". *Gavur,* meaning "an infidel", is a term, heavily laden with negative connotations, applied by Turks to Islamic disbelievers, especially Christians. Similarly, the word *Almancı,* "Germanite", connotes that the emigrants are non-Turkish "foreigners", associated with Europeans and Christians. Thus, Turks visiting Turkey are seen as tourists in a place they consider their home. This stigmatization is common among the upper-middle class Turks, who often perceive Turkish immigrants as *nouveau rich*, working class, peasants.

Üstüner and Holt's (2007) description of second-generation squatter women in Turkey, also applies to the second-generation informants in this study, whose relation to their parents' villages is one of *deterritoralization*, lacking in a natural connection. Many of these informants migrated to European cities, often having never experienced the consumer acculturation that they would have gained had they lived in large Turkish cities. Upon arriving in Europe, they lived in immigrant enclaves and stuck to their roots, thus severely affecting their acculturation process, resulting in lower cultural and social capital.

In summary, in a less industrialized country, such as Turkey, where socio-cultural structures create barriers for social mobility, Turkish transmigrants may hold economic capital but this does not necessarily transfer into cultural and social capital, necessary to allow them to be accepted and participate in Turkish society. This can manifest itself as stigmatization of the consumers, which then can result in them feeling alienated from the community of which they consider themselves to be a part. The transmigrants' identity positionings in various national and socio-cultural contexts are prob-

lematic because they are far from being fluid. Building on previous literature (Caglar 2002; Üstüner and Holt 2007; 2010) the contributions suggest conceptualization of transmigrant identity positionings in the cultures of origins similar to those that have been conceptualized in the cultures of destination.

SESSION OVERVIEW

A great deal has been learned in recent years about the role of culture in consumer psychology. However, despite the rapidly accumulating evidence of culture as a determinant of consumer behavior, nearly all of the evidence has dealt with a broad-based cultural distinction – the distinction between individualist (IND) and collectivist (COL), or independent and interdependent, cultural classifications (Shavitt et al. 2006). This distinction is profoundly important, and thus represents the most broadly used dimension of cultural variability for cross-cultural comparison (Gudykunst & Ting-Toomey, 1988). However, there are limitations on the insights afforded by any broad dimension. This session unites under a common theme of investigating novel cultural dimensions that can afford a more nuanced understanding of cultural patterns in consumer behavior. Specifically, the papers in this session focus on power distance beliefs (PDB), or the extent to which a society accepts human inequality in the distribution of power, wealth, or prestige (Hofstede 1980), and on honor cultures, or those in which a person's claim to virtue is the value of the person in his own eyes and the eyes of his society (Cohen 1998). Although both of these dimensions have emerged as reliable predictors of a variety of patterns in social behavior (e.g., reliance on fair processes or violence for resolving disputes, Brockner et al. 2001; Cohen 1998), relatively less is known about their role in consumer behavior. This session is aimed at filling this gap.

The first paper by Lalwani, Torelli, J. Wang, & Y. Wang investigates the effects of the interplay between consumers' PDB and their position in the social hierarchy (i.e., low vs. high social standing) on preferences for premium over generic brands. In a first multi-country study using actual purchases of national (more premium) brands and private labels (more generic brands), they find that, after controlling for other cultural dimensions in Hofstede (1980) framework (e.g., IND) and other relevant country-level factors (e.g., level of devel-

opment of private labels), high (vs. low) PDB was associated with *higher* preference for premium (national) brands over generic (private label) brands. This effect was stronger for functional (vs. symbolic) products. In a second study using priming procedures, low (vs. high) status consumers exhibited higher preferences for premium over generic brands of functional products, but only under high (and not low) PDB. In contrast, high (vs. low) status individuals exhibited higher preferences for premium over generic brands of symbolic products, but only under low (and not high) PDB. These findings are interpreted in terms of the instrumentality of premium brands for conveying social status, something of value in high (vs. low) PDB contexts, and particularly so for low status individuals when buying common functional products.

The second paper by Winterich and Zhang explores the effects of the link between PDB and perceived outcome efficacy on charitable giving. Because people in high (vs. low) PDB cultures are more likely to accept social inequalities and to believe that everyone should have a defined place within the social order, they are hypothesized to have lower outcome efficacy (i.e., the expectation that one can contribute to effective solutions), which in turn should decrease their charitable giving to aid others (i.e., aiding others will not change the social order). An exploratory study using multi-country data on charitable giving showed that PDB negatively predicted percentage of giving, private philanthropy, and volunteering at the country-level, even after controlling for other cultural (e.g., IND) and country-level factors (e.g., GNP). A series of studies measuring PDB at the individual-level or using priming procedures further showed that high (vs. low) PDB resulted in less charitable giving via lower perceptions of outcome efficacy. These findings have important implications for understanding cross-cultural patterns in charitable giving beyond predictions using the IND-COL distinction.

The third paper by May, Monga, and Kalaignanam focuses on an unexplored variable in consumer research—endorsement of honor values, and its effect on responses to brand failures. Across three lab studies and one archival data study on real consumer complaints across different U.S. states (known to vary in ascription to honor values), the authors find that endorsement of honor values positively predicts retaliatory behavior in the case of a brand failure. They also find that this relationship is stronger in the event of a process (vs. outcome) failure and is attenuated when high-honor consumers are given the opportunity to personally punish the service person responsible. Perceptions of abuse were found to mediate the effects. These findings contribute to our understanding of the cultural factors that can trigger vengeful behavior and consumer satisfaction.

The final paper by Wang, Wang, and Fang investigates the effect of PDB on consumers' assessments of desirable personality traits ascribed to brands. In a series of studies, the authors find that high (vs. low) PDB increases the likelihood of associating favorably-evaluated personality traits with in-group (vs. out-group) brands (i.e., rating in-group brands higher in terms of desirable personality traits than out-group brands). They further demonstrate that consumers' tendencies to categorize brands according to the social groups they represent mediate the relationship between PDB and ascribing desirable personality traits to in-group (vs. out-group) brands.

The papers share several important linkages on affording a more nuanced understanding of cultural patterns in consumer behavior be-

yond the IND-COL classification, while adding slightly different perspectives. Collectively, the papers provide evidence for the effects of power distance beliefs and culture-of-honor values on consumption decisions both at the cultural group level (i.e., entire countries or regions within a country) as well as at the individual level, which highlights the usefulness of these novel cultural factors. The papers also illuminate on some of the psychological processes associated with these cultural dimensions (e.g., low outcome efficacy in high PDB cultures, perceptions of being abused in cultures of honor, or brand social categorization). In keeping with the theme of the conference (Appreciating diversity), the papers in this special session investigate a diverse set of consumption-related outcomes (e.g., brand preferences and choices, charitable giving, brand evaluations, complaining behavior) that are culturally-patterned when considering the dimensions of power distance and honor values. The findings in this session should appeal specifically to scholars interested in cross-cultural consumer behavior, donating behavior, advertising, branding and more generally to those interested in the psychological processes underlying product evaluation.

The Interplay between
Power Distance, Position in the Social Hierarchy, and Product Type: Consequences for Consumers' Preferences for Premium over Generic Brands

EXTENDED ABSTRACT

In his celebrated treatise on the "leisure class," Veblen (1899) introduces the notion of conspicuous consumption as a way of conveying one's wealth and social status to others. This observation has spawned considerable research explaining why and when consumers' prefer premium or luxury brands that are instrumental for symbolizing high-status (e.g., Rucker and Galinsky 2008; Han, Nunes, and Dreze 2010). As judged by the global growth of these brands, consumers in every culture appear to rely on these brands for enhancing their status. Nevertheless, some researchers suggest that there seems to be a higher need for premium brands as status symbols in cultures that accept and expect power differences between citizens (i.e., those that are high in power distance belief or PDB) (de Mooij & Hofstede 2010; Kim & Zhang 2011). In these cultures, people emphasize status, prestige, and wealth as these form the basis of their standing in society (Hofstede 2001), which in turn leads these people to prefer premium (vs. generic) brands. However, the empirical evidence for this premise is mixed at best. Although some small-scale studies suggest that consumers high (vs. low) in PDB attach more importance to products' brand names (Bristow and Asquith 1999; Robinson 1996), other large-scale studies show no relationship between power distance and the role of brands as signals (Erdem, Swait, and Valenzuela 2006). We propose that past research on the topic has neglected to consider important factors that moderate the link between PDB and preference for premium brands. Specifically, we investigate in this research the impact of one's position in the social hierarchy (high vs. low) and the type of product under consideration on the link between PDB and preference for premium brands.

One's position in the social hierarchy can be a strong determinant of consumer behavior. Because high-status individuals often accumulate wealth and acquire power (Magee and Galinsky 2008), research suggests that they develop preferences for products offering utility (e.g., performance, quality, Rucker and Galinsky 2009), rather than for the sake of ascertaining status. However, high-status consumers facing choices of luxury products can still choose high-status products that only those "in the know" can recognize (i.e., most expensive products with 'quieter' logo designs, Han et al. 2010).

In other words, high-status individuals can be quite discerning in their product choices and can choose functional, performance based products in one context, and high-prestige products in another. This is consistent with the view that high power/status individuals engage in situation-specific judgment and behavior (Guinote & Vescio 2010). In contrast, low status/power individuals tend to respond in less situation-specific ways (Guinote & Vescio 2010), and to base their choices more on status affordances than on performance-based reasons (Rucker and Galinsky 2009). Because in high (vs. low) PDB societies prestige and wealth shape vertical relationships between socio-economic classes, the tendencies just described should be particularly strong in high (vs. low) PDB contexts. We thus propose that under high PDB, and when choosing among functional products that offer utility, low- (vs. high-) status individuals should be more likely to prefer premium brands associated with status over generic brands promoted on the basis of performance. However, because for symbolic products most people would rely on social identity criteria like prestige and status, both high and low-status consumers would prefer premium over generic brands. These effects should be weaker (or absent) in low PDB contexts that do not emphasize prestige and wealth in shaping social relationships.

Based on the notion that private labels are commonly positioned as generic brands that offer a price discount for lower or comparable quality, relative to national brands (Vaidyanathan & Aggarwal 2000), study 1 operationalized the relative preference for generic (vs. premium) brands as the market share of private labels in the country. We estimated a linear model with the country-level share of private label brands (from Euromonitor database; N = 519) for different product categories varying along the functional-symbolic continuum (e.g., hair care, household care, or apparel) as the dependent variable, and country-level scores for power distance, uncertainty avoidance, masculinity, and individualism (Hofstede, 2001), the GINI coefficient (a measure of country's income inequality), the level of private label development in the country, the level of product symbolism, and the interaction between this last term and the power distance score as predictors. As expected, power distance emerged as a significant negative predictor of private label share, suggesting that in high (vs. low) PDB countries consumers prefer less private label than premium brands. Furthermore, this effect was qualified by a significant PDB x product symbolism interaction, such that the negative relationship between PDB and private label share was higher for functional compared to symbolic products. Considering that the sample in the study comprised low and middle status consumers, these findings support the hypothesis that in high PDB contexts, low and mid-status consumers prefer premium over generic brands, and particularly so for functional products.

In study 2, we manipulated power distance belief (high vs. low) and status (high vs. low) between –subjects and asked participants about their preferences for premium over generic brands of functional and symbolic products (within-subjects). Results showed that in the high PDB condition, low (vs. high) status participants exhibited greater preferences for premium (over generic) brands of functional products. In contrast, they showed similar higher preferences for premium brands of symbolic products. These differences were not observed in the low PDB condition.

The findings in this research are consistent with the notion that, in high (vs. low) PDB contexts, people low (vs. high) in status prefer premium (over generic) brands due to their instrumentality for conveying social status, something of value in high PDB contexts. Furthermore, this is particularly the case with functional products that are often more likely to be impacted by cultural factors (Lee and Shavitt 2006; Monga and John 2010). A third study for which

data collection is underway explores the mediating role of the instrumentality of premium brands for fulfilling status concerns on the reported effects.

Equality Equals Efficacy: The Effect of Power Distance Belief on Charitable Giving

EXTENDED ABSTRACT

Charitable giving differs significantly across cultures, with Australia and New Zealand found to be the most generous countries in the world (Charities Aid Foundation 2010). Though not among the wealthiest countries, these countries are both characterized by low power-distance belief. Power-distance belief (PDB hereafter) has been defined as the degree of power disparity the people in a culture expect and accept (Hofstede 1984, 2001; Oyserman 2006). Can such a belief impact consumers' charitable giving? Though much attention has been given to individualism/collectivism (Aaker and Lee 2001; Oyserman and Lee 2007), Oyserman (2006) notes that PDB was the first cultural factor identified by Hofstede (1984). We theorize that the accepted inequality among those with high PDB results in lower perceptions of outcome efficacy, which represents the evaluation of the extent to which one can contribute to effective solutions (e.g., Stern et al. 1999; Van Liere and Dunlap, 1978). In turn, those with higher PDB donate less.

The central difference between high- and low-PDB cultures does not lie in actual power disparity per se, but in people's attitudes toward power disparity. Consumers in high PDB cultures tend to be more likely to accept inequality. Accordingly, high PDB cultures facilitate a norm that everyone should have a "defined" place within the social order. Consumers who are aware of these social orders feel the existing social order should be well respected and any effort in altering this order tends to be regarded as fruitless (Bourdieu 1984; Miller et al. 1993). Thus, we expect consumers in this social order-salient mindset to believe that aiding others will not change the social order, or, in other words, have low outcome efficacy.

In contrast to high PDB cultures, the norm in low PDB cultures is to maintain and respect the equality inherent in social interactions (Hofstede 1984, 2001). Even though an actual disparity in power may exist, individuals in these cultures do not believe that differences in power, wealth, and prestige are inevitable (Oyserman 2006). As such, consumers may seek out opportunities to achieve equality and should believe that aiding others will make a difference in changing the unjust social order. Given the expectation and acceptance of (in)equality in (high) low PDB cultures, we theorize that PDB influences 1) perceptions of outcome efficacy when aiding others (due to unavoidable social order) to achieve equality, and 2) charitable giving. Specifically, high PDB consumers will have lower perceptions of outcome efficacy and donate less to charities to aid others than low PDB consumers.

Exploratory analysis revealed that country-level power-distance belief (Hofstede 2011) predicted percentage of giving, private philanthropy, and volunteering at the country-level, even after controlling for collectivism, education, GNP, and income inequality. Therefore, we conducted a series of studies to examine this pattern at the individual level and demonstrate causality. In the first study, we measured PDB of online survey participants and, after a filler task, asked them to choose between a donation to a charity or a bonus payment for themselves. PDB predicted choice of donation, regardless of self-construal, such that those with higher PDB were less likely to choose the donation. Study 1B replicated this finding when PDB was made temporarily accessible using a sentence-scrambling task (Zhang, Winterich, and Mittal 2010). We next examined the underly-

ing mechanism of outcome efficacy (Steg and de Groot 2010). As in Study 1, measured PDB predicted donation intentions, but, importantly, this effect was mediated by outcome efficacy such that those with higher PDB had lower outcome efficacy which led to lower donation intentions.

In Study 3, we examined the moderating role of charity recipient to causally test our proposed psychological process of outcome efficacy (Spencer, Zanna, and Fong 2005). If consumers with higher PDB choose not to donate because they believe inequality will exist regardless of their efforts to aid less fortunate others, then these consumers should not differ from those with lower PDB in their donations when the donation benefits others regardless of social class. This study considered recipients to be the general public or specifically the poor and needy. The study was a 2 (PDB prime: high vs. low) X 2 (charity recipient social class: lower vs. higher) between-subjects design with a non-profit organization described as advocating art for everyone and improving communities versus advocating art for families in poverty. Results revealed a significant interaction between PDB and charity recipient such that PDB predicted donation likelihood for lower social class charity recipients but not for higher social class charity recipients. Moreover, outcome efficacy mediated this effect on donation likelihood, supporting our theorizing.

A final study sought to identify a boundary condition for the effect of PDB on charitable giving such that consumers, regardless of PDB, would donate to a charity aiding those in the low social class at the same rate that those with low PDB do. We focus on cause involvement as the potential moderator. PDB was primed between-subjects and involvement with the arts was measured continuously with participants asked to allocate 50 cents to a charity for the arts versus a bonus payment to themselves. A significant interaction revealed that PDB only predicted donation allocation for those with low cause involvement. When cause involvement was high, donation allocations did not differ by PDB. Again, outcome efficacy mediated this effect such that those with greater cause involvement had higher perceptions of outcome efficacy even when in the high PDB condition.

These results have important theoretical implications for understanding the drivers of charitable giving, particularly cultural factors beyond collectivism. By understanding the role of outcome efficacy in this effect, we can suggest ways in which this effect of PDB can be overcome to increase donations, which may be particularly important given the increasing standard of living among consumers from developing countries such as BRIC. We hope this research advances understanding of factors influencing charitable giving, moving from individual and cultural level variables beyond those of self-construal or collectivism.

Eye for an Eye: The Effect of Honor Values on Consumer Responses to Brand Failures

EXTENDED ABSTRACT

Brand failures are becoming increasingly common and publicized. Examples include the recent recall of Tylenol products from the market place, the unreasonable increase in Netflix prices, and the listing of Bank of America and AOL in MSN money's "customer service hall of shame." Compounding these problems, huge advancements in social media allow consumers to exact revenge on businesses that have wronged them. Social networking websites (e.g., Facebook) and anti-business websites (e.g., walmartsucks.com) allow consumers to retaliate with far more ease and speed than ever before. Despite the vast amount of research which has been done in the area of brand failures (Ahluwalia et al. 2000; Dawar and Pillutla,

2000; Folkes 1984; Klein and Dawar, 2004; Pullig, Netemeyer, and Biswas, 2006), there is no research that addresses the role that honor values may play in consumers' response to such failures.

People who endorse honor values believe that one's worth or value is not necessarily a given; it must be earned and acknowledged by others (Pitt-Rivers 1966). Honor values are important because they vary not only across individuals, but also across geographic regions and cultures. People who endorse honor values are particularly sensitive to abuse (Ijzerman et al. 2007; Cohen et al. 1996). Cohen et al. (2006) found that people who do not endorse honor values were relatively unaffected by a person bumping into them and muttering an insult, while people who do endorse honor values were more likely to perceive abuse. Drawing upon this research, we propose that, people who strongly endorse honor values are more sensitive to brand failures, and therefore more likely to engage in retaliatory behaviors, such as complaining to the firm, spreading negative word of mouth, or posting negative online reviews.

In study one, participants were primed with either high or low honor and then exposed to a scenario that depicted a restaurant service failure. As expected, the participants in the high honor condition expressed a greater desire for vengeance than the participants in the low honor condition did.

In study two, we examine the effects of regional variations in honor. For example, residents of some states in the American South are more likely to endorse honor values (Cohen and Nisbett 1994; Nisbett and Cohen 1996). We examined transactional data spanning a twelve year period (1997-2009) from a U.S. catalog retailer. The database provides information on issuance of special coupons given to pacify angry customers (who were wronged by the retailer). We consider issuance of such coupons as a proxy for customer complaining to the firm because consumers who express their anger and complain are given these special coupons. Complaining is an important kind of vengeful behavior (Bechwati and Morrin 2003). No other coupons were issued in this period. We supplemented this database with demographic data, state-level honor scores (Nisbett et al. 1996), and individualism scores (Vandello and Cohen 1999). We estimated a probit model that links coupons issued to honor scores. We also controlled for several factors (e.g., individualism/collectivism, income, age, years of schooling, and population). We predicted and found that honor is positively related to issuance of coupons. Individualism is not significantly related to the likelihood of coupon issuance.

In study three, we examine the effects of honor on retaliatory behavior across process and outcome failure situations. An outcome failure refers to when an aspect of the promised product or service is not performed, resulting in an economic loss (e.g., a restaurant that served poor quality food). A process failure refers to a situation in which the product or service is not delivered in a satisfactory manner, resulting in a social loss (e.g., status, esteem) (e.g., a restaurant where the waiter ignores the customer) (Chan and Wan 2008). We used a 2 (ascription to honor values: high vs. low) X 2 (failure type: outcome failure scenario vs. process failure scenario) between subjects design. We used a different stimulus in this study, consisting of a computer service failure scenario. Honor was measured using an honor scale (Cohen and Nisbett 1994). Because process failures tend to be more social in nature, and honor values are associated with social situations, we predicted that a stronger effect of honor values on vengeful behavior would emerge in the process failure than in the outcome failure conditions. Our results supported our prediction and perceptions of abuse by the firm mediated the effects of honor on retaliatory behavior.

In study four, we examine the process mechanism. We used a 2 (ascription to honor values: Republicans vs. Democrats) X 2 (punishment: present, absent) between subjects design. In this study, honor was operationalized using political party identification. In general, the Republican Party endorses issues that are important to high honor consumers (e.g., gun ownership, strong national defense; Cohen 1996) A pretest confirmed this intuition, as Republicans scored higher on an honor scale than Democrats did. Since people who endorse honor values believe that honor is something that can be both lost and regained, and are driven to maintain honor, giving these people an opportunity to restore lost honor should attenuate the desire to retaliate against the brand. We predicted that for people high in honor, desire to engage in retaliatory behavior against the brand after the service failure would be lower when allowed to have a hand in punishing the offending service employee vs. when not allowed, whereas for people low in honor there would be no significant difference across conditions. Our results supported our prediction and perceptions of abuse mediated the effects of honor and punishment on retaliatory behavior.

Our findings make important contributions to the area of branding, brand failures, and cultural values.

Power Distance Belief and Brand Personality

EXTENDED ABSTRACT

Brands, as consumption symbols, carry important cultural meanings in consumers' minds. Past research has showed that different cultures influence consumers' perceptions of various brand personality dimensions (e.g., Aaker et al. 2001). In this research, we investigate the effect of power distance belief (PDB hereafter) on brand personality evaluations. PDB refers to the extent to which people "accept and expect that power is distributed unequally" (Hofstede 2001, p. 83). Though marketing scholars gradually recognize the importance of examining the influence of PDB on consumer behavior, only a handful of studies have done so (e.g., Zhang, 2011). We extend the current stream of research on PDB to variations in consumers' assessments of personality traits ascribed to brands and identify the underlying mechanism of these variations.

People with high PDB expect to see unequal power distribution in a society and attend to differences among various classes within the social hierarchy (Gaertner et al. 1989). Therefore, we argue that they are more aware of in-group--out-group differences and thus tend to regard in-group members as more superior than out-group members. In this research, we extend this social categorization concept to the brand level. Since brands carry important symbolic meanings, we expect that consumers may also arrange brands into a hierarchy according to the groups that these brands symbolize. We refer to this as an individual's brand social categorization tendency. People high in PDB, who accept power disparity in a society and believe that power should be distributed unequally, should cognitively develop a high tendency to arrange objects such as brands in a hierarchy according to the groups associated with these brands. In contrast, people with low PDB would perceive relatively equal power distribution in a society, which should lower their tendency to categorize brands in this manner. Therefore, we expect that high (vs. low) PDB should increase the likelihood of associating favorably-evaluated personality traits with in-group (vs. out-group) brands. More importantly, we propose that brand social categorization tendency mediates the relationship between PDB and ascribing desirable personality traits to in-group (vs. out-group) brands.

We conducted a series of studies to test our hypotheses. Study 1 explored the relationship between PDB and brand personality traits.

The sample consisted of 926 coffee consumers in three major cities in Mainland China. Participants were instructed to think about a coffee store brand they frequently go to (in-group brand). Power distance beliefs (PDB) and five dimensions of brand personality were measured. The results showed that PDB exerted a significantly positive influence on the ratings for the five brand personality traits (all ps < .05).

Study 2 used two experiments to test the potential mediation effect of brand social categorization tendency. In Study 2A (N = 64), participants were either primed with high or low PDB. They were then given ten brands of sportswear and were asked to imagine each brand as a person and categorize the brands as in-group members, out-group members, and those with no clear associations with either group. Brand social categorization tendency was measured by three items, adapted from Gaertner et al. (1994) (e.g., I usually feel that the brands belong to different social classes). The main dependent variable was the perceived difference between in-group and out-group brands. Results showed that individuals with high PDB displayed greater brand social categorization tendencies than those with low PDB. Furthermore, participants in the high-PDB condition perceived a greater difference between in-group and out-group brands (M = 5.82) than those in the low-PDB condition (M = 4.41, F = 16.92, p < .05). To enhance generalizability and the robustness of our finding, we conducted Study 2b using a different categorization measure in a different product category.

In Study 2b (N = 62), Chinese participants followed a similar procedure with a few exceptions. Ten familiar brands of cell-phones were used as stimuli, and participants were asked to categorize these ten brands by drawing circles including the brands they thought belonged to the same group. We expected that the stronger the social categorization tendency participants have, the more circles that they should draw. The results showed that participants in the high-PDB condition drew more circles (M = 3.47) than those in the low-PDB condition (M = 2.56; F = 16.31, p < .05), indicating that individuals with high (vs. low) PDB tend to categorize brands more in terms of their associations with social groups. Next we conducted Study 3 to directly test brand social categorization tendency as mediator of the relationship between PDB and the extent to which desirable personality traits are ascribed to brands.

In Study 3, upon the completion of the PDB priming task, participants were asked to imagine Adidas (an in-group brand, from a pretest) and XTEP (an out-group brand) as individuals and to rate the two brands on the "competence" dimension (rated as the most important brand personality trait in sportswear category based on the pretest). Results indicated that individuals in the high-PDB condition associated Adidas more with the desirable "competence" dimension (M = 5.44) than those in the low-PDB condition (M = 4.79, p < .05). In contrast, individuals in the high-PDB condition associated XTEP less with the same dimension (M = 3.19) than those in the low-PDB condition (M = 3.70, p < .05). Further, participants in the high- (versus low-) PDB condition perceived the difference between the desirable trait ascribed to the in-group and the out-group brand as significantly larger ($M_{high-PDB}$ =2.24, $M_{low-PDB}$ =1.10, p < .05). In sum, these findings suggest that high (vs. low) PDB increases the likelihood of associating favorably evaluated personality trait with in-group (vs. out-group) brands. Furthermore, our mediation analysis showed that this effect was mediated by participants' tendency to categorize brands according to their associations with social groups.

Our research makes important contributions to the current brand personality literature by investigating the link to a less-researched cultural dimension: power distance beliefs. Brand social categorization tendency was found to mediate the relationship between PDB and the difference in desirable personality traits ascribed to in-group and out-group brands.

SESSION OVERVIEW

When experiencing daily interactions we often think of the momentary evaluation of an experience and its following evaluations as one. However, we now have mounting evidence to the contrary from psychology and neuroscience studies. Eating the chocolate or remembering its taste an hour later are distinguishably different experiences. We trust our memories and evaluation of past events and attach high confidence to them. Our evaluation of past experiences is often shaped by their encoding in our brains and the momentary emotional state we are at upon recalling them. Remembering, therefore, is just another form of evaluation – prone to many failures.

In this session we will address the notion of experience versus its following recount through evaluation, and focus on its effects on consumer decisions. In a sequence of four talks, we will address multiple facets of the problem and suggest methods to assess the difference between experience and reappraisal, as well as evidence for its direct effects on choice and decision-making.

To address these notions, Karim Kassam will initiate the session by showing a novel imaging study that proposes evidence for identifiable emotions signatures that generalize across individuals. That is, a method by which we can isolate a certain emotion by reading brain activity when a subject is experiencing a certain feeling. The emotions tested vary and include complex emotions such as pride, embarrassment and shame. Presumably, these emotions, which are not necessarily accessible to the subjects themselves or to a direct survey can then be read using this method in order to infer consumer evaluation of current experience and of past experiences.

Following this emotional evaluation introduction, William Hedgcock will show the results of a series of studies, which focus on a type of emotional difference between the experience and its evaluation. Dr. Hedgcock's work focuses on a type of decisions prone to what s known as the framing effect, where decision makers respond differently to problems that are described in positive or negative terms despite the fact that the outcomes are objectively identical. In terms of evaluation of past choices, the framing effect provides evidence to the fact that our evaluations are not only likely to be mistaken but can easily be manipulated by the choice of question asked during the evaluation process. Additionally, Dr. Hedgcock will introduce the notion of emotion suppression as a tool that is often used by subjects to regulate their choices based on emotions.

The third project, presented by Hilke Plassmann, will look at the manifestation of the problem in effective consumer choices. In Dr. Plassmann's work, subjects are asked to evaluate a preference based on their past experience – in the particular case, the taste of wine - and are showing biased choice based on monetary rewards received earlier. This direct manipulation of the choice acts as another evidence for the difference between the pure objective taste, which we deem the experience, and the following modified evaluation.

While the previous three presentations addressed the choice and the evaluation mainly using imaging techniques and behavioral responses, the fourth presentation will target the question using an alternative method, which is proven more precise yet less spatially distributed and quite invasive: directly recording of the activity of single neurons in the brains of humans undergoing neurosurgery. Moran Cerf's presentation will demonstrate the ability to identify signature correlates of emotions similar to the work shown in the first presentation, only at the level of individual neurons. Dr. Cerf demonstrates the ability to identify single-neuron correlates of the experience and the regulation of a given emotion while patients are either empathizing with emotional content expressed, or while the patients are regulation the emotions and trying to change their evaluation of it. Regulation of the emotion will be demonstrated both using internal manipulation by the patients, or external biases of decision making as shown in the third work.

The four talks will address the ability to exhibit emotion and experiences in the lab, and scientists the ability to measure these emotions using various methods ranging from surveys, to imaging and invasive recordings of single neurons in the brains. The talks will show evidences for the differences between the direct experiences and the following evaluation of it over time, with evidence for the ability to bias decisions under certain conditions of reward or framing. Finally, the four presenters will show alternative methods used to regulate or enhance such biases and will address their potential usage in consumer psychology.

Audience and level of Completeness

The potential ACR audience for this session is quite broad. This session will be of interest to researchers in the following areas: attitudes and intentions, affective and emotional processing, and decision making. In addition, it will be of interest to practitioners who use survey research methodologies, and researchers interested in exposure to imaging techniques and the novel single-neuron recording in humans.

All four presentations will present the results of completed studies.

Discussion

Moran Cerf will be the leading a discussion at the end of the session. Dr. Cerf is has been involved in both neuroscience and mar-

keting research, and has published papers in both fields as well as decision-making studies. Method-wise, his work has involved both imaging works and single-neuron recordings, which are the main methods discussed in the session. He therefore has a unique perspective for discussing these papers and leading a discussion about an appropriate research agenda for continued work in this area.

Plan for the Session

Each work will be presented for 15 minutes, followed by 5 minutes of question and answer. We will leave 15 minutes at the end for a general audience discussion.

Identifying Emotions on the Basis of Neural Activation

EXTENDED ABSTRACT

Development of reliable measures of specific emotion has proven difficult. Self-report, still the gold standard, is vulnerable to deception and demand effects. Physiological measures such as heart rate and skin conductance show some ability to discriminate between broad categories of emotion but have limited ability to make finer classifications. Facial expressions have also been used to categorize a subset of emotions, but emotions can occur in the absence of facial expressions and facial expressions can occur in the absence of emotion. Neural circuits that mediate certain emotion-related behaviors (e.g. freezing) have been identified, but researchers have yet to achieve reliable identification of emotions on the basis of neural activation. In short, existing methods of emotion measurement suffer from a variety of limitations.

Neuroimaging data has held the promise of providing more powerful methods for identifying emotions, but the promise of fMRI has yet to be realized. The search for neural correlates of emotion may have been hampered by the use of statistical methods not well suited to the task of identifying spatially-distributed activation signatures from very large data sets. Indeed, recent meta-analyses of fMRI studies using univariate analyses failed to find any region that was specifically and consistently activated by a single emotion.

Rather than search for neural structures associated with specific emotions, we applied recently developed multi-voxel pattern analysis techniques to identify distributed patterns of activity associated with specific emotions. These techniques relax linearity assumptions and acknowledge the fact that neural responses to emotional stimulation occur in many brain areas simultaneously. These algorithms frequently result in increased predictive power, and recent research suggests that they hold promise for classifying emotion using neurological and physiological data.

We applied a Gaussian Naïve Bayes pooled variance classifier to neurological data to classify a broad variety of emotional experiences. Participants were method actors experienced with entering and exiting emotional states on cue. Prior to the neuroimaging session, each wrote scenarios that had made them feel or would make them feel emotional states denoted by 18 words grouped into nine emotion categories: anger (angry, enraged), disgust (disgusted, revolted), envy (envious, jealous), fear (afraid, frightened), happiness (happy, joyous), lust (lustful, horny), pride (proud, admirable), sadness (sad, gloomy), and shame (ashamed, embarrassed). Participants also wrote a calm scenario that was used as a baseline. In the scanner, participants were given nine seconds to imagine the scenario and enter the appropriate emotional state, followed by eleven seconds to exit that state, rate their emotional intensity, and prepare for the next trial. Once this portion of the session was complete, participants viewed 12 disgusting images and 12 calm/neutral images in random order.

We first examined the ability of our classifier to identify a participant's emotion on a particular trial on the basis of his/her neural activation during the other trials. In the cross-validation procedure used to assess emotion identification accuracy, the classifier was trained on four of the six presentations of a word and tested on the average of the two presentations held out. We report the mean rank accuracy of the classification performance, that is, the percentile rank of the correct emotion category in the classifier's posterior-probability-ordered list of emotions, averaged across the 15 ways of choosing two of six presentations. If the classification were operating at chance level, one would expect a mean normalized rank accuracy of 0.50, indicating that the correct emotion appeared on average in the fifth position in the classifier's output of a ranked list of all nine emotions. The rank accuracies for this within-subject analysis ranged from 0.72 to 0.90, with an average of 0.84, well above the chance classification rate of 0.5 (a mean accuracy greater than .51 would be significant at the $p = .05$ level). Thus, a participant's neural activation patterns on one subset of trials could be used to reliably identify their emotions on a separate subset of held-out trials, indicating that participants exhibited consistent patterns of neural activation for all emotion categories.

Next we examined whether a participant's specific emotions could be identified on the basis of other participants' activation patterns. For these tests, the emotions experienced by each participant were identified using a classifier trained on the activation data from the other nine participants. Despite the challenges presented by individual variability in functional organization and methodological difficulties in normalizing morphological differences, the classifier achieved a mean rank accuracy of 0.70, well above chance levels (accuracy of 0.56 significant at the $p = .01$ level). Our classifier predicted the emotions experienced using activation patterns of other participants at significantly better than chance levels for eight of ten participants, suggesting that the neural correlates of emotional experience share significant commonality across individuals.

Finally, we investigated whether patterns of activation observed in self-induced emotion trials could predict the emotional content of a stimulus of an entirely different modality. We trained a classifier using participants' neural activation during word-cued self-induced emotions, and tested whether it could identify the emotional content of a visual image. Successful classification would indicate that the activations observed correspond to emotional experience in general, rather than remembered or imagined emotional experiences specifically. This classification identified responses to disgust pictures with a rank accuracy of 0.91, well above chance rates (accuracy of 0.74 significant at the $p = .01$ level). Thus, even though the classifier had not encountered neural activation in response to pictures, it was able to accurately identify the emotional content of pictures. The results demonstrate a consistency in the neural representation of emotional response to qualitatively different stimuli.

In sum, we show that specific emotional states can be identified on the basis of their neural signatures, and that these signatures are reliably activated across episodes, across individuals, and across different types of emotional experiences. The results inform our understanding of emotional processes, highlight the predictive value of specific emotions, and suggest the potential to infer a person's emotional reaction to an arbitrary stimulus – a flag, a brand name, or a political candidate, for example – on the basis of neural activation.

Risk and Attribute Framing: They're Different

EXTENDED ABSTRACT

Framing effects occur when decision makers respond differently to problems that are described in positive or negative terms despite the fact that the outcomes are objectively identical. Framing effects are most often treated as homogenous phenomenon, though some research suggests there may be several distinctive types of frames (Levin, Schneider, and Gaeth, 1998). Two of the most common framing types that have been identified are risk and attribute framing. Risk frames involve a choice between a risky and a riskless option, and individuals typically have a higher preference for risky options when the problems are described in negative terms. In contrast, attribute frames involve evaluations where options are either risky or riskless and attribute descriptions, such as quality, are manipulated. Individuals typically give higher evaluations for options when the attributes are described in positive terms (e.g., % chance of being successful) and lower evaluations when the attributes are framed in negative terms (e.g., % chance of being unsuccessful).

Critically, these different framing effects may be caused by independent processes (Levin, Gaeth, Schreiber, 2002; Van Schie & Van der Pligt, 1995). In fact, within subject measurements of risk and attribute framing have not been significantly correlated (Levin et al., 2002). Additionally, risk framing and attribute framing correlate with different personality traits. Risk framing preference reversals correlate with high neuroticism, low openness, high conscientiousness, and low agreeableness (Levin et al., 2002). In contrast, individual differences in attribute framing correlate with low conscientiousness and high agreeableness (Levin et al., 2002). Note that though these two personality traits are correlated with risk framing as well, the correlations are in opposite directions.

There is some evidence that risk framing is associated with emotional processes (De Martino, Kumaran, Seymour, Dolan, 2006); though the evidence is mixed (Talmi, Hurlemann, Patin, Dolan, 2010). De Martino et al. (2006) found a correlation between "rational" decision making and activity in the ventromedial prefrontal cortex (VMPC). They further found that the anterior cingulate cortex (ACC) and the amygdala were involved in framing. In contrast, Talmi and colleagues (2010) did not find any differences between patients with amygdala damage and controls.

We conducted a series of behavioral and functional magnetic resonance imaging studies to investigate processing differences in risk and attribute framing using a within subject valence manipulation. The studies reported here examined (1) which personality traits were correlated with risk and attribute framing, (2) how risk and attribute framing effects were affected by emotion suppression instructions, and (3) the neural correlates of risk and attribute framing. We predicted:

Risk and attribute framing would have different personality trait correlates.

Attribute framing would be affected by emotion suppression instructions while risk framing would not be affected by emotion suppression instructions.

Risk and attribute framing would show distinct patterns of neural activation. Specifically, we predicted attribute framing effects would be more strongly associated with activity in regions of the brain such as the amygdala and VMPFC (regions associated with emotional processing) than risk framing.

Here we provide a series of studies demonstrating that independent processes likely govern attribute and risk framing.

Risk and Attribute Framing Correlate Study

Participants responded to risk and attribute framing questions as well as filling out the Big 5, and questions designed to measure their levels of risk and loss aversion. Attribute framing effects were not correlated to risk aversion, loss aversion, or any of the Big 5 personality traits (all ps > 0.15). On the other hand, risk framing effects were correlated with loss aversion (p < .05), neuroticism (p < .05), and numeracy (p < .05). This provides some preliminary evidence that risk and attribute framing may be caused by independent mechanisms.

Emotion Suppression Study

Participants responded to risk and attribute framing questions. Some of the participants received standard instructions to choose options they preferred the most while others received additional instructions to adopt a detached an unemotional attitude when choosing their preferred alternative. Participants in the control condition had the standard set of results. Negative risk framing increased risk seeking (p < 0.01) while negative attribute framing increased quality seeking (p < 0.05). However, results were different when participants received emotion suppression instructions. In this case, risk framing still lead to risk seeking (p < 0.01) but attribute framing did not lead to quality seeking (p = 0.41). Thus, emotion suppression did not affect risky framing but it did affect attribute framing.

fMRI Framing Study

Participants responded to risk and attribute framing questions while we measured brain activation with functional magnetic resonance imaging (fMRI). As expected, negative risk frames resulted in risk seeking (p < 0.01) while negative attribute framing resulted in quality seeking (p < 0.05). Preliminary analyses indicated the attribute framing effect was associated with activity in the amygdala and prefrontal cortex, whereas the risk framing effect was associated with activity in the parietal lobe. Moreover, there is very little overlap in activity between attribute framing and risk framing.

We provide considerable evidence that risk and attribute framing effects have different causes. We find risk framing is correlated with loss aversion, neuroticism and numeracy while attribute framing is not correlated to any of these measures. Further, we find emotion suppression affects attribute framing but not risk framing. Finally, we show risk and attribute framing have different neural correlates. Our results suggest researchers shouldn't assume risk and attribute framing are driven by the same processes.

How Incidental Affect Alters Subsequent Judgments: Insights from a Human fMRI Study

EXTENDED ABSTRACT

People do not have stable, coherent and readily accessible preferences that can be reliably measured through self-report. Instead, judgments are constructed on the spot and recent, contextual factors exert a disproportionate influence on judgments (Payne, Bettman, and Johnson, 1992; Slovic, 1995). These contextual influences include feelings that are unrelated to the judgment (such as moods, emotions, and expectation of receiving a reward, Schwarz & Clore 1996). Why is the brain susceptible to these types of rewards that engender such changes in revealed preferences? To address this question, we discuss the impact of incidental affect on the neural representation of experienced value, an essential computation in the process of value-based decision-making.

We scanned human subjects' brains (N=19, 6f, aged 21-46 years) using fMRI while engaging in a task that first involved the receipt of a monetary reward ($0, $50, $200) for real using a one-armed bandit task and subsequently the receipt of a food reward (two

different liked wines). During the tasting task, subjects were instructed to evaluate how much they liked the taste of each wine.

Behavioral analysis showed that the incidental rewards (i.e. amounts won from the slot machine) significantly biased participant's judgments of how much they enjoyed the wines (F(1, 18) = 7.46, p<.01). No effect on reaction times was found.

We ran a set of different univariate fMRI analysis. First, we looked for brain areas correlating with the size of monetary reward and found that the size of incidental rewards triggered activity changes in different brain areas previously found to be involved in reward processing (i.e. vStr, dStr, amygdala, insula, inferior OFC). Second, we investigated brain areas that correlate with the size of reported experienced value (EV) and found that EV was encoded in brain areas that also have been previously found to encode EV (i.e. vmPFC, the inferior lateral OFC, anterior insula). Third, we analyzed the neural correlates of how the judgement of the consumption experience is biased by the size of the incidental reward. Interestingly, we found that incidental rewards affect EV through a negative correlation in two of the EV areas mentioned above, the insula and the inferior lateral OFC. Our own data and also previous studies could show that activity in these brain areas correlate negatively with taste pleasantness.

Our results show that incidental rewards have an effect of reported OV. Interestingly, our fMRI results reveal that incidental affect bias taste processing on an earlier stage as compared to more cognitive cues (i.e. the price of the wine, semantic label of an odor, Plassmann et al. 2008). Finally, it seems that incidental affect "make subjects dislike the wines less" instead of liking them more as compared to other papers that have looked at a cognitive modulation of EV.

Single Neuron Correlates of Emotion Regulation In Humans

EXTENDED ABSTRACT

Adult humans have the ability to regulate their emotions, an ability that emerges late in development and breaks down in some psychiatric diseases. A leading neurological model of emotional representations in the brain hypothesizes that the amygdala modulates prefrontal cortex activity by top-down influences. The basis of emotion regulation, however, has never been investigated in humans at the single neuron level. This research provides the first extensive study of what happens to the activity of individual neurons in the human brain as people experience and regulate their emotions while viewing emotional moving images.

In order to test participants' ability to control and regulate their emotions we used a novel technique: recording the activity of single neurons directly from the brains of humans, while they were exhibiting emotions or regulating them.

Participants were 8 epilepsy patients undergoing brain surgery for possible clinical resection of the seizure foci, who agreed to participate in research studies during their hospital stay. During a clinical procedure, up to 128 electrodes were implanted in the exposed brain of each patient. These electrodes allow for the continuous recording of single neuron activity. This ability to record the brain's activity in its highest resolution allows us to examine how thoughts and emotions are expressed using the brain's own language of electrical spiking in individual neurons (Cerf et al., 2010; Kreiman et al., 2000; Gelbard et al., 2008) rather than imaging activity related to oxygenation in areas each containing many thousands of neurons, as in the method used in fMRI research, which is of significantly lower temporal and spatial resolution (Mukamel et al., 2005).

Participants viewed a number of short video clips, including excerpts from films, public-service ads, and political ads, intended to prompt emotional reactions. We also included neutral control clips designed not to induce emotional reactions. Participants were instructed first to view all of the clips and to let their feelings flow naturally. Following the viewing of the clips participants rated each clip on scales measuring emotion, engagement, and arousal. Next, participants were instructed to again view both the emotional and the control clips, but this time were instructed to regulate their emotions. That is, participants were instructed to suppress their positive or negative emotions such that the feelings they felt during the first viewing would not manifest during the second viewing. Patients also reported whether they had been able to successfully regulate their emotions.

In order to determine the timing of the onset and offset of emotional content in the clips, a set of healthy participants (n = 44) first independently rated the clips continuously for their emotional content (positive/negative). Participants watched the clips in real-time and were instructed to rate them using a moving dial continuously. We used their ratings to estimate the moments of the onset and duration of emotional content while testing the neurological patients.

In trials where participants subjectively reported successfully regulating their emotions, we compared the spiking activity of single neurons in their brains in the two conditions. Cells in the amygdala – part of the brain which is commonly implicated with emotions, primarily negative ones such as fear and disgust – showed increased activity when participants viewed film clips during the first exposure. That is, when participants viewed the film clips naturally. However, during the second viewing, when the participants reported successful regulating of their emotions, we observed a gradual decrease in the amygdala firing over time, controlled by activity in the Orbito-Frontal Cortex (OFC), which is commonly said to be the seat of top-down executive control of emotions. These results show direct neuronal evidence for humans' ability to regulate emotions.

Effectively, we found that neurons in the amygdala were modulated not only by emotional content in the stimuli, but also by the patients' volitional regulating of emotions. Participants' initial response to the stimuli occurred within an early temporal epoch, followed by a later epoch where responses were modulated by the regulation instruction, suggesting an early and mostly bottom-up response within the amygdala followed by a later response that is driven by top-down influences.

Using the activity of OFC neurons alone, we could predict a) how the content of the films affected participants (i.e., whether they would report feeling specific discrete emotions while watching the content), and b) whether they let these emotions naturally manifest, or whether they suppressed them. Decoding performance was above 90% during the first 3s of exposure to the emotional clips. Negative emotions were decoded within 1s from the onset of the emotional moment in the clip and were reflected by a change of 5STD above or below (dependent on the neurons excitatory or inhibitory properties) the baseline firing rate. Baseline was established during passive viewing of the screen without content.

These results should be of interest to consumer psychologists who study emotions, as they provide direct evidence of emotions in single-neuron activity in the human brain, and show the mechanisms underlying emotion regulation at the single-neuron level. The results also demonstrate the direct effect of the viewing of different types of emotional content on the human brain. They suggest that it is possible to use single-neuron activity to monitor the effect of different kinds of emotional content on consumers – whether they are reacting emotionally to the content, whether they are reacting positively or

negatively to the content, what specific emotions they are feeling, and whether they are able to control their emotional reactions.

The novel method of direct recording of neuronal activity from human brains will be of great interest to consumer psychologists, and we believe this conference is a perfect forum for exposing consumer psychologists, for this first time, to this new and unique method of measurement. We believe that this method could be used to examine a wide range of topics of interest to consumer psychologists, including how memories are formed in real-time, and how people form associations between one piece of information and another – such as a brand and its associations. Ultimately, this method can be used to examine how people form judgments and make choices in real-time, while directly examining the brain's own coding mechanism.

SESSION OVERVIEW

Each year Americans spend $700 billion on food. Whether it's in a store, restaurant, school cafeteria, or at home, each day consumers are confronted with myriad food options. The choices that people make, both about what to eat and how much to eat, play a large role in determining their health, obesity, and well-being. But while people generally recognize the importance of their diet, they often don't appreciate the drivers of eating behavior.

In this proposed session, we consider various factors that shape food choices and consumption. Two of the papers focus on how food choices are influenced by environmental factors such as social norms and food color. The two other papers focus on person variables, including self-control and childhood environment. All four papers provide insight into how these factors influence food preferences. Importantly, each paper goes beyond mere measures of food liking and presents findings for the actual quantity of food consumed. It is only with measures of intake that we can make stronger claims about subsequent effects on health and well-being.

In the first paper, Redden and colleagues present three field experiments in elementary school cafeterias testing different interventions for increasing kids' consumption of vegetables. They find that placing photos of specific vegetables on lunch trays increased carrot and green bean intake by 178%. They also show that serving school children carrots at the table as they waited to be called to enter the cafeteria line increased carrot intake by 430%.

In the next paper, Haws examines how individual differences in self-control influence the "variety effect" – the notion that the presence of variety leads people to eat higher quantities of food. In a series of experiments, she shows that trait self-control plays a critical role in how variety influences eating. For people low in trait self-control, for example, the presence of variety increased snack consumption by 73%. But for people high in trait self-control, the presence of variety increased snack consumption by only 14%.

The third paper by Cantu and Griskevicius investigates how food color affects consumption. Drawing on the idea that the color red has reliably served as an indicator of a food's (e.g., fruit and berries) ripeness, sweetness, and adaptive value, they present three experiments testing how cues to redness affect consumption. They find that people eat about twice as many chocolates when the candies are wrapped in red wrappers.

In the final paper, Hill and colleagues investigate how morality stressors influence women's food consumption. Drawing on theory in biology, they propose that mortality stress should have different effects depending on women's childhood environment. Across three experiments, they show that whereas mortality cues *increase* food consumption for women who grew up poor, mortality stress *decreases* food consumption for women who grew up wealthy.

The papers in this session highlight two types of factors driving food consumption the person and the situation. Across the four research projects, there is consistent evidence that both types of factors play a central role in what people eat and how much they consume. By using a diversity of perspectives (behavioral economics, evolutionary psychology, consumer traits), and a variety of methods (lab studies and field experiments), this session delivers a rich understanding of factors driving food consumption. This approach and the importance of the core topic of food will appeal to a wide range of audiences, including those interested in food preferences and consumption, consumer health, public policy interventions, variety, self-control, and evolutionary approaches.

Interventions to Get School Children to Eat More Vegetables

EXTENDED ABSTRACT

Childhood obesity remains a significant public health concern in the United States, especially among minority populations. Eating behaviors that include low intakes of fruits and vegetables and high intakes of energy-dense foods are risk factors for childhood obesity. According to national dietary intake data (NHANES 2007-2008), approximately 90% of children 8 years-old and older do not meet the current recommendation for total daily vegetable intake. In this research, we test the effectiveness of three interventions to increase vegetable intake at an elementary school cafeteria with approximately 800 students.

The relatively new field of behavioral economics has increased awareness of the effectiveness of small environmental changes to alter behavior. These so-called "nudges" have been effective in a range of settings (Thaler and Sunstein 2010), with the notion that people are more likely to engage in behaviors they feel like they "freely" chose. We propose that interventions will be more effective when they make children actively choose and consume the vegetables for themselves (i.e., without being coerced). Specifically, we test how much the following three small interventions (or nudges) will increase vegetable intake at an elementary school cafeteria: (1) increasing the portion size, (2) providing photos on lunch trays to suggest that taking vegetables is the norm, and (3) serving vegetables before the rest of the meal.

Prior research has shown that the quantity people consume increases as they are served larger servings of food (Wansink 2004). People tend to infer from the portion size what a typical person eats. People then subsequently follow this consumption norm, leading to a positive relationship between portion size and quantity consumed.

People have a tendency to finish the entire serving in front of them (Siegel 1957), suggesting that portion size largely determines the quantity consumed.

Study 1 tested whether increasing the portion size for a vegetable (carrots) and a fruit (oranges) by 50% would increase intake in an elementary school cafeteria. Compared to a control day with an identical menu, school children ate 12% more carrots and 24% more oranges. However, a limiting factor of this intervention for vegetables was that less than 10% of the school children placed carrots on their school tray (versus 33% for oranges). Therefore, the consumption norm for vegetables could not have any effect for 90% of the children.

In Study 2, we developed an intervention to more directly address the fact that very few school children would take the necessary first step of putting carrots on their plate. Here, we employed a nudge based on social norms, which have long been recognized as a particularly powerful way to shape behavior. Norms reflect both what most people think should be done and what most people actually do (Cialdini, Reno, and Kallgren 1990; Deutsch and Gerard 1955), and people often use them as a cue to infer the best course of action (Cialdini 2001). In the school cafeteria setting, we created a norm to eat vegetables by adhering a photo of green beans and a photo of carrots in two separate compartments on the lunch tray. We expected these photos would indicate that others typically select and place vegetables into those compartments and that they should do so too. Compared to a control day with an identical menu, this intervention increased the percentage of students taking green beans from 6% to 15%, and the percentage taking carrots from 12% to 37%. More importantly, those putting the vegetables on their trays subsequently ate them as overall consumption per student in the cafeteria increased by 133% for green beans and 178% for carrots. Furthermore, this intervention required minimal time and cost (about 20 minutes and $0.03 per 100 trays).

In Study 3, we tested how we could make children willingly choose to consume vegetables by making them more attractive. Given that liking depends on how a stimulus compares to a reference point (Helson 1964; Parducci 1995), a vegetable will generally be unappealing when compared to more tasty unhealthy foods like pizza and chicken nuggets. To combat these contrast effects in liking, we propose that healthy foods will be more appealing when eaten in isolation. This would give a moderately liked healthy food a "fighting chance" to be chosen, liked, and ultimately consumed more. Furthermore, when it is the only food present, people may be more likely to clean their plate and eat all of it (Geier, Rozin, and Doros 2006; Siegel 1957). We therefore predict that, when both a healthy and an unhealthy food will be eaten, intake of the healthy food will increase when it is consumed first by itself without the unhealthy food present. Study 3 tested this prediction by first serving the school children carrots at the table as they waited to be called to enter the cafeteria line. Compared to a control day with an identical menu, this intervention increased the intake of carrots per student by 430%.

Overall, we show that three interventions each increase vegetable intake from 12% to 430%. The most effective interventions were those focused on encouraging children to simply put vegetables on their tray. Thus, future research should concentrate on designing small "nudges" that encourage children to be open to and select vegetables. Once children get past this initial hurdle of avoidance, they appear open to subsequently eating the vegetables on their tray. Finally, future efforts to improve the dietary habits of children and increase vegetable intake may benefit from simpler interventions like ours rather than expensive educational efforts.

In Control of Variety:
How Self-Control Reduces the Effect of Food Variety

EXTENDED ABSTRACT

Variety typically leads to increased consumption. A recent review refers to this phenomenon as the *variety effect* (Remick, Polivy, and Pliner 2009). Using a meta-analytic approach, Remick et al. (2009) conclude that while situational factors influence the variety effect, internal factors including gender, BMI, and dietary restraint do not. This work proposes that an overlooked moderator of the variety effect is general self-control.

Self-control has been linked with numerous long-term positive life outcomes, including better grades and job performance, healthier interpersonal relationships and higher self-esteem (Tangney, Baumeister, and Boone 2004). Given the pervasiveness of variety in our daily food options, I anticipate that the long-term nature of self-control will influence patterns of consumption in a healthy way, in this case through reducing the variety effect, consistent with the tendency of those higher in self-control to better monitor their behavior and be less susceptible to environmental influences. In a series of three studies, I examine the impact that variety has on preferences for various types of foods as well as the resulting influence on the quantity consumed.

In Study 1, 266 participants were asked how many candies they wanted to eat for an afternoon snack. In the variety condition, participants were shown a variety of snacks (Hershey's, Kit Kat, and/or Reeses miniatures), whereas the single snack condition offered only one of the three snacks. We later assessed general self-control. Consistent with prior research, the variety effect emerged such that participants who saw the various snacks indicated they wanted more overall. However, an interaction between the variety condition and self-control also emerged ($p < .01$), such that the effect of self-control on quantity desired was more than four times larger in the variety condition than in the single snack condition. As well, self-control matters in the variety case ($p < .01$), as low self-control people showed a 40% higher quantity than those with high self-control in a spotlight analysis.

Study 2 used consumption of assorted snacks as the dependent measure. As in the first study, participants were either in a variety or no variety condition, with each group receiving 3 separate servings of miniature cookies (Chips Ahoy, Nutter Butters, and/or Oreos). Participants received these snacks in three rounds, with the order of snacks randomized in the variety condition. They performed unrelated, but timed tasks after receiving each snack in order to allow time for consumption. Following the study, consumption was measured and recorded. As in study 1, there was again evidence of the variety effect overall, but also the interaction with self-control. For those low in self-control, the variety effect led to about 73% more consumption than a single snack whereas this increase was only 14% for those high in self-control. As such, this study demonstrates the interaction between variety and self-control by extending our findings to differences in actual consumption.

In Study 3, all participants actually consumed a variety of snacks. Specifically, participants were given a plate with small samples of nine common snack foods representing three each of healthy, medium, and unhealthy snacks. Participants rated their enjoyment of each snack in random order. Participants then received a plate with five chocolate chip cookies and were told to enjoy them while watching a video. Our purpose was to create a level of satiation with unhealthy snacks to see how this satiation would impact subsequent liking for the variety of snacks. Participants then rated the same nine snacks again, and separately completed the general self-control scale. I predict that people high in self-control would show a greater drop in liking across all of the snacks, demonstrating that their satiation spread further, thereby reducing the appeal afforded by variety. This would provide additional evidence of a weakening of the variety effect. The drop in liking ratings for each of the three food types were submitted to a repeated-measures ANCOVA with the snack type as a within-subjects factor, and trait self-control as a continuous covariate. I found the predicted interaction between food type and trait self-control, such that those with high trait self-control seem to satiate spontaneously on all of the foods while those with low trait self-control satiated little on the other food types (especially on the unhealthy foods), suggesting that the variety increased satiation across the board for those high in self-control but not for those low in self-control.

Overall, three studies using different approaches, including actual food consumption, to demonstrate an important factor in understanding the influence of variety on patterns of preference and consumption. Specifically, this work identifies general self-control as an internal factor that moderates the variety effect, which may help explain positive health outcomes over time as those with higher self-control are less susceptible to dramatically increasing their consumption of or preference for foods in the presence of variety.

Red, Ripe, and Ready:
Effect of Food Color on Consumption

EXTENDED ABSTRACT

People are confronted with multiple food choices every day. How do they decide which foods to eat – and how much to consume? Building on past research showing that environmental cues can influence food consumption (Wansink 2004), we examine how food color influences food desirability and consumption.

All of our ancestors successfully solved the challenge of determining which foods to eat. As omnivorous generalists, humans can obtain nutrients from a wide variety of foods. However, some foods have always been more adaptive than others. For example, our ancestors would have benefitted more from consuming foods that were calorie-rich and easy to digest rather than eating foods that contained few calories and were difficult to digest (Rozin 1999).

We propose that an important cue that helps determine a food's adaptive value is its color. Research in biology shows a link between a species' diet and the nature of that species' vision (Smith et al. 2003). Specifically, meat-eating carnivores such as dogs and tigers tend not to have trichromatic color vision and often see in black and white. By contrast, omnivores such as humans and other primates have trichromatic color vision that differentiates between green and red colors. Biologists have argued that because omnivores consume plants (e.g., fruits and berries), color vision may have evolved to help determine the adaptive value of food (Dominy & Lucas 2000). For example, the color of fruits and berries, which universally vary on a green-to-red spectrum, reliably serves as an indicator of their adaptive value, whereby redness is associated with high adaptive value: Redness tends to signal ripeness, a desirable sweet taste, easy digestibility, and higher nutritional value (Goff & Klee 2006).

Given the association between the color red and the adaptive value of food, we examined how the color red relates to food psychology and consumption. We hypothesized that the color red in the context of food should be associated with (1) automatic tendencies to approach red-colored foods, and that (2) people should consume higher quantities of red-colored foods.

Experiment 1 tested people's automatic tendencies to physically approach the color red versus the color green. We used an established behavioral task, in which people made physical movements using a joystick to approach stimuli presented on a computer screen, whereby the speed of the movements was the dependent measure (Chen and Bargh 1999). The experiment had two between-subjects conditions that manipulated the context in which people saw the color red and green: Colors were presented either in a food context or in a non-food context (control). Context was manipulated by priming people either with food-related thoughts or with neutral control thoughts before assessing the speed at which people approached the color green and the color red.

Results showed that in the control condition people were slightly (non-significantly) slower to approach the color red than green. However, when people were first primed with food-related thoughts, they were significantly faster to approach the color red, $F(1,57)=8.94$, $p=.004$; $M_{Control}=778$ ms, $M_{Food}=687$ ms. Thus, in the context of food, people were faster to approach the color red.

Experiment 2 tested how food color influenced the quantity of actual food consumption. The study had two between-subjects conditions, whereby all participants watched a video, but they were provided with one of two different types of snacks (chocolate candies): The candies were either wrapped in red wrappers or in green wrappers. We measured the quantity of candies eaten during the movie. Results showed that participants who were given snacks wrapped in

red ate nearly twice as many candies as participants who were given snacks wrapped in green, $t(93)=-2.707$, $p=.008$; $M_{Green}=1.84$ candies, $M_{Red}=3.46$ candies.

Experiment 3 sought to identify a condition when the color red exerts the strongest effect on food consumption by testing a theoretically-derived moderator of the effect. Because the color red has been a reliable indicator of food ripeness and sweetness throughout evolutionary history (Goff & Klee 2006), we hypothesized that the color red would have the strongest effect for the consumption of sweet foods rather than non-sweet foods (e.g., salty foods). Experiment 3 therefore had a 2 (food color: red vs. green) X 2 (food type: sweet vs. salty) between-subjects design. All participants watched a video and were given either candies or tortilla chips as snacks. However, the foods were either red or green. We measured the quantity of food eaten. Findings showed an interaction ($p < .05$). Conceptually replicating Study 2, people ate more candies in the red than in the green condition. However, color did not influence the consumption quantity of salty foods.

Across three studies, we find the consistent pattern that consumers have a natural attraction to red foods. We attribute this behavior to the adaptive value of food signaled by the color red: it has ripened and can be enjoyed when eaten. Therefore, when encountering an ideally sweet food, consumers approach the food faster and subsequently consume more of it when it is red (versus green). Our research establishes these basic effects, and it highlights the importance of color for food palatability. We believe this knowledge can assist food marketers in making their products more attractive and more importantly more enjoyable.

Mortality Threat Can Increase or Decrease Women's Caloric Intake Depending on Their Childhood Environment

EXTENDED ABSTRACT

Why do some women obsess over calories and go to extreme measures to prevent weight gain, while others eat without thought, having little concern for how their food choices affect their body weight? In this research, we draw on an evolutionary perspective on eating, which suggests that women's caloric intake is related to fertility. Importantly, because female fertility across animal species is known to be regulated by environmental conditions indicating high mortality, we propose that women's eating behavior might be influenced by perceptions of mortality dangers. In three experiments, we examine if, when, and why mortality dangers influence women's eating psychology and food consumption.

From an evolutionary perspective, all organisms, including humans, vary on whether they follow a 'Fast' or a 'Slow' evolutionary strategy (Ellis et al. 2009). *Fast strategies* are associated with more rapid sexual development, earlier ages of reproduction, and higher quantity of offspring. *Slow strategies*, by contrast, are associated with slower sexual development, later ages of reproduction, and lower quantity of offspring. This means that whereas fast strategists behave in ways to facilitate immediate reproduction, slow strategists delay reproduction.

Whether organisms, including humans, adopt fast versus slow strategies depends on the stressfulness of their early-life environment (Ellis et al. 2009). For example, whereas people growing up in stressful low-SES environments tend to adopt faster strategies, people growing up in less-stressful high-SES environments tend to adopt slower strategies. Importantly, research shows that behavioral tendencies associated with fast versus slow strategies are especially prominent when individuals are facing mortality dangers (Griskevicius et al. 2011). Specifically, mortality threat leads people from low-SES background to exhibit fast strategy behaviors such as wanting to start a family sooner. In contrast, the same mortality threat leads people from high-SES background to exhibit slow strategy behaviors such as delaying reproduction.

Because fast and slow strategies differ in the timing of reproductive activity, these strategies also directly relate to women's caloric consumption. This is because women's ability to reproduce depends on having substantial amounts of body fat (Anderson and Crawford 1992). Because female reproductive timing and capacity depend on body fat, this means that reproductive timing and capacity can be sped up *or* slowed down by adjusting body fat levels (Salomon et al 2008; Wasser and Barash 1983). That is, whereas increasing caloric intake increases the likelihood that a woman is physically able to reproduce, decreasing caloric intake suppresses female reproduction.

Because fast strategies are associated with immediate reproduction, they might be associated with *increased* caloric intake to facilitate this immediate reproduction. By contrast, because slow strategies are associated with delaying reproduction, they might be associated with *decreased* caloric intake to delay reproduction. Given that behavioral tendencies associated with fast versus slow strategies is most prominent under mortality threat (Griskevicius et al. 2011), in three experiments we investigated how mortality threat influences women's eating psychology and behavior. Building on past research, we predicted that mortality cues should have different effects on depending on whether women grew up in low-SES versus high-SES environments. Whereas those from *low-SES* backgrounds should respond to mortality by *increasing* fatty food intake to facilitate body fat accumulation (consistent with a fast strategy), women from *high-SES* childhoods should respond to mortality by *decreasing fatty food intake* to hinder body fat accumulation (consistent with a slow strategy).

In Study 1, we experimentally manipulated mortality cues by having people read a news article about increasing rates of violent crime or having them read a control article. We then examined women's (and men's) desire for food by measuring the size of their drawing of cookies, which were drawn from memory viewed earlier in the session. Results revealed that for women growing up in more stressful, lower SES environments, the mortality news articles *increased* desire for food. In contrast, among women growing up in

more advantaged high-SES environments, mortality cues *decreased* desire for food. No such effects were found for men.

In Study 2, mortality cues were manipulated by having women view a slideshow with visual images of escalating violent crime or control images. Women were then offered snacks (cookies and pretzels) that they could take with them when leaving the laboratory. Findings conceptually replicated the results of Study 1. Specifically, women who grew up in more stressful, lower-SES environments, mortality cues significantly *increased* the number of food items taken. Among women growing up in more advantaged environments, however, these same cues significantly *decreased* the number of food items taken.

Study 3 examined whether mortality cues would influence women's beliefs about calorie regulation and desire to prevent weight gain. Consistent with the results from Studies 1 and 2, Study 3 found that for women growing up in lower SES environments, morality cues significantly *decreased* desire to restrict calories and prevent weight gain. Among women growing up in more advantaged environments, however, these cues significantly *increased* desire to restrict calories and prevent weight gain. Additionally, the changes in calorie restriction were found to be fully mediated by the changes in weight regulation desires.

These studies provide important new insights into the complex relationship between environmental cues and women's food regulation behavior and have important implications for understanding women's consumption behaviors.

SESSION OVERVIEW

Time delay is a ubiquitous phenomenon in consumer life. Prior research has shown that delay discounts the peripheral aspects of a consumption scenario and increases the importance of central aspects of the decision (e.g., Trope and Liberman 2003). In the waiting literature, research has shown that people's experiences with a consumption episode are usually negatively correlated with delay because sooner is better (Taylor 1994). Yet other research suggests that more negative experience during waiting can also increase goal desirability (Koo and Fishbach 2010). Furthermore, different consumers might use different strategies to regulate their time and decisions (Lauer 1981). How does delay and time elapse play a role in consumer behaviour? This session tries to expand our understanding of the effect of time delay and duration by systematically examining the effect of delay/time elapse on consumption enjoyment and decisions across diverse domains, and conversely, how consumers form duration perception as a result of their ongoing consumption experience.

The session begins with a paper by *Lee and Tsai* that examines how price promotions influence hedonic consumption experience immediately after payment versus after a delay. The findings suggest that discounts make instant consumption more enjoyable; however, this pattern reverses when consumption is delayed due to consumers' changed feelings and involvement. *Sellier and Avnet* further investigate how consumers with different temporal regulation strategies react to different promotion strategies offering different time flexibility. For example, they demonstrate that clock-time style results in higher preferences towards delayed services with more waiting than immediate service, compared with event-time style, because clock-time consumers can shift tasks around more easily. Following up these findings, *Zhao, Soman and Yang* propose and show that more waiting time and a greater number of people behind during waiting lead consumers to value the delay more highly and to consume at higher levels because they need to compensate for their perceived sunk cost. Finally, while the first three papers examine the effect of delay/duration of waiting on consumption decisions and experi-

ence, *Ilyuk, Block and Faro* take a reversed direction and investigate how current consumption experience impacts the perceived efficacy duration of a product, a previously neglected construct. Their findings suggest that higher difficulty of the current experience leads to shorter perceived efficacy duration of the product and thus increases the frequency of intake of the product.

The papers in this session proposal are all in advanced stages of completion, with multiple studies conducted and full papers available. Taken together, the session is designed to provide an integrative overview of new research aimed at enhancing our understanding of the role of delay in consumption enjoyment, consumer spending and other aspects of consumer decisions. In this sense, the session helps to further the conference mission of appreciating diversity by examining the role of delay in these diverse areas. Besides their theoretical contributions, the findings in this session also provide important implications to enhance consumption experiences in situations involving delay and waiting, and to increase consumers' health and welfare by changing their perceived efficacy duration of drugs. The likely audience for this session will be consumer researchers in general and specifically those who are interested in consumers' decision-making related with time and duration. Thus we expect to draw the interest of a wide range of researchers.

The Immediate and Delayed Effects of Price Promotions on Post-Purchase Consumption Experience

EXTENDED ABSTRACT

Consumers generally believe that getting a good deal for a product would enhance their hedonic experience of consuming the product. The present research examines this intuition. We find that getting a price discount can make consumption more enjoyable. However, contrary to lay beliefs, when consumption is decoupled from payment with a time delay, price promotions actually diminish consumption enjoyment over time. While prior research has documented the effects of price promotions on sales and perceived quality (e.g., the placebo effect in which discounts have been found to decrease perceived efficacy of *utilitarian* products – Shiv, Carmon, and Ariely 2005), we systematically investigate the effect of price promotions on post-purchase *consumption experience of hedonic products* over time.

On the one hand, getting a good bargain can elevate moods (Heilman, Nakamoto, and Rao 2002), which spills over to consumption experience and makes consumption more enjoyable. On the other hand, paying a lower price may reduce the psychological need to recover one's expenditure (Gourville and Soman 2002); thus, the less a consumer has paid for a product, the less relevant the consumer perceives the product to be, and the less involved he/she becomes during consumption. The resulting lower involvement thus makes evaluation less extreme (Petty and Brinol 2010) and diminishes the intensity of consumption enjoyment. Given that mood effects are often transient while involvement effects might be more persistent, we propose that if a product is consumed immediately after payment, price promotions should enhance consumption enjoyment. However, if the consumption is delayed, the negative effect of price promotions (due to lower involvement) will dominate.

To test our hypotheses, we conducted four experiments (three of which involving real spending and product consumption) in which

we manipulated how much participants paid for a product and when they consumed the product after payment. Experiment 1 employed a 2 (discount: 0% vs. 50%) x 2 (consumption: immediate vs. delayed) between-subjects design. Specifically, participants first earned a wage by completing an unrelated study. Then, in the main "shopping study," they used (some of) that money to purchase one of two given music recordings either at the full price or a (50%) discounted price. After paying for their chosen recording, participants were given the recording on an iPod either immediately or after a 25-minute delay, asked to listen to the recording, and then evaluate how much they enjoyed listening to it. To control for perceived quality, the music recording was the same in all conditions unbeknownst to the participants. As expected, for immediate consumption, price promotions increased consumption enjoyment, whereas for delayed consumption, the effect was reversed. More important, mediation analysis showed that mood mediated the effect of promotions for immediate consumption but not for delayed consumption. We replicated these findings in Experiment 2 using a different sensory stimulus (chocolates) with an extended time delay (1 week).

In Experiment 3, we attempted to gain insight into consumers' affective and cognitive reactions to price promotions using a similar consumption context as Experiment 1, and therefore, to obtain process evidence for the hypothesized dual factors—positive feeling and involvement—in accounting for the observed interaction effect. The results demonstrate that while consumers may be insensitive to the transient nature of feelings (due primarily to affective misforecasting; Gilbert et al. 1998), their insight into the persistent effect of price-induced involvement is consistent with the results of experiments 1 and 2.

Nonetheless, to further demonstrate the role of involvement in the delayed-consumption results, we manipulated stimulus valence in Experiment 4. Specifically, the proposed involvement account predicts that, over time, price promotions should weaken consumption experience, making the experience of consuming a liked product (i.e., orange juice with honey) less enjoyable, and conversely, a disliked product (i.e., orange juice with vinegar) less unpleasant. Indeed, for immediate consumption, price promotions enhanced consumption experience regardless of stimulus valence. However, for delayed consumption, price promotions made the tasty juice less enjoyable and the sour juice less unpleasant. Mediation analysis confirmed that involvement during consumption mediated the effect of price promotions for delayed consumption. The results also ruled out perceived quality as an alternative explanation, suggesting that these effects of promotions can operate above and beyond price-quality associations.

Our work provides new insight to the literature on the psychological effects of price promotions on hedonic consumption experiences over time. Contrary to lay beliefs, getting a good deal actually reduces consumption enjoyment if consumption is decoupled from payment with a time delay. Besides the placebo effect, our findings also complement prior work on the psychology of payment that examines the difference between pre-payment and post-payment on consumption experience (Prelec and Loewenstein 1998) by investigating the effect of promotions on consumption experience at different points in time *after* payment Further, our empirical findings may offer a potential alternative explanation for the extant finding that price promotions can have negative long-term effects on customer satisfaction and brand loyalty.

Clock-time, Event-time and Consumer Decision-Making

EXTENDED ABSTRACT

Time is a continuum on which consumption activities occur in succession from past to present to the future. Two ways in which individuals schedule tasks over time have been documented (e.g., Lauer 1981; Levine 1997): 1) "clock-time," where individuals divide time into objective and quantifiable units, and let an external clock dictate when tasks begin/end; and (2) "event-time," where tasks are planned relative to other tasks, and individuals transition from one to the next when they internally sense that the former task is complete (Lauer, 1981). To illustrate, clock-time individuals may have breakfast at 8 am, work from 9 am to 5 pm, dine at 6.30 pm. Event-time individuals begin work after breakfast, linger at the market for however long it takes to have one's basket full, and leave work when they can "call it a day". Recent research suggests that people's adoption of a clock-versus event-time scheduling style is related to successful self-regulation (Avnet and Sellier 2011).

This research documents two critical ways in which these scheduling styles differ in their influence on consumers' decision-making. A first difference is that clock-time consumers slice time into quantifiable, independent units, which provides them with the ability to switch tasks around more easily than event-time consumers, who view time as a sequence of events following one another, and are therefore relatively more captive of their task ordering. This greater flexibility of clock-time consumers leads to three predictions: first, they should value consumption contexts enabling them to rearrange tasks more than event-time consumers (H1). Second, a reliance on clock-time implies two costs, which influence decisions about impulsive consumption opportunities: (1) one is that of being used to incurring "empty" time whenever a task takes less time to complete than anticipated. Clock- (vs. event)-time consumers should better respond to opportunities taking place during empty time because they fill an otherwise wasted slot (H2); (2) in the context of an unscheduled opportunity appearing outside of empty time, clock-time consumers should require more time to think about the rearrangement of tasks than event-time consumers, because the latter only postpone all their tasks to later (H3). A second difference is that clock-time consumers are concerned with efficiency (getting things done) whereas event-time consumers are focused on effectiveness (doing things well). From this, we derived the prediction that clock-time (vs. event-time) consumers are generally likely to purchase discounted items independent of whether they need those items at the time of purchase. In sharp contrast, event-time consumers should seek to purchase items when they can use them (H4).

Across five studies, we either measured participants' chronic reliance on clock- (event-) time (Studies 1-4) or primed them with these scheduling styles (Study 5). Consistent with H1, clock-time (vs. event-time) participants in a first study were more likely to buy products online rather than at a brick-and-mortar store, p < .05, presumably because shopping online is possible any time.

A second study involved 111 participants reading consumption scenarios. In a first scenario, participants imagined that they saw that a designer store is running a 30% one-day sale. A salesperson further explained that they could buy a coupon extending the 30% discount for two months. Again supportive of H1, we found that clock-time participants showed a higher preference and willingness to pay for coupons they could use later but had to pay for, compared to a free coupon they could only use immediately, both p < .05.

In a second scenario, participants reported their readiness to seize an unexpected discount opportunity during empty time. Participants imagined they were purchasing items at a department store

and could get 20% off if they used coupons they could request at the other end of the store. Imagining their next scheduled task was 15 minutes later, clock-time participants indicated they were willing to spend more time getting the coupons than event-time participants, one-tailed p < .05 (H2).

In a third scenario, participants were unexpectedly offered to leave the next day for a 3-day trip to a secluded beach resort, all expenses paid, provided the decision was made right away, we found that – compared to event-time participants - clock-time participants were significantly less ready to immediately go on the trip, needed time to think about it more, and would be more likely to only go on the trip if it were at least a week later (all p's < .05, H3).

A third study had 55 students react to a reservation service for restaurants that normally have a "no reservation" policy, allowing consumers to book a table in exchange for a fee. Indicating that clock-time consumers are more comfortable around empty time than event-time consumers (H3), we found that clock-time participants liked the idea less than event-time participants (p < .03) and intended to tell others about it less (p = .05).

A fourth and fifth study tested H4. In both studies, participants imagined that the season was winter (or summer) and that some stores at their mall are offering up to 50% off. We told them to assume that they were thinking of buying the products on sale at some point anyway. Their time scheduling style was either measured (Study 4) or primed (Study 5). Subjects reported their likelihood of buying the discounted summer (e.g., sunglasses) and winter products (e.g., boots). The key replicated finding is that clock-time consumers are more likely to purchase discounted items off-season than event-time consumers, who prefer to buy discounted items during the season in which the items can be used. Together, these findings suggest profound ways in which task scheduling styles shape decision-making.

What's Queuing Worth?
Sunk Effort and the Value of A Queue Position

EXTENDED ABSTRACT

Consumers routinely have to wait in queues to obtain a product or service. In this research, we examine the manner in which people value their position in a queue and the effect of this valuation on their subsequent consumption decisions. Specifically, we investigate the effect of two cues in the queuing environment: the time spent in the queue and the number of people behind. We hypothesize that more time spent in the queue and a greater number of people behind lead people to value the wait more highly and to consume at higher levels because of the perceived sunk cost.

Our predictions are based on prior research on mental accounting (Thaler, 1985) and the psychology of queuing (Koo and Fishbach, 2010; Zhou and Soman, 2003). Research on mental accounting suggests that when people prepay to purchase an experience such as a ski pass, they open a mental account for the purpose and tag it with a negative balance – the disutility of the payment they have just made. The only way in which they can satisfactorily close their mental account "in the black" (i.e., without a loss) is by consuming what they paid for (Prelec and Loewenstein, 1998), even if it rains on the ski day. We propose that people think about the queuing experience much like how they think about the utility of a transaction, following the same principles of mental accounting. As such, people in queues value the effort/psychological cost they have expended to achieve their position in the queue, and they seek to be compensated for it through product purchase or other form of reimbursement so that they can close the mental account in the black. Because the longer people have to wait, the more effort is involved and the

greater their negative emotional reactions are (Taylor 1994), we predict that greater time of wait leads to greater valuation of the queue and hence greater consumption required to make up for the wait. Second, because pervious research has demonstrated that number of people behind in a queue impacts people's queuing behavior (Koo and Fishbach, 2010; Zhou and Soman, 2003), we predict that people would also take number of people behind as a cue to evaluate their effort expended so far. Therefore, when the number of people behind is larger, people perceive higher psychological cost. Consequently, they need a higher level of benefit to compensate for their efforts, and consume at a higher level.

Our findings in three studies largely supported our hypotheses. While Study 1 examined the interaction between time of wait and number of people behind, Study 2 further investigated the effect of waiting time and Study 3 further investigated the effect of number of people behind. In Study 1, we asked participants to imagine that they were waiting in queue in a popular restaurant. During waiting they were told that the restaurant will be closing due to unforeseen circumstances and they will receive a gift certificate to compensate for the waiting. Across different conditions, participants were either told that they have been waiting for 20 minutes or for 45 minutes, and that there were either 5 vs. 10 groups behind them. Participants were asked to indicate the amount of compensation they would request. Consistent with our prediction, we found that people requested a higher amount of gift certificate after waiting for longer time (45 min.) compared with waiting for shorter time (20 min.). However, this effect was attenuated when there were 10 groups of people behind them: Participants requested higher amount of compensation regardless how long they have waited, presumably because they used number of people behind (10 groups) as an additional cue for their perceived effort of waiting. A mediation analysis supported our proposition that the perceived cost of waiting drove the observed interaction between time of wait and number of people behind on the valuation of the queue position.

In Study 2, we directly manipulated personal waiting cost (high vs. low) and examined its interaction with time of wait on people's consumption decisions in a restaurant. We found that when people had to undergo a wait themselves and thus perceived high wait cost, they tended to order a more expensive meal after spending more time waiting. However, when they did not have to wait themselves and thus the perceived psychological cost of the wait was low, this effect was attenuated. In Study 3, we examined the effect of number of people behind in a field setting and found that when the cue of the number of people behind was salient, consumers at a car wash chose the more upgraded and expensive car wash options when the number of people (cars) behind was large, but this effect was attenuated when the cue was difficult to observe.

These findings contribute to the literature on queuing and value perception. Our research represents the first piece of work to apply mental accounting to an investigation of how waiting time and number of people behind in a queue impact the value perception of the queue, and how this valuation is translated into different consumption levels.

Is it Still Working? The Effects of Task Difficulty on
Perceived Duration of Product Efficacy

EXTENDED ABSTRACT

As consumers, we often wonder how long products will last or, alternatively, how long before they "wear off." How long will the morning brew give you energy? How long will the headache medicine relieve pain and keep the excruciating headache from coming

back? Despite the pervasiveness of such questions and their importance in determining consumption—namely intake frequency—there has been no research on consumers' judgments of product efficacy duration.

In the present research, we take a neglected construct—perceived duration of product efficacy—and propose that contextual factors, namely the tasks consumers perform during and after product consumption, affect such judgments. Specifically, we demonstrate the consumer belief that duration of product efficacy depends on the difficulty level of a cognitive task one performs.

Importantly, evidence supports that this lay belief has no basis in scientific fact. There is no increased energy utilization during tasks that require more vs. less cognitive effort (Clarke and Sokoloff 1998; Gibson and Green 2002; Lennie 2003; Gibson 2007; Kurzban 2010). The efficacy duration of a product's active ingredients (e.g., half life of medication, glucose metabolism) is determined by factors such as genetics and body weight; for the average, healthy individual who is not glucose depleted, no physical or cognitive task that he/she performs can change its kinetics. Despite the scientific evidence to the contrary, across three studies we demonstrate that consumers hold the belief that product efficacy duration is shorter (vs. longer) when they perform a difficult (vs. easy) cognitive activity.

In study 1, we obtain evidence that perceived duration of product efficacy—measured by actual consumption in real-time—depends on the difficulty of the task one performs. We administered a reading task and manipulated task difficulty by adjusting font style, using degraded font in the difficult condition. Participants were placed in either the difficult or easy task condition and given Jelly Belly Sport Beans® (note that the short-term energy enhancing jelly beans have an actual onset time of 30 minutes, which experimentally controls for any glucose entering the system) to eat while they worked on the task. They were instructed to eat another Sport Bean® whenever they felt the effects wearing off and to press [SPACE BAR] each time they did so. These key presses captured perceived efficacy duration. As hypothesized, perceived efficacy duration was shorter for those in the difficult font condition ($M_{difficult}$ = 6.25 minutes) than for those in the easy, standard font condition (M_{easy} = 8.15 minutes; $F(1, 100) = 6.16$, $p < .05$). While our main dependent variable was an on-line judgment of product efficacy duration, retrospective judgments of product efficacy duration showed an identical pattern of results such that those in the difficult font condition judged the Sport Beans® to have a shorter efficacy duration than those in the easy font condition ($M_{difficult}$ = 2.90 vs. M_{easy} = 3.41; $F(1, 109) = 4.24$, $p < .05$). Additional measures collected in this study ruled out the alternative explanation that results were due to differences in negative affect, decreased alertness, fatigue, or motivation across conditions.

In study 2, we manipulated perceived rather than actual task difficulty. In this study, we also varied consumers' beliefs about efficacy duration via a priming technique that either reinforced the belief that duration depends on context, or countered the belief with evidence that duration is context-independent. Participants were given the same instructions to eat Jelly Belly Sport Beans®, this time while working on identical GMAT reading comprehension questions that were supposedly either difficult or easy. When participants read that efficacy duration is often dependent on contextual factors, the effect from study 1 replicated ($F(1, 162) = 4.80$, $p < .05$). In contrast, when they read that efficacy duration is not dependent on contextual factors, they did not exhibit the pattern of results found in our previous study ($F < 1$).

In study 3, we find that the presentation mode of manufacturer's "suggested intake" (interval vs. fixed time format) affects duration judgments such that an interval (vs. fixed) format yields duration estimates in line with the malleable intuitive belief. When instructions for medication (Advil) are presented in an interval format (e.g., "Take every 2 – 4 hours") versus a fixed time (e.g., "Take every 3 hours"), the same interactive effect with task difficulty emerges as in the previous study, such that participants in the interval format condition estimate efficacy duration to be shorter when anticipating to perform a difficult (vs. easy) task ($M_{difficult}$ = 2.89 vs. M_{easy} = 4.28; $F(1, 166) = 5.97$, p = .02). However, those presented with intake instructions in a "fixed" format show no significant difference in duration estimates across difficult and easy conditions ($F < 1$).

Across three studies, we demonstrate that consumers hold an intuitive belief that product efficacy duration is context dependent; duration judgments are shorter (vs. longer) when consumers engage in cognitive tasks perceived to be difficult (vs. easy). These findings have important implications for product (mis)use. A potential consequence of the documented belief includes product over- and under-consumption which, undoubtedly, affects consumer health and well-being.

SESSION OVERVIEW

All too often, consumers find themselves making decisions deviating from their initial expectations. Indeed, product perceptions are often biased by the incorrect but also unintended and unconscious use of perceptual aspects in consumers' decision making (Kahn, Luce, & Nowlis 2006). These biased perceptions might lead to suboptimal decisions (Hoegg & Alba 2007). In fact, extrinsic factors such as price and irrelevant product attributes have been identified to bias consumers in this manner. For example, it has been shown that visual cues can be more instrumental in driving taste perceptions than actual taste (Hoegg & Alba 2007) and that consumers incorrectly rely on assortment aspects rather than inherent hunger or diet restrictions to derive the appropriate consumption amount (Kahn & Wansink 2004). These findings demonstrate that consumers' consumption decisions are often influenced by factors that bias their expectations and in turn might influence their behavior. Especially in the context of food consumption, investigating how and why consumption biases influence expectations and consumed amount is timely, since obesity rates are rising.

Therefore, it is important to understand these types of consumer biases such that one can mitigate their negative impact (Kahn et al. 2006). The papers in this session fit this need as they all provide insight into potentially biasing factors in the consumption environment. Indeed, these papers provide new findings with respect to the nature of consumer biases, and simultaneously offer consumers strategies that may help them to avoid suboptimal decisions or even

unwanted behavior (i.e. increased consumption). In doing so, this session adds to existing research (e.g., Chandon & Wansink 2007a; Raghunathan, Naylor, & Hoyer 2006; Shiv, Carmon, & Ariely 2005) that has sought to identify negative biases on consumption.

In the first paper, Gros, Klesse, Meise and Dahl show that customization can be a source of bias in consumers' product perceptions (i.e. healthiness perception). They establish the counterintuitive finding that selecting your own ingredients as compared to receiving a prepared product decreases its perceived healthiness. In the second paper, Madzharov, Ramanathan and Block focus on the unexamined biasing factor that color brightness might have on food consumption. Not only do they show that people consume more from food products in light colors than from food products in dark colors but they also investigate the relevant role of the cognitive and affective reactions to food color that lead to this biased consumption. The third paper by Gros, Geyskens, Goukens and de Ruyter investigates the effects of brand labels on the consumed amount of snacks. Three studies show that the consumed amount of branded versus private label products depends on the consumption goal/context. The last paper by Plassmann, Chandon, Wadhwa, Linder, and Weber investigates how different nutrition claims associated with health perceptions of foods influence expectations about taste. Behavioral studies suggest that people perceive light vs. organic food claims to be lower in flavor pleasantness and intensity. However, fMRI data shows it is only experienced intensity, but not pleasantness that differs.

Taken together, these papers (all in advanced stage) disclose four unobtrusive factors that foster consumer biases in a food consumption context. This session does not only demonstrate that subtle cues might lead to counterintuitive consumers' product evaluations but, more importantly, they might even, unexpectedly, alter consumption behavior. As this session integrates diverse paradoxical phenomena in a food consumption context and integrates a diversity of research techniques (behavioral data and neuroscience data), we believe it contributes to the topic "Appreciating Diversity". We believe that this session will draw attention from a diverse audience. More specifically, it is expected to appeal to those interested in consumer biases, food consumption, self-control, and self-regulatory processes.

Mix it Baby - the Effect of Self-creation on Perceived Healthiness

EXTENDED ABSTRACT

Nowadays consumers are often given the opportunity to customize a certain product (Bendapudi & Leone 2003). Even companies in the food industry (e.g., M&Ms, Chocomize or Mymuesli) engage customers in the production process. That is, consumers have the possibility to select between different chocolate toppings or cereal ingredients and can create their individual product.

The primary purpose of this research is to explore whether the mere act of selecting one's own ingredients for a given food/drink influences its perceived healthiness. Considering the increasing trend for customization as well as the rising rates of obesity, it is relevant to investigate whether customizing food products could bias consumers' healthiness perceptions. In doing so, this research intends to add to existing research that identifies factors, such as price (Shiv et al. 2005), health positioning (Chandon & Wansink 2007a), and healthi-

ness (Raghunathan et al. 2006) which bias consumers' product perceptions. We present three studies to demonstrate that the mere act of selecting one's own ingredients as compared to buying the complete product decreases its perceived healthiness. Further, we show that this effect occurs independently of whether individuals perform the mixing action themselves or merely select the ingredients of their choice.

Study 1 fulfills the purpose to investigate whether students that mix their own juice and those that obtain a ready-made juice differ in their healthiness perceptions of the drink. For this purpose we asked students (N=85) entering the university whether they would like to have a free glass of juice in exchange for answering a questionnaire. Depending on the condition the student either saw one carafe containing a mixture of juices (non-creators) or three different carafes (self-creators), each containing a different juice. Since we want to test whether the mere act of selecting ingredients influences individuals' healthiness perceptions, we need three juices that do not differ in perceived healthiness. Based on a pre-test (N=38) we selected cranberry, lemon and orange juice since these juices were rated as equally healthy and tasty. After participants mixed their juice or obtained the prepared mix they were given a short questionnaire. The dependent variable was the perceived healthiness of the juice measured on a 7 points semantic differential scale (1=healthy and 7=unhealthy). An ANOVA with the healthiness ratings of the juice as dependent variable revealed that self-creators ($M_{self-creators}$=2.88, SD=0.21) rated the juice as significantly less healthy than non-creators ($M_{non-creators}$=2.12, SD=0.21; $F(1,83)$=6.58, $p<0.05$).

Study 2 replicates these findings in a laboratory setting. For generalizability of our findings, we make use of food (i.e., cereal). In line with study 1 we intend to explore whether selecting your own cereal ingredients as compared to obtaining a prepared mix decreases the perceived healthiness of the cereal. Participants (N = 62) were assigned to a self-creator condition or non-creator condition. While the self-creators selected the cereal ingredients of their choice (dried strawberries, dried apples, hazelnuts and almonds; pre-tested to be equal in perceived healthiness and taste), the non-creators obtained a prepared mix of ingredients. Before participants were allowed to eat the cereal, they indicated its perceived healthiness on an 11 point Likert scale (0=unhealthy, 10=very healthy). An ANOVA with the healthiness ratings of the cereal as the dependent variable revealed that self-creators ($M_{self-creators}$=6.39, SD=0.32) rated the cereal as significantly less healthy than non-creators ($M_{non-creators}$=7.29, SD=0.32; $F(1,60)$=4.07, $p<0.05$).

Study 3 fulfills the purpose to explore whether this effect is dependent on the physical act of mixing the ingredients together oneself. To test this we manipulate whether participants (N = 114) can create their own cereal (self-creators vs. non-creators) and whether they perform the action of mixing themselves (yes vs. no). We make use of cereal but use different ingredients (i.e., walnuts, pumpkin seeds and dried strawberries; pre-tested to be equally healthy and tasty). The set-up for study 3 is similar to study 2. However, we manipulate whether participants perform the act of mixing their ingredients themselves or whether a researcher assistant takes care of this. That is, self-creators can either fill the ingredients of their choice together themselves or tell a researcher which ones to mix. Similarly, non-creators can either fill the pre-determined ingredients together themselves or a researcher takes care of this. Before participants were allowed to eat the cereal, they indicated its perceived healthiness. A two-way ANOVA with healthiness ratings of the cereal as the dependent variable revealed a statistically significant main effect for creating your own cereal with self-creators rating the cereal as less healthy ($M_{self-creators}$=7.29, SD=0.23) than non-creators (M_{non-}

$_{creators}$=7.93, SD=0.22; $F(1,110)$=4.02; $p<0.05$) irrespective of who performs the action of mixing the ingredients.

Our studies reveal customization as a factor that biases consumers' healthiness perception: The mere act of selecting ingredients oneself decreases consumers' healthiness perception. We believe that this decrease in perceived healthiness could be due to altered variety perceptions. Extant research revealed that consumers' perceptions of variety are not necessarily contingent on the actual number of options present but can be influenced by assortment structure (Kahn & Wansink 2004) or categorizations (Mogilner, Rudnick, & Iyengar 2008). In line with this, we argue that selecting ingredients oneself might alter individuals' variety perceptions because it draws individuals' attention to the separate ingredients (i.e., sub-categories) rather than the product as a whole. Consequently, we argue that self-creators are more likely to recognize high- or low variety, i.e. three/four different ingredients than non-creators as in our experiments. In line with this argumentation study 3 demonstrates that self-creators rate the perceived variety as lower than non-self-creators. Further, we argue that individuals associate product variety with healthiness. That is, we predict that self-creators perceive the product as less healthy because they perceive it to contain less variety than non-creators. In a follow-up experiment, we intent to test this argumentation explicitly by manipulating the variety of ingredients participants choose from. If our effect is indeed caused by the fact that self-creators perceive the choice set to offer less variety, the effect should be blocked or even reversed if they can choose from a high variety of ingredients.

The Best of Both Worlds: Effects of Product Color Brightness on Hedonic Food Consumption

EXTENDED ABSTRACT

Color of food is essential for the consumption experience as it forms expectations about the food's flavor, freshness and taste (Chandon and Wansink 2010). In modern days, more and more foods are created in colors that do not necessarily match their natural color or have little relation to flavor (e.g., Gatorade drinks, Goldfish crackers, M&Ms). Advances in food coloring technology have made it possible for food companies to use color in innovative ways in order to differentiate their products, add variety to their assortments, and even to bring more fun and excitement to the food experience. Despite a dramatic increase in the variations and shades of colors and the corresponding increase in consumers' acceptance of them, scant attention has been paid to the topic of color in a food context in the consumer research literature (Labrecque and Patrick 2012).

Much of the consumer behavior research on color has looked at the effects of specific hues or hue categories (e.g., red vs. blue), while it has neglected the effects of color brightness, defined as the degree of lightness or darkness of the color (Labrecque and Patrick 2012). However, extant research from psychophysics and psychology posits that color brightness can produce strong systematic effects on people's emotions, perceptions and behavior (Meier, Robinson, and Clore 2004). For instance, previous research has found that lighter vs. darker colors evoke more positive affect and carry more positive meaning, and that people automatically perceive light objects positively and dark objects negatively (Meier et al. 2004). In the present research, we build on these findings, and propose that color brightness of the food will serve as an implicit perceptual and affective cue that ultimately biases food consumption.

Over a series of five studies, we present evidence that the color brightness of a hedonic food serves both as an automatic evaluative cue about its taste and healthiness and as an input to in-the-moment emotions that ultimately bias the volume of food consumed. We

demonstrate that light-colored foods are seen as both healthier and tastier, and are consumed more than dark-colored snacks. In addition, we show that the increased consumption of light-colored foods is due to a heterogeneous emotional response, with some people doing so due to increasing positive emotions and others due to decreasing negative emotions.

In study 1a we begin an investigation of the effect of food color brightness on consumption volume with two colors that vary on brightness but not on hue and chroma in order to control for these two properties of color. Study 1a was run as a single factor (product color brightness: light vs. dark color vs. control) between-subject design where respondents were given white M&Ms in the first condition, black M&Ms in the second, and gray M&Ms in the control condition. Respondents consumed more of the white M&Ms than the gray and black M&Ms. These effects were robust even after controlling for factors such as color preference, product liking, hunger and dietary restraint. In Study 1b we replicated these effects of increased consumption of the light-colored food with a different food product and shades of color, namely Golden Oreos which have a light, beige color, and Original Oreos which have a dark, black-brown color.

In study 2a, we used an IAT test to investigate the nature of the evaluations that people have of food that differs on color brightness. The results show that light-colored snacks are automatically seen as healthier, but also as tastier than dark-colored snacks. Thus, light-colored foods develop a positive halo that is deeply internalized, thereby evoking an automatic positive response among consumers, in terms of both the short-term hedonic and the long-term functional consequences of consumption. In study 2b we use a process-dissociation test and show that the health-related evaluations are stronger than the taste-related evaluations.

In Study 3 we examine how color brightness affects the dynamics of both positive and negative emotions over time as people consume the food. The results revealed that the effect of product color on emotions is heterogeneous. Two distinct latent classes of individuals were identified from the emotion data: a) High positive, Low negative, and b) High positive, High negative. In the first class, light-colored foods caused a strong ramp-up in positive emotions compared to dark colored foods, but had no effect on negative emotions. In the second class, light colored foods caused a significantly reduced level of negative emotions over time compared to dark colored foods, but had no effect on positive emotions. In addition, the analysis revealed that these emotion trajectories mediated the effect of color on consumption.

In the present paper we identify a new food halo, namely the effect of color brightness as a perceptual cue that automatically influences evaluations, in-the-moment emotions and actual consumption. We contribute to the literature on stimulus-based effects on food consumption by being the first to show that the color of the food itself influences consumption volume. This work also represents the first research in consumer behavior to provide an in-depth exploration of the effects of color brightness. In doing so, we also contribute to the consumer behavior and color psychology literatures by providing a moment-to-moment analysis of the effect of color during actual consumption.

Red Bull versus Red Thunder - The Influence of Brand Labels on Consumption Amount

EXTENDED ABSTRACT

Existing literature illustrates and supports that marketing actions can affect consumers' judgments, expectations and behavior. Studies investigating the influence of branding information on be-

havior showed, for example, that the energy brand displayed on cars in video games can affect the driving style (e.g. speed (Brasel & Gips 2011)), and that the pricing of an energy drink can impact objective performance metrics, also referred to as the placebo effect (Shiv et al. 2005). However, none of them investigated the effects of brand information on the consumed amount of that specific product. This is however an urgent matter given that the number of consumers switching from national brands to private label brands is drastically increasing (Steenkamp, Van Heerde, & Geyskens, 2010).

Based on the placebo effect literature in marketing, we assume that branded products are perceived to be more effective and of higher quality compared to private label brands. These differences in perception might affect the consumed amount of these products in two opposing ways. On the one hand, the higher effectiveness and quality signaled by a branded product might lead consumers to consume more of the branded product to generate more added value. On the other hand, previous research has shown that consumers trade off taste reductions for increased consumption. That is, labeling food as "healthy" reduces consumers' taste expectations (Raghunathan et al. 2006) and labels such as "low-fat" increase food intake (Wansink & Chandon, 2006). Following this reasoning, it might be that consumers compensate for the perceived lower quality of private label products by consuming more of them.

This research intends to shed some insight in these opposing predictions. Interestingly, we see that the answer is not as univocal as previously thought. Across three studies, we see that the relationship between branding and consumption depends on the consumption context. More specifically, if a product (e.g., candy) is consumed for a purpose in line with the general positioning of the brand (e.g., pleasure), consumption is expected to be higher for the branded product since this product is of higher quality and therefore expected to be more effective in contributing to reach the purpose. In other words, attributes communicated through the branding of a product become more relevant and thus consumers will consume more of the product to derive those benefits. However, interestingly, if a product (e.g., candy) is consumed for no particular purpose (e.g. recognition task), consumption is expected to be higher for the private label product since consumers want to compensate the lower quality by consuming more.

Study 1 (N=182) investigates the effect of brand information on the consumed amount of cola candies in two different consumption contexts. Cola candies are advertised as a product to enjoy. Participants were given a bowl of cola candies[1], preceded by a text with either no specific brand information, a "well-known and internationally recognized brand", or a "private label" information, and were asked to rate the candy either on taste enjoyment (Product Related context) or taste recognition (Product Unrelated context). A two-way ANOVA with consumption amount as the dependent variable revealed a statistically significant interaction effect (F(2,176)=5.700, p < .05), indicating that in the Related Context condition more of the "branded" cola candies is consumed compared to the "private label" cola candies or the cola candies without any brand information. However, in the Unrelated Context condition, participants ate more of the "private label" cola candies compared to the "branded" cola candies or the cola candies without any brand information.

Study 2 (N=78) replicates these findings with another hedonic product (i.e. chocolate spread) and with an adjusted manipulation in which the consumption time was kept constant (exactly 12 minutes). Chocolate spread is also positioned as a product to enjoy. The results of the 2 (Label: Nutella vs Private label) x 2 (Product Related con-

---

1   In all three studies the branded product was used. All products were pre-tested on their hedonic/functional perception.

text: enjoyment of a movie vs Product Unrelated context: remembering details of a movie) design indicate a significant interaction effect on consumption $(F(1,71)=5.470, p < 0.05)$. In the Related Context condition, more is consumed "Nutella" chocolate spread compared to "private label" chocolate spread. However, in the Unrelated Context condition, more is consumed of the "private label" chocolate spread compared to the "Nutella" chocolate spread.

Study 3 (N=92) intends to rule out an alternative hypothesis for the above-found effect. That is, in the two previous studies, the product related context was always an hedonic context, while the product unrelated context was a utilitarian one. This might drive the results. In this study we therefore used a product that is positioned as a product that is consumed for utilitarian reasons (i.e., Red Bull). A 2 (Label: Red Bull, Private Label) x 2 (Product Related context: non-verbal reasoning test vs Product Unrelated context: watching a movie) design reveals a significant interaction effect on consumption amount $(F(1,88) = 10.192, p < 0.01)$, replicating the findings of the previous studies. When doing a non-verbal reasoning test (Product Related context), participants consume significantly more of the Red Bull energy drink compared to the energy drink labeled as a private label. When the consumption does not have a particular purpose (Product Unrelated context), participants consume significantly more of the energy drink labeled as a private label compared to the energy drink labeled as Red Bull if the consumption.

Throughout three studies, we show that the consumed amount of branded versus private label products depends on the consumption goal/context. Interestingly, when the product does serve the consumption purpose, people consume more of the product if it is labeled as a well-known brand. However, if the product does not serve the consumption purpose, people consume more of the product if it is labeled as a private label. These findings imply that positioning branded products as serving a particular purpose seems to be a profitable strategy since it increases consumption of the branded product.

The Low Intensity of Light: Behavioral and fMRI Insights into the Effects of "Light" and "Organic" Claims on Flavor Processing

EXTENDED ABSTRACT

Why has people's weight kept increasing even though "healthy" foods have become more popular? One explanation is that people eat more when foods are positioned as healthy (Chandon & Wansink 2007a; Provencher, Polivy, & Herman 2009; Wansink & Chandon 2006). However, other studies (Raghunathan et al. 2006) have shown that people expect healthy food to taste less good. How can we reconcile these two findings and understand why people eat more when they expect the food to taste less good?

One reason is that people eat more when the food is presented as "healthy" (either as "diet," or "organic") because they expect that it contains fewer calories and hence that they can eat more of it without gaining weight (Chandon & Wansink 2007b; Provencher et al. 2009; Wansink & Chandon 2006; Schuldt & Schwarz 2010). On the other hand, these healthfulness claims differ with respect to consumers' expectations about the tastiness of the food. Unlike light foods, organic foods are perceived to be both healthy AND tasty (Niewold 2010).

Exploring answers to these conflicting findings about health associations, we examine how claims that the food is "light," "organic," or "regular" influence flavor perceptions using behavioral, self-reported, and neuro-imaging data. By doing this, we test another explanation of the "low fat food and high fat people" phenomenon, which is that people expect food positioned "light" to have a less

intense flavor, and hence consume more of it to achieve the desired levels of hedonic satisfaction.

In the first study, 57 participants were asked to sample a regular version of a drink and then to match the flavor pleasantness or flavor intensity of this drink with another (not sampled) drink that was either labeled as "healthy" or "organic". To do this, they were provided with concentrated pure flavor extracts, which they were asked to add to either the "regular" drink they had just sampled or the other drink. Participants added more flavor to the "light" drink than to the "regular" drink $(F(1, 56) = 77.61, p<.001)$, regardless of whether they were asked to match them on pleasantness $(M_{light}=4.85$ SEM=.49 vs. $M_{regular}=0.58$, SEM=.26) or on intensity $(M_{light}=5.63$, SEM=.73; $M_{reg}=0.68$, SEM=.26). As predicted, the organic claim had opposite (though weaker) effects $(F(1, 56) = 7.46, p<.01)$: People added more flavor to the regular drink in both the pleasantness matching task $(M_{organic}=1.01$, SEM=.31vs. $M_{reg}=2.05$, SEM=.47) and the intensity matching task $(M_{organic}=1.43$, SEM=.39 vs. $M_{reg}=3.06$, SEM=.71). Overall, the study showed, from behavioral data, that people expect "light" to be worse than "regular", which is in turn worse than "organic", in terms of both flavor pleasantness and intensity.

In the second study (N=58), we investigated how flavor expectations induced by health claims affect how the flavor is actually experienced using both self-reported and functional magnetic resonance (fMRI) data. Consistent with the expectations obtained in Study 1, experienced pleasantness was higher in the "regular" $(M_{reg}=5.62$; SEM=0.21) than in the "light" condition $(M_{light}=5.27$; SEM=0.21; $T(1,28)=2.93$; $p<.005)$. Another comparison also showed that pleasantness was higher in the organic condition $(M_{organic}=6.09$; SEM=0.16) than in the regular condition regular $(M_{reg}=5.58$; SEM=0.17; $T(1,28)=3.74$; $p<.001)$. Ratings of experienced intensity were also consistent with the expectation results found in study 1 for light claims $(M_{reg}=5.83$; SEM=0.17 vs. $M_{light}=5.19$; SEM=0.19; $T(1,28)=3.66$; $p<.001)$ but not for organic claims, which did not significantly affect experienced flavor intensity $(M_{organic}=5.68$; SEM=0.14 vs. $M_{reg}=5.68$; SEM=0.14; $T(1,28)=0.04$; p=.52).

Analyses of the brain activity while people were consuming these identical foods were consistent with the reported ratings for intensity, but not for pleasantness. The "light" label reduced activity in the brain area encoding flavor intensity (i.e. the ventral striatum, amygdala), and activity in this area was similar in the "organic" and "regular" conditions. The "organic" label increased brain activity in the area encoding flavor pleasantness (i.e. the orbitofrontal cortex), which was consistent with the ratings. However, activity in the area encoding pleasantness was similar in the "light" and "regular" conditions, contrary to what the self-reports indicated. These results support earlier findings about the unreliability of self-reported measures of flavor intensity, which did not adequately represent brain activity, and demonstrate the value of measuring brain activity to understand the effects of food claims. More importantly, they show that people actually experienced similar taste pleasantness for light food.

Given the interesting pattern of results for the "light" claims, in a third study, we focused on

the effects of "light" claims. We asked 34 participants to add milk to a drink powder that either claimed to be "light" or "regular". People added less milk when the powder was labeled as "light" (M = 294.26 ml, SEM = 36.85ml) than "regular" (M = 327.08 ml, SEM = 49.09 ml; $F(1,32)= 8.52$, p<.01). Yet, they expected to need to drink more of a pre-mixed version of the

drink to feel full for three hours when the powder was labeled "light" (M =675.23 ml, SEM = 55.01 ml) vs. "regular" (M=403 ml, SEM = 36.03 ml; $F(1,32)= 3.19$, p<.08).

Overall, our results show that "light" and "organic" claims, while both seen as improving the healthfulness of the food, have mostly opposite effects in terms of the flavor of the food. Organic claims improve expected flavor intensity and both expected and experienced pleasantness, and these results are consistent across all measures.

Our results about the effects of "light" claims reveal an intriguing pattern. People think that "light" foods have a less pleasant and less intense flavor, before and after consuming them, which is why they expect that they have to drink more of it to be satiated. However, fMRI data shows that "light" claims only influence experienced intensity, but not pleasantness. Thus, people may overeat light products because of reduced perception of flavor intensity—yet may misattribute it to lower taste pleasantness. This may explain the paradoxical phenomenon that people overeat light products even though they expect to like them less. It also offers a potential solution: Let people compensate for the lower expected intensity of light products by increasing the dosage of the flavor component, rather than by eating more of it.

Darren W. Dahl, University of British Columbia, Canada
Jennifer J. Argo, University of Alberta, Canada

SESSION OVERVIEW

The question of how we are affected by the others around us is one that has preoccupied philosophers and psychologists, among others. Humans are commonly characterized as "social animals" and conventional wisdom often dictates that lives enriched with social interactions are more rewarding. Indeed, findings show that people who spend more quality time with others (per day) tend to be more satisfied with their lives (Goldsmith and Goldsmith 2010). Further, social isolation, or loneliness, which results from a dissatisfaction with the quality or quantity of one's social relationships can have a variety of negative cognitive, behavioral and physiological consequences (for review see Hawkley and Cacioppo 2010). However, conventional wisdom and prior research notwithstanding, this session will demonstrate that there are a variety of contexts in which "hell is other people" (Sartre 1944) illustrating the dark side of consumer behavior that can come as a result of social interactions and social comparisons.

Specifically, this session contains three papers that highlight when and how others can promote more impulsive and selfish consumer behaviors and concludes with a fourth paper that highlights important moderators to this pattern. The first paper by Griskevicius and colleagues examines how sex ratio (the ratio of men to women in the social environment) can affect consumer decision making. The authors find that when men perceive a relative abundance of men (or a shortage of women) their spending behavior becomes more impulsive and they are more likely to engage in conspicuous consumption. Building on this work, the second paper by Youn and Goldsmith tests how priming envy, an emotion rooted in social comparison, affects subsequent unrelated decisions. These authors find priming envy towards others leads consumers to become more selfish, more hard working, and more prone to conspicuous consumption due to an underlying shift towards an agentic orientation. Next Lamberton,

Kristofferson and Dahl explore the consequences of envy in an interpersonal context. These authors find that consumers with high self-esteem will congratulate envied others, but covertly sabotage them; however, those with low self-esteem will either react overtly against the envied other or take their negative feelings out on the envied product rather than the envied person. Having shown the negative ramifications that social interactions and social comparisons can bring, the final paper by Lin, Dahl, and Argo rounds out the session by examining the factors that make consumers more forgiving towards others. Specifically, this paper explores a variety of variables that increase the likelihood that consumers will make excuses for the others' violations (e.g., when they violate social norms) as opposed to condemning them. All projects are in advanced stages of completion.

Because these projects approach the topic of how social interactions and social comparisons affect consumer behavior from very different perspectives (e.g., theory is drawn from evolutionary psychology, social psychology, the emotions literature and marketing) we expect that this session will be of interest to a wide audience. Further, because these four papers all feature research that makes substantial theoretical contributions to the existing work on how others influence consumer behavior while being grounded in phenomenon that are marketing relevant, we expect that the practical insights each paper suggests will make this session appealing to many.

Mo' Men, Mo' Problems: Sex Ratio, Impulsive Spending, and Conspicuous Consumption

EXTENDED ABSTRACT

How does the ratio of men to women influence consumer behavior? We show that an abundance of men leads other men to become more impulsive, save less, and borrow more. A scarcity of women also led men to increase conspicuous consumption, including spending more money on engagement rings.

Macon and Columbus are two cities in the U.S. state of Georgia. Despite being less than a hundred miles apart, the residents of each city have drastically different spending habits: The consumer debt of people living in Columbus is an astounding 2.7 standard deviations higher than that of people living in Macon—a difference of $3,479 per consumer. What might account for this staggering divergence in borrowing and spending across the two nearby cities?

We suggest that this difference in debt might be linked to an often overlooked difference between the two cities: the ratio of single men to women in each area. Whereas in fiscally-responsible Macon there are only 0.78 single men for every woman, in debt-heavy Columbus there are 1.18 single men for every woman. In the current research we use both archival data and some of the first experimental manipulations of perceived sex ratio to examine how sex ratio influences financial decisions and spending.

The ratio of males to females is known to be an important factor in determining animal behavior. Animal research shows that imbalanced sex ratios tend to have the strongest effects on male behavior. When females become scarce (male-biased sex ratio), males intensify mating and competition behavior. For example, as sex ratio shifts from female-biased to male-biased, male grey mouse lemurs allocate more effort on mate search and courtship (Eberle and Kappeler

2004), and male European bitterlings intensify intra-sexual competition (Mills and Reynolds 2003).

Sex ratio also varies in human populations. For example, whereas Las Vegas, Nevada, has 1.16 men per every woman, Birmingham, Alabama, has 0.88 men per every woman (Kruger 2009). Sex ratios can also vary between nations. China, for example, will soon have a surplus of over 40 million men (Hesketh 2009).

Given that sex ratio influences mating and competition behavior in animals, we hypothesize that sex ratio may affect people's consumer behavior. Mating effort and intra-sexual competition in humans is associated with increased men's conspicuous consumption (Griskevicius et al., 2007; Sundie et al., 2011) and increased men's desire for immediate financial rewards (Van den Bergh, Dewitte, & Warlop, 2008). Given that a scarcity of women should amplify men's mating and competition behavior, we predicted that a male-biased sex ratio should lead men to become (1) more impulsive, (2) save less and borrow more, and (3) spend more money on mating and status-related products.

Study 1 examined the relationship between sex ratio in 120 US cities and two behavioral measures of economic impulsivity: (a) average number of credit cards owned by residents in each city and (b) average amount of debt carried by people in each city. Results revealed a positive correlation between sex ratio and number of credit cards, $r(134) = .24$, $p = .005$, and amount of debt, $r(134) = .19$, $p = .025$. A scarcity of women in American cities is related to owning more credit cards and having a higher amount of debt.

Study 2 used an experiment approach. Participants first viewed photo arrays of men and women that were ostensibly indicative of the local population. The arrays either had more men, more women, or equal sex ratio (control). Then, participants made a series of inter-temporal financial choices involving real monetary incentives. For example, people chose between receiving $37 tomorrow versus $54 in 33 days. Findings showed that sex ratio had no effect on women's inter-temporal choice. For men, however, sex ratio produced a large effect. As predicted, a male-biased ratio led men to opt for immediate financial rewards, $t(199) = 3.26$, $p = .001$. This means that as women became scarce, men desired immediate monetary rewards.

In Study 3 participants read news articles describing the local population as either having more single men or more single women. Participants then indicated how much money they would save each month from a paycheck, as well as how much money they would borrow each month for immediate expenditures. Findings showed that sex ratio again had no effect on women's saving or borrowing. However, male-biased sex ratios led men to save less money, $t(95) = 2.90$, $p = .005$, cutting their monthly savings by 42%. A scarcity of women also led men to want to borrow 84% more money for use toward immediate expenditures, $t(95) = 2.29$, $p = .025$.

Study 4 investigated how sex ratio influences spending. The study focused on two types of expenditures: (1) *mating-related* expenditures (Valentine's Day gift, dinner date, engagement ring) and (2) *status-related conspicuous* products (new car, designer handbag/wallet, and designer sunglasses). Findings showed that a scarcity of women led men to pay more for both mating-related and status-related products, $t(143) = 3.18$, $p = .001$. When the sex ratio was male-biased, for example, men paid $6.01 more for a Valentine's Day gift and $278 more for an engagement ring.

Our findings highlight people's sensitivity to a particular feature of the social environment—the ratio of men to women. Just as sex ratio has important effects on animal behavior, we find that sex ratio has theoretically consistent effects on human behavior. In addition, the current studies suggest that sex ratio might have far-reaching consequences for many economic decisions and, potentially, whole economies.

The Green Eyed Monster is Motivated: How Incidental Envy Triggers an Agentic Orientation

EXTENDED ABSTRACT

We live in a world where others (ranging from celebrities to peers) have things that we want yet we do not or cannot own. For this reason, envy is common among consumers. Envy is an emotion that results from upward social comparisons, which can be made deliberately or unintentionally (Mussweiler, Ruter, and Epstude 2004). It activates mixed emotions: causing both longing and wishfulness along with self-criticism and dissatisfaction (Smith, Kim, and Parrott 1988). Prior research demonstrates that envy causes consumers to focus on the person or object that arouses the emotion (e.g., showing that we are willing to pay more for products that we envy, Van de Ven, Zeelenberg, and Pieters 2011). However, far less is known about how the incidental activation of envy can affect judgments and behaviors in unrelated domains.

We hypothesize that incidental feelings of envy will affect unrelated judgments and behaviors by way of activating a more agentic orientation (Hogan 1982). Prior work has distinguished between agentic and communal motivations, defining agency as the desire to "get ahead" in a given context, even if this comes at the expense of others. Conversely, communion refers to the desire to "get along" by incorporating others in one's goal pursuits (e.g., Rucker, Galinsky and Dubois 2012). We will test if incidentally activating envy increases agentic behavior in subsequent, unrelated decisions (e.g., resource distribution, self-regulation, and consumption). Furthermore, we posit that this agentic behavior will only emerge when people feel envious toward others, but not when they feel envied by others. Said differently feeling dissatisfied with oneself in comparison to others will cause consumers to act in a more self-focused way, however, priming the concept of envy, more generally, will not. We test this prediction across three studies.

In our first study, incidental envy was activated through an episodic recall task (Malatesta and Izard 1984), which asked participants to recall a time they felt envy towards others (other-envy condition). Results from this condition were then compared to two control conditions, one in which participants were asked to recall their activities from last week (control condition) and a second in which participants were asked to recall a time someone else felt envy towards them (self-envy condition).

After completing the incidental envy manipulation, participants were asked to participate in a dictator game (i.e., asked how much they would want to keep for themselves and how much they would want to allocate to a hypothetical other that they were paired with in the game, total amount = $5). In line with our prediction that incidentally activating envy toward others will produce a more self-focused, agentic orientation, we observe that those primed with other-envy kept significantly more money for themselves (allocating less to others) than those in either the control condition or in the self-envy condition (amount allocated to others: $M_{other-envy}$=$2.37; $M_{control}$=$2.89; $M_{self-envy}$=$3.00; $p's<.05$). Not only do these results provide preliminary support for our hypothesis that envy promotes an agentic orientation (seen here in retention of resources at the expense of others), but we also observe that merely priming the concept of envy does not produce this pattern. This suggests that the role of the self, particularly perceptions of the self as inferior compared to others, in the experience of envy is vital to generate the agentic response.

Study 2 was designed to test more directly for the role of envy as a motivational force to "get ahead." For this study, participants were randomly assigned to the other-envy versus control conditions described previously. After completing the episodic recall task, they were then asked to solve a series of anagrams that were presented as part of an unrelated task. The final anagram was unsolvable, and the time spent persisting on this task was used as the dependent measure, as time spent persisting on unsolvable tasks is often used as a proxy for motivation (Shah and Higgins 1997; Shah, Higgins, and Friedman 1998). In line with our predictions, the results demonstrate that the activation of incidental envy increased motivation on the task (seconds spent on the unsolvable task: $M_{other\text{-}envy}$=83.62; $M_{control}$=41.89; p<.05).

Study 3 was designed to build on the results of studies 1 and 2 by testing for the role of incidental envy more directly on consumption decisions. Because flaunting material resources is instrumental to gaining social status (Veblen 1899), we argue that an agentic orientation (here, caused by envy) should increase consumers' desire for such goods. In this study, participants were assigned to one of the three conditions described in Study 1, then presented with an array of luxury products (e.g., Hermes belt, Prada sunglasses, Louis Vuitton bag etc.), and instructed to answer what percentage of its retail price they were willing to bid on an auction, ranging from 0 to 120% (in line with prior research, this measure was used to reduce the variance that might occur with open-ended responses; Rucker and Galinsky 2008). The results support our prediction: when people recalled experiences of envying others, they were willing to pay more for conspicuous goods than either the control condition or the self-envy condition (% of retail: $M_{other\text{-}envy}$=54.76; $M_{self\text{-}envy}$=43.10; $M_{control}$=43.17; p's<.05)

Taken together, these studies suggest that experiencing envy towards others, and not merely activating the concept of envy, triggers an agentic mindset that leads to distinct behaviors in various domains. Specifically, other-envy lead people to be more selfish with resources (Study 1), work harder (Study 2), and engage more in conspicuous consumption (Study 3). We are in the process of conducting additional studies to demonstrate: (1) that the activation of an agentic orientation mediates the effect of envy on these behavioral outcomes and (2) that the increase in consumption is specific to domains where one could gain social status. We conclude with a discussion of the theoretical and practical implications for these findings.

(Secretly) Blowing out Candles to Make Ours Burn Brighter: The relationship between self-esteem, malicious envy, and interpersonal behaviors

EXTENDED ABSTRACT

Intuition suggests that self-confident individuals respond to difficult social situations with magnanimity. For example, on seeing others succeed where they have failed, the high-self esteem individual claps the victor on the back with a smile, while the low self-esteem individual bitterly retreats to a corner to lick their wounds. Such observations lead us to equate high self-esteem with stronger moral character in the face of painful social emotions like envy.

We argue that this relationship may not hold true if one looks beyond overt actions or considers multiple types of envy experiences. To challenge this intuition, the present research documents the behavior of individuals of varying level of self-esteem when experiencing envy. We consider both benign and malicious envy (following Van deVen et al. 2011), create real envy situations, and examine both overt and covert behaviors toward the envied individual.

Study 1 followed a 2 (malicious or benign envy) x 2 (no winner, winner) x self-esteem (continuous) between-subjects design. Self-esteem was collected approximately 3 weeks prior to the session, using the Rosenberg (1979) scale. Participants visited the lab in groups of 4 or 5 with one confederate. They were told that their business school was offering an opportunity to interview for a marketing internship at a popular company (Lululemon athletic clothing). However, only a few students would be able to interview. In the *benign envy* sessions, award was dependent on relevant work experience provided to career services earlier in the semester via an in-class survey. In the *malicious envy* sessions, participants read that envelopes had been placed under the seats in the room. The envelopes indicated who would be selected for the interview. Further, in some sessions, the confederate was simply another participant and there was no winner. In others, the confederate won and celebrated appropriately.

After learning if anyone had won the internship opportunity, we captured both overt and covert behaviors toward the winner. Overt behavior was captured by allowing participants to help the interview winner prepare. Willing individuals would be contacted immediately after the session to set up a coaching meeting. Willingness to help was captured on a 1 (not at all willing) to 7 (very willing) scale. Covert behaviors were captured by asking participants to anonymously provide 5 practice interview questions for the winner. Quality of these questions as determined by two condition-blind judges constituted our covert behavior measure.

An ANOVA was estimated using envy type condition, winner/no-winner condition, and participants' self-esteem scores to predict both overt and covert behavior. We first note results consistent with intuition: higher self-esteem individuals were significantly (p < .05) more likely to overtly help the interview winner than lower self-esteem individuals. No other interactions or main effects emerged.

However, analyzing covert behavior provided yields a three-way interaction of benign/malicious envy, whether the winner was present or not, and self-esteem (p = .01). When the interview recipient deserved to win the internship (benign envy condition), none of our manipulated or measured factors influenced question quality (p > .3). This supports the findings of van de Ven (2011) regarding the non-hurtful tendencies of benign envy. By contrast, when the award was random (malicious envy condition), higher self-esteem individuals provided significantly lower-quality interview questions than lower self-esteem individuals when the confederate was a winner as opposed to when the confederate was simply another participant. Thus, higher self-esteem individuals were willing to covertly sabotage undeserving victors.

Study 2 focused on malicious situations and tested for that meditational role of envy. We also wanted to see if covert harm to the envied other bled over onto the envied product. This study followed a 2 (winner-present, no winner present) x self-esteem (continuous) design. Participants had the opportunity to win a set of Vancouver Canucks tickets. A confederate was once again present in all conditions, and in the winner-present conditions, was awarded the tickets during the session based on a random seat assignment.

As part of a presumably unrelated task, participants later read that they would be randomly assigned another individual about whom to form "thin-slice" judgments. In reality all participants were assigned the confederate. Their evaluation of the confederate on various positive personality traits (e.g., hardworking, intelligent, etc.) formed our measure of covert behavior. We also collected willingness-to-pay for the Canucks tickets in a list of other event tickets in the area. Embedded in a battery of measures at the close of the session were three questions asking participants to rate how much they

felt envious, jealous, or as though someone was better off than they were during the session, indexed to form an envy measure.

Mirroring study 1, higher self-esteem individuals showed a significantly worse evaluation of the confederate when the confederate had won the tickets as opposed to when they had not won (p < .05). Envy mediated effects on evaluations of the confederate. Surprisingly, we found that this relationship was inverted for WTP for the envied product (but saw no effects on other ticket prices): Lower self-esteem individuals showed significant *decreases* in value for the tickets when a winner had been in their session, in those cases valuing it significantly less than did the higher self-esteem individuals.

Thus, it appears that while higher self-esteem individuals express envy via covert actions toward the envied person, lower self-esteem individuals exhibit a sour grapes effect, taking out their frustration on the product and overtly refusing help. Thus, it may be that our equation of moral strength and self-esteem exists because this sour grapes effect is expressed publicly. Still, high self-esteem responses may be no less damaging, though better-hidden, and warrant further research and intervention.

Do the Crime, *Always* Do the Time? Insights into Consumer-to-Consumer Punishment Decisions

EXTENDED ABSTRACT

Social order can be disrupted by norm violations in consumption contexts (e.g., cutting the line, hovering), and previous research has established the theoretical conceptualization that restoration of social order that was disrupted by norm violations can be demonstrated through a victim's (or bystander's) decision to punish the norm violator (Bernhard et al. 2006; Golash 2005; Miethe and Meier 1994). Diverging from the conventional conceptualization that the restoration of social order is achieved through punishment, the current research investigates whether consumers can also achieve social order through the excusing of norm violators in various consumption contexts.

While previous literature has focused on defining the purpose of punishment (e.g., whether the intent of punishment is to seek retribution or to teach the norm violator a lesson; Kolber 2009), and identifying individual difference factors that enhance punishment tendencies (e.g., justice sensitivity, Gollwitzer et al. 2009), little is known about the boundary conditions of the punishment decision. We address this research gap by identifying factors that can influence the level of punishment delivered by consumers. Specifically, we investigate whether consumers can achieve social order by mitigating punishment against another consumer who has violated a consumption norm. The specific instances we explore are a) if social order has already been restored by the actions of other parties in the consumption environment (Study 1), b) if a norm violator has experienced an unjustified adversity (Studies 2a/b), and c) if the violator holds a position that is aspirational (Study 3). In our studies, we consider two categories of punishment (Skinner 1953): positive (i.e., punishment which involves the presentation of an undesirable stimulus such as scolding or a physically demanding task) and negative (i.e., punishment which involves the removal of a desirable stimulus from the norm violator such as withholding assistance).

Study 1. This study employed a 2 (norm violation: present vs. absent) x 2 (action by another party: yes vs. no) + (control) between-participants design. The context of the study was a product evaluation task, in which participants were asked to evaluate a shirt at a display table. To manipulate norm violation, the confederate either created a mess (vs. did not create a mess) at a store display table. To manipulate action by another party, the experimenter verbally scold-

ed (vs. did not scold) the confederate. The confederate then "accidently" knocked over a pile of papers in front of the participant, and the punishment measure was determined by whether the participant refrained from helping the confederate pick up the papers. We show that when social order was restored by the punishment delivered to the norm violator by another party, i.e., store employee in the retail context, consumers mitigated the likelihood of punishment.

Study 2a. This study employed a 2 (norm violation: present vs. absent) x 2 (adversity: yes vs. no) between-participants design. To manipulate adversity, the participant either witnesses another passenger experiencing a computer failure (vs. no failure) at an airline counter. To manipulate norm violation, the passenger in the scenario either cut in line (vs. did not cut in line) later on at the security checkpoint. Results show that when a norm violator faced an unjustified adversity that disrupts the perceived social order, i.e., negative consumption event, social order is achieved by excusing the norm violator.

Study 2b. This study employed a 2 (norm violation: present vs. absent) x 3 (adversity: yes – personal control vs. yes – no personal control vs. no) between-participants design. The context of the scenario involved the participant witnessing a norm violation at a post office. To manipulate norm violation, a consumer who arrived at the same time as a woman with the baby stroller either moved in front (vs. did not move in front) of the woman as she made her way through the door with the stroller. To manipulate adversity, the consumer was either of average weight (vs. obese). Additionally, the obese target was described as someone who lives a sedentary lifestyle (vs. had a medical condition that causes weight gain). The results show that when a norm violator experienced an unjustified adversity that is beyond personal control, i.e., negative physical attribute due to medical condition, social order is again achieved by excusing the norm violator.

Study 3. This study employed a one cell (aspirational position: yes vs. no) + control between-participants design, and business students participated. The context of the study was the evaluation of a personal training service whereby the participants were asked to design a physical exercise routine for the confederate who was posing as a participant. Norm violation was held at a constant for the aspirational position conditions, so the confederate arrived 5 minutes late for the study. To manipulate aspirational position, the confederate either casually mentioned that he had a job interview with a large marketing company (vs. café on campus). To measure punishment, participants indicated the number of push-ups (range from 0-50 repetitions) the confederate should be asked to complete. We find the aspirational position held by the norm violator changes the subsequent punishment required to restore social order. Here, justification for the norm violation mediates this relationship between the aspirational position and the level of punishment delivered.

Discussion. Previous work in consumer behavior has focused on identifying important consumption norms and determining how the promotion of these norms can change people's behaviors (e.g., Goldstein et al. 2008). Our research diverges from this line of work by exploring how consumers react toward those who violate norms in the consumption context. Based on the theoretical conceptualization that disrupted social order can be restored through punishment of the norm violators, the current research contributes to our understanding of consumers' reactions toward norm violators by providing new insight into how consumers use the level of punishment delivered as a means to address a norm violation that has occurred in the consumption context.

Not What I Expected: Unanticipated Consequences of Product Exposure and Use

Paper #4: Exposure to Unattainable Luxury: Boomerang Effects on Extrinsic and Materialistic Goals

Katrien Meert, Ghent University, Belgium

Inge Lens, KU Leuven, Belgium

Mario Pandelaere, Ghent University, Belgium

SESSION OVERVIEW

Consumers often seek out products or brands in the service of satisfying personal goals, and marketers may try to stimulate consumption by making these goals salient. For example, consumers may believe that by purchasing specific products or brands, they can express unique aspects of themselves (Berger and Heath 2007), close gaps in identity (Wicklund and Gollwitzer 1982), affiliate with others (Mead et al. 2011) or even feel more powerful (Rucker and Galinsky 2008) and marketers may strengthen this perceived link through promotional campaigns or messages. In this session, we examine contexts where consumer and marketer intuitions about brand and luxury exposure may boomerang; when seeking out or promoting products may have unintended, and sometimes even deleterious, consequences.

First, Cutright and colleagues demonstrate that by using products and brands to the end of expressing the self, consumers may actually be suppressing their overall religiosity. In this manner, subtle exposure to brands through choice or trial can actually cause people to "lose their religion." Samper, Bettman and Fitzsimons show that consumers, in an effort to put their best foot forward by choosing a higher end item for a high-stakes task(e.g., Armani Suit for a job interview, Odyssey Golf Club for a putting task), may actually polarize their self-perceptions of success and failure. While consumers using a high end branded item who succeed on a task feel significantly more skilled than those using a neutral item, these consumers also feel significantly more frustrated and less skilled when using this branded item if their performance was unsuccessful. Mourey, Olson and Yoon examine this phenomenon in the domain of affiliation, where they show that while social exclusion increases desire for brands that may fulfill interpersonal needs, using these anthropomorphized products can actually lead consumers to be less likely to seek out human connections. Finally, Meert, Lens and Pandelaere examine this phenomenon through a marketer's lens, showing that standard practices of trying to persuade consumers and encourage materialistic goal pursuit by showing images of luxury can actually

backfire when consumers are presented with *unattainable* luxury. Specifically, the salience of unattainable luxury can lead to reduced interest in material goods and even increased prosocial behaviors. The fourth paper facilitates an integration of these unintended consequences across consumer and marketer-related goals.

Given its unique, counterintuitive focus, this session is expected to appeal to a broad segment of ACR members. The four papers, all at advanced stages, are expected to generate interest among individuals with interests in anthropomorphism, branding, goal pursuit and motivation, luxury goods, priming, product use, religion, consumer welfare and marketing applications. All speakers (Cutright, Samper, Mourey and Meert, indicated by asterisk, below) have agreed to serve if the proposal is accepted.

In sum, this session brings together a diverse set of papers examining the unintended effects of brand or product exposure in religious, aspirational, affiliative and luxury contexts. By combining a breadth of papers that address this similar phenomenon, we underscore the importance of understanding the downstream consequences of consumption and shed greater insight into how the goals of consumers and marketers may be undermined by exposure to initially desirable products or brands.

Finding Brands and Losing Your Religion?

EXTENDED ABSTRACT

Whether you consider it to be a source of deadly extremism or the pathway to humanity's highest potential (Pargament, 2002), few will deny the power of religion. In this research, however, we ask whether religiosity (i.e., the centrality of religion in one's life) can be undermined by the presence of brand name products. We reason that when brands are salient, religion will be devalued, given that people often use brands to satisfy similar self-expressive needs as religion (e.g., Shachar, Erdem, Cutright, & Fitzsimons, 2011). However, we expect that the salience of brands will lead to lower levels of religiosity only when individuals are able to incorporate the brands as meaningful extensions of themselves. When brands do not allow individuals to communicate a part of "self", they are unlikely to be viewed as acceptable substitutes for religion.

Study 1 tested our basic hypothesis that the salience of brands leads to lower levels of religiosity. The experiment contained two between-subject conditions: high brand salience versus low brand salience. In the high brand salience condition, participants chose between two branded products, 10 different times. For example, in one choice, they decided between a red Adidas shirt and a green Adidas shirt. In the low brand salience condition, participants chose between the same pairs of products except the brand names were removed. After making their choices, participants completed the Religious Commitment scale (Worthington et al., 2003, e.g., "My religious beliefs lie behind my whole approach to life"). Consistent with hypotheses, results indicated that the high brand salience condition reported significantly lower religious commitment than the low brand salience condition.

In Study 2, we explored the breadth of the hypothesized effect by investigating how brand salience would impact items indirectly related to religion. In particular, we were interested in how brand salience would influence attitudes towards malls that resembled churches versus those that did not. We expected that high brand salience would cause people to devalue religion and apply these at-

titudes towards malls that resembled churches. The experiment's design was a 2(brand salience: high vs. low; between subjects) x 2(mall type: high church resemblance vs. no church resemblance; within subjects).

Participants were randomly assigned to a high brand salience condition or low brand salience condition as in Study 1. After making their choices, participants evaluated a series of six malls, half of which strongly resembled churches while the others did not. Participants then indicated how much they liked each mall (7pt scales).

Results revealed no significant main effects, but there was a significant interaction of brand salience and mall type on liking. When evaluating the malls that resembled churches, the high brand salience condition liked the malls less than the low brand salience condition. When evaluating the malls that did not resemble churches, the two conditions did not differ from one another. This study therefore suggests that brands not only impact basic reports of religiosity, but even color individuals' perceptions of objects that are loosely associated with religion.

In the studies reported thus far, we have used an inherently self-expressive context to reveal the hypothesized effect of brands: choice exercises that allowed people to express themselves with the brands to which they were exposed. In the next study, we wanted to more explicitly demonstrate that the relationship between brands and religiosity exists only when brands are incorporated into one's expression of self. Thus, Study 3 was designed to manipulate the degree to which products are incorporated into the self by altering individuals' physical relationship with the product. We hypothesized that wearing a brand would provide a strong opportunity for individuals to incorporate the brand into one's expression of self (e.g., Gino, Norton, & Ariely, 2010), while simply looking at a product would not. Accordingly, we expected that when individuals wore a branded product (versus a non-branded product), religiosity would decline. We did not expect this relationship to exist when individuals simply looked at the brand. In other words, we expected "wearing" a brand to have similar effects as "choosing" a brand since each of these contexts allows people to say something about themselves with brands. We expected that simply "looking at" a brand would be less likely to aid self-expression.

The design was a 2(brand salience: high vs. low) x 2(self-expressive context: high vs. low). In half of the sessions participants came into the lab and were given an Apple-branded lanyard (high brand salience). In the remaining sessions, participants were given a plain black lanyard (low brand salience). After receiving their lanyards, half of the participants were told to wear and evaluate the lanyard (high expression). The remaining participants were told NOT to wear it; just to look at it and evaluate it (low expression). Participants then completed the Religious Commitment scale.

There were no main effects of brand salience or self-expressive context on religious commitment. However, a significant interaction of the two conditions emerged. In the high self-expression condition (i.e., wearing the lanyard), individuals in the high brand salience condition (Apple) reported lower religious beliefs than individuals in the low brand salience condition. Within the low self-expression condition (i.e., looking only), the high and low brand salience groups were not significantly different from one another. This study therefore reiterates the notion that brands only lead to lower levels of religiosity when incorporated into expressions of the self.

In summary, these studies have demonstrated that beliefs about God waver when brands take center stage in individuals' minds. We've found that this is most likely to be true when brands are incorporated into the self and serve as a tool for self-expression. This research offers not only an understanding of the power of brands in shaping individuals' most sacred beliefs, but also sheds light on the value that many individuals assign to religiosity. It seems that what many consider sacred is often treated as merely a means to an (expressive) end.

Rolling the Dice with Premium Products: Using a High End Product Polarizes Self-Perceptions of Performance

EXTENDED ABSTRACT

Phrases like "dress for success," or "you've got to look the part" suggest that having the right accoutrements for a performance task (fancy golf equipment on the course; a new tailored interview suit) can be beneficial to success. Importantly, while we may purchase elite branded products in the hopes that these products will help us perform well, sometimes we may succeed, while other times we may still fail. In the current research, we examine how a performance outcome interacts with the type of product used to influence self-perceptions. That is, if we use products to pose as the ideal self that we have not quite arrived at, how does this affect how we feel when we succeed or fail?

We draw from work on priming and self-concept (DeMarree, Petty and Wheeler 2005) to examine this question. Research has shown that objects can serve as primes to increase the accessibility of related aspects in self-concept (Kay et al. 2004). In this sense, the use of a high end golf club may make the construct of a skilled golfer more accessible. Success with a high end golf club assimilates to this construct, thereby strengthening the link between the self and elite golfer, resulting in greater self-perceptions of skill and talent. However, if the construct of "skilled golfer" was initially accessible through choice of a high end club, failure with a high end club contrasts even more starkly against this construct, thus making self-perceptions seem even poorer. In this manner, individuals should feel more skilled following success with a high-end (vs. low-end) product, and importantly, they should also feel even less skilled following failure with this same high-end (vs. low-end) product. This should be particularly pronounced for individuals who are more reliant on accessible inward beliefs to guide their self-perceptions, specifically, for low self-monitors (Snyder & Tanke 1976). Thus, we suggest that there may be both pride and pain associated with posing, and test this across three studies.

Study 1 used a two-cell design to test the basic effect of product type in a failure situation. Twenty-eight undergraduates read a first-person scenario about purchasing a new interview suit in which they were randomly assigned to choose an Armani or Dockers suit. Depending on condition, participants were then told that their interview was successful (unsuccessful). Participants then rated their self-perceptions of how skilled they would feel at interviewing. Results revealed that individuals who had chosen the high end Armani (vs. low end Dockers) suit felt less qualified for the interview position. Thus, this study reveals preliminary evidence that using a high end product can make failure feel more extreme.

In Study 2, we tested this effect in an actual golfing performance context, looking at the effects of product use on both failure and success, and examining the role of the self by comparing situations in which one is assigned to (non self-relevant) vs. chooses (self-relevant) to use a high end product. Four hundred and twenty eight participants were randomly assigned to the conditions of a 2 (product: high end Odyssey club vs. low end Basic club) x 2 (selection: choice vs. assignment) design. Participants were informed that they would be evaluated on their putting skills from a distance of 4.25 ft. and presented with two clubs: the high end Odyssey or the

low end Basic. Participants were either assigned to use a high (low) end Odyssey (Basic) putter, or were allowed to choose their putter. Participants completed one putt, and either succeeded or failed. Neither the choice vs. assignment of a putter nor the use of a Basic vs. Odyssey putter influenced success or failure. As such, we crossed these two factors with success vs. failure to yield a 2 (product: high end vs. low end) x 2 (selection: choice vs. assignment) x 2 (success vs. failure) between-subjects design. All cells had at least 21 participants. Participants then rated their self-perceptions of how skilled they felt at putting. Results revealed a significant selection x club x outcome interaction and showed that for individuals assigned to a putter, there was no difference in self-perceptions across putters following failure, and no difference across clubs following success. In the choice conditions, however, following failure, individuals felt more negative self-perceptions of skill if they had chosen the Odyssey vs. Basic putter. Following success, individuals felt more positive self-perceptions if they had chosen the Odyssey vs. Basic putter. Thus, high end (vs. low end) product choice makes one feel even more skilled after success, but even less skilled after failure. Importantly, the role of choice suggests that the linking of the product to one's self-concept must be present for these effects to hold. In Study 3, we probe the role of self-concept more deeply by examining the impact of self-monitoring.

In Study 3, we examined the role of self-monitoring in this phenomenon to further understand the process by which product use drives changes in self-concept and hence self-perceptions. Because we wanted to look at a domain that was particularly important to undergraduate business students, we returned to the interview scenario. One hundred and seventy-six undergraduates were randomly assigned to a 2 (product: high end vs. low end) x 2 (outcome: success vs. failure) x self-monitoring (measured) design. Participants read a scenario in which they were debating whether to purchase an Armani or H&M suit for a highly anticipated job interview. Participants were randomly assigned to "ultimately decide" on the Armani (H&M) suit and read a short passage describing their interview as highly successful or highly unsuccessful. Participants then rated their self-perceptions of interviewing skills and completed the revised self-monitoring scale (Lennox and Wolfe 1984), which was unaffected by the manipulations. Results revealed that as before, following failure, using a high end (vs. low end) suit made people feel worse about their interviewing skills, while following success, using this high end (vs. low end) suit made people feel better about their interviewing skills. Measures of positive and negative emotion also paralleled these results. Most importantly, these effects were driven by low self-monitors, suggesting that low self-monitors' greater reliance on the mental contents associated with the high end suit, as well as the success or failure that may assimilate or contrast to this content, likely drives changes in self-perceptions.

Thus, these results suggest that using high end products can have unanticipated consequences on self-perceptions. While individuals typically gravitate toward choosing higher end goods to emulate the individuals they aspire to be, their use may have polarizing effects resulting in sweeter success, but sourer failure.

It's Smiling at Me: Satisfying Social Needs Through Consumer Products…At the Expense of Genuine Relationships

EXTENDED ABSTRACT

Beginning with imaginary friends and teddy bears in childhood, human beings demonstrate a fundamental need for belonging that continues across the lifespan (Baumeister & Leary, 1995; Maslow,

1943). Although social needs are often fulfilled through contact with other people, it seems plausible that consumer products could fulfill similar needs. For example, consumers might purchase goods and services hoping to attain love, affection, and emotional pleasure. Seeking social need fulfillment through products may, paradoxically, serve as a detriment to interpersonal relationship development and maintenance. The objective of the current research is to explore how the consumption of products, in general, can come at the cost of social relationships when products satisfy the needs customarily fulfilled by other people.

Just how far people supplement human interactions with product interactions is a matter warranting careful study. Research suggests the possibility of consumers developing relationships with nonsocial objects that mirror interpersonal relationships (Aggarwal, 2004; Fournier, 1998). Further evidence indicates that individuals readily perceive objects as gendered (Guthrie, 2007), brands as having personality (Aaker, 1997), and brand-related characters as human (Rook & Levy, 1999). Social exclusion may play a role in these findings, however, such that those craving human contact may more readily "see" people in their products. Research by Epley, Waytz, Akalis, and Cacioppo (2008) shows that people who feel more chronically disconnected from others anthropomorphize more than those who feel more connected. Indeed, individuals who are well integrated in their social networks are less likely to seek additional bonds relative to their more deprived counterparts (Baumeister & Leary, 1995).

We propose that when a social need exists, products may satisfy it in a way similar to people, which reduces the likelihood of seeking interpersonal fulfillment. Baumeister and Leary (1995) propose, but never empirically test, that social relationships "…should substitute for each other, to some extent, as would be indicated by effective replacement of lost relationship partners and by a capacity for social relatedness in one sphere to overcome potential ill effects of social deprivation in another sphere." We seek to demonstrate that consumers who perceive a void in affiliative bonds may be able to derive similar social benefits from product consumption.

Study 1 involved a 2(words: control, negative social) x 2(Roomba: anthropomorphized, non-anthropomorphized) between-subjects design. Undergraduate students completed a computerized word task where they identified the number of syllables in words flashed on the screen. Participants viewed 40 randomly presented words: 20 control words (e.g., guitar, banana, lampshade) and either 20 negative social words (e.g., excluded, unaccepted, unloved) or 20 neutral words. Following this priming task, participants completed an ostensibly unrelated task in which they were told a company was interested in the shopping behavior of young adults. Participants were shown a Roomba vacuum, but half were randomly assigned to see a version in which the product's features resembled a smiling face (anthropomorphized) while the other half saw the same Roomba turned 90-degrees clockwise so that the product was identical but did not resemble a smiling face (non-anthropomorphized). Participants then answered several questions regarding their impressions of the Roomba including their familiarity with the product, willingness to pay, how attached or dependent they might become on the product, and a series of ratings regarding the following characteristics: attractive, desirable, efficient, high-maintenance, reliable, stylish, unsafe, and has a mind of its own.

Results revealed a significant interaction between prime and Roomba condition showing that participants primed with negative social words and shown an anthropomorphized Roomba were willing to pay more and become attached to the product. Interestingly, these participants were also more likely to see the product as both

more attractive and as having a mind of its own, suggesting greater sensitivity to the product's humanistic attributes.

To see whether this sensitivity would influence consumption decisions, Study 2 utilized a 2(social exclusion, non-social negative control) × 2(anthropomorphized, non-anthropomorphized product) between-subjects design. Undergraduates were randomly assigned to one of two essay conditions: social exclusion ("a time you felt very excluded by other people") or a nonsocial negative control ("a time you did worse than expected on an academic assignment"). Participants were then presented a version of iRobot's Roomba as done in Study 1. A series of rating scales followed the Roomba presentation to assess product perceptions.

Results revealed a significant interaction between the two independent variables for purchase likelihood, after controlling for Roomba ownership: the anthropomorphized version was preferred among socially excluded individuals but not control participants. More importantly, socially excluded participants expressed a greater likelihood of buying the anthropomorphized Roomba over its non-anthropomorphized counterpart. Additionally, results replicated the finding in Study 1 showing that socially excluded participants were willing to spend more money on an anthropomorphized Roomba than the control group.

Study 3 replicated Study 2 with a more heterogeneous sample and focused on social behaviors rather than product perceptions. A similar design was used: 1) individuals wrote about a time they felt either socially included or excluded (no control group), 2) viewed either an anthropomorphized or nonanthropomorphized Roomba, and 3) responded to a series of items including whether they wanted to wait alone or with others for subsequent tasks. Results yielded a significant interaction between the two independent variables in desire for social contact. Means indicate that those made to feel excluded were more likely to prefer waiting alone when presented with an anthropomorphized version of the Roomba compared to those also made to feel excluded who were presented with a nonanthropomorphized version. Presumably, the excluded individuals were able to "fill the void" when presented a humanlike product.

In sum, we find initial evidence for the idea that perceptions of social exclusion 1) make consumers more sensitive to humanistic attributes of products, 2) influence the kinds of products they might buy, and 2) those products influence social behavior. We hope future results will further support our central argument: If social needs can be satisfied through products, consumers may not seek fulfillment through other people and, therefore, increase their risk of negatively impacting real social relationships.

Exposure to Unattainable Luxury: Boomerang Effects on Extrinsic and Materialistic Goals

EXTENDED ABSTRACT

While ample research has investigated consumers' motives to buy luxury products (e.g., Vigneron & Johnson, 2004), it is less clear whether exposure to luxury influences people's values and goals. As luxury consumption is related to materialism (e.g., Belk & Pollay, 1985), it seems obvious to assume that exposure to (images of) luxury increases materialistic and related extrinsic (Kasser, 2002) goal pursuit. Indeed, advertising exposure – which frequently displays images of luxuries – is linked to materialism (e.g., Paek & Pan, 2004); however, studies are correlational or quasi-experimental at best, precluding causal inferences. In addition, results of our pilot study show that people generally think that exposure to luxury induces materialism.

At first sight, one may expect that exposure to *unattainable* (i.e. unaffordable) luxury produces a similar outcome. A second pilot study confirmed this. However, based on goals literature, we propose that the influence of exposure to luxury is much more complex than is usually assumed.

People tend to commit to a goal that is likely to be achieved and to disengage from goals that are difficult to attain (Kruglanski et al., 2002). When the likelihood of attainment is deemed too small, one may even abandon the goal (Baumgartner & Pieters, 2008). We propose that the affordability of consumer goods serves as a signal of the likelihood that one may successfully attain one's extrinsic and material goals. Hence, we propose that exposure to attainable luxuries might strengthen the endorsement of extrinsic and materialistic goals while exposure to unattainable luxuries might decrease it.

Study 1 tests this prediction. 152 students were asked to either decorate a highly expensive villa (i.e. unattainable luxury) versus a mainstream house. Specifically, participants received a floor plan of a villa versus smaller house and sets of photos with possible interiors per room to choose from (luxurious versus common interiors). Participants placed the pictures of their choice on the floor plan. A pretest measured the attainability of the villa/mainstream house (i.e., the likelihood of living in the decorated type of home within ten years from now). As expected, participants believed that the villa would be significantly less attainable within ten years than the mainstream house.

As an additional manipulation of attainability, participants were encouraged (versus not) to imagine themselves owning the home they decorated (the imagination procedure aims to render the luxurious villa less unattainable). Overall, participants were randomly assigned to one of four conditions (type of home: expensive villa vs. mainstream house; simulation: imagination vs. no imagination). Subsequently, we measured materialism (Richins & Dawson 1992) and extrinsic goal pursuit (Aspiration Index; Kasser & Sheldon 2000).

For both dependent variables, type of home interacted significantly with simulation. In contrast to prior intuitions (cf. pilot study), participants were significantly *less* materialistic after decorating the expensive villa versus the mainstream house in the condition without explicit imagination. However, imagining (versus not) owning the villa significantly increased materialistic values, while no such effect was found with regard to the mainstream house. A fairly similar data pattern was found for extrinsic goal pursuit.

These results suggest that consumers try to cope with their inability to own the exposed luxuries by downplaying the importance of material wealth. After all, participants only indicate attaching less importance to materialistic and extrinsic values when being exposed to *unattainable* luxuries, not when the same luxuries seem less unattainable as a result of simulating owning them.

Study 2 tests this assumption more explicitly by also assessing the role of self-esteem. Rather than manipulating attainability, we now measured participants' perception of their own ability to afford the advertised products. Forty-two students either saw six print ads for moderately expensive products (to allow for variation in participants' feelings of affordability; e.g., Hugo Boss clothing) or no ads (control condition). Next, we measured extrinsic goal pursuit (like in Study 1) and self-esteem (Rosenberg 1965). After a number of unrelated tasks, participants in both conditions judged for each ad whether they could afford the advertised product. An index of perceived affordability was computed. Affordability was measured at the end of the experiment to assess whether these concerns affected self-esteem and goal pursuit without being actively cued (as in Study 1).

Both for extrinsic goal pursuit and for self-esteem, we found a significant interaction between condition and perceived affordability. Advertising exposure increased extrinsic goal pursuit and self-esteem of participants who believed they could afford the promoted luxuries, but decreased it for participants who felt they could not afford them. Finally, a mediated moderation analysis showed that self-esteem partially mediated the effect of condition and affordability on extrinsic goal pursuit.

These results raise the question whether exposure to unattainable luxuries merely causes people to *say* that materialism and extrinsic goal pursuit are less important, or whether they also *intend to act* upon this belief. Hence, study 3 examines the impact of luxury consumption on prosocial behavior in the context of a dictator game (Hoffman et al., 1994). Fifty-seven respondents were exposed to either 30 exclusive luxury pictures (e.g., private jet; unaffordable luxury condition), 30 photos depicting functional products (e.g., cal-culator; functional condition) or to no pictures (control condition). Next, all respondents evaluated different organizations and indicated their favorite charity. Subsequently, participants were asked to allocate €10 between themselves and their favorite good cause.

Consistent with the previous studies, the amount of money donated to a good cause was significantly higher after exposure to unattainable luxury than after exposure to functional products or in the control condition.

In sum, common intuition (cf. pilot study) suggests that *any* exposure to luxury would increase materialism. However, our results show that exposure to extreme and *unattainable* luxury (e.g., through reruns of *MTV Cribs*) may decrease how important consumers find such luxury, and extrinsic goals, more generally. Interestingly, exposure to unattainable luxury may potentially even instigate prosocial behavior. To conclude, our results may contribute to the debate on advertising exposure and increased materialism.

Goal-Driven Financial Decisions:
Understanding the Role of Consumer Goals in Financial Decision Making

Paper #4: Consequence of Motivated Goal Setting on Sequential Goals in Investment Decision Making

Cecile Cho, University of California, Riverside, USA

SESSION OVERVIEW

Reports abound throughout the media regarding a plethora of financial hardships being faced by consumers. Regardless of recent turmoil in various economic markets, a consistent factor contributing to lowered consumer financial well-being resides in the debt repayment and investment decisions consumers make individually. One underexplored question is the role that consumers' goals play in their financial decisions. The purpose of this session is to provide insight into consumers' goal-driven financial decisions and each of the four papers examines a different aspect of this question.

The first paper by Kettle, Trudel, and Häubl reports three studies that examine how debt repayment strategies influence consumers' motivation to repay debt and show that paying down debt accounts sequentially (versus simultaneously) increases the motivation of low self-control consumers, who are most likely to have debt in the first place. The second paper by Gal and McShane analyzes data from a leading U.S. debt settlement company to show that completing discrete debt management subgoals motivates overall goal attainment. These authors find that closing debt accounts early in a debt management program, regardless of the size of the debt accounts, is predictive of eliminating one's debts. The third paper by Salisbury and Nenkov presents two studies featuring US adult consumers, which examine how borrowers' future- versus present-oriented debt repayment goals interact with credit card information disclosures to influence debt repayment behavior and perception of progress toward paying off debt. They find that the effects of repayment goals on perceived progress differ from the effects on repayment behavior, even when accurate goal-related information is provided. Finally, the fourth paper by Cho offers four experiments that provide evidence that setting a minimal, conservative financial goal (vs. high goal) and achieving it leads to a spike in the level of risk taken in subsequent financial decisions due to a persistent loss frame. All four projects included in this session are at advanced stages of completion, and the working manuscripts for all four of the papers, as well as all of the cited references, are available upon request.

This symposium is a model of "appreciating diversity," and therefore embodies the theme of 2012 ACR, because the researchers featured in the session study the role of goals in financial decisions

by spanning various theoretical domains, multiple methodological approaches, and sample characteristics. Researchers will discuss lab-based experiments as well as large-scale studies with real US consumers, and actual field debt settlement data to provide insight into consumers' goal driven financial decisions and choices.

Beyond being of interest to academic researchers studying financial decision making and goal pursuit and motivation, the work presented in this session will have important implications for individual consumers repaying their debts, individual investors managing their portfolios, public policymakers, financial services firms, as well as the fiduciaries responsible for structuring financial instruments and investment options in general.

Helping Consumers Get Out of Debt Faster: How Debt Repayment Strategies Affect Motivation to Repay Debt

EXTENDED ABSTRACT

Consumers with multiple debts can choose among different strategies for paying down their debt accounts (Amar et al. 2011). In particular, they can repay their accounts sequentially (one at a time) or simultaneously (allocating the same amount to each account). We propose that paying down accounts sequentially (versus simultaneously) differentially affects the motivation of individuals with low (versus high) trait self-control.

By closing down individual accounts, a sequential strategy enhances the appearance of progress toward the long-term goal of becoming debt-free, and can thus increase goal commitment and motivation (Kivetz, Urminsky, and Zheng 2006). We predict that using a sequential strategy will increase motivation - and thus lead to people becoming debt-free sooner - but only for individuals who chronically lack self-control.

Results from three studies support this prediction. Participants began each study in debt (divided into 5 equal accounts). They earned money in a word-generation task, and had to first pay off their debt before they could keep any earnings. Participants completed 10 performance rounds; accounts were updated after each round.

In study 1, half of the participants were randomly assigned to a debt repayment strategy, and the other half chose a strategy. Low self-control individuals earned more money when paying off their debt accounts sequentially (versus simultaneously) whether they were randomly assigned to a strategy or chose it.

We tested our goal-pursuit account in study 2 by manipulating the amount that individuals earned per word. In the attainable-goal condition (in which all participants were able to get out of debt), we replicated the results of study 1. However, in the unattainable-goal condition (in which it was nearly impossible to get out of debt), debt repayment strategy did not affect the motivation of low self-control individuals.

In study 3, participants received a recommendation for either the simultaneous or sequential strategy (82% followed it). Low self-control individuals performed better when paying off their debts sequentially (versus simultaneously), and they also performed better when they followed the recommendation. Thus, the motivation of low self-control consumers was greatest when they followed the recommendation to repay accounts sequentially.

This research is the first to examine how debt repayment strategies influence consumers' motivation to repay debt. Paying down

debt accounts sequentially (versus simultaneously) increases the motivation of low self-control consumers - precisely those who have difficulty achieving long-term goals (Baumeister, Vohs, and Tice 2007) and are most likely to have debt in the first place (Meier and Sprenger 2010).

Can Small Victories Help Win the War? Evidence from Consumer Debt Management

EXTENDED ABSTRACT

Globally, consumer debt is measured in the trillions of dollars, with U.S. credit card debt alone amounting to approximately $1 trillion and with U.S. residents, on average, holding five credit cards each (Experian 2009). How best to reduce and eliminate debt is therefore an important question for consumers in a modern economy.

The popular and influential American personal finance guru Dave Ramsey advocates an approach to reducing and eliminating debt that involves paying off small debt balances before larger ones because he believes that paying off the smaller balances can motivate an individual to subsequently pay off the larger balances. Ramsey terms this approach the "snowball method," arguing that consumers need "some quick wins in order to stay pumped enough to get out of debt completely" (Ramsey 2009b,a). Ramsey is not alone in this view, with advocacy of this approach common among consumer financial advisors (Hamm 2007; Think Money, Ltd. 2009).

However, from a normative perspective, the size of the account balance consumers pay off first should not matter to their ability to reduce or eliminate their debt. Rather, consumers should focus on paying higher interest balances first regardless of the size of the account balance (after making minimum payments on all accounts to avoid penalties and surcharges). This approach is thus advocated by the U.S government.

We obtained a highly unique data set that allows us to examine this question on a time horizon measured in years with real world behavior and high stakes consequences for the individuals concerned. In particular, we obtained data from a leading U.S. debt settlement company that allow us to examine the question of whether closing accounts early in a debt management program predicts whether consumers succeed in eliminating their debts independent of the size of the closed account balances. That is, is closing a greater number of outstanding balances early in a debt repayment program predictive of debt elimination regardless of the size of the closed account balances?

Our main finding was that closing off debt accounts—independent of the dollar balances of the closed accounts—was predictive of eliminating one's debts at any point in time during participation in a debt settlement program. In fact, the fraction of debt accounts paid off appeared to be a more powerful predictor of whether or not one eliminates one's debts than the fraction of the total dollar debt paid off, despite the latter being a relatively more objective measure of progress towards the debt elimination goal. More striking still, the dollar balance of closed debt accounts was not predictive of debt elimination when accounting, nominally, for closed debt accounts.

In addition to specific implications for how different forms of goal progress affect goal pursuit, our findings make a more general contribution to research on goals by highlighting possible temporal shifts in the importance of different determinants of goal pursuit in the short run versus the long run. Specifically, whereas prior research has identified important psychological processes whereby attainment of a subgoal demotivates individuals from persisting in pursuit of their goal (Amir and Ariely 2008; Fishbach, Dhar, and Zhang 2006; Khan and Dhar 2006), our research suggests that the impact of these processes might be attenuated over a longer time horizon. Given that many important goals are pursued over long periods of time, our findings call for more research examining how psychological processes affect goal pursuit over long time horizons.

The Influence of Debt Repayment Goals on Repayment Decisions and Perceived Progress

EXTENDED ABSTRACT

Managing personal debt is an ongoing challenge for many consumers. Average credit card debt amongst U.S. consumers was approximately $6,600 per household in mid-2011. Managing that debt load can be difficult, and it can be very expensive – U.S. consumers paid $94 billion in credit card interest in 2009 alone (Meijer et al. 2011).

A recent study by the U.S. Federal Reserve Bank suggests that many Americans underestimate how much credit card debt they owe, with an estimated 34% gap in aggregate (Brown et al. 2011). This is likely to have adverse effects on the debt repayment goals consumers set for themselves, as well as on their actual repayment behavior. For instance, this gap in perceptions could lead consumers to underestimate the time needed to pay off their debt as well as the amount they will pay in interest, causing them to adopt present-oriented goals and spend more instead of repaying their debt, potentially incurring more debt than they can comfortably shoulder

Public policymakers encourage lenders to disclose loan cost information to enable borrowers to make more informed debt repayment decisions (e.g., the CARD Act). In the current research we examine how the presence of information about loan interest cost and payoff time interacts with consumers' repayment goals to influence debt repayment decisions and perceptions of debt repayment progress.

Two experimental studies, with 570 adult U.S. consumers, examined the effect of repayment goals and loan information on repayment decisions and perceived debt payoff progress. In both studies, participants were shown a hypothetical credit card bill and asked how much of the credit card balance they would repay. Study 1 included three experimental conditions in which we manipulated the loan payoff time information participants received on their credit card bill: 1) only loan balance, interest rate, and minimum payment required information, 2) additional information about how much time it will take to pay off the loan if the minimum required amount were repaid each month, and 3) additional information about how much time it will take to pay the loan if an amount larger than the minimum were repaid each month. Study 2 used a similar procedure, but had seven information conditions presenting information about either the interest cost participants would incur if the minimum required or some larger amount were repaid each month, and/or loan payoff time information similar to study 1. We further measured whether borrowers had a future-oriented (i.e., pay off debt balance fast to have more money for other purposes in the future) or a present-oriented (i.e., pay the least amount possible to have more money for other purposes in the present) repayment goal. Finally, we assessed participants' repayment decisions as well as their perceived progress toward paying off the loan balance. A series of analyses were conducted to test the effects of goal type and information type, controlling for participants' income, financial knowledge, attitude toward debt, temporal orientation, and credit card repayment habits.

Results indicate that repayment goals had a robust effect on repayment amount. Participants with a future-oriented goal to pay off the balance fast tended to repay *more*, while participants with a present-oriented goal to repay the least amount possible repaid *less*. Interestingly, the negative effect of holding a present-oriented goal was larger when payoff time information was present. The loan cost information and payoff time information manipulations had little direct impact on repayment amount.

Repayment goals also influenced participants' perceived progress toward paying off their loan, and these effects were moderated by the type of information present on the credit card statement. A future-oriented goal to repay the loan balance fast had a significant positive effect on perceived progress, after controlling for repayment amount, suggesting a kind of optimism toward achieving loan payoff. This positive effect on perceived progress was further enhanced by the presence of payoff time information on the credit card bill. This suggests that, while disclosing payoff time information may not increase repayment amount (and therefore speed up loan repayment), it has the potential to increase consumers' perceptions of progress toward paying off the loan. In other words, for borrowers with a future-oriented payoff goal, providing loan payoff time information does not change goal-oriented behavior, but it does change (i.e., increase) perceptions of goal progress.

We found no significant main effects of payoff time information on perceived progress. On the other hand, the presence of loan cost information had a significant negative effect on perceived progress (after controlling for repayment amount); this was the case regardless of repayment goal type. Thus, disclosing loan cost information may lead borrowers to feel more pessimistic about making progress toward loan payoff.

Finally, a present-oriented goal to repay the least amount possible had significant effects on perceived progress, after controlling for repayment amount, but the valence of the effect varied across information conditions. Having a present-oriented goal had a significant *positive* effect on perceived progress in all conditions, except one: when participants were provided with information about the loan payoff time associated with repaying only the minimum each month, a present-oriented goal had a significant *negative* effect on perceived progress. Thus, having a present-oriented goal to pay the least amount possible *decreased* perceived loan payoff progress when time information was present and *increased* perceived progress otherwise.

Our findings regarding the effects of repayment goals and information disclosure on perceived debt repayment progress are noteworthy because past research has shown that perceptions of goal progress (even progress that is illusory and artificial) increase consumers' effort toward achieving the goal (e.g., Kivetz, Urminsky, and Zheng 2006; Nunes and Dreze 2006). We add to this literature stream by providing insight into the differential effects of having present- versus future-oriented goals and receiving time- versus money-related information on perceived goal progress.

A third follow-up study is planned, aimed at clarifying the theoretical mechanisms underlying the effects observed in studies 1 and 2. In this study participants' future- and present-oriented goals, as well as actual progress towards debt repayment, will be manipulated. Perceived progress toward goal achievement, as well and perceived feasibility and desirability of goal achievement, will be measured.

The key contributions from these studies will inform our understanding of how consumer goals interact with information disclosure to influence consumer debt repayment behavior and perception of progress toward paying off debt. These findings have important implications for consumers, public policy makers, as well as for lenders. They are particularly timely given recent legislation (e.g., CARD Act) related to the types of disclosure information that must be revealed to consumers of credit, which often involves the provision of cost- and time-related loan payoff information.

Consequence of Motivated Goal Setting on Sequential Goals in Investment Decision Making

EXTENDED ABSTRACT

Imagine that you have decided to invest in the financial stocks of emerging markets. Markets have been rather volatile with much fluctuation. Given the uncertainty of the financial markets, you de-

cide that you would be happy as long as it returns a little over what you would get from a bank deposit, and allocate your money into the conservative stocks with low risk. At the year's end you find that your portfolio has done better than the bank rates, but also finds out that many other stocks have done even better, achieving double the rate of return. For the next period, what would be the level of risk you take? Would you take on greater risk? Stay the course with the same set of stocks? Or take on less risk since you achieved your goal? Given how often decisions are made in a sequence of decision periods, surprisingly little attention has been given to understanding investment decisions and judgments within its sequential decision making context.

In this research, we examine the relationship between what we term "strategic goal setting," confirmation of the goal, and the subsequent level of risk taken, in the domain of investment decision making. More specifically, our research investigates the consequence of setting a minimal, conservative performance goal (vs. high goal) on the subsequent target setting for a risky decision when the goal is successfully obtained. Whereas individuals often set lower investment targets assuming they will be happy if only the target is met, this assumption is often unfulfilled because the reference point is no longer the initial goal but a higher, "could-have-been" performance level (Cho and Johar 2011). We predict and find that, due to the upward shifting reference standard, low-goal setters are likely to find themselves in the domain of losses, and become more risk seeking in their subsequent investment decisions. Our hypothesized process model is as follows:

Goal Level → Feedback (confirmed) → Outcome compared to higher reference point than goal → domain of losses → Risk at T2

Across four studies involving investment decisions, we asked individuals to set return goals for their investment portfolios, pick three stocks in a simulated investment task, confirm their goals (feedbacks which match the performance to their return goals), then ask them to set another goal for the next period. Respondents were induced to pick low or high goals via priming tasks (approach-avoidance orientation, delight vs. disappointment) then were told that their investment goals were met for that period (goals confirmed for all conditions), followed by satisfaction measures, then the key measure: target goal for the next investment period. We found that the low-goal setters set target performances that were consistently higher (greater magnitude of increase) than the high-goal setters (studies 1 and 4). This pattern was observed even when the actual performance level was controlled for (studies 2 and 3).

We adopt the framework of prospect theory to conceptualize our finding (Kahneman and Tversky 1979). A central concept within prospect theory is the framing effect: individuals tend to avoid risks when perceiving an outcome as gains or exceeding a reference point, and they seek risks when an outcome is perceived as losses or performing below a reference point. In other words, when one achieves the goal one set out to achieve, or when one's targeted performance has been obtained, this should put the person in a domain of gains. Based on this model, a corresponding prediction would be that on the subsequent risk-taking decision, one would be less inclined to risk the gain already obtained (Heath, Larrick and Wu 1999). In short, confirmation of goal should lead to risk-aversion. We demonstrate that confirmation of goal leads to greater risk seeking in the subsequent decision among those who set conservative goals due to the tendency to upward compare. Because individuals tend to compare their outcome to a higher reference standard, and this upward comparison process creates a loss frame in which the low-goal setter perceives a more intense loss frame than the high-goal setter. Our finding is consistent with the literature on misprediction of future affect and more broadly, lend insight into the topic of unstable risk preferences.

SESSION OVERVIEW

The objective of this session is to gain a greater appreciation of the persuasive value of narratives. A traditional social science approach to persuasion has focused on how individuals respond to rhetoric, or argument-driven messages, such as those captured by dual-route perspective models (e.g., Petty and Cacioppo 1986). This approach is in contrast to daily practice, where individuals exist in, and readily engage with, an environment saturated with narratives.

Scholars in a number of fields recognize the persuasive value of narratives and, importantly, that narratives invoke a form of processing that is different from a traditional, argument-oriented approach. These stories (or narratives) depict events and consequences for characters, in contrast to informational and expository communication that presents reasons and arguments in favor of a particular focus. Green and Brock (2000) introduced the concept of "transportation" to the social science literature, which describes the experience of immersing in a narrative and involves processes such as emotional involvement, the generation of imagery, and suspension of disbelief.

A growing number of studies anchored in academically-oriented, consumer-related domains have demonstrated that narratives affect the attitudes and behavior of their audiences. Researchers in the consumer domain are likely to benefit from a deeper understanding of the processes involved in and the impact of narrative transportation, particularly given the wide array of consumer-oriented stimuli that use a narrative format, such as advertisements, consumer reviews, brand narratives, and WOM communications. Consumers often actively seek narratives, and routinely underestimate the persuasive impact they have on their attitudes and behaviors.

Previous work has identified a range of narrative effects that impact both health and social behaviors (Green, Strange, and Brock 2002). These studies have identified a number of relevant theoretical mechanisms (emotional and cognitive engagement, identification, reduced counter-arguing, imagery) and have established their effect on behavioral and pre-behavioral outcomes, but the causal mechanisms and relative importance of these relationships are not yet well understood (Moyer-Guse 2008). An objective of this session is to introduce consumer researchers to the as-of-yet unexplored potential of narrative persuasion. We anticipate that further research in this area is likely to make a contribution to the consumer field, given the frequency and willingness with which people engage with narratives, the extent to which they pervade our daily environment.

The study of narratives has a long tradition within literary analysis and communication, which acknowledge that stories are central to how humans think and make choices. This topic area allows a variety of intellectual vantage points to converge, both fostering the appreciation of academic diversity and promoting scholarly work between disciplines. Buselle introduces a conceptual overview of narrative persuasion from a communications perspective, organizing the different genres and media platforms that induce narrative processing. Kreuter presents a review of 10 years of health-oriented research that applies narratives to address breast cancer. Escalas applies narratives in a consumer context, and Hamby presents a framework that integrates determinants, mediators, and moderators that have been examined in narrative research.

Narrative Engagement across Media Forms and Levels of Interactivity

EXTENDED ABSTRACT

The recognition that telling audiences about events and characters dates back to Aristotle (Herrick 1997). However, only within the past half-century have social scientists focused on stories as tools of persuasion (Green and Brock 2000), and even more recently, explored the relations between the narrative experience and its outcomes (Busselle and Bilandzic, forthcoming). Research into communication, entertainment-education, and advertising has incorporated both theoretical and methodological elements of narrative processing and persuasion (e.g., Durkin and Wakefield 2008; Moyer-Gusé 2008). This work has been extended to the influence of narrative elements in videogame experiences (Ip 2011).

Central to narrative persuasion research is the premise that information presented in a narrative form is not only different in structure – based on characters and events rather than claims and evidence – but also produces a fundamentally different experience. Further, the nature and quality of that experience mediates the influence of the narrative on the reader, viewer or player. Specifically, the more engrossing the narrative experience the greater the narrative's influence (e.g., Green & Brock 2000; Moyer-Gusé and Nabi 2010). Currently, narrative persuasion research is challenged by competing conceptualizations of what it means to be engaged, absorbed, or transported. This challenge is complicated further by the different media forms narratives may take, such as a medical-drama program, a drama-advertisement on TV or in YouTube. These varying forms, genres and levels of interaction offer opportunities for narrative experiences that may be quite different from each other and may require different methodological and measurement tools. The focus on narrative across different media forms raises questions about the extent to which narrative experiences are similar or different depending on the nature of the message and the characteristics of the media platform.

The present paper describes a conceptual structure to organize narrative experiences across genres and media platforms based on the extent to which they approximate real life experiences. The paper reviews the theoretical and conceptual explanation used to describe and understand narrative experiences, such as mental model construction, flow experiences, and imagery production and outlines

theoretically separate dimensions, such as attention, comprehension, identification, and presence (Busselle and Bilandzic 2009) and how those experiential processes may manifest across different media forms, formats and genres.

Narratives in Cancer Prevention:
A Review of a 10 year Research Program

EXTENDED ABSTRACT

This presentation will summarize findings from a decade-long research program examining audience effects of personal experience narratives. The narratives studied in this research are breast cancer survivor stories collected on video from African American women and shown to other African American women without breast cancer. Outcomes of interest across a series of independent studies include beliefs, perceptions, recall, and health behaviors.

The promise and appeal of narrative lies in its familiarity as a basic mode of human interaction. People communicate with one another and learn about the world around them largely through stories. Kreuter et al. (2007) have proposed a typology of narrative application in cancer control that has four distinctive capabilities: (1) overcoming resistance; (2) facilitating information processing; (3) providing surrogate social connections; and, (4) addressing emotional and existential issues, and are applicable to outcomes across the cancer control continuum (e.g., prevention, detection, diagnosis, treatment, survivorship).

The breast cancer survivor stories were collected in St. Louis, MO. We elicited stories from 36 African American women who had been diagnosed with breast cancer and 13 family members of these women. Survivors ranged in age from 35-67, had been survivors for <1 to >23 years, and 91% were members of one of five different African American breast cancer survivor support groups in St. Louis, MO.

African American women (n = 489) ages 40 and older were recruited from low-income neighborhoods in St. Louis, MO and randomly assigned to watch the narrative or informational video. Effects on mammography use, cancer-related beliefs, recall of core content and a range of reactions were measured immediately post-exposure and at 3- and 6-month follow-up. The narrative was better liked, enhanced recall, reduced counter-arguing, increased breast cancer discussions with family and was perceived as more novel. Women who watched the narrative also reported fewer barriers to mammography, more confidence that mammograms work, and were more likely to perceive cancer as an important problem affecting African Americans. Use of mammography at six month follow-up did not differ for the narrative versus informational groups overall (49% vs. 40%), but did among women with less than a high school education (65% vs. 32%, *p* < .01), and trended in the same direction for those who had no close friends or family with breast cancer (49% vs. 31%, *p* = .06) and those who were less trusting of traditional cancer information sources (48% vs. 30%, *p* = .06). The findings suggested that narrative forms of communication may increase the effectiveness of interventions to reduce cancer health disparities, and may have particular value in certain population sub-groups (Kreuter et al. 2010).

One consistent finding across studies was the role of affect, or emotional responses to the videos. A community-based convenience sample of African American women (n = 59) used an audience response device to report the intensity of their emotional reaction while watching the video. We assessed the correspondence between video content and emotional responses, types of emotion experienced, and recall of video content. Strong emotions were more likely to correspond to contextual information about characters in the video and less likely to correspond to health content among women who watched the narrative compared to those who watched the informational video (p < .05). Both videos elicited strong emotional responses, but the type of emotion differed. Women who watched the narrative video were more likely than those who watched the informational video to report feeling attentive (41% vs. 28% respectively), inspired (54% vs. 34%) and proud (30% vs. 18%), and less likely to feel upset (8% vs. 16%) (*p* < .05). Women in the narrative group were also more likely to mention the women's personal stories than health information in open-ended recall questions. Lessons learned from this research program are discussed as well as directions for future research.

The Effects of Social Relationships on
Narrative Persuasion

EXTENDED ABSTRACT

Americans feel more socially isolated than two decades ago— 10% of respondents in a social science survey had no one to discuss important matters with in 1985, as opposed to 24.6% in 2004 (McPherson et.al. 2006). Socially isolated people tend to behave more aggressively, are less prosocial, and less cooperative with others (Twenge et.al. 2007). Despite a rich psychology literature on how social isolation affects people in terms of interpersonal social behaviors and physiological reactions, there is limited research on how loneliness, the subjective feeling of social isolation (Hawkley and Cacioppo 2007), affects consumers.

We examine how loneliness affects consumers' responses to narratives. Consumers encounter various forms of narratives daily. They read books, watch movies, listen to stories, and are constantly exposed to narrative marketing communications, such as advertisements (Escalas 1998). Although abundant evidence suggests that narratives can be highly persuasive through the process of narrative transportation (e.g., Green and Brock 2000), it is not clear whether lonely consumers are more or less likely to be transported into narratives.

Lonely people not only have a strong desire to form meaningful connections with other human beings, they are also more likely to create human connections with nonhuman gadgets (Epley et al 2008). For example, lonely (vs. non-lonely) people think that a wheeled alarm clock that "runs away" has its own mind and can experience emotions. These findings suggest that lonely people might be more likely to be transported into narratives. On the other hand, stories often portray human interaction to which socially isolated individuals might not relate well. In three studies, we examine whether lonely consumers will be more or less transported into narrative contents and how such transportation affects persuasion.

The first study examines the relationship between loneliness and narrative transportation. One hundred participants read a short story taken from Chicken Soup for the College Soul. The four-page story is about a college student and a depressed customer who help cheer each other up by being considerate and caring. The story has been used in previous research to generate various levels of transportation (Wang and Calder 2006). Participants' transportation was measured by a 15-item transportation scale (Green and Brock 2000). After reading the story and responding to the transportation scale, participants also responded to the revised UCLA loneliness scale (Russell 1996). Participants' responses to the scales were summed into transportation scores (α = .84) and loneliness scores (α = .90). A regression analysis showed that the more lonely the participants, the more they were transported to the story (β = .41, *t* = 2.65, *p* = .01).

The second study examined whether the effect of loneliness on transportation will occur in advertisements rather than a story. Participants (n = 238) evaluated two ads. The print ad featuring a young man and woman showed a jar of Borghese Fango mud mask and a product description. The story board of a TV commercial for Folgers coffee consisted of 10 snapshots of a family enjoying the coffee during the holidays. Each participant evaluated both ads, with order counterbalanced. Participants evaluated each ad (1 = unfavorable, bad, uninteresting, poor quality; 7 = favorable, good, interesting, good quality) and responded to the ad transportation scale and the loneliness scale.

Regression analyses showed that, consistent with results of the first study, lonely participants were more likely to be transported into the print ad ($\beta = .21$, $t = 2.87$, $p < .01$). In addition, highly transported participants showed more favorable attitude toward the ad ($\beta = .06$, $t = 11.2$, $p < .001$). However, loneliness did not affect ad attitude directly.

The same set of analyses on the commercial story board revealed a different pattern. Lonely participants were less likely to be transported into the story board ($\beta = -.22$, $t = -2.84$, $p < .01$). Whereas transportation into the story board led to more favorable ad attitude ($\beta = .07$, $t = 13.37$, $p < .001$), loneliness also had a marginal effect on ad attitude ($\beta = -.01$, $t = -1.78$, $p = .08$). Mediation analyses support transportation's mediating role between loneliness and ad attitude.

Two potential explanations might account for the different patterns between print and story board. Modality may moderate feeling transported; that is, lonely people are more easily transported into print ad but less into TV commercials. This is consistent with the findings of study 1, which used a text-only medium. Alternatively, the warm family interaction in the Folger's ad was more social than the Borghese ad, making it difficult for a socially isolated individual to relate to the story. We are conducting a third study to further examine these alternative explanations using a 2 (modality: print vs. TV) × 2 (ad focus: social vs. non-social) design. Participants will again evaluate one print ad and one TV ad story board. However, some participants will see the social version of ads (featuring more people) whereas others will see the nonsocial version (featuring no human interaction). The study is underway and we will be able to present the results at ACR.

A Framework of Narrative Persuasion

EXTENDED ABSTRACT

Researchers in social psychology and related fields have studied persuasion based on rhetoric for the past 70 years, yielding a detailed understanding of factors that enhance or diminish the effectiveness of argument-driven, persuasive communications. In contrast, the study of narrative persuasion has gained momentum only within the past 15 years, and researchers are still working toward a full understanding of the factors that influence narrative persuasion and the psychological mechanisms responsible for these effects.

Researchers from a variety of disciplines such as psychology (Green and Brock 2000), education (Slater and Rouner 2002), communication (Hinyard and Kreuter 2007), advertising (Phillips and McQuarrie 2010) and marketing (Escalas 2007) have contributed to the area of narrative persuasion. The recent growth in the study of narratives from different social science orientations highlights the need for an overview of how extant research interrelates and contributes to our understanding of narrative persuasion mechanisms. We present a framework that integrates narrative persuasion research relevant to consumer behavior.

We organize this literature drawing in part from McGuire's Communication Matrix (1989), a popular theory that considers both input and output variables pertaining to the persuasive communication process. A number of studies have demonstrated that a narrative format (input) can impact a number of persuasion-related outputs; e.g., the audience's beliefs about narrative-related topics (Fazio and Marsh 2008) and behavior consistent with messages contained in a narrative (Durkin and Wakefield 2006).

More recent studies have examined mediators of this narrative effect (primary and secondary processes, as conceptualized in our model). For example, Kreuter et al. (2010) found that women who viewed a narrative video (compared with an informational video) experienced more positive and negative affect, identified more with the message source, and were more engaged. This, in turn, lead to reduced counter-arguing, which influenced the behavioral correlates of perceived barriers, cancer fatalism, and message recall.

In our framework, the initial category of "inputs" includes structural factors such as narrative format, a fact or fiction label (Green et al. 2006), and the quality of the text in terms of sequence coherence and message production elements (Kreuter et al. 2007).

After exposure to a narrative, several mediating mechanisms are evoked, including the experience of emotion (Appel and Richter 2010), production of imagery (Phillips and McQuarrie 2010), telepresence (Slater and Rouner 1996), cognitive engagement (Chang 2009) identification with the characters portrayed in the narrative (Cohen 2001). Many authors label the occurrence of these factors as "transportation" (Green and Brock 2000) or "narrative engagement" (Busselle and Bilandzik 2009).

Research indicates these initial steps involved in processing narratives lead to a second set of mental processes, such as reduced levels of counter-arguing against assertions embedded in the narrative (Moyer-Guse and Nabi 2010), increased levels of self-referencing (Escalas 2007), perceived narrative realism (Busselle and Bilandzik 2009), elevated levels of story-relevant risk perception (Moyer-Guse and Nabi 2010), and the willing suspension of disbelief such that a reader temporarily accepts the constructed story world as reality (Chang 2009).

The outcomes commonly examined include belief change, behavioral intention, enjoyment, knowledge, and attitude change. The primary and secondary processes are mediators that link the "input" factors with the "output" factors.

Many studies indicate that this sequence has several moderators. For example, need for affect moderates the relationship between transportation and outcome beliefs, such that people with higher levels of need for affect are more persuaded (Appel and Richter 2010). Expertise appears to moderate the relationship between narrative format and transportation, contingent on the context (Green 2004). Other moderators examined in the context of narrative persuasion include need for cognition (Appel and Richter 2007), transportability (Mazzocco et al. 2010), sensation seeking (Jensen, Imboden, and Ivic 2011), and persuasion knowledge (Escalas 2007).

We anticipate this framework will facilitate a systematic discussion of past research on narrative persuasion and to highlight areas in which more research is needed, working toward a more complete understanding of the factors that influence narrative persuasion and the psychological mechanisms responsible for these effects.

Financial Incentives and Consumer Choice

Chair: Boris Maciejovsky, Imperial College London, UK

Paper #1: Consumer Reactance to Conditional Price Promotions
    Aylin Aydinli, London Business School, UK
    Marco Bertini, London Business School, UK

Paper #2: Placebo/Placui Effects of Marketing Actions: Consumers Get What They Pay/Paid For
    Bram Van den Bergh, Erasmus University Rotterdam, The Netherlands
    Bart de Langhe, University of Colorado, USA

Paper #3: Macroeconomic Threat Increases Preference for Mainstream Products
    Stacey Finkelstein, Columbia University, USA
    Kimberly Rios, University of Chicago, USA

SESSION OVERVIEW

The objective of this session is to highlight the differential effects of financial incentives on consumer behavior. The session is comprised of three papers that show the negative (Aydinli & Bertini), the time-dynamic (Van den Bergh & de Langhe), and the macroeconomic (Finkelstein & Rios) effect of financial incentives.

Aydinli & Bertini show the boundary conditions of contingent price promotions by demonstrating that these promotions may provoke reactance when consumers' perceive them as constraining their freedom. Van den Bergh & de Langhe examine the time-dynamic effects of price promotions and show that such promotions may lead to specific product efficacies. And finally, Finkelstein & Rios show that incentives in the form of a macro-economic threat that potentially restricts financial resources promotes domestic products over fair trade products.

The main contribution of the session is to demonstrate that a single marketing variable, in this case, *financial incentives*, can lead to different effects that range from positive to negative, and that vary across time, thereby affecting choice. The likely audience for this session are scholars who work on pricing, promotion, consumer choice, and behavioral decision-making. All three papers in this session have been completed and provide important implications for the design of financial incentives that may have repercussions beyond the realm of consumer behavior.

Consumer Reactance to Conditional Price Promotions

EXTENDED ABSTRACT

The marketplace is replete with promotional offers that are conditional on certain additional behaviours. Basically, the motivation of the firm is to have conditions on their promotions to ensure that certain behaviours take place in exchange for the discount. However, in this paper we point out that such conditional price promotions can sometimes backfire, resulting in more cautious decision-making by the consumer.

Building on reactance theory (Brehm 1966) and adding to the growing literature on reactance within consumer contexts (e.g. Fitzsimons 2000; Fitzsimons and Lehmann 2004; Kivetz 2005) as well as to the recent interest in the broader affective and cognitive implications of price promotions (Aydinli and Bertini 2012; Chandon et al. 2000), we propose that consumers may perceive conditional promotions as intended to influence their purchase behaviour, thereby constraining their freedom and self-determination. In order to reassert their freedom, consumers may act more cautiously in terms of their product choices through selection of cheaper and fewer options than they otherwise would.

Consistent with our hypothesis, we found that compared to unconditional promotions, conditional promotions reduce consumers' overall spending with the firm as they shift consumer preferences towards cheaper and fewer options as well as lower their commitment with the firm. Further, the results of our experiments underscore the role of reactance in this process.

In Experiment 1, the participants were asked to choose among three types of rental options that were differently priced based on the features of the available cars. They were also asked to select several additional products and services that were charged separately from the rental fee. The experiment employed a single factor (no promotion vs. unconditional promotion vs. conditional promotion) between subjects design. The conditional promotion had the sentence "… conditional on the person picking up the car from the branch of the company at the central train station" added to the description in the unconditional promotion condition. Consistent with our hypothesis, we found that participants' total spending was lower in the conditional promotion than in the unconditional promotion ($p < .01$) and in the no promotion condition ($p < .05$). Participants in the conditional promotion preferred cheaper rental options and were willing to spend less on additional services than participants in the unconditional promotion ($p < .01$ and $p < .04$, respectively). Importantly, participants evaluated the two types of promotional offers as equally attractive, ruling out a value-based response ($F < 1$).

In Experiment 2, we looked for evidence for the role of reactance in driving the observed effects. Prior research suggests that reactance is less likely to occur when the restriction of freedom is justifiable or legitimate (Brehm 1966). Thus, we predicted that the conditional promotion would arouse less reactance if the firm's behaviour is perceived as legitimate, mitigating consumers' cautious behaviour. The type of conditional promotion we used was a channel discount. Participants were randomly assigned to the no promotion, high reactance promotion, or low reactance promotion conditions in the context of purchasing a cable TV and Internet service. Participants in the high reactance promotion condition were told that the firm was offering a discount for using an online channel to sign up for the service. In contrast, participants in the low reactance promotion condition were told that the firm was offering the discount for using an online channel because Internet subscriptions were cheaper to process, which in turn allowed them to share the savings with customers. Participants were asked to choose between two TV packages (Base Pack, Max Pack) and among three Internet connection speed (2MB, 4MB, Max Speed). They were also asked if they would add a separately charged telephone service to their chosen bundle. As expected, in the high reactance promotion condition participants' overall expenditure was lower than in the low reactance promotion condition ($p < .01$) and in the no promotion condition ($p < .05$). As such, the former preferred more basic TV packages with lower speed of Internet and were less likely to add a telephone service to their chosen bundle.

Due to difficulties in measuring situational reactance, in Experiment 3, we used a trait-level measure to provide evidence of a reactance process. We examined whether our effects are stronger among individuals who are more likely to experience reactance. We predicted that the conditional promotions would induce cautious decision making more among high reactance (vs. low reactance) consumers.

The experiment utilized a 2 (Promotion: unconditional vs. conditional) x 2 (Trait Reactance) mixed design. Participants were asked to choose among three differently priced gym membership options as well as three different contract terms available for membership. They also indicated the additional services they were most likely to purchase during their membership. The conditional promotion was framed as a referral discount with the sentence "…conditional on the new customer joining with a second person" added to the discount offer description in the unconditional promotion condition. As predicted, high reactance participants were willing to spend less on membership and additional services when the gym offered a conditional promotion than when no condition was attached to the promotion ($p < .01$). However, there was no corresponding effect among low reactance participants ($p = .73$).

Overall we demonstrate that promotions that are conditional on certain additional behaviours can sometimes backfire. Our findings delineate the situational and dispositional conditions under which conditional promotions are and are not effective, while also shedding light on the mechanism behind our effects. As such, we provide an important counterpoint to the notion that consumers respond favourably to economic incentives.

Placebo/Placui Effects Of Marketing Actions: Consumers Get What They Pay/Paid For

EXTENDED ABSTRACT

Marketing actions can produce placebo effects. For instance, the efficacy of a product may decrease when the price of a product is lowered (Shiv, Carmon, and Ariely 2005). The placebo effect results from consumers' reliance on marketing activities to form expectations about product quality (e.g., "*you get what you pay for*"). However, when consumers learn about product efficacy through first-hand experience, the relative reliance on extrinsic aspects to evaluate product quality may decrease in favor of using intrinsic cues (Levin and Gaeth 1988; Rao and Monroe 1988). In the present research, we investigate whether consumers continue to rely on information extracted from marketer controlled sources after product experience. In addition, we investigate to what extent the placebo effect persists over time. As the placebo effect is largely unconscious (Shiv et al. 2005), (un)favorable product experiences may unknowingly sustain expectancies in subsequent product experiences. Current price promotions could therefore affect product efficacy at future consumption episodes. In two 'longitudinal' experiments, we address the role of product experience in the placebo effect and investigate whether the placebo effect is a transient or persistent phenomenon.

In the first experiment, individuals' mental performance was tested after consuming a cup of coffee from an unknown brand. Consistent with the placebo effect (Shiv et al. 2005), individuals who consumed regularly priced coffee (€2, high price condition) found more words in a word search puzzle than individuals who consumed the same coffee at a price discount (€0.9, low price condition). Two weeks later, these same individuals consumed the same coffee as before and were again randomly assigned to a high (€2) and a low (€0.9) price condition, yielding 4 conditions (price$_{time1}$: high vs. low × price$_{time2}$: high vs. low). Those in the "high$_{t1}$&low$_{t2}$"condition were told that "*the product is now on sale*", whereas those in the "low$_{t1}$&high$_{t2}$" condition were told that "*the price promotion ended*". Participants in the "high$_{t1}$&high$_{t2}$" and "low$_{t1}$&low$_{t2}$" conditions were told that the price was the same as before. Individuals who consumed high priced coffee at time2 found more words in the word search puzzle than individuals who consumed low priced coffee at time2. Current marketing activities seem therefore capable of pro-

ducing *tenacious* placebo effects ("you *still* get what you pay for"): Even after product experience, individuals continue to use an extrinsic cue as a signal for product quality. Interestingly, the price of time1 exerted a significant influence on the performance at time2: Participants who consumed high priced coffee two weeks earlier performed better at time2 than participants who consumed low priced coffee two weeks earlier. We refer to this phenomenon as a *placui* effect of marketing actions (Latin for "*I have pleased*" rather than placebo, Latin for "*I shall please*"): Prior marketing activities affect current product efficacy.

In the second experiment, we aimed to uncover the mechanism behind the placui effect. Individuals' mental performance was tested after consuming an energy drink with a high price, low price or "for free". Consistent with the placebo effect, individuals who consumed a regularly priced energy drink (€2, high price condition) found more words in a word search puzzle than individuals who consumed the energy drink at a price discount (€0.69, low price condition). Importantly, individuals who believed that "*the university received the energy drink in bulk as free samples*" (€0, zero price condition) performed better than individuals in the low price condition and not significantly different from those in the high price condition (performance$_{t1}$: high$_{t1}$ ≈ zero$_{t1}$ > low$_{t1}$). This suggests that not all price promotions instigate placebo effects. One week later, the same participants consumed the same energy drink as before, after being randomly assigned to the high (€2) or low (€0.69) price condition, yielding 6 conditions (price$_{t1}$: high vs. low vs. zero × price$_{t2}$: high vs. low). Replicating experiment 1, individuals who consumed a high priced energy drink at time2 found more words in the word search puzzle than participants who consumed a low priced energy drink at time2 (i.e., a tenacious placebo effect, as individuals continue to use price as a cue for quality, even after product experience). The price at time1 also exerted a significant influence on the performance at time2 (i.e., a placui effect): Participants who consumed a high priced energy drink one week earlier performed better than participants who had consumed a low priced drink one week earlier. Most importantly, the placui effect seemed to be driven by prior marketing rather than by prior performance. Indeed, although the performance of zero$_{t1}$-individuals was similar to the performance of high$_{t1}$-individuals at time1 (performance$_{t1}$: zero$_{t1}$ ≈ high$_{t1}$ > low$_{t1}$), the performance of zero$_{t1}$-individuals was significantly lower than the performance of high$_{t1}$-individuals at time2 (performance$_{t2}$: high$_{t1}$ > low$_{t1}$ ≈ zero$_{t1}$). That is, prior marketing (i.e., price discounts), not prior performance, instigates the placui effect.

Across experiments, we obtain evidence for three variations on the placebo effect: 1) a *regular* placebo effect (the effect of price$_{t1}$ on performance$_{t1}$); 2) a *tenacious* placebo effect (the effect of price$_{t2}$ on performance$_{t2}$); and 3) a *placui* effect (the effect of price$_{t1}$ on performance$_{t2}$). The tenacious placebo effect suggests that current marketing activities may at times overrule expectations based on prior experience. The placui effect suggests that product performance is not only affected by current marketing actions, but by prior marketing activities as well. Therefore, we can conclude that consumers not only get what they *pay* for (placebo effect), but also that they get what they *paid* for (placui effect).

Macroeconomic Threat Increases Preference for Mainstream Products

EXTENDED ABSTRACT

Previous research has explored the role of individual differences in consumer ethnocentrism (Shimp & Sharma, 1987; Shimp et al, 1995; Watson & Wright, 2000) and sensitivity to value-based claims

(Shuldt, Muller, & Schwarz, 2011) to explain preferences for mainstream and fair trade options, respectively. In the present research, we examine the role of intergroup threat in people's preferences for mainstream relative to fair trade products. Intergroup threat can take several different forms (for reviews, see Riek, Mania, & Gaertner, 2006; Stephan, Ybarra, & Morrison, 2009). These forms include realistic threats to a group's power, material resources, and safety (Maddux, Cuddy, Galinsky, & Polifroni, 2008; Morrison & Ybarra, 2008), symbolic threats to a group's values and way of life (Morrison & Ybarra, 2009; Pereira, Vala, & Leyens, 2009), and social identity threats to a group's reputation (Ellemers, Spears, & Doosje, 2002) or morality (Cameron, Duck, Terry, & Lalonde, 2005). Here, we focus on a particular form of realistic threat that we refer to as *macroeconomic threat* – threat to a group's economic position and resources. We do so because macroeconomic threat is especially relevant to evaluations of material goods and products. Broadly speaking, macroeconomic threat is an important contextual variable to study because the state of the economy is constantly in flux. As such, understanding how consumer's attitudes, preferences, and behaviors shift as a function of changing economic times is crucial.

Under conditions of realistic threat, desirable material resources are seen as scarce, and people will take steps to assert the power and status of their own group over other groups (Levine & Campbell, 1972). Recent research has begun to investigate the specific effects of macroeconomic threat. This research attests that macroeconomic threat activates attempts to restore and maintain the ingroup's equality relative to outgroups (Butz & Yogeeswaran, 2011).

Although realistic (e.g., macroeconomic) threat has been shown to increase intergroup biases like prejudice, much less is known about other effects of such threat. In the context of macroeconomic threat, one possible effect could be differential evaluations of material resources that benefit the ingroup versus outgroups. Specifically, a threat to the macroeconomic climate may lead people to choose products that are made domestically and cater to the masses ("mainstream products") over products that are made internationally and promote global social justice ("fair trade products"). This preference for domestic products would reflect a desire to safeguard the national economy against threat.

We conducted two studies to test the role of macroeconomic threat in preferences for mainstream and fair trade products. To explore the unique impact of macro-economic threat on preferences for mainstream products, we compared participants who read an article about the instability of the current macroeconomic climate to those who read a threatening article not related to the economy (i.e., an article about global warming) and those who read a neutral article (see Butz & Yogeeswaran, 2011 for this manipulation of macro-economic threat). Next, participants evaluated a series of mainstream and fair trade products (e.g., Tazo Tea versus Zhena's Gypsy Tea). The mainstream and fair-trade products were pre-tested to ensure that they were equally desirable and attractive to our subject population with the only difference being how common/mainstream the products were viewed by our subject population. We predicted and found that compared to those who read the neutral article (control condition) or those who read the threatening article about the environment (non-macroeconomic threat condition), those who read about a threatening macroeconomic climate evaluated mainstream products more favorably. Importantly, this effect was not driven by differences in affect after reading the threatening articles. Interestingly, participants' evaluations of fair trade products did not shift as a function of which article they read (macroeconomic threat vs. environmental threat vs. control), possibly because participants might have experienced social desirability concerns that prevented them from derogating products that are marketed in such an inclusive way. In study 2, we had participants choose between earning a mainstream or fair-trade product for compensation. By having participants choose which product they would like, versus evaluating both products, we attempted to alleviate social desirability concerns.

In study 2, participants read an essay about either the instability of the macroeconomic climate or a control topic, prior to choosing a product as compensation for taking place in the study. As compensation, participants chose between earning a $10 gift certificate for Hickory Farms (mainstream option) or Global Exchange (fair-trade option). Pre-testing indicated both gift certificates were equally desirable and that consumers inferred they could get a similar value for their money at both websites; the only difference was that one option (Hickory Farms) was perceived to be a more mainstream brand than the fair-trade option (Global Exchange). After indicating which product they wanted to consume, participants completed the Social Dominance Orientation (SDO; Pratto et al., 1994) scale as a measure of their support for inequality and hierarchy in society. We found that macroeconomic threat increased consumers' preferences for mainstream products. We also predicted that this effect was strongest among people high in SDO, who are especially sensitive and responsive to threats to their group's position.

Two studies demonstrate that perceived macro-economic threat impacts preferences for mainstream options. Specifically, those who feel their economic livelihood is threatened shift towards preferring mainstream options. These studies have implications for marketers of mainstream (fair trade) products, who could heighten (decrease) consumers' sense of economic instability to boost sales of their products.

CONCLUSION

This session will further the conference's mission of appreciating diversity by providing a forum that discusses how a single marketing variable, in this case, *financial incentives*, can lead to entirely different effects that range from positive to negative, and that vary across time, thereby affecting choice.

Counterintuitive Effects of Mood, Environmental Cues, and Lay-Beliefs in Food Consumption Contexts

Paper #4: The Unhealthy = Filling Intuition

Rajagopal Raghunathan, University of Texas at Austin, USA
Jacob A. Suher, University of Texas at Austin, USA

SESSION OVERVIEW

Explorations into the various influences that promote or mitigate consumption of unhealthy food has yielded important, and sometimes counter-intuitive, theoretical insights. For instance, we now know that consumers often "eat with their eyes" rather than with their stomachs; that is, they stop eating when their plate is empty rather than when they feel full (Wansink 2007). We also know that obesity can be an epidemic and spread like a disease (Christakis and Fowler 2007).

For those interested in regulating their food consumption, at least three major lessons have emerged. The first lesson is that we should watch out for moments in which we are vulnerable to overconsumption of unhealthy food. Findings reveal that we have a predilection for such food when we are feeling sad or when our ego is depleted. The second lesson is that we should stay away from tempting stimuli whenever possible: avoidance is the best policy (Hoch and Loewenstein 1991). The third lesson is that we should watch out for sub-conscious influences that steer us toward unhealthy food. Raghunathan et al. (2006) show that most of us aren't even aware of the influence of the unhealthy = tasty intuition—which steers us toward unhealthy food when we want something tasty—on our food choices.

The set of four papers in this special session report findings that challenge each of these three themes from past research. The first paper, by Salerno, Laran and Janiszewski, suggests that, although sadness or the presence of indulgent environmental cues may individually promote unhealthy eating, together, they steer people toward healthy choices. In their first study, the authors show that the tendency to consume healthy food is higher when an indulgence prime is combined with sadness, but not when it is combined with anger. The next two studies provide evidence for the proposed underlying mechanism: sadness cues increase vigilance against danger of overindulgence.

The second paper, by Boer and Dewitte, suggests that people are sometimes more likely to choose healthy food when temptation levels are more (vs. less) intense. In study 1, the authors use construal level to manipulate intensity of temptations. In studies 2 and 3, they use hot vs. cold imagination to do the same. Across all three studies and across various measures of temptations (including amount

of saliva secreted), the authors find evidence for their thesis: that the greater the temptation, the greater the tendency to resist consumption of tempting food.

The third paper, by Wilcox, Hagtvedt, and Kocher, explores the influence of luxury primes on eating. At first blush, one may expect the influence of luxury primes to be similar to that of the presence of indulgent environmental cues. However, these authors find that luxury primes actually have the opposite effect: they steer people toward healthy (vs. unhealthy) choices. Studies 1 and 2 establish the basic effect, while studies 3 and 4 document evidence for the proposed mediating mechanism. Specifically, these studies document evidence that exposure to luxury primes results in lower indulgence of food because of a reduction in discrepancy between the actual and ideal selves.

The final paper, by Raghunathan and Suher, explores the influence of the unhealthy = filling intuition. They find that people infer unhealthy food to be more filling and, therefore, feel that they can go longer without eating if they have just consumed less (vs. more) healthy food. The first study uses the IAT procedure to document that people implicitly subscribe to the unhealthy = filling intuition. Study 2 provides evidence that subscription to the intuition leads people to rate a food item portrayed as less (vs. more) healthy as more filling. The study also shows that people feel that they would need to consume less of an unhealthy (vs. healthy) item to stay away from getting hungry for the same period of time. A study in progress aims to show that actual consumption of unhealthy (vs. healthy) food lowers hunger levels to a greater extent.

Together, these papers make a compelling case for how the lessons we appear to have learned from past research must be applied with caution. Specifically, although it may generally be a good idea to watch out for the effect of sadness on the tendency to indulge, it turns out that this may not always be the case. Those feeling sad may actually be quite "safe" when surrounded by indulgent cues. Similarly, although it may generally be a good idea to avoid being tempted, it turns out that intense temptations can actually stimulate an even stronger self-control mechanism such that we are more capable of avoiding temptations when we are more (vs. less) intensely tempted. There is another reason why indulgent cues may lead to lower consumption of indulgent food: they lower the discrepancy between actual and ideal selves. Finally, while many lay-beliefs may have a detrimental effect on food consumption, it turns out that the unhealthy = filling intuition may actually have a beneficial effect. Those who subscribe to this intuition feel that they can go for longer without consuming food when they have just consumed less (vs. more) healthy food.

Researchers interested in the topic of food and obesity, as well as those interested in the topic of self-control are our primary audience. However, we expect the session to be of general interest as well, given the breadth of theoretical constructs covered.

The proposal contributes to the theme of diversity by bringing together various theoretical perspectives—from motivational and cognitive to perceptual—together to shed light on a topic (food consumption) of universal interest and appeal.

How Sadness Signals Danger of Over-indulgence

EXTENDED ABSTRACT

The act of indulging can be a precarious experience for many consumers. Oftentimes, the margin for error is small in terms of exercising self-control and indulging in moderation versus experiencing self-control failure and over-indulging. This balancing act is complicated by the fact that consumers can be led to indulge by factors such as indulgent environmental cues (Geyskens et al. 2008; Laran and Janiszewski 2009) and the experience of negative emotion (Garg, Wansink, and Inman 2007; Gross 1998). Because indulgent food consumption represents a self-control dilemma, even an initial indulgent act by consumers can be perceived as a complete self-control failure, resulting in excessive indulgence (Cochran and Tesser 1996; Polivy and Herman 1985). This risk of over-indulgence is a concern for many consumers, as it can lead to maladaptive consequences such as weight gain and obesity (Wang and Beydoun 2007). Our current research investigates how this potential risk of over-indulgence is ironically what causes indulgent environmental cues and sadness, two factors that have been shown to increase indulgent consumption in isolation, to result in increased healthy consumption when experienced concurrently. We find that this effect occurs because sadness exerts an informational function on consumers' goal-directed behaviors. Where an indulgent cue would normally signal to indulge, we find that sadness increases the sensitivity for harm to occur and signals the risk of over-indulgence. This perceived risk of over-indulgence leads consumers to the seeking of protection in the form of virtuous consumption. As a result, this protective function of sadness, in the presence of an indulgence goal, allows consumers to better regulate their behavior and ultimately aid in consumers' pursuit of wellbeing.

In study 1, we tested our proposed effect and found that virtuous consumption only occurs when an indulgence prime is combined with sadness and not other negative emotions such as anger. Participants were randomly assigned into either an indulgence or neutral prime in combination with the induction of either anger or sadness. The priming task had participants unscramble sentences, where each sentence contained one word that was related to either indulgence or a neutral construct. Then participants read and responded to a hypothetical scenario that either evoked anger or sadness. Lastly, participants completed a purportedly unrelated food preference task. In this task, participants rated the desirability of 20 equally liked foods, half of which were perceived as healthy and the other half as indulgent but unhealthy. In the neutral prime groups, angry and sad participants were both significantly more likely to prefer tasty food to healthy food, a finding consistent with emotion regulation research (Andrade and Cohen 2007). More importantly, within the indulgence prime, we found that only participants experiencing sadness were significantly more likely to prefer healthy over tasty foods, showing that other emotions do not trigger the same sense of danger towards over-indulgence that sadness does.

In study 2, we established process evidence and found that the virtuous consumption observed within the indulgence and sadness combination is driven by an increased sense of danger towards over-indulgence. We also tested whether this sense of danger is specific to cues that signal to indulge or if it applies to other environmental cues such as exercising self-control. If the threat of over-indulgence is also present with cues signaling self-control, this should lead to increased danger-related cognitions and decreased indulgent consumption. Study 2 used the same sentence unscrambling task as study 1 to create indulgence, self-control, or neutral priming groups in combi-

nation with the induction of no emotion or sadness. Mediation was assessed using a scrambled word task previously shown to be an implicit measure of mental construct accessibility (Arndt et al. 2007). Participants solved 25 incomplete words in total (e.g., "w_r_", for which the solution is "word"), where six words had the potential to be either neutral or danger-related constructs (e.g., "_anger" for which the solution is "ranger" or "danger"). Participants completed the same food preference task from study 1. While both self-control and indulgence priming groups experiencing sadness displayed an increased desirability for healthy foods, only the indulgence and sadness condition constructed a significantly greater number of danger-related words and indicated a significantly lower preference for tasty foods.

In study 3, we investigated whether the sense of danger observed within the indulgence and sadness combination becomes stronger as the initial cues to indulge strengthen. Research in the area of priming and goal pursuit has shown that stronger priming effects can lead to stronger motivated behavior (Dijksterhuis and van Knippenberg 1998). Using the same manipulations from study 2, participants were assigned to either a neutral, indulgence, or strong indulgence prime and then induced to feel sadness or no emotion. The strong indulgence prime required that participants completed an additional task of viewing pictures of indulgent foods and clicking on the foods they liked most (Geyskens et al. 2008). Participants were then asked to choose between two gift card options, one being a virtuous "grocery store gift card" and the other being an indulgent "trendy restaurant gift card". We found evidence of an amplified indulgence prime, where participants in the no emotion groups were more likely to select the trendy restaurant as the indulgence prime became stronger. More importantly, we found that the people experiencing sadness in these same indulgence primes were significantly more likely to choose the virtuous grocery store as the indulgence cues became stronger.

Reducing Eating Motivation by Intensifying Prior Temptations

EXTENDED ABSTRACT

Nowadays, a common practice at schools or at home is to restrict physical access to temptations, such as candys, potato chips and soft drinks. But the short term success that this protective, but artificial, environment entails may not lead to long term success (e.g. Fisher & Birch, 1999). When children leave home or school, they enter an environment of easily accessible temptations . In this research, we explore how exposure to temptations can in some circumstances reduce consumption in a durable way (e.g. Fischbach et al. 2003, Geyskens et al 2008, Kroese et al 2009).

Past research has shown that behavioral conflict is associated with self-control failure (e.g. Boon et al. 1998; Meltcafe & Mischel 1999). However, other research has illustrated the involvement of behavioral conflict in the activation of brain areas associated with enhanced self-regulation (Bush, 2001), which, in turn, might induce behavioral change (e.g. Miller and Cohen, 2001). In line with this, it has been shown that exposure to temptations in situations where the consumer cannot succumb, reduces free consumption of similar temptations in subsequent situations (Geyskens, Dewitte, Pandelaere, & Warlop 2008; Dewitte, Bruyneel, & Geyskens 2009). Based on cognitive control theory, we suggest that the process underlying this behavioral change is the spontaneous and durable change in incentive value of the temptation (see Russo et al 1996) . Thus, the primary contribution of this paper is to explore if alterations in the incentive value to consume (e.g. Russo, Medvec and Meloy 1996)

are a plausible process underlying behavioral change. We also test our underlying assumption that the exposure-induced behavioral change (Geyskens et al. 2008) replicates in pre-adolescent children (aged 8-11).

We build on Michel's (1970) delay of gratification paradigm to create a situation where children are exposed to temptation but simultaneously autonomously decide not to consume, with a view to obtaining a larger reward. In study 1, we look at the effects of this exposure on behavior. In study 2, we demonstrate the importance of behavioral conflict during exposure for the effect to occur and the role of changes in the incentive value to consume, as measured by saliva and self-reported attitudes . The secondary contribution of this paper is to shed some light on the emergence of the substantial gender differences in eating behavior and the processes governing it (e.g. Cooke & Wardle 2005; Wansink, Cheney and Chan 2003). For that reason, we include boys and explore to what extent their behavior and the underlying processes can be distinguished from that of girls.

In study 1, we designed an earning game where pre-adolescents were repeatedly asked to choose between having one candy/marble now, or earn three candies/marbles later. We boosted the manipulation power by repeating the exposure on four consecutive days based on cognitive literature suggesting that high frequencies of behavioral conflicts enhances people's ability to deal with behavioral conflict (Logan and Zbrodoff, 1979). By tripling the reward, we made sure children would chose to delay. On the fifth day, we measured self-regulation through consumption of candies (Schachter, Goldman and Gordon 1986). We expected that those who had been in the candy condition would consume less than in the marble condition. Indeed, girls consumed less in the candy condition relative to the control condition. For boys, consumption did not differ between the candy and the control condition. Across gender, there was no difference between girls and boys in the candy condition. In the control condition, girls consumed more relative to boys.

Our first aim for Study 2 was to assess changes in the incentive value to consume in response to behavioral conflict. For this, we used an explicit, self-report measure and, to reduce possible demand effects, a saliva measure. Salivary response is a preconsummatory, physiological and uncontrollable response to food palatability and related to the motivation to acquire food. Second, to demonstrate the importance of behavioral conflict in the pre-exposure effect, we added a condition, where we exposed participants to temptation but suppressed behavioral conflict. Specifically, we created two instruction sets for the delay of gratification procedure. In the hot imaginary condition, we intensified the appetitive aspects of the candy and thereby boosted behavioral conflict by directing participants' attention to the hot features of the candy. In the cool imaginary condition in contrast, we reduced the intensity of the temptation, and thereby the behavioral conflict, by emphasizing the non-tempting, cool aspects of the candy. For the control condition, we used two different experimental versions. Both were designed to let participants do a similar task without exposure to actionable food temptations and without ideation instructions. As none of the analyses yielded differences between these two versions of the control condition, they were merged into one condition in the remainder of the paper. Findings suggest that for girls, salivary flow after delay decreases in the hot imagination condition relative to the cool imagination condition. A similar pattern can be observed between the hot imagination condition and control condition, but this difference did not reach statistical significance. Likewise, no differences in salivation were found between the cool imagination condition and the control condition. A different pattern emerged for boys: they salivate more in the hot

imagination condition and the cool imagination condition (the two condition with exposure to temptation) than in the control condition (no exposure to temptation). The two exposure conditions did not differ. Viewed from a different angle, boys salivate more relative to girls in the hot imagination condition, but not in the cool imagination or control condition, illustrating a profound gender difference when temptation intensity is increased during pre-exposure. For the self-report measure the pattern was consistent with that of saliva for girls: They considered the candy to be less tasty in the hot imagination condition relative to the cool imagination condition and the no imagination condition. Boys did not evaluate the tastiness differently between the hot imagination, the cool imagination and the control condition. Again in line with the results on saliva, girls found the chosen candy less tasty than boys in the hot imagination condition. No other gender differences were found in the cool imagination condition and the control condition.

In line with our expectations, we show that a boost of behavioral conflict during past exposure without consumption reduces pre-adolescents consumption over a time span. In addition, our findings suggest that this is driven by a reduced physical and psychological incentive to consume. Moreover, we show that it is not necessarily exposure to temptations in itself, but behavioral conflict that triggers behavioral adaptation processes. However, we find this only for girls. Further research needs to investigate gender differences in food regulation and how this process might lead to hyperopic behavior in the food domain.

Encouraging Ideal Behavior by Imagining Luxury Consumption

EXTENDED ABSTRACT

People maintain a set of traits that they ideally would like to possess, such as wealth, good health and physical fitness. This idealized version of the self, representing people's hopes and aspirations, serves as a key source of motivation (Higgins 1987). For example, many people ideally would like to maintain a thin physique. In order to achieve or maintain this ideal, they may eat lighter meals, choose healthier foods and avoid behaviors that would create a discrepancy between their actual state (i.e., the actual self) and ideal state (i.e., the ideal self).

Much of the previous research on the ideal self has focused on the negative effects of ideal self discrepancies on behavior. It is generally assumed that making people aware of ideal self discrepancies results in negative emotions, antisocial behavior and less motivation (Strauman and Higgins 1987). Ways to reduce ideal self discrepancies and encourage ideal behavior has been largely unexplored.

In this research, we explore the relationship between luxury consumption and the ideal self. We introduce luxury consumption as one mechanism for reducing ideal self discrepancies to encourage behavior consistent with the ideal self. Specifically, we show that, because luxury products are linked to people's hopes and aspirations, imagining the consumption of luxury products increases the perception that the actual self is aligned with the ideal self. This leads people to subsequently engage in behaviors that are consistent with the ideal self (e.g., making healthier food choices). Additionally, we demonstrate that this effect is moderated by public self-consciousness. Public self-consciousness increases people's attention to discrepancies between their actual and ideal self (Scheier 1976). Thus, we show that making people publically self-conscious while imagining luxury consumption leads them to subsequently engage in behaviors that are more inconsistent with the ideal self.

In study 1, participants were randomly assigned to one of three conditions. In the luxury condition, participants chose their favorite brand from a list of ten luxury brands (e.g., Louis Vuitton, Gucci) before writing about the experience of consuming a product by the selected brand. In the everyday condition, participants were asked to choose their favorite everyday brand (e.g., American Eagle, The Gap) before writing about the experience of consuming a product by the selected brand. In the control condition, participants were asked to choose their favorite luxury brand before writing about their typical day. Afterwards, all participants were given an unrelated study examining food choices. Participants in the luxury condition were more likely to make a healthier choice than those in the everyday and control conditions.

In study 2, participants were randomly assigned to the same consumption conditions as study 1. Afterwards, they were administered an unsolvable anagram task purportedly as a short-test of their verbal abilities. Consistent with the results of study 1, participants

in the luxury condition persisted longer at the task than those in the everyday or control conditions.

In study 3, we investigated the moderating effect of public self-consciousness. In the low self-consciousness conditions, participants wrote about consuming a luxury or everyday brand using the same procedure as prior studies. In the high self-consciousness conditions, participants also wrote about the experience of consuming a luxury or everyday brand, but were encouraged to write about the experience of consuming the product in public. Participants were then given two unrelated studies on food consumption and charity involvement. Participants in the low self-consciousness conditions were more likely to make a healthy choice and more willing to donate their time to charity in the luxury condition than in the everyday condition. Additionally, participants in the high self-consciousness luxury condition were less likely to make a healthy choice and less willing to donate their time to charity compared to those in the low self-consciousness luxury condition. These results were mediated by public self-consciousness.

In study 4, we examined the effect of luxury consumption on ideal self discrepancies. Participants were assigned to the same writing conditions from study 3. Afterwards, they were administrated the Integrated Self Discrepancy Index (Hardin and Lakin 2009), which is as a measure of ideal self discrepancies. As expected, in the low self-consciousness conditions, participants who wrote about luxury indicated that there was less of a discrepancy between their actual and ideal self in the luxury condition than in the everyday condition. Participants in the high self-consciousness luxury condition indicated that there was a greater ideal self discrepancy compared to those in the low self-consciousness luxury condition.

Although previous research has focused on the negative effects of ideal self discrepancies, this current research demonstrates the positive effects of reducing ideal self discrepancies on behavior. Specifically, we show that reducing ideal self discrepancies by imagining luxury consumption encourages healthier food choices, greater motivation and more altruistic behavior. Thus, an understanding of ways to tap into the ideal self is of substantial importance for understanding consumer behaviour at the individual level, as well as broader issues like the U.S. obesity epidemic.

The Unhealthy = Filling Intuition" (Rajagopal Raghunathan and Jacob Suher)

EXTENDED ABSTRACT

An important theme to emerge from research on decision-making is that we are often unaware of the forces that shape our judgments and choices. In the context of food, for example, most of us are unaware of the influence of the unhealthy = tasty intuition on our enjoyment and choices of food. In the present research, we investigate the influence of a related intuition, the "Unhealthy = Filling" intuition on food choice. Interestingly, unlike the unhealthy = tasty intuition, which steers consumers toward unhealthy food, and therefore appears to have a detrimental influence, we report findings which suggest that the unhealthy = filling intuition may actually have a beneficial impact on food choices. Specifically, because people consider unhealthy food to be more filling, we find that people feel that they can go longer without consuming any additional food if they feel that they have consumed unhealthy (vs. healthy) food. Given that the primary cause for obesity is over-consumption of food, this suggests that people may be better off when they believe that they have just consumed unhealthy (vs. healthy) food.

We report results from two studies below. Our first study uses the implicit association test (IAT) to establish that people implicitly

assume an inverse relationship between healthiness and fillingness. The second experiment confirms our prediction that less (vs. more) healthy food is: (1) inferred to be less filling and (2) participants feel they can go longer without feeling hungry if they have just consumed less (vs. more) healthy food. We obtained these patterns regardless of explicitly reported belief in the unhealthy = filling intuition, suggesting that, like the unhealthy = tasty intuition, the influence of the unhealthy = filling intuition is also implicit.

The objective of the first study was to assess whether people implicitly subscribe to the unhealthy = filling intuition. Using standard IAT procedure, participants were asked to categorize relevant stimuli into categories that were either congruent with the intuition, or incongruent with it. A second condition was created to show that unhealthy food is associated with filling rather than with nourishing or sustaining concepts. In this condition, participants categorized stimuli into categories that were congruent and incongruent with an unhealthy = nourishing intuition. Findings revealed support for implicit belief in the unhealthy = filling intuition, but not the unhealthy = nourishing intuition. Specifically, response latencies were smaller when participants categorized stimuli into categories that were congruent (vs. incongruent) with the unhealthy = filling intuition. In contrast, response latencies were larger when participants categorized stimuli that were congruent (vs. incongruent) with the unhealthy = nourishing intuition. These results show that people implicitly believe that unhealthy food is more filling; even as they implicitly believe that unhealthy food is less sustaining or nourishing.

The second study was a controlled lab experiment in which we asked participants to compare healthy and unhealthy versions of the same food item on dimension of healthiness, tastiness and fillingness. We also ask participants to tell us how much of the healthy and unhealthy versions of the food they would have to eat to feel full for a set period of time. Finally, we asked participants to report how strongly they believed in the unhealthy = filling intuition, using a 1 – 7 scale. Two main findings emerged from this study. First, we found that the healthier a food item is perceived to be, the lower its inferred fillingness. This relationship held regardless of explicitness of belief in the unhealthy = filling intuition, conceptually replicating the IAT results in suggesting that subscription to the intuition is implicit. Second, participants reported that they would need to consume a smaller quantity of the unhealthy (vs. healthy) item in order to not get hungry for a set period of time.

In a proposed third study, which is in progress, we will observe the influence of perceived unhealthiness on actual consumption levels. Participants will be given either a healthy snack or a less healthy version of the same snack in compensation for participating in the experiment. In reality, the snack will be the same across the two conditions. At the end of the experiment, we will measure the amount of the snack consumed, and the extent of hunger reported while leaving the experiment. We expect to find the following pattern of results: controlling for the actual amount of snack consumed, and other relevant variables (such as gender, how hungry they were when coming into the experiment, and BMI), those led to believe that the snack was healthy will report feeling hungrier and will also report a desire to eat sooner than those led to believe that the snack was unhealthy. We expect this pattern to be particularly pronounced among those who report stronger explicit belief in the unhealthy = filling intuition.

Taken together, these studies show that people implicitly subscribe to the unhealthy = filling intuition, and that, unlike the unhealthy = tasty intuition, this intuition has a beneficial impact on food consumption, at least from a caloric standpoint.

SESSION OVERVIEW

Online social networks (OSNs), such as Facebook and Twitter have experienced exponential growth in membership in recent years. As of 2010, 74% of American internet users visit social networks regularly and an average user spends one quarter of the time online on these sites. The most popular online social network is Facebook with 155 million users in America and 845 million users worldwide. Surveys show that 48% of 18-34 year old users check their Facebook account right when they wake up, 28% of which report doing so before even getting out of bed. These numbers demonstrate that online social networking sites have become a part of our everyday lives, revolutionizing the way we spend our time, the way we communicate and the way we maintain relationships. But why do people use these sites in the first place? And how does using these sites impact consumer behavior and well-being? While it is clear that online social network usage is frequent and important, questions about what drives people to use them, and the general impact they have on its users are not well understood. Focusing on both, the antecedents and consequences of online social networks, this session aims to answer these questions. The session unifies four complementary papers that examine the motivators for online social networking, as well as the consequences they have for consumer well-being, their judgment and decision making, and marketers more generally.

The first paper examines the antecedents of online social networking. Using multilevel linear modeling with a large sample of social media users, Hoffman and Novak investigate why people use online social networks. Compared to previous research, which has mainly stressed social connections as a motivation to engage in OSN, they examine how both, social goals and content goals can interact with dispositional tendencies and motivational orientation to satisfy needs of relatedness, autonomy and competence.

The second paper looks at both, a motivator for, and a consequence of online social networking. Many OSNs allows users to share short messages about their thoughts, feelings and actions (e.g., Facebook status updates) with their online social network. Buechel and Berger examine why people post such self-relevant content on-line. Using survey and experimental data they suggest that sharing such messages is driven in part by emotionally instability. In particular emotionally unstable individuals use this feature to express their emotions, and doing so helps boost their well-being by increasing perceived social support after negative emotional experiences.

The next two papers focus on the consequences of online behavior. Wilcox and Stephen show some surprising and important negative consequences of using Facebook. Experimental data shows that browsing Facebook (as opposed to a neutral website) leads to an increase in spending and a decrease in performance on a persistence self-control task. A correlational study establishes the relationship between Facebook usage and a number of negative health and financial well-being markers. These negative consequences, they argue, result from an increase in self-esteem after exposure to Facebook, which can activate a narcissistic state and result in self-control failure. Finally, Tsai, Zhao and Soman investigate the influence of online social networks on consumers' judgment. In four studies they show that the mere knowledge of virtual others leads to less extreme objective and subjective judgments. The reason for this, they propose, is that virtual others increase the uncertainty about the accuracy of their judgments, which leads to a decrease in judgment confidence and consequently the need to conform. This need to conform then reduces the extremity of judgments. Consistent with their theorizing, they find that making conforming undesirable mitigates the virtual others effect, leading to judgments that resemble a control condition with no knowledge of virtual others.

Taken together, this set of complete papers provides a deeper understanding of the motivators to engage in online social networking and its consequences for consumer decision making, self-control and well-being. Given the novelty and the timeliness of the session topic, its practical importance, as well as its theoretical relevance for many areas of consumer behavior, such as emotion regulation, self-control, goal pursuit and judgment and decision making, the session is expected to appeal to a large audience in the field of consumer research. The session is thus likely to produce a fruitful interdisciplinary discussion that will lead to more research on online social networks and online consumer behavior more generally.

Need Satisfaction from Interacting with People versus Content: The Roles of Motivational Orientation and Identification with Social Media Groups

EXTENDED ABTRACT

As social media use continues to increase, it is critical for consumer behavior researchers to gain a deep understanding of what motivates consumer use and leads to need satisfaction. Using the self-determination theory framework which stresses that a*utonomy, competence,* and *relatedness* foster motivation and engagement for activities, we evaluate how motivational orientation and the importance to identity of one's online social groups (ISM) influence how relatedness, autonomy and competence (Deci and Ryan 2000) need satisfaction may emerge from one's interactions with either other people or content. Although it may seem obvious that social media use can drive the experience of feeling related, consumers may seek additional fundamental experiences from social media goal pursuit, including competence and autonomy (Deci and Ryan 1985).

In the Web's early days, Hoffman and Novak (1996) noted that computer-mediated communication was differentiated from traditional mass media because it incorporated both person-interactivity and machine-interactivity. While the likelihood of satisfying basic needs through person-interactivity is fairly obvious, the satisfaction of such needs through machine- (i.e. via social media technology) interactivity, or interactivity with social media *content*, is less clear. Researchers examining social media usage tend to consider social media goals as those for which the primary objective is to connect with other people (e.g. Sheldon, Abad and Hinsch 2011), but in addition to interacting with other people when using social media, people also engage in behaviors focused primarily on either consuming or creating social media content (Hoffman and Novak 2011). We denote the former goals, social goals, and the latter goals, content goals.

In our framework, whether or not these fundamental needs are satisfied depends on the goal-specific motivations underlying goal pursuit, along with dispositional tendencies. For example, a person high in a dispositional need for relatedness may be particularly motivated to use social media to experience the satisfaction of relatedness needs. But as social media interactions take place in a social context involving other groups of people, a disposition uniquely relevant to the context is also likely to play an influential role. We argue that such a disposition involves the importance to one's identity of one's online social groups, a construct we refer to as identification with social media (ISM). This construct is adapted from the identity aspect of collective self-esteem (Luhtanen and Crocker 1992) and derives from the idea that individuals are motivated to maintain and enhance their collective or social identity, not just their personal identity (Rosenberg 1979). As such it captures the importance of one's social groups to one's self-concept.

Our conceptual model predicts how the type of social media goal individuals pursue while engaging in social media behavior is likely to moderate the relationship between 1) need satisfaction and intrinsic motivational goal orientation (hypotheses 1a, 1b and 1c), 2) need satisfaction and introjected (a form of extrinsic) motivational goal orientation (hypotheses 2a, 2b, and 2c), and 3) need satisfaction and the individual difference ISM (hypotheses 3a, 3b and 3c).

Multilevel data were collected at both person and goal levels in a web-based study of 338 participants. At the goal level (Level 1), participants identified their five most important objectives when using social media and rated each objective on goal importance, need satisfaction (relatedness, autonomy and competence), intrinsic and introjected motivation, and two process measures (direct experience and control). At the person level (Level 2), we collected four dispositional measures (ISM, relatedness, autonomy and competence) and five types of social media usage. The 1690 goals were classified by two independent judges into three categories: social goals, content goals, or not classifiable due to insufficient information (Krippendorf's alpha =.865, see Hayes and Krippendorff 2007). Disagreements were resolved by consensus and 40 goals that could not be classified were eliminated.

To test our three sets of hypotheses, multilevel linear models were estimated using maximum likelihood, using the sample of all social and content goals (n=1650). Separate models were fit for each of the three dependent goal-level variables, relatedness, autonomy and competence. The model for each dependent variable included the following fixed effects: main effect for goal type (Level 1), main effects for intrinsic and introjected motivation (Level 1), main effect for ISM (Level 2), interaction of goal type-by-intrinsic motivation (hypotheses 1a and 1b), interaction of goal type-by-introjected motivation (hypotheses 2a and 2b), and the cross-level interaction of goal type-by-ISM (hypotheses 3a and 3b). In addition, the hypoth-

esis model included three control variables – goal importance (Level 1), social media usage (Level 2), and need disposition (Level 2). For need disposition, the Level 2 dispositional covariate was used that corresponded to the Level 1 goal-specific dependent variable (i.e, relatedness, autonomy, or competence). Goodness-of-fit tests, parameter estimates and tests of significance are omitted in the interests of space.

Hypotheses were tested by evaluating conditional slopes. All hypotheses were supported. Higher intrinsic motivation led to greater relatedness need satisfaction for social goals compared to content goals (hypothesis 1a), higher intrinsic motivation increased autonomy more for content goals than for social goals (hypothesis 1b), and intrinsic motivation equally increased competence for both social and content goals hypothesis 1c). Hypotheses 2a and 2b predicted the reverse pattern of results for introjected motivation for relatedness and autonomy need satisfaction. Content goals, compared to social goals, led to higher relatedness when motivation was introjected (hypothesis 2a) and autonomy increased more for social goals compared to content goals when introjected motivation was high (hypothesis 2b). Similar to hypothesis 1c, introjected motivation increased competence for content goals, as well as social goals (hypothesis 2c).

Identification with social media boosted the experience of relatedness need satisfaction for content goals (hypothesis 3a) and amplified the experiences of autonomy and competence need satisfaction for social goals (hypotheses 3b and 3c). Multilevel structural equation modeling tested the hypothesized processes. ISM was found to increases relatedness need satisfaction for content goals by strengthening the experience of a more direct online social connection and ISM increased autonomy and competence need satisfaction for social goals by facilitating feelings of control in online social contexts. These results establish several fundamental effects that may be useful as consumer behavior researchers work to increase fundamental understanding of why people use social media.

Facebook Therapy?
Why People Share Self-Relevant Content Online

EXTENDED ABSTRACT

The Internet has become a pervasive part of everyday life, yet its impact on well-being is not well understood. Researchers (Kraut et al. 1998; Tonioni et al. 2012) and cultural critics (Yoffe 2009) argue that the Internet is addictive and that it reduces face-to-face interaction, leaving people depressed, anxious, and lonely. Further, sites based on social interaction (i.e. Facebook) are said to be merely "havens…for people with poor self-image…and narcissists demanding the world's attention," (DiSalvo 2010, p. 53), oftentimes leading to disapproval by other users (Buffardi and Campbell 2008; Forest and Wood 2012). They are associated with negative health and financial behaviors (Wilcox and Stephen 2012) and expose users to physical and cyber risk (Gross and Acquisity 2005). Given these downsides, why is online social networking so popular?

We suggest that certain online behaviors may improve well-being short-term. One of most popular features of many online social networks is micro blogging, a feature that gives users the opportunity to post short messages (e.g. status updates) about their thoughts, feelings, or actions for their online friends to read and potentially respond. Though one might argue that these "updates" are driven by vanity or by the need for extraverts to maintain existing social ties (Gosling et al. 2011) we argue that the sharing of such information with online friends can have another function. In particular, we suggest that users frequently share emotions through status updates and

that this type of sharing can aid emotion regulation, boosting well-being after negative emotional experiences by eliciting expected social support (Rimé 2009).

This "social buffer" we hypothesize is of particular importance for low emotionally stable individuals. Low emotionally stable individuals experience emotions more intensely (Barr, Kahn, and Schneider 2008) and negatively (Costa and McCrae 1980) and are less adept at regulating their emotion on their own (Gross and John 2003). Although this leaves them with a heightened need to share their emotions with others (Saxena and Mehrotra 2001), low affiliation and their tendency to be socially apprehensive (Luminet et al. 2000) makes it difficult for these individuals to do so offline. Consequently, we argue that they are more likely to rely on their online social network to help them deal with their emotions. After all, their online friends increase their perceived social capital (Ellison, Steinfield, and Lampe 2007) and the online setting makes emotional sharing less threatening (Bargh and McKenna 2004). In tree studies we test this possibility.

In study 1 we examine whether low emotionally stable individuals update their status more frequently and share more emotions when doing so. Participants in this study were asked to report how often they updated their Facebook status. In addition they were asked to copy their 10 most recent status updates into the survey. They then reported the extent to which they used OSNs to interact with people, share experiences, share emotions, display identity, or to seek information from other users. They also completed the Big Five Personality Inventory (Gosling, Rentfrow, and Swann 2003). Regression analysis revealed that emotional stability was the only personality factor significantly related to status updating, whereby less emotionally stable participants reported updating their status more frequently. This relationship was mediated by their self-reported motivation to use online social networks to express emotion. Furthermore, content analysis of their status updates revealed that less emotionally stable individuals expressed more emotions in their updates.

In study 2 we test whether this increased emotional sharing is unique to online social networks. Participants randomly assigned to an offline condition reported the frequency of sharing their emotions in person. Participants in an online condition reported the frequency of sharing their emotions through status updates. Participants in this condition also reported how often they updated their Facebook status, as well as their preference for online vs. offline sharing. Finally the Big Five personality factors were assessed. As expected, a significant interaction revealed that while low emotionally stable individuals shared more emotions online than emotionally stable ones, this tendency was not observed in offline sharing, making this tendency unique to online sharing. Replicating the findings of study 1 with a different population, the results also again demonstrate that less emotionally stable people post more status updates and further, that this relationship is mediated by their preference for online over offline emotion expression.

In Study 3 we examined the consequences of such emotional sharing. First, negative affect was induced through false feedback on a performance task (Forgas 1991). Participants also provided a known other's email address to ensure that a known other was similarly activated across conditions. Next, they completed a "writing study". Some participants wrote about a control topic (office products). The other three conditions wrote about their current emotions, either (1) in private, or (2) to be shared with the known other who they were told would not be able to respond or (3) who might respond. Finally, participants reported their current well-being, perceived social support (Metzler 2003), and emotional stability (Mc-Crae and Costa 2004). Results demonstrated that emotional writing

to a known other who might respond helped low emotionally stable individuals repair well-being after negative experiences. These benefits did not accrue for participants writing in general (control), writing about emotions (i.e. venting), or sharing emotion with a known other alone. Instead, the notion that a known other would read what they had written and potentially respond (as on OSNs) boosted well-being. Finally, consistent with our theorizing, this boost in well-being from sharing with potential response was mediated by perceived social support.

These results of the three studies provide insight into a motivator for, and benefit of, online social networking. Emotional unstable individuals are more likely to post status updates and write about their emotions when doing so. Further, such emotional writing, paired with the potential to receive social support – as on social networking sites – helps them repair well-being after negative experiences.

Are Close Friends the Enemy?
Online Social Networks, Narcissism and Self-Control

EXTENDED ABSTRACT

Online social networks are having a fundamental and important influence on society. Facebook, the largest social network, has over 750 million active users (www.facebook.com). Despite their popularity, a systematic understanding of the effect of social networks on consumer behavior remains elusive. Does using a social network, for instance, impact the choices consumers make in their daily lives? If so, what effect does social network use have on consumers' well-being?

People use social networks to fulfill a variety of social needs, including affiliation, self-expression, and self-presentation. Consequently, social network use can have a positive effect on how people feel about themselves and their well-being. For instance, when adolescents receive positive feedback on their social network profile, it enhances their self-esteem and well-being (Valkenburg, Peters, and Schouten 2006). Importantly, people tend to share mostly positive information about themselves to others on social networks (Gonzales and Hancock 2011). Thus, simply browsing a social network has been shown to momentarily increase users' self-esteem (Gonzales and Hancock 2011).

While high levels of self-esteem are often associated with positive social behavior, there also is a "dark side" to high self-esteem, particularly when it comes in the form of narcissism. Narcissism is often conceptualized as a personality trait that is associated with high levels of self-esteem and self-promoting tendencies. We propose that narcissism may not only be a personality trait, but also a state that can be activated by social network use. Specifically, we argue that since social networks facilitate self-presentation and boost self-esteem, the use of a social network should lead people to adopt a narcissistic mindset. We further propose that this mindset will remain active after social network use and affect behavior after the users have logged-off the network.

These predictions were tested in four studies. We demonstrate that browsing a social network lowers self-control, thereby reducing performance in subsequent tasks requiring self regulation. Additionally, we demonstrate that browsing a social network can lead people to display other narcissistic tendencies, such as defensive self-enhancement. Importantly, these effects emerge only for consumers who maintain relatively strong ties to their friends on the social network.

In study 1, one hundred sixty-nine Facebook users from an online panel participated. The study was comprised of three parts

that were disguised a separate studies. In the first part, participants answered several general questions about their Internet use including how close they are to their friends on Facebook, which served as a measure of tie strength. Next, participants were administered a website viewing task where they either browsed Facebook or a popular news website (CNN.com) for five minutes. Finally, respondents participated in an online auction for a new Apple iPad. As expected, participants submitted higher bids (i.e., displayed less spending control) during the auction after browsing Facebook compared to CNN. com. However, the effect emerged only in people with strong ties to their Facebook friends.

Study 2 was designed to rule out the possibility that Facebook use simply makes people more impulsive by examining how Facebook use influences persistence in an unsolvable anagram task, which is a more general measure of self-control (Vohs and Heatherton 2000). Additionally, we measured self-esteem after the task. As expected, participants with close ties to their Facebook friends gave up quicker at the unsolvable task after browsing Facebook. Conditional indirect effects analyses using a bootstrap method (Preacher, Rucker and Hayes 2007) found that the effect of browsing Facebook on persistence is mediated by self-esteem for those with strong ties to their Facebook friends.

The purpose of study 3 was to demonstrate that browsing a social network can lead people to adopt a narcissist mindset. Consequently, we had people browse or not browse Facebook before having them complete the 40-item Narcissistic Personality Inventory. The findings demonstrate that those with strong ties to their Facebook friends report higher levels of narcissism after browsing Facebook. Conditional indirect effects analyses found that the effect of browsing Facebook on narcissism is mediated by self-esteem for those with strong ties to their Facebook friends.

In study 4, we examine the relationship between social network use and longer-term well-being. Five hundred forty-three Facebook users from an online panel covering the general population of U.S. Internet users participated in an online survey. They survey included several questions about social network use and behaviors related to poor self-control in eating and financial decision-making. The findings demonstrate that greater Facebook use is associated with a higher body-mass index (BMI), a greater likelihood of binge eating, more credit card debt and a lower credit score. However, the effect emerges primarily in people with close connections to their Facebook friends.

Social networks, such as Facebook, are now part of the daily lives of hundreds of millions of people around the world. Indeed a number of psychological benefits can be derived from social network use. However, this research demonstrates that using a social network (Facebook) may have a detrimental effect on behavior by lowering consumers' self-control. These results are concerning given the increased time people spend using social networks, as well as the worldwide proliferation of access to social networks anywhere anytime (i.e., via mobile smartphones, smart TVs, tablet computers, etc.). Given that self-control is important for maintaining social order and personal well-being, this subtle effect could have widespread impact. This is particularly true for adolescents and young adults who are the heaviest users of social networks and have grown up using social networks as a normal part of their daily lives.

The Facebook Effect: Are Judgments Influenced by the Knowledge That Others Are Also Evaluating?

EXTENDED ABTRACT

As web-based social networks proliferate, companies increasingly rely on virtual social communities to conduct market research and promote products. To encourage participation, companies often inform respondents that members of their virtual community are also evaluating the same products ("100 of your friends are also participating in this survey"). The present work examines how the knowledge of virtual others influences judgments. Specifically, we propose that the mere knowledge of virtual others highlights the uncertainty in the correctness of judgment (compared with social norm or consensus). The decrease in confidence, in turn, activates a need to conform and thus systematically reduces the extremity of judgments.

Results of four experiments provided support for this hypothesis in various domains including financial forecasting, movie box office revenues, and art work. Unlike previous research on social influence, we developed a new paradigm that allows us to test how knowledge of virtual others influences judgments without having to provide any consensus information to respondents. This feature increases the generality of our work as this information is often difficult to verify or observe in virtual communities.

To test the effect of virtual others, we first conducted a field experiment on Facebook. Participants were recruited into a social community on Facebook and asked to participate in a trivia game in which they were asked to estimate future and past events, including stock prices, currency exchange rate, and movie box-office revenues. In the virtual-other condition, we told participants that members of their community on Facebook were also participating in the study. In the control condition, we skipped this instruction. To demonstrate the role of need to conform, we added a consensus condition in which participants predicted the judgments of the members of the Facebook community about the same events. We offered performance-based incentives to control for effort and motivation. Consistent with our hypothesis, the results showed that participants in the virtual-other condition were less extreme (closer to the midpoint of the scale) in their estimation than were control participants. The results from the virtual-other condition also more closely tracked the perceived consensus than the results from the control condition, confirming the role of need to conform. Furthermore, we observed that participants in the virtual-other condition were less confident in the correctness of their estimation than were the control participants, which increased their need to conform to (perceived) consensus and reduced the extremity of judgments.

In study 2, we further tested the extremity hypothesis by manipulating the valence of judgment targets and using art work as the stimulus, which provides a conservative test for the effect of virtual others. Art is often perceived as a matter of personal taste and should be less prone to the need to conform. However, consistent with the Facebook study, we found that participants were less extreme in their evaluation of art work such that they were less positive about an attractive poster but more positive about an unattractive poster.

In the next two studies, we tested the moderating role of need to conform directly. Specifically, we manipulated need to conform by varying the similarity of members of a virtual community (peer vs. senior citizens; study 3) and activating a lay belief that being different from others is desirable or undesirable (study 4). Results of these two studies consistently showed that need for conformity is a key driver for the effect of virtual others. When participants perceived members of their virtual community as dissimilar to them (i.e., senior citizens) and thus need for conformity was low, or when

they were primed with a lay belief that conformity is undesirable, their judgments were as extreme as the control group. The similarity manipulation also allowed us to rule out priming as an alternative explanation. That is, if the knowledge of virtual others reduced judgment extremity by simply priming participants to behave in a way that was similar to their community members without increasing their motivation to conform, then exposure to senior citizens should cause participants to be more conservative in their financial forecasts as senior citizens often do. However, we found the opposite. Participants in the dissimilar (senior citizen) condition were as extreme in their forecasts as the control group. Further, in study 3, we tested the mediating effect of confidence. We found that the knowledge of virtual others reduced confidence in judgments, which mediated the extremity of judgments.

Our findings contribute to the literatures on social influence by extending the effect of need for conformity to virtual communities and examining the role of confidence in the mechanism that underlies the effect of virtual others. Imagine that a person, alone in a closed room, is evaluating a new product, advertisement, or another person. Clearly, whether or not a virtual community is also evaluating the same object has no bearing on whether and how this person would be judged by the community (it would not have access to his/her response), unlike when community members are physically present. However, across four studies, we found that the mere knowledge of virtual others reduces the extremity of judgments. As virtual social communities proliferate, the present research also raises important issues concerning potential biases in data collected via virtual social networks for academic researchers, policy makers, and practitioners. In the virtual world, consumer evaluations of delight or disgust may be dampened and reported as a mild liking or a mild disliking.

    Darren W. Dahl, University of British Columbia, Canada

SESSION OVERVIEW

One of the most important elements in sales success lies in customer treatment in a retail setting (Crosby et al. 1990; Dwyer et al. 1987). It has been suggested that how consumers are treated and served during their purchase experiences greatly influences their subsequent judgment and decision making (Crosby et al. 1990). Despite its significance in practice, customer treatment has received little attention in consumer research. Existing research on consumer behavior in a sales context has primarily focused on the consumption outcomes as well as the outcomes' impact on consumers' future decisions (Keillor et al. 2000). However, much remains to be learned about how the means (e.g., how consumers are treated and served during a sales experience) influence various outcomes (e.g., consumers' judgment and decision making).

In an attempt to advance our understanding of the impact of customer treatment, this session brings together four papers that provide insights on how consumers are treated and served during a sales experience may influence their judgment and decision making. Specifically, this session investigates the following questions: How do consumers' responses towards the service change when they are treated with extra benefits during a purchase? How do consumers' evaluations of persuasion tactics change when they are confronted with salespeople's persuasion attempts? How does consumers' satisfaction towards a shopping experience change if they are served by a salesperson versus a sales team, and further, a coordinated team versus an uncoordinated team?

In the first paper, Jiang, Hoegg, and Dahl investigate consumers' responses towards the service when they are receiving extra benefits from a salesperson. They show that such preferential treatment can produce social discomfort when the treatment is experienced in a public environment. This effect is moderated by whether the treatment is witnessed, as well as how justified it is.

In the second paper, McFerran and Argo also explore consumers' responses towards preferential treatment by focusing on another beneficiary group – guests of VIPs. They demonstrate a "status by association" effect, such that the preferential treatment makes the guests experience the same (or more) status than their sponsor. Further, this effect is moderated by the ambiguity of the true identity of the status holder, and the guest's social distance from the VIP.

In the third paper, Xie, Rank, and Grayson examine consumers' evaluations of persuasion tactics when they are confronted with salespeople's persuasion attempts. They find that consumers' persuasion knowledge can moderate the target-observer asymmetry regarding perceived effectiveness of persuasion tactics. The moderation effect is mitigated when consumers are motivated to maintain or enhance positive self-perception.

Finally, in the fourth paper, Wang, Hoegg, and Dahl investigate consumers' satisfaction when they are treated with team service. They show that either a behavioral entitativity cue (e.g., coordinated behaviors among team members) or a physical entitativity cue (e.g., wearing the same uniform) of a sales team may enhance customer satisfaction. However, a sales team that lacks perceived coherence may undermine customer satisfaction, compared to a sales individual. Further, they demonstrate that the two entitativity cues may jointly determine customer satisfaction towards the service.

We believe that this session will appeal to a wide audience at ACR. There has been a relative dearth of consumer research on the impact of customer treatment. This session advances the literature by investigating various topics in customer treatment (e.g., preferential treatment, persuasion attempts, team service), and by providing insights on how each treatment may affect consumers' judgment and decision making. All research is in advanced stages – sixteen studies in total with three to five studies in each paper. Further, this session echoes the conference mission of appreciating diversity by including a variety of topics while maintaining a coherent theme, and by embracing research collaborated by researchers across the U.S. and Canada.

Consumer Reactions towards Preferential Treatment

EXTENDED ABSTRACT

Preferential treatment, where some people but not others are offered extra benefits, is a common phenomenon in consumption contexts, such as shopping in a store or dining in a restaurant. If you were the beneficiary in these contexts, how would you feel about receiving such preferential treatment in front of other people who do not receive the benefits? Conventional wisdom, management practice, and prior research would suggest you should be more satisfied (Lacey, Suh and Morgan 2007; Homburg, Droll and Totzek 2008; Dreze and Nunes 2009). However, we suspect that satisfaction with receiving preferential treatment may be a function of the context in which the treatment is received. In particular, we argue that the nature of the environment in which preferential treatment is offered and the basis on which the customer is selected can dramatically alter consumer evaluation of the experience.

We propose that customers' feelings and behaviors when they are treated preferentially in a public environment would be different from the outcomes in a private environment. More specifically, when preferential treatment is received in the presence of other consumers who do not receive such treatment, concerns about unfavorable evaluations from other individuals could lead to feelings of social discomfort (Miller and Leary 1992; Dahl et al. 2001). These feelings would accompany any positive emotions associated with receiving

special treatment, potentially lowering satisfaction and altering consumption behavior. When no other consumers are present, however, these negative consequences should not materialize. Moreover, we argue that consumers will feel concern about negative impressions from others and experience the subsequent feelings of social discomfort when they receive a preferential treatment that lacks justification and is offered in a setting with a social audience that witnesses the behavior.

Studies 1A and 1B tested the idea that although consumers believe that they will feel only positive emotions after receiving preferential treatment, the actual experience can involve a mix of both positive and negative emotions when the preferential treatment is offered in the presence of others. The two studies utilized the same 2 (treatment: preferential vs. common) x 2 (environment: social presence vs. no social presence) between-subjects design, and the same shopping scenario, with the only difference being that Study 1A was a hypothetical case but Study 1B was a real experience. Social presence was manipulated by whether there were other customers in the shopping environment. In this shopping scenario, participants received a 25% discount through a random "scratch and save" draw. In the preferential condition, they were told that they are the only customer getting the deal, but in the common condition, everybody got the deal. Results from the hypothetical study (1A) showed that people assume that receiving preferential treatment will increase their satisfaction, whether in public or private. Interestingly, when actually experiencing the preferential treatment (1B) in a social environment, participants reported both negative and positive emotions and the negative feeling of social discomfort mitigated their overall satisfaction and reduced actual purchase.

Study 2 tested two factors that moderate the negative outcomes of preferential treatment, i.e., witness and justification of preferential treatment. In this study, participants visited a booth, where a local retailer was giving away three personal care product samples. The preferential treatment was the extra sample offered. In the justified condition, extra samples were offered because of their loyalty status. In the non-justified condition, they were offered without any explanations. We also distinguished two types of social presence, i.e., witness and no witness. Results showed that an individual who accepts preferential treatment without justification bears the risk of appearing undesirable, and when being witnessed by people who do not receive the same benefits, can feel socially uncomfortable. However, the feeling of social discomfort diminishes when there is no witness, even though there may still be other people present.

In study 3, we revisited the discrepancy between Studies 1A and 1B, and examined why people cannot predict the social discomfort when asked to imagine receiving preferential treatment in a social environment. We proposed that the failure to recognize these negative emotions is due to a processing mindset that results in a tendency to overlook background or contextual information when making predictions about an event. In the study, we manipulated people's processing mindsets to process events in either a holistic or analytic manner. Results showed that when people imagined a scenario and made an appraisal, their responses resembled the case when they were prompted to adopt an analytic mindset. When promoted to adopt a holistic mindset, their appraisal of the situation was closer to the real experienced responses.

This research contributes to the literature on preferential treatment, social influence, and focalism bias. We demonstrated that social discomfort can emerge when preferential treatment is experienced in a public environment. Moreover, adopting a holistic mindset enables people to capture the social elements and predict more accurate responses.

Status By Association

EXTENDED ABSTRACT

Status and social hierarchies are ubiquitous in human societies. In marketing, status is commonly signalled by brand names, but it can also by endowed by loyalty program rewards, where certain customers receive a disproportionate share of a firm's attention or resources. This preferential treatment can take for example the form of dedicated check-in lines, special discounts, and exclusive lounges for profitable/loyal customers – treatments which are designed to make these individuals feel special. While research has examined the implications of consumers receiving versus not receiving preferential treatment (i.e., VIPs vs. non-VIPs), the present research diverges by examing a third group of consumers: *guests* of VIPs. Guests are individuals who share in the preferential treatment received by VIPs not because they have earned this right due to their brand loyalty or purchase volume, but rather because many loyalty programs entitle a VIP to bring others (e.g., family member, friends, colleagues). For example, such guests might include a spouse of a frequent flyer receiving lounge access or working-class staff receiving an opportunity to enjoy the corporate box at a sporting event. Do these guests feel "special" and what consumption implications does this have? When should reward programs allow consumers to bring guests?

We propose a "status by association (SBA)" effect, such that status can extend from a "true deserver" to the individual's associates. Support for why status may rub off on those around them comes from research on emotional contagion (Hatfield et al. 1994; Neumann and Strack 2000; Ramanathan and McGill 2007), spontaneous trait transference (Argo and Main 2008; Winter and Uleman 1984) and contagion effects (Argo et al. 2006; 2008). We conduct four studies to demonstrate both *how* and *when* status contagion is likely to occur, and its impact on the likelihood of spreading positive word-of-mouth.

In Study 1, we demonstrate the tendency for the status by association effect (SBA) to occur. This study used a one-factor design with four between-subject levels. Participants read a scenario indicating that they are planning on attending a nightclub [a common service experience for this population, as well as one that frequently has benefits of status (e.g., VIP sections, free beverages, special entrances)]. In the scenario, participants read that upon arrival they notice that there is a long line at the nightclub. In the *self* condition, participants read that they have a VIP card that allows them to jump the line. In the *friend* condition participants read that their friend has a VIP card that allows both of them to skip the line. In the *same benefit control* condition, the participant knows someone who is already at the front of the line so the participant will get in right away and will not have to wait (i.e., no status but still get to cut the line). In the *no benefit control* condition, participants arrive before the line forms, so access is gained into the club without waiting (i.e., no status but no special and/or negative treatment). Results demonstrate that individuals feel more status in both the self and friend conditions (which do not differ from one another) as compared to the two control conditions.

Study 2 identifies a boundary condition for the effect, namely the ambiguity of the true identity of the status holder. Specifically, we predict that when the identity of the true status holder is unclear, greater SBA should occur. This is because we derive satisfaction from the exhibition of goods rather than mere ownership (Veblen 1899; Mason 1981). A 2 (holder of the status marker: self vs. friend) x 2(ambiguity of the true identity of the status holder: high vs. low) between-subjects design tested our predictions. The procedure mirrored the "self" and "friend" conditions from Study 1, with the fol-

lowing exception: in the scenario when the other patrons in line see the participant entering ahead of them, it was made either *ambiguous* or *unambiguous* to other patrons as to who is the true cardholder. We also assess positive WOM intentions as an additional dependent measure. Results revealed an interaction, where the greatest status was (equally) felt by VIPs in the unambiguous condition and guests in the ambiguous condition. Further, greater status mediated increased WOM intentions.

Study 3 was similar to study 2, except that we also manipulated social distance of the guest (close friend vs. distant acquaintance), in a 2x3 design. Results revealed an interaction, where ambiguity mattered for both VIPs and socially distant guests (same pattern as Study 2), but ambiguity had no effect for socially close guests: they felt equal status regardless. Again, increased WOM intentions were mediated by felt status.

Study 4 is a field study of status contagion involving both the owner and guests in real luxury suites at a professional football game. Respondents self-identified as either owners or guests of the suite in a survey. We also assessed a different type of social distance (friends of friends). Results reveal that guests feel more status than owners, regardless of whether they were actual friends or merely friends of friends. Again, higher felt status mediates higher WOM intentions. Moreover, this effect is negatively related to the number of games people have watched from the suite (i.e., more games, lower felt status and low WOM intentions), suggesting that status decays over time and that WOM is harder to cultivate among long-standing status holders. Finally, results also reveal that guests use marginally fewer of the suite's perks, suggesting that they are not more expensive to service. Collectively, our results show that frequent status holders may require more and more perks to feel the same felt status over time as a person who only experiences VIP treatment on a single (or very few occasions).

In sum, our research suggests that there may be a significant return in the form of positive WOM from status contagion without the incurrence of a large cost. Thus, allowing VIPs to bring guests may be more beneficial than firms might think.

Target-Observer Asymmetry in the Use of Persuasion Knowledge

EXTENDED ABSTRACT

Persuasion knowledge (PK) aids consumers when responding to persuasion attempts as "targets" or "observers" (Friestad and Wright 1994). Research has documented the "target-observer asymmetry" of perceived sincerity of marketers due to consumer suspicion of marketers' ulterior motives (Campbell and Kirmani 2000). That is, consumer "targets" are cognitively busier than "observers", and therefore the former become less suspicious when persuasion knowledge is not accessible. When persuasion knowledge is accessible, the asymmetry becomes less salient.

The purpose of this research is to examine the target-observer asymmetry in regard to consumer judgment about the effectiveness of persuasion tactics. In five studies, we find consumers with *low PK* rate persuasion tactics as more effective as an observer than a target. In contrast, *high PK* consumers, rate the tactics effective despite the target/observer perspective. However, when the notion of "being influenced by tactics" is activated, consumers are motivated to maintain or enhance positive self-perception. As a result, PK-induced moderation effect is mitigated.

In study 1, participants were presented with a scenario in which a consumer is shopping for wine. They were asked to evaluate the scenario from either a target or an observer perspective. The store employee presents the consumer with a more expensive bottle of wine, while warning that is the last bottle. Next, participants rated the extent to which the tactic would affect the consumer's purchase decision, followed by an individual difference scale of PK (Bearden et al. 2001). Results suggest *low-PK* participants rated the tactic more effective as an observer than as target. *High-PK* participants' rated the tactic equally effective as an observer or target. In study 2 and 3, we examined if accessibility of persuasion knowledge and cognitive business account for the observed PK moderation effect.

In study 2, participants read the same scenario with accessibility of persuasion knowledge being primed (or not). Prior to the scenario, half of the participants saw a screen shot of a website that suggested a discount offer would be expiring (primed). They then saw the same screen shot suggesting the offer would be ending on a different day, after the pervious deadline had passed. The other half participants read the scenario directly (not primed). Results replicated the moderation effect of PK; but the priming had no significant effect on perceived effectiveness.

In study 3, participants read the scenario from the observer perspective. Cognitive capacity was manipulated by asking participants to remember a set of numbers (or not) while reading the scenario. The results suggest both *high-PK/busy* and *high-PK/non-busy* participants rated the tactics as equally effective. The pattern remains the same for the *low-PK* participants. These results suggest accessibility or cognitive busyness does not necessarily account for the observed PK moderation effect. In study 4 and 5, we further explored a motivational account based on self-concept enhancement.

In study 4, participants first completed a "persuasion IQ test" (i.e., ten ambiguous multiple-choice questions about the knowledge of persuasion tactics). Right after the test, they were given feedbacks that they were very knowledgeable (i.e., 9 out of 10 correct) or not knowledgeable (i.e., 4 out 10 correct). Next, they read the same scenario from study 1. A 2 (Feedback: positive vs. negative) X 2 (Perspective: target vs. observer) X 2 (PK: high vs. low) three-way interaction was significant. Specifically, when feedback was positive, both *high- and low- PK* participants rated tactics as more effective as an observer than as a target. When the feedback was negative, the observed pattern in study 1 and 2 was reversed: *high-PK* participants rated the tactic more effective as an observer than target; *low-PK* participants rated the tactic equally effective as an observer or target.

In study 5, participants were presented with a different scenario in which a store employee flatters a consumer for his/her choice of clothing before or after the purchase decision (Campbell and Kirmani 2000). A 2 (Flattery: before vs. after purchase decision) X 2 (Perspective: target vs. observer) X 2 (PK: high vs. low) three-way interaction was significant. When flattery was made before the purchase decision, both *high- and low- PK* participants rated the tactic more effective as an observer than target. When flattery was made after the purchase decision, the moderation effect of PK was replicated. Combined, these results suggest PK can moderate the target-observer asymmetry in the perceived effectiveness of persuasion tactics. The effect can be mitigated when consumers are motivated to maintain or enhance positive self-perception. This research extends the literature by revealing a motivational account underlying the target-observer asymmetry in the use of PK.

The Impact of Sales Team's Perceived Entitativity on Customer Satisfaction

EXTENDED ABSTRACT

Team-based selling has been a growing sales strategy (Cummings 2007). Surprisingly, although the team approach is highly

prominent in industry, academic research on team selling is sparse (Ahearne et al. 2010). This research seeks to fill this gap by investigating *whether* and *how* the perceived entitativity of a sales team can affect customer satisfaction.

Entitativity refers to the degree to which a social collection is perceived as having "the nature of an entity" (Campbell 1958). Prior research has suggested two distinct cues to entitativity perception. Behavioral-based entitativity contends that coordinated collective behaviors among group members imply common goals, leading to increased entitativity perceptions (Ip et al. 2006). Physical-based entitativity posits that similarity in physical characteristics indicates common traits, also resulting in greater perceived entitativity (Dasgupta, Banaji, and Abelson 1999). Building on these findings, we hypothesize that either a behavioral-based entitativity cue (e.g., coordinated behaviors among team members) or a physical-based entitativity cue (e.g., wearing the same uniform) results in enhanced customer satisfaction.

Further, we predict that the interaction between the two entitativity cues is multiplicative. Specifically, the team produces the greatest customer satisfaction when both cues indicate high entitativity. However, customer satisfaction is undermined if either cue suggests low entitativity. We argue that such effects occur because a low (versus high) entitativity cue is more diagnostic in making entitativity judgment. According to schematic processing (Reeder and Brewer 1979), whenever a low entitativity cue exists, perceivers would use it as diagnostic information to conclude that the group is no longer cohesive and unified, leading to lower customer satisfaction. Further, such interaction on customer satisfaction is mediated by the team's perceived entitativity.

Study 1 tested the impact of the behavioral entitativity cue on customer satisfaction. We operationalize the behavioral cue by a salesperson's rationalized referral (e.g., lack of expertise) of another salesperson. We employ a 2 (indication of low expertise: yes vs. no) x 2 (referral: yes vs. no) between-subjects design. Participants read a scenario in which they went to purchase an e-book reader and asked one of the two salespeople for product information. In the indication-of-low-expertise conditions, the salesperson said, "I'm sorry that I'm no good at the e-book reader." In the referral-to-another-salesperson conditions, he said, "Let me introduce you to Ben." Participants were asked to indicate their satisfaction towards the team. Results are consistent with our hypothesis. Specifically, when a team referral was present, a rationalized referral (i.e., indicating low expertise in the product category) enhanced customer satisfaction relative to a non-rationalized referral. Moreover, our findings suggest the circumstances under which an individual's service might be advantageous

compared to a team's service. Specifically, when the salesperson did not indicate his capabilities beforehand, proceeding with individual service increased customer satisfaction, compared to involving another team member without reason.

Study 2 examined the impact of physical entitativity cue on customer satisfaction. We employed a one factor between-subjects design (same uniform vs. different uniforms vs. one salesperson-control condition). Participants read a similar scenario in which they went to purchase an electronics product. The salesperson either introduced another salesperson for further service (team conditions) or served the customer himself (control condition). The physical cue of the salespeople was manipulated by presenting their pictures in the narrative. Participants were asked to indicate their satisfaction with the service. As predicted, results revealed that the sales team in the same uniform produced higher customer satisfaction than the team in different uniforms, and the individual salesperson. The contrast between the latter two conditions was also significant, indicating that the team in different uniforms actually impaired customer satisfaction, compared to the individual.

Study 3 investigated the interaction between physical and behavioral cues on customer satisfaction. We used a 2 (indication of low expertise: yes vs. no) x 2 (uniform: same vs. different) between-subjects design. We shot a video featuring a similar scenario, in which a salesperson either indicated his low expertise in the product before introducing the second salesperson, or directly referred the customer to the second salesperson without any rationale, and the team wore either the same or different uniforms, depending on condition. Participants were asked to indicate their satisfaction towards the team and each salesperson. Entitativity was measured by the extent to which the two salespeople were perceived as a coherent group. Results revealed a significant interaction between physical and behavioral cues on customer satisfaction. Consistent with the multiplicative effect, the team produced the greatest customer satisfaction when both cues indicated high entitativity. However, customer satisfaction was undermined if either cue suggested low entitativity. Mediation analysis confirmed the mediating role of perceived entitativity. More interestingly, a super-additive effect was found when both cues suggested high entitativity. Specifically, when the team employed rationalized referral *and* wore the same outfit, customer satisfaction towards the team was greater than the average satisfaction towards the individuals.

This research contributes to the team-selling literature as well as advances entitativity research by examining the impact of sales team's perceived entitativity on customer satisfaction, and by demonstrating a multiplicative effect when the two entitativity cues interact.

Creativity at Different Times in Life

SESSION OVERVIEW

From the zealous adoption of innovative products to the widespread passion for do-it-yourself goods, today's consumers not only value creative aspects of the goods they consume but also enjoy engaging in creative activities themselves (Dahl and Moreau 2007). To win the hearts of these consumers and thrive in a competitive global market, firms have to constantly innovate and develop creative products and services. Thus, understanding psychological processes underlying creative ingenuity is important for both consumer satisfaction and corporate success (e.g., Burroughs and Mick 2004; Moreau and Dahl 2005). The purpose of this proposed special session is to interest and attract more consumer researchers to this domain, by presenting a diverse set of recent research findings on people's creativity at different times in life, and by fostering a discussion of potentially interesting questions regarding theoretical developments in this domain, thereby sparking future research.

The four papers in this proposal each discusses creativity in a different stage of life. In the first presentation, Carpenter and Yoon show that while aging has long been thought to negatively affect cognitive ability, it can facilitate creativity performance. This effect is driven by the elderly's vulnerability to distracting information. Further, young individuals who are more vulnerable to distractions are also more creative. The second presentation by Chaplin and Norton focuses on children, 3-12 years in age, and shows that younger children are more creative than their somewhat older counterparts: Younger children (ages 3-6) are more likely to exhibit creative, carefree behaviors than older children (ages 7-12) because the development of children's 'Theory of Mind' increases their sensitivity to criticism from others.

In the third presentation, Yang and Chattopadhyay show that awareness of the end of life inhibits diverse exploration of ideas and impairs creativity, and that locus-of-control moderates this effect—while high internal locus-of-control individuals can be more creative problem solvers in many situations, their creative ability is inferior to those with moderate levels of locus-of-control under mortality salience. Finally, in the fourth presentation, Nunes, Drèze, Cillo, Prandelli, and Scopelliti examine, through a large scale empirical investi-

gation, how the designs of fashion designers—who are at the prime of their creative careers—evolve over time. Refuting the notion that iconic fashion designers are independent creative visionaries, the researchers show that the designs by fashion designers themselves and their competitors in prior years significantly affect the designers' creativity and designs in the current year. Each presenter will have 15 minutes to present their project, leaving 15 minutes for discussions between the presenters and audience.

This special session contributes substantively to the theme of the ACR 2012 conference—appreciating diversity. The session brings together creativity researchers from different parts of the world, who have explored the impact of time and age on creativity in different contexts involving participants from a diverse range of age, demographic, and cultural groups. The four presentations highlight a wide range of theoretical perspectives on creativity and yield implications for consumers, firms, and society. Through the session, we hope to bring consumer researchers' attention to creativity research, initiate discussions on a wide set of factors that impact creativity, and spark future research on creativity in consumer contexts. Finally, this session would appeal to a diverse range of consumer researchers, such as those interested in creativity, fashion and design, aging, cognition, memory, motivation, developmental psychology, and mortality salience.

Creativity and Aging: Positive Consequences of Diminished Inhibitory Control

EXTENDED ABSTRACT

Consumers of all ages often make decisions about products and services in complex and busy consumption environments. In such environments, consumers have to ignore or inhibit a vast amount of distracting information in order to make more effective and satisfying choices. One theory of information processing suggests that as people age, they become more vulnerable to the effects of distracting information due to normal age-related declines in inhibitory control (Hasher, Zacks, and May 1999). While this has typically been discussed as a negative feature of normal cognitive aging, the current line of research seeks to investigate positive outcomes associated with vulnerability to distraction. Past research suggests that distracting information can prime older adults with concepts that improve performance on the Remotes Associates Task (RAT; Kim, Hasher, and Zacks 2007). Better performance on the RAT is thought to be associated with cognitive flexibility and convergent thinking. In addition, research on creativity suggests that when the goal is complex, such as a creative or artistic goal, divergent thinking is enhanced, in part, by an attention to distracting (and often seemingly irrelevant) information (Kasof 1997).

The present line of research seeks to merge the separate literatures on inhibitory processes and on creativity by investigating how greater disinhibition of seemingly distracting information can enhance performance on subsequent tasks requiring divergent thinking. We hypothesize that enhanced vulnerability to distracting information will lead to greater creativity in both young and older adults. We reason that a difficult inhibition task will cause features of the distracting information to remain activated and enhance performance on an unrelated creativity task. In two studies we test our hypothesis

that difficulty in inhibiting distracting information leads to the generation of more original recipe ideas.

Study 1: One hundred and ninety-four undergraduates (mean age = 19; 93 females) at the University of Michigan were recruited to participate in a study on reading comprehension. Participants were randomly assigned into one of two distraction conditions, or a control condition. All participants read a mundane passage about a person going on a regular trip to the grocery store. Participants in the control condition read the passage in italicized font without any distracting information. Participants in the first distraction condition were asked to read the italicized passage with irrelevant food related words (e.g., avocado, chicken) periodically embedded in upright font. Their task was to "read all of the italicized words" in the passage. In the second distraction condition, participants read the same italicized passage with food related words periodically embedded in upright font, but the task was to "ignore all of the upright words." These instructions were adapted from pre-existing distraction paradigms (Kim et al. 2007). After completing the reading task, participants answered a few short comprehension questions. They then completed a creativity task where they were given 5 minutes to generate and write down as many cooking recipes as possible.

Following a coding procedure developed by Cheong, Burks, and Lee (2008), the recipes were scored by two blind judges who were self-identified "cooking connoisseurs." Each recipe was judged on 3 items --dish creativity, deliciousness, and potential popularity-- on a 5-point scale ranging from 1 (low) to 5 (high). These three items were then averaged together to create an "originality composite" score. Results indicated that young participants in the two distraction conditions generated recipes with significantly higher originality composite scores than those in the control condition (p = .031). Participants in the two distraction conditions also generated significantly more recipes in the allotted 5 minutes than those in the control condition (p < .001).

Study 2: Twenty-three community-dwelling older adults (mean age = 76; 12 females) were recruited to participate in a reading comprehension task. Older adults are a population with declining inhibitory control, which is generally viewed as having negative consequences for attention and memory. If, however, we find that vulnerability to distraction enhances performance on subsequent tasks requiring divergent thinking, this would provide further support for the idea that declines in inhibitory control may have benefits for tasks requiring creativity. The procedure in this study was identical to that described in Study 1. Results indicated that older adult participants in the two distraction conditions also generated recipes with significantly higher originality composite scores than those in the control condition (p = .001).

Overall, the results of two studies provide initial support for our theory that reduced inhibitory control can have positive consequences for creativity on tasks that require divergent thinking. Importantly, these facilitative effects occur for both young and older adults. In contrast to the well-documented detrimental effects of declines in inhibitory control associated with normal cognitive aging, our findings suggest positive consequences for creativity. Additional research is underway to further decompose the relationship between inhibitory mechanisms and creative processing. This includes determining what relationship a vulnerability to distracting information has to both divergent and convergent forms of thinking. Better understanding the relationship between disinhibition and creativity is important because consumers of all ages are faced with complex decision environments that require inhibition of distracting information in order to make more satisfying consumption choices. Our results suggest one context in which greater vulnerability to distraction may actually be beneficial.

Why Some Children Move and Groove So Well: A Look at Creative Performance and Theory of Mind

EXTENDED ABSTRACT

Chaperoning a middle school dance – with girls and boys in their early teens slouched against the bleachers, carefully monitoring their peers and refusing to dance despite the booming music – inevitably leads adults to comment: "Why aren't they dancing?" This refusal to dance is particularly notable because many of these same children, just a few years earlier, were prone to dance, sing, and more generally *perform* constantly – in school, at home, in the backseat of the car, and while watching television – with huge smiles and obvious relish. Why do people lose this willingness to perform – to sing and dance – as they age? We suggest that it is the very development of children's awareness that their peers might be judging them – itself an offshoot of the generally positive development of an ability to take the perspective of others – that robs them of the joy of getting out on the dance floor when the latest Lady Gaga track starts playing. We gave children the opportunity to behave in a creative, carefree manner – asking them to perform impromptu singing and dancing – and measuring their willingness to do so, as well as their ability to adopt the perspectives of those who might be watching (and judging) them.

The development of theory of mind (ToM) over the course of childhood is generally viewed as representing a positive development – allowing people to understand social norms and to "fit in" to social groups (Gauvain 1998; Liddle and Nettle (2006); Walker 2005; Walker and Shore 2011). Typically, ToM begins to develop around age 4; by age 5 or 6, success at ToM tasks becomes common, with some further development throughout school-age years (Chandler, Sokol, and Hallett 2001; Perner and Wimmer 1985; Wellman, Cross, and Watson 2001; Wimmer and Perner 1983). We predicted that increases in ToM deprive older children of the joy that comes with creative behaviors – like singing and dancing – due to the heightened sensitivity to criticism that ToM engenders (Dunn 1995). We chose singing and dancing since these behaviors have been shown to have significant benefits for health and well-being (Bonilha 2008; Brown et al. 2005; Clift et al. 2008; Bungay, Clift, and Skingley 2010; Verghese 2003); unfortunately, these are also behaviors that are subject to scrutiny by others, as evidenced by television shows like "American Idol."

One hundred fifty-nine children (81 girls, 78 boys) aged 3 through 12 participated in the experiment, and completed two tasks: a creative performance task and a task assessing ToM. The tasks were counterbalanced; order did not influence our results. In the performance task, we presented four options in a random order: sing a song, perform a dance, circle specific shapes on a page, or fill a square with a predefined color. (The first two tasks are associated with creative expressions, while the latter two tasks involve little creativity). Participants selected two tasks to complete in front of the experimenter. We assessed ToM with three measures: "Sally and Anne" false belief task (Baron-Cohen, Leslie, and Frith 1985); "Cookie Box" misleading container test (Gopnik and Astington, 1988); "Duck and Lion" social test (Nguyen and Frye 1999). Following McAlister and Peterson (2006), we summed the responses to form a composite measure of ToM (range: 0 to 3).

Based on previous research suggesting pervasive competency on ToM tasks by age 6 (Wellman et al. 2001), we divided children into two groups for analysis: younger children (ages 3-6) and older

children (ages 7-12). As expected, older children ($M = 2.59$, $SD = .76$) had a more developed ToM compared to younger children ($M = .87$, $SD = 1.17$), $t(157) = 11.24$, $p < .001$.

More than twice as many younger children chose the creative tasks (singing or dancing) than older children: 59.7% of younger children selected singing and 50% dancing, compared to just 25.8% and 21.5% of older children, $\chi^2s(1) > 13.81$, $ps < .001$. Similarly, younger children were less likely to choose the non-creative tasks (circling and coloring; 41.9% and 48.4%) than older children, who overwhelmingly preferred these tasks (70.1% and 82.5%), $\chi^2s(1) > 12.42$, $ps < .001$. Put another way, only 11.3% of young children passed up the chance to sing and dance, whereas 55.7% of older children avoided both of these creative behaviors.

ToM mediated these differences in creative behaviors: The effect of age on the total number of sing and dance was significantly reduced (from $\beta = -.48$, $p < .001$, to $\beta = -.03$, $p = .72$) when ToM was included in the equation, and ToM significantly predicted singing and dancing ($\beta = -.67$, $p < .001$), such that ToM fully mediated the impact of age on willingness to sing and dance, Sobel's $Z = 6.83$, $p < .01$. (This analysis also holds when treating age as a continuous variable, Sobel's $Z = 6.36$, $p < .01$).

These results suggest that the development of ToM comes with costs, by decreasing people's willingness to engage in creative, carefree tasks that bring them joy due to the heightened concern with evaluation that ToM engenders. While some research has documented the link between ToM and negative behaviors such as antisocial deception (Repacholi, Slaughter, Pritchard, and Gibbs 2003), our results suggest that ToM can also decrease the prevalence of positive behaviors. Our results are also relevant to understanding "savant syndrome" in people with autism, who lack ToM (Baron-Cohen, Leslie, and Frith 1985; Treffert 2009). Our results suggest that one reason for the extraordinary creative abilities of some autistic may be the absence of the performance anxiety experienced by children without autism.

How Awareness of the End of Life Impacts Creativity

EXTENDED ABSTRACT

From natural disasters (e.g., earthquakes, hurricanes) to terrorism and wars (e.g., September 11) to social unrest (e.g., riots, murders) to accidents (e.g., car/plane crashes, train derailments), we are constantly exposed to information that makes our own mortality salient. At times, we may even be quite close to such misfortunes (e.g., living in New Orleans during Hurricane Katrina, working in Japan during the Fukushima nuclear emergency). This research explores how awareness of death affects creative ability and what type of individuals are more sensitive to this effect.

Extant research shows that mortality salience, or awareness of one's death, elicits existential anxiety and, to buffer against this paralyzing anxiety, people deploy terror management strategies to create a sense of meaning and order, seeking to transcend death (e.g., Solomon, Greenberg, and Pyszczynski 1991; Greenberg, Solomon, and Pyszczynski 1997). Because cultural values provide meaning and structure to one's world and represent permanence beyond any individual's demise, mortality salience intensifies people's adherence to their cultural values and worldviews (e.g., Greenberg et al. 1990; Rosenblatt, Greenberg, Solomon, Pyszczynski, and Lyon 1989). This effect has been shown to be unique to death (as opposed other aversive events) and occurs outside of consciousness (Greenberg, Pyszczynski, Solomon, Simon, and Breus 1994).

While numerous studies on terror management theory have focused on the impact of mortality salience on evaluations of self and others (see Burke, Martens, and Faucher 2010 for a review), the current understanding of how mortality salience impacts creativity is limited (Routledge, Arndt, Vess, and Sheldon 2008). Seeking to fill this gap in the literature, the current research proposes that mortality salience inhibits access to information outside of one's conventional knowledge, as a means to protect the coherence and stability of one's core cultural values and worldviews. This inhibition occurs because access to peripheral information that may conflict or cast doubt on one's core values and worldviews, can make adherence to them more difficult, reducing the effectiveness of this terror-management strategy. Thus, mortality salience is likely to hamper assess to divergent information in memory, impairing creative ingenuity.

Further, given that death represents the ultimate form of loss of control for human beings—we cannot prevent our eventual demise nor exert any control over post-mortal events (Becker 1973)—mortality salience may impact people with different control beliefs differently. While individuals with high internal locus-of-control believe that event outcomes are primarily controlled by their own efforts and actions, those with moderate internal locus-of-control believe that they have control over only some events (Rotter 1966). The first group's beliefs are irreconcilable with the notion of death, leading to the elicitation of stronger terror-management behaviors under mortality salience. This, in turn, impairs their creative ability more. Consequently, while individuals with high internal locus-of-control can be more creative problem solvers in many situations (e.g., Burroughs and Mick 2004), their creativity ability is likely to be inferior to those with moderate level of internal locus-of-control under mortality salience.

Our propositions were tested in three experimental studies. Study 1a examined whether mortality salience (MS) inhibits assess to divergent knowledge. Participants first responded to a locus-of-control scale (Rotter 1966). Following a widely used TMT paradigm (Burke, Martens, and Faucher 2010), participants were then asked to write down thoughts regarding either their own death (MS condition) or viewing TV programs (control condition). Next, they completed the Positive and Negative Affect Schedule (Watson, Clark, and Tellegen 1988), which captured participants' affective states and served as a delay task (cf. Pyszczynski, Greenberg, and Solomon 1999). Thereafter, participants in both conditions were asked to write down all the place names they could think of with "A" as the first letter. Consistent with the hypothesis that mortality salience inhibits access to divergent information in memory, participants in the MS condition wrote down significantly fewer foreign place names (e.g., Algeria, Antarctica, Australia) than those in the control condition. Further, a significant interaction effect between the locus of control measure and mortality salience manipulation was found. Analysis of the interaction revealed that, in the MS condition, participants with high internal locus-of-control wrote down significantly fewer foreign place names than those with moderate internal locus-of-control; however, the opposite was true in the control condition.

The experimental procedure for Study 1b and 2 was similar to that of Study 1a. In Study 1b, a set of Remote Associate Test (RAT; Mednick 1962) questions was utilized to investigate the impact of MS on participants' ability to connect disparate semantic concepts. In Study 2, participants were given a managerial decision making task—deciding what new business should go into a commercial property where a restaurant had just gone bankrupt (adapted from Goncalo and Staw 2006). Providing further support for our hypotheses, participants in the MS condition correctly answered fewer RAT questions (Study 1b) and were more likely to follow the precedence, i.e., using the space for a restaurant again (Study 2). Locus-of-control moderated the effect of MS on participants' responses in both

studies. While those with high internal locus of control exhibited better performance in the control condition, they were outperformed by those with moderate locus of control in the MS condition. Finally, ruling out an affect-based account of the results we found in the three studies, including the PANAS scores in the analyses did not change the findings.

Overall, these results not only shed light on the impact of mortality salience on information accessibility and creative problem solving, but also illuminate the role of control beliefs in terror management theories. Further, our findings contradict lay intuitions: A survey of mid to senior level executives at a large logistics firm revealed that the majority (67%) would put high locus-of-control managers in charge of problem solving, in crisis scenarios (e.g., natural disasters or terrorist attack that resulted in a major loss of life). Our results, however, suggest that those with moderate locus-of-control may be more creative problem solvers in those dire scenarios.

How Fashion Designers Develop New Styles: Creative Epiphany Versus Market Feedback

EXTENDED ABSTRACT

The fashion world is characterized by change. Like other creative industries including music, theater, and publishing, the public appetite for something novel in fashion seems insatiable. Fashion thrives on change, and the success of the industry as a whole depends on its ability to introduce new styles. World renowned design houses such as Chanel, Prada, Gucci, and Balenciaga and their top designers Karl Lagerfeld, Miuccia Prada, Frida Giannini, and Nicolas Ghesquière are devoted to introducing distinctive, original styles each season. But how fashion designers derive their inspiration is often shrouded in mystery. Like musicians, actors, and authors, designers are prone to see themselves as visionaries and creativity as an epiphany, impervious to outside influence. For example, Karl Lagerfeld, creative director at the helm of Chanel since 1983, claims his best work is effortless, coming to him in his sleep.

Despite ongoing research in fashion within many disciplines, data driven research on style changes across time is conspicuously absent in the literature. To the best of our knowledge, there exist no systematic empirical investigations regarding how styles change over time. As such, no research examines whether and how innovation in fashion depends on influences outside of the firm, such as market feedback and competitors' behavior. This research sets out to determine whether fashion designers are indeed immune to caprices of the market. Specifically, we investigate whether fashion designers attend to market feedback. In doing so, we empirically test if and how the relative success or failure of styles introduced in the past affects new styles that are subsequently introduced. If designers are immune to criticism, we should observe no relationship. If, however, designers are shrewd marketers attuned to what critics say, the styles they introduce each season should be more similar to those styles that were reviewed more positively in the past and less similar to less positively received styles. Thus, we would expect to observe a systematic relationship between what they do and what they have done, as well as what their competitors, have done.

Our data collection occurred in multiple stages. We obtained a listing of all brands that were included in the catwalk calendars of Milan and Paris from 1999-2007 (fall/winter and spring/summer). Only those companies that put on runway shows with their seasonal collections during Fashion Week for at least five years were included in our data set. This resulted in 38 companies, with 22 from Milan and 16 from Paris. To develop a metric to gauge the extent to which each designer's style changed from year to year, we compared prototypical pieces that were offered commercially following each show. To this end, we collected every ad published in Vogue Italia, Vogue France, Elle Italia, and MarieClaire France for all of the design houses each year. We used these ads to assess the change in style for a specific designer or design team. We focused on 11 primary types of garments (e.g., dresses, pants, etc.). Judges coded each garment on some subset of 13 style elements that were appropriate for the particular type of apparel. For example, tops were evaluated on sleeve length while pants were not. Six elements were evaluated using continuous measures (e.g., sleeve length, neckline), while seven elements were comprised of multiple discrete measures (e.g., color, fabric). Our data therefore included information on styles introduced by 38 design houses across nine years for two seasons derived from 5,343 advertisements. Taken together, this created what we refer to as the style genome for each of the 38 designers for each of the 18 seasons in our sample.

We label the difference between any two style genomes (across time but either within or across designers) as the style distance. A style distance measure reflects the relative change in styles and was constructed by calculating the Euclidean distance in a 61-dimensional space based on the 61 style measures using the 13 style elements for the 11 garment types. The style distance is a single number that is indicative of the relative change in styles across time, but is always calculated within season (fall/winter, spring/summer). We also collected critical reviews of the catwalk shows for each major season (spring/summer, fall/winter) for each year in the sample (1999-2007). We took differences in reviews as an indicator of relative success or failure in the market and consider more positive reviews as greater acceptance of a style by the marketplace.

Our main focus was to explore how new styles were affected by reviews of past styles. First and foremost, we observe a tendency for designers to move away from styles that were reviewed less favorably in the past. Designers, intentionally or unintentionally, stick closer to styles that have been well-received in the past and shy away from those not as well-liked. Empirically, we demonstrate that designers distance themselves further from previous styles over time, exactly how far they move is moderated by how the market responded to specific styles in the past. This result dispels the long-held myth of the designer as dictator unfettered by how the market responds to his or her creations.

We also observe a tendency for designers to move away from styles introduced by other designers' that were reviewed less favorably in the past. This suggests that not only do designers' attend to how the market responds to the designs they introduced previously, but they are keenly aware of, and respond to, what the market says about other designers' previous styles. These results provide the first empirical evidence that styles evolve based on market forces as well as creative forces, documenting the dynamic interaction between fashion houses and their customers in a recurring feedback loop.

Our data and our results suggest that fashion designer, as commercial artists, are not only sensitive to their own past successes and failures when deciding what new designs to introduce, but shows they also consider competitors' past work and how those styles have fared in the marketplace. Ours is the first empirical evidence of market feedback impacting new product introductions in an industry based on aesthetic innovation. The paradox of fashion is the conflict between looking distinctive while giving the impression of a certain degree of uniformity. Understanding how aesthetic innovation occurs, and what drives its acceptance or rejection is an important area that should garner a lot of attention in the future.

SESSION OVERVIEW

The research described here shows how relatively small, yet well-planned interventions can lead to significant changes in behavior. Influencing behavior change is an ongoing challenge in today's society. In response, psychology, economics and consumer behavior researchers have been trying to find effective ways to induce new habits (e.g., Choi et al. 2004; Cialdini 2003). Recently, Thaler & Sustein (2009) proposed that it is possible to change behavior by manipulating the context in which individuals make decisions (i.e., nudges). The four papers included in this session take the nudge approach and provide new evidence for behavior change in applied settings.

The papers focus on three domains of social concern: health, wealth and the environment, which consumer research is poised to address. Consequently, the present work provides practical strategies for improving practices in these areas, via the use of economic and psychological theories. All papers included in this session involved field experimentation, and spanned the globe. As such they appeal broadly to both those who conduct randomized experimental work as well as those who are interested in exploring behavior change in diverse real world settings.

The first two papers apply concepts of self-control, commitment and normative feedback to address overeating and sedentary behavior. The paper by Schwartz et al. shows that urging self-control through simple prompts and pre-commitment can significantly improve nutrition behavior. For instance, consumers accept offers to reduce their calorie intake by taking smaller portions of side-dishes in a fast food restaurant. Taking a different approach to health, the paper by John and Norton addresses how to increase activity (i.e., reduce sedentary behavior) in a work setting through the use of walk-stations – treadmills attached to elevated workspaces – while also giving employees feedback on their own and coworkers' walkstation usage. Results show that walkstation usage declines over time, and that this decline is greater when participants are given information on peers' usage levels, presumably due to a tendency to converge to the lowest common denominator.

The final paper by Baca-Motes et al. highlights the potential use of a commitment device to increase individuals' compliance with environmental appeals. Results show that guests who make a specific commitment to environmental behavior and are given the chance to strengthen this commitment with a publicly displayed symbol (an environmental pin) are more likely to reuse their towels during their hotel stay, arguably via signaling.

We are convinced this session will be of broad interest to the ACR community, as it addresses important topics and provides insights regarding the ways we can change behavior (for the better). Finally, this session complements the theme of this year's ACR conference, "appreciating diversity", in that the interventions tested were applied to a diverse set of contexts with diverse sets of populations.

Taming Temptation: Targeting Self-Control Increases Healthy Food Behaviors

EXTENDED ABSTRACT

The obesity epidemic lacks a clear and actionable solution. Some communities have taken first steps towards healthier diets with interventions that require prominent nutritional information. Such interventions rely on information to encourage healthier food choices. Behavioral science research has shown, however, that while information-based interventions (e.g., mandatory calorie labeling) can effectively change attitudes, they often fail to change actual behavior. As an alternative, we propose tackling the problem from a different angle. Specifically, we have targeted the temptation to make unhealthy food decisions through a series of field and web-based experiments that specifically focus on activating self-control. Our results show that this strategy is effective, easily implemented and especially welcomed by consumers.

First, we conduct a series of field experiments were at a Chinese fast-food restaurant. In Study 1 participants were asked by restaurant staff if they wanted to "cut over 200 calories from their meal" by taking a half-portion side dish (ranging in calories from 440-570). In one condition the participants were merely prompted to cut back, in a second condition they were offered a nominal (25 cent) discount along with the prompt and the third condition was a baseline condition. One-third of the participants accepted the offer, enough to lower the overall number of calories served not only to downsizers, but over the entire restaurant population. Study 2 replicated and extended these findings by demonstrating the same pattern of results and showing that the downsizing prompt was better than calorie labeling at reducing the number of calories served. Study 3 once again replicated this pattern of results, and demonstrated that meal downsizing resulted in significantly fewer calories served. Moreover, an analysis of leftovers in Study 3 showed that meal downsizing not only led to fewer calories being served, but also to fewer calories being consumed.

All three studies took place over multiple day blocks that alternated several days each of baseline activity, the downsize prompt (with and without either a small incentive or calorie labeling), and another baseline. Customers were unaware that a study was taking place and all data were recorded through daily cash register receipts.

Table 1 shows that while customers almost never spontaneously ask for a half portion side dish, anywhere from 18-33% were willing to take one when it was suggested (p < .05 in all studies)—even without an incentive (Study 1). In addition calorie labels were not effective—either before and after it was introduced and especially compared to the downsize prompt (Study 2). Study 3 also assessed the weight of patrons' leftovers and found that regardless of how

much food consumers started out with, everyone left an average of 2oz of food on their plates. This allowed us to determine that meal downsizing not only influences the amount of food purchased, but the amount of food eaten. Finally, the cash register receipt data also revealed there was no evidence of compensation whereby participants who downsized then opted for more highly caloric entrees.

Next, we examined the effectiveness of pre-commitment on shoppers at a popular grocery store in South Africa. Members who ordinarily receive a 25% discount on their healthy food purchases were asked if they would be willing to put their discount on the line by pledging to increase the number of healthy food items by a certain percentage. For example, members were asked if they would pledge to increase their percentage of healthy food items from 25% to 30% in order to maintain their 25% discount. Those who reach the goal get the healthy food discount on all items, but those who fail to reach the goal lose the discount on ALL healthy food items. The data showed that 2/3 of the incentive program members said they were willing to put their discount on the line and pre-commit to buying healthier food at the grocery store. We are now running a field experiment with members from the same population to determine how effective this program is in an actual shopping environment. These data will be presented.

We close by noting that public health interventions often focus on giving information to help consumers make better choices. In reality, this information may have limited ability to change behavior. Our research takes a different approach—one that targets self-control as the primary contributor to poor eating habits. These strategies are effective, easy to implement and are often welcomed by both consumers and retailers. As such, these findings have significant implications for both marketing and public policy.

Exercising to the Lowest Common Denominator

EXTENDED ABSTRACT

Sedentary behavior has been on the dramatic rise in the United States in recent decades. Half of occupations required at least moderate physical exercise in the 1960s; just one fifth did so in 2010 (Church et al., 2011). As a result, average daily occupation-related energy expenditure has decreased by more than 100 calories over the same time period, a reduction that alone can account for a significant portion of the increase in average body weight (Church et al., 2011). In a field study, we attempted to reduce sedentary workplace behavior by introducing walkstations – slow-moving treadmills attached to elevated workspaces enabling employees to walk while working – giving employees feedback on their own and their coworkers' walk-station usage, and measuring the impact of the health behaviors of coworkers on usage over time.

People's desire to align their behavior with descriptive norms can lead to positive behavior change if the target behavior is positive and people are underperforming relative to the descriptive norm, but also to "boomerang" effects if the target behavior is positive and people are outperforming the descriptive norm (Cialdini et al., 1990; Schultz et al., 2007). While some previous research has documented the positive effects of social support on health behavior (e.g., Berkman, 1986; Cohen & Syme, 1985), recent research suggests that peers can exert more downward than upward pressure on health behaviors, such as research demonstrating that obesity can "spread" though social networks (Christakis & Fowler, 2007); in one study of United States Air Force Academy students, being randomly assigned to squadrons with peers who were less fit in high school predicted the probability of failing the academy's fitness requirements, and these downward effects were driven in particular by exposure to the least physically fit students (Carrell et al., 2011).

But through what proximal mechanism do these distal effects occur? How do the health behaviors of one's peers in the short term create these longer-term health outcomes? Social facilitation suggests that group behavior tends to converge upon the dominant response (Zajonc, 1965); in one study, many participants who had agreed to volunteer their time stopped volunteering as soon as someone else had stopped: once anyone exhibited the dominant response – in this case, *not* volunteering – others followed suit (Linardi & McConnell, 2011). The obesity epidemic and increase in sedentary workplace behavior suggest that with respect to physical activity, the dominant response is *not* to exercise. As a result, feedback on others' walkstation use could cause dyad and group behavior to converge to the dominant response – sitting down – such that people's exercise would converge to the lowest performing member of the group: the lowest common denominator.

Employees (*N*=224) at a US company participated in a six month between-subjects randomized field experiment. In the "hold-out" control condition, participants could not use the walkstations. In three experimental conditions, participants were asked to use the walkstations and sent a personalized weekly email. In the *solo* condition the email summarized the participant's walkstation usage for the previous week; in the *duo* condition – in which each participant was randomly paired with another participant – the email summarized the participant's and their partner's usage. In the *quintet* condition – in which each participant was randomly grouped with four others – the email summarized each participant's and the other four participants' usage. The study was conducted with employees from three differ-

Table 1: Calories per customer (SE)

*p < .05, **p<.01, ***p<.001.

ent work sites of the same company in the same city; randomization was stratified by work site. To use the walkstations, employees entered their unique employee ID; our primary outcome measure was walkstation usage assessed by these login data, which allowed us to assess how often and for how long each employee used the machine.

Walkstation use declined over time ($F(1, 2896)=86.8$, $p<.0005$) – in general, participants reverted to the dominant response over time – but this main effect was qualified by an interaction between time and feedback condition ($F(2, 2896)=4.62$ $p=.01$). In both the *duo* and *quintet* conditions, usage declined faster than in the *solo* condition ($F(1, 2898)=5.11$, $p=.02$). This greater decline in usage in duos and quintets was driven by the fact that usage converges to that of the least frequent user – the lowest common denominator. We first identified each quintet's top performer (the participant with the highest usage), worst performer (the lowest common denominator), and the three "middling" performers in month one, then tracked their behavior in months 2-5 and month 6. Middling performers converge over time to the lowest common denominator, rather than being pulled upward by the top performer. For duos, the same pattern is apparent: over time the top performer is pulled more toward the bottom performer than the reverse. When we randomly group solo participants into post-hoc "quintets," we see no evidence of similar convergence; the same holds true when we group solos into post-hoc "duos." This lack of convergence in these synthetic groups offers further support for the specific impact of social feedback on convergence to the lowest common denominator.

We showed that the impact of social feedback on walkstation usage was to decrease health behaviors: usage declined more in the *duo* and *quintet* conditions than in the solo condition, due to a tendency for people to converge to the lowest common denominator. Our results do not suggest that social feedback always leads to worse behavior; social support can be beneficial in improving people's health (Berkman, 1986; Cohen & Syme, 1985); they do suggest, however, that when the dominant response for a behavior is the negative one (from not exercising to overeating) that social feedback is likely to reinforce rather than ameliorate. Given the power of the dominant response in shaping social behavior, future research should explore the impact of framing behaviors as the dominant response – even when they are not – on health behaviors; in our paradigm, we could have shown participants in quintets *only* data from the top performer, changing the ostensible dominant response, decreasing the salience of the lowest common denominator, and perhaps changing behavior for the better.

Commitment and Environmental Behavior Change: Evidence from the Field

EXTENDED ABSTRACT

Influencing sustainable behavior is an ongoing challenge in psychology and consumer behavior research. One example is that of hotel towel reuse programs, which typically ask guests to "do their part" for the environment by reusing their towels. It is hoped this will trigger conservation minded behavior, but data shows participation rates are generally low (30-38%) (Goldstein et al. 2008). Normative appeals can increase participation (e.g., Goldstein et al. 2008), yet an estimated 50% of hotel patrons remain unresponsive. Furthermore, the "social norm" solution relies on communicating a typically false social "norm"—the majority of guests in most hotels do not reuse their towels.

In this paper we propose a novel approach for increasing guests' participation in hotel towel reuse programs. Specifically, we suggest that allowing guests to actively express their interest in joining hotels' environmental efforts by reusing their towels would consequently increase the likelihood they would do so. In order to test this proposition, we ran a large, intensive field experiment (N = 4,345) in a California hotel to examine how committing to practice sustainable behavior at check-in would influences guests' subsequent compliance with eco-friendly behavior during their stay. Results show that specific commitments coupled with a publicly displayed symbol (environmental pin) increased towel reuse, arguably via signaling and dissonance avoidance.

We predict that guests' participation in towel reuse programs would increase if they initially choose to commit to do so, presumably because *choosing* to commit sends a signal to the individual that she cares about the environment, which should promote consistent behavior (self signaling; see Ariely & Norton 2008; Bem 1972; Bénabou & Tirole 2011). Additionally, we argue that allowing guests to express their commitment to the environment publicly would reinforce their commitment and further increase sustainable behavior (e.g., Ariely et al. 2009). Finally, we expect that guests' participation would be positively affected if their commitment *specifies* the steps required to achieve such behavior (e.g., Wright & Kacmar 1994).

Guests were randomly given the option at check-in to join the hotel's environmental efforts through two types of commitments: General (commitment to be environmentally friendly during stay) or Specific (commitment to reuse towels during stay). To reinforce signaling, some guests received a "Friend of the Earth" pin. This resulted in a two (Commitment Specificity: general, specific) by two (Symbol: pin, no pin), between-participants, design. We also included three external control conditions: "Message Only"—guests were only exposed to the hotel's environmental message, "Pin Only"— guests only received a pin, and "No Manipulation". Our main measure of compliance was the likelihood of towel reuse—hanging towels to be reused the next day.

A logistic regression analysis showed Specific Commitment guests were more likely to hang a towel relative to General Commitment guests ($M_{Specific}$ = 66.6% vs. $M_{General}$ = 61.0%; $Wald(1)$ = 4.49, p = .034). The regression further revealed a significant effect of Symbol: guests that received a pin were more likely to hang a towel (M_{Pin} = 68.0%, M_{NoPin} = 59.6%), $Wald(1)$ = 10.02, p = .002). The interaction was not significant. A comparison to the three control conditions revealed that Specific Commitment plus Pin guests were more likely to hang a towel than guests in any of the control conditions ($p's < .001$), while General Commitment plus Pin guests were only more likely to hang a towel than Pin Only guests (p = .016). When using a Bonferoni correction for multiple comparisons, the Specific Commitment plus Pin condition differed from all other conditions, and there were no other significant differences.

Overall, we found that a commitment alone is relatively ineffective in motivating behavior—the increase in desired behavior occurred only when the commitment was detailed and action-oriented. Based on past work, we propose that an abstract, diffused, commitment requires very little effort to be fulfilled. In contrast, a more specified commitment promotes subsequent behavior consistent with the desired change. In addition, guests signing this specific contract further signal to themselves that they in fact care about the environment, which increases the likelihood that they will behave consistently with that identity. When coupled with a symbol to reinforce their commitment, guests were most likely to practice sustainable behavior, supporting our proposition that adding a social component would further promote behavior change. Notably, the commitment itself was entirely symbolic—once guests completed the check-in process they were able to exist in anonymity and behave as they wished, since they were unaware that their behavior would be moni-

tored. From the perspective of hotels, and other entities attempting to motivate certain behaviors, our approach offers a simple alternative that hinges on individuals' self-identity. Adding one small step to the check-in process significantly increased guests' eco-friendly behavior leading to savings of both scarce resources and money.

SESSION OVERVIEW

People often exhibit a preference for variety in choice: we buy an assortment of cereals, yogurt flavors, and beverages rather than pick our favorite option multiple times. Variety-seeking behavior is fundamentally intriguing because, although people can usually select their favorite options repeatedly, they often choose to include less-preferred options (McAlister and Pessemier 1982). Perhaps not surprisingly, variety-seeking has generated a considerable amount of research focusing on the reasons for this behavior (Kahn and Ratner 2005 for review), such as uncertainty about future preferences (Read and Loewenstein 1995; Simonson 1990), a preference for varied experiences (Ratner, Kahn, and Kahneman 1999), and social norms favoring variety (Ratner and Kahn 2002).

But while it is clear that people tend to incorporate variety in their choices for various reasons, new insights suggest that variety may serve additional purposes, and have further antecedents and consequences, than previously considered. Can variety-seeking be driven by vicarious satiation from products that others choose to consume? Might variety serve as a self-presentation instrument, through which consumers convey information about their preferences? Can perceptions of variety be influenced by solely altering the presentation format? And is the notion of variety as "the spice of life" actually related to physical spiciness?

The current session addresses these and related questions as it offers cutting-edge insights into the role of variety-seeking in consumer behavior. The first paper (Tu and Fishbach) finds that the variety of products a group of people would choose to consume is larger than the variety of products an equivalent group of people would identify as their favorite. This is because people's desires for certain products can be vicariously satiated by others' consumption-oriented choices, but not from others' stated preferences The second paper (Sela and Maimaran) shows that people use variety as a means of conveying information about the strength of their preferences, choosing less variety to signal strong preferences for socially-desirable options (e.g., highbrow products) and more variety to signal weak preferences for socially-undesirable options (e.g., lowbrow products).

Whereas the first two papers focus on novel antecedents and roles of variety-seeking, the next papers examine perceptions of variety and the embodied underpinnings of variety seeking. The third paper (Townsend and Kahn) illustrates how visual versus verbal presentation format differentially influences perceived variety. While visual presentation is beneficial in small choice-sets, in larger ones it increases perceived variety and complexity, ultimately leading to greater choice overload and deferral, compared to a verbal presentation format. Finally, the fourth paper (Mukherjee, Kramer, and Kulow) takes an embodied cognition perspective and shows that people choose more variety after eating spicy food, reflecting the adage that "variety is the spice of life".

Taken together, the papers illuminate the social, informative, structural, and physical aspects of variety and variety-seeking. Considering the ubiquity of variety-seeking behavior, and the breadth of topics these papers cover, the session should be of interest to a broad set of audiences. Not only should it appeal to researchers working on judgment, decision making, and choice, but also to those who study satiation, self-presentation, processing styles, and embodied cognition more generally.

Preferring the Same, but Consuming Differently: Vicarious Satiation and Variety-seeking in groups

EXTENDED ABSTRACT

A key finding in previous research is that people tend to seek variety. Whereas most of the research examined variety-seeking at the individual level (Kahn and Lehmann 1991; McAlister 1982; Ratner and Khan 2002; Read and Loewenstein 1995; Simonson 1990), consumers also seek variety at the group level (Ariely and Levav 2000). In fact, lots of consumption related decisions are made in groups, where each consumer's decision can be viewed as part of a group's decision. Therefore it is imperative to understand the driving forces of variety-seeking behaviors at the group level.

Ariely and Levav (2000) showed that the variety of products chosen by a group is larger when group members announce their choices sequentially rather than making choices individually, mainly due to information-gathering motivation and self-presentational concerns. In this paper, we propose vicarious satiation as a novel factor that can account for this effect, and base our hypothesis on two separate lines of research. Firstly, experiencing or anticipating satiation from consumption (McAlister 1982; Read and Loewenstein 1995) is one major reason that people seek variety. Secondly, research on vicarious effects showed that people could vicariously share others' experience, such as goal fulfillment (McCulloch et al. 2011; Wilcox et al. 2009), depletion (Ackerman et al. 2009), loneliness (Wesselmann, Bagg, and Williams 2009), cognitive dissonance (Norton et al. 2003). Therefore we argue that other's choice of consumption goods can vicariously satiate one's own desire for them, resulting in variety-seeking in choice at group level.

To test this hypothesis, we directly compared variety-seeking in choice with variety-seeking in preference at the group level across four studies. Specifically, we asked participants to either choose products that they wanted to consume or identify products that they preferred, after learning about others' choices or preferences. We predict that people would seek more variety in making choices than stating preferences. This is because, although both others' choices

and preferences can provide positive information about the chosen or preferred items, only the former can vicariously satisfy one's own desire, leading to greater variety-seeking.

In study 1, we used dyads, and showed participants several pairs of products (e.g., bookends, chairs, water bottles). Depending on conditions, we asked participants to either make a choice ("which one will you choose?") or state their preference ("which one do you like better?") regarding each product pair sequentially. We measured the variety of products chosen or preferred by these dyads, and found that the variety in "making choice" condition is larger than that in "stating preference" condition.

Because preference sometimes implies choice and choice indicates preference, in study 2, we used a stronger manipulation to better distinguish these two constructs. Specifically, we used several pairs of gendered-products that matched the gender of our target participants (e.g., men's shoes/wallets/belts for male participants, and women's shoes/wallets/belts for female participants). We asked participants to either make consumption-oriented choices or state preferences after a confederate did the same thing. In "making choice" condition, the gender of the confederate was the same as that of the products (i.e., the confederate was male/female when the products were men's/women's); whereas in "stating preference" condition, the gender of the confederate was different from that of the products (i.e., the confederate was male/female when the products were women's/men's). The logic is that, when the gender of the confederate does not match that of the products, his/her preferences can no longer imply choice (or consumption). We measured the variety of products chosen or preferred by these dyads, and again found that the former is greater than the latter.

Study 3 extended the context of vicarious satiation from between two individuals to between an individual and a group. Specifically, we showed participants several pairs of products (e.g., lamps, clocks, napkin holders) and told them that these products have recently been tested among a panel of consumers. In the "making choice" condition (vs. "stating preference" condition), we randomly picked one item from each product pair and told participants that this item was the most-chosen one (vs. the most-preferred one) by the consumer panel. We asked participants to either make choices or state preferences regarding each product pair and then measured the variety of products incorporated by the "grand group", which consisted of our target participant and the consumer panel (fake group members). The variety index for this grand group would be higher if our target participants don't follow the consumer panel's decisions. Results showed that people indeed were less likely to follow the consumer panel's decisions (i.e., greater variety-seeking) in making choices than in stating preferences.

Having shown the basic effect, we further explored whether vicarious satiation and the tendency that people seek variety in choice can translate into purchase intentions. We reason that because other's choice of a consumption item can vicariously satisfy one's own desire for it, people should exhibit lower purchase intentions when a product is chosen by others than preferred by others, although both others' choice and preference can provide positive information about the product. Therefore in study 4, we showed participants a series of food items – for example, Quaker oatmeal (Raisin & Spice), Orville popcorn (Movie Theater Butter) - and asked about their intentions to purchase the items. Before they made their decision, we told participants that these products were either the "most-chosen items", or "most-liked items", of a large group of people we recently surveyed. We found that people's purchase intentions were lower after knowing that a product was chosen by most people, than preferred by most people.

Across four studies, we found the consistent pattern that the variety of products a group of people choose to consume is larger than the variety of products they identify as their preferred ones. By merely manipulating decision type (i.e., choices or preferences), we held factors such as self-presentational concern, need for uniqueness, pressure to conform, etc. constant. By directly comparing variety-seeking in choice with variety-seeking in preference, we provided evidence for the vicarious satiation account.

Less is More: Variety as a Preference Strength Signal

EXTENDED ABSTRACT

People often exhibit a preference for variety when selecting multiple items from a category on a single occasion. We buy an assortment of yogurt flavors, snacks, and herbal teas rather than pick our favorite option multiple times, even though doing so forces us to include less-preferred options (McAlister and Pessemier 1982). This preference for variety is explained in terms of uncertainty about future preferences (Read and Loewenstein 1995; Simonson 1990), a tendency to prefer varied experiences (Drolet 2002; Ratner, Kahn, and Kahneman 1999), and social norms favoring variety (Ariely and Levav 2000; Ratner and Kahn 2002).

Although most prior work has focused on factors that lead people to increase the amount of variety in their selections, are there situations in which less, rather than more variety would be preferred? We propose that people selectively choose smaller or larger amounts of variety to convey information, both to others and to themselves, about the strength of their preferences. We demonstrate that choosing a small variety is often perceived as an indication of strong and identity-related preferences for the selected options, whereas choice of a large variety is perceived as an indication of weaker and identity-unrelated preferences.

This proposition leads to novel predictions that are unexplained by previous accounts. Specifically, we predict and demonstrate that people often vary the amount of variety they choose as a means of conveying desirable information about the strength or weakness of their preferences for options in socially-desirable vs. undesirable domains. Four experiments support this prediction and demonstrate that when self-presentation cues are present (e.g., when expecting to be evaluated by others), they incorporate less variety in choices among socially-desirable options (e.g., healthful and highbrow products), thereby expressing strong preferences for such options, and more variety in choices among socially-undesirable options (e.g., unhealthful and lowbrow products), thereby expressing weak preferences for such options.

Experiment 1 demonstrates that people rely on the association between smaller variety and stronger preferences as a guide when trying to convey information to others through their choices. Specifically, we asked participants to imagine they either wanted others to infer that they had strong, identity-relevant preferences for the selected options or did not want others to make such an inference. Participants then indicated whether they would choose a small or a large variety of options, in various domains. The results show that participants explicitly said they would choose a small variety when they wanted others to think they had stronger and more identity-relevant preferences and a large variety when they did not want other to make this inference about them.

Experiment 2 examined conditions that lead people to strategically choose different amounts of variety, as a means of conveying information about the strength of their preferences. Participants were asked to choose 3 snacks from a healthful versus unhealthful assortment. Using an expected evaluation manipulation (Ratner and

Kahn 2002; Simonson and Nowlis 2000), we manipulated whether healthful options were perceived as socially-desirable in that situation. The results show that participants who expected their choice to be evaluated by nutritionists and health-professionals (for whom healthful snack was socially-desirable, based on a pretest) chose *less* variety among healthful snacks, thereby signaling stronger preferences for these options, and *more* variety among unhealthful snacks, thereby signaling weaker preferences for these options, compared to participants who expected their choices to be evaluated by academics (pretested to be less healthfulness-neutral) or participants who did not expect to be evaluated at all.

Experiment 3 demonstrates the process underlying the effect of anticipated evaluation on variety-seeking by directly manipulating social desirability. If people choose different amounts of variety to signal the strength of their preferences for socially-desirable versus undesirable options, then the effect of anticipated evaluation should *reverse* depending on which type of options are perceived as more versus less socially-desirable in a given context. College students selected among movies starring either highbrow or lowbrow actors, but we manipulated whether highbrow versus lowbrow options were perceived as more socially-desirable in that particular context (we did that by varying the evaluators' identity). The results show that participants chose less variety among movies starring highbrow actors when expecting to be evaluated by faculty members, whom we manipulated to be seen as having a highbrow taste. However, this effect reversed when participants expected to be evaluated by students, whom we manipulated to be seen as having a lowbrow taste. That is, they chose more variety among movies starring highbrow actors and less variety among movies starring lowbrow actors.

Experiment 4 demonstrates that people use variety to convey information not only to others but also to themselves, as a means for bolstering their self-view. Participants were first primed to feel either certain or uncertain about their own level of sophistication. Then, they selected three movies starring either highbrow or lowbrow actors. Consistent with our theory, they selected less variety among highbrow options and more variety among lowbrow options after being primed with sophistication-*uncertainty* than with sophistication-certainty. Moreover, choosing a smaller variety among highbrow options boosted participants' sophisticated self-perceptions.

Taken together, these findings provide a novel explanation for variety-seeking behavior and support our hypothesis that people choose variety strategically, to signal their preferences for options with socially (un)desirable traits. The results suggest that people choose less (vs. more) variety to signal stronger, more identity-relevant (vs. weaker, identity-irrelevant) preferences for socially-desirable (vs. undesirable) options. Further, although prior work has focused on consumers' tendency to incorporate *more* variety in their selections, the current findings suggest that a small variety is often more diagnostic than a large variety as an indicator of underlying preferences.

The "Visual Preference Heuristic" and the Influence of Visual versus Verbal Depiction on Perceived Assortment Variety

EXTENDED ABSTRACT

Variety in choice options tends to be an attractive feature (Sellars 1991 as cited in Kahn 1995) and variety-seeking is understood to be a common consumer behavior (McAlister and Pessemier 1982). And yet, variety can increase perceived complexity and, moreover, too much variety can be overwhelming leading to decreased motivation to choose and harming subsequent satisfaction (Jacoby, Speller, and Berning 1974; Iyengar and Lepper 2000). Therefore, it seems a balance must be struck between providing enough variety so as to attract consumers, without overwhelming them with options.

A natural question that arises from this discussion is to consider how variety is perceived. We investigate this by focusing on the presentation form of the options, whether products are presented visually in pictures or verbally in words. We examine what type of presentation form is preferred and also whether presentation form influences the decision-making process including perceptions of variety and choice.

Specifically we look to inherent differences in the processing of images and words to form our hypotheses. Prior research describes images processed in a quick gestalt manner where all attributes are generally processed in parallel. In contrast, the processing of words requires a piecemeal approach which is slower and sequential in nature (Hart 1997; Paivio 1986). We hypothesize and find a decreased effectiveness of visual depiction for large choice sets occurs because of this difference in processing. The gestalt processing used to examine individual images carries over to affect the manner in which the entire choice set is considered resulting in a faster and less systematic approach. Additionally, because gestalt processing allows for easier identification of attribute interactions (Holbrook and Moore 1981; Veryzer and Hutchinson 1998), visual depiction of choice options increases the perceived variety of the choice set. While increased perceived variety is generally positive in smaller choice sets, in larger choice sets it can be accompanied by increased perceived complexity. In contrast, the more deliberate and systematic piecemeal processing necessary with verbal depiction increases processing time, which is helpful in larger choice sets and further explains the observed differences in choice behavior resulting from the two presentation forms. Moreover, because this more automatic and holistic processing of words likely feels easier than that of text, we predict decision-makers will prefer visual depiction over verbal even when it is not ideal. Indeed, in an initial pretest, we provide evidence for a "visual preference heuristic;" consumers overwhelmingly choose visual over verbal depiction 81%, t(97) = 7.63, p < .01) and this preference exists regardless of choice set size (x^2 (1, N= 46) = 2.71, p=.10).

Then in five studies we examine the impact of presentation format on assortment processing, perception, and choice behavior. Study 1 shows that in larger choice sets image depiction can lead to greater perceived complexity (M_{visual} = 6.1, M_{verbal} = 4.6, F(1,117) = 16.04, p < .001) and a higher likelihood to abstain from choice (visual = 16%, verbal = 3%, $\chi^2(1)$ = 6.15, p = .01) than text depiction. Study 2 examines option recall to offer further evidence for an interaction of choice set size and presentation format on processing efficacy. We find a significant interaction between presentation format and number of options (F(1,201) = 57.82, p < .001). Among 8 options, respondents who saw images perform better on an aided recognition task than those who saw verbal descriptions (M_{verbal} = 1.9, M_{visual} = 2.9, F(1,97) = 46.59, p < .001). However among 27 options, respondents who saw images perform worse on the aided recognition task than those who saw verbal descriptions (M_{verbal} = 8.1, M_{visual} = 7.5, F(1,102) = 6.14, p = .02).

The final three studies examine whether in fact the difference in processing of images and words are causing both the visual preference heuristic as well as the differences in assortment perception and choice behavior observed in the prior studies. In study 3, we use eye-tracking software to observe the actual process with which options are examined. We find no systematic differences in processing styles in small choice sets between visual and verbal depictions, but in larger choices sets verbal depiction causes respondents to use

a more systematic, piecemeal process whereby they spend longer examining each option, use a pattern similar to reading, and as such skip fewer options than when presented with visual depiction.

In study 4, we find further evidence that the differences inherent in piecemeal and gestalt processing cause the variations in assortment perceptions choice behavior between verbal and visual depiction observed. Specifically we show that if we force participants to process more systematically, as they do with verbal stimuli, the negative effects of visual depiction for larger choice sets are diminished; for both verbal and visual depiction choice overload and propensity to opt out of choice decreases with an increase in choice options (27 rather than 8) (options = 12.0%, 27 options = 2.0%, $\chi^2(1) = 3.63$, $p = .057$) and there is no effect of presentation format (visual = 6.0%, verbal = 8.0%, $\chi^2(1) = .08$, $p = .78$).

Finally, in study 5, we consider a more realistic boundary condition to our findings by employing existing familiar products and depicting them with either brand names or photographs. Consistent with all of our previous studies, the photographic visual stimuli result in more perceived variety than do the brand name verbal stimuli ($M_{visual} = 8.0$, $M_{verbal} = 7.4$, $F(1,101) = 6.42$, $p = .01$). However, unlike our previous studies, because of familiarity with the products, participants to do not take longer to review the text choice set ($M_{visual} = 18.9$, $M_{verbal} = 20.6$, $F(1, 100) = .64$, $p = .42$) nor rate the image choice set as more complex ($M_{visual} = 4.2$, $M_{verbal} = 5.2$, $F(1,101) = 8.05$, $p = .01$). We conclude with a discussion of the implications of our findings for managers and researchers.

Variety and the Spice of Life: The Effect of Spicy Gustatory Experiences on Variety-Seeking

EXTENDED ABSTRACT

Consumers often seek variety in their choices (McAlister and Pessemier 1982; Ratner, Kahn, and Kahneman 1999; Simonson 1990). Reasons for variety-seeking that have been identified include uncertainty about future preferences (Kahn and Lehman 1991) and anticipated satiation (McAlister 1982). Interestingly, and consistent with the idiom that variety is the spice of life – that is, that one's life will be more interesting if it includes a variety of experiences – consumers also engage in variety-seeking to make a positive impression on others (Ratner and Kahn 2002), given that choosing greater variety is reflective of being a more interesting person. The current research takes the expression that variety "spices up" one's life and provocatively examines the reverse. Specifically, adding to emerging findings on embodied cognition, we test if gustatory sensations of greater spiciness will lead to increased variety in consumers' choices.

Theories of embodied cognition suggest that not only does the mind control the body, but that the body also influences the mind (e.g., Barsalou 2008). Much research in the area of embodied cognition has investigated the effect of bodily movement on cognition. For example, Labroo and Nielsen (2010) find that movement towards aversive stimuli results in more favorable evaluations of them. As well, firming one's muscles increases willpower and ability to withstand temptations (Hung and Labroo 2011). Recent research has also explored the cognitive consequences of sensory experiences, such as touch and smell. For example, holding a warm versus cold cup results in a target person to be judged warmer versus colder (Ijzerman and Semin 2009; Williams and Bargh 2008; Zhong and Leonardelli 2008). Interestingly, a fishy smell tends to arouse suspicion in people (Lee and Schwarz 2011), showing that a sensory experience can indeed influence cognitions that include metaphors. Our research tests if tasting more (vs. less) spicy food results in greater variety-seeking

behavior, based on the association between variety and spicing up one's life.

In study 1, 72 participants were assigned to a more (vs. less) spicy taste condition in a one-factor between-subjects design. Respondents were informed that they were participating in a series of unrelated studies, the first of which would be a taste test for a tortilla chip. After tasting either the more or less spicy chip, they completed the variety-seeking task. Specifically, following Levav and Zhu (2009), participants chose three highlighter pens out of six possible colors, which constituted our main dependent variable. Participants were told that they could choose the highlighters in any combination of colors, which they would receive following the experiment.

Next, they evaluated their tortilla chip experience, rated the extent to which they liked spicy food and tortilla chips, and how often they ate spicy food. None of the means differed between conditions; Fs < 1.

Manipulation checks confirmed that our manipulation worked as intended: participants who ate the more spicy tortilla chip judged it to be spicier ($M = 5.07$) than those who ate the less spicy chip ($M = 1.43$; $F(1, 69) = 109.52$, $p < .001$). Importantly, and consistent with our hypothesis, participants who tasted the relatively more spicy chip chose more variety in the color of their highlighters, as compared to those who tasted the less spicy chip; $M = 2.92$ versus 2.62, respectively; $F(1, 69) = 6.24$, $p < .05$.

Thus, we found that a spicy gustatory sensation increases variety-seeking. However, if indeed spiciness brings to the fore the benefits of variety, then – once variety has been chosen and thus life has been made more interesting – it should have less of an effect on a subsequent, second variety-seeking task. We test this hypothesis, and an alternative explanation based on positive affect (Kahn and Isen 1993), in study 2.

In study 2, 68 participants were assigned to conditions in a 2 (chips: more vs. less spicy) X 2 (intervening task: variety-seeking vs. control) between-subjects design. Similar to study 1, the current study ostensibly consisted of a series of unrelated tasks, the first of which was a taste test for a tortilla chip. After tasting the more or less spicy chip, participants in the control conditions completed a filler task, while those in the variety-seeking intervening task conditions were asked to list three ice creams flavors they would choose for the next three weeks. Finally, all participants completed the focal variety-seeking task, choosing three chocolates to take home in any combination out of six possible brands.

Manipulation checks and ancillary measures identical to those of study 1 confirmed that our manipulation worked as intended and that the both chips were enjoyed equally. Further, no effects on positive affect were obtained. A 2 (chips: more vs. less spicy) X 2 (intervening task: variety-seeking vs. control) ANOVA on the number of different chocolates chosen yielded the expected interaction; $F(1, 64) = 4.10$, $p < .05$. Specifically, participants in the control condition chose more variety when they had tasted the more ($M = 2.88$) versus less ($M = 2.28$) spicy chip; $F(1, 64) = 7.51$, $p < .05$. Conversely, when provided the opportunity to express variety in the intervening task by selecting ice cream flavors, participants no longer differed in the variety of the chocolates chosen after tasting the more ($M = 2.38$) versus less ($M = 2.41$) spicy chip; $F(1, 64) < 1$.

A third study, currently underway, tests priming as an alternative explanation. Specifically, participants are presented with 'Hot Tamales' spicy candy in a study that ostensibly consists of two parts. Participants in the experimental condition will first complete a candy taste study, which consist of eating and evaluating the spicy candy, before the second study consisting of a variety-seeking task. Those in the control condition will receive the candy at the beginning of the

study, but will be told not to eat it until they have completed the first study consisting of the variety-seeking task. Greater variety-seeking when participants receive and consume the candy, as compared to when they receive but do not consume the candy, will be consistent with our embodied cognition-based explanation, but inconsistent with a priming account.

New Directions in Word-of-Mouth

SESSION OVERVIEW

Talking with others is a fundamental consumer motive. People tell friends about new restaurants, forward online content to co-workers, and post online reviews about products they like (or hate). Further, these behaviors have a large impact on consumer behavior. Word-of-mouth influences the products people buy, movies they watch, and online communities they join (Chevalier and Mayzlin 2006; Trusov, Bucklin and Pauwels 2009; Huffaker et al. 2011). Consequently, there has been lots of recent interest in word-of-mouth and social media (e.g., Facebook and Twitter). Firms spend a good deal of effort trying to generate word-of-mouth (e.g., encouraging people to write reviews) and create content that consumers will share.

But while it is clear that word-of-mouth is both frequent, and important, less is known about how firm activities shape WOM generation and its consequences. Intuition suggests that more controversial ads will be talked about more, but is that really the case? Companies often ask consumers to rate their experiences, but could using a 5 vs. 100 point scale affect consumer's propensity to share WOM? How can brands create valuable virality, or content that is not only shared but also has positive downstream consequences for the brand (e.g., boosts evaluation or purchase)? How does paying people to write reviews impact review quality and how does disclosure of payment influence consumer evaluations?

This session examines these, and related questions, as it integrates various research perspectives to examine how firm activities affect both the generation and outcomes of word-of-mouth. **Chen and Berger** show that while controversy makes topics more interesting to talk about, it also reduces comfort. Consequently, the effect of controversy on conversation depends on how aspects of the situation (e.g. identity disclosure) and the audience (friends vs. strangers) shape these complementary mechanisms. **Chen and Godes** show that rating an experience on a 5-pt (vs. 100-pt) scale leads to higher WOM intention. These results reflect a rating-certainty effect where the rater believes that her rating captures accurately her underlying utility. **Akpinar and Berger** provide evidence that while soft sell ad appeals (e.g., stories or cool content) are more likely to be shared than hard sell appeals (e.g. emphasizing product features), they are

less likely to have a positive impact on purchase likelihood and brand evaluation. Consequently, to create valuable virality, brands must make soft appeal ads where the brand in an integral part of the narrative. Finally, **Stephen et al.** show how paying for reviews and disclosing payment impacts actual and perceived review quality. While paying consumers actually leads to higher quality reviews and does not negatively impact perceptions of review quality, disclosure can either increase or decrease perceptions of product quality because of the contrast between expectations and actual experience.

Consistent with ACR 2012's theme, this session offers diversity in several ways. First, while prior work usually examines the drivers and effects of word-of-mouth separately, this session bridges the gap to simultaneously examine the causes and consequences of word-of-mouth. Second, rather than focusing solely on one methodological approach, this session brings together a variety of methods (e.g., experiments and empirical analysis of field data) to address the questions at hand. Third, each paper attacks these phenomena from a unique perspective, delivering diverse but complementary insights. The co-chairs (Ezgi Akpinar and Jonah Berger) will integrate the talks and open discussion about potential directions for future work in this exciting area.

Given how fundamental word-of-mouth and social transmission is to our daily lives, and recent interest in social media, we expect this session will be of substantial interest to a host of contingencies. Not only should it appeal to researchers working on word of mouth and attitude change, but also to those who study advertising, social influence, consumer-generated content, persuasion and the effects of rating scales. This should produce a fruitful interdisciplinary discussion that will encourage more research in the area.

When Controversy Begets Conversation

EXTENDED ABSTRACT

Conversation topics vary on how controversial they are, or whether they are marked by opposing views (Merriam-Webster 2003). Some advertisements, topics and brands are relatively non-controversial while others are more divisive. GoDaddy.com, for example, often makes risqué Super Bowl ads, while Chevy's ads tend to be less contentious. Topics like the weather are less controversial than gay marriage.

But how does controversy impact conversation? The lay belief among marketers and consumers is that controversy increases conversation (Steel 2011). But is that actually the case?

Further, people engage in all types of conversations. They post anonymously on online discussion boards or have conversations on Facebook; they chat face-to-face with friends or converse with strangers. Might these different contextual factors impact the relationship between controversy and conversation, and if so, how?

We theorize that the impact of controversy on conversation will depend on two countervailing forces. On the one hand, controversy can boost conversation because it is interesting. Differences in opinion can liven things up, and people talk about interesting things to entertain others (Heath et al. 2001) or fulfill self-enhancement goals (e.g., signal that the speaker is interesting, Berger and Schwartz 2011). On the other hand, controversy can decrease conversation by making people uncomfortable. People want to be socially accepted, and interpersonal conflicts, such as those generated by con-

troversial topics, can jeopardize acceptance. How controversy shape conversation, then, will depend on the strength of the two underlying processes.

Contextual factors such as identity disclosure and conversation partner (e.g., friend vs. stranger) should moderate the relationship between controversy and conversation by acting upon these underlying processes. The effect of interestingness is likely to remain static across situations since interesting topics are likely to remain interesting across settings. However, if discomfort reflects concerns about social acceptance, then it should be weaker in contexts when social acceptance concerns are less salient (e.g., when there is no identity disclosure) or less threatened by discussion of controversial issues (e.g., when talking to friends).

Three studies examine (1) how controversy affects conversation, (2) the underlying drivers, and (3) how this relationship varies in different conversation contexts.

Field Study 1: Our first study uses articles from a real news website to look at how the amount of controversy an article evokes impacts the number of comments it receives. We collected over two hundred articles as well as the number of comments each received (~5,000 comments overall. Two independent coders then rated each article on controversy (1 = not at all controversial, 7 = very controversial). Regressing the number of comments articles received on both the linear and squared controversy ratings shows an inverted-U relationship between controversy and conversation. Low levels of controversy increase conversation. But past a moderate controversy, additional controversy fails to increase (and even decreases) conversation. This is particularly noteworthy given the moderate level at which the effects of controversy start to reverse.

Study 2: In our second study, we experimentally manipulate controversy to observe directly examine its causal impact on conversation. We also test the underlying processes of interest and comfort and also explore how identity disclosure moderates the relationship between controversy and conversation by affecting comfort.

Participants were randomly assigned to condition in a 2 Disclosure (No disclosure vs. disclosure) x 3 Controversy (low vs. moderate vs. high) design. They listed a broad topic in current events (e.g., "taxes") and then listed three subtopics, one that is high, middle, and low in controversy (e.g., "corporate bailout", "taxing the rich", and "sales tax"). Participants were asked to imagine having an online conversation with a stranger in which everyone was either using aliases (No Disclosure condition) or real names (Disclosure condition). Then, they were randomly given one of the subtopics they listed and asked to rate how likely they would be to talk about the subtopic in that conversation. They also rated how interesting they found the subtopic to be and how (un)comfortable they would feel talking about the subtopic.

Results show that disclosure moderate the relationship between controversy and conversation. In the no disclosure condition, controversy has an inverted-U relationship with conversation where moderate level of controversy increases conversation (M_{low} = 4.24 vs. $M_{moderate}$ = 5.61, p = .02). However, additional controversy decreases conversation ($M_{moderate}$ = 5.61 vs. M_{high} = 4.04, p < .01). In the disclosure condition, controversy doesn't increase conversation (low same as middle same as high, ps >.23) and appears to decrease conversation (M_{high} = 3.58 vs. M_{low} = 4.87, p < .05). Mediation analyses show that when people do not disclose identity, conversation is driven primarily by interestingness. When identity is disclosed, however, conversation is driven by both interestingness and comfort.

Study 3: In our third study, we further test our framework and examine how conversation partner (friend vs. stranger) affects people's propensity to talk about controversies.

We again asked participants to list a general topic and three subtopics that varied in level of controversy. Then we manipulated the audience by asking them to imagine having a face-to-face conversation with either a friend or stranger. Then, they rated each of the three subtopics they listed on likelihood of talking (main DV), interestingness, and discomfort.

Results reveal that conversation partner moderates the relationship between controversy and conversation. When talking to friends, controversy increases conversation. A move from low to moderate levels of controversy increases conversation (M_{low} = 3.65 vs. $M_{moderate}$ = 4.81 p = .02). Beyond that point, however, additional controversy fails to further increase conversation ($M_{moderate}$ = 4.81 vs. M_{high} = 5.00, p = .68). When talking to strangers, conversation is flat across the three controversy conditions (M_{low} = 3.78 vs. $M_{moderate}$ = 3.52, and M_{high} = 3.48, pairwise comparisons all insignificant). Mediation analyses reveal that when talking to friends, conversation is driven primarily by interestingness; however, when talking to strangers, the positive effect of interesting is canceled out by discomfort.

Taken together, result show that (1) controversy doesn't necessarily increase conversation, (2) interesting and comfort drive the effects, and that (3) situational factors moderate the outcome by affecting the underlying processes.

Rating with Confidence: Rating Certainty and Word-of-Mouth Behavior

EXTENDED ABSTRACT

Online product ratings represent a common outlet for consumers to express their post-consumption (dis)satisfaction about product performance. Consumers, as product reviewers, evaluate products based on their consumption experience via ratings and reviews on retailer websites such as Amazon.com and Yelp.com or manufacturer websites such as Apple.com and dominos.com. It has been consistently shown that product ratings, as a part of WOM, have a significant impact on product sales (Chevalier and Mayzlin 2006; Chintagunta et al 2011; Zhu and Zhang 2010). While most research has focused on the impact of product reviews on those reading them, little attention has been paid to their impact on those providing them. We address this question here by investigating a product reviewer's subsequent WOM behavior after writing a review or rating a product.

In a pilot study, we found that different rating scales led to different levels of WOM. Respondents asked to rate an experience on a 5-pt scale report higher WOM intention compared with those rating on a 100-pt scale. To our knowledge, no existing theory explains this effect. We hypothesize that the result is driven by a general psychological construct which we label "rating certainty." According to this theory, a product reviewer's "true" utility must be mapped to the platform's chosen rating scale. The fidelity of the mapping process in communicating the rater's true utility varies across contexts. This fidelity – the extent to which one's chosen rating captures accurately her underlying utility – is the essence of rating certainty. Finally, when a consumer has higher rating certainty, we argue that she is more likely to transmit WOM.

While our theory is based on rating certainty, it is also entirely plausible that attitude certainty may play a similar role. That is, when people are more certain about their attitude, the likelihood of performing attitude-associated behavior, such as engaging in WOM, will increase (Bassili 1996; Tormala and Petty 2002). However, we stress that rating certainty differs from attitude certainty in that the former captures one's certainty toward the rating while the latter captures certainty toward the attitude target. To demonstrate that these two constructs are distinct, we present the results of a discriminant

validity analysis. Moreover, we control for attitude certainty in all analyses.

Next, we examined the impact of rating scale on WOM and the mediating role of rating certainty. One hundred and twenty two adults from Amazon Mechnical Turk participated in a video rating study. The study design was a 2 (rating scale: 2pt or 5pt) x 2 (certainty measure order: rating certainty first (RC) or attitude certainty first (AC)). Participants first watched a 2-minute video and then rated the video on either a 2-point or 5-point rating scale anchored from awful to excellent. In the RC condition, we measured rating certainty via four 9-point items which had been chosen based on a previous scale development study. These included: "How sure are you that the rating score you assigned is precise?", "How definite is your rating score of the video?", "The rating score I assigned was clear", and "The rating score I assigned was precise." We combined these four items to generate a rating certainty index (Cronbach's α= .95). Next, we measured participants' attitude toward the video and their certainty with respect to the attitude measure (Barden and Petty 2008). In the AC condition, we first measured participants' attitude certainty and then their rating certainty. We counterbalanced the question order of RC and AC to control for any order effect. Since the results show no order effect, we combined these two conditions in our analysis. Finally, we assessed WOM likelihood on a 7-point scale.

We found the predicted rating-scale effect: participants were more likely to transmit WOM in the 5-pt condition than in the 2 pt condition (M_{2pt}=2.2, M_{5pt}=2.8, $p < .04$). Moreover, rating certainty was higher in the 5 pt condition than in the 2 pt condition (M_{2pt}=6.4, M_{5pt}=7.6, $p < .04$). Notably, we find no effect of rating scale on attitude certainty: participants in the two scale conditions are equally certain about their attitude toward the video (M_{2pt}=8.0, M_{5pt}=7.9, $p = .69$). This suggests that rating scale is not a source of attitude certainty and, thus, that attitude certainty does not explain the effect of scale on WOM. Finally, we perform a mediation test which supports the hypothesis that the effect of rating scale on WOM can be explained by rating certainty. The five-point scale induces higher levels of rating certainty leading to higher levels of WOM.

In sum, we develop and validate a measure of rating certainty and demonstrate its discriminant validity with respect to attitude certainty. Finally, we demonstrate that rating certainty can be affected by the chosen rating scale and that, in turn, it may be an antecedent to WOM intention.

Valuable Virality: The Effect of Advertising Appeals and Brand Integralness

EXTENDED ABSTRACT

What influences whether ads are not only highly shared (i.e., viral) but also increase product evaluation and sales of the brands that create them (i.e., valuable)?

Recent research has shown that word-of-mouth can boost diffusion and sales (e.g., Godes and Mayzlin 2004, 2009; Goldenberg et al. 2009). Consequently, many organizations and brands have invested lots of resources in trying to craft content that consumers will talk about and share. But there are two difficulties with this approach. On the one hand, most people don't like to share things that look like ads, so companies try to create outrageous or funny content (e.g., Subservient Chicken or Old Spice). On the other hand, while it's great to make viral content, the content will only help the brand if it changes downstream consumer behavior, such as increasing brand evaluation or purchase. How can companies craft content that is not only viral, but also valuable?

We suggest that valuable virality depends on two key factors: ad appeal (hard vs. soft sell) and brand integralness (whether brand is integral to the advertising plot or not). While *hard sell* appeals focus on product features using a sales orientation, *soft sell* appeals convey a story through indirect mechanisms (i.e. showing beautiful scenes or evoking affective reactions such as humor and surprise, Okazaki, Mueller and Taylor 2010). As noted above, people don't like to share things that look like direct persuasion attempts and soft sell appeals might be shared more because they provide more interesting content.

That said, soft sell appeals are not very useful if they don't boost product evaluation or choice. Further, consumers realize advertisers are trying to persuade them and may dislike ads that they know are trying to trick them (Friestad and Wright 1994). Consequently, we suggest that to generate valuable virality, the ad must not only be interesting content but the brand must be integral to the narrative - woven in so deeply that it's directly connected to the underlying story.

We test this possibility in two studies. In Study 1, we exposed participants to either (1) a soft sell-brand integral ad; (b) a soft sell-brand not integral ad or (c) a hard sell ad (brand integral by default). Then they reported their evaluation of the ad and likelihood of sharing it, as well as their evaluation of the brand, and likelihood of purchase.

Results show how appeal type and brand integralness influence different dependent variables differently (Figure 1). As predicted, soft sell appeals boosted sharing and ad evaluation. Compared to the hard sell appeal, participants said they would be more likely to share either of the soft sell appeals and evaluated them more favorably.

The effects differed, however, for brand evaluation and purchase. As predicted, while hard sell appeals boosted brand evaluation and purchase above soft sell appeals where the brand was not integral, soft sell appeals where the brand was integral had the most positive effects.

In Study 2, we rule out alternative explanations and provide deeper insight into the mechanism behind the effects. While the results of Study 1 are supportive, one might wonder whether it was something about the ads themselves, rather than the integralness of the brand, that drove the effects. To rule out this possibility, we created two versions of each ad. The ad content itself was the same, but we varied what type of product the ad was for to manipulate integralness. So across conditions, the same ad was either integral or not depending on whether the product it was for fit with the ad content. We also tested why non integral soft sell appeals reduce brand evaluation and choice by measuring how participants feel about persuasive attempts.

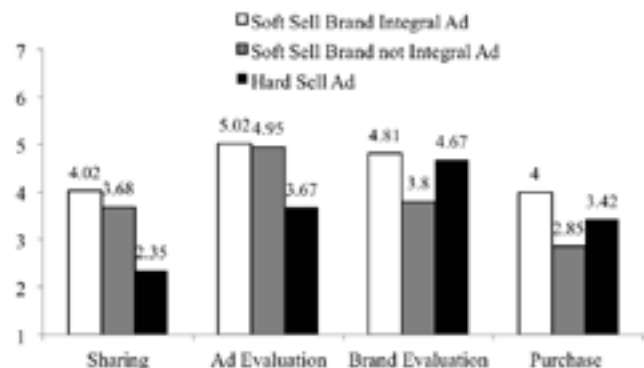
A 2 (product category) × 3 (ad type) ANOVA was conducted on the various dependent measures. As expected, and extending the results of Study 1, the manipulations had different impacts on different


Figure 1. The Effect of Advertising Appeals and Brand Integralness

dependent variables. While soft sells boosted sharing and ad evaluation compared to hard sells, only integral soft sell appeal boosted brand evaluation and purchase. Further, mediation analyses show that these effects are driven by the extent to which consumers find the ad persuasive attempts as acceptable and not very manipulative. When the brand is integral to the ad, persuasive attempts seemed more acceptable and less manipulative and therefore those brands receive more favorable evaluations and purchase intentions.

Taken together, these results show how content (e.g., ads) can be crafted so that it is both highly shared and beneficial to the brand or organization that made it. While soft sell appeals are more likely to be shared, the brand must be integral to the ad to receive the benefits of brand evaluation and purchase. This is driven by consumers' perceptions of advertiser's persuasive attempts. Overall the findings suggest how to generate virality that is also valuable to the brand.

Does Paying For Online Product Reviews Pay Off? The Effects of Monetary Incentives on Content Creators and Consumers

EXTENDED ABSTRACT

This research considers whether offering incentives to encourage consumers to write online product reviews is beneficial for firms. We propose that paying customers will result in more helpful reviews because offering content creators an explicit incentive may encourage them to take a more professional approach to the review-writing task. Paradoxically if content consumers know that the content creator was paid they may form less favorable expectations of product quality based on the review. Specifically, when incentive provision is disclosed, review consumers doubt the quality of the reviewed product. The doubt induced by payment disclosure is hypothesized to distort product judgments resulting in a shift of evaluations toward a neutral or indifferent attitude when the review is valenced. Paying content creators may therefore ironically decrease review-based product evaluations even though the review itself is more helpful.

We test our predictions in four experiments. In all experiments, participants were members of a large online panel in the U.S. In the first part of Study 1, participants were content creators who played an online game and then wrote a review about it. Participants were randomly assigned to either receive no incentive or a $1 incentive for writing their review. We find that paying an incentive had no impact on perceived effort, or difficulty related to writing the review.

In part 2 of Study 1, subjects were content consumers. Each was randomly assigned one of the reviews generated in part 1 and asked questions about the helpfulness, positivity, and objectivity of the review. Using random effects regression, we find a significant positive effect of incentive provision on helpfulness ($b = .18$, $t = 2.16$, $p = .03$), but not positivity ($p = .78$) or objectivity ($p = .73$). We also show that increasing review helpfulness (through incentive provision) may lead to content consumers being more interested in product trial.

Using a similar procedure, Study 2 examined how content consumers' product evaluations are affected by incentive disclosure. Participants were randomly assigned to one of four conditions in a 2 (no disclosure vs. disclosure) x 2 (no incentive vs. $1 incentive) between-subjects design. In the disclosure (no-disclosure) conditions, participants were (were not) given information about whether the content creator was paid to write the review. The incentive manipulation was the same as that used in Study 1.

We tested how incentives and disclosing them affected content consumers' product evaluations (1 to 5 stars) and their willingness to pay for the game as an app download ($0 to $0.99). We find that

product evaluations are *lower* when content creators are incentivized and content consumers are aware of this. In addition, willingness to pay dropped from 81 cents to 25 cents when the reviewer was incentivized and incentive provision was disclosed.

In Study 3 we replicate the Study 2 findings in a different product category (music) and rule out the possibility that consumer-generated reviews are only influential in the absence of more reliable information.

Participants were randomly assigned to one of six conditions in a 3(silent vs. not paid vs. paid) x 2(no additional information vs. additional information) between-subjects design. The first factor manipulated the specificity of the incentive disclosure (silent: no information regarding incentives provision; not paid: "the person who wrote this review was not paid"; paid: "the person who wrote this review was paid"). This new manipulation allowed us to check whether our results hold when disclosure is ambiguous.

The second factor manipulated the inclusion of information from a more realistic source in the participant's information set (no additional information: basic description of the band whose music video was the subject of the review; additional information: basic description of the band and a three page *Rolling Stone* magazine article that positively described the band's history and was created for this study).

We replicate our prior findings by showing that disclosure has a significant main effect on product evaluation ($F(2, 212) = 3.94$, $p = .02$). The main effect of additional information and the two-way interaction were not significant ($p > .6$). The mean product evaluation was lower when the participants thought the content creator had been paid ($M_{paid} = 3.38$) than when nothing was disclosed ($M_{silent} = 3.69$) or when receiving no payment was disclosed ($M_{not-paid} = 3.62$). The evaluation-lowering effect therefore holds despite changes to how incentive disclosure is conveyed and whether or not additional product information is available to content consumers.

Study 4 shows that the effect of incentive disclosure on content consumers' product evaluations is mediated by an increase in doubt in product quality and that this process only occurs when reviews are positive. Additionally, this study examines whether changes in review-based product evaluations caused by incentive disclosure carry over to affect post-experience evaluations.

The product used in this study was the game from the first two studies. Participants were randomly assigned to one of six conditions in a 3 (paid $0 vs. paid $0.75 vs. paid $1.25) x 2 (positive review vs. negative review) between-subjects design. The incentive-disclosure manipulation was similar to that used in the previous studies except that we used two non-zero conditions ($0.75 and $1.25) to show that our previous results were not specifically due to disclosure of a $1 incentive. The valence manipulation involved randomly presenting participants with either a positive or a negative review.

Using the procedure for testing moderated mediation detailed in Preacher, Rucker, and Hayes (2007), we find that the effect of incentive disclosure on pre-experience product evaluation was mediated by doubt when the review was positive. Furthermore, we find that the effect of incentive disclosure on product evaluations through doubt carries over to affect product evaluations when additional experiential information is available.

This research shows that information related to whether a content creator is incentivized can make a difference not only to how the generated content is interpreted by a consumer but also in their assessment of the focal product in both the short-term (at the stage of forming expectations of product quality) and long-term (lowering product evaluations even after having first-hand product experience).

SESSION OVERVIEW

Why do some products, ideas, and behaviors catch on? Some products become popular, some innovations spread, and some catchphrases or sayings become successful. Others never seem to get traction and fade quickly. What makes certain things diffuse more than others?

These questions have been investigated from a number of research perspectives. Sociologists and marketing scientists have examined how social network structures impact diffusion (Christakis and Fowler 2009, Goldenberg, Libai, and Muller 2001). Behavioral researchers have examined how psychological motives influence what people decide to share (Cheema and Kaikati 2011; Wojnicki and Godes 2008). Others have looked at how characteristics of the cultural items themselves, such as whether stories are more or less emotional, shapes what goes viral (Heath, Bell and Sternberg 2001; Berger and Milkman 2012). But while each of these research streams has separately examined diffusion, little work has integrated these perspectives.

This session brings together diverse work on social networks, sender characteristics motives, and item characteristics to shed light on the behavioral processes behind diffusion. While early adopters are seen as the key to diffusion, might their psychological motives actually lead them to share less, reducing diffusion? Might sensory phrases (e.g., "bright student" rather than 'smart student") be more likely to diffuse over time? How do social network structures impact both the creativity of ideas people generate, and their diffusion? How can success in certain local neighborhoods be used to predict overall success in the broader social network?

This session addresses these, and related questions, as it integrates multiple research perspectives to shed light on what drives social contagion. The first two papers focus on psychological drivers of transmission. Moldovan, Steinhart, and Ofen demonstrate that

while early adopters are motivated to share word-of-mouth to boost their social status, sharing information can also reduce their uniqueness. Consequently, they often adopt a tactic of sharing while scaring, or telling others about how difficult the product is to use. Using both experiments, and 200 years of data from 5 million books, Akpinar and Berger show that phrases which create a metaphorical link to the senses (e.g., bright student or warm welcome) diffuse more widely than their semantic analogues (i.e., smart student or kind welcome) because they are more memorable.

The next two papers examine the role of social networks in diffusion. Stephen, Zubcsek, and Goldenberg show that having more sources of inspiration (i.e., higher degree and thus more neighbors) does not necessarily improve one's ideas. Rather, it depends on how interconnected (i.e., clustered) one's neighbors are, and the nature of the idea generation task (general vs. specific task). Goldenberg et al. use a social networks database to show that large and dense clusters in a social network are better predictors of success of innovative adoption than other clusters and random samples.

Taken together, these talks illuminate the psychological and sociological processes that shape diffusion and cultural success. Given recent interest in social networks, social media, and social contagion, the session should appeal to broad range of researchers including those who study user-generated content, diffusion and new product adoption as well as those interested in social influence, attitude change, needs for distinction, social networks, and embodied cognition more broadly. The co-chairs (Jonah Berger and Ezgi Akpinar) will integrate the talks and open discussion about potential directions for future research.

Further, as highlighted in this year's program, the session also brings a diversity of methodological perspectives to address these important research questions. The papers cover a wide span of methodologies from experiments and social network analysis to analytic modeling, and empirical analyses of large datasets. As a whole, the talks will deliver diverse but complementary insights on what factors shape diffusion and social epidemics. While sociologists, physicists, and marketing scientists have begun to pay more attention to social contagion, this session integrates a variety of perspectives to examine how psychology and consumer behavior shape these important phenomena.

"Share and Scare": Solving the Communication Dilemma of Early Adopters with a High Need for Uniqueness

EXTENDED ABSTRACT

Early adopters are frequently discussed in the literature as individuals who play an essential role in new product success (Rogers 1995). Early adopters are the first to adopt an innovation, and are therefore the first to recommend it to later adopters. The literature (and practice) consequently treats early adopters as "social salespeople" of new products (Goldsmith and Flynn 1992; Mahajan, Muller, and Srivastava 1990; Midgley and Dowling 1993; Rogers 1995). This, however, may not always be the case. In this research we explore the unwillingness of early adopters to "spread the word" about innovations they adopt. Specifically, we propose that early adopters often face a communication dilemma. While they are inherently motivated to share information about the innovation to others, and

reinforce their social status as early adopters, they are aware that this status is diluted as the number of adopters increases. To remain among a selected few who use or possess the innovation, they may intentionally scare others from adopting it too. We therefore name the solution of this dilemma as "share and scare".

The current research reveals the underlying mechanism that drives this dilemma among the early adopters. This mechanism is a product of consumers' need for uniqueness; namely, a positive need to be different relative to other people (Tepper and Hoyle 1996; Tian, Bearden and Hunter 2001). Need for uniqueness is strongly tied to the adoption of unusual and scarce products (Tian et al. 2001). By definition, innovations are scarce, since it is possessed by few or none in its early stages in the market. Therefore, we claim that this dilemma is experienced by early adopters who are driven by elevated need for uniqueness and thus value the uniqueness of the innovation as one of its most beneficial utilities. Early adopters with a high need for uniqueness will therefore desire to express their uniqueness in the presence of a group. However, by "showing off" their new adoption, early adopters increase the risk that other consumers will also adopt the innovation, thereby diminishing early adopters' uniqueness.

Study 1 demonstrates the existence of the dilemma among early adopters with a high need for uniqueness and for different product categories.

Study 2 identifies a possible boundary condition for the dilemma. This study demonstrates that the dilemma would be experienced only when the innovation faces an immediate public launch, and is not experienced for innovations for which launch is expected to be in the future. Results show that when the innovation is not anticipated to be available on the market in the near future, early adopters with a high need for uniqueness are less likely to be concerned that others will imitate them, and therefore report on lower dilemma levels. However, in the future launch condition, there is not a significant difference within the levels of the dilemma across consumer groups.

Study 3 explores how the dilemma is affected by the type of audience that is exposed to the early adopters' word of mouth. Its findings reveal that when the target audience is less likely to imitate the early adopter (i.e. laggard audience), or when the early adopters wish to be imitated by the target audience (i.e. super ordinate audience), early adopters report on lower levels of the dilemma compared to when facing a peer audience.

Studies 4 and 5 shed more light on the "share and scare" solution of the dilemma by showing that early adopters with a high need for uniqueness are more likely recommend the product but at the same time to warn others about it. Study 4 shows that while all consumer groups are willing to recommend both innovative and non-innovative products, early adopters with a high need of uniqueness also intend to scare others from adopting an innovative, but not an existing, product. Study 5 explored additional aspects of the "share and scare" communication and showed that this behavior is relevant for a privately consumed product as well.

The communication dilemma and the "share and scare" solution indicate that, unlike what is "expected" from them, early adopters may not always be willing to spread the word about innovations they adopt, and may intentionally delay or even derail the diffusion process.

This research also integrates into and extends the chasm theory. The chasm is a break in the diffusion process between early and later adopters, presumably because of a lack of communication between the two markets (Moore 1999, Goldenberg, Libai and Muller 2002). However, we suggest that communications in fact exists between the two markets, as early adopters "share" information about the product. Yet, the nature of the information they provide may not acceler-

ate the adoption of the innovation, as they sometimes "scare" others from adopting it.

Managers should be aware of the existence of the communication dilemma when launching innovative products and consequently execute campaigns that overcome this reluctance.

The Cultural Success of Sensory Metaphors

EXTENDED ABSTRACT

Language varies over time (Lieberman et al. 2007; Nowak, Komarova and Niyogi 2002; Pagel, Atkinson and Meade, 2007). There are often many ways to convey the same thing and linguistic variants often act as substitutes. In 1800s, for example, people used the phrase "popular topic" but now the phrase "hot topic" is more en vogue. Why are certain linguistic variants more culturally successful than others?

We suggest that linguistic variants which relate to senses in metaphoric ways should be more successful. A kind person can be described as "warm", an unpleasant note as "sour". Sensory experiences serve as analogical basis for expressing abstract concepts with metaphors (Gibbs and Tendhal 2006; Lakoff and Johnson 1980). Calling a person "warm" suggests the person is inviting, just like a warm shower might be.

Sensory metaphors have important consequences for human thought and behavior (Lee and Schwarz 2010; Zhong and Leonardelli 2008). Humans scaffold abstract concepts onto existing knowledge acquired through sensory experiences with the physical environment. So when an abstract concept is encountered (e.g. feeling socially excluded at a reception), the sensory neural cues associated with the formation of that concept are triggered (e.g. feeling cold), and downstream behaviors (e.g. desire for warm foods and drinks) or expression of the concept (e.g. chilly reception) are based on the activated sensory cues. Thus, abstract concepts can be processed using cues of sensory experiences, even without physically interacting with any sensory stimuli.

Sensory metaphors (e.g., warm person) should be more culturally successful in part, because they are more likely to be remembered. Sensory metaphors may be easier to remember because they activate the same brain regions as sensory experiences (Stilla, Sathiana and Sathian 2012). Further, retrieval of sensory experience knowledge (e.g. "cat has fur") is more automatic, and involves less processing than semantic knowledge (e.g. "cat needs training"; Golberg et al. 2007). Consequently, compared to semantic analogues, there should be stronger associations between sensory metaphors and sensory experiences which should make them easier to retrieve.

Sensory metaphorical phrases may also be easier to remember because they have multiple and accessible linkages with memory. While non-sensory phrases are only stored with their semantic meaning, sensory metaphors are stored both in semantic and sensory codes. Further, the sensory cues are prevalent in the environment. Thus, we expect that increased number of associative cues, some of which are more accessible in the environment may boost memory.

Two studies investigate whether sensory metaphors are (1) more culturally successful over time and (2) more memorable.

In first study, we examined the cultural success of sensory metaphors. First, we compiled an extensive list of sensory metaphors (e.g. bright student) and their semantic analogues (e.g. intelligent student and smart student). Then we recorded the success of each phrase over time using the Google Books corpus. This dataset allowed us to track the number of times phrases were mentioned every year in over 5 million digitized books from 1800 to today. We com-

pared the use of sensory metaphors and semantic analogues using a Poisson model with linear and quadratic effects.

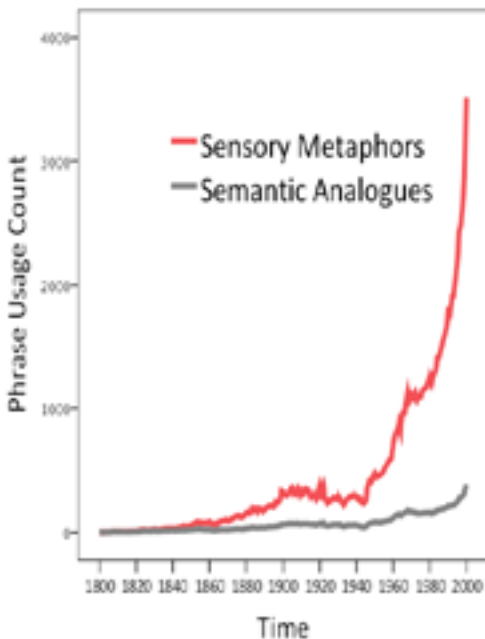
As illustrated in Figure 1, rigorous modeling results show that sensory metaphors are more successful over time, with an increasing quadratic trend ($\beta_{Time*Sensory\ Metaphors}$ = .024, p < .001; $\beta_{Time^2\ *Sensory\ Metaphors}$ = -3.55E-5, p < .001; higher than zero for all value of time).


Figure 1- Sensory Metaphors are Used More Frequently over Time

Study 2 experimentally examines whether sensory metaphors are more memorable. Further, we test the underlying role of relation to the senses and greater prevalence of associative cues.

Participants received 32 randomly selected phrases from the pool used in Study 1. Some participants rated each phrase on the extent to which it relates to senses while others rated each phrase on the number of associations it has with other words and ideas. After filler tasks, participants completed an unaided-recall task where they wrote down as many of phrases as they could remember.

The results support our theorizing. First, compared to semantic analogues, sensory metaphors were more likely to be remembered. Second, as predicted, sensory metaphors were rated as more related to the senses and having more associative links. Third, a multiple mediation analysis shows that the effect of phrase type on memory is partially driven by the combination of their sensory nature and prevalence of associative cues.

Alternative mechanisms have difficulty explaining these effects. More emotional (Mackay and Ahmetzanov, 2005), interesting, or descriptive phrases might be more memorable, and concrete, visualizable information may be easier for people to retrieve (Rubin 1995). The sensory metaphorical phrases used here, however, did not differ from the semantic analogues on any of these dimensions. Also, Study 1 still holds if we only look at non-visual sensory metaphors.

Taken together, these findings illustrate how senses shape cultural success in language. Compared to linguistic variants with similar meanings, sensory metaphors are more (1) memorable and (2) culturally successful over time. These findings not only speak to the reciprocal influence between individual psychological processes and collective outcomes (Gureckis and Goldstone 2009) but also em-

bodied cognition, and neural linkages between sensory processing and language.

Ideation and the Spread of Innovative Ideas in Social Networks

EXTENDED ABSTRACT

A growing trend in marketing involves firms using crowd sourcing as part of the product development process. Firms tap the apparent wisdom of consumers to solicit ideas for new products and suggestions for how to improve or extend existing product. In practice, crowd sourced product ideation has led to a proliferation of firm-specific online communities where consumers can submit ideas. Typically the consumer community then discusses, criticizes, elaborates on, and votes on ideas, and firms use this information to help them decide which ideas to develop further. Firms using this approach include BMW, Dell, Delta Air Lines, Google, Kraft, Lego, P&G, and Starbucks. A challenge, however, is soliciting high-quality *innovative* ideas from consumers. Like any social network, information (in this case idea) can diffuse throughout these communities. While this may facilitate the propagation of good ideas that leads to even better ideas, it may also result in mediocre or even bad ideas spreading and negatively impacting the quality of the ideas provided by other members of the networked community.

This research examines the role played by network structure and an individual's network position in product ideation networks/communities in affecting their ability to produce innovative ideas. A novel experimental approach was taken whereby participants were linked to each other through a custom-built online product ideation platform. The platform allowed us to manipulate the network structure, thereby allowing us to vary specific parameters related to participants' positions and connectivity in their networks. We focused on manipulating participants' numbers of neighbors (i.e., their degree), which influenced how many sources of inspiration they were exposed to, and how interconnected participants' neighbors were (i.e., their clustering coefficient), which influenced how independent their sources of inspiration were. Our main hypothesis was that while being exposed to many sources of inspiration can potentially help participants produce highly innovative ideas, this would only happen when their neighbors were not tightly interconnected. In other words, we predicted an interaction between degree and clustering such that idea innovativeness is higher when participants have high degree but low clustering.

In four studies, participants were assigned to networks and various positions (nodes) in networks and contributed product ideas over multiple rounds. Participants could see ideas submitted by other participants to whom they were directly connected. Network structures were predetermined and varied between groups to allow us to examine how properties of individuals' local networks (size/degree and interconnectedness/clustering) affected (1) social contagion and idea diffusion processes within each network over time and (2) ultimately the innovativeness of the ideas.

Our main hypothesis was supported across four studies. Having more sources of inspiration (higher degree) does not necessarily improve one's ideas. In fact, more sources of inspiration can lower one's innovativeness when their neighbors are connected to each other (i.e., a negative interaction between degree and clustering). This effect is moderated by the nature of the ideation task with respect to how general or specific it is. In more specific (and structured) ideation tasks, ideas diffuse over the network and, provided that individuals are exposed to multiple sources of inspiration with whom they are not tightly interconnected (i.e., lower clustering); good ideas

will spread and be improved upon, resulting in higher levels of output idea innovativeness. However, when the task is more general (and unstructured) initial ideas tend to be more eclectic, thus making it harder for any single concept to "catch on" and spread throughout the network. These effects were found in a variety of contexts, including generating ideas for mobile banking smartphone apps, ways to improve the air travel experience for commercial airline passengers, and ideas for making Facebook more useful to people.

Overall, this research shows that social networks and consumers' positions in them can influence their ability to influence others and be influenced by others in the context of crowd sourced product ideation. While having connections indeed can facilitate the spread of ideas, those connections do not always facilitate the spread of innovative ideas.

Local Neighborhoods as Early Predictors of Innovation Adoption

EXTENDED ABSTRACT

"As Maine goes, so goes the nation". This proverb of U.S. politics suggests that what happens in a particular neighborhood can be a good predictor of a much larger population (in this case the United States, or more precisely who wins the presidential election). More generally, both political scientists and managers spend considerable effort trying to find ways to predict the behavior of large populations. This paper focuses on predicting innovation adoption based on what we term predictive neighborhoods (groups of connected individuals whose adoption patterns evolve similarly to, yet earlier than, overall population behavior). We demonstrate that some neighborhoods can indeed be used to predict overall adoption and that their predictions are superior to those of random samples.

Previous research has shown that product adoption decisions are influenced by social peers and relationships (see Godes et al. 2005; Goldenberg et al. 2009; Libai 2005; Libai et al. 2009; Trusov et al. 2008b; Valente 1995; Van den Bulte and Joshi 2007; Watts and Dodds 2007). Research also provides evidence of the benefits garnered from an advantageous network position and the structural properties of one's local network. These properties include the resources of one's direct network (Burt 1997; Lin 2001), the number and strength of ties (e.g., Granovetter 1973) and closure or local clustering (Coleman 1990; Lin 2001).

A few studies have found that the individual adoption process is driven by group adoption (Jones and Ritz 1991; Kim and Srivastava 1998). However, these studies focus on cases where group adoption precedes individual adoption within that group. Here we consider the case of social networks characterized by a high clustering coefficient (Watts and Strogatz 1998). This paper first investigates how the individual adoption decisions within a neighborhood are influenced by the properties of the clusters to which they belong, and second, whether certain local neighborhoods can be reliable predictors of overall network adoption (i.e., are predictive neighborhoods).

We first show analytically that for success-failure predictions, random samples (the common standard in marketing) are less useful than specific clusters in the network. If correct, this means that using a random sample may not be the best way if a network structure exists, and if it is known. We predict that large and dense clusters that have high betweenness centrality (at the cluster level) should be better predictors of success than other clusters and random samples.

We then tested empirically this conjecture using a network data with multiple diffusion processes over it (the Korean Cyworld newtrok).

In the period of this study, the number of members in the Cyworld database grew from 2,492,036 in December 2003 to 12,685,214 in July 2005. In October 2006, there were about 22 million registered members and an average of 20 million monthly unique visitors. Many people considered Cyworld a part of their everyday life and as a tool for building relationships and sharing information about their lives on their homepages. A key aspect of the service, for our purpose, allows people to customize their homepages by including documents, photos, and other "goodies" at no charge. Members can also decorate their minihompy (personal homepage) with paid items such as virtual household items—furniture, electronics, wallpapers. People can also adopt items such as pictures or video clips directly from the minihompies they visit (called "scrapping" in Cyworld.). This study focuses on this latter type of adoption, using data from December 2003 to July 2005.

We examine a set of 114 neighborhoods analyzed earlier. We identified the number of scraps (adoptions) for each item and eliminated those with fewer than 20 adoptions (i.e., niche products and abject failures which had very sparse data on which to base analyses). Of the remaining products, the top 10 items (in effect the "mega hits") were adopted by between 104 and 7952 people while the bottom 30 were adopted by 20-25 individuals, meaning highly successful items were adopted at a rate of at least four times greater, and in many cases at an order of magnitude greater, than less successful ones.

As a measure of how well a local neighborhood predicts adoption in the total network, we used the correlation between adoption in a neighborhood at the time 5%, 16%, and 50% of the eventual market had adopted it (i.e., early adoption in the neighborhood), and eventual total network adoptions after the adoption process is completed. Using these 40 items, (the top 10 plus the bottom 30), we then compared the ability to predict total adoption in the overall market based on a) a random sample (the "gold standard" of market research) of size 200, similar to the average cluster size of 214, b) the average of all the neighborhoods in the network, and c) the 20 clusters with the highest correlation between their adoption at the time 16% of the market had adopted and eventual market adoption.

The empirical results show that certain neighborhoods do predict adoption better than random and stratified samples as well as samples of innovators. Further, they predict about as well as samples of social hubs whose use requires knowledge of the entire network structure.

The Nosy Decision Maker: How the Sense of Smell Influences Consumers' Decisions

SESSION OVERVIEW

While sensory marketing has recently gained a lot of attention in the realm of consumer research, most studies in this domain have focused on visual and auditory aspects (Krishna 2009, 2012). In contrast, olfaction has received relatively less attention in the consumer literature. In that regard, this special session focuses on olfaction and our main objective is to present a series of studies exploring the influences of olfactory cues on consumption-related decisions and behaviors. This session also seeks to encourage discussion on the broader theme of sensory influences in consumer decision making and attract participation from researchers with a common interest in different aspects of sensory marketing.

Past research in the consumer literature has examined how scent impacts memory (Krishna, Lwin and Morrin 2010; Morrin and Ratneshwar 2003). What are rarely considered in these studies are individual differences in the sense of smell and the interaction of other senses with that of the sense of smell. In line with the conference's "Appreciating Diversity" theme, the first paper by Lin, Childers and Cross takes into consideration individuals' varying abilities to smell (ranging from a heightened sense of smell to a diminished or even absent sense of smell) and investigates its impact on consumer-related decisions for products and ads. Thus, this paper examines the role of olfaction in consumer behavior and how individual differences in olfaction ability and preference affect memory, judgment, and decision making.

Exploring the relationship between olfaction and vision, Lwin, Morrin, Chong and Tan investigate the manner in which olfactory cues attract and increase a person's attention to ad information using eye-tracking methods. Another paper in this session (Biswas, Labrecque and Lehmann) focuses on the sequential order effects of olfactory and visual stimuli and how the outcomes translate into food taste perceptions. Morrin, Pham, Lwin and Bublitz also explore the complementary sensory relationship between olfaction and taste, and how dietary restraint moderates the effects. The extent to which olfaction affects taste expectations and actual eating behavior is thus explored in two of the studies (Biswas et al.; Morrin, Pham, Lwin and Bublitz).

The four papers comprising this special session on sensory influences all focus on olfaction and its role on consumer's information processing and decision-making. However, each paper embraces diversity by taking into account different dimensions of individual differences. Lin et al focus on individual differences in sense of smell, and examine how this varying ability influences their decisions in product purchase, judgment and scent memory. They also investigate the concerns individuals with either heightened or diminished sense of smell may have in the marketplace and household and methods of coping. Morrin et al examine restrained eaters and non-restrained eaters and find that there are individual differences in the effect of moral cleansing on chocolate consumption. Studying another dimension of food consumption, Biswas et al find that individuals under different states of hunger form opposite expectations for taste, depending on the order of encountering olfaction and visual cues. Finally, in Lwin et al's paper, they find that only when scent is congruent with the object in the ad, will people pay more attention to the information presented to individuals. Further, they find this effect is enhanced when the ad element is concrete versus abstract in nature.

In addition to the variety of topics related to the sense of smell, these papers use a variety of research methods to investigate their research questions. Lin et al take a multi-method approach, with a combination of surveys, in-depth interviews, experimental designs and neuroscience methods to address their broad research objective of understanding the impact of individual differences in olfactory ability. Lwin et al approach their research using eye-tracking methodologies. Morrin et al and Biswas et al use behavioral experiments to address food consumption decisions.

This session therefore contributes to the conference theme by embracing a diversity of approaches to the topic, a range of methods, with researchers from several areas of the world (Singapore, Hong Kong and the U.S.) with diverse cultural and geographic origins. Given the relatively nascent state of this topic domain, it is likely to lead to discussions for future research ideas.

Completion stage: Data have been collected and analyzed for all papers.

The Smell Factor: Individual Differences in Olfaction Memory, Judgments and Decision-Making

EXTENDED ABSTRACT

Olfaction is often a subtle, but important, tool used by consumers in their memory associations, social and marketplace interactions and their judgments and evaluation of product and consumption choices. Yet, although there are a growing number of studies on the loss of smell, primarily in medical journals (Miwa et al 2001; Aschenbrenner et al 2007), this is still a greatly under-researched area in the marketing and psychology literature. In addition, very little, if any, research has been done looking at individual differences in smell based on the level of olfactory sensitivity in consumers. This research examines individual differences in olfaction on consumer memory, judgments and decision making. We specifically study the

impact of olfaction in consumers with a complete loss of smell (anosmia) or a diminished olfactory sensitivity (hyposmia); those with an enhanced olfactory sensitivity (hyperosmia) and those who have a normal sense of smell.

Stevenson (2010) identifies three main functions of the olfactory system: to aid or complement ingestive behavior; to avoid environmental hazards; and to facilitate social communication. In their research on anosmics, Miwa et al (2001) noted that olfactory loss primarily affected food and safety related activities, but also had an effect on quality of life. Aschenbrenner et al (2007) discussed the social implications, noting that individuals with olfactory loss avoid mealtime interactions with friends, showing a reluctance to comment on food they can't really experience and also reported going out to eat at restaurants less often. Thus, there is an impact both on social interactions and purchase behavior. However, research on hyperosmics has even been more limited with a focus on odor intolerance (Nordin et al 2003; Dalton 1999). Thus, we know little about how smell fits into the everyday lives and shopping patterns of individuals with elevated olfactory abilities.

Thus our research questions are as follows. 1) What is the role of olfaction in consumer behavior? 2) What are the individual differences in olfaction ability and preference? 3) How do these differences affect olfaction memory, judgments and decision making?

To answer these questions, we use a multi-phase design approach, which incorporates a mix of qualitative and quantitative studies, both sequential and embedded (Creswell and Clark 2011). There are four phases in the overall study. In phases 2 to 4, individuals differing in olfactory sensitivity (diminished, sensitive, normal) were specifically recruited. Part 1 is a questionnaire study with approximately 700 undergraduate student participants, using a mix of existing olfactory scales (c.f., Wrzeniewski et al 1999; Martin et al 2001). In the 2nd phase, based on the survey responses in phase 1, 240 undergraduate participants, differing in reported olfactory sensitivity were selected for behavioral experiments. These were extensions of studies by Krishna et al (2010) and Bulsing et al (2007). In the 3rd phase, in-depth interviews incorporating two olfaction tests (UPenn BSIT; Sniffin' Sticks) were conducted with 35 mature participants (ages ranged from 25 to 70 years old). In these interviews, the researchers explored issues of safety, food consumption, social and marketplace interactions and overall consumer well-being. The final phase of the project is an ERP study with 60 participants where the neuro-responses to olfactory related words are recorded.

Across the scales used, we see a similar pattern of results: a U-shaped relationship with hyperosmics a little higher than normals and the decreased group (hyposmics and anosmics) in the middle. This is the pattern for the different scales testing the use of smell, the dispensability of smell, liking through smell, emotions and smell and attention to odors. Findings across the studies also illustrate that not only do those in the heightened group see smell as a more important aspect of life than those in the diminished group, but odors and scents are shown as better able to elicit memories for this group versus the diminished group. This is potentially disturbing as smell is considered very important for its ability to facilitate recall of past experiences (Stevenson 2010).

Olfactory sensitivity is also seen to impact where, how and why individual consumers make purchase decisions and what consumption choices they make. The sense of smell is a taken for granted, but heavily relied upon, sense that often becomes a salient factor when it is seen as deviating from the norm or affects social, workplace or marketplace interactions. Coping strategies used to counteract these effects are both cognitive and experiential and fall into the categories of avoidance, compensation, removal and deliberation. The authors

explore the nuances of olfactory sensitivity and develop a typology of smell-related triggers and phases. Results indicate that olfactory-related responses are often involuntary, context-driven, complement our other senses and perceived in relation to others.

Based on our studies (n = 781), approximately 10% of the population sampled has no ability or a diminished ability to smell (which mirrors the existing literature), 19% fall into the heightened category and 71% fall into a normal range. This research thus makes a theoretical contribution to our existing knowledge of individual differences and sensory influences, by exploring the impact of olfaction across all three groups and fostering appreciation for the sensory aspects of consumer diversity. Level of olfactory sensitivity is seen to affect memory, judgment and decision making. It also has an impact not just on consumption choice, but also on the purchase decision process and the overall shopping experience. Yet, unlike other sensory stimuli (vision, touch, taste, hearing), consumers' expectations of marketplace accommodation are low and marketplace responses to consumer concerns are unconsidered, low or misguided. Finally, this study uses a mixed method approach to understanding individual differences in olfaction, triangulating across methods with a scope that has not been previously used in the consumer behavior literature. The authors show that a diversity of approaches and perspectives serves to highlight and illuminate the importance and implications of olfaction on consumption.

Exploring the Dark Side of Chocolate: Moral Cleansing and Licensing Among Restrained Eaters

EXTENDED ABSTRACT

The obesity rate in the U.S. has doubled since 1980, and now stands at about a third of the adult population, with another third classified as overweight. Overeating can have negative consequences not only for one's health, but also for one's psyche, in terms of the social stigma associated with it. Dietary restraint refers to the chronic effort to restrict food intake, especially of forbidden foods or those considered fattening. Individuals who score high on measures of dietary restraint (e.g., Herman and Polivy 1980) have greater concerns about their shape and weight and exhibit a strong desire for thinness. We argue that for many dieters, overeating or eating "forbidden" foods is associated with acting contrary to social norms, and thus has a negative impact on their moral identity. One's moral identity is typically measured in terms of beliefs that one is caring, compassionate, fair, friendly, generous, helpful, hardworking, honest and kind (Aquino and Reed 2002; Hart et al. 1998). For dieters it can also involve food consumption behavior. We argue here that in addition to environmental cues impacting dieters' eating behavior, their dynamic moral self-worth also plays a role. Both moral cleansing (remunerative moral strivings) and moral licensing (relaxed moral strivings) have been observed in other domains (Jordan, Mullen and Murningham 2011) and we expect to observe them in the domain of food consumption.

Embodied cognition theory suggests that metaphors are used to link abstract concepts to physical and sensory experiences (Barsalou 2008, Lakoff and Johnson 1980). In this way, physically cleansing the body can lead to beliefs about moral purity. Smelling a citrus scent activates concepts related to cleanliness (Holland, Henriks and Aarts 2005; Schnall, Benton and Harvey 2008). Hand washing has been shown to not only physically clean but also to psychologically cleanse an individual of past moral transgressions (Zhong & Liljenquist 2006). We explore here the potential ability of physical cleansing to morally cleanse dieters of their misdeeds in terms of forbidden food consumption, which will be evident in their feeling licensed to

re-indulge in forbidden food consumption. The physically cleansing products in this study contain scents strongly associated with cleansing activities (mint, citrus).

Two hundred and three undergraduate students participated for a small cash payment. The design consisted of a 2 (tasting condition: eat chocolate, resist eating chocolate) x 3 (cleansing condition: groom with haircomb; cleanse with handwipe, cleanse with toothbrush) full factorial. Participants were randomly assigned to one of the six cells. All participants were provided with a sample of chocolate. They were instructed to look at, smell, and touch the chocolate and either eat it [or not] and to provide an evaluation of the product. Participants then evaluated a haircomb (i.e., were groomed but not cleansed), a citrus-scented handwipe (i.e., were cleansed), or a toothbrush with mint-scented toothpaste (i.e., were cleansed). After completing various closed items in a survey, participants chose a gift from a selection of chocolates, pencils, and erasers, arranged randomly on a table, on the way out of the experiment. Their gift choice was covertly recorded.

We conducted a logistic regression on whether or not chocolate was chosen on the way out of the experiment (yes, no) as a function of tasting condition, cleansing condition, dietary restraint, and all possible interactions. Two effects were significant: the 2-way interaction between dietary restraint and cleansing condition, and the 3-way interaction between dietary restraint, cleansing condition, and tasting condition. We find that among those low in dietary restraint, there are no significant differences in likelihood of taking chocolate on the way out of the experiment within cleansing conditions as a function of whether the participant had eaten or resisted chocolate. However, among those high in dietary restraint who were not cleansed (i.e., used the haircomb), significantly fewer took chocolate on the way out if they had tasted versus resisted chocolate. Among restrained eaters, cleansing with either a citrus-scented hand wipe or toothbrush with minty toothpaste compared to grooming with a comb significantly increased the likelihood of taking chocolate on the way out of the experiment, if chocolate had been tasted. We thus find that physical cleansing absolves only restrained eaters from what only they perceive as moral transgression associated with forbidden food consumption.

Love at First Sight or at First Smell?
Order Effects of Olfactory and Visual Cues

EXTENDED ABSTRACT

Prior research, across multiple disciplines, has documented the effects of different types of sensory stimuli inputs on the evaluation of products. These studies have typically examined the effects of sensory stimuli such as color, scent, touch, and taste. Some studies have also examined the effects of multiple sensory stimuli such as touch and taste or vision and touch (Krishna 2012). However, no study has examined how the *sequential order* in which multiple sensory stimuli are encountered influence product evaluations. This is especially relevant since in many real world situations, consumers can encounter multiple sensory stimuli sequentially (and not simultaneously, especially since different sensory cues are acquired differently. For example, visual stimuli can be evaluated with a greater degree of non-proximity than olfactory or haptic stimuli. That is, objects can usually be seen from a further distance than they can be smelled. On the other hand, for visual stimuli processing, one needs to have the object in the line of vision, whereas olfactory stimuli can be evaluated omnidirectionally. Hence, cases can be made for different sensory stimuli to be encountered in sequentially different orders. As an illustrative example, suppose a consumer enters a chocolate shop, and smells the chocolates first before she actually sees them versus if the consumer first sees the chocolates (e.g., through the store window) before she smells them. Would the consumer's evaluation of the chocolates be influenced by the sequential order in which she sees versus smells the chocolates? The present research attempts to make an important first step in trying to answer this research question.

Our propositions and hypotheses are influenced by recent work in the domain of interaction and carryover effects between sensory stimuli and the related sensory-neurological reactions (Krishna 2012; Rolls et al. 2010), along with research on order effects (Biswas et al. 2010). We test our propositions/hypotheses with the help of five experiments. First, Study 1 examines the sequential order effects of evaluating a beverage's visual aspects such as color (henceforth referred to as "V") versus olfactory/scent aspects (henceforth referred to as "O"). Study 1 used a single-factor (sequential order of sensory stimuli: V-O vs. O-V) between-subjects design experiment. A concocted beverage was used as the product in Study 1, with the beverage color and scent determined through a series of pretests. Participants were given the beverages in cups with lids and were asked to take off the lids after receiving the beverages. In the V-O condition, participants received the beverages in transparent cups, whereby they could see the color first before they could smell the beverage. In the O-V condition, participants received the beverages in opaque cups of similar quality, with the odor dissipating through the porous lid. As a result, they could smell the scent of the beverage first before they could see the beverage color. To ensure that the quality of the cups did not influence consumer taste perceptions (e.g., Krishna and Morrin 2008), the quality and price of the cups were identical, with the only difference of the cups being opaque versus transparent. The results of Study 1 showed that a beverage's taste is more favorably evaluated when participants encounter the visual aspects of the product prior to the olfactory aspects (that is, the sequence of V–O leads to more favorable evaluations than the sequence of O–V).

Study 2 then provides additional process evidence and also examines sensory cue order effects across a non-food context and the moderating effects of individual visual processing tendency (e.g., Wyer, Hung, and Jiang 2008). The results show that overall product evaluations are higher when the visual stimulus is earlier in a sequence of sensory stimuli, with the effects primarily being driven by those who are high on visual processing tendency.

Although the results of Studies 1 and 2 support our theoretical premises related to sensory carryover interactions and the sequential dominance of the visual cues over olfactory or auditory cues, there can be a potential alternative explanation of the results related to the role of short term working memory (e.g., Biswas et al. 2010). Hence, in order to further investigate which of the two underlying processes (sensory carryover versus role of working memory) is more dominant, Studies 3A and 3B were conducted. These studies examine the order effects of evaluating a food's visual and olfactory aspects when the visual color is desirable but the olfactory aspect (scent/odor) is undesirable (henceforth referred to as O') or when the olfactory aspect is desirable but the visual color is undesirable (henceforth referred to as V'). The results of Study 3A show that taste perceptions are higher for V-O' than for O'-V and the results of Study 3B show that taste perceptions are higher for O-V' than for V'-O.

Finally, Study 4 identifies a boundary condition (by examining the moderating effects of hunger) whereby the effects of Study 1 are reversed. Under low hunger, consumers have more favorable product taste perceptions for the V-O than the O-V sequence, consistent with the results observed in Study 1. However, under high levels of hunger, the effects get reversed, whereby consumers' taste percep-

tions were higher for the O-V, than the V-O, sequence. This occurs because the odor/scent of a food has stronger sensory impact under high levels of hunger.

Taken together, the results of the five experiments reveal interesting theoretical and practical insights regarding the effects of sequential presentation of sensory stimuli (e.g., olfactory and visual) on consumer product evaluations.

Seeing what you Smell:
An Eye Tracking Analysis of Visual Attention

EXTENDED ABSTRACT

Interest in sensory marketing is on the rise, with growing evidence that sensory inputs such as scent can enhance consumer both product evaluations (Spangenberg, Crowley and Henderson 1996) and memory for product information (Krishna, Lwin and Morrin 2010; Morrin and Ratneshwar 2003). Most studies to date have investigated such effects using relatively distal measures such as self-reported attitudes and/or delayed recall. The present research investigates the effect of scent on visual attention to elements in print advertisements with eye-tracking technology. We explore whether the presence or absence of a pleasant scent increases attention generally, or only when objects in the ad are semantically congruent with the odors being smelled.

In this research we manipulate not only the presence or absence of scent, but also the congruency between the scent (if present) and objects in the ad. Cue congruity refers to the degree to which a particular cue, such as a product's scent, complements a target stimulus (Bone and Ellen 1999). In the present research we operationalize congruency in terms of the semantic associations between the scent and product or service promoted in a print advertisement.

The literature on scent and attitudes suggests congruent odors often increase consumer evaluations (Spangenberg, Sprott, Grohmann and Tracy 2006), but the literature on scent and memory is mixed. Morrin and Ratneshwar (2003) found that incongruent ambient scents were just as effective as congruent ambient scents at enhancing recall and recognition of brand names and packaging. Nevertheless, Bone and Ellen (1999) argue that incongruent scents, which are those that are perceived by the consumer as not fitting with the product, may interfere with the processing of relevant brand information. Do only congruent scents facilitate the processing and storage of product information and enhance accessibility to stored information and elaboration through the process of attention? We seek to explore this issue by examining the effect of scent on visual attention to elements in print advertisements.

The use of eye-tracking technology has been relatively scarce in consumer research, although studies are beginning to emerge (e.g., Wedel and Pieters 2000). In the current set of studies, a Tobii T60 Eye Tracker (integrated into a 17" TFT monitor) was used to record the visual activity of participants. Upon entering the laboratory, participants were seated at a desk where several scent stimuli, a canister of coffee grounds, and the eye-tracking monitor had been set up. Each of the scent stimuli contained filter paper that had been infused [or not] with an essential oil. The eye tracker was calibrated according to each individual's height and position. Participants sniffed five scent packets, one at a time, as they viewed each of five advertisements. The participants were exposed to five randomly ordered ads for hypothetical brands in different product categories, one of which was the target ad. For the target ad we measure eye fixation count, which indicates degree of drawing attention to stimulus, and eye gaze fixation length, which indicates overall interest in the stimulus. Pre-determined areas of interest (AOI's) representing the location of a manipulated ad element (word or picture) were mapped out. In between each ad, coffee grounds were sniffed to clear out nasal passages. After viewing the ads, participants completed a survey booklet with other measures.

Three studies were conducted using this procedure. In study one, a strawberry scent was [or was not] sniffed while viewing a full color advertisement for a hypothetical brand of food coloring. The ad contained pictures of four bottles of colored liquid. The bottle in the upper right quadrant appeared either in grey or red to manipulate color congruency with the strawberry scent. In study 2, a lemon scent was [or was not] sniffed while viewing an ad for a juice bar. The advertisement contained pictures of four different smoothie ingredients. The item in the upper right quadrant was either a lemon or banana to manipulate congruency with the lemon scent (controlling for color congruency). In study 3, a citrus scent was [or was not] sniffed while viewing either a pictorial ad for a retail superstore or a text-based ad for taekwondo services. In the upper right corner of each ad was a woman cleaning a kitchen sink [or placing a book on a shelf] in the visual ad; or the word "clean" [or "walk"] in the verbal ad.

We conducted analyses of variance on mean fixation count and fixation length as well as other measures captured in the survey booklet as a function of scent (yes, no) and ad element congruency (yes, no). Across the studies we find that sniffing a scent increases both eye fixation count and length of eye gaze on the area of interest *only* when the scent is congruent with an object in the ad. Moreover, we find that the size of the enhanced attention effect is larger when the ad element is concrete versus abstract in nature. Implications for consumer multi-sensory processing are discussed.

SESSION OVERVIEW

According to a recent 2010 study by Booz & Co., 83% of Consumer Packaged Goods companies planned to boost their spending on shopper marketing in the next three years, and 55% of the companies ranked shopper marketing as their top investment. These efforts are increasingly focused on stimulating unplanned purchases.

The proposed session brings together four papers that provide new insights into the causes and consequences of impulse buying and shopping more broadly. The session begins with Huang, Hui, Inman, and Suher, who use advanced portable video-tracking technology to track the in-store behavior of 250 shoppers. They propose and test a comprehensive framework of shopping-trip-level and point-of-purchase drivers of unplanned purchases. This is followed by two papers that delve into specific situational factors that influence what shoppers buy in a store. Specifically, Bertini, Pirc, and Valenzuela investigate how different shelf-space arrangements in the retail environment (i.e., vertical vs. horizontal vs. random) influence shoppers' propensity to buy hedonic versus utilitarian products. Zwebner, Goldenberg, and Lee examine the effect of a sensory factor—temperature—on shoppers' valuation of a variety of products. Both groups of researchers also study and discuss the psychological mechanisms that underlie their respective effects. Finally, Rick, Pereira, and Burson examine a phenomenon that drives many unplanned purchases—retail therapy—and explore whether and why shopping when distressed actually helps to alleviate distress.

Overall, these papers highlight several new insights into the causes and consequences of unplanned purchases using a diverse set of research methodologies (surveys, field and incentive-compatible lab experiments, video-tracking) and explore a variety of cognitive and affective processes (fluency, congruency, emotional attachment, emotion regulation). Given the relevance of these effects to consumers' daily lives and marketers' bottom lines, this session should be of interest to a wide range of psychologically- and managerially-minded consumer researchers who are interested in retail environments, sensory marketing, fluency, emotion and decision-making, and anyone who is fascinated by the factors that can affect their shopping and buying behavior.

Capturing the "First Moment of Truth": Understanding Point-of-Purchase Drivers of Unplanned Consideration and Purchase Using Video Tracking

EXTENDED ABSTRACT

The majority of grocery purchases are unplanned at the category level (Inman et al. 2009). Because of the economic importance of unplanned spending, manufacturers and retailers alike are very interested in understanding in-store drivers of unplanned purchases in order to optimize their shopper marketing strategies (Grocery Marketing Association study, 2007). They are especially interested in understanding shopping behavior at the point of purchase, termed by Procter & Gamble as "the first moment of truth". In particular, given the importance of product consideration in product purchase (Hauser and Wernerfelt 1989), retailers try to identify trip- and point-of-purchase- level factors that lead shoppers to make more unplanned considerations, and raise the likelihood that these considerations will turn into actual purchases.

With a few notable exceptions (e.g., Stilley et al. 2010), previous academic research on unplanned purchases often relies on scanner data (e.g., Inman et al. 2009). Typically, a shopper's purchase, as recorded by scanner data, is compared to an entrance survey to identify whether a certain purchase is planned or unplanned. What happens *during* the trip (e.g., how a shopper considers and purchases from each product category), however, is not recorded. As such, previous studies are typically limited to studying the influence of demographic (e.g., gender) and psychographic (e.g., impulsivity) factors on unplanned purchases. Point-of-purchase behaviors along the shopping path are rarely considered. In this research, we address two important questions about unplanned considerations and purchases. First, what shopping trip-level characteristics are related to a higher number of unplanned considerations? Second, for each unplanned consideration, what aspects of point-of-purchase behavior are related to a greater likelihood of conversion to purchase?

We first hypothesize that both the length of the shopper's travel path and the extent to which she follows the most efficient path to obtain her planned items are associated with the number of unplanned considerations she will make. Specifically, the longer the distance that a shopper travels in the store, the more in-store stimuli she will get exposed to, which may in turn trigger forgotten needs and lead to unplanned purchases (Granbois 1968). Thus, we hypothesize that a longer in-store travel distance is associated with more unplanned considerations. We then predict that when grocery shoppers do not plan forward efficiently to take the shortest path connecting all the products they plan to buy, they may focus on the actions that maximize immediate utility rather than ones that maximize utility over a relatively longer time horizon (Hutchinson and Meyer 1994). This diminished regard for future consequences is often hedonically driven and correlates with a powerful and persistent urge to buy immediately (Rook 1987). Thus, we hypothesize that shoppers who take a less efficient shopping path through the store are likely to engage in more unplanned considerations.

We then predict that a few consideration characteristics can be related to whether an unplanned consideration will convert into an actual unplanned purchase. First, the wide variety of sensory stimuli presented in grocery shoppers' decision environment might activate their important shopping goals and therefore increase their engagement in a product purchase (Celsi and Olson 1988). Since this heightened product engagement generally leads to greater purchase intentions (Bloch and Richins 1983), we expect that the more engaged a shopper is during an unplanned consideration, the more likely it is to result in a purchase conversion. Specifically, we hypothesize that longer consideration duration and more product touches, both of which are indicative of higher engagement (Peck and Childers 2003), is associated with a higher likelihood of a purchase conversion.

We then hypothesize that a "deep" consideration where fewer products are considered in greater amount of detail may be more likely to result in a purchase conversion than a "wide" consideration where more products are considered within the same amount of time. By focusing their attention on a small number of products, shoppers may feel more involved with the specific product, which makes them more likely to purchase it (Bloch and Richins 1983). In contrast, by having more products in the field of view, shoppers could easily suffer from "choice overload" and become less likely to make a purchase (Iyengar and Lepper 2000). Therefore, the fewer shelf displays viewed by the shoppers allow them to be more focused on certain products (i.e., a "deep" type of consideration) and thus more likely to make an unplanned purchase. In addition, by physically standing closer to the product shelf, the shopper's field of vision will necessarily contain fewer products.

Finally, shoppers may reference in-store circular, coupons, or interact with store employees while they are engaged in an unplanned consideration. Shoppers' ongoing information search during a particular decision results from different motives such as obtaining tangible consumer benefits or seeking hedonic feelings (e.g., Punj and Staelin 1983). Since outcomes of both motives lead to a higher likelihood of product purchase (Rook 1987), we hypothesize that referencing external information relevant to the current product under consideration relates to greater purchase conversion.

We tested these hypotheses in a field study that was conducted in a medium-sized grocery store located in a northwestern U.S. city, where we had around 250 shoppers wear portable video cameras to observe each incidence of their point-of-purchase decision making process. We also collected their shopping intentions, and gathered relevant demographic and psychographic information by asking them to complete both an entrance and an exit survey. Eyecam videos were then coded and analyzed. Consistent with our hypotheses, we find that longer in-store travel distance and lower shopping "efficiency" lead to more unplanned considerations. We further show that an unplanned consideration is more likely to develop into an actual purchase if a shopper (i) spends more time in consideration, (ii) touches more products, (iii) references external information (e.g., circular, coupon, smart phone), (iv) stands closer to the shelf, (v) views fewer product shelf displays, and (vi) interacts with the store staff. Managerial implications of our findings are discussed.

Boosting Promotional Effectiveness with Thoughtful Product Displays

EXTENDED ABSTRACT

Options available to consumers are typically displayed in a two-dimensional "canvas." Prior research shows that there is indeed a difference in consumers' reactions to displays in which products are oriented vertically or horizontally (Valenzuela and Raghubir 2009). However, despite the importance of shelf placement in consumers' decisions, consumer researchers have paid little attention to it (but see Chandon et al. 2009; Drèze, Hoch, and Purk 1994). This paper adds to the literature by showing that firms can improve the effectiveness of promotional campaigns by managing the orientation of product displays. Key to our theory is the distinction between goods with a high hedonic or utilitarian content. We find that any orientation, vertical or horizontal, boosts the sales lift of a good that is primarily hedonic, while only vertical orientation is desirable when the discounted good is mostly utilitarian in nature.

We propose that product display orientation, horizontal or vertical, influences decisions through two different mechanisms: fluency and congruity (Hsee and Rottenstreich 2004). Fluency is linked to the psychological cost of the decision making process. The experience of difficulty accompanying a decision process may influence consumers' evaluation of the decision outcome (Novemsky et al. 2007). If consumer decision-making is fluent, the positive experience that accompanies the process of choosing becomes an input to the evaluation of the choice itself making choice more likely. We believe that the mere existence of order in a display of choice options will enhance fluency as consumers find it easier to access information before making a decision. Congruity, by contrast, is related to the feeling that the obtained information is right. The literature shows that when consumers find schema-consistent information they tend to use simple heuristics instead of engaging in more systematic processing (Sujan, Bettman and Sujan 1986). For example, a possible simple heuristic identified by Inman, McAlister and Hoyer (1990) was that products placed at the end of the aisle are considered a good deal, even when they are not.

This paper investigates whether product display orientation effects are different for products with high hedonic and utilitarian content (Dhar and Wertenbroch 2000). Consumers deciding on hedonic goods are expected to be processing more affectively and may favor perceptual inputs in their decision-making such as the feeling of fluency. If an ordered display by itself is able to enhance feelings of fluency, we would expect display order (independent of its orientation) to enhance sales and, thus, the size of the promotional lift. By contrast, when consumers buy utilitarian goods, they tend to process information more analytically, and cognitive determinants such as congruency may become relevant. In this context, we expect that only display order that is consistent with consumer shelf schemas would lead to a larger promotional lift. The literature supports consumers are most aware of the vertical shelf schema, which accounts for "top-bottom" or vertical order (Valenzuela, Raghubir and Mittakakis 2012). We test this pattern of effects using an in-store field experiment and then explore the proposed underlying mechanism using a controlled lab experiment.

A field experiment tested the hypothesized pattern of effects at a large European grocery retailer. It was conducted as an end of aisle promotion with 58 SKUs from a regular assortment of 17 product categories at 10 test stores together with 10 control stores to enable comparison of stores of similar type, size, traffic, location and presence of competitors. The field test was implemented as regular promotional activity, and the orientation of the products on the promotional display represented three conditions: random, horizontal or vertical (Figure 1). We measured quantities sold in the pre-promotion period, during promotion and after promotion period. All three periods had equal lengths of 13 days. Analysis corresponds to the variable *Promotional Lift* or the ratio of the quantity sold during the promotional period and the quantity sold before the promotional period. Prior to the field test we pre-tested consumers' perceptions

of the extent of hedonic and utilitarian content of the 17 different categories. Product type variable was defined as *(Hedonic – Utilitarian) ratings* and named *HU.*
Figure 1: Orientation conditions, from left to right: vertical, horizontal, random

We performed three spotlight analyses exploring the difference in promotional lift in the three order conditions and two product types: more hedonic (mean centered *HU* + one standard deviation) and less hedonic goods (mean centered *HU* – one standard deviation). Results revealed that utilitarian products (-1 SD) enjoyed a larger promotional lift when displays were ordered vertically than horizontally or randomly ($M_{vertical}$ = 3.04, $M_{horizontal}$ = 2.16, M_{random} = 2.40). On the other hand, in the case of hedonic products (+1 SD) both vertical and horizontally ordered displays provide larger promotional lifts than random displays ($M_{vertical}$ = 3.73, $M_{horizontal}$ = 3.50, M_{random} = 2.87). We performed a nested regression providing simultaneous test for all the proposed patterns of results controlling for additional variables influencing promotional lift such as expenditure in other promotional elements: Hedonic goods have higher promotional lift compared to utilitarian goods. Vertical orientation increases promotional lift for both hedonic and utilitarian goods. Horizontal orientation increases promotional lift only for hedonic goods.

Overall, when decisions involve hedonic goods, consumers process more affectively. Any ordered display despite its orientation generates fluency, which enhances promotional sales. On the other hand, when the decision involves utilitarian goods, consumers process more analytically and congruity matters. In that case, it is only the more prevalent vertical orientation that enhances promotional sales.

The Temperature Premium:
How Physical Warmth Increases Product Valuation

EXTENDED ABSTRACT
A variety of environmental factors in a store can influence how consumers shop and what they buy (Bitner 1992; Kotler 1973; Krishna 2011). However, the impact of an important dimension of our physical surroundings—temperature—on consumer behavior has been relatively little examined (for an exception, see Hong and Sun 2012). In the present research, we focus on this topic and, in particular, examine the influence of temperature on consumers' product valuation.

Recent research has shown that temperature is an important factor in interpersonal relationships (Kang et al. 2010; Williams and Bargh 2008). The findings in this literature share the main idea that it is warmth, and not coldness, which leads to an individual's favorable attitudes towards others. Given this association between physical warmth and positive feelings, it is likely that warmth will also increase favorable attitudes in the consumption arena. Drawing on this idea, we suggest that warmth generates favorable emotions which in turn increase product valuation.

The first two experiments were designed to test the basic effect of temperature on product valuations. In experiment 1A, 98 participants were seated in either a pre-warmed or a pre-cooled room (ad-

justed to 26ºC or 18ºC respectively). Next, they evaluated a varied set of 11 consumption products (i.e., a pack of M&Ms candy, a wireless computer mouse, a can of Coca Cola, a six-pack of Duracell batteries, a pampering massage, a CD of a popular singer, a two-liter jug of milk, a cup of coffee, a container of popcorn, Dove bath gel, and a Gap t-shirt). We found that participants who evaluated these products in ambient warm temperature were willing to pay more for the products (standardized *M*'s of .13) than those who evaluated them in cool temperature (standardized *M*'s of -.11; $t(96)$ = 2.26, p = .026).

In experiment 1B, we used a different temperature manipulation, asking 46 participants to touch a warm (vs. cool) therapeutic pad as part of an initial study in which they had to evaluate a new product. Next, in a second purportedly unrelated study, participants were asked to indicate their willingness-to-pay for both a hedonic product (a slice of chocolate cake) and a utilitarian product (batteries). Again, those who had experienced physical warmth were willing to pay significantly more for both products, as compared to those who had experienced physical coolness (M_{warm} = 16.13 vs. M_{cool} = 11.85; $t(44)$ = 3.41, p = .001). Together with experiment 1A, this experiment shows that physical warmth increases product valuation, demonstrating the existence of a *temperature premium*.

The purpose of the next two experiments was to examine the underlying process for this temperature premium. Experiment 2 was designed as a mediation study which involves real consequential choice, hence examining the external validity of the temperature premium phenomenon. Sixty participants touched a warm (vs. cool) pad as in experiment 1B, and then evaluated a real pen and rated their current affective reactions towards the pen (using a seven-item scale [Derbaix 1995]; α = .85). Finally, to thank them for their participation, participants were given a choice between receiving the pen and receiving 3 NIS. The results again suggest that valuation of the pen increased in the warm condition: 77% of participants in the warm condition chose the pen over money, compared to 47% in the cool condition (c^2 = 5.71, p = .017). Importantly, participants' affective reactions mediated the positive effect of warmth on product valuation as indicated by a bootstrap mediation analysis (95% CI: .02, 1.43).

Experiment 3 was designed to further test the role of affect in the temperature premium phenomenon by employing the findings of recent research indicating that emotional reaction is associated with reduced perceived distance (Van Boven et al. 2010). Specifically, we investigated whether physical warmth would also affect distance perception, which would implicate the role of emotions in the observed effects. An online pretest demonstrated that participants experiencing warmth estimated their distance from Paris to be closer than the control group (M_{warm} = 3439.9 km vs. $M_{control}$ = 4130.2 km; $t(120)$ = -2.44, p = .016). The results of experiment 3 revealed a similar pattern in a more controlled (lab) setting. Specifically, 66 participants were first exposed to a warm versus cool pad as before, and were then asked to estimate their distance from a pen that was placed 40 centimeters in front of them. We found that exposure to warm (vs. cool) temperatures reduced participants' perceived distance to the pen (M_{warm} = 26.19 cm vs. M_{cool} = 38.28 cm; $t(76)$ = -3.86, p < .001), further supporting the affect-based account. Additionally, physical warmth again increased valuation of the pen (M_{warm} = 8.56 NIS vs. $M_{control}$ = 7.31 NIS; $t(76)$ = 2.02, p = .047), replicating our previous findings.

In summary, using a variety of products and temperature manipulations, the current work shows that physical warmth increases product valuation, demonstrating the existence of a temperature premium. Importantly, the findings suggest that consumers' positive emotional response to target products in the presence of physical warmth underlie these results. Besides contributing to the atmo-

spherics and sensory marketing literature, our findings also add to the growing literature on embodiment effects. Finally, we offer practical implications by demonstrating the positive influence of appropriate physical warmth in the buying environment.

The Benefits of Retail Therapy: Choosing to Buy Alleviates Sadness

EXTENDED ABSTRACT

How do people regulate their negative affect? Psychologists have documented several common (and often ineffective) responses to negative affect (e.g., rumination). Consumer researchers have also argued that negative affect encourages shopping, a phenomenon commonly known as "retail therapy." We examine whether and why retail therapy is an effective way to regulate negative affect. We focus on shopping's potential to alleviate sadness in particular, as previous research has demonstrated that sadness can increase the desire to buy (Cryder et al. 2008; Lerner, Small, and Loewenstein 2004).

Qualitative research supports the notion that retail therapy can help to alleviate sadness (e.g., Atalay and Meloy 2011). While suggestive, prior research on the effectiveness of retail therapy is plagued by at least two important limitations that cloud interpretation of the findings. First, research in this area has not utilized random assignment. Instead, this work has relied on surveys and interviews with people who chose to engage in retail therapy. Without randomly assigning participants to shopping or equally engaging "control" activities, it is unclear whether shopping conveys benefits above and beyond those produced by distraction or the mere passage of time.

Second, research in this area has relied entirely on retrospective reports of how shopping influenced affect. For example, Faber and Christenson (1996, p. 809) administered a questionnaire that assessed the "frequency of feeling each of nine different mood states immediately before deciding to go shopping and how often they were experienced while shopping." Because "shopping" has many components, including browsing, choosing, paying, acquiring, and consuming, retrospective reports of the effects of "shopping" cannot shed light on which component(s) are necessary for healing to occur.

This is not merely a descriptive shortcoming. Instead, differences in the effectiveness of different components could shed light on why shopping helps to alleviate sadness. To develop hypotheses about why some components will be more influential than others, we consider sadness from an appraisal theory perspective (e.g., Lerner and Keltner 2000). Appraisal theory suggests that the way people cognitively appraise their environment can be both a cause and consequence of different emotions. Smith and Ellsworth (1985) identified six dimensions that best characterize the appraisals that differentiate emotions: the extent to which the current situation is pleasant, predictable, demanding of attention, demanding of effort, under human (versus situational) control, and under one's own or other people's control.

Smith and Ellsworth (1985) found that sadness, more than any other investigated emotion, was associated with a perceived lack of personal control. People who are sad are especially likely to view personally relevant outcomes as governed by some combination of other people's desires and chance. To the extent that these appraisals create or maintain the experience of sadness, aspects of shopping that help to restore a sense of personal control may in turn alleviate sadness.

The ability to choose tends to enhance one's sense of personal control (e.g., Langer 1975). Because choices are inherent to shopping (e.g., choosing what to buy), shopping may help to restore a sense of control and thus alleviate sadness. In particular, there is reason to expect that choosing to buy will be more likely to restore a sense of control than choosing not to buy. People do not buy the vast majority of products they encounter, so arguably choosing not to buy is the default action in shopping environments. In fact, choosing not to buy when faced with several alternative goods is sometimes referred to as a "no-choice" option (e.g., Dhar 1997). Therefore, we posit that choosing an item to buy is especially likely to alleviate sadness.

Study 1 examined whether merely simulating shopping helps to alleviate sadness. We utilized a hypothetical shopping paradigm to determine whether making buying choices (even without the subsequent attainment of a good) was sufficient to help alleviate sadness.

We collected a baseline measure of affect and then showed a sad video to all participants. Participants were then randomly assigned to either choose which of several products they would (hypothetically) buy (Buyers) or judge which of those products would be most useful for travelling (Browsers). (The buying and browsing tasks lasted the same amount of time.) We then took a final measure of affect.

We found no significant difference between final and baseline levels of sadness among Buyers. Browsers, however, were significantly sadder at the end of the experiment than at baseline. Thus, Buyers were more likely to be "healed" by the end of the experiment.

Study 2 examined whether the benefits of choosing to buy persist when participants must actually part with money to obtain a good (that is, when shopping for real). We also examined whether making a buying decision helps to alleviate anger. Anger is generally as unpleasant as sadness, but is associated with a much greater sense of personal control (Keltner, Ellsworth, and Edwards 1993). Thus, we did not anticipate that making a buying decision, which should help to restore a sense of personal control, would help to alleviate anger.

We paid participants up front for participating and then took a baseline measure of affect. Participants then watched a video previously demonstrated to induce both anger and sadness. We then randomly assigned participants to Shopping or Browsing conditions. In the Shopping condition, participants either bought one of several snacks (Buyers) or did not buy one (Non-Buyers). Buyers did not consume their snack in the lab. In the Browsing condition, participants inspected the same set of snacks and ranked them based on perceived amount of food-coloring (Browsers). We then took a final measure of affect.

Consistent with Study 1, there was no significant difference between final and baseline levels of sadness among Buyers. Non-Buyers and Browsers were significantly sadder at the end of the experiment than at baseline. All participants were significantly angrier at the end of the experiment than at baseline, consistent with our theoretical account.

Taken together, our results do not support the broad notion that shopping alleviates negative affect. Instead, our evidence suggests that buying helps to restore control and alleviate sadness.

Paper #4: Space, Time and Getting Things Done: The Role of Mindsets in Goal Pursuit
Dilip Soman, University of Toronto, Canada

SESSION OVERVIEW

People generally make purchases with a specific goal in mind. But can they effectively attain the goal? While economists believe that consumers have stable and well-defined preferences about desired ends and act in ways that reliably achieves these ends, psychologists find that people do not always pursue goals in a rational and effective manner. In this session, we explore such anomalies in goal pursuit. We aim to highlight findings that demonstrate instances when consumers' choices and behaviors violate normative theories and reveal the cognitive mechanism underlying these anomalies. Specifically, the first two papers show that consumers' goal pursuit behaviors appear inconsistent with rational behavior axioms, whereas the last two papers focus on how contextual cues drive consumers to behave differently under similar goal pursuit situations.

The first paper, by Derek Koehler and Cade Massey, asks whether consumers seek to maximize their ultimate utility from goal pursuit. In particular, the authors study goal abandonment and investigate whether consumers neglect opportunity costs in a pursuit of a goal with uncertainty. Normatively, if goal attainment is uncertain, consumers should consider giving up their current goal pursuit at some point in order to maximize their gain and minimize their loss. However, they found that consumers tend to over-persist on their goals, forging opportunities offered by alternative pursuits.

The second paper, by Luxi Shen and Ayelet Fishbach, examines choice consistency and focuses on consumers' preference for uniqueness in a goal-based choice. They identified the uniqueness heuristic such that consumers choose unique options for one single goal but defer from that option when choosing for multiple goals. This heuristic leads to a preference reversal: Consumers prefer a unique option either for Goal A or for Goal B, but when choosing for both Goal A and B together, they prefer an ordinary option.

The third paper, by Anastasiya Pocheptsova, Jordan Etkin, and Ravi Dhar, considers how goal-related mindsets affect the approach that consumers adopt for multiple-goal pursuit. Although previous literature suggests that consumers faced with multiple goals usually switch between pursuing their multiple goals, their findings showed that consumers at times prefer to highlight the pursuit of one of their goals at the expense of other co-active goals. They further identified

the role of implemental mindset (vs. deliberative mindset) in driving this effect.

The last paper, by Dilip Soman, takes an integrative perspective on how incidental contextual cues effect consumers' initiation of goal pursuit. In one of his studies, he found that the patience (commitment) of consumers in a queue depends on whether they were already inside a queue guide area (a visual boundary of the task system) regardless of the length of the area, though normatively the decision of dropping a queue should be a function of the absolute time/distance expected to wait. Based on consistent findings across the domains of space and time, the author develops a new framework for understanding the interplay between incidental contextual cues and the implemental mindset.

Together, these four interconnected papers provide interesting perspectives on when consumers' goal pursuit decisions and behaviors appear inconsistent, explore the cognitive structure underlying the goal pursuit anomalies, and specify when the anomalies may help consumers effectively attain their goals and when they may not. The papers yield insights into consumer goal pursuit across a wide range of settings, and carry theoretical as well as practical implications for consumer research. Data collection in all papers is complete and all participants have agreed to present, should the session be accepted. The chairs will facilitate audience discussion drawing connections between the session topic, anomalies in goal pursuit, and other areas of consumer research.

Opportunity Cost Neglect in Goal Pursuit Under Uncertainty

EXTENDED ABSTRACT

Consumer choices are often made in the context of goal pursuit. Weight-loss products are purchased on the basis of their anticipated contribution to progress toward a weight-loss goal; financial investment products are selected in the context of a retirement or other savings goal; subscriptions to online dating services are made with the goal of establishing a romantic relationship. One notable feature these examples have in common is that the goal's achievability is uncertain.

Much of the recent work on decision making in goal pursuit has focused on self-regulatory mechanisms that influence trade-offs between short-term expenditures (e.g., of effort) and long-term rewards associated with goal achievement (e.g., Heath, Larrick, and Wu 1999; Fishbach and Dhar 2005). A simplifying assumption typically made in such research is that the goal in question can be achieved and is worth achieving (i.e., benefits of goal achievement outweigh its costs). On such analyses, the primary implications of goal proximity or rate of progress are motivational, in that willingness to expend effort to make further progress toward a goal may vary with its proximity and how progress toward it is construed (e.g., Fishbach, Dhar, and Zhang 2006).

In many decisions we face, however, there is uncertainty about a goal's achievability. There may come a point at which a goal may not be worth continued pursuit because the anticipated benefits of goal achievement are outweighed by its costs. Often such uncertainty can be at least partly resolved over time as progress toward the goal is made: One can calculate whether, in light of this progress and the cost at which it was attained, the expected returns of achieving the

goal justify the costs of its continued pursuit. Optimal decision making, on this account, relies on belief revision, i.e., reassessment of whether the current goal should be continue to be pursued, or should instead be abandoned. Suboptimal goal pursuit behavior, then, can arise from miscalculation of cost and benefits of continued goal pursuit (i.e., leading to adoption of a suboptimal goal-pursuit strategy), as well as from the more familiar self-regulation challenges the underlie failure to execute an otherwise optimal goal-pursuit strategy. We suggest that the problem-solving aspect of goal pursuit, that is, how costs and benefits are and ought optimally to be integrated in decisions about whether to continue to pursue a goal, has been relatively understudied.

In the present research, therefore, we investigate decisions about whether to abandon or continue pursuit of a goal whose achievability is uncertain. Typically, decisions of this type are faced sequentially, as progress toward the goal is made and can be used to update the likelihood and value of goal achievement (e.g., an entrepreneur who faces continual decisions about whether to make further investments in a business project). Appropriate responsiveness to progress feedback is needed for optimal decisions -- one must balance the risk of abandoning the goal too early against pursuing it too long.

A challenge in studying this issue is identifying optimal decision-making. We build on the classic ball-and-urn paradigm to develop a task allowing the quantification of goal pursuit's costs and benefits. With this approach it is possible to gauge any systematic bias toward over-persistence or under-persistence. In each round, one of two urns containing red and green balls is randomly selected. Participants--who know the composition of each urn but not which one was selected for the current round--choose whether or not to draw balls from it. If the participant draws a target number of green balls (the "goal"), he or she receives a payoff. Draws are made without replacement, at a fixed cost deducted from an initial endowment for the round. The challenge is that only one of the two urns contains enough green balls to achieve the goal. The participant may quit the round at any time and keep what remains of the initial endowment. Thus, the participant must continually assess whether to persist or, alternatively, to abandon the goal. Multiple rounds of the game are played (with one randomly-selected round played for real money), allowing assessment of whether goal pursuit decisions improve with experience.

In multiple studies we investigate the impact of reward size and probability on participant behavior. We also evaluate performance in a variation of the paradigm in which participants can abandon urns in exchange for draws from other urns, rather than for a fixed payment. Across all studies we find a strong tendency to over-persist. That is, participants invest too much in trying to achieving success on the current urn, relative to an optimal benchmark suggesting that expected returns of goal achievement are outweighed by the anticipated cost of achieving it. This tendency is exacerbated by insufficient sensitivity to reward size and probability, and is worse in studies in which the foregone benefit is additional opportunity rather than a fixed payment.

Across studies we find the largest bias when a decision-maker receives "bad news" (makes relatively slow progress) in the early stages of goal pursuit. Optimal play requires abandonment in such circumstances. As a result, a Bayesian player is certain to sometimes abandon (ex-post) achievable goals (favorable urns), making up for it via more future opportunities. Our participants, on the other hand, rarely mistakenly abandon an achievable goal (favorable urn), but at the cost of leaving themselves far fewer opportunities for future goal achievement. There is no evidence from our studies that this bias is attenuated with task experience. We suggest that cost-benefit trad-

eoffs between current (or focal) and future (or alternative) opportunities is a fundamental tension in goal pursuit and ripe for additional psychological investigation.

The Uniqueness Heuristic:
A Preference for Unique Options for a Single Goal

EXTENDED ABSTRACT

When painting their bedroom, will homeowners select spring tulip red or beige? Would they make a different choice when painting their living room? This research explores people's preferences for unique versus non-unique choice options.

Previous research has examined several factors that contribute to a preference for non-unique options, including a desire to reduce risk (Simonson and Tversky 1992), to make an easily justifiable choice (Shafir, Simonson, and Tversky 1993; Simonson 1989), and to conform to a perceived social norm (Asch 1955; Simonson and Nowlis 2000). In contrast, other research has documented people's need for uniqueness (Ariely and Levav 2000; Berger and Heath 2007; Tian and McKenzie 2001), which leads to a preference for unique options.

In light of the existing research, we identify a "uniqueness heuristic" -- a stronger preference for unique options when choosing for a single goal than when choosing for multiple goals. We explain the uniqueness heuristic as the trade-off between multi-finality (i.e., how many goals one option serves) and instrumentality (i.e., how well one option serves each of the goals) in the cognitive network of goal system (Kruglanski et al. 2002; Zhang, Fishbach, and Kruglanski 2007). According to our analysis, unique options appear highly instrumental to a few goals, whereas non-unique options appear less instrumental but can serve many goals.

We further predict a preference reversal: What people choose for each single goal alone differs from what they choose for all the single goals together. For example, people may choose a unique restaurant either to dine with friend A or to dine with friend B, but choose a non-unique restaurant for dinner with both A and B.

In six studies involving different choice contexts, we tested the uniqueness heuristic with subtle and naturalistic goal activation, ruled out alternative explanations such as risk aversion, and explored the underlying mechanism.

In Study 1, we adopted the conceptual definition of uniqueness -- atypicality, that is, how remote one option is from the prototype of its category. Specifically, we designed a list of ice-creams with unique flavors (orange dark chocolate ice-cream and rosy vanilla ice-cream) and non-unique flavors (chocolate and vanilla). In the weeks around the Valentine's Day, we asked customers at a campus café to think of a friend who might be telling her felling to her crush and choose an ice-cream for one of the following purposes: (single goal a) to celebrate she entered a new relationship, (single goal b) to comfort her because she was rejected by her crush, and (multiple goals) to either celebrate or comfort because they were still waiting for her. We found that the atypical (unique) ice-cream flavors were preferred in both single goal cases but the typical (non-unique) ice-cream flavors were preferred in the multiple goal case.

The rest of the studies experimentally manipulated the uniqueness of an option by configuring different choice sets. The same option can be of low frequency and thus appears unique in one choice set (e.g., a French restaurant among many Italian restaurants), but be of high frequency and thus appears non-unique in another choice set (e.g., the French restaurant among many other French restaurants). In Study 2, participants chose a restaurant for dinner with one friend (single goal) or five friends (multiple goals). We found a preference

for the unique restaurant in the choice set (either one French restaurant among Italian restaurants or one Italian restaurant among French restaurants) for one friend but not for five friends.

Similarly, in Study 3, participants preferred a unique suitcase (either soft-sided among hard-sided, or hard-sided among soft-sided) for one upcoming trip (single goal) but not for multiple upcoming trips (multiple goals).

In Study 4, we examined choices with real consequence. Participants chose and sent a card to their family members. This experiment again confirmed the uniqueness heuristic and suggested a preference reversal: Participants preferred the uniquely-shaped card for their aunt alone and for their uncle alone, but not for both their aunt and uncle.

In Study 5, we ruled out an alternative explanation, risk aversion, by comparing choice for one goal versus one out of multiple goals. Participants selected the unique wine (either Californian among Australian or Australian among Californian) when shopping for one future occasion (single goal) but not when shopping for one out of four potential future occasions (multiple goals). The real outcome risk for experiencing a unique option was equal in both conditions and thus our finding suggested that the uniqueness heuristic cannot be explained by risk aversion.

Finally, in Study 6, we examined the underlying mechanism of the uniqueness heuristic. Participants chose apples, either red among green or green among red, for one experimenter (single goal) or for one of six experimenters (multiple goals) and made predictions on how much the apples would be enjoyed either before or after choosing. We found that participants used the uniqueness heuristic when choosing before predicting but not after. We also found that participants based their choice for single goals on their predictions regardless of whether they chose before or after predicting and their choice for multiple goals on their predictions only when they make predictions first. These findings confirmed the uniqueness heuristic, revealed its mechanism, and suggested that thinking about the instrumentality of each option before choosing can prevent the preference reversal by the uniqueness heuristic.

Blind to All Else:
The Role of Mindsets in Multiple-Goal Pursuit

EXTENDED ABSTRACT

It is now well established that consumer behavior is goal-driven (Bargh and Gollwitzer 1994; Kruglanski et al. 2002; Markman and Brendl 2005). Consumers typically have multiple goals that they try to pursue at the same time, for example, simultaneously wishing to be fit and to eat tasty foods, and to socialize with friends and achieve greater success in the workplace. When consumers maintain multiple goals, they will often temporarily disengage from initial pursuit of one goal to attend to their other co-active goals, a dynamic referred to as balancing (Dhar and Simonson 1999; Fishbach and Dhar 2005; Kivetz and Simonson 2002).

In contrast, the present research focuses on situations when consumers may instead selectively focus on the pursuit of only one of their multiple goals, a dynamic referred to as highlighting (Dhar and Simonson 1999). We propose that the propensity to highlight in multiple-goal pursuit is moderated by the cognitive orientation that consumers naturally adopt during different phases of goal pursuit. Mindsets theory (Gollwitzer 1990; Heckhausen and Gollwitzer 1987) demonstrates that goal pursuit can be construed via two different cognitive orientations: deliberative and implemental mindset. The deliberative mindset consists of evaluating the pros and cons of pursuing an intended goal whereas the implemental mindset consists of deciding where, when, and how to act in order to implement the intended goal (Gollwitzer, Heckhausen and Steller, 1990; Chandran and Morwitz 2005).

We argue that being in an implemental mindset for one of multiple co-active goals will lead consumers to inhibit the activation level of alternative pursuits, decreasing the likelihood of deviating from target goal pursuit (goal shielding; Shah et al. 2002). Consequently, consumers will highlight pursuit of a single goal at the expense of their other co-active goals, affecting choice of goal-related products, or means, to multiple-goal attainment. Specifically, we predict that consumers will repeatedly select means related to the goal associated with an implemental mindset, forgoing opportunities to balance multiple-goal pursuit by alternating between means related to several of their co-active goals. We further argue that implemental mindsets will affect consumers' preferences for products that would allow them to simultaneously pursue multiple co-active goals (i.e., "multifinal means"). While previous literature has shown increased preference for such means in multiple-goal contexts (Chun et al. 2011, Kopetz et al. 2011), we propose that consumers in implemental mindset would be less likely to prefer multifinal means as a consequence of highlighting the pursuit of only one of their several co-active goals.

Five studies provide support for these propositions. Study 1 shows that being in an implemental (vs. deliberative) mindset for one of two co-active goals results in a decrease in the accessibility of other co-active goals. In a word search task designed to measure goal accessibility, participants in an implemental (vs. deliberative) mindset for one of two goals (i.e., the target goal) found fewer words related to their non-target goal ($M_{implemental}$ = 1.31, $M_{deliberative}$ = 1.01; $F(1, 138)$ = 8.89, $p < .01$). Studies 2a and 2b examine the effect of mindsets on highlighting in the sequential choice of products. In study 2a we show that participants in an implemental (vs. deliberative) mindset for one of two co-active goals were more likely to repeatedly choose products consistent with only that goal, disrupting the process of balancing in multiple-goal pursuit (preference for second product: $M_{implemental}$ = 78.9% vs. $M_{deliberative}$ = 33.3%; χ^2 = 7.84, $p < .01$). Study 2b extends this finding by demonstrating that consumers in an implemental mindset for one of their multiple co-active goals decline opportunities to pursue their other goals, even when such opportunities do not affect the pursuit of the target goal. Specifically, we show that participants in an implemental (vs. deliberative) mindset are more likely to postpone choice than to choose an option consistent with their other co-active goal ($M_{implemental}$ = 95% vs. $M_{deliberative}$ = 69%, χ^2 = 4.07, $p < .05$).

The next two studies demonstrate the effect of mindsets on preference for multifinal means. Study 3a shows that in a simultaneous choice paradigm, consumers in an implemental mindset are less likely to prefer multifinal product assortments than are consumers in a deliberative mindset. Specifically, when given the option to construct a balanced product assortment to pursue two co-active goals (health and indulgence), participants in an implemental mindset favored their target health goal (number of products selected: $M_{healthy}$ = 6.52 vs. $M_{indulgent}$ = 4.30; $F(1, 135)$ = 25.97, $p < .001$), whereas participants in a deliberative mindset favored a more balanced product assortment ($M_{healthy}$ = 6.01 vs. $M_{indulgent}$ = 5.36; $F(1, 135)$ = 2.06, $p > .1$). Finally, study 3b extends this finding to a consequential choice setting by showing that consumers in an implemental (vs. deliberative) mindset for one goal are less likely to select an option that allows for the simultaneous pursuit of their multiple co-active goals ($M_{implemental}$ = 37% vs. $M_{deliberative}$ = 62.5%; $\chi^2 [1]$ = 4.18, $p = .04$).

This research makes several contributions to past work on goal-related mindsets and the dynamics of multiple-goal pursuit. First, we

identify implemental mindset as an important boundary condition to previously established dynamics of balancing in multiple-goal pursuit. Second, we show that consumer mindsets moderate the established preference for means that help consumers pursue multiple goals at the same time; despite having multiple co-active goals, consumers in an implemental mindset for one of those goals are less likely to use multifinal means. Taken together, our research extends current knowledge of the dynamics of multiple-goal pursuit and of the role played by goal-related mindsets in influencing consumer choice.

Space, Time and Getting Things Done: The Role of Mindsets in Goal Pursuit

EXTENDED ABSTRACT

The achievement of most behavioral goals is preceded by a phase in which consumers approach the goal over space and time. In this stream of research, I study goal pursuit during this phase of approach and address the question of how consumers' goal commitment and implementation activity is affected by their proximity to the goal. Results from both the domain of time (Tu and Soman 2012) and space (Zhao, Lee, and Soman 2012) show that consumers tend to partition the approach into distinct categories – a "later and there" category in which the outcome is spatially and temporally distant and a "now and here" category in which it is proximal. The categorization process can be facilitated by any cues in the environment that facilitate perceptual, semantic or conceptual similarities. In the domain of space, for example, we find that a space that is labeled "inside," or space that is demarcated by the use of area rugs and queue guides is more likely to be categorized as proximal to the goal. In the domain of time, categorization is facilitated by duration markers – events like the end of the month or year, or other salient episodes in consumers' lifetimes (e.g., a birthday, the end of an academic term) such that outcomes that happen before the salient marker are categorized as "now" and those that will happen after the marker are categorized as "later."

Prior research has also documented that consumer's cognitive processing changes as a function of their distance from the goal. For instance, Lewin (1926), Heckenhausen (1987) and Gollwitzer (2012) have all made the distinction between the motivation phase [a phase where the consumer plans and strategizes] and the volition phase [when tactics are executed to get the desired outcome]. Gollwitzer (2012) and others (e.g., Xu and Wyer 2010) use the term mindset to capture these differences. In a deliberative mindset, the consumer

plans; in an implemental mindset, the consumer does. An implemental mindset can be characterized by the willingness to make and commit to a choice, by a sense of optimism about achieving the desired outcome, and by heightened action orientation more generally. Xu and Wyer (2010) argue that implemental mindsets are triggered by the activation of procedural knowledge, but not much else has been written about when during goal pursuit does a consumer switch from a deliberative mindset to an implemental one.

I propose that categorical processes provide a key input into determining when the mindstate transition happens. The physical and temporal movement from the "there and later" to the "here and now" triggers a mindset change. In particular, the urgency associated with the "here and now" puts people in an implemental mindset and hence they are more likely to work to accomplish the final outcome.

Two completed papers provide empirical evidence on which this framework is based. In the domain of time, we find (Tu and Soman, 2012) that when a task that is due D-days from now is due this period as opposed to the next, participants invest greater effort to achieve the task. Likewise in the domain of space, we (Zhao, Lee and Soman 2012) observed people waiting to check into a flight or use an ATM machine, and found that they were very likely to keep all of their documentation (e.g. tickets, passport, ATM card) ready as soon as they stepped onto an area rug in front of the service area. Across 12 experiments in both domains, we find evidence for goal accomplishment, commitment, effort and optimism when consumers are "here and now".

In this talk, I will

- Develop a new theoretical framework of goal pursuit and mindsets

- Present some selected evidence from two completed papers; Tu and Soman (2012) in the domain of time and Zhao, Lee and Soman (2012) in the domain of space.

- Discuss additional ways of categorization that may produce counter-intuitive results, for example situations in which people who are physically or temporally distant could be more action oriented by the activation of another categorization cue. For example, a professor is more motivated to work on next Tuesday's class on the preceding Tuesday when s/he is teaching her previous class because all Tuesdays may be categorized as "teaching days."

- Integrate the findings and discuss implications for consumer behavior, marketers, and policy makers and for the theory of goal pursuit more generally.

Raising the Bar: New Insights into the Development of an Optimal Donation Solicitation

Paper #4: For Charities not all Aesthetics are Created Equal: The Differential Effects of Aesthetics With and Without Cost Implications on Response to Donor Solicitations
Shweta Oza, University of Miami, USA
Claudia Townsend, University of Miami, USA

SESSION OVERVIEW

Charities service very diverse populations and provide for many vital services, such as health care, education, housing and disaster relief. However, they are continually confronted with growing competition for resources. Increased need for charitable support has necessitated that nonprofit organizations utilize the most effective means of communicating with the consumer (White and Peloza 2009). The objective of this session is to provide new insights into how non-profit organizations can more effectively construct their donation solicitations. A major contribution of this session will be its implications for how non-profit organizations (or companies interested in pro-social activities) should manage their fundraising efforts.

Recognizing the importance of charitable contributions, researchers have worked rigorously to identify factors influencing donation behavior (Bendapudi, Singh and Bendapudi 1996; Reed, Aquino and Levy 2007). The projects in the session extend this work, examining factors which have generally been overlooked or understudied by previous research. Broadly speaking, influences on donation behavior can be categorized into (1) those integral to the donor (e.g. donor's gender identity: Winterich, Mittal and Ross Jr. 2009) and (2) those external to the donor, contextual or situational factors (e.g. the presence of incentives: Bénabou 2005). Importantly, the projects in this session consider these two types of factors both separately and as they interact.

MacDonnell and White demonstrate how an internal factor, donor's construal orientation, interacts with an external factor, type of donation solicited, to influence donation behavior. Similarly, Paniculangara and He show how the interaction between an internal factor, donor's sense of empathy, and an external factor, donor's distance from the recipient, effects contributions. Fajardo and Townsend identify two parts to the donation decision and examine how they are differentially influenced by internal and external considerations. They build on this knowledge to develop a more effective donation solicitation with internal appeals addressing the decision to donate and external appeals addressing the quantity decision. Then, in contrast to these three papers and the majority of the work in this area, Oza and Townsend consider an entirely external consideration – aesthetics of a donation appeal – to offer additional insights on solicitation

optimization above and beyond the informational persuasions used to motivate donation.

Individually, each project offers recommendations for how to optimize donation. Taken together, the papers in this session provide a blueprint for an effective donation appeal including when to present the appeal, how it should be designed, structured and specifically worded. Researchers interested the non-profit sector and/or pro-social behavior in general would be interested in the session. Given the diverse range of substantive topics to be covered, we also hope to draw attendees who are interested in research on advertising, persuasion techniques, public policy issues, construal level theory and aesthetics. By identifying and examining a diverse range of factors influencing donation behavior and making specific recommendations on how to optimize donation appeals, the session makes great contributions to the fields of persuasion and consumer behavior in general and pro-social marketing in particular.

All of the papers in this symposium are in a very advanced stage. They all have well-developed theoretical frameworks and have completed substantial empirical work. Notably, all these projects include at least one measure of real donation behavior. The working manuscripts for all of the papers in this session (as well as all of the cited references) will be available upon request.

Construing Charity: Consumer Construal Level and Charitable Contributions of Time Versus Money

EXTENDED ABSTRACT

According to construal level theory (Trope and Liberman 2003), mental representations of events influence how individuals process information (Fujita et al. 2006), and these construals, in turn, guide choices, preferences, and behaviors (Trope, Liberman, and Wakslak 2007). A low-level construal is characterized as being more concrete in terms of specific, subordinate, and contextualized features, whereas a high-level construal is one that is more abstract in that it represents events in terms of general, superordinate, and de-contextualized features (1989; Liberman and Trope 1998). The current research proposes that while money might be commonly viewed at a relatively concrete level, time might be construed as being more abstract. Further, it is posited that this has implications for marketers requesting charitable support on the part of consumers.

Past research demonstrates that the level at which the consumer construes a particular action can indeed influence various consumer outcomes including brand extension evaluations (Kim and Roedder John, 2008), product attitudes (Lee et al. 2010), and recycling behaviors (White, MacDonnell and Dahl 2011). For example, White et al. (2011) find that a "match" of construal-level with message frame (e.g., abstract messages with gain frames; concrete messages with loss frames) leads to the most positive consumer recycling behaviors and intentions.

Research does suggest that the manner in which consumers perceive time and money do indeed differ (Leclerc et al. 2005; Okada and Hoch 2003). Here, we forward the novel hypothesis that money (time) might be viewed more concretely (abstractly). This is because money is often considered in a concrete, lower-level manner as it serves as a "common currency" that many goods, services, and experiences must be broken down to in order to evaluate. Time, on the other hand, is a more experiential, general, and abstract concept. Given this, we propose that utilizing congruent messaging (concrete

vs. abstract) with donation request (paired with money vs. time, respectively) will lead to the most positive charitable support. These predictions were examined across two pretests and three studies. In two pretests, we show that thinking about money (time) leads to more concrete (abstract) thoughts when considering product usage (i.e., an iPod) and recalling a consumption experience (i.e., a date). Next, we turn to the prediction that a match of message (concrete vs. abstract) to the type of charitable support requested (money vs. time) will lead to the most positive charitable responses.

The first study utilized a 2(message: concrete vs. abstract) x 2(donation type: money vs. time) mixed-model design, with donation type as the within-subjects factor. Participants ($N = 86$) read one of two charitable appeals asking for contributions to a hunger-related cause (both with the same branding elements). The first appeal pretested as being more concrete in nature ("contribute to serving breakfasts to children"), and the second pretested as being more abstract ("contribute to addressing hunger for children"). Participants then reported how many dollars and hours (in counterbalanced order) they were willing to contribute to the charitable cause. These measures were standardized for comparison. A mixed-model ANOVA revealed a significant message x donation interaction ($F(1,83)=4.28$, $p<.05$). When presented with a more concrete appeal, consumers were more apt to give money ($M=.442$) than time ($M=.081$; $t=2.94$, $p<.05$). When provided with an abstract appeal, consumers intended to give more time ($M=.296$) than money ($M=-.133$; $t=2.41$, $p<.05$).

To provide converging evidence for our construal level account, study 2 examined individual differences on construal level. Participants (N=60) were then asked to indicate how many dollars and hours they were willing to contribute to the cause communicated in a marketing message. Each measure was converted to a z-score for analysis. Construal preferences were assessed using Vallacher and Wegner's (1989) 25-item "action identification" scale and these were averaged such that lower (higher) scores represented a more concrete (abstract) construal preference. For analysis, a difference score between time and money donations was calculated, with higher numbers indicating greater time donations. Linear regression revealed that the continuous mean-centered action identification scale significantly predicted charitable contributions of time versus money ($\beta = .30$; $t(58)=2.16$, $p<.05$). Thus, those disposed to more abstract construals were more likely to donate time (vs. money).

In the third study, we examined real consumer behaviors. The construal level of the message was varied to be more concrete or abstract (as in study 1). Participants ($N = 72$) were run individually and were asked to contribute either time or money and their actual behavioral contributions were observed. The z scores of actual dollar and hour contributions were used as the dependent measure. In addition, participants completed measures of positive moods. The appeal (concrete vs. abstract) by donation type (money vs. time) between-subjects interaction on actual contributions was significant ($F(1,68)=8.65$, $p<.01$). When the cause was presented as being concrete consumers were more likely to donate money ($M=.39$) versus time ($M=-.21$; $t=2.15$, $p<.05$), whereas when the cause was presented in more abstract terms consumers were more likely to donate time ($M=.13$) versus money ($M=-.49$; $t=2.24$, $p<.05$). Bootstrapping analysis revealed that the effects were mediated by positive mood states (confidence interval .0020 to .1598; $p < .03$). The pattern of results showed that the most positive moods emerged when there was a match of construal-level of the message with the donation type.

Taken together, the results have implications for both theory and practice. Theoretically, the findings that money is viewed more concretely, while time is viewed more abstractly build upon past work both examining consumer construal-level and consumer differences in perceptions of time vs. money. Practically, the results suggest that charitable organizations wishing to generate monetary support might profitably make more concrete appeals to consumers. For example, appeals that highlight how the money would be used, along with the specific programs that will be supported might be particularly successful. Conversely, when the goal is to recruit individuals to donate their time, broader appeals that discuss the general cause might be more successful.

Empathy, Donation, and the Moderating Role of Psychological Distance

EXTENDED ABSTRACT

It is well-established that empathy has a positive effect on charity, both in psychology (Eisenberg and Miller, 1987) and marketing (Bagozzi and Moore, 1994). We show that the effect of empathy on donation is contingent on psychological distance between donor and recipient.

Empathy is defined as "Einfühlung" the original German word roughly translated as "to feel one's way into." In other words, "being cognitively aware of another person's internal states and/ or putting oneself in the place of another and experiencing his or her feelings" (Bagozzi and Moore, 1994, p.58) or "one's ability to experience and understand another person's affective or psychological state" (Argo, Zhu, and Dahl, 2008, p. 615). Bagozzi and Moore (1994) found a partial mediation of empathy on a decision to help while Eisenberg and Miller (1987) used a meta-analytic approach to reveal significant positive effects of empathy on prosocial behavior. We argue that the effect of empathy on donation is moderated by psychological distance (Liberman, Trope and Stephan, 2007), with the role of dispositional empathy magnified by closer psychological distance between donor and recipient. Dispositional empathy is a stable trait and its *effect* depends on how easy it is to envision another's situation. Decreased distance between donor and recipient would facilitate such a process and therefore enhance the effect of dispositional empathy on donations.

Hypothesis: Psychological distance will moderate the effect of dispositional empathy on donations. The beneficial effect of greater empathy will be exacerbated when the donor and recipient are separated by lesser distance (physical, temporal, and hypothetical) and attenuated when there is greater distance.

The above hypothesis was tested in four experiments, with psychological distance manipulated between subjects and dispositional empathy measured. The first three experiments studied the donation of time in the form of extra credit points. Participants were students of an introductory marketing course and could participate in research to earn ten additional course credit points (in a 1000-point class). They read that another student could not participate due to illness or work. Participants were asked how many of their points would they donate to this unfortunate student. Barring the manipulation of psychological distance, no other information about the needy student was provided. It must be emphasized that when completing the questionnaire, participants committed to making an actual donation and they were debriefed following submission of the questionnaire. Within the questionnaire, participants completed a measure of dispositional empathy (Davis, 1980), for which Cronbach's α was found to be acceptable. Manipulation checks indicated the success of the distance manipulation in each experiment.

In the first experiment, we studied the moderating role of physical distance. Seventy undergraduate students were assigned to one of the two levels of physical distance. All participants were

enrolled in the introductory marketing section on the main campus of the university. There was a similar section at a satellite campus about one hundred miles away. Half the participants considered a recipient enrolled in the satellite campus (farther physical distance) and the rest considered a recipient enrolled in the main campus (closer physical distance). The results revealed a significant interaction between dispositional empathy and physical distance in participants' donation of their extra credit points ($F (1, 66) = 6.44$, $p < .05$). Planned comparisons indicated that dispositional empathy was significant in predicting donation only at closer physical distance but not at farther physical distance.

The second experiment documented the moderating effects of temporal distance. Sixty-eight participants were assigned to one of two levels of temporal distance. The experiment was conducted in the first half of the semester. The scenario indicated that the unfortunate student would either receive the donation within a week (closer temporal distance) or at the end of the semester (farther temporal distance). There was a marginally significant interaction between temporal distance and dispositional empathy on the likelihood of donating extra credit points ($F (1, 65) = 3.16$, $p < .10$). Planned comparisons indicated that dispositional empathy was a significant predictor of likelihood of donation only in the condition of closer temporal distance but not at farther temporal distance.

Hypothetical distance was manipulated in the third experiment. Sixty-nine participants considered a scenario portraying one of two levels of hypothetical distance. Participants read that a student had been chosen to receive their donation (closer hypothetical distance) or read that a student would be chosen (farther hypothetical distance), a manipulation used previously (Small and Loewenstein, 2003). We found a significant interaction between dispositional empathy and hypothetical distance in determining actual donation of extra credit points ($F (1, 65) = 4.91$, $p < .05$). This interaction arose from the significant effect of dispositional empathy at closer hypothetical distance but not at farther hypothetical distance.

In experiment four, we studied the donation of money and endowed sixty participants with five one-dollar notes in an envelope. Our dependant variable was the number of notes they transferred to an envelope meant for a student at lesser or greater hypothetical distance, manipulated in the same fashion as in experiment three. We found a marginally significant interaction between dispositional empathy and hypothetical distance on donations of actual dollars ($F (1, 56) = 2.69$, p = .1). As shown previously, this interaction arose from the significance of dispositional empathy in predicting dollar donations at closer hypothetical distance but not at greater hypothetical distance. In this experiment we also ruled out a possible confound of Inclusion of Others in Self using a previously validated measure (Winterich, Mittal and Ross, 2009).which yielded no significant difference. We discount the possibility of our distance manipulation leading to feelings of "oneness."

To sum up, the role of dispositional empathy in charitable donation depends on psychological distance between the donor and the recipient. Consistent results are observed using different manipulations of psychological distance and different measures of donation. Our findings contribute to a better understanding of charitable behavior, particularly with respect to the interactive effects of empathy and psychological distance. Not-for-profit organizations may better plan fundraising efforts by taking into account the various forms of psychological distance existing between the donor and the recipient.

Splitting the Decision: Increasing Donations by Recognizing the Differential Impact of Internal and External Considerations

EXTENDED ABSTRACT

When considering a charitable donation, the decision-maker decides whether to make a donation (choice) and then how much to donate (quantity). Building off the idea of two-stage valuation models (Kleindorfer and Kunreuther 1988; Slovic and Lichtenstein 1968; Winter and Fried 2001) researchers interested in pro-social behavior have suggested that these decisions are driven by different factors (e.g. Smith, Kehoe, and Cremer 1995; Smith and Berger 1996; Dickert, Sagara, and Slovic 2011). Considering such findings in aggregate we hypothesized and found that donation choice is determined primarily by considerations internal to the decision-maker (e.g. self-identity, self-relevance) while donation quantity is determined primarily by external factors (e.g. neediness of victims, effectiveness of organization).

Additionally, we extended our findings by applying them to a different context and testing a new optimal structure for solicitations. Prior work has demonstrated that providing excessive information may cause anxiety and poor decision-making (Reuters 1996; Shenk 1997). Thus, we hypothesized that an optimal solicitation structure would be one that explicitly separates the two decisions and enables different persuasive arguments to be offered for the choice and quantity decisions. Indeed we find that this solicitation structure maximizes both number and amount of donations.

In study 1a we manipulated moral-identity, an internal factor, and hypothesized that our manipulation would influence donation choice but not donation quantity. Participants first completed a brief questionnaire and received false feedback identifying them as having either a high or low moral-identity. They were then shown a hypothetical donation appeal for a fictitious non-profit organization, Foster Support, described as providing clothing and toys to foster children. As expected, a larger percentage of participants in the high moral-identity condition selected to make a donation than in the low moral-identity condition (High moral identity = 91.7%, Low Moral Identity = 50%, $X^2 = 6.84$, $p < .01$). Donation quantity, however, remained unaffected by moral-identity; participants in the high moral-identity condition did not estimate a higher donation amount than participants in the low moral-identity condition ($M_{high} = \$35.51$ vs. $M_{low} = \$26.91$, $F(1, 58) = 1.02$, $p = .32$). In study 1b we manipulated self-relevance of the charitable cause, another factor internal to the decision-maker, by describing Foster Support as operating either within the participant's state-of-residence or across the nation. Results replicated study 1a; self-relevance affected donation choice (High Self-Relevance = 81%, Low Self-Relevance = 52%, $X^2 = 4.22$, $p < .05$) but not donation quantity ($M_{high} = \$24.93$ vs. $M_{low} = \$23.24$, $F < 1$).

Having shown that two different internal factors influence the decision of whether to donate but not donation amount, in study 2 we considered two external factors and predicted that the opposite would be true, that donation quantity would be affected but not donation choice. First, in study 2a we manipulated seriousness of the cause. All participants saw a donation appeal for Project No Isiolo, a fictitious organization providing mosquito nets to individuals at risk of contracting Isiolo Fever. We manipulated seriousness of the cause between subjects by describing Isiolo Fever as resulting in either short-term discomfort (low seriousness) or death (high seriousness). In accordance with our predictions donation choice was not affected by the seriousness of the cause (High Seriousness = 74%, Low Seriousness = 63%, $X^2 = 1.19$, $p > .10$). In contrast, the decision of how

much to donate was significantly influenced; participants reading the high seriousness appeal offered a higher donation amount than participants reading the low seriousness appeal ($M_{high\ seriousness}$ = \$28.58 vs. $M_{low\ seriousness}$ = \$16.64, $F(1, 139)$ = 8.46, $p < .01$). In study 2b we manipulated the efficiency of the charitable organization by including information about Project No Isiolo's overhead expenditure. As in study 2a, donation choice was not influenced by our manipulation (High Efficiency = 73.7%, Low Efficiency = 61.1%, X^2 = 0.67, $p > .10$), while donation quantity was (M_{high} = \$44.45 vs. M_{low} = \$28.48, $F(1, 56)$ = 5.52, $p < .05$).

Having separately examined the influence of internal and external factors on donation behavior, in study 3 we combine the two by offering both types of persuasions and varying which type is paired with which donation decision, choice or quantity. Participants considered one of two versions of a donation solicitation for a non-profit, Community-in-Schools (CIS). The two versions of the appeal letter varied in terms of the *order* of information presented while holding actual information content constant. In one version of the appeal, internal factors – self-relevance and donors' self-view – were emphasized as participants considered whether to make a donation. The decision of how much to donate was then accompanied by information on external factors. In the other version of the appeal the order in which the information was presented was reversed; external factors were emphasized prior to donation choice and factors internal to the donor were emphasized prior to the quantity decision. In accordance with our predictions the former version of the appeal led to both a higher rate of donations (54% vs. 37%, X^2 = 4.32, $p < .05$) and a higher average donation amount (M = \$12.43 vs. M = \$9.37, $F(1, 65)$ = 4.27, $p < .05$). Study 4 was a field replication of study 3 where we varied the actual solicitation letter sent by CIS to potential donors. Indeed, in the context of real dollar donations, the effects both on donation choice and donation quantity replicated prior studies.

Having established the discreet and differential effects of internal and external factors on the decisions whether and how much to donate, in study 5 we extended our findings by testing the impact of explicitly splitting the decisions. Additionally, we applied our theory to a new context, willingness to participate in an online educational program. We found that compared to the traditional solicitation structure which offers all information upfront, splitting the two decisions and aligning the arguments with the decision they most influence maximized both adoption rate (choice) and predicted amount of effort (quantity). Thus, this research offers an optimal set-up for a broad range of persuasive solicitations.

For Charities not all Aesthetics are Created Equal: The Differential Effects of Aesthetics With and Without Cost Implications on Response to Donor Solicitations

EXTENDED ABSTRACT

Many of the findings in judgment and decision-making have been tested or applied in the context of charitable direct marketing (e.g. donation solicitations or requests for volunteer work). Prior work has considered concepts such as providing an anchor (Fraser, Hite, and Sauer 1988), framing in positive or negative valence (Stone 1992), or utilizing the availability heuristic (Smith and Berger 1996) in an effort to optimize the language used by non-profit organizations to gain support. An area where less research has occurred is in consideration of the overall look of the solicitation. Holding the text and information constant, can a solicitation be made more effective? In line with prior work, an initial hypothesis might suggest that, what applies in advertising or other persuasive techniques will apply in this context as well. As such one might predict that the bet-ter looking or aesthetically pleasing something is, the more effective and persuasive it will be (e.g. DeBono and Harnish 1988).

However, better aesthetics likely come at a price, literally, that is, there are some aspects of making a solicitation more attractive that likely cost more. And when the context is non-profit organizations cost perceptions come into play. Non-profits are judged by their efficiency and frugality with sites such as charitywatch.org and charitynavigator.org set up to do exactly this. Charitable organizations must justify extra expenses (Marchand and Lavoie 1998). Indeed, prior work suggests that in contrast to for-profit organizations, for non profits a higher price tag can actually turn off rather than entice patrons (Griffiths 2005). Spending too much may make patrons feel their money is being used improperly and result in negative evaluations of the organization's competence. In fact research by Aaker et al. (2010) reveals that, at a baseline, non profits are considered less competent than for-profit organizations and they must use subtle cues connoting credibility to garner the same willingness to pay for products as would be offered to for-profit organizations.

As such we hypothesize that not all aesthetics cues are equally beneficial in increasing response to a charitable direct marketing solicitation. Specifically we separate aspects of aesthetics that imply something about the cost of the solicitation from those that do not. We predict that these two classes of aesthetic will have differential and interacting effects on solicitation response such that, donation amounts are higher when the solicitation mailers are aesthetically pleasing and perceived to have lower costs associated with them as compared to when the solicitation mailers are aesthetically pleasing and perceived to have higher costs associated with them. We examine this in two lab studies and one field study.

Study 1 was a 2 ("Aesthetics"- aesthetics separate from cost: high, low) by 2 ("Perceived Cost" - aesthetics related to cost: high, low) design lab study where undergraduate students were shown a solicitation from a hypothetical non-profit and asked whether and how much they would be willing to donate. Aesthetics separate from cost was manipulated by varying the alignment of the text and border, type of border, fonts, and color of the cardstock. Perceived cost was manipulated by varying the thickness of the cardstock, whether the mailer was a postcard or letter and envelope, and whether it included a pre-paid return envelope. Pretests confirm our manipulations. Examining amount donated we find a significant main effect of Aesthetics ($M_{Low\ Aesthetics}$ = \$11.28, $M_{High\ Aesthetics}$ = \$21.83; $F(1, 236)$ = 3.65, $p = .05$) and no effect of Perceived Cost ($M_{Low\ Cost}$ = \$19.88, $M_{High\ Cost}$ = \$13.23; $F(1, 236)$ = 1.375, $p = .24$). Importantly, there is a significant interaction of the two (F(1, 236) = 3.67, p = .05). Among the Low Aesthetics conditions there is no difference between the two Perceived Cost conditions ($M_{Low\ Cost}$ = \$9.35, $M_{High\ Cost}$ = \$13.21, $F(1,230)$ = .26, $p = .60$). However among the High Aesthetics conditions there is a significant benefit of the low Perceived cost ($M_{Low\ Cost}$ = \$30.40, $M_{High\ Cost}$ = \$3.25, $F(1,230)$ = 4.32, $p = .039$).

Next, we tested our predictions in a real world context using a field study. We partnered with a non-profit organization and created four versions of the invitation to be sent to their mailing list for their annual benefit gala. The invitations varied in appearance in line with the design of study 1. Examining the amount spent on tickets we find no main effect of Aesthetics ($M_{Low\ Aesthetics}$ = \$44.14, $M_{High\ Aesthetics}$ = \$53.69; $F(1, 288)$ = .15, $p = .70$) nor of Perceived Cost ($M_{Low\ Cost}$ = \$58.83, $M_{High\ Cost}$ = \$38.99; $F(1, 288)$ = .65, $p = .42$). However, there is a significant interaction of the two (F(1, 288) = 4.01, p = .04). Among the Low Aesthetics conditions there is no difference between the two Perceived Cost conditions ($M_{Low\ Cost}$ = \$29.51, $M_{High\ Cost}$ = \$58.77, $F(1,148)$ = .37, $p = .54$), though directionally in line with study 1. However among the High Aesthetics conditions there is a

marginal benefit of the low Perceived cost ($M_{\text{Low Cost}}$ = $88.16, $M_{\text{High Cost}}$ = $19.21, $F(1,139)$ = 3.71, p = .056).

The results of the first two studies demonstrated the differential effects of aesthetics with and without cost implications and support our hypothesis. In the last study we examined a boundary condition for this effect. We posited that perceptions of cost associated with aesthetics cues could act as a proxy for organization's competence and as such influence the donation amounts. As such in study 3, in addition to varying aesthetics and cost as in study 1, we also varied competence of the organization by providing information about the organization's overhead expenditure. The results indicated that competence moderates the effect of aesthetics and perceived cost on donation amounts. Taken together the results of these studies have a potential to help non-profit organizations optimize their donation solicitation mailers and avoid unnecessary expenses.

Consumer Sociality and Happiness

SESSION OVERVIEW

Aristotle described happiness as "the best, noblest, and most pleasant thing in the world…the highest good (Aristotle. Nichomachean Ethics, 1925)." Additionally, we know that individuals place great weight on the acquisition of products and experiences in their pursuit of happiness (Pelletier, 2009). Despite the relevance of happiness and the widespread pursuit of happiness through consumption, the factors that influence consumer happiness are still vastly unknown.

The present papers, which are either completed works or are at an advanced stage of completion, demonstrate that social factors associated with purchases not only deserve more attention but also figure as potential explanations for certain purchases' ability to advance happiness. Such factors are especially important given that they are often the backdrop against which much of our behaviors as consumers occur. We know, for example, that our purchases are often exposed to or shared with (i.e., told to) others, that we often use our purchases to reflect our social self, and that many of our purchases involve social interaction. Accordingly, this session presents four papers illustrating that consumer happiness is enhanced when a purchase is exposed to others (Chugani and Irwin), shared with others (Bastos and Brucks), reflective of one's social self (Gilovich and Carter), or conducive to social interaction (Caprariello and Reis).

Together, these investigations make several valuable contributions. First, they enlarge our understanding of the relationship between purchases and happiness. Second, they help to demystify the distinction between experiential and material purchases by examining different purchases' ability to reflect (Carter and Gilovich) and enhance (Bastos and Brucks) the self, and to facilitate social interaction (Caprariello and Reis). Finally, they add to the literature on the effects of social forces by investigating the different roles those forces play in consumption—e.g., a silent spectator of a consumption experience (Chugani and Irwin), an active audience for a recounted consumption (Bastos and Brucks), a component of the constructed social self (Gilovich and Carter), or a partner in a consumption experience (Caprariello and Reis).

The first paper highlights the powerful role of social factors by examining the effect of social presence on consumption happiness. Chugani and Irwin examine this relationship through the lens of hedonic adaptation: the process by which the magnitude of the happi-

ness derived from product purchases diminishes over time so that positive (negative) purchases tend to become less positive (negative) over time. The researchers gather real-time adaptation data and find that when consumers are cognizant of social contexts, the presence of others slows down the process of hedonic adaptation: consuming a product in the presence of others keeps consumers happy with positive purchases and unhappy with negative purchases for longer periods of time than consuming a product in isolation. This impeding of adaptation results from consumers viewing their possessions through the eyes of others, keeping the initial affective intensity of the possession fresh in their minds.

In accordance with Chugani and Irwin's findings on the importance of the social environment in facilitating happiness with purchases, Bastos and Brucks show that post-purchase sharing (i.e., telling others) mediates the effect of purchase type on happiness. Precisely, they find that the superiority of experiential purchases over material purchases in advancing happiness (Van Boven and Gilovich, 2003) can be explained by people's greater inclination to share the former with others. Additionally, they show that people expect to be more highly regarded by others as a result of sharing their life experiences versus their material objects. This expectation, in turn, explains people's stronger inclination to share experiences (vs. objects). The authors limit the long abstract to one study in order to offer a deeper explanation of procedures and findings (which replicate across all studies). For conference presentation purposes four studies will be presented.

Next, Carter and Gilovich strengthen the premise that the link between a purchase and the social self is critical for consumer happiness. They argue that, due to their intangibility, experiences exist in our collection of memories instead of in the physical world, as do objects. Accordingly, they present empirical support for the proposition that experiences form a larger part of the self (i.e., people see them as being closer and more representative of the self), and that this aspect explains why experiential purchases are more satisfying than material purchases. Thus, this research suggests that life experiences (vs. material goods) contribute more to the social self and, consequently, afford greater rewards.

Lastly, Caprariello and Reis provide further evidence for the importance of considering the relationship context of consumption in understanding consumer happiness with purchases. Specifically, the authors find that the ability of a purchase to promote social interaction predicts the amount of happiness generated, and that this factor helps explain the experiential vs. material distinction found in prior literature (Van Boven and Gilovich, 2003). These findings suggest that spending money to do or have things with others may be one method for promoting happiness.

In summary, this research suggests that social factors play an important role in consumer happiness from the perspectives of consumption setting, post-purchase interpersonal sharing, construction of a social self, and interpersonal relatedness. Separately these works shed light on nuanced processes, and together they provide a broad and coherent understanding of the happiness phenomenon. As such, they should be well-received by a wide audience and especially valuable to researchers interested in consumer happiness and the related concepts of the social environment, social sharing, social self, and social relationships.

This session embraces diversity by 1) suggesting a diverse set of novel constructs that affect happiness, 2) illuminating different

perspectives through which to define sociality, 3) presenting a rich variety of experimental approaches, and 4) including a geographically and culturally diverse team of researchers.

What Are Others Thinking?: Hedonic Adaptation in Public Consumption Contexts

EXTENDED ABSTRACT

Happiness (and unhappiness) with purchases generally diminishes over time: positive purchases become less positive and negative purchases become less negative (Frederick & Loewenstein, 1999); this process is often termed "hedonic adaptation". We examine the effect of an everyday social force on adaptation by asking how the presence of others while experiencing a product affects adaptation to that product. Four studies show that public contexts impede adaptation by inducing consumers to consider what others think of their product. Consumers who like their product assume others view their product favorably, and this enjoyable experience impedes adaptation over time.

Study 1

Study 1 tracked real-time adaptation to a product in lab. Participants were either (1) out of view from each other with dividers between lab stations (private condition) or (2) allowed to be seen by others, with no dividers (public condition). We manipulated cognizance of public context by asking participants either to report on an experience where they were the center of attention (priming cognizance of public context) or to describe a picture of a mundane fish or lamp (neutral prime). We then gave participants one of 9 products and tracked adaptation by measuring initial happiness and happiness at two other subsequent points.

There was an interaction between consumption context, public context cognizance, time period, and initial happiness ($F(1,188)=7.95$, $p<.01$). For those who were primed with public context cognizance (but not for those who received the neutral prime), a public context kept those who were initially happy with their product happy for a longer period of time ($F(1,188)=6.75$, $p=.01$) and those who were initially unhappy with their product unhappy for a longer period of time ($F(1,188)=3.21$, $p=.07$) than a private context. In sum, in a public context, with a public prime, adaptation was impeded.

Study 2:

Study 2 replicated the methodology of Study 1. However, rather than priming cognizance of public contexts, we measured participants' Self Monitoring scores. High self monitors are more chronically cognizant of being observed in public than are low self-monitors (Lavine & Snyder, 1996; Snyder & DeBono, 2008). Thus, we would expect SM scores to operate similar to the prime used in Study 2, providing triangulating evidence for our public cognizance moderator. We collected happiness at two time points.

There was a significant interaction between SM score, consumption context, and initial happiness with the product on happiness at Time 2 ($F(1,299)=4.23$, $p<.05$). Consumption context had a significant effect among high self monitors (fitting model at high SM score: consumption context X Time 1 happiness interaction, ($F(1,299)=4.25$, $p<.05$) but not among low self monitors (fitting model at low SM score: consumption context X Time 1 interaction, ($F(1,299)=.91$, NS). For instance, a public consumption context kept high (but not low) self monitors who were initially happy with their products happier for a longer period of time ($F(1,299)=7.27$, $p<.01$) than did a private context. Thus, Study 2 again showed, using a combination of our manipulated public/private variable and a measured

variable, that the more consumers are cognizant of public contexts the more slowly they adapt to products.

Study 3

Study 3 tests our mechanism directly by manipulating whether participants are cued to see their products through others' eyes (others' eyes manipulation). We placed all participants in a public context and asked them to report initial happiness with one of 8 products we gave them. Then, half reported how happy they thought *others* in the room thought they were with their product (others' eyes prime), and the other half answered filler questions (neutral prime). Participants then reported their happiness with the product two more times throughout the session so that we could track adaptation.

There was a significant "others' eyes" manipulation X time period X initial happiness interaction on happiness at a given time period ($F(1,136)=5.22$, $p<.05$). Participants in the neutral prime condition experienced adaptation to their products over time (significant time period X initial happiness interaction, ($F(1,136)=15.44$, $p<.001$) but participants who were cued to look at their product through others' eyes did not exhibit adaptation at all (non-significant time period X initial happiness interaction, ($F(1,136)=.95$, NS).

Summary

Three studies provide evidence that public (vs. private) consumption contexts impede adaptation among individuals who are aware of being in a public context by causing consumers to view their products not only through their own eyes but also through the eyes of others.

Verbal Sharing: Purchase, Tell Others, and Be Happy

EXTENDED ABSTRACT

Recently, the relation between purchases and happiness has received increased attention from academics and the popular press (Flatow, 2009; Pelletier, 2009). A common finding is that experiential purchases are better than material purchases at advancing happiness (Van Boven & Gilovich, 2003). A question that deserves further attention, however, is: What mechanism(s) underlies such effect?

Aiming to address that question, we drew on the disclosure and social sharing literatures to argue that consumers of experiences (e.g., taking a kayaking trip) are more likely than consumers of objects (e.g., buying a kayak) to share (i.e., tell others about) their purchases and to, in turn, enjoy the benefits of such activity (hypothesis 1 below). To provide support for this proposition, two questions should be addressed: 1) Why would people be more inclined to share experiential than material purchases?, and 2) How beneficial is sharing?

With regards to the first question, previous research (Van Boven, Campbell & Gilovich, 2010) shows that individuals form less favorable impressions of people associated with material (vs. experiential) purchases, and enjoy having conversations about experiential purchases more than about material purchases. Van Boven et al. thus conclude that "being associated with materialistic rather than experiential pursuits can pose a barrier to successful social relationships (p. 560)." Accordingly, we expect that people are more inclined to share their experiential (vs. material) purchases; and that such behavioral difference is driven by their expectations that sharing experiential (vs. material) purchases will lead others to form more favorable impressions about them (hypothesis 2 below).

Answering the second question, research suggests that sharing leads to far-reaching benefits. For example, sharing provides the teller with greater positive affect and well-being (Gable, Reis, Impett, & Asher, 2004). Additionally, it brings interpersonal rewards in the form of teller's greater liking for the listener as a result of having disclosed to him/her (Collins & Miller, 1994). Lastly, sharing benefits the disclosed event itself. It helps one achieve a better understanding of the shared event (Finkenauer & Rime, 1998), "creates an opportunity for reliving and reexperiencing the event" (Gable et al. 2004, p. 229), and "make[s] the event both more memorable to oneself and to others (Langston, 1994, p. 1113)." Harrigan (2001) summed the relevance of sharing by stating, "Happiness held is the seed; happiness shared is the flower". So, compelling evidence indicates various benefits of sharing. What remains unknown, however, is whether post-purchase sharing affects a purchase's ability to advance happiness.

Based on the above-mentioned findings, we argue that consumers of experiential (vs. material) purchases are more inclined to share the details of their purchase with others and, in turn, more likely to draw rewards (i.e., happiness) from doing so (H1), and that those consumers' expectations for how they will be regarded by others explain the difference in inclination to share (H2). This mediated-mediation can be formally hypothesized as:

Hypothesis 1: *Sharing will mediate the effect of purchase type on happiness.*

Hypothesis 2: *Regard will mediate the effect of purchase type on sharing.*

Experimental Design

To test our two hypotheses, we conducted an experiment with 95 participants who were randomly assigned to one of two conditions: material vs. experiential purchase. Participants were given instructions of what constitutes a material (or experiential) purchase and were asked to recall and write about a fifty-dollar personal purchase that reflected the condition they were in. Next, participants answered, on 7-point Likert scales, questions related to happiness (e.g., When you think about this purchase, how happy does it make you?), sharing behavior (e.g., I would feel excited about sharing the details of my object/experience; I would want to share with others the details of my object/experience), and regard (I think the person listening to me would regard me more highly after learning about my object/experience).

Results

Our results supported hypothesis 1. Specifically, we conducted four regressions (*a-d*) and a Sobel (1982) test of mediation and found that (*a*) experiential purchases advanced significantly more happiness than did material purchases ($F(1, 94) = 3.97$, $p = .04$). Further,

significant effects were found when (*b*) the mediator (i.e., sharing) was regressed on the IV (i.e., purchase type) ($F(1, 94) = 8.73$, $p = .004$), and (*c*) the DV (i.e., happiness) was regressed on the mediator ($F(1, 94) = 18.49$, $p < .001$). Importantly, (*d*) when happiness was regressed on both purchase type and sharing the previously significant main effect of purchase type on happiness became nonsignificant ($p = .36$). In line with this, our Sobel test showed a significant result ($z = 2.34$, $p = .01$). As hypothesized, these results suggest that sharing mediates the effect of purchase type on happiness.

To test hypothesis 2, we conducted a similar set of analyses and found significant effects for (a) purchase type on sharing ($F(1, 94) = 8.73$, $p = .004$), (b) regard (i.e., the mediator) on sharing ($F(1, 94) = 10.75$, $p = .001$), and (c) purchase type on regard ($F(1, 94) = 3.92$, $p = .05$). Revealingly, when both purchase type and regard were included in the model, the relation between purchase type and sharing was attenuated ($F(1, 94) = 2.40$, $p = .01$). Finally, the Sobel test indicated a marginally significant effect ($z = 1.66$, $p = .09$). These results support the premise that regard plays at least a partial mediating role in the effect of purchase type on sharing.

According to these analyses, the following picture emerges from our research: Experiential purchases are better than material purchases at advancing happiness (replicating Van Boven & Gilovich, 2003), and sharing mediates that effect. The difference in sharing is explained, in turn, by how people expect to be regarded as a result of their sharing. To our knowledge, this is the first research in marketing that examines the role of sharing in advancing consumer happiness. Moreover, these findings illustrate how important post-consumption events are for happiness. This is especially relevant given previous evidence suggesting that pre-consumption states (e.g., a sense of anticipation), but not post-consumption ones, are effective in generating happiness (Nawijn, Marchand, Veenhoven, & Vingerhoets, 2010).

On the Importance of Experiential Purchases to Defining and Preserving the Self-Concept

EXTENDED ABSTRACT

Can money buy happiness? Generally, the answer is thought to be no. However, it may simply be that people are not spending their money wisely. Previous research suggests that greater happiness can be found in experiential purchases (e.g. meals at restaurants, vacations, and concerts) than with material purchases (e.g. clothes, jewelry, and gadgets; Carter & Gilovich, 2010; Van Boven & Gilovich, 2003). One of the cited reasons for this difference in satisfaction is that experiences make a greater contribution to the "social self" than do material possessions. So far this has not been empirically demonstrated. The present research aims to do just that, as well as to examine whether this is qualified by trait materialism.

Why might experiential purchases form a greater part of the social self than material possessions? We believe there are several reasons, but one of the most important is that experiences, being largely intangible, exist primarily in memory, whereas possessions are largely tangible objects that persist in the physical world. It is partly because they persist in memory that experiences become more truly part of who we are, as it is our collection of memories and experiences that define us.

If experiences do form a larger part of the social self, why would they be more satisfying than possessions? First, being physical objects, material possessions are subject to the ravages of time. Clothes get dingy and torn, mp3 players become obsolete, cars break down. Experiences, on the other hand, may actually see their greatest benefit over time (Carter & Gilovich, 2010). Indeed, people tend to take the "rosy view" of experiences over time, even though the actual experience might be fraught with disappointing moments (Mitchell et al., 1997; cf. Nicolao, Irwin & Goodwin, 2009).

Second, and related to the first, as part of the social self, memories of purchased experiences can be embellished using the same sorts of motivated biases that allow people to maintain positive self-views (e.g. Dunning, 2005). Being intangible, experiences may be more open to construals or (re)interpretation than possessions, an essential part of the process of motivated reasoning (Kunda, 1990). It may be that evaluating the quality of one's experiences is, in essence, evaluating aspects of oneself, and as a result, people are motivated to see those experiences in a positive light, particularly over time.

We first wanted to test whether people do, in an almost literal sense, think of their experiential purchases as being closer to their social self than their material purchases. Participants were first asked to briefly describe 8 important purchases they had made, four material, and four experiential. Borrowing a page from work on the different conceptions of self in independent and interdependent cultures (Markus & Kitayama, 1991), we showed participants a sample diagram where circles representing different family members were plotted around a Self-circle such that the proximity of the family member represented the degree of overlap with the self. Participants were asked to follow a similar logic in plotting each of the eight purchases around a central Self-circle. We measured the distance from the center of each purchase's circle to the center of the Self-circle. As predicted, participants plotted their experiences closer to the Self than they did their possessions, paired $t(47) = 2.09$, $p < .05$. This result was not qualified by participants' trait materialism.

Next, we wanted to know if people would choose to use their experiential purchases more than their material purchases when describing themselves. Again, participants were asked to recall and briefly describe 10 purchases, five material, and five experiential. They were then asked to tell their life story, and were encouraged to incorporate into the narrative the purchases they had previously listed where appropriate. As predicted, participants included more of their experiential purchases (40%) than their material purchases (22%) into their life narrative, paired $t(89) = 5.94$, $p < .001$. Again, participants' level of materialism did not qualify these findings.

Most importantly, we wanted to know whether these findings could help explain why experiences tend to be more satisfying than possessions. We asked one sample of participants whether a stranger would have greater insight into their "true self" as a result of knowing about their experiential or material purchase history. As predicted, participants believed that knowledge of a their experiences was the clearer window to their self, $t(120) = 4.08$, $p < .001$. This belief was also significantly correlated with participants' greater satisfaction with a specific experience over a specific possession ($r = .19$, $p < .05$).

One consequence of experiences being a greater part of the self is that people would be less willing to give up those memories, as it would mean deleting a part of the self (Gilovich, 1991). In a final study, participants were asked to recall and briefly describe either a material or experiential purchase, and then to imagine that they could go back in time and swap out their memories of that purchase for memories of a different purchase. Participants were more satisfied with their purchases in the experiential than in the material condition. Participants in the material condition were both less satisfied with their purchases, $t(58) = 2.22$, $p < .04$, and more willing to exchange their memories than participants in the experiential condition, $t(58) = 2.88$, $p < .01$. This difference in how closely participants clung to the memories of their purchase mediated the difference in satisfaction between conditions, Sobel $z = 1.99$, $p < .05$.

These results, taken together, suggest that people do indeed hold their experiences more closely to their social self than their possessions, and that this tendency helps to explain why, ultimately, experiences tend to be more satisfying than possessions. What's more, it was not only those low in materialism who show this tendency, suggesting that there may be a disconnect between what materialists believe will be meaningful to them, and what actually is. Indeed, from many angles, it seems that purchasing experiences will ultimately prove a better investment for one's well-being.

It's the Company that Counts:
Shared Experiences and Possessions Make People Happier than Experiences and Possessions Alone

EXTENDED ABSTRACT

One reliable way to elevate happiness appears to be spending money on life experiences over material possessions (Van Boven & Gilovich, 2003). Van Boven and Gilovich defined experiential purchases as "events or series of events that a person lives through" (2003, p. 1194). In a series of studies, they found that people reported greater happiness by spending their discretionary money – money spent with the intention of increasing happiness – on experiences rather than on material possessions. Importantly, this effect replicated in a nationally representative sample and has been documented in retrospective, concurrent, and longitudinal reports of well-being (Howell & Hill, 2009; Nicolao, Irwin, & Goodman, 2009).

The present research proposes that distinguishing spending along a materialism-experientialism dimension overlooks another important difference between life experiences and material possessions: Typically, experiences are more likely than material things to involve other persons. Extensive research shows that social relations, especially those that foster feelings of connectedness, are influential sources of happiness (e.g., Argyle, 1999; Berscheid & Reis, 1998; Baumeister & Leary, 1995; Reis, Clark, & Holmes, 2004). We suggest that the *sharing* involved in experiences is central to their benefits relative to material possessions. If correct, happiness would be obtained indirectly from experiential activities, and directly from sharing the activities interpersonally.

On the other hand, material possessions tend to be associated with self-oriented motives, such as a desire to signal uniqueness (Berger & Heath, 2007), status (Griskevicius, Tybur, Sundie, Cialdini, Miller, & Kenrick, 2007), and identity (Belk, 1988), or to bolster self-esteem (Escalas & Bettman, 2003). Thus material possessions in and of themselves tend to lack the central quality of experiences

that make them amenable to improving happiness – the involvement of others.

In Study 1, we tested how the happiness benefits of experiential buying varied as a function of social involvement. Here, 327 participants were randomly assigned to pick between 1 of 2 kinds of purchases – between material objects and social experiences, material objects and solitary experiences, and solitary and social experiences. When comparing material purchases to social experiences, participants were significantly more likely to indicate that social experience would make them happier, $M = .70$, $\chi^2(1) = 151.36$, $p < .001$. When comparing material purchases to solitary experiences, participants were significantly *less* likely to indicate that solitary experiences would make them happier, $M = .38$, $\chi^2(1) = 54.22$, $p < .001$. Finally, when comparing solitary to social experiences, participants were significantly more likely to indicate that social experiences would make them happier, $M = .85$, $\chi^2(1) = 465.08$, $p < .001$. These results make clear that sharing experiences with others is necessary for deriving happiness from the experience. In fact, when presented with the option of a material possession or an experience *without* others, participants favored the material good over the experience.

Nevertheless, these results raise the question: Can the value of material possessions be enhanced by involving others? Some material possessions can certainly *facilitate* social interactions (e.g., board games, sports equipment, and stereo systems for family rooms). Furthermore, people strategically act on this knowledge by spending money for this purpose (e.g., to re-affiliate following rejection; Mead, Baumeister, Stillman, Rawn, & Vohs, 2011). If social interactions are as critical to happiness as research suggests, then material possessions obtained in the service of enhancing social interaction may make people happier than material objects obtained primarily for personal use. From this reasoning, we propose that proper understanding of the happiness benefits of life experiences versus material possessions requires consideration of whether one's purchases are meant to be shared or solitary. Crossing these two dimensions results in four possibilities: Shared experiences, shared possessions, solitary experiences, and solitary possessions. We hypothesize that the social-solitary dimension better predicts anticipated happiness from spending than the materialism-experientialism dimension.

In Study 2, 308 participants were given definitions of discretionary spending and were asked to think about the last time they spent their discretionary money to further their happiness. No other leading instructions were given. After describing the purchase and rating their happiness with it, participants self-coded the purchases into experiential-material and social-solitary categories. Based on this four-category conceptualization, we found evidence for the effects of social involvement on happiness but not for experientialism. In other words, we found that, collapsing across self-coded material and experiential purchases, the effect of sharing purchases on happiness was significant, $F(1, 295) = 10.76$, $p < .001$, such that social purchases were recalled as making people happier ($M = 3.89$) than purchases for solitary consumption ($M = 3.45$). Neither the main effect of experiential-material consumption nor the interaction were significant $F < 1.0$, $F(1, 295) = 2.11$, *ns*, respectively.

To ensure that our results were not biased by participants rating themselves, three coders, blind to conditions, rated every purchase along the same two dimensions as before. We found the same results with coder ratings as we had found with participant ratings, $F_{social-solitary}(1, 297) = 6.29$, $p = .01$, all other Fs < 1.0, with social experiences ($M = 3.77$) trumping solitary experiences ($M = 3.45$). In this study, therefore, we extended prior research by showing that the happiness benefits of social involvement, whether for experiential or materialistic purchasing, trump the happiness benefits of experi-

ential buying per se. Furthermore, these results can not be explained by socially desirable responding, because participants were not led to think about the potential value or drawbacks of presenting themselves either experientially or materialistically (Van Boven, Campbell, & Gilovich, 2010).

Overall, these results are consistent with recent findings that spending money on others makes people happier than spending money on oneself (Dunn et al., 2008). Although evidence suggests that merely reminding people of money distances the self from others (Vohs, Mead, & Goode, 2006), overcoming a self-reliant mindset to spend money to do or have things with others, rather than to do or have things strictly for oneself, may be an important outlet for promoting sustainable happiness (Lyubomirsky, Sheldon, & Schkade, 2005).

Paper #4: Waiter, There's a Fly in My Soup (and I Have an iPhone)! How Evaluation Timing can Impact Customer Reviews

Christine Ringler, Rutgers University, USA
Andrea C. Morales, Arizona State University, USA
Nancy J. Sirianni, Texas Christian University, USA

SESSION OVERVIEW

These papers focus upon the process of consumption in a variety of ways: by jointly investigating the discrete stages of the choice process, considering the emotions consumers feel when confronted with a stockout during a choice situation, assessing the impact of interruptions on consumption and exploring how the timing of evaluations impact the overall positivity of those evaluations. Broadly, each of the papers examines consumer satisfaction across the consumption process, predicting high levels of dissatisfaction depending upon the timing of judgment, the emotions felt or interruptions experienced during the consumption experience. The first paper (Mandel and Nowlis) emphasizes the distinction between satisfaction after choice but before consumption, compared with satisfaction after consumption. The second paper (Coleman Williams and Fitzsimons) focuses upon emotional reactions during the consumption process and their implications for decision satisfaction and downstream behaviors. The third paper (Isakman, Cavanaugh, MacInnis and Ülümen) focuses upon how curiosity-evoking interruptions to consumption can influence satisfaction levels. The fourth paper (Ringler, Morales and Sirianni) examines how the timing of when consumers provide evaluations influences consumer satisfaction. Together these papers suggest that the way in which the consumption process unfolds, rather than simply the moment of consuming the chosen item, influences consumer satisfaction in substantial ways.

The first paper in this session (Mandel and Nowlis) examines the separate and joint effects of forming expectations, making a choice and actually consuming the chosen item on consumption enjoyment. Results show that consistent with the cognitive dissonance literature, participants who formed expectations and chose, but did not consume, bolstered their choices by showing a divergence of alternatives after forming expectations. However, participants who formed expectations, made a choice, and then consumed their choice experienced lower consumption enjoyment than those in other conditions, due to the convergence of option attractiveness after consump-

tion. This research offers implications for the many studies published on the topic of dissonance, examining the degree to which the frequently obtained effect of spreading of alternatives persists after consumers have consumed their selections.

The second paper in this session (Coleman, Williams and Fitzsimons) examines the emotions consumers feel in response to experiencing a stockout. Previous research has shown that stockouts reduce decision satisfaction and lead to store or brand-switching behaviors and negative word of mouth. In this paper, the authors suggest that the effect of stockouts on satisfaction is mediated by their immediate emotional reactions to the stockout situation. Results show that consumers often feel anger and disappointment in response to a stockout and that these emotions differentially predict the actions consumers take in response to a stockout. Results suggest that consumers nearly always feel disappointed in response to a stockout but that they are likely to feel angry when the stockout affects an item they are highly committed to or when the stockout feels personal. Three studies demonstrate that consumers naturally experience anger and disappointment in response to stockouts, and that anger leads to greater levels of damaging retaliatory behaviors (e.g., store switching) while disappointment predicts choice deferral.

The third paper (Isakman, Cavanaugh, MacInnis and Ülkümen) examines the impact of increasingly common curiosity-arousing contexts on consumption experiences. Daily occurrences of ringing cell phones, incoming email notifications, or unopened mail can evoke curiosity about who is calling or writing, what they have to say, and whether there is good or bad news to be learned. Defining curiosity as a feeling of deprivation that arises when there is a gap between what one knows currently (i.e., someone is trying to get in touch with me) and what wants to know (who is it and what do they want to tell me), the paper suggests that individuals in a state of curiosity feel deprived because the resolution of the curiosity-evoking event is self-relevant but unknown to them, and may interrupt consumption in order to attend to these events. Results show that that curiosity-evoking events evoke a feeling of deprivation and a state of discomfort that motivates an impulsive search for resolution. Such information seeking behavior disrupts the consumption experience and undermines its enjoyment.

The fourth paper in this session (Ringler, Morales and Sirianni), in contrast, suggests that taking time to provide evaluations during consumption can lead to more favorable reviews and higher levels of satisfaction than evaluations provided after a delay. Results demonstrate that these effects are driven by higher levels of negative emotions at the time of delayed evaluation, suggesting that merely asking customers for feedback one week after their experiences creates negative feelings that then color consumer evaluations. Consumers find delayed evaluations to require a greater expenditure of effort as they work to recall their real-time feelings and experiences. This extra effort leads to more negative affect and thus decreased evaluations and satisfaction.

This session is likely to be of interest broadly to ACR members, including those interested in consumer satisfaction, those who study emotions, and those interested in how new technologies might influence consumer behavior. The session furthers the conference's mission of appreciating diversity in a variety of ways. While all the papers in this session focus broadly upon consumer satisfaction or

dissatisfaction as the consumption process unfolds, they approach that topic from different directions.

The Road Not Taken: The Effect of Forming Pre-Choice Product Expectations and Making a Choice on Subsequent Consumption Enjoyment

EXTENDED ABSTRACT

Consumers often form expectations about products before choosing and consuming an option. For example, a consumer attending a wine-tasting might form detailed expectations about the attributes of each wine, such as whether it will be fruity, earthy, pungent, or resinous. Will this person enjoy consuming the chosen wine more or less than someone who does not form such detailed expectations? While prior research has examined how the acts of forming expectations, choosing, and consuming can independently influence satisfaction or consumption enjoyment, this paper is the first to demonstrate that the combination of all three is both necessary and sufficient to systematically lower consumption enjoyment.

One line of prior research, based on the theory of cognitive dissonance (Festinger 1957) suggests that forming expectations prior to choice may increase consumption enjoyment, because consumers may want to defend their choice by increasing their stated preference for the chosen option. This phenomenon is known as "spreading of alternatives," because individuals indicate a higher attractiveness differential between the options after choice, compared to before choice (Brehm 1956). Although thousands of studies have been published on the topic of cognitive dissonance since the 1950s, to our knowledge not a single study has investigated whether such spreading of alternatives persists after consumers have consumed their selections. We examine this question in our studies.

A second line of prior research suggests that thinking too hard about the available options (which may occur while forming such expectations) may lower product satisfaction (Wilson and Schooler 1991). In attempt to reconcile these disparate prior findings, we propose that when consumers form expectations, consistent with the cognitive dissonance literature, the attractiveness of the two product options diverge after choice (but only when the product is not in fact consumed, as is typical in this literature). However, consistent with more recent literature (Litt and Tormala 2010), we also predict that after forming expectations, choice, *and* consumption, the attractiveness of those same two options converge; that is, the chosen option becomes less attractive and the unchosen option becomes more attractive (Carmon et al. 2003). This convergence of alternatives leads to regret and ultimately reduces consumption enjoyment.

The purpose of study 1 was to examine the joint effects of forming expectations, making a choice, and consuming that choice on option attractiveness and consumption enjoyment. We conducted a 2 (Formed expectations: Yes vs. No) x 2 (Made a Choice: Yes vs. No) x 2 (Product Consumed: Yes vs. No) between-subjects design with 436 participants who chose between two equally attractive flavors of jelly beans: Very Cherry and Green Apple. Participants in the formed expectations condition provided ratings for of how much they expected each option to be sweet, tart, refreshing, flavorful, sour, chewy, and good tasting. Participants in the no expectations condition did not give any such ratings. Participants in the choice condition chose between the two jelly beans, and participants in the no choice condition received an assigned jelly bean. Participants in the consumption condition consumed the chosen or assigned jelly bean, while participants in the no consumption condition did not consume a jelly bean.

We calculated the attractiveness differential as the difference in attractiveness between the chosen/assigned and unchosen/unassigned option. Consistent with prior research on the spreading of alternatives, the attractiveness differential was significantly larger when participants made a choice than when they did not make a choice. Furthermore, in support of our predictions, participants who formed expectations, made a choice, and consumed that choice enjoyed the product significantly less than participants who did not form expectations, but did make a choice and consume that choice. Consistent with the cognitive dissonance literature, participants who did not consume bolstered their choices by showing a divergence of alternatives after forming expectations. However, as predicted, participants who formed expectations, made a choice, and then consumed their choice experienced lower consumption enjoyment than those in other conditions, due to the convergence of option attractiveness after consumption.

One limitation of study 1 is that, unlike in classic cognitive dissonance studies, we did not look at the change in attractiveness ratings over time within a single participant. Our preliminary findings suggest a timing component; that is, consumers' ratings of two options diverge after choice, but then they converge after consumption due to regret or disappointment. In order to establish these changes over time, we implemented an experiment (otherwise similar to study 1) in which each participant rated the two product options (jelly beans) at three different time periods: after forming expectations (when applicable), after choosing, and after consuming their choice.

Our analysis revealed a replication of study 1, in which the combination of forming expectations, making a choice, and consuming that choice reduced consumption enjoyment. More specifically, participants enjoyed consuming their choices significantly less when they had first formed expectations than when they had not. Second, participants who formed expectations indeed demonstrated a significant spreading of alternatives when rating the attractiveness of the chosen option after choice (M = 4.55 after expectations vs. M = 5.33 after choice) and a significant convergence of attractiveness after consumption (M = 4.74 after consumption). This finding provides further support for the idea that the product options shift in attractiveness at various stages in the decision process.

We are currently running additional studies to uncover the cognitive process underlying these results. It is possible that consumers who bolster their choices feel disappointed after consumption due to expectation disconfirmation. Alternatively, because demonstrating spreading alternatives in preferences reduces cognitive dissonance and thus psychological discomfort (Elliot & Devine 1994; Galinsky et al. 2000), it is possible that the act of consumption reduces such discomfort, rendering this bias no longer necessary. To tease apart these alternative explanations, study 3 (ongoing) measures how well consumption of the products matched participants' expectations and their disappointment and psychological discomfort levels, as well as individual differences in regret tendencies. Study 3 also extends the findings of the first two studies to an additional product category (music).

Angry Avengers or Disappointed Deferrers: Consumers' Emotional Reactions to Stockouts

EXTENDED ABSTRACT

Stockouts are a common retail experience, with estimates in the range of an average of 10-20 percent of items being unavailable on a typical afternoon (IHL Group 2008). Given the practical importance and general prevalence of stockouts, understanding consumer responses to out-of-stocks and the costs of product unavailability has

been an area of considerable interest both in marketing and supply chain management.

The behaviors consumers engage in following a stockout can vary considerably, thus impacting key players in the chain differently: from buying another brand in the same store (hurting the manufacturer, but not the retailer) or switching to another store altogether (hurting the retailer, but not the manufacturer), to long-term effects such as negative word of mouth and reduced attitudes toward the store and the brand. Few papers have examined the underlying causes of consumer response to stockouts, or what drives consumers to choose one behavioral response over another. In this research, we seek to better understand when and why consumers retaliate with specific behaviors when encountering a stockout.

In four experiments we examine when and why stockouts impact consumers' retaliatory behaviors, focusing upon the mediational role of emotions and satisfaction jointly. We predict that two emotions will be important for stockouts: anger and disappointment. Anger tends to arise when an individual's goal progress is impeded: feels caused by another person, perceived as controllable by that other person, and seems personally directed (Frijda, Kuipers, & ter Schure 1989). Anger typically leads to active retaliation and an antagonistic response. This is in contrast to disappointment, which is caused by the situation, is perceived as uncontrollable, and is impersonal. Disappointment leads to more passive retaliation, where the individual attempts to change the situation (Zeelenberg et al. 1998).

We examine when consumers are likely to experience anger versus disappointment in response to a stockout and how those discrete emotions lead to different patterns of retaliatory behaviors toward a retailer or brand. With this focus, we look more deeply at the psychological processes that mediate stockout experiences on consumer evaluations and reactionary behaviors. Results demonstrate that consumers naturally experience anger and disappointment in response to stockouts, and that anger leads to greater levels of damaging retaliatory behaviors (e.g., store switching) while disappointment predicts choice deferral.

In a first exploratory study, we examine whether consumers naturally discuss stockout experiences in emotional terms, and specifically if anger and disappointment are innate reactions to an out-of-stock situation. Participants were asked to recall and describe their most recent stockout experience. Participants described a variety of stockout situations, across different retailers, for items at different price levels. Across their open-ended responses, 60% of respondents mentioned experiencing an emotion in response to a stockout: specifically, 40% of respondents experienced disappointment, while 16% mentioned feeling angry or furious, and two respondents (4%) mentioned another emotion—panic. Thus, more than half of the respondents mentioned emotions in their discussion of stockouts.

The second study sought to manipulate aspects of the stockout situation in order to determine the underlying causes of the different emotional reactions—and whether each emotion predicts a specific punitive response. Participants completed an engaging online shopping task in which they were purchasing a cake to take to a dinner party. Two factors were manipulated: the availability of their preferred cake (in-stock, out-of-stock), and their commitment to the preferred cake (high, low). Following the cake purchase situation, participants completed a variety of measures, including: emotion ratings, their satisfaction with the decision process, likelihood of returning to the bakery in the future (store switching), and what they would tell their friends about the bakery (word-of-mouth). Participants' feelings of anger were affected by availability, such that participants who experienced a stockout were significantly angrier than those whose cake was available; this result is qualified by a significant interaction of

availability and commitment, such that when their cake was out-of-stock, highly committed participants were angrier than those with low commitment to the out of stock item. On the other hand, disappointment was only affected by availability—commitment did not amplify consumers' feelings of disappointment. Similarly, decision satisfaction was also only impacted by availability; unsurprisingly, participants whose preferred cake was out-of-stock experienced lower satisfaction with their decision.

In the third study, the personalization of the stockout announcement was manipulated such that participants entered their name at the beginning of the study, and then—upon reaching the checkout counter—the baker told them that he would never sell their preferred cake to a person with the subject's name (personal), or simply that he had already sold the last one of their preferred cake (impersonal). Participants were more angry when the stockout was personal (M = 5.56) than impersonal (M = 4.50; F(1, 254) = 14.659, p < .001), yet disappointment was equal across the two conditions (Mpersonal=4.43, Mimpersonal=4.06, p > .75). Similarly, individuals who felt personally targeted for the stockout were less likely to return to the bakery (M = 30.01) than those who received an impersonal stockout (M = 51.91; F(1, 254) = 27.196, p < .001), and this result was mediated by feelings of anger (z = -2.48, p < .05). This study demonstrates that with higher commitment comes greater anger, which then leads to retaliatory behaviors; while disappointment remains constant.

In Study 4 participants complete the same cake shopping scenario but we manipulate their commitment level by having them first specify what cake they would buy (chocolate, carrot, or fruit) and, in the high commitment condition, write about why that cake would make a good gift. Also, in this study, after experiencing a stock-out of their preferred cake participants were given the option of either choosing another in-stock cake or indicating they would choose to go to another bakery altogether. As in the previous studies, highly committed participants were more angry (M = 4.39) than low commitment (M = 3.44; F(1, 145) = 7.622, p < .01). Interestingly, disappointment was also higher in the high commitment condition (M = 3.88) than the low (M = 3.28; F(1, 145) = 5.154, p < .05). Commitment also affected the likelihood that an individual would choose to go to a different store, such that high commitment led to a higher likelihood of store switching (β = 1.519, p < .001). Anger ratings partially mediated the effect of commitment on store switching (z = -1.817, p = .062), while disappointment ratings did not (z = 1.54, p > .15).

These studies tell a consistent story of emotions in reactions to stockouts: anger and disappointment are integral to the experience of stockouts. In particular, as an individual becomes more committed to a particular option, the likelihood of experiencing anger increases. Importantly, experiencing anger predicts whether the individual will switch stores—seen in the repeated mediation of commitment on store switching by anger. Interestingly, disappointment seems to be a relatively invariant component of stockout experiences: few aspects of the stockout situation changed the experience of disappointment, suggesting that *any* stockout will lead to disappointment. Understanding what emotions a consumer will experience upon encountering a stockout has implications for predicting the downstream retaliatory behaviors, as well as suggesting courses of action that stores can take to reconcile with consumers.

The Effects of Curiosity on Consumption Enjoyment

EXTENDED ABSTRACT

Consumers increasingly face curiosity-arousing contexts. For example, daily occurrences of ringing cell phones, incoming email

notifications, or unopened mail can evoke curiosity about who is calling or writing, what they have to say, and whether there is good or bad news to be learned. Consistent with Loewenstein (1994), we define curiosity as a feeling of deprivation that arises when there is a gap between what one knows currently (i.e., someone is trying to get in touch with me) and what wants to know (who is it and what do they want to tell me). Individuals in a state of curiosity feel deprived because the resolution of the curiosity-evoking event is self-relevant but unknown to them.

Despite the prevalence of curiosity evoking events in consumers' lives, limited consumer behavior research has focused on the effects of curiosity. We ask the novel question of whether and to what extent the interruption of a consumption episode (i.e., a dinner, a nice drive, a movie, a massage, a concert, a book) by a curiosity-evoking event (i.e., a ringing cell phone) impacts enjoyment of the consumption experience.

On the one hand, prior research shows that interruption can increase consumption enjoyment. Specifically, (Nelson and Meyvis 2008) showed that breaks increase enjoyment with positive experiences and decrease enjoyment with negative experiences. Their theorizing is based on the notion that breaks disrupt hedonic adaptation and intensify the consumption experience. Based on this research, one might expect that a curiosity-evoking event that interrupts a consumption experience might enhance consumption enjoyment.

However, we predict the opposite. Our theoretical framework suggests that curiosity-evoking events do more than interrupt. By evoking a feeling of deprivation they create a state of discomfort about the gap between what one knows and what wants to know. They motivate an impulsive search for resolution. Indeed, prior research confirms that when in a state of curiosity, consumers seek information and are more responsive to that which is received (Menon and Soman 2002; Steenkamp and Baumgartner 1992). Such information seeking behavior disrupts the consumption experience and may undermine its enjoyment. Moreover, social forces (norms against answering phones or emails while dining with others), legal forces (laws against texting while driving) or physical limitations (phones that are out of reach during a massage) may prohibit information resolution. Under such circumstances we anticipate that individuals ruminate about the curiosity-evoking event and that such rumination further undermines consumption enjoyment.

One field study and two experiments provide preliminary evidence consistent with these predictions. In study 1, Three hundred individuals completed a short survey immediately following movie screenings. Respondents were asked to evaluate their enjoyment of the movie and whether or not they received calls, emails or texts during the movie itself. The results indicated that participants enjoyed the movie significantly less, if they checked their phones or received a phone call during the movie. Although correlational, this study provides some preliminary evidence that a curiosity-evoking event reduces consumption enjoyment.

Study 2 provided a more rigorous test of the link between curiosity and consumption enjoyment. Specifically, study 2 was designed to determine whether the observed effects were attributable to curiosity and not merely distraction. Seventy-seven individuals were randomly assigned to one of three experimental conditions (curiosity, distraction, or control). All respondents were seated in a comfortable chair and asked to evaluate a foot massager by having a 3-minute foot massage. Respondents' belongings, including their cell phones, were placed nearby but beyond reach. In the curiosity condition, we called participants' cell phones during the massage experience. In the distraction condition, we remotely operated a fan located near the participant. Respondents in the control condition heard no inter-

ruption. At the conclusion of the massage, participants rated their enjoyment. As hypothesized, enjoyment of the foot massage was significantly lower in the curiosity condition than in the distraction and control conditions, which were equivalent. The results of study 2 suggest that curiosity-evoking events can decrease consumption enjoyment, and this effect is not driven by pure distraction.

Study 3 was designed to provide a conceptual replication and extension our findings by examining the process underlying the relationship between curiosity and consumption enjoyment. Study 3 offers an initial test of whether curiosity's effect on enjoyment is explained by attention to and rumination about the curiosity evoking event. Eighty-six participants were randomly assigned to curiosity, distraction or control condition. Participants were asked to play a Mario Kart Nintendo Wii driving game for four minutes. In the curiosity condition, respondents placed their cell phones on a table next to the chair at which they were seated. To evoke curiosity, we called respondents on their cell phone once while they played. In the distraction condition, we placed an iPod on the same table by respondents' chairs and created a distraction by remotely starting the iPod. Immediately following the game, respondents were asked to rate their enjoyment of the game. Consistent with study 2, we found that enjoyment with the videogame experience was significantly lower in the curiosity than in the distraction and control conditions, which did not differ. To measure attention, we coded participant behavior, i.e, whether and how frequently they looked at their cell phones or iPod. Meditation analyses showed that attention mediated the effect of curiosity on enjoyment.

Although work in progress aims to further explore the mechanism driving our results, the current findings add to our understanding of the effects of curiosity. Importantly our work suggests that curiosity negatively impacts consumption enjoyment, has different effects on consumption experiences compared to simple distractions or interruptions, and that its effects are driven by a rumination mechanism that takes attention away from the consumption experience. To the best of our knowledge, this work is the first to examine curiosity in a context independent of the focal consumption experience. Hence, our findings also contribute to the incidental emotion literature by showing how curiosity that is unrelated to the focal task impacts overall enjoyment.

Waiter, There's a Fly in My Soup (and I Have an iPhone)! How Evaluation Timing can Impact Customer Reviews

EXTENDED ABSTRACT

Mobile technology and reviewer-driven applications like Yelp!, Citysearch and Amazon.com enable customers to evaluate products and services in real-time. According to the head of mobile applications at Citysearch, the practice of real-time reviewing is beneficial for customers because it empowers them to express what they are currently feeling as they use products and receive services. Further, Citysearch views immediate evaluations as more honest and informative than those written after a delay, thereby increasing their value to consumers who use posted reviews in their own decision-making (Miller 2009). While immediate evaluations can prove beneficial to consumers, what does this mean for the companies being reviewed and whose reputations are at stake? Generally speaking, how does timing affect the valence of consumers' product, service and brand evaluations? Are ratings more positive (negative) when they are written in the heat of the consumption experience, or after a delay, when the experience has ended and customers have had some time to cool off?

Across four studies, we provide strong evidence supporting our theory about the role of delayed feedback timing and its negative effect on consumer attitudes. When consumers give feedback about a product or service consumed after a time delay has occurred (vs. in real-time), they should report more negative evaluations of the experience, lower levels of satisfaction, and more negative affect. In contrast, when products or services are evaluated in real-time, overall evaluations and satisfaction are higher, regardless of product or service quality.

The goal of study 1 is to investigate how evaluation timing impacts consumer evaluations regardless of the quality of the consumer's actual service experience. As such, in study 1, a quasi-field study (using a pizza delivery company), we ran a 2x3 between-subjects experimental design with feedback timing (immediate vs. delayed) and quality of the service delivered (substandard vs. standard vs. above standard) as the experimental factors. We randomly assigned participants to one of the six conditions for a total of 164 undergraduate students who received course credit for their participation. We uncover evidence to support a delayed feedback effect whereby participants report lower satisfaction with their service experiences and more negative attitudes toward the company that delivered those experiences when feedback was submitted one week after the service encounter as compared to instances when feedback was submitted immediately following the service encounter.

The main objective of the second study is to extend our findings beyond service contexts to the lower involvement consumption context of everyday consumer packaged goods (paper towels). In Study 2, we ran a 2x2 between-subjects experimental design with feedback timing (immediate vs. delayed) and quality of the paper towel (low vs. high) as the experimental factors. Specifically, in study 2 we seek to determine whether the same findings are observed with the evaluation of something as basic as a paper towel, while broadening our investigation to look at whether affect is also affected in the delayed feedback conditions. The findings of study 2 provide additional support for the existence of a delayed feedback effect. Consistent with study 1, we found that when feedback was elicited after a delay, evaluations of the product and likelihood to purchase that product were lower than when feedback was elicited immediately following the product sampling experience. We are able to demonstrate that it is not the baseline mood at the time of product interaction that is coloring the evaluation. Rather, Study 2 demonstrates that the negative emotions reported by study participants were significantly more prevalent at the time of the delayed evaluation (time 2) over what was reported at the baseline (time 1). This lends support to the idea that merely asking customers for feedback one week after their experiences creates negative feelings and these color consumer evaluations.

The primary goal of Study 3 is to gain a better understanding for why, when soliciting customer feedback after a delay, a decrease in product and service evaluations occurs. Namely, we are interested in the amount of perceived effort by the consumer when completing the evaluation at time 2. Study 3 also extends our contribution by examining the effectiveness of incentives offered to customers for taking part in follow-up surveys, such as nominal gift cards. We randomly assigned seventy-three undergraduate participants to a one-factor (incentive: no incentive vs. gift card) between-subjects experimental design. Evaluation timing was held constant in this study in that all participants were asked to evaluate products after a delay. Consistent with studies 1 and 2, results indicated that evaluation and satisfaction at time 1 were significantly higher than at time 2. Additionally, results indicated that the perceived effort at time 1 was significantly lower than the perceived effort at time 2. Thus, as hypothesized, participants perceived there to be more effort expended when they were asked to complete a survey one-week after the consumption experience as compared to when they were asked to complete a survey during the experience. This resulted in decreased satisfaction and decreased evaluations of the product. Additionally, it appears that participants expect some type of incentive when completing a follow-up survey, but by offering a small two-dollar gift card, participants' need for an additional incentive decreases significantly.

The main objective of study 4 was to gain a better understanding of the underlying process. We test evaluation of the paper towels via a quality manipulation in either real-time or after a delay. Additionally, we measure perceived effort as a potential mediator for those in the delayed feedback condition. Consistent with the previous studies, we find evaluations of the product to be lower in the delayed feedback condition, regardless of paper towel quality. Additionally we find perceived effort to be higher when feedback is delayed versus immediate. In the open-ended portion of the survey, participants indicated that they perceived effort to be higher in the delayed feedback condition because it was difficult to recall the exact feeling and experience of the product when it wasn't directly in front of them. Together this set of results confirms our proposed theory that by asking for feedback after a delay, perceived effort increases, resulting in lower evaluations and decreased levels of satisfaction for products, services, and firms.

Conflicted Choices: New Perspectives on Choice Conflict

Chair: Andrea Bonezzi, New York University, USA

Paper #1: When Two is Better than One: Polarization and Compromise in Unrestricted Choice

Gülden Ülkümen, University of Southern California, USA

Paper #4: Choice Overload with Repeated Choice Exposures: The Role of Preference Retrieval and Variety

Simona Botti, London Business School, UK
Sheena Iyengar, Columbia University, USA
Yangjie Gu, London Business School, UK

SESSION OVERVIEW

In many everyday decisions consumers experience choice conflict, stemming from the need to make difficult trade-offs between the available choice alternatives. Understanding how consumers chose when faced with decision conflict is important because their choices ultimately influence their happiness and well being. Prior research suggests that experiencing choice conflict might lead consumers to choose a compromise option that provides moderate levels of performance on all desired attributes (Simonson 1989; Simonson and Tversky 1992), defer choice and avoid purchasing any of the available options (Dhar 1997; Tversky and Shafir 1992), or seek variety and purchase multiple options (Simonson 1990). This special session aims to advance our understanding of how consumers deal with decision conflict. The four papers offer a diversity of innovative perspectives that enhance the breadth of our knowledge in this area of research, providing a coherent yet diverse set of findings.

The first paper, by Bonezzi, Chernev and Brough, argues that the strategy consumers use to resolve decision conflict is contingent on purchase quantity restrictions. In particular, this paper shows a polarization effect, whereby, when purchase quantity is not restricted to a single option, consumers tend to resolve decision conflict by choosing multiple options with extreme attribute values rather than a single compromise alternative. This polarization effect in unrestricted choice is attributed to consumers' desire to resolve decision conflict by maximizing gains rather than minimizing losses.

The second paper, by Sela and Simonson, argues that certain features of a choice problem can prompt consumers to deal with choice conflict by adopting either compensatory (trade-off based) or lexicographic (criterion-based) decision strategies. In particular, attribute frames that appear generic and not unique to the choice-set being evaluated induce criterion-based decision-making. In contrast, attribute frames that make the attributes seem local and relevant to the particular problem at hand induce tradeoff-based decision-making. Notably, while criterion-based decision strategies lead to selection of compromise alternatives, tradeoff-based decision strategies lead to selection of extreme alternatives.

The third paper, by Malkoc and Ülkümen, argues that the degree of decision conflict consumers experience when choosing among two or more products can be influenced by the comparison focus adopted. In particular, focusing on the similarities among the available choice alternatives increases decision conflict, compared to focusing on the differences among the available choice alternatives. Importantly, this paper shows that the width of the categories to which consumers are exposed before making a choice influences the comparison focus they will adopt for the choice at hand, thus influencing decision conflict.

The fourth paper, by Botti, Iyengar and Gu argues that psychological conflict stemming from choosing from larger versus smaller choice sets can be mitigated by repeated choice exposures. Repeated choice exposures reduce conflict by increasing familiarity with the choice task and allowing consumers to retrieve previously-established preferences, thus decreasing the cognitive and emotional conflict associated with perusing a great number of options in larger choice sets. However, when consumers cannot retrieve their initially established preferences, the choice overload effect reverses and choosing from smaller sets generates less decision confidence than choosing from larger sets.

Taken together, these four papers advance our understanding of how consumers make decisions under conflict. Overall this session offers a coherent set of innovative perspectives that enhance the breadth of our knowledge in an established area of research. We expect this session to appeal to a broad audience, and be of particular interest to researchers studying choice and decision making. Data collection in all papers is complete, or at an advanced stage of completion. All participants have agreed to present, should the session be accepted.

When Two is Better than One: Polarization and Compromise in Unrestricted Choice

EXTENDED ABSTRACT

When faced with a decision involving tradeoffs between the available choice alternatives, consumers often attempt to resolve decision conflict by selecting a compromise option (Simonson 1989; Simonson and Tversky 1992). In particular, prior research on the compromise effect has shown that the choice share of an option increases when it becomes the middle alternative in a choice set, rather than one of the extremes (Kivetz, Netzer, and Srinivasan 2004). Choosing a compromise option resolves conflict by enabling consumers to minimize tradeoffs between attributes of the available options by avoiding the lowest levels of performance on any single attribute (Simonson and Tversky 1992).

Most of the existing research on the compromise effect, however, has investigated situations in which consumers are restricted to choosing a single alternative from a given set of options (Benartzi and Thaler 2002; Dhar and Simonson 2003; Simonson and Nowlis 2000). In reality, however, purchase quantity is often discretionary and consumers frequently choose multiple items. This raises the question of whether and how removing the single-option restriction from the choice task will influence consumer preferences for how to resolve decision conflict.

In this research, we argue that when choice is unrestricted, consumers tend to resolve decision conflict by choosing multiple options with extreme attribute values rather than a single compromise alternative. We propose that this polarization effect is a function of the degree of decision conflict experienced by consumers. In par-

ticular, we argue that preference for multiple extreme options is more pronounced when decision conflict is high rather than low, a prediction opposite to previous findings in the context of restricted choice, which show that heightened decision conflict increases preference for the compromise option at the expense of the extremes. We attribute this polarization effect to consumers' desire to maximize gains on each attribute, rather than settling for intermediate performance on both.

We documented this polarization effect in unrestricted choice across three empirical studies. In experiment 1, we documented the polarization effect by showing that that when choice is unrestricted, choice share of the compromise option declines as consumers opt to resolve decision conflict by selecting multiple extreme options rather than a single intermediate one. Consistent with the compromise effect, choices across four product categories showed that when participants could select only one of three available options (ABC), preference for B was higher than when the set consisted only of AB or BC. However, when participants were permitted to select two options, preferences shifted toward the combination AC rather than B. For example, in the headache medications category, participants were shown three options which varied in how quickly they relieved pain (onset) and how long they lasted (duration). In restricted choice, people preferred medication B, which had a moderate onset and moderate duration. However, in unrestricted choice, preference for B declined and instead people preferred a combination of two extreme medications—A, which had the shortest onset but shortest duration, and C, which had the longest onset but longest duration. This polarization effect was consistent across each of the four categories tested.

In experiment 2, we provided evidence that choice conflict drives this polarization effect by showing that the polarization effect becomes more pronounced as decision conflict increases. We manipulated conflict by varying the range of attribute values of the two extreme options (A and C) while holding constant the attribute values of the compromise option (B). For example, in the sunscreen category, the difference in UVA protection between the two extreme options A and C was 40% in the low conflict condition but 80% in the high conflict condition. These results are consistent with our theory that the polarization effect occurs as consumers attempt to resolve conflict differently in unrestricted versus restricted choice.

In experiment 3, we provided further evidence for the underlying process by showing that the polarization effect is more likely to occur when consumers focus on maximizing gains rather than minimizing losses. Prior to articulating their preferences, participants in one condition listed the advantages of each option in the choice set, whereas participants in another condition listed the disadvantages of each option. Results indicated that the polarization effect in unrestricted choice was attenuated among participants who focused on the disadvantages rather than on the advantages of each option.

The present research provides an important contribution to the literature on choice conflict and the compormise effect. Contrary to prior findings that in restricted choice consumers attempt to resolve decision conflict by selecting a compromise option, we show that in unrestricted choice, consumers are less likely to select the compromise option and instead display a preference for extreme options. Our results further suggest that the greater the conflict a consumer experiences when deliberating about the different choice options, the more likely he is to choose multiple extreme options rather than a single intermediate one when choice is unrestricted. From a conceptual standpoint, our findings lend support to the notion that the polarization effect occurs because people wish to resolve conflict by maximizing gains; polarization is likely to occur when people focus

on the advantages of having both options, but is likely to be attenuated when people recognize the disadvantages of choosing extreme options.

By Tradeoff or by Criterion: Bottom-Up Construction of Constructive Decision Rules

EXTENDED ABSTRACT

When faced with a choice problem, decision makers often engage in tradeoffs to identify the best option. Alternatively, they may first identify the more important attribute(s) and then proceed to select the best option given these criteria. These strategies roughly correspond to compensatory and lexicographic decision strategies, respectively, which have been discussed extensively in the JDM literature (Bettman, Luce, and Payne 1998).

However, whereas the traditional view sees the choice between such decision strategies as a top-down process, largely determined by people's information processing goals (e.g., balancing accuracy vs. cognitive effort, minimizing negative emotion, or maximizing ease of justification; Bettman et al. 1998), we propose that the tendency to focus on tradeoffs versus criteria can be driven by bottom-up features of the choice problem itself. That is, certain problem domains and attribute frames may cause decision makers to focus on tradeoffs, whereas others call for use of generic criteria.

Moreover, choice based on criteria (i.e., the lexicographic strategy) itself has generally been treated as contingent on people's ability to recruit relevant beliefs and preferences in a top-down manner, either from memory or from other available sources (e.g., a consumer may choose based on the belief that reliability is the most important attribute for a car). However, we demonstrate that people may use the lexicographic strategy and choose based on criteria even when they cannot retrieve or otherwise rely on meaningful preferences and values. Namely, criterion-based decision making may be driven not only by the availability of relevant criteria but by a metacognitive belief that one should have consistent priorities in a certain domain.

We identify two bottom-up factors that influence the choice between tradeoff- and criterion-based decision-making. First, we argue that attribute descriptions or frames that appear generic and not unique to the choice-set being evaluated, tend to induce criterion-based decision-making. In contrast, attribute frames that make the attributes seem local and relevant to the particular problem at hand induce tradeoff-based decision-making. In addition, we show that dispositional and situational influences (e.g., nonconscious primes) can induce tradeoff- versus criterion-based decision-making, causing people to use lexicographic strategies even in the absence of applicable criteria.

We demonstrate these propositions in five studies using the compromise effect (Simonson 1989; Simonson and Tversky 1992). Prior research has demonstrated that selection of the compromise (i.e., middle) alternative typically reflects compensatory tradeoff-making (Dhar, Nowlis, and Sherman 2000; Khan, Zhu, and Kalra 2011). In contrast, choice of an extreme option is more likely to reflect criterion-based selection (i.e., the belief that one attribute is more important).

In study 1, we show that three-option choice problems involving generic attributes tend to produce extreme choices whereas problems in which the attributes seem more local and relevant only to the specific product at hand lead people to choose the middle option. Further, we show that the tendency to compromise is stronger among people high in self-monitoring (Snyder 1987), whereas the tendency to select an extreme option is stronger among low self-monitors. This suggests that the tendency to use a tradeoff versus criterion-

based strategy may be influenced by general individual dispositions that affect the tendency to base decisions on situational cues versus inner attitudes and beliefs.

In study 2, participants were primed with words related to either calculation (e.g., compute, exchange), principles (e.g., faith, opinion), or neutral words (e.g., birds, fabulous). Then, they made choices from a number of three-option choice-sets. The results indicate that, whereas the calculation prime increased the tendency to select the middle option compared to the control condition, the principles prime increased the tendency to select an extreme option. Thus, a mere "principles mindset" caused people to employ a criterion-based decision strategy.

One might argue that a principles prime and low self-monitoring decrease the tendency to choose the middle option because they lead people to reflect on their preexisting attitudes for familiar options. However, study 3 demonstrates that these effects are independent of existing attitudes by using a truly hypothetical product with hypothetical attributes. We first primed half of the participants with principles by having them write about a situation in which their decision was strongly influenced by personal values and principles. The other half served as control group. We then asked participants to choose among three made-up options differing on two made-up attributes. Whereas 82% chose the middle option in the control condition, this decreased to 64% in the principles prime condition ($p < .06$). Taken together, these results suggest that criterion-based decision-making may be driven in part by a metacognitive notion that one has or should have relevant criteria in a certain domain, independent of the actual availability of such criteria.

Study 4 demonstrates how specific task characteristics can activate one mode of preference construction versus the other. Before making choices, some participants rated the importance of each of the two attributes that define the choice set on two separate scales (one for each attribute), which highlights the distinct goal underlying each polar dimension. Others rated the attributes on a single bi-polar scale, which highlights the tradeoff between them. The results indicate that participants who rated the attributes separately were more likely to choose an extreme option compared to a control condition, whereas those using a single bi-polar scale were more likely to choose the middle option.

Our last study (in progress) examines how the framing of attributes as generic (e.g., capacity and portability for a BBQ grill) versus local (e.g., cooking area and weight) induces criterion- versus tradeoff-based decision-making, respectively, resulting in increased choice of extreme options versus an increase in the choice of the compromise option.

Taken together, the studies make an important contribution by demonstrating that the choice of decision strategies itself may be constructed, based on bottom-up factors rather than top-down information processing goals.

Blurring Similarities and Differences: The Role of Category Width on Salient Comparison Orientation

EXTENDED ABSTRACT

Almost all purchase decisions consumers make involve a comparison between two or more products. When purchasing a car, computer, or even a wristwatch, consumers focus on either the similarities or differences between options. Retailers often strategically sway what consumers pay attention to (e.g., a salesclerk pointing out similarities or differences), hoping to influence their ultimate choice. We suggest that the adopted comparison focus have important implications for whether two products are perceived to be similar or different - regardless of their objective similarity. Furthermore, consumers' perceptions of product similarity have other important consequences on decision conflict and preference strength. For instance, to the extent that consumers view options as similar, they would have a harder time differentiating them and thus increasing their choice difficulty, decreasing their strength of preference and influencing their willingness to pay for options.

Previous literature suggests that certain contexts make similarities or differences relatively more salient and the decision makers are likely to adopt this salient comparison focus in their evaluations. However, this research is mute on whether there is any factor that would lead consumers to deviate from this salient focus. We argue that while important, contextual salience might not be sufficient in understanding why consumers adopt or not adopt a salient comparison focus. In particular, we examine how the width of categories consumers have been previously exposed to (Ulkumen, Chakravarti, and Morwitz 2009) would influence the adaptation of salient comparison focus.

Our theory suggests that being exposed to narrower (broader) categories leads to use of more (less) dimensions in evaluations and decisions (Ulkumen et al. 2009). Accordingly, we argue that while the uni-dimensional broad categorizers will follow the cues given by the context and adopt the salient comparison focus, while the multi-dimensional narrow categorizers will attend to both similarities and differences – regardless of the salient cues in the environment. We also show that this shift in comparison focus alters perceptions of similarity, and influence choice conflict, evaluations of a new product offering, and preference strength.

In study 1 (N = 86) participants first completed the category width (CW) manipulation, where they responded to questions about themselves that had either many, narrow response categories (narrow condition), or few, broad response categories (broad condition). Next, they considered two backpacks, which were described by a salesclerk as either similar to or different from each other. Participants made a choice and reported their relative consideration of the similarities and differences between these products while making their choice. We found that CW moderates the effect of salient orientation on consideration of similarities and differences. That is, while the broads adopt the focus (similarities *or* differences) suggested by the context, narrows are less sensitive to the context and consider both similarities *and* differences.

Study 2 (N = 108) extended this effect to similarity perceptions as it pertains to multi attribute products. Participants first completed the same CW manipulation. Next, they made choices between two target products in three categories (beer, TV, car). Target products were presented together with two additional products that either had more extreme attribute values (designed to make the target products more similar) or fell between the target products (and made the target products appear more different). Participants indicated their perceived similarity of the two products, both on attribute level and overall. We find that while broad categorizers adopted the salient cue and thus found the options more similar (dissimilar) when the surrounding options were extreme (in between), the similarity judgments of the narrow categorizers were uninfluenced by the salient cues.

In study 3 (N = 92), we explored the downstream consequences of this effect to consumers' strength of preference and decision conflict. Participants first completed the same CW manipulation. Next, they saw a furniture catalog and made a choice between two target chairs. We manipulated salient comparison focus by visually varying the background chairs to be either similar or different from target chairs. Participants reported their decision confidence and conflict,

preference strength, and their relative consideration of similarities and differences. As expected, we found that board categorizers who focus on the salient similarities (differences) experienced higher (lower) decision conflict, and lower (higher) confidence and preference strength. As expected, this was not the case for narrow categorizers. Moreover, these effects were mediated by the relative consideration of similarities and differences.

Lastly, in study 4 (N = 84) we investigate a different context where similarity perceptions are of utmost importance. We explore consumer's responses to a stock out, where the new alternative offered is either similar to or different from their original selection.

Participants completed a different manipulation of CW, followed by a choice among several backpacks. They were told their selection was out of stock and were offered an alternative backpack, which was either objectively similar to or different from their selection. We measured participants' attitudes toward the new backpack, and their consideration of similarities and/or differences while choosing. As before, we found that the focus manipulation influenced attitudes only for broad categorizers, such that participants liked the new offering more when they focused on its similarity to the original backpack, than when they focused on its difference. Moreover, as in study 3, relative consideration of similarities and differences mediated the effect.

In four studies we show that the experienced choice conflict, preference strength and product evaluations are significantly influenced not only by the salient comparison orientation, but also by the width of categories consumers are previously exposed to in an unrelated context. Using multiple manipulations of similarity orientation, we demonstrate that consumers exposed to broad categorizations experience more choice conflict when a similarity (vs. difference) orientation is made salient. In contrast, consumers exposed to narrow categorizers consider both similarities and differences between products regardless of the salient comparison orientation.

Choice Overload with Repeated Choice Exposures: The Role of Preference Retrieval and Variety

EXTENDED ABSTRACT

Research on choice overload has shown that the psychological conflicts involved in choosing from larger, versus smaller, sets can decrease satisfaction and decision confidence (Iyengar and Lepper 2000). And yet, in real life consumers seem able to cope with large assortments better than researchers would expect, as they not only regularly make choices from these assortments, but also demand more choices and variety. How can we reconcile consumers' apparent ability to handle extensive choice with the evidence for its detriments? One possibility is that participants in choice overload studies are typically asked to make one-shot decisions, whereas in real life consumers often have the option to make repeated choices over time. One may expect that repeated choice exposures mitigate choice overload. Larger sets, relative to smaller ones, increase the likelihood of finding the option that best matches individual preferences because of their greater variety. In the one-shot decisions investigated in choice overload, this benefit is overwhelmed by the higher level of cognitive and emotional conflict associated with perusing numerous, versus fewer, options, which results in lower decision confidence. In contrast, it is plausible that repeated choice exposures reduce conflict by increasing familiarity with the choice task (Alba and Hutchinson 1987), and therefore enhance consumers' confidence with decisions made from larger sets.

In this paper, however, we hypothesize a more complex relationship between repeated choices and decision confidence, and specifically that this relationship depends on the interaction between preference retrieval and variety. When the preferences expressed in an initial choice cannot be retrieved in a subsequent choice, lower variety will progressively reduce the confidence of consumers choosing from smaller, relative to larger, sets and reverse the choice overload effect. In contrast, when these preferences can be retrieved, these consumers' original greater confidence will persist over time despite lower variety.

We build this hypothesis on two findings. First, consumers construe their preferences based on the available alternatives and tend to retrieve these initial preferences when making subsequent choices (Hoeffler and Ariely 1999). Second, variety is less important when preferences are more clearly established, as in the case of small-set choices, than when they are more uncertain, as in the case of large-set choices (Simonson 1990). If consumers cannot retrieve their preferences in subsequent choices, for example because the initial selection becomes unavailable, they need to re-engage in the choice task and re-construct their preferences. For consumers choosing from smaller, relative to larger, sets, repeated exposures to the choice task are unlikely to further reduce the already low level of decision-related conflicts; rather, reiterated attempts to preference construal will just heighten the disadvantages of limited variety (Chernev 2003) and gradually reduce their higher initial confidence. Conversely, if the preferences initially construed can be retrieved at a later time, these consumers' original greater confidence is unlikely to be negatively affected by low variety. Consumers choosing from smaller, versus larger, sets will be more likely to simply retrieve those preferences without re-engaging in the choice task, thereby maintaining their initial relative superior confidence over time.

We test these predictions in two studies. In the first study, we prevented participants from retrieving their preferences and expected a reversal of the choice overload effect. Participants were exposed for 10 subsequent days to the same selection of iTunes, either 300 songs (large-set condition) or 30 songs (small-set condition). Each day, participants were emailed a survey. The first part of the survey assessed their satisfaction with the song chosen in the previous day, the second part required them to choose another song, and the third part included questions about the choice-task difficulty. Because each selected iTune was downloaded on participants' computers, they had to re-engage in the choice task at each exposure. Consistent with choice overload, on the first exposure participants reported greater difficulty and stress, and lower decision confidence, in the large-, versus small-, set condition. Over the subsequent nine exposures, the choice process became easier and less stressful for participants confronted with a larger, relative to a smaller, set. As predicted, decision confidence decreased in the small-, as compared to the large-, set condition, and on the last exposure choosing from a smaller set generated lower confidence than choosing from a larger set.

In the second study we allowed participants to repeat their choices. This study involved five choice exposures on five consecutive days to the same selection of chocolates that was either large (large/same: 50) or small (small/same: five), such that participants were free to choose the same chocolate in different days. We confronted these two conditions with a third one that, similar to the large-set condition in study 1, offered greater variety but no possibility for preference retrieval. In this third condition, participants were also exposed to a small set of five chocolates, which however changed every day, forcing participants to re-engage in the choice task at each exposure (small/different). Each day participants chose a chocolate from one of the three sets, tasted it, and answered a questionnaire similar to the one employed in study 1.

Consistent with choice overload, on the first exposure choosing from both smaller sets was considered easier, less stressful, and conducive to greater decision confidence than choosing from the larger set. Over repeated exposures, choosing became increasingly easier and less stressful for participants in the large-set condition than for those in both small-set conditions. As we predicted, however, decision confidence remained higher in the small/same condition relative to the large/same condition, indicating that the choice overload effect persisted over time. In addition, in line with previous results, participants in the small/different condition became increasingly less confident relative to those in the other two conditions, indicating that variety is less important when preferences can be retrieved.

In conclusion, these results suggest that choice overload can be mitigated by repeated choice exposures, but only when consumers cannot settle on the preference they have construed within the initial choice-set boundaries.

SESSION OVERVIEW

Beliefs about others' preferences, attitudes, and valuations are an important element in consumer decision-making (West 1996). We rely on these beliefs in a variety of strategic situations, from gift giving to pricing, from product adoption to voting, from word of mouth to bidding and negotiations. A large literature on social projection finds that people egocentrically estimate positions they themselves endorse as more common than positions they don't endorse (Lord, Lepper & House, 1979; Marks & Miller, 1987; Mullen, et al., 1985).

However, beyond this basic effect, little research has attempted to illuminate the interplay between one's own preferences versus what is known, hypothesized or inferred about others, when estimating others' preferences and making strategic choices. This represents a critical gap in our understanding, as our choices and decisions are rarely formed in a vacuum but instead usually involve incorporating our (incomplete) knowledge of others. The papers in this session investigate this important emerging topic and find that prior research on beliefs about others does not account for the ways that reasoning about others changes when taking into account what is known or assumed about others.

In the first paper, Orhun and Urminsky investigate estimates of others' evaluations of the choice options, when others' choices are known (e.g., for others making the same or opposite choice relative to the self). They find evidence of conditional projection, such that a person's evaluation of the option she chose influences her beliefs about how others evaluated either the same or opposite options that they, respectively, chose. This projection of corresponding evaluations to opposite choosers, in particular, suggests a process of analogical reasoning about others that is incompatible with prior accounts of social projection and false consensus.

In the second paper, Gershoff and Broniarczyk look at conditional inferences in advice giving. They find that the influence of what is known about others on one's own preferences and the influence of one's own preferences on estimates of others can be confounded in people's minds. As a result, consumers are prone to systematic errors in conditional probability estimates involving their own preferences consistent with differences in the accessibility and diagnosticity of

the relevant sample space for the task. Consumers are more accurate when making probability judgments associated with giving recommendations (compared to receiving them), particularly when the conditioning information was not attribute based.

In the third paper, Frederick investigates the effect of aggregating hypothetical conditional estimates about different types of others, when making judgments regarding aggregate quantities or group means – such as the number of pieces of sushi needed for a party. Imputed quantities were calculated by eliciting subsidiary judgments: how many people would enjoy the focal good ("not much", "somewhat", "a lot", or "I'd love it!") and the average willingness to pay among people in each category. These imputed quantities were more accurate than direct "dead reckoning" estimates.

In the fourth paper, Minson, Ruedy and Schweitzer demonstrate a novel way in which others may unwittingly reveal the kind of information that informs conditional inferences in strategic settings: the questions they ask. They compared three types of questions. *General* questions lack a specific line of investigation and convey the impression that the asker is not knowledgeable. *Positive Assumption* questions ask about a specific issue, but communicate the assumption while problems are possible, no concerns currently exist. *Negative Assumption* questions ask about a specific issue with an implicit assumption that a problem exists. The inferences participants made about their negotiation counterparts based on their questions dramatically affected their level of honesty during the negotiation.

These papers go beyond the existing literature on general social projection, to investigate the pervasive but understudied phenomenon of conditional inferences about others across different inference contexts, including product valuation, voting, advice giving and word of mouth, and negotiation. These papers present a new and more sophisticated understanding of the manner in which what we know or infer about others, how we relate those others to ourselves, and even how we hypothetically segment others all systematically influence our beliefs, and inform strategic decisions. We anticipate that this session will generate interest among a diverse group of ACR attendees, including those who are interested in interpersonal interactions, inference and belief formation and strategic decision-making. We believe that this session will suggest important new directions for future research into social inference and influence.

Conditional Projection: How Own Evaluations Impact Beliefs About Others Whose Choices Are Known

EXTENDED ABSTRACT

In this paper, we investigate how people's ratings of their choice options impact their beliefs about others' ratings, both for others making the same as well as the opposite choice. Consider, for example, a consumer who has chosen a Sony camera over a Panasonic camera. How will her own evaluations of both cameras influence her beliefs about how those who also chose Sony (*same-choosers*) or those who instead chose Panasonic (*opposite choosers*) evaluated both cameras? Contrary to existing theories of false consensus, we find *conditional preference projection:* beliefs about others are based on the assumption that their choices arose from corresponding preferences to one's own. Thus, for example, the higher the Sony-chooser rated Sony, the more she would believe that *opposite chooosers* (e.g.

Panasonic choosers) would rate their own preferred camera (Panasonic) highly. Conversely, the less negatively the Sony-chooser rated the one she did not choose (Panasonic), the more she would believe that opposite-choosers would likely not be as negative about their rejected camera (Sony).

Our conditional projection account is distinct from three alternative acounts that arise by extending existing models of social projection to estimating the evaluations of opposite choosers:

I. Direct negative projection of one's own evaluation of an option. In this case (suggested by the differentiation account, Mullen, Davidio, Johnson and Copper 1992), a person with high evaluations of her chosen option is expected to believe opposite-choosers to have lower evaluations of that same option (compared to another person with lukewarm evaluations). Evaluations of Sony among Panasonic choosers would be *lower* for Sony choosers with higher evaluations of Sony.

II. Direct positive projection of one's own evaluation of an option. In this case (suggested by the induction account; Dawes 1989, Hoch 1987), a person with higher evaluations of her chosen option would be more likely to believe that opposite-choosers have more positive evaluations of this option (albeit lower than their evaluations of the other option, which they chose). Evaluations of Sony among Panasonic choosers would be *higher* for Sony choosers with higher evaluations of Sony.

III. Lack of projection to opposite-choosers, since opposite choosers are an out-group. In this case, (suggested by the selective anchoring account, Clement and Krueger 2002), everyone would on average have the same beliefs about opposite-choosers' evaluations. Sony choosers' estimated evaluations of Sony among Panasonic choosers would not depend on the Sony choosers' own evaluations.

Across five studies, we examine people's beliefs about the evaluations of same-choosers and opposite-choosers. In particular, the proposed pattern of projection to opposite-choosers distinguishes our account of conditional projection from the extensions of existing choice projection theories to evaluations discussed above. We provide evidence for our predictions using across-people differences in ratings of choice options, within-person changes in ratings, as well as manipulated differences in participants' ratings. In Study 1, we focus on political decision making as a particularly appropriate context to study the formation and implications of one's beliefs about others. In data collected right before the 2008 Presidential election, we explored if and how a person's own evaluations about Obama and McCain shaped her beliefs about others' evaluations, conditional on knowing which candidate they support. For both general voters (N=351) and a sample of lab participants incentivized for accuracy (N=72), we confirm our conditional projection account. Obama voters' evaluations of their chosen candidate, Obama, primarily influenced their estimates of McCain voters' evaluations McCain. Likewise, Obama voters' evaluations of their rejected candidate, McCain, primarily influenced their estimates of McCain voters' evaluations Obama. Moreover, in a recontact study conducted before and after the first presidential debate, we confirm the same pattern of results for how *changes* in one's own candidate evaluations corresponded to changes in beliefs about opposite-choosers' candidate evaluations.

In Study 2 (N=159), we replicated our results in the context of technology adoption (evaluations of the Nintendo Wii and Sony PS3 videogame consoles), another context in which people's beliefs about others can be important for understanding their own choices. In Study 3 (N=151), we use the context of art posters to replicate the findings and rule out the possibility of reverse causation as an explanation. We show that learning about opposite-choosers' evaluations of two posters does not influence one's own evaluations. However,

participants' own evaluations did affect their estimates of the corresponding evaluations of opposite-choosers.

In Study 4 (N=65), we further address causality concerns by experimentally manipulating evaluations of digital cameras (Sony and Panasonic), by either making participants aware of additional unavailable information about the cameras, or not. We find that those in the unaware condition rate their chosen camera higher, and the differences in own evaluations is conditionally projected to both same- and opposite-choosers. In Study 5 (N=274), we investigate the effect of spontaneous changes in post-choice evaluations of digital cameras over time (absent new information) on beliefs about others. We found that ratings for the rejected camera were lower in the second wave (one week later) when participants no longer had detailed information in front of them. Correspondingly, they estimated that evaluations of both same and opposite choosers' respective rejected cameras would be lower as well.

Across the studies, we identify belief in similar decision processes as moderators, confirm that people endorse our account of "analogical projection" as a descriptor of their own decision process and rule out reverse causation (e.g. preferences influenced by beliefs) and belief in negative correlations as explanations.

'Tis Better to Give Than to Receive: Preference Estimates Conditioned on Own and Other's Preferences

EXTENDED ABSTRACT

Consumers are both givers and receivers of advice. Sometimes they recommend products to others. Sometimes they seek out recommendations from others (Gershoff, Broniarczyk, West 2001). Since information is neither perfect nor costless, and the future is uncertain, the recommendations that they give and receive are not always accurate. Therefore, both when giving and receiving advice, consumers often must make estimates about own and others' preferences (Loewenstien and Schkade 1999; West 1996).

Frequently these estimates are conditional probabilities involving both one's own and another's preferences or evaluations (Gershoff et al. 2001). For example, for the task of giving a recommendation to a friend, you might consider the conditional probability that your friend will like an alternative given that you liked it; P(other +|self +). For the task of receiving a recommendation, you might consider the conditional probability that you will like what your friend liked; P(self +|other +). Although both tasks require consideration of both one's own and other's preferences, the conditional probabilities to be estimated differ in that one is the inverse of the other.

This research presents three studies that explore accuracy in estimates of probability of liking conditioned on one's own another's preferences Prior work has shown that that people's ability to assess conditional probabilities depends on the task (Gershoff et al. 2001) and information presentation (Gigerenzer and Hoffrage 1995). One error that has been observed is the occasional mistaking of P(A|B), with its inverse, P(B|A) (Bar-Hillel 1983). An explanation for this finding is that a category that is more accessible or perceived to be more diagnostic tends to be adopted as the denominator, or sample space, for the conditional probability estimate (Sherman, McMullen, Gavanski 1992; Brase Cosmides, and Tooby 1999). Depending on whether a consumer is giving or receiving a recommendation, the appropriate sample space for assessing the conditional probability differs. When giving a recommendation it is the set of alternatives that the consumer has given a positive rating. When receiving a recommendation, it is the set of alternatives that the other individual has given a positive rating.

Where a categorization schema for the relevant sample space is difficult to access, people may rely on a more accessible schema that may appear diagnostic because it is related to the task at hand and or is relevant for similar tasks (Hilton and Fein 1989). Compared to information about another's preferences, information about one's own preferences is likely to be more accessible, and generally more relevant. Indeed, information that is self-relevant has been shown to be easier to recall and to be perceived as more important than information that is not self-relevant (Bower and Gilligan 1979). Categorizing a set of alternatives in terms of one's own likes and dislikes is likely to be a more natural way to categorize the alternative space than in terms of another's likes and dislikes. Thus, it is predicted that people will be less accurate when assessing P(self+|other+) (assessing a received recommendation), compared to assessing P(other+|self+) (assessing a given recommendation), but task characteristics that influence categorization in terms of one's own versus others' preferences will moderate this effect.

Study one asked 146 participants to examine and rate 50 posters while simultaneously learning the ratings of another participant. Next participants estimated P(self +| other +) and P(other +| self +). The order was counterbalanced. As predicted, the correlation between estimates of P(self +| other +) and actual (r = .271; z = 1.96, p = .05) was significantly less than the correlation between estimates of P(other +| self +) (r = .467). There was also more absolute error estimates of P(self +| other +) (M = .2215) than P(other +| self +) (M = .1825; F(1,145) = 7.002, p < .01).

Study 2 manipulated organization of information. Eighty participants sorted posters into those they liked and disliked or into those a partner liked and disliked. In the self-sort condition, accuracy echoed that of study 1. There was greater correlation for estimated and actual P(partner+|self+) (r = .81) than for P(self+|partner+) (r = -.08; Z = 5.42; p < .001). Sorting by partners' preferences attenuated this. The correlation between estimated and actual P(partner+|self+) (r = .41) was not significantly different from P(self+|partner+) (r = .44; Z = .135, p > .1). The same pattern of results held for measures of absolute values of accuracy.

Study 3 explored boundaries on accuracy in conditional probability estimates involving one's own preferences. One hundred and twenty four participants made estimates of the probability that they would like an alternative conditioned on an attribute of the alternative (either the subject of the poster, or the catalog where it is sold) rather than conditioned on another's preference. Because thinking about a set of alternatives in terms of commonly used descriptive attributes is likely to be a natural way to categorize the alternative space, in study 3 it was predicted that estimates of P(self+|attribute) would show less error than estimates of P(attribute|self+). As predicted, correlation of estimates and actual for P(self +| attribute) (r = .632, p < .001) were greater than for P(attribute| self +) (r = .104, *p* = .250; z = 4.981, p < .001). Likewise there was less absolute error for P(self +| attribute) (M = .1338) compared to P(attribute| self +) (M = .1617) (F(1,122) = 3.870, p = .051).

In three studies we found that consumers are prone to systematic errors in conditional probability estimates involving their own preferences consistent with differences in the accessibility and diagnosticity of the relevant sample space for the task. Probability estimation errors were consistent with better accuracy associated with the task of giving compared to receiving recommendations (Study 1 and 2). However the errors could be attenuated by categorization of information at the time of exposure (Study 2) and the presence of other more salient natural level categories (Study 3).

Estimating Central Tendencies:
Dead Reckoning vs. Decomposition

EXTENDED ABSTRACT

Predicting aggregate quantities, such as the number of pieces of sushi needed for a party can be done either by "dead reckoning" or by decomposing the global judgment into subsidiary elements (How many people will come?; How many pieces will the typical person eat?) I find that the large systematic biases found by Frederick (2012) in judgments of average valuation for products and services can be attenuated, or even eliminated by decomposing the task of dead reckoning a central tendency of some focal group into subsidiary judgments about the distribution of some other trait (such as liking) followed by the conditional judgments of valuation based on levels of liking.

In the focal study, 663 picnickers in Boston were shown two "goods" – DVDs of the first four seasons of *The Sopranos* and a two hour cheese tasting event held at a local cheese store. All respondents first indicated the most that they would be willing to pay for the presented good. Thereafter, respondents were randomly assigned to one of two prediction groups. The direct prediction group then simply predicted the mean valuation among all others taking the survey. By contrast, the "decomposed" prediction group first indicated how much they, themselves, would enjoy the focal good ("not much", "somewhat", "a lot", or "I'd love it!"), then estimated the percentage of other respondents in each of these four response categories, and then estimated the average willingness to pay among people in each categories (which, of course, includes the category in which they placed themselves). Although respondents in the decomposed prediction group were never directly asked to estimate the mean willingness to pay of the population, their subsidiary estimates entail such a prediction, and a predicted mean can be *imputed*.

As shown in Tables 1 and 2, among the *direct* prediction group, estimates of the mean valuations significantly exceeded the actual mean for both the Sopranos DVDs ($85.80 vs. $46.05; paired t(336) = 11.72; p<0.0001) and the cheese tasting event ($64.30 vs. $46.13; t(339) = 3.89; p<0.001). For the decomposed group, the bias was diminished for the Sopranos DVDs ($70.35 vs. $46.13; t(258) = 11.72; p<0.0001), and eliminated for the cheese tasting event (Estimates = $35.11 vs. Actual = $33.19; t(260) = 1.17; p>0.24).

The judgments rendered by the decomposed prediction group help distinguish two potential sources of the overestimation bias reported by Frederick (2012): an exaggerated sense of how much the target population likes the focal product, and an exaggerated sense of how much others would be willing to pay conditional on their stated level of liking. For the *Sopranos* DVDs, both quantities were exaggerated, such that the bias remained substantial, even in the decomposed prediction group. However, for the cheese tasting event, respondents underestimated how much people would like it, but overestimated how much people of a given liking level would be willing to pay. These errors roughly cancelled such that imputed estimates were very close to the true mean.

The bottom four rows of each table report estimates for respondents with different levels of liking for the good. Consistent with other work on projection, the imputed estimates of "fans" (those who loved the good or liked it a lot) exceeded the imputed estimates of "non fans" (those in the lower two liking groups). Note, though, that aside from helping to disentangle various elements of the "X effect" (Frederick, 2012), this study also helps distinguish different kinds or levels or "depths" of projection. For example, a *Sopranos* fan may project their enthusiasm for the show onto either their estimate of the frequency of fellow fans or onto the monetary valuations of those

who are lesser fans, or both. These results suggest that projection is predominantly of the first type. If one looks down any of the columns, the bottommost four rows are often strikingly similar. When asked to make predictions *conditioned on* another feature known to vary (in this case liking), participants were *not* anchored on their own valuations. For instance, though cheese lovers would pay an average of $54 for a ticket to the cheese tasting event, compared to just $7 among those with the lowest level of expressed liking, those two different groups made identical predictions of the valuation of the low interest group ($8).

There *is* Such a Thing as a Stupid Question: Question Disclosure in Strategic Communication

EXTENDED ABSTRACT

Consumers require information from others to guide decisions. Situations ranging from home purchases, to medical decisions, to investment choices are characterized by information dependence (see Adair & Brett, 2005; Galinsky, Maddux, Gilin & White, 2008; Gino & Moore, 2008). For example, in evaluating a used car buyers are dependent, at least in part, on the seller providing accurate information about the vehicle's condition. In these settings, individuals seek information from counterparts who often have incentives to conceal unfavorable facts. We term interactions characterized by asymmetric information and motivated disclosure *strategic information exchanges*.

In strategic information exchanges scholars advise individuals to ask questions (e.g. Malhotra and Bazerman, 2007; Nierenberg, 1986; Shell, 1999; Thompson, 2005). This advice, however, is predicated on an incomplete conceptualizations of questions. Specifically, prior work has overlooked the critical role questions play in *revealing* information. In this paper, we develop the following thesis: the questions individuals ask not only solicit information, but also disclose information. We define the previously unexplored phenomenon of questions revealing information as *question disclosure*. We develop a new theory, the Question Disclosure Model, for organizing related findings and report experimental results that demonstrate question disclosure and its consequences.

We characterize responses to questions with respect to (a) the attributes respondents mention, and (b) the overall valence (positive/negative) of the information. For example, in replying to a question about an apartment, a landlord could describe attributes such as the neighborhood, the amenities, or the building. The valence of those features might be positive (e.g. lively restaurant scene) or negative (e.g. noisy neighbors), affecting the overall valence of the description. According to our model, the inferences that individuals make based on questions they receive influence the valence of the response and the features mentioned.

In our experiment, we tested the predictions of the QDM by introducing three types of questions that lead to different inferences about the asker's knowledge structures and intentions. We expect these different types of questions to influence the content, valence,

Table 1. Estimates of others' values conditioned on own and others' liking (DVDs)

Valuation of Sopranos DVDs [direct] and decomposed not much		Liking $_{frequency}$			
		some what	a lot	I'd love it!	
Actual	[$46] $46	16_{27\%}$	43_{37\%}$	65_{28\%}$	92_{8\%}$
Estimated (overall)	[$86] $70	18_{15\%}$	41_{23\%}$	71_{31\%}$	112_{31\%}$
by "not much" group	$62	15_{17\%}$	25_{22\%}$	62_{30\%}$	99_{32\%}$
by "somewhat" group	$71	18_{14\%}$	30_{23\%}$	71_{31\%}$	113_{32\%}$
by "a lot" group	$74	22_{14\%}$	31_{24\%}$	78_{33\%}$	117_{28\%}$
by "I'd love it!" group	$86	20_{15\%}$	23_{20\%}$	83_{28\%}$	131_{37\%}$

Table 2. Estimates of others' values conditioned on own and others' liking (Cheese)

Valuation of cheese tasting event [direct] and decomposed not much		Liking $_{frequency}$			
		some what	a lot	I'd love it!	
Actual	[$46] $35	7_{13\%}$	25_{27\%}$	44_{34\%}$	54_{26\%}$
Estimated (overall)	[$64] $33	9_{24\%}$	22_{31\%}$	41_{27\%}$	71_{19\%}$
by "not much" group	$27	8_{33\%}$	19_{31\%}$	42_{22\%}$	63_{14\%}$
by "somewhat" group	$31	9_{23\%}$	23_{36\%}$	41_{25\%}$	67_{16\%}$
by "a lot" group	$33	11_{23\%}$	23_{31\%}$	45_{31\%}$	76_{15\%}$
by "I'd love it!" group	$38	8_{20\%}$	21_{25\%}$	40_{27\%}$	73_{28\%}$

and consequently the veracity of responses. We term these questions types: *General* questions*, Positive Assumption* questions*,* and *Negative Assumption* questions.

General questions pose a broad inquiry about a situation, a good or a service (e.g. "How is the project going?"). General questions lack a specific line of investigation and convey the impression that the asker might not be knowledgeable about the topic of discussion. *Positive Assumption* questions ask about a specific issue, but communicate the assumption that no problems exist (e.g. "The project is not likely to run over budget, is it?"). These questions reveal an awareness of a possible issue, but either a lack of concern or interpersonal discomfort with pursuing an assertive line of questioning. *Negative Assumption* questions ask about a specific issue, and communicate an implicit assumption that a problem exists (e.g. "How much over budget is this project likely to run?"). Negative Assumption questions communicate knowledge of potential problems and comfort with pursuing an assertive line of questioning.

In our study, participants negotiated with a confederate regarding the sale of a used iPod. We assigned every participant to the role of "Seller" and randomized them into one of three conditions. Across conditions, the confederate asked a General, a Positive Assumption, or a Negative Assumption question. The participants were provided several pieces of information about the iPod including color, age, memory capacity, and working condition. In particular, we were interested in whether participants would reveal to their counterpart that the iPod has a history of undiagnosed crashes, which in the past have resulted in the loss of all stored music.

In line with the predictions of the Question Disclosure Model, participants judged negotiation counterparts who asked a Positive Assumption or Negative Assumption question to be more knowledgeable than counterparts who asked a General question. They also judged counterparts who asked a Negative Assumption question to be more determined to gather accurate information than those who asked either a General or a Positive Assumption question. Consequently, the content of the responses and the valence of the responses differed across conditions, and these differences were mediated by the inferences participants made.

Most importantly, the information revealed in the question dramatically affected the likelihood that participants revealed the truth about the working condition of the iPod. Participants were much more likely to inform the buyer that the iPod had a history of crashing when they were asked a Negative Assumption question (89.0%) than when they were asked a Positive Assumption question (61.1%), *chi squared*(1) = 15.2, *p* < .001, or a General question (8.1%), *chi squared*(1) = 95.2, *p* < .001, (comparing Positive Assumption and General question conditions, *chi squared*(1) = 45.5, *p* < .001). Supporting the QDM, participants changed both the content and valence of the response as a function of questions they received.

Our work suggests that consumers readily draw inferences about others based on the questions they ask. Furthermore, such inferences lead to changes in important behaviors, such as revealing unfavorable information in the course of a transaction. Prior research has considered questions strictly as a tool for gathering information. The Question Disclosure Model provides a framework for investigating the manner in which questions reveal information and the effects of this phenomenon on consumer behavior.

Feeling Mixed? When, Why and To What End Do We Feel Mixed Emotions?

Paper #3: Mixed Emotional Experience is Associated With and Precedes Improvements in Well-Being
Hal E. Hershfield, New York University, USA
Jonathan M. Adler, Franklin W. Olin College of Engineering, USA

SESSION OVERVIEW

Over the past decade, scholars in marketing and psychology have investigated whether individuals can experience mixed emotions, the psychological processes associated with such experiences and the individual differences and situational factors that make them more or less likely. The majority of this work has focused on understanding when individuals are likely to experience discomfort in response to mixed emotions (e.g. Williams and Aaker 2002), with findings suggesting young, Caucasian Americans and those with a concrete construal mindset (Hong and Lee 2010) likely to experience discomfort and thus to find mixed emotions aversive.

Building upon, and yet in contrast to this previous work, the papers in this session suggest that mixed emotions are frequent experiences, even among those for whom past research has suggested they might be aversive. Mixed emotions may, in fact, even be deliberately sought. The papers in this session suggest that mixed emotions may be integral to goal pursuit and personal achievement, can be an essential component in meaning making, particularly in the face of adversity, may be perceived as reflecting reality, and can be processed fluently depending upon an individual's perspective toward them.

The first paper in this session (Mukherjee, Kramer & Lau-Gesk) suggests that consumers may not always want to avoid mixed affective experiences, particularly in the domain of goal pursuit and personal achievement, because a combination of positive and negative experiences is associated with the creation of meaning. In particular, the addition of some negative affect to goal pursuit can enhance feelings of accomplishment through hardship. This research suggests that while mixed-ness can be aversive when individuals are focused on the process of goal achievement, a focus on the outcome links mixed-ness to meaning-making and to more enjoyment of the experience itself.

The second paper (Hung and Mukhopadhyay) examines the impact of visual perspectives on the fluency with which consumers process advertising evoking mixtures of hedonic and self-conscious emotions, and hence on attitudes to products featured in the appeals. Results show that consumers who adopt a third-person, observer perspective process self-conscious emotional ads more fluently and evaluate them more favorably, while consumers adopting a first-person, actor perspective process ads that highlight hedonic emotions more fluently and evaluate them more favorably.

The third paper (Hershfield and Adler) suggests that concurrent experiences of conflicting emotions in times of adversity can ultimately lead to greater well-being over time. Individuals who sought therapeutic treatment for a wide variety of life events were asked to write about their experiences. These narratives were coded and results show that blends of happiness and sadness in response to therapy were associated well-being over time. As in the first paper, this research suggests that the blends may not have been pleasant at the time of their experience, but are shown to have a prospective influence, such that the impact of mixed emotions on well-being unfolds over time.

This session is likely to be of interest to ACR members studying emotions generally as well as those studying mixed emotions and those who are investigating well-being and how consumers find meaning in consumption experiences. The session furthers the conference's mission of appreciating diversity in a variety of ways. First, the papers investigate mixed emotions in a variety of settings, from the more traditional advertising context, to video game playing and to coping with life-stressors and therapeutic interventions. The papers in the session also examine a variety of different types of mixed emotions, from happiness and sadness to mixtures of hedonic and self-conscious emotions. Previous work on mixed emotions has focused upon when mixed emotions can be construed as more or less negative and aversive. This session, in contrast to that previous literature, focuses upon when mixed emotions might actually be processed fluently, actively pursued and associated with meaning-making and enhanced well-being, which is a substantial contribution to the current literature on mixed emotions.

Finding Meaning in Mixed Affective Experiences

EXTENDED ABSTRACT

Past research has shown that mixed affective experiences generally are aversive unless consumers find a way to cope with their associated discomfort (Williams and Aaker 2002). Yet consumers often knowingly seek out experiences that elicit both positive and negative affect. For example, skydivers find enjoyment from feeling intense happiness and fear during their jump (Celsi, Rose, and Leigh 1993). Thus, many mixed affective experiences are those that consumers actually wish for rather than wish to avoid. Responding favorably to this type of mixed affective experience seems not a function of coping with unpleasantness, but rather enjoying its pleasantness. Departing from past research which examines mixed affective experiences that consumers want to avoid, we investigate those that consumers actually desire. Specifically, we address two interrelated questions. First, can mixed affective experiences be more enjoyable than pure positive ones? And second, what makes such mixed affective experiences enjoyable to consumers?

We propose that in the context of mixed affective experiences that involve goal pursuit and personal achievements, mixed affective experiences can be more enjoyable than pure positive ones because consumers derive more meaning from the experience. This is based on past research which has discussed the importance of goal pursuit in deriving meaning where meaning is defined as having a sense of purpose and attainment of goals that are important to an individual (King et al. 2006). Thus, mixed affective experiences that involve goal pursuit not only are associated with mixed affect but are also likely to be linked with meaningfulness. In turn, consistent with re-

search showing that meaningfulness is often associated with greater levels of enjoyment (Csikszentmihalyi 1990), we suggest that consumers may seek out and enjoy mixed experiences from which they derive meaning. Further, we argue that mixed affective experiences can be enjoyed more than pure positive ones. This is because when engaged in goal pursuit, consumers may infer that detriments, such as negative affect, are necessary evils to experience on the way to success, as popularized by the expressions of "no pain, no gain," or "the road to accomplishment is through hardship." For example, Kramer et al. (2011) found that consumer responses to medications with severe, as compared to mild, side effects were more favorable. Further, a bad-tasting cough syrup was judged to be more effective at fighting colds than a good-tasting one. Likewise, Loewenstein (1999) found that the pain endured during mountain climbing reveals one's strength under harsh conditions to others.

To test our proposition, we directly examined mixed affective experiences that involve goals and personal accomplishments, such as mastering a videogame or a challenging mountain bike ride. We conducted a field study in a videogame arcade where 41 patrons played a videogame of their choice. After playing the game, participants reported their affective intensity and overall evaluations. As expected, results showed that participants evaluated the experience as significantly more enjoyable when it was mixed versus pure positive (6.09 vs. 5.5; $F(1, 39) = 4.64$, $p < .05$). In our second study, we examined the mediating role of meaningfulness. We also included felt discomfort measures to rule it out as an alternate mediator to demonstrate the novelty of desirable mixed affective experiences. Further, since we suggest that consumers obtain meaning from mixed affective experiences when such experiences are associated with goals and personal achievement, we theorized that this effect should emerge when consumers focused on the end goal (of accomplishment). Thus, in the next study, we manipulated the focus of participants' thoughts to either emphasize the end goal of achievement (outcome-focus) or emphasize the process or steps that lead to the goal (process-focus) (Escalas and Luce 2003).

One hundred and fifteen undergraduate students participated in a study on mountain-biking. A 2 (affective experience: mixed vs. pure positive) X 2 (focus: outcome vs. process) ANOVA on participants' enjoyment yielded the expected affective experience X focus interaction ($F(1, 111) = 4.62$, $p < .05$). Enjoyment of the mixed affective experience was significantly greater than the pure positive one (6.53 vs. 6.00; $F(1, 111) = 5.49$, $p < .05$). However, type of affective experience did not impact the level of enjoyment for participants in the process focus condition (6.15 vs. 6.26; $F(1, 111) = .31$, $p > .10$). To examine whether meaningfulness mediated the interaction between affective experience and focus on enjoyment ratings, a mediated moderation analysis was conducted (Muller, Judd, and Yzerbyt 2005). Results showed that the effect of type of affective experience on enjoyment is mediated by meaningfulness. However, and as expected, the observed effects only emerged for consumers who were focused on the outcome or end goal of the experience, as compared to the process. Further, findings showed that felt discomfort did not mediate the joint influence of type of affective experience and focus on enjoyment.

Together, the findings from our two studies show that mixed affective experiences are not only enjoyable but they can even provide more enjoyment than pure positive affective experiences. This adds to research across different domains of mixed experiences such as mixed affect (Williams and Aaker 2002) and cognitive dissonance (Elliott and Devine 1994).

Putting the Consumer in the Picture:
Visual Perspectives and Mixed Emotions in Advertising

EXTENDED ABSTRACT

Advertising appeals that describe a consumption experience often elicit mixed emotions. Typically, such advertisements portray cognitively complex stimuli or phenomena (Larsen, McGraw, and Cacioppo 2001). For example, Williams and Aaker (2002) studied responses to an ad for a brand of photographic film, where a person was ostensibly commenting on a photograph of themselves as a baby posed with their now deceased grandmother. The commentary here was in the first person. ("My Nana, Emma, passed away this past year... I loved sharing time with her. I miss her…".) What factors influence the effectiveness of such mixed-emotional advertising? In this research, we investigate how the use of different visual perspectives, e.g., first versus third person, might influence consumers' responses to such mixed appeals. In so doing, we aim to identify one important factor that facilitates the processing of appeals that elicit mixtures of emotions, and therefore influences attitudes towards the advertised products.

Consumers viewing advertising such as the above may visualize the advertised situation and transport themselves into it in one of two ways. They may view the situation in the first person as if they are living it, as in William's and Aaker's stimuli, or they may observe the situation as if they are watching a movie of themselves. In either case, they may use the elicited emotions as bases for evaluating the product (Sujan, Bettman and Baumgartner 1993; Escalas 2007). Hung and Mukhopadhyay (2012) demonstrated that the visual perspectives people take to view a given situation influence the intensity of the emotions people experience, such that people who take an actor's (i.e., first person) perspective feel stronger hedonic emotions whereas those who take an observer's perspective experience stronger self-conscious emotions. Based on this, we argue that when depicting mixed emotions, ads that use an actor's (observer's) perspective facilitate the processing of the hedonic (self-conscious) emotions involved. The ease with which the emotion is processed should consequently increase evaluations of the advertisement as well as the advertised product.

Product consumption often involves simultaneous experiences of different specific emotions (Larsen et al. 2001; Williams and Aaker 2002). For example, an ad portraying the consumption of a late-night snack because one has to study for an exam thereby foregoing a concert by one's favorite band might elicit both the hedonic emotion of sadness (for missing out on the concert) and the self-conscious emotion of pride (for studying hard). Hedonic emotions such as excitement and sadness are relatively spontaneous and can be elicited without much cognitive deliberation whereas self-conscious emotions such as pride and guilt are characterized as being accompanied by thoughts about how others might evaluate me/the desirability of my behavior (Leary 2007). Given the difference in the nature of these emotions, recent findings show that visual perspectives, which dispose people to focus on different aspects of information (Jones and Nisbett 1972), might influence people's experience of these emotions (Hung and Mukhopadhyay 2012). Actors, who pay more attention to situational circumstances, might respond more fluently to aspects of events that elicit hedonic emotions. Observers, who pay more attention to the 'me' in the situation (i.e., as if one is seeing a movie of oneself), might respond more fluently to aspects of events that elicit self-conscious emotions.

Building on these findings, we examine the role of visual perspectives in responses to advertising appeals which feature product consumption experiences that typically elicit mixed emotions. We

propose that actors' (observers') perspectives should facilitate the processing of an appeal that highlights a hedonic (self-conscious) emotion in a product consumption experience that typically elicits a mixture of hedonic and self-conscious emotions. Consequently, the ease with which actors (observers) process the appeal should increase evaluations of the appeal itself as well as the advertised products.

Three experiments support these propositions. Participants took either an actor's or an observer's perspective to process an appeal that described a product consumption experience eliciting a mixture of hedonic and self-conscious emotion (experiments 1 and 3). Regardless of the valence of the emotion highlighted, actors evaluated the ad and the advertised product more favorably when the ad highlighted a hedonic emotion than observers did. In contrast, observers evaluated the ad and the advertised product more favorably when the ad highlighted a self-conscious emotion than actors did. Experiments 2 to 3 further examined whether similar effects of visual perspectives occur when the use of visual perspectives were subtly manipulated by the appeal. Participants processed an ad describing a mixed-emotional experience that elicits a positive (negative) hedonic emotion of excitement (sadness) and a negative (positive) self-conscious emotion of guilt (pride). The mixed-emotional experience involved either studying in the library while one's favorite band was in concert (simultaneous sadness and pride), or attending the concert despite an exam the next day (simultaneous excitement and guilt). The visual for the ad featured a photograph of a library scene or a concert scene, as viewed on a mobile phone. The text in the ad however highlighted only one of the four emotions involved: positive hedonic (excitement), negative hedonic (sadness), positive self-conscious (pride), or negative self-conscious (guilt). Visual perspectives were manipulated integrally, using tag-markers on the photograph itself. Participants reported their attitudes towards the ad, and the advertised products. Across three studies, results consistently showed that the ad and the advertised product were evaluated more favorably when participants took an actor's (observer's) perspective to view a mixed-emotional situation that highlighted a hedonic (self-conscious) emotion. This effect was mediated by the ease of processing the appeal, and was observed when the visual perspective was induced incidentally as well as integrally by the advertisement, and whether the advertisement was viewed subsequently or simultaneously.

Overall, this research contributes to the understanding of the conditions under which mixed emotional appeals are likely to be fluently processed, thereby increasing consumers' evaluations of advertised products. This research also sheds new light on the role of visual perspectives in the impact of appeals that depict integral and mixed emotions, by examining the relative impact of mixed emotions that might typically be elicited in product consumption experiences portrayed in emotional appeals. Theoretical and practical implications will be discussed in the session.

Mixed Emotional Experience is Associated With and Precedes Improvements in Well-Being

EXTENDED ABSTRACT

The respective benefits and drawbacks of positive and negative emotional experience on well-being have been well documented (e.g., Lyubomirsky, King, & Diener, 2005). Yet, considerably less attention has been given to the ways in which the experience of mixed emotions – that is, the concurrent experience of positive and negative emotions – can affect well-being. A notable exception is the co-activation model of health proposed by Larsen and colleagues (2003), which holds that experiencing positive emotions concurrently with negative emotions may detoxify them, transforming a negative emo-tional experience into fodder for meaning-making and subsequently enhanced well-being. Although recent work has tested the postulates of Larsen's model on physical health (Hershfield, Scheibe, Sims, & Carstensen, Under review), very little research to date has directly examined the connection between mixed emotional experience and enhanced well-being. In the present study, we investigated whether mixed emotional experience – specifically the concurrent experience of happiness and sadness - prospectively benefits improvement in well-being. The context for this investigation was a naturalistic longitudinal study of psychotherapy in an outpatient clinic. Psychotherapy is fundamentally concerned with emotional experience (Greenberg & Safran, 1987) and provided an opportunity to assess the unfolding relationships between mixed emotional experience and well-being. The present study aims to demonstrate that concurrent happiness and sadness may temporally precede improvements in well-being.

When facing negative events in the course of one's life, people may choose to either suppress negative emotions (Gross & John, 2003) or express them (e.g., Pennebaker, 1997). There are benefits and drawbacks to both approaches, but failing to confront negative events can ultimately lead to increased stress levels (Pennebaker, Kiecolt-Glaser, & Glaswer, 1988). Larsen and colleagues (2003) propose that a third strategy, one of "taking the good with the bad", might actually benefit individuals during difficult times by allowing them to confront adversity and ultimately find meaning in life's stressors (a eudaimonic outcome), as well as to feel better in their wake (a hedonic outcome). In their co-activation model, allowing for the experience of positive emotion alongside negative emotion prompts individuals to face negative life events and gain insight into them. Larsen and colleagues' model thus suggests that during difficult situations, a mix of positive and negative emotions may be optimal for well-being. For instance, when experiencing the loss of a loved one, allowing positive memories to be experienced alongside sadness could potentially lead to a healthier bereavement process (Folkman & Moskowitz, 2000). As Davis and colleagues (Davis, Zautra, & Smith, 2004) note, one key to resilience across the adult life span, may be the "ability to maintain affective complexity in the face of life's inevitable difficulties" (p. 1155).

Although prior work offers preliminary evidence for the positive role that the blending of positive and negative emotion can play in well-being, none has systematically examined the *prospective* benefits that mixed emotions may have on well-being over time in a fine-grained way. Thus, in the present study, we sought to examine whether mixed emotional experiences are prospectively linked to enhanced well-being.

Forty-seven adults (M_{age} = 36 years) who sought treatment at a major outpatient clinic for a wide variety of problems, ranging from significant psychopathology to more typical life events such as divorce or the transition to parenthood, were enrolled in the present study prior to beginning treatment. In order to tap a broad conception of well-being encompassing both hedonic and eudaimonic elements (Ryan & Deci, 2001), the Systemic Therapy Inventory of Change was selected as the primary outcome measure (STIC; Pinsof & Chambers, 2009). To assess the emotional content of participants' experiences in psychotherapy, we collected private narratives about participants' perspectives on treatment. The present study asked participants to reflect in writing on their thoughts and feelings associated with being in therapy, including the way they saw the treatment fitting into their overall life or sense of self. As such, the narratives discussed both participants' life events as well as their experiences in treatment.

A team of two trained raters (undergraduate research assistants, trained by the first author, who were blind to the hypotheses of the study and unfamiliar with the coactivation model) coded the narratives for their emotional content. Previous theoretical and empirical work on mixed emotional experience has taken a broad approach to operationalizing the construct, including generic categories of "positive" and "negative" emotional experience. In contrast, in the present study we sought to empirically identify the specific blend of positive and negative emotions that are associated with improvements in well-being. Given that happiness and sadness were the only specific emotions to show a significant relationship with well-being over time, the six other specific emotions were dropped from subsequent analysis and a composite variable, representing instances when happiness and sadness co-occurred, was created.

The primary analytical strategy applied growth curve modeling to the data. This technique is well-suited to accommodate missing data and unbalanced spacing of assessment points, both of which are inevitable in data collected from a naturalistic sample. The results indicate that participants who experienced a concurrent mixture of happiness and sadness during the course of treatment enjoyed subsequent improvements in their well-being. This finding remained significant when controlling for the impact of the passage of time as well as that of dispositional personality traits associated with affect. In addition, the results suggest that the significant association between the experience of concurrent happiness and sadness is uniquely related to well-being at the following assessment point, but not concurrently, when controlling for the independent impacts of happiness and sadness themselves. In other words, mixed emotional experience was seen to have a prospective influence on well-being, but its concurrent association with well-being was explained by the independent effects of happiness and sadness. This suggests that mixed emotional experience may have a distinct prospective potency; its association with well-being unfolds over time. Thus, while the concurrent experience of happiness and sadness in the face of adversity might not provide immediate benefit, it may signal enhancements in well-being in the near future.

SESSION OVERVIEW

Numerical stimuli in marketing are ubiquitous. For example, they are used by companies to communicate the performance of products or information about product attributes, they facilitate the interpretation of rating scale anchors, and they are used by consumers to monitor goal progress. Examining how consumers extract meaning from numbers is therefore crucial to understanding consumer decision making. This symposium consists of four papers that interconnect at different levels. Together, they provide new perspectives on numerical cognition and, more generally, the psychology of consumer decisions.

The first paper, by **Peters and Meilleur**, shows that numerical information drives early attention and subsequent choices. They argue that low Arab numerals are associated with a focus of visual attention to the left and that high Arab numerals are associated with a focus of visual attention to the right. Presenting a low (1) versus high (9) digit between two decision options also impacts choice in line with the authors' selective attention account.

The second paper, by **de Langhe and Puntoni**, draws attention to a factor contributing to consumers' willingness to pay for technological progress. The performance of many technologies is expressed in terms of speed (e.g., Internet bandwidth). Four studies show that consumers misunderstand the relationship between increases in speed and time savings. They hold the belief that the same increment in speed provides the same time saving regardless of whether the initial speed is low or high, even though time savings become in fact smaller as speed increases. The studies also show how to reduce this bias by drawing attention to time (e.g., via experience or by restructuring numerical information).

The third paper, by **Burson and Larrick**, examines how perceptions of magnitude affect conclusions about attribute importance that are inferred from conjoint studies. By multiplying a ratio scale by an arbitrary factor, numerical scales that are used to describe product attributes can be contracted (e.g., 1-10) or expanded (e.g., 1-100). The relative importance of attributes inferred from conjoint

studies is greater when the scale is expanded, but decreasingly so because of decreasing sensitivity.

The fourth paper, by **Davis, Bagchi, and Lee**, investigates how the order of presentation of effort and reward information affects goal pursuit and examines the role of numerosity in this effect. In three studies, they manipulate the numerosity of the metric used to express the amount of effort required to meet a goal and found that in the presence of large number (connoting high effort requirements), presenting the rewards before the effort reduces effort salience and energizes consumers.

Because of the fundamental importance of numerical cognition for understanding consumer psychology, we expect this special session to be of interest to a wide audience. The session will appeal to researchers on topics as diverse as (1) motivation and goal achievement, (2) marketing research, scaling, and conjoint analysis, (3) attention, (4) decision making, and (5) innovation. Data collection in all papers is complete and the session features a total of 13 studies using a variety of paradigms and methods (e.g., choice, conjoint, priming). All participants have agreed to present, should the session be accepted. The chair will facilitate audience discussion drawing further connections between the new perspectives introduced in this session and other areas of consumer research.

In sum, we believe that this proposal fits both the spirit of ACR special sessions and the theme of the conference—appreciating diversity. In addition to the diversity of approaches to numerical cognition that the papers exemplify, the session also brings together researchers from different areas of research, including marketing, management and psychology. The participation of Ellen Peters, a leading psychologist and numeracy researcher, is especially noteworthy.

Numerical Cognition and a Mere-Looking Effect in Multi-Attribute Choice

EXTENDED ABSTRACT

Selective attention has been a long-standing theme in decision research (Einhorn & Hogarth, 1981; Weber & Johnson, 2009), but studies have not manipulated early attention in complex, multi-attribute decisions outside of awareness and independent of participant goals. In the present paper, we take advantage of symbols learned in early childhood – integers from 1 to 9 – that are not obviously directional but have been shown to have a left-to-right spatial orientation that can subtly shift attention (Dehaene, Bossini, & Giraux, 1993; Fischer, Castel, Dodd, & Pratt, 2003).

In four studies, we used these incidental attentional shifts to test their influence on high-level cognitive processes involved in multi-attribute binary choices. Of course, just because individuals look in the direction of information does not mean that they process or use it in decisions. However, some evidence exists for a disproportionate influence of early information on decisions (Weber & Johnson, 2009; DeKay et al., 2009; Russo et al., 2006). Thus, we hypothesized that presentation of an incidental small or large Arabic digit (physically located between two choice options) would shift visual attention to the left and right options, respectively, and information attended earlier would disproportionately influence information processing and choice – a mere-looking effect.

Results of the present four studies provided converging evidence, across diverse decision paradigms, to support the causal role of covert and overt shifts of attention in influencing the processing and valuation of decision options. In Study 1, the attention shift created by implicit cues – a "1" or "9" – located between two real choice options produced preference reversals. Faced with a simple choice between two identical erasers, "1" participants were more likely than "9" participants to choose the left-side eraser (65.2% and 33.3%, respectively; $\chi^2(df=1)=4.5$, p=0.03, $\varphi=.32$). Study 1 provided evidence that the presentation of Arabic integers activated magnitude and shifted early attention to information that influenced choice. The effect occurred despite spatial attention being driven exogenously, from a normatively irrelevant and incidental source.

In Study 2, participants chose between two hypothetical vacation spots – one with average attributes; the other with both positive and negative attributes (materials adapted from Shafir et al., 1993). In a 2x2 between-subjects design, participants were shown either a large "1" or "9" in the middle column, with enriched Spot B's positive or negative attributes on top. When the enriched option was attended early, top-to-bottom attribute order significantly influenced choices; when the average option was attended early, the top-to-bottom order of attributes for the enriched option had little influence (interaction: Wald $\chi^2(df=1)=9.1$, $p=0.003$, $f=.22$). In particular, when attention was directed left ("1"), B's attribute order did not influence choice; 60% versus 62% of participants chose Spot A when B's negative versus positive attributes, respectively, were on top. However, among "9" participants (attention directed rightward), significantly more participants chose left-side Spot A when B's negative attributes were on top (85%) than when its positive attributes were (47%). Mere looking did not produce simple liking of whatever is looked at first; instead, it biased choices based on processing the first-attended information.

Studies 1 and 2 provided initial evidence that the spatial orientation of the mental number line can orient attention and alter choices when no real difference exists between options (Study 1) or when the choice is hypothetical (Study 2). Study 3 provided evidence that "mere looking" at information matters in choices among consumer goods, specifically when choosing between a decision of the head and a decision of the heart. In this case, participants chose between two snacks – one that tasted better and another that was healthier. Such choices involve a tradeoff between perceived taste and healthiness; how individuals process these tradeoffs is unclear, however. Previous studies have indicated that decreasing available cognitive capacity can increase choices of the less healthy option (Shiv & Fedorikhin, 1998). In the present Study 3, cognitive capacity was not altered; instead, attention was simply directed first at one option or the other. Participants chose between Regular and Baked Lays (counterbalancing their left/right order) with "1", "9", or nothing between them. When nothing was in between the snacks, 69% and 19% of participants, respectively, chose Baked Lays, respectively, when it was on the left or the right. This result is congruent with previous eye-tracking results indicating that about 75% of participants in a binary choice look at the option on the left first (Krajbich et al., 2010). With Baked Lays on the left and using the attention manipulation, participants were more likely to choose them in the "1" condition compared to the "9" condition (60% and 31%, respectively, chose Baked Lays). With Baked Lays on the right, the effect reversed, with participants significantly less likely to choose them in the "1" than the "9" condition (47% and 75%, respectively, chose Baked Lays).

Finally, in Study 4, choices between 41 food pairs that varied in perceived healthiness and tastiness were made with "1", "9", or "5" between options in each pair. Our prior choice effects were replicated. Preliminary analysis of eye tracking data supported the hypothesized information-processing mechanisms.

That the attentional effects of conventional, overlearned symbols can guide attention and influence choices suggests a strong link between visual attention and choice. Broader implications of this and other research also further highlight the constructive nature of choice (Lichtenstein & Slovic, 2006; Payne, Bettman, & Schkade, 1999), and, importantly, point towards some of the subtle influences that marketers and other information providers can exert on choices.

Need for Speed?

EXTENDED ABSTRACT

Technology often advances by increasing the speed of specific processes and, consequently, by reducing the time required to perform a particular task. Marketers tend to express the performance of time-saving technologies in terms of their speed. For example, the performance of computers' CPU is expressed in megahertz (MHz = cycles per second), Internet bandwidth is expressed in megabits per second (Mbps), the performance of printing technologies is expressed in pages per minute (ppm), and the performance of kitchen robots is expressed in rotations per second (rps). Increases in speed result in time savings. The speed of a product is thus a diagnostic *feature* allowing consumers to assess the *benefit* they receive in terms of time saved.

Marketing theory suggests that, to maximize sales, in their communication to consumers marketers should focus on benefits as opposed to features. This suggests that marketers' focus on speed may negatively affect consumers' willingness to pay for technological progress. Our research shows that, in fact, consumers are willing to pay more for time-saving technologies when marketers highlight speed rather than time. This result occurs because consumers misunderstand the relationship between speed increases and time savings. They think this relationship is linear (i.e., an increase in speed has the same effect on time saved regardless of whether speed is low or speed is high), while in fact the relationship between speed and time is nonlinear (i.e., an increase in speed has a larger effect on time saved when speed is low than when speed is high).

In a first study, participants indicated how much they were willing to pay for 5 data transfer speeds (1MBps; 2 MBps; 3 MBps; 4 MBps; 5 MBps). Before indicating their willingness to pay, about half of participants were given the opportunity to actually experience how long it takes to download a 30 MB file with each transfer speed. For participants without actual experience, willingness to pay was linearly related to increases in data transfer speed. For participants with actual experience, willingness to pay was linearly related to time savings.

In a second study, participants rank-ordered five increases in printer speed (ppm) in terms of time saved (A: 15 ppm to 30 ppm; B: 5 ppm to 15 ppm; C: 18 ppm to 26 ppm; D: 12 ppm to 17 ppm; E: 7 ppm to 10 ppm). Participants' rank-order reflected increases in speed (A > B > C > D > E). That is, participants believed that larger increases in terms of ppm also result in larger time savings, while the correct ordering in terms of time saved should have been: B > E > A > D > C.

In a third study, participants were asked to choose between four kitchen robots that differed in terms of speed and price (A: 2.50 rps for $200; B: 3.33 rps for $250; C: 4.17 rps for $300; D: 5 rps for $350). For half of participants, we also highlighted the performance of the kitchen robots in terms of time savings. These participants were also presented with the performance of each kitchen robot in terms of seconds per rotation (A: 0.4 spr; B: 0.3 spr; C: 0.24 spr; D:

0.2spr). Participants receiving restructured numerical information in terms of seconds per rotation were more likely to choose a less expensive kitchen robot. While rotations per second highlights speed, seconds per rotations facilitates mental calculations regarding time saved.

To extend our findings to a setting where "slower is better", we also examined a situation where consumers pay a certain amount of money for a service per unit of time. In the context of mobile phone plans, for instance, consumers pay a specific rate where a lower cost per unit of time (i.e., a slower outflow of money) is preferred over a higher cost per unit of time (i.e., a faster outflow of money). In a fourth study, participants were asked to imagine they were willing to spend $50 per month on their mobile phone plan. We told participants that their current provider considered increasing their rate. Participants were asked how likely they were to switch to another provider if their current provider decided (a) to increase their rate from $0.10 to $0.15 per minute and (b) to increase their rate from $0.20 to $0.30 per minute. If participants accurately assess how the rate increase affects the number of minutes they can call for $50 per month, they should be more likely to switch when their rate increases from $0.10 to $0.15 (i.e., a loss of 167 minutes) than when their rate increases from $0.20 to $0.30 (i.e., a loss 83 minutes). However, participants indicated they would be more likely to switch when their rate increased from $0.20 to $0.30, again reflecting the erroneous mapping of speed on time.

In sum, companies' focus on communicating speed when promoting time-saving technological improvements of existing products leads consumers to overvalue technological progress. We will discuss the importance of our findings for marketers, but also for public policy makers.

Tipping the Scale: Discriminability Effects in Measurement

EXTENDED ABSTRACT

In Ireland, a District Court judge reduced the speeding charge of a driver who had been clocked going 180 kilometers per hour in a 100 kilometer per hour zone. Looking at this decision, an outside observer might conclude that the court believed the driver's speed was less important in the decision than, say, his previous driving record. However, the judge's explanation for the decision was that the speed did not look "as bad" when converted into 112 miles per hour in a 62 mile per hour zone (Associated Press, 2007). Objectively, speeding by 80 kph is still violating the law by the same proportion as speeding by 50 mph and thus warrants the same penalty. Any scale with ratio properties can be converted from one scale to another (without changing the information provided by the scale) by multiplying the original values by some constant factor. However, this trivial transformation is psychologically consequential, as is clear in this example: The expanded scale highlights the difference between the speed limit and the driver's speed, making that difference seem large. In contrast, the contracted scale minimizes the difference (Pandelaere, Briers, & Lembregts, 2011).

There are decades of research on how people perceive and interpret numerical attributes in psychology and in marketing. In summarizing these traditions, Mellers and Cooke (1994) propose a three-stage sequence by which a perceiver evaluates a multi-attribute object. First, there is a perceptual stage in which specific attribute levels are translated into internal representations. Then, there is a weighting stage in which different internal representations of attributes are combined into an overall judgment. Finally, there is a response stage in which an overall judgment is expressed as a judg-

ment or choice. Market researchers attempting to understand consumer behavior often try to back attribute weighting (the second stage) out of observed preferences or choices (the final stage). For example, conjoint researchers infer participants' attribute importance from their responses. We argue that, like an outside observer of the Irish court decision, conjoint researchers may inappropriately attribute observed choices to attribute importance when what is actually guiding choice is the internal representation of the difference in products.

To test this hypothesis, we expand and contract attribute scales in a conjoint design and observe the impact on choice and inferred attribute importance. We propose that these manipulations directly influence internal representations because people focus on the attribute value and neglect the attribute's scale magnitude—alternatives seem more different on that expanded attribute and are encoded as such. This leads to shifts in choice, and thus in attribute importance inferred using the usual conjoint method. We go on to verify that the *actual* importance of attributes to participants is *not* influenced by scale expansion, only the internal representation. In addition, we show that because of diminishing sensitivity to scale expansion, extreme scale expansion does not continue to influence that internal representation.

Specifically, in each of two studies, we find that participants' choices closely track the expanded attribute in the conjoint design, replicating past research (Burson, Larrick, & Lynch, 2009). Because conjoint analysis determines the relative importance of a particular attribute by observing its impact on choices relative to the impact of other attributes, the natural conclusion of a market researcher examining one of our conditions in isolation would be that the attribute using an expanded scale is a very important attribute to consumers. Critically, however, our experiments show that this cannot be the case because that importance seems to vary from condition to condition. For example, in Study 1 one attribute appeared to be the most important attribute in choice when it was presented on an expanded scale (54%), but appeared to become less and less influential when it was contracted (44%). A similar pattern was revealed in Study 2 (relative importance of expanded conditions = 62% vs. contracted condition = 46%). These results are a statistical artifact. Just as the Irish judge in our opening example did not suddenly discount the importance of speeding in his penalty decision, participants in our studies are not revising the importance of product attributes. Rather, attribute expansion directly influences internal representations of products—exaggerating differences in products—but importance of an expanded attribute is no greater than that of a contracted attribute.

We confirm that relative importance is a statistical artifact by examining the rated importance of each feature. There was no change in these ratings in response to scale expansion. Furthermore, scale expansion was found to impact mental representations of the alternatives: Participants believed that an attribute had larger differences in the expanded conditions.

These findings have important implications for market researchers as our studies show that attributes represented on expanded attributes only *appear* to have inflated importance in consumer choice. The interpretation of a conjoint analysis will be sensitive to attribute expansion, thus marketers should take care when they choose how to infer preferences or how to describe their products. Furthermore, Study 2 also reveals that, due to diminishing marginal utility, scale expansion has its limits: Expanding an attribute from a 100 point to a 1000 point scale did not increase preference for the product that performed well on that attribute, nor the inferred importance of the attribute. Therefore, market researchers should also recognize the boundaries of scale effects.

When to Put the Cart in Front of the Horse: How Presentation Order of Goal Reward and Effort Information Affects Goal Pursuit

EXTENDED ABSTRACT

Why do consumers often fail to begin working towards a beneficial goal? One possibility may be that while effort has to be invested immediately, the benefits occur later. Thus, effort may be more salient at the outset and may overweigh perceptions of the benefits to be accrued from the outcome later. How can effort perceptions (effort salience) be altered to initiate action and/or goal-pursuit? We suggest that changing the presentation order of goal outcome and effort may influence how salient the effort is and may affect goal-pursuit.

Most research has focused on how motivation to pursue goals can be increased as the reward gets proximal. For instance, animals and humans have been shown to move faster when approaching a reward (Hull 1932; Kivetz, Urminsky, and Zheng 2006). Endowing consumers with progress at the outset can also increase acceleration (Nunes and Dreze 2006). However, it is not always possible to endow progress (e.g., when preparing for an exam, it is not possible to tell students that they have already reviewed a few chapters). We show one way in which consumers can be motivated to pursue goals at the initial stages of goal-pursuit.

We argue that when the effort involved in attaining a goal is perceived to be large (e.g. expressed via high numerosity; To get an "A" review 300 pages), presenting the reward first (To get an "A") followed by effort (review 300 pages) reduces effort salience relative to when effort is presented first followed by reward (Review 300 pages to get an "A") and has beneficial effects on goal-pursuit. This effect of information presentation order on effort is attenuated when smaller numerosities are used to express effort (To get an "A" review 10 (30 page) chapters). We demonstrate this effect in three studies. In study 1 we show the basic effect. In study 2, we show that this effect only occurs when the outcome is far (and thus effort required is large) and provide process support. Finally, in study 3, we prime focus (outcome vs. process), and show that the order effects persist when focus is on outcomes (vs. process), and show meditational support.

Study 1: Reviewing Course Materials for a Grade

We used the scenario described above. We told undergraduates the requirements to get an "A" in a class and manipulated presentation order and numerosity, as described above. Thus, we used a 2 Order (reward-effort vs. effort-reward) x 2 Numerosity (high vs. low) full factorial between-subjects design. Participants indicated the likelihood of pursuing an "A", effort perceptions, and the likelihood of recommending this class to friends. An ANOVA revealed the predicted order x numerosity interaction ($F (1, 96) = 4.01, p < .05$) for pursuit likelihood. Participants were more likely to pursue an "A" when reward was presented first in the high numerosity condition ($M_{reward\text{-}effort} = 5.71$ vs. $M_{effort\text{-}reward} = 4.64; p < .02$), but no difference emerged when numerosity was lower ($M_{reward\text{-}effort} = 6.19$ vs. $M_{effort\text{-}}$

$_{reward} = 6.25; p > .85$). Similar patterns emerged for perceptions of effort (interaction: $F (1, 96) = 4.31, p < .05$) and recommendation likelihood (interaction: $F (1, 96) = 5.33, p < .05$).

Study 2: Pursuing a Loyalty Reward

Participants learned that they could earn a reward upon accruing a certain number of points (effort). We manipulated presentation order by stating the reward first or the effort first. In the high (low) numerosity condition, 1,000 (100) points were needed. However, the step-sizes were also higher (10 vs. 1 point(s) per dollar). Therefore, the amount needed to earn the reward was constant ($100). Participants were either close to or far away from the reward. We thus used a 2 Order (reward-effort vs. effort-reward) x 2 Numerosity (high vs. low) x 2 Reward Distance (far vs. near) design.

Analysis revealed three-way interactions with consistent patterns of means across a range of dependent variables; program attractiveness ($F(1,335) = 4.72, p < .04$), likelihood of earning the reward ($F(1,335) = 5.38, p < .03$), satisfaction ($F(1,335) = 2.78, p < .10$), positive store perceptions ($F(1,335) = 3.03, p < .09$), recommendation likelihood $F(1,335) = 4.55, p < .04$), store loyalty ($F(1,335) = 6.76, p < .009$). Presenting reward first had a positive effect on the aforementioned variables relative to presenting the effort first when numerosity was high and the reward was far. Order effects did not emerge in other conditions. We also found that progress perceptions mediated the three-way interactions reported above.

Study 3: Priming Focus on Outcome or Process

Study 3 used a scenario similar to that used in study 2. We only used the far conditions and primed participants to focus on the outcome of achievement or on the process involved in achievement. We used a 2 Order (reward-effort vs. effort-reward) x 2 Focus (outcome vs. process) between-subjects design. Analysis revealed two-way interactions for program attractiveness ($F(1,152) = 5.64, p < .02$), satisfaction ($F(1,152) = 6.44, p < .02$), positive store perceptions ($F(1,152) = 4.78, p < .04$), and loyalty ($F(1,152) = 3.41, p < 0.07$). A consistent pattern of means appeared for these variables; the presentation order of reward and effort influenced perceptions with outcome-focus, but not with process-focus. Thus, when focusing on the process, effort is salient regardless of order. Although, priming people to focus on the outcome reduces the salience of effort, this salience is restored when effort is presented first. Progress perceptions mediated the effects of the variables reported above.

Conclusions

Findings are consistent across three studies—the presentation order of goal reward and effort information influences perceptions when the effort required to attain the goal is expressed in a high numerosity medium and the goal is distant. When goal reward is presented first, individuals see the goal in a more positive light relative to when the effort is presented first. We argue that presentation order influences the salience of the effort required, which in turn, influences perceptions related to the goal. We discuss implications and future research.

Mental Representations of Uncertainty and Risk

Paper #4: Outcome Neglect: How Guessing Heuristics Supersede Expected Value

Oleg Urminsky, University of Chicago, USA
Adelle Yang, University of Chicago, USA

SESSION OVERVIEW

Dealing with uncertain decision outcomes is a paramount challenge in consumer decision making. Consumers choose between brands while having imperfect knowledge about product quality; they participate in lotteries with different probabilities and outcomes; they choose between financial products with great uncertainty about future returns. Despite the complexity of dealing with uncertain prospects, consumers make decisions like this on a daily basis, and strikingly, most often they do this relying on judgment only. This session consists of four papers that provide new perspectives on consumer choice by showing how consumers' mental representations of risky prospects deviate from central assumptions made by standard psychological and economic models of decision making.

The first paper, by Rothschild and Goldstein, examines whether laypeople can comprehend and estimate the statistical moments (mean, variance, skewness, and kurtosis) of observed numerical information. The survey tradition in economics assumes only aggregated responses are useful and the behavioral literature suggests individual estimates are biased (e.g., the overconfidence and related literatures). Rothschild and Goldstein, however, show that laypeople's understanding of these subtle statistical moments is more accurate than is currently believed. New methods based on graphical interfaces allow non-experts to produce accurate estimates of all four moments of a distribution.

The second paper, by Wu and Yeomans, examines how people form reference points when choosing between risky decision alternatives. Most empirical tests of prospect theory either use the status quo as the reference point or code the outcomes relative to some pre-determined reference point. Wu and Yeomans show, however, that reference point formation is affected by very basic attentional processes. Because people use the most recent outcome as a reference point (a recency effect), they are more likely to choose a risky gamble when outcomes are revealed in an ascending rather than descending order. This is because individuals are typically risk-averse when gambles are framed as gains, but risk-seeking when the same outcomes are coded as losses.

The third paper, by de Langhe and Puntoni, examines how people mentally integrate uncertain gains and losses. Landmark norma-

tive and descriptive theories of decision making (like expected value theory and prospect theory) assume that people integrate, or combine, uncertain gains and losses using an additive integration rule (gain – loss). De Langhe and Puntoni show, however, that people show the pervasive tendency to rely on the payoff ratio (gain/loss), implying multiplicative integration of gains and losses. Reliance on the payoff ratio when choosing between mixed gambles leads to (1) suboptimal monetary outcomes when payoff ratio and expected value are dissociated and (2) to risk seeking (aversion) when choosing between mixed gambles with a negative (positive) expected value. The latter finding qualifies prospect theory's prediction of general risk aversion for mixed gambles.

The fourth paper, by Urminsky and Yang, shows that the maximization of expected utility can best be seen as one of many potential heuristics available to people. Depending on the goal that is activated by the context (e.g., accurately guessing a number in a lottery), people may rely on many other potential heuristics. They show that in both lab and field studies, when people have to guess an amount they could win, they neglect the fact that higher guesses represent the same probability of winning but a higher conditional payoff. They label this effect "outcome neglect".

The mental representation of uncertainty and risk is a fundamental topic that is likely to appeal to a wide audience, for instance, researchers interested in behavioral decision theory, behavioral economics, attention, numerical cognition, and consumer financial decision making. In line with the spirit of ACR special sessions and the theme of the conference—appreciating diversity—the session also brings together research scientists with different backgrounds such as marketing, management, and business (Yahoo!). The participation of George Wu, a world-renowned expert on decision making under uncertainty, is especially noteworthy. All participants have agreed to present, should the session be accepted. The chair will facilitate audience discussion drawing further connections between the new perspectives introduced in this session and other areas of consumer research.

Lay Understanding of the First Four Moments of Observed Distributions: A Test of Economic and Psychological Assumptions

EXTENDED ABSTRACT

Numbers abound in everyday life; laypeople regularly observe prices, sizes, distances, and beyond. Mental representations of this information can inform decision making, much as statistical summaries inform scientific inference.

Economic theory suggests that people coordinate subjective expectations with subjective utilities to determine what actions are undertaken. A fairly standard assumption in modeling is that individuals have perfect expectations. When generalizing from empirical data, it is similarly standard to only trust revealed behavior as the expression of both expectations and utility. Thus, economists study utility by assuming perfect expectations and study expectations by assuming rational utility calculations.

The practice of surveying assumes that, in aggregate, individual estimates of the first moment are unbiased. However, the individual decision making tradition has long reported biases that affect individual-level expectations, such as anchoring effects, primacy effects, recency effects, and attention to local maxima (e.g., peak-end biases).

While expected to be unbiased in aggregate, the view that individual-level estimates of expected value are accurate has no champions. Indeed, the "wisdom of the crowd" logic is based on that idea that estimates are inaccurate, though in symmetrical ways.

In survey research, it is common to ask laypeople what they believe to be an "average" value. However, there are many measures of central tendency, such as mean, median, and mode, and it is not clear which definition respondents assume.

The psychological literature assumes that estimates of the second moment are too narrow, the so-called overconfidence effect, which is moderated by various question formats that lead to better calibration and discrimination. We test, under the various elicitation techniques, whether estimates of distributions exhibit systematic overconfidence. Finally, there has been little research in any discipline on lay intuitions of third and fourth moments: skewness and kurtosis. Our tests of understanding the third and fourth moments help establish a baseline and gauge human sensitivity to higher moments.

In this research, we control the statistical information presented to decision makers and then gauge the degree to which people's perceptions of the first four moments are accurate. In order to simulate the natural flow of numerical information that decision makers might encounter in watching the news or observing prices over time, we provide participants with sequences of 100 numbers, drawn from six distinct beta distributions of varying shapes. Randomly assigned groups use one of multiple elicitation techniques to express beliefs about the quantities they observed.

At the start of the experiment, the participants are told "Imagine we have a bag with a million ping pong balls in it. Each ball has a value between 1 and 20 written on it. In the next 100 seconds, we will randomly choose 100 balls from the bag and show you their values." When the presentation begins, each number appears on screen for 3/5 of a second so that the participant sees 100 numbers in one minute. Participants are told "Now imagine we are throwing the 100 balls back into the bag and mixing them up. We will now draw 100 balls at random from the bag. We will refer to this as our *second draw*." After this, participants are randomly assigned to one of four main question sequences.

In the first condition we ask the respondents to create a full probability distribution that would describe the second draw. We do this by providing a graphical user interface with which the respondent can distribute 100 balls into buckets representing the 20 possible numbers of the distribution.

The second condition elicits fractiles of a distribution by asking respondents to "think about our second draw of 100 balls [and] imagine they were arranged in front of [the respondent] with the smallest values on the left and the largest values on the right. " We then ask them to provide the likely values of the 5th, 25th, 50th, 75th, and 95th balls from the left.

The third and fourth conditions address the first moment directly. In the third condition we ask the respondent to provide the mean of the second draw, providing the definition of a mean. This contrasts with the fourth condition, in which we ask for the "average" of the second draw, leaving the participants free to interpret the term as they wish, with the purpose of gaining insight into how people understand the term "average".

The fifth condition addresses the second moment directly. Participants are asked to provide the value they are 90% certain a random ball would be greater than and, in addition, a value they are 90% certain a random ball would be less than.

The sixth and seventh conditions take a step back and address the full distributions, rather than the moments that define them. In the sixth condition, participants try to identify the distribution they observed in a forced-choice task involving two histograms. The seventh condition is identical, except that participants choose between tables of numbers.

By way of results, we find that laypeople are able to produce accurate estimates of all four moments of a distribution: point-estimates -- including distinctions between the mean, median, and mode -- confidence ranges, and representations of the skewness and kurtosis. We show how the "average" relates to these different measures and that laypeople are able to make meaningful distinctions between these different kinds of average when they utilize a graphical elicitation method. Using new methods, including graphical interfaces that allow the specification of an entire distribution, we allow non-experts to expressed information that they have, but would be unable to communicate in ordinary surveys.

Recency and Reference-Point Formation:
The Effect on Risky Choice Behavior

EXTENDED ABSTRACT

Prospect theory posits that outcomes are evaluated relative to a reference point (Kahneman & Tversky, 1979), with individuals typically risk-averse when gambles are framed as gains, but risk-seeking when the same outcomes are coded as losses. However, most empirical studies either use the status quo as the reference point or code the outcomes relative to some pre-determined reference point (for exceptions, see Abeler et al., 2011; Camerer et al, 1997; Heath Huddart & Lang, 1999; Heath, Larrick & Wu, 1999). Until recently, there has been almost no empirical or theoretical literature on how reference points are determined and updated.

Recently, Koszegi & Rabin (2006, 2007, 2009) proposed a theoretical model in which reference points are "rational expectations" of future outcomes (see Arkes et al. (2008) and Baucells & Weber (2011) for two recent empirical studies of reference point formation). We suggest that Koszegi and Rabin's theory is an incomplete account of the process of reference point formation. Consider, for example, an investor who has seen a series of prices for a stock. Beliefs may not be rational because an investor believes in momentum or regression effects. Moreover, there may also be attentional or memory biases that may influence how individuals weight information and hence make decisions.

In this paper, we examine how a very basic attentional bias, recency, influences reference point formation and ultimately whether participants choose a risky gamble. We control explicitly for beliefs by providing participants with objective information about the choices involved. We nevertheless find that participants are more likely to choose the gamble over a sure thing if the highest value of the gamble is revealed last, rather than first. We argue that this result is consistent with a recency-based reference point account. If the largest outcome serves as a reference point, then outcomes will be viewed as losses, a domain in which individuals are most likely to be risk-seeking.

Study 1

Study1 used a 2 x 2 between-subjects design in which participants saw outcomes either in an ascending or descending sequence and were either endowed with a gamble or the expected value of a gamble. The three possible outcomes were $2, $3, and $10. Participants who were endowed with the gamble were given the option to switch to a sure thing of $5, while others were given the option to switching from a sure thing of $5 to the gamble. To increase the possibility of an attentional bias, participants completed 3 minutes

of anagrams as a distraction after revealing each of the first two outcome values. After participants saw the final outcome, they were given the choice between the gamble or a sure thing (at EV).

Results

One hundred and forty participants were recruited through a downtown community sample. We analyzed the between-subjects effects of order and endowment in a binary logistic regression and found that both main effects are significant, with no interaction between the two. Participants gambled more when they were given the payments in ascending order (48.6%) than in descending order (33.3%). Participants also gambled more when they started with the lottery (50%) than when it was the sure thing (31.9%).

Discussion

We replicated Sprenger & Andreoni's (2011) finding of an endowment effect for risk, which could be the result of either an effect on risk preferences (Koszegi & Rabin, 2007), or a possession-based endowment effect (Brenner et al., 2007). We also find that participants gamble more when the last value was the highest than when it was the lowest, consistent with a recency-based account of reference point formation. One alternative explanation is that there is an effect of affect on risk preferences (Loewenstein et al., 2001) rather than an effect of attention on reference point formation. That is, participants may have felt happy after getting a high final value and which led them to be more risk-seeking. To rule out this alternative explanation, we must test multiple value sets, varying both the final value (low or high) and the relative order (ascending or descending).

Study 2

We conducted a second study to examine the robustness of our effect and to minimize the effect of positive affect. We implemented a within-subjects design and simplified the design from Study 1: the gambles had two rather than three outcomes and participants were always endowed with the gamble. We used 6 different gambles, ($1,$3), ($1,$6), ($1,$9), ($4,$6), ($4,$9), and ($7,$9), with each gamble shown in either ascending or descending order. To test for the ascending series as affect account, we used gambles in which the highest outcome was relatively low or relatively high.

During each of the 12 rounds of the study, participants learned the "heads" value of a coin, then spent 45 seconds doing anagrams as a distractor, then learned the "tails" value of the same coin, and finally chose between staying with the gamble or switching to a sure expected. After all 12 rounds, one of the 12 coins was randomly chosen from a bag and flipped "for real."

Results

Overall, participants were more likely to gamble when the same value pair was presented in ascending order (45.1%) than in descending order (40.3%). We found this directional pattern for 5 of the 6 series. A logistic regression, controlling for the fixed effects of value pair and participant, confirms this effect. A separate logistic regression that includes the value of the final outcome replicates this finding and shows no effect of that final value on risk preferences.

Discussion

We replicate the recency effect in a within-subjects design in another paradigm where beliefs are held constant. Note that we do not find evidence that the absolute level of the second value has an effect on risk preferences, which would be predicted by an affect account. Rather, we argue that increased attention on the second value, through both recency and the built-up anticipation during the anagrams, caused it to be a more salient comparison standard for the

choice. Consequently it received more weight as a reference point for evaluating the attractiveness of the gamble.

The Role of Payoff Ratio in Decision Making Under Uncertainty

EXTENDED ABSTRACT

Many decisions involve the possibility of financial gains and losses. Our understanding of decision making under risk is based on Expected Value Theory (Pascal, 1670/1966), Expected Utility Theory (von Neumann & Morgenstern, 1944), and Prospect Theory (Kahneman & Tversky, 1979). These landmark theories share the fundamental assumption that people integrate, or combine, expected gains and losses using an additive integration rule.

To illustrate, imagine that you are asked to choose between two gambles. With gamble A, you either win $5 or lose $9. With gamble B, you win $15 or lose $20. Which gamble should you choose, gamble A (+5, .50; -9, .50) or gamble B (+15, .50; -20, .50)? Additive integration implies subtracting expected losses (or a transformation thereof) from expected gains (or a transformation thereof). According to Expected Value Theory, for instance, the value of gamble A is -2 (i.e., $EV_A = 2.5 - 4.5$) and the value of gamble B is -2.5 (i.e., $EV_B = 7.5 - 10$). According to Prospect Theory, the value of gamble A is -5.72 (i.e., $PT_A = 2.06 - 7.78$) [1] and the value of gamble B is -10.29 (i.e., $PT_B = 5.42 - 15.71$). Both normative and descriptive theories of decision making therefore predict a preference for gamble A. We presented 109 college students trained in economics and statistics with this choice and 68% opted for gamble B ($\chi^2(1) = 10.96$, $p < .001$). We claim that people prefer gamble B because it has a more attractive gain/loss ratio, or payoff ratio (i.e., $15/20 = 0.75$), than gamble A (i.e., $5/9 = 0.56$).

In general, additive integration is suitable when the quantities to be integrated are commensurable—that is when they have a common standard or belong to the same category—but is not suitable when the quantities to be integrated are not commensurable. For example, when choosing between two jobs differing in workload (measured in hours) and salary (measured in dollars), to compute a summary statistic that jointly considers time and money, one does not subtract the number of hours worked from total dollars earned. In situations where the quantities to be integrated are not commensurable, multiplicative integration is appropriate. For example, a useful statistic to compare the two jobs could be dollars per hour.

Additive integration thus assumes that gains and losses are commensurable. From a normative point of view, this is of course warranted because gains and losses are typically measured with the same standard (e.g., money). From a psychological point of view, however, the assumption that gains and losses, even when measured with the same standard, are perceived as commensurable is not straightforward. Recent developments in emotion research (Cacioppo, Gardner, and Berntson 1999, Larsen, McGraw, and Cacioppo 2001) and neuropsychology (Yacubian et al. 2006; Zhong et al. 2009) suggest that losses are not merely the opposite of gains, but that they are experienced as something different altogether. When evaluating risky decision alternatives, people may therefore have a natural tendency to integrate gains and losses using a multiplicative rule. If so, the payoff ratio is a summary statistic that people may be especially sensitive to.

In a theoretical analysis, we analytically derive the conditions under which payoff ratio, expected value, and prospect theory are

---

1   Consistent with Tversky and Kahneman (1992), these estimates are based on a value function with an exponent of .88 and a loss aversion parameter of 2.25.

dissociated. This analysis also predicts that reliance on the payoff ratio as a proxy for expected value leads to risk aversion (seeking) for mixed gambles with a positive (negative) expected value, whereas prospect theory predicts general risk aversion for mixed gambles. Five empirical studies support the payoff ratio as an important driver of risky choice.

In our first study, participants rated one of four gambles on a scale from -10 (*extremely unattractive*) to +10 (*extremely attractive*): A(+4, .50; -2, .50), B(+8, .50; -5, .50), C(+2, .50; -4, .50), and D(+5, .50; -8, .50). Across both the positive (A and B) and the negative domain (C and D), participants rated the gambles with the higher payoff ratio, gambles A and D, as more attractive than the gambles with the lower payoff ratio, gambles B and C, although the gambles with the lower payoff ratio had a higher expected value.

In our third study, participants were asked to choose two times between pairs of gambles. The first pair of gambles was: A(+300, .50; -150, .50) and B(+500, .50; -200, .50). According to expected value, prospect theory, and payoff ratio, participants should favor gamble B. We constructed the second pair of gambles by adding a sure gain of $100 to all payoffs of the first pair of gambles: C(+400, .50; -50, .50) and D(+600, .50; -100, .50). Similar to the first pair, gamble D is superior to gamble C in terms of expected value and prospect theory. However, adding a sure gain of $100 reversed the rank of the two gambles in terms of payoff ratio. If individuals rely on payoff ratio to choose between gambles, we should observe a preference reversal across the two gamble pairs. Consistent with reliance on the payoff ratio, 78% of participants chose gamble B over gamble A and 64% of participants chose gamble C over gamble D.

In our fifth experiment, all participants are presented with a gamble A (+60, .50; -30, .50). Half of participants are presented with another gamble B (+80, .50; -__, .50) for which the loss is missing. The other half of participants are presented with a gamble C (+__, .50; -40, .50) for which the gain is missing. Participants are asked to match the two gambles in terms of attractiveness. We find that most participants match the payoff ratio of both gambles, but not the expected value.

We will discuss the implications of multiplicative integration for multi-attribute evaluations and attitude formation.

Outcome Neglect:
How Guessing Heuristics Supersede Expected Value

EXTENDED ABSTRACT

In decision-making, we often face situations where the goal of "getting it right" is highly salient, but the differences in consequences if we succeed may be more easily overlooked. Consider a common radio call-in contest: a winning number, representing the prize amount, has been selected within some known range, and the caller has to guess it. If the caller guesses correctly, she will win exactly that amount. Thinking in terms of expected utility (or any utility-maximization approach which incorporates probabilities and outcomes), the right strategy is to guess the highest possible number, as long as all payoffs have equal probability. However, we show that people very rarely use this strategy.

In the first study, participants made a single guess, for an amount drawn from a uniform distribution between $1 and $20, in increments of $.50. They were told that if they guessed correctly, they would win that amount of money, and that they would see the distribution of everyone's prize amounts at the end, to enable them to confirm. While the optimal guess was $20, 85% of participants gave a lower guess. The average guess was $13.11, significantly lower than $20.

In the second study, participants in a classroom setting played a sequential game. A prize amount was drawn at random from a pack of cards numbered between $1 and $10.95, in increments of $.05, in front of the participants. They then took turns guessing, and after each person's guess, all the participants were told whether the actual amount was higher or lower. When a participant guessed correctly, a new number was drawn, until all the participants had the opportunity to make one guess (4 rounds). Participants' guesses were scored from 1 (highest valid guess) to 0 (lowest valid guess). The average guess was .67, significantly lower than 1. While participants gave significantly higher guesses earlier in each round, there was no evidence of learning from observing others' outcomes (better guesses in later rounds). We also found some evidence that round numbers were more likely to be guessed.

In the third study, we analyzed 154 valid guesses made by callers to an actual radio contest, over the course of two months. In each game, a number between $750 and $2012 was chosen and callers made a guess. Similarly to Study 2, if the guess was correct, they won the guessed amount, but if not, whether their guess was too high or too low was announced on-air for the benefit of subsequent callers. Across 36 games, the first caller's guesses averaged $1381, significantly lower than the optimal guess of $2012. Rescaling all guesses to the interval between 1 (highest valid guess) and 0 (lowest valid guess), the average guess was .5, significantly lower than the optimal guess of 1. This did not vary with the time, number of elapsed guesses in that game, or the expected value of the best guess. These findings were confirmed with data from a second radio station contest with the same general format but a different audience demographic.

The field data confirms the presence of outcome neglect in a real-world setting with high potential stakes. It is important to note that callers' behavior could be explained by several alternative accounts, including not believing that the numbers were randomly drawn, wanting to help others by "narrowing down" the range of valid numbers or thinking that doing so might even benefit oneself in the future. However, the lab studies rule out any of these accounts.

Our findings have important implications for several lines of research. Our results suggest that maximizing utility is best seen as one of many potential heuristics available to people, which can be easily overlooked when the goal (e.g. "accurately guessing a number") suggests other heuristics as potentially more relevant. We will discuss the potential for re-framing manipulations to make utility maximizing heuristics more salient and thereby eliminate the effect.

While the irrationality of participants' behavior is clearly demonstrable in the specific setting we use, we argue that the basic notion of outcome neglect generalizes to many other goal-pursuit settings where the negative impact may be more difficult to identify. Arguably, a common mistake is to overinvest in low-payoff tasks because we want to "get it right", or to choose lower-payoff tasks strictly because of their feasibility, failing to adjust for the expected value. In these settings, outcome neglect may be an important cause. Lastly, we note that our findings represent a fairly strong failure of "wishful thinking", as participants' guesses did not reflect wishful thinking, even though it was in their interest to do so in this setting.

Identity Structure and the Boundaries of Identity Marketing

Paper #4: Identity Cues in Product Rating Distributions? The Role of Self-Concept Clarity in Consumer Preferences

Bella Rozenkrants, Stanford University, USA
S. Christian Wheeler, Stanford University, USA
Baba Shiv, Stanford University, USA

SESSION OVERVIEW

The powerful influence of identity on consumer behavior has captivated scholars and practitioners alike for decades (e.g., Belk, 1988; Levy, 1959). Identities that are salient (i.e., currently activated by context cues) guide behavior, and research demonstrates that consumers prefer products and messages that match their salient identity (Aaker, 1990; Wheeler, Petty, & Bizer; Reed, 2004). Accordingly, identity marketing has become a cornerstone of marketing theory and practice. But is simply seeking to match consumer identity enough? The present session presents evidence for the role of the consumer identity structure in preference and effectiveness of identity marketing. Specifically, we provide a deeper understanding of identity marketing by investigating the influence of identity clarity and identity structure on consumers' motivation to regulate and protect their identities.

The first two papers examine how features of the self-concept representation itself (specifically its clarity and integration) affect preferences and behavior. Rozenkrants, Wheeler, and Shiv examine the role of self-concept clarity, or the extent to which people have clearly defined identities or self-views. Results show that people with low-self concept clarity prefer products with bimodal rating distributions as opposed to unimodal rating distributions. This is because products with polarizing (liked by some and hated by others) ratings are seen as more self-expressive. Similarly, Saint Claire and Forehand examine inter-identity structure. They show that people approach identity mismatching when they hold an associated (highly integrated) inter-identity structure and inter-identity competition is low or when they hold a disassociated (weakly integrated) inter-identity structure and inter-identity competition is high. Effects are driven by inter-identity associations or by identity-valence associations depending on whether inter-identity competition is low or high, respectively. The latter two papers examine how features of identity marketing (specifically its explicitness and extremity) affect consum-

er preferences and behavior. Bhattacharjee, Menon, Reed, and Berger show that people who have a clear definition of an identity and high identity relevance are turned off by marketing that defines the terms of identity expression. Instead, these consumers prefer identity marketing that merely references their identity and does not threaten their freedom in identity expression. Klesse, Goukens, Geyskens, and de Ruyter examine the structure of current and ideal identities. They show that when women are primed with extremely idealized identities, such as skinny models, they ironically behave in ways that run counter to the ideal, and actually gain weight. These findings suggest that identities that are made salient through exaggeration are seen as unattainable because of the large discrepancy between the current and ideal selves.

Together, these papers[1] emphasize the importance of identity clarity and structure, and provide a more complete and integrative view of how self-concept and identity marketing interact to shape preferences and behavior. Given the fundamental nature of these concepts, we expect that the session will be well attended by researchers interested in branding, advertising, persuasion, social cognition, attitudes, and consumer backlash, as well as in self and identity. In highlighting both the diversity of consumer identities and diversity in the way those identities are represented, our session complements this year's theme of "Appreciating Diversity."

Escaping the Crosshairs: Possibilities and Perils in Identity Marketing

EXTENDED ABSTRACT

Marketing messages often appeal to consumers based on identities they possess. Jif peanut butter targets mothers by suggesting that, "Choosy Moms choose Jif." DirecTV advertises, "If you call yourself a sports fan, you gotta have DirecTV!" Similarly, Gamefly.com urges, "You call yourself a gamer? You have to have it!" Such approaches are consistent with decades of consumer research suggest that identity marketing leads to increased purchase and deeper loyalty (e.g., Berger and Heath 2007; Escalas and Bettman 2005; Levy 1959; Reed 2004).

In contrast, we propose that messages that explicitly connect consumer identity expression to the purchase of a particular product can backfire. Specifically, while marketing messages that merely reference consumer identity (*identity-referencing* messages) are beneficial, we argue that messages that explicitly define the terms of consumer identity expression (*identity-defining* messages) actually reduce purchase. The persuasive intent of identity-defining messages is especially salient, and thus, they may be perceived as an attempt to influence consumers and limit options for identity expression. Because autonomy is especially crucial in the context of identity expression (Deci and Ryan 1985; Kivetz 2005), these messages are likely to backfire. In order to reassert their autonomy, consumers may avoid products that would otherwise naturally resonate with their identity.

Five studies test this theorizing. An initial study sought to assess whether managers can anticipate consumers' need for autonomy in identity expression and craft messages accordingly. We expected that managers would prefer identity-defining messages,

---

1   All the papers are in advanced stage: either in the last stages of data collection or under review.

since they are more explicit and more clearly intended for the target segment. A panel of actual executives selected one of three messages to advertise an environmentally friendly, biodegradable soap to a segment of "green" consumers: "Charlie's: A good choice for consumers." (non-identity), "Charlie's: A good choice for green consumers." (identity-referencing), and "Charlie's: The only good choice for green consumers!" (identity-defining). As expected, managers preferred the identity-defining message ($\chi^2(2) = 7.36$, $p < 0.03$), and predicted that it would lead to higher purchase than both the non-identity baseline ($t(57) = 7.59$, $p < 0.001$) and the identity-referencing message ($t(57) = 2.06$, $p < 0.05$). Confirming our expectations, ratings of explicitness in targeting were highly correlated with predicted purchase and perceived consumer freedom in identity expression ($rs(58) > .67$, $ps < .001$).

A second study tested the accuracy of managerial predictions by testing these same messages in a consumption scenario. We also tested the mechanism underlying these effects in two ways. If these effects are driven by identity, as we suggest, then they should occur only among consumers whose target identity is salient (e.g., Reed 2004). Accordingly, we primed participants with a green versus neutral identity. Moreover, we tested the proposed mediating mechanism of freedom in identity expression. As expected, message type had no influence among neutral participants. However, among green participants, contrary to managerial predictions, the identity-defining message decreased purchase relative to the identity-referencing message ($t(68) = 6.54$, $p < .001$) and even relative to the non-identity baseline ($t(66) = 2.24$, $p < .03$). This effect was mediated by reduced perceptions of consumer freedom in identity expression ($b = -0.29$, $z = -3.61$, $p < .001$), supporting our theorizing.

A third study using the same stimuli built on these findings by measuring instead of manipulating identity. We also tested a real behavior: actual choice of a sample of the target versus a neutral soap. As predicted, these effects held for actual soap choice, and were moderated by identity centrality (i.e. the extent to which an identity is deeply important). Message type had a significant effect on soap choice among high-centrality participants ($\chi^2(1) = 9.94$, $p < .01$), but no effect among low-centrality participants ($\chi^2(1) = 2.29$, $p > .13$).

A fourth study examined our proposed mechanism using a different moderator: individual sensitivity to constraint (Hong and Faedda 1996). Moreover, to establish external validity, we used a sample of mothers and actual identity marketing messages from the marketplace: "Moms like you choose Jif" (identity-referencing) versus "Choosy moms choose Jif!" (identity-defining). Mothers reacted increasingly against the identity-defining message as individual sensitivity to constraint increased ($\chi^2(1) = 4.49$, $p < .04$), further clarifying the mechanism.

Finally, a fifth study investigated an instance in which autonomy might be undesirable: when consumers are highly uncertain about what an identity means to them. According to our theorizing, greater identity definition is likely to be preferred in such cases. To test our predictions, we primed parent identity certainty versus uncertainty (Gao, Wheeler and Shiv 2009). While certain parents reacted against identity-defining messages (vs. identity-referencing; $F(1,142) = 4.59$, $p < .04$), uncertain parents welcomed identity definition and actually increased purchase ($F(1, 142) = 5.98$, $p < .02$), supporting our theoretical account.

While the literature has focused exclusively on the possibilities of identity marketing, our findings highlight its perils. Together with the drive to construct and define the self, the need for a sense of autonomy in doing so is one of the fundamental motivations of the self. Hence, considering consumer autonomy appears particularly crucial in the context of identity expression. Our findings simultaneously offer a caveat to the identity marketing literature and validate the power of the identity construct.

When Do Consumers Prefer Mistargeted Products? The Effect of Structure and Competition on Preference for Identity-(In)Consistency

EXTENDED ABSTRACT

A working-parent may prefer work-oriented products or family-oriented products depending on whether her employee or parent identity is active. Although the literature supports the notion that consumers have multiple identities and that priming a given identity can prompt approach toward identity-consistent (and avoidance of identity-inconsistent) preferences and behaviors (Forehand and Deshpande 2001; Forehand, Deshpande, and Reed 2002; Grier and Deshpande 2001; Zhang and Khare 2009), attention to the situations or factors that facilitate such response is sparse. We argue that two critical determinants of preference for identity (in)consistency are 1) The underlying inter-identity structure and 2) The level of inter-identity competition.

Past research within the Bicultural Identity Integration (BII) literature has shown that biculturals with a highly integrated, or "associated," inter-identity (II) structure demonstrate the typical identity priming effect whereby individuals approach behaviors consistent with the primed identity and avoid behaviors inconsistent with the primed identity. Alternatively, biculturals with a weakly integrated, or "disassociated," II structure demonstrate a contrastive effect wherein they avoid (approach) identity-consistent (-inconsistent) behaviors (Benet-Martinez et al. 2002; Cheng, Lee, and Benet-Martinez 2006; Mok and Morris 2009, 2010; see also Sacharin, Lee, and Gonzalez 2009; Zou, Morris, and Benet-Martinez 2008). These effects are argued to occur due to the positive and negative valence associations with cultural identity held by high and low BII consumers respectively (Benet-Martinez et al. 2002; Cheng et al. 2006; Mok and Morris 2009).

The above valence-driven effects are well established within the literature on cultural identity. However, it has also been suggested that consumers cognitively organize multiple identities within an associative network where identities may be associated or disassociated in a more benign, valence-neutral way (Amiot et al. 2007; Greenwald et al. 2002; Luna, Ringberg, and Peracchio 2008). As such, spreading activation suggests that priming one identity should inhibit the activation of disassociated identities (e.g., Hugenberg and Bodenhausen 2004) and facilitate the activation of associated identities. In this case, one would expect the typical priming effect in the presence of *disassociated* identities as individuals approach (avoid) the activated (inhibited) identity. Alternatively, when consumers possess associated identities one would expect dual approach of both the activated identity and the associated identity. These novel predictions are contrary to those of BII theory and are driven simply by the inter-identity association rather than by valence.

To reconcile the competing predictions regarding the influence of II structure on preference for identity (in)consistency, we propose that the predictions of BII will hold when II competition is high but not when II competition is low. The valence-driven effects of BII may be especially prevalent when two identities have a high degree of direct competition and associated stressors (Benet-Martinez and Haritatos 2005; Cheng et al. 2006). However, across the broader realm of consumer identities (e.g., student, female,

sister, tennis player), high direct competition need not necessarily be the case. Thus, identities may be associated or disassociated in a more benign, valence-neutral way facilitating the predicted II association-driven effects.

We tested the foregoing predictions in three experiments. Across experiments we used scenarios to manipulate II structure and II competition between undergraduate participants' "student" and "friend" identities. We varied whether participants rated identity-consistent or identity-inconsistent products by priming an identity (student vs. friend) and presenting them with the same product targeted toward a matching or mismatching identity (student vs. friend).

In experiment 1 (n = 78), the interaction between Inter-Identity Competition and Identity-Product Consistency was significant ($p < .01$) such that when II competition was high (low), participants in a disassociated II structure had higher (lower) attitude ratings for the identity-inconsistent product relative to the identity-consistent product; $M = 5.78$ vs. 4.92 (5.03 vs. 5.93). This supported the notion that valence-driven BII effects are found under high competition but the novel II association-driven effects are found under low competition. In experiment 2 (n = 77) we further explored II structure's influence under low II competition. The interaction between II Structure and Identity-Product Consistency was significant ($p < .05$) such that participants in a disassociated II structure again had a lower relative preference for the identity-inconsistent (vs. –consistent) product; $M = 5.02$ vs. 5.80. Critically, participants in an associated II structure had no difference in relative preference between products, supporting the proposed dual approach model; $M = 5.86$ vs. 5.35. Experiment 3 (n = 109) further explores the counter-intuitive effect where an associated II structure leads to approach toward identity-inconsistent behavior. The interaction between II Structure and Identity-Product Consistency was significant ($p < .05$). Participants in a disassociated II structure rated an identity-inconsistent product equally to a control product which did not target a specific identity; $M = 5.27$ vs. 5.39. Participants in an associated II structure counterintuitively rated the identity-inconsistent product higher than the control product; $M = 5.92$ vs. 4.91. This pattern also held for a measure of purchase intentions ($p < .05$). The effects on preference were mediated by perceived product fit (Sobel ps $< .01$; Bootstrap ps $< .05$). When primed with their friend identity, for example, participants in an associated II structure actually felt that a *student*-targeted product fit their needs. This supports the notion that priming a given identity also activates associated identities and their inherent needs and preferences.

In sum, the present research provides an important update to identity theory by demonstrating that consumer preference for identity (in)consistency depends on both inter-identity structure and inter-identity competition. Under high II competition consumers demonstrate the typical preference for identity-consistency only with an associated II structure; consumers actually counter-intuitively approach identity-*in*consistency under a disassociated structure. Under low II competition, the typical preference for identity-consistency is found only under a disassociated structure; the counterintuitive approach toward identity-consistency is found under an associated structure. Considering that the broader realm of identity is likely to have low II competition, marketing campaigns should encourage an associated II structure to facilitate approach.

Repeated Exposure to the Thin Ideal and its Implications for the Self: Two Weight Loss Program Studies

EXTENDED ABSTRACT

Body image is an important part of our identity (Harter 1999). Through comparing ourselves to others we become aware of our self-image and of how we would (or should) want to look like (Festinger 1954). Nowadays, the media bombards us with models that are considerably thinner than the majority of the female population (Levine & Smolak 1996) and, hence, constitute an ideal out of reach for most women. The consequences of this exposure have been researched abundantly, primarily demonstrating that self-esteem and body satisfaction decrease when dieters are exposed to thin media images (Grabe, Ward, & Hyde 2008).

Surprisingly, existing research on the behavioral consequences has been limited to a single exposure and assessment of eating behavior right afterwards. Our research adds to and advances existing research by taking a goal perspective and exploring how constant exposure to thin models influences dieters' desire to reach a thinner self over time. We believe a longer time perspective is needed during which the motivation to reach the desired ideal and eating behavior is concurrently investigated. Accordingly, we explore over time whether being constantly confronted with the thin ideal motivates or demotivates dieters to obtain a thinner self.

On the one hand, exposure to thin models could motivate dieters to obtain a thinner self: Specifically, research on the non-conscious effects of subtle cues on behavior suggests that primes activate more enduring effects when the prime is perceived as distant form the active self-concept (Sela & Shiv 2009). In this context, a perceived discrepancy between individuals' active self-concept and the cue signals that the goal has not been attained and, hence, functions as a motivator (Dijksterhuis, Chartrand, & Aarts 2007). However, on the other hand, according to the goal gradient hypothesis (Hull 1934) or the 'goals loom larger' effect (Brendl & Higgins 1995) the motivation to attain a certain goal increases as the desired end state approaches. That is, if a goal becomes closer and easier to attain, individuals become more confident (Tubbs, Boehe, & Dahl 1993) and allocate more effort in order to reach the desired end state.

We conducted two weight loss program studies (each lasted for one week) in order to explore whether constant exposure to the thin ideal increases or decreases individuals' motivation to reach a thinner self and fosters goal consistent or inconsistent behavior over time. For both studies we invited female students that wanted to lose weight. They received an eating diary enabling them to note down exactly what they ate after every consumption occasion (i.e., breakfast, lunch, dinner, and snacks in between). For half of the participants the cover of the diary featured an extremely thin model while for the other half of the participants the cover featured a neutral dieting-related image (study 1) or a moderately thin model (study 2). Participants were weighted at the begin and the end of the weight loss program.

The findings of study 1 (N= 48) demonstrate that constant exposure to the thin ideal while trying to lose weight backfires: participants who were exposed to the thin model (Mt = 4.08) perceived a thinner self as significantly less attainable than participants in the control condition (Mc = 5.08; $F(1,46) = 6.29$, p < .05). Further they (Mt = 1284.75) consumed snacks higher in calorie content than the control condition (Mc = 754.15; $F(1, 46) = 4.92$, p < .05) and gained weight (Mt = -.23) rather than lost weight as the control condition ($F(1, 46) = 5.24$, p < .05; Mc = .87)[2].

---

2   We express the weight gain/loss not in absolute terms but in relation to participants' initial weight. A negative value implies

In study 2 (N = 42) both conditions are exposed to a model. However, while the treatment condition is confronted with an extremely thin model the control condition is exposed to the same but normal-sized (photoshoped) model. This enables us to test whether particularly the exposure to an unrealistically thin model triggers the perception that the thinner self is unattainable and causes individuals to give up. Study 2 reveals a significant difference in weight loss success: while participants exposed to the moderately thin model manage to lose weight ($M_c = .013$), participants confronted with the extremely thin model did not lose weight ($M_t = .003$; $F(1, 40) = 6.56$, $p < .05$). Following Zhao, Lynch, and Chen (2010) we applied a bootstrap test to establish whether perceived attainability mediates this effect. The results reveal the mean indirect effect to be positive and significant (a x b = .0022), with a 95 % confidence interval excluding zero (.0051 to .0001).

While existing research has demonstrated that exposure to thin models influences dieters' motivation to diet and eating behavior, the assessment was limited to behavioral consequences right afterward. In this research, we show that it is important to explore the consequences of exposure to thin model cues over time: although the omnipresence of thin models in our environment fosters the desire for a thinner self, it at the same time, hampers individuals' attempt to reach this ideal identity. By this, an individual realizes that the thin ideal is, for her, not that easy to attain which results in disengagement from the goal.

Existing research on self-identity has shown that several activities help to build a stock of knowledge about oneself. For instance, individuals develop several self-schemata (Markus 1977), which are specific ideas or pieces of information about the self and its characteristics. In forming these self-schemata individuals think of recent experience of success or failure they have had (Baumeister 2010). We add to this by showing that exposure to thin models changes the importance that individuals attach to certain self-schemata and the willingness to engage in actions needed to obtain their ideal self. That individuals engage in goal inconsistent behavior, i.e. eating unhealthy snacks (study 1), to a greater extent after repeated exposure to a thin model implies that this constant confrontation with their ideal self, decreased individuals' motivation to achieve it.

Identity Cues in Product Rating Distributions: The Role of Self-Concept Clarity in Consumer Preferences

EXTENDED ABSTRACT

Online retailers like Amazon synthesize consumer reviews in terms of means and distributions of star ratings. Whereas the mean rating conveys the average liking for the product, the distribution conveys the level of agreement among consumers. The present research probes how the shape of rating distributions and levels of agreement among reviewers affect consumer preferences.

Distinctiveness theory posits that people selectively focus on traits that emphasize their peculiar and unique characteristics (McGuire, McGuire, Child, & Fujioka, 1978; McGuire & McGuire, 1988). The need to establish distinctiveness is particularly salient when people feel uncertain about themselves (Baumgardner, 1990). Frequently, this uncertainty is addressed by adherence to firm and extreme attitudes (Sherman, Hogg, & Maitner, 2009). Hence, people have a heightened need to achieve distinctiveness and clarify their self-concept when they are uncertain about who they are.

One indicator of self-certainty is self-concept clarity. Self-concept clarity reflects the extent to which people hold clearly defined self-beliefs (Campbell, 1990). Generally, it is the sense of knowl-

edge about who you are and what you stand for. Because lacking certainty and clarity in one's self-views is aversive (McGregor & Marigold, 2003), those with low self-concept clarity are motivated to establish a consistent self-view. Because choice of products with identity-relevant characteristics helps maintain a well-defined identity through time (Kleine, Kleine, & Allen, 1995), one way to rectify a compromised self-concept is to choose products to re-establish and clarify a certain identity (Englis & Solomon, 1995; Gao, Wheeler, & Shiv, 2009). We propose that another way to satisfy this need is by choosing polarizing products, because products that are not homogenously liked help consumers differentiate themselves.

The shape of rating distributions signals the degree of consensus regarding product appeal and allows consumers to assess their preferences relative to others. Unimodal distributions are clustered around a particular rating, decline in the tails, and convey a clear consensus on the level of appeal. On the other hand, bimodal distributions have two clusters, with one cluster in the high ratings and the other one in the low ratings. Because bimodal distributions indicate a lack of consensus about a product, products with bimodal rating distributions can make one more distinctive, and hence be more self-defining.

Because preference for products with bimodal distributions suggests disagreement with a larger share of people than in the unimodal condition, people who are motivated to hold a clearer self-view should favor products with bimodal distributions. Thus, we predict that as compared to high self-concept clarity consumers, those with low self-concept clarity should find products with bimodal distributions more appealing.

In experiment 1, we examined people's lay theories about rating distributions. Participants chose the product types (generally liked, generally disliked, or polarizing) that they perceived to be the most informative about one's identity and most self-expressive. These measures created a single factor of identity relevance, with polarizing products seen as the most identity relevant, $c^2(2) = 101.87$, $p < .01$.

In experiment 2, we examined the influence of self-concept clarity and rating distributions on product evaluations. Participants saw a movie poster ("Contagion"), along with the movie synopsis, and were randomly assigned to see the bimodal or unimodal distribution (same mean rating). Ratings of the perceived quality, likelihood of enjoyment, and likelihood of seeing the movie were consolidated into a desirability factor. We measured self-concept clarity using a validated scale (Campbell et al., 1996). A significant interaction emerged, $b = -0.74$, $t(145) = -2.41$, $p = .017$, such that participants with low self-concept clarity preferred movies with bimodal distributions, whereas participants with high self-concept clarity preferred movies with a unimodal distribution.

The purpose of experiment 3 was to manipulate self-concept clarity. Participants were randomly assigned to complete a task designed to lower or heighten self-certainty (Hogg, Sherman, Dierselhuis, Maitner, & Moffit, 2007). They then completed the self-concept clarity scale. Next, participants were asked to imagine they were considering movie purchase and were provided with ratings (unimodal or bimodal) from previous viewers. This was done to ensure that the use of the specific movie in experiment 2 did not drive the results, because of genre or other confounding factors. This was followed by the experiment 2 desirability questions. Although the certainty manipulation did not have a direct effect on movie preferences, a moderated mediation path was significant, 95% CI [-0.2123, -0.250]. Participants in the uncertainty condition had lower self-concept clarity scores, and this led them to have higher preferences for the movie with a bimodal, relative to unimodal, distribution.

weight gain.

We conducted experiment 4 to explore whether group polarization was driving this effect. To clearly convey polarization, we simplified our distributions into three categories: like, dislike, or neutral. The procedure mimicked experiment 3, except that the feedback from previous consumers was polarizing [neutral], "65% really enjoyed the movie" and "35% really disliked [had neutral feelings about] the movie." Results revealed a significant interaction, $b = -0.41$, $t(162) = -2.04$, $p = 0.04$. Although participants high in self-concept clarity preferred the movie with the neutral ratings, this effect was attenuated for participants low in self-concept clarity, despite the fact that the polarizing movie had an objectively lower rating than the neutral movie.

Our examination of the role of product rating variance in product evaluation shows an influence of self-concept clarity. Surprisingly, this need to clarify one's identity persists despite the negativity bias. Adding to the identity driven consumption literature, the results suggest that polarizing products may provide a way for self-uncertain consumers to feel a sense of certainty and assert their identity. This implies that retailers should look to rating distributions to understand their customers, and attempt to appeal to self-uncertain consumers (e.g. adolescents) with polarizing products.

Beyond the "Pain of Paying:"
The Role of Specific Emotions in Consumers' Reactions to Prices and Payment Decisions

Chair: Shelle Santana, New York University, USA

Christian Laesser, University of St.Gallen, Switzerland, USA

Paper #4: Beyond Clarity and Confusion: Affective Responses to Price Framing in the Airline Industry
Shelle Santana, New York University, USA
Vicki G. Morwitz, New York University, USA

SESSION OVERVIEW

Apart from Prelec and Loewenstein's (1998) "pain of paying," research on the specific role that emotions play in consumer reactions to prices and to payment decisions has been sparse. The papers presented in this session aim to close this gap by examining how affect and emotions influence reactions to price promotions, the present value of money, discrepancies between reference prices and purchase prices, and price framing. Although pricing has received considerable attention from marketing researchers, the approach has been almost exclusively from a cognitive perspective. The goal of this proposed session is to expand our current understanding of the role that emotions play in pricing and payment situations. Each paper investigates this research objective from a unique theoretical perspective using different methodological approaches.

The first paper by Aydinli and Bertini examines the relationship between consumers' emotional responses and price promotions. Applying a dual process account of decision making, the authors posit and show that price promotions reduce the motivation for thinking and pave the way for affective decision making. As a result, price discounting results in stronger preference for emotionally-laden products as well as valuations that are scope insensitive and more polarized. Results from five experiments support the authors' hypotheses and shed new light on the emotional implications of price promotions.

The second paper by Thomas and Park shows that negative emotions can have a positive effect on consumer financial decision making. In contrast to the widely held view that emotions are detrimental to rational decision-making, the authors show that emotional decision making can reduce the present bias in consumers—especially for those who are predisposed to regret spending money (Tightwads). Three experiments show that when consumers are primed with feelings (vs. calculation), they exhibit reduced levels of present bias in financial decisions. Results from a third study using skin conductance to measure arousal provide further support.

The third paper by Engeler and Laesser posits that specific emotions arise from discrepancies between a consumer's purchase price and various reference prices. Specifically, when a purchase price is lower than a consumer's maximum WTP, consumers will experience pride in themselves about their positive consumer surplus. However,

when a purchase price is lower (higher) than their expected reference price, consumers will experience gratitude (anger) toward the seller. Three field studies widely support these predictions. Furthermore, these emotional states related to self- versus seller attributions predict post-purchase behavior such as positive WOM and repurchase intentions.

The fourth paper by Santana and Morwitz examines consumers' emotional responses to different ways airlines present prices that include fees. This topic has received considerable attention in both the popular press and from government agencies in the wake of new regulatory requirements calling for more price clarity and transparency from airlines. Three laboratory studies show that some common ways that fees are framed (e.g., drip and a la carte fee listing) can result in high negative emotions and low positive post-purchase behavior. These negative emotional reactions stem from consumers' reactions to the additional fees (versus higher total prices or base prices). However, the authors also show that these negative emotions can be reduced when fees are presented as a mixed bundle (where a la carte and equivalent package prices are shown concurrently).

Audience: The potential ACR audience for this session is quite broad. Apart from providing new theoretical insights for researchers interested in behavioral pricing, the session will attract a cross-section of ACR conference attendees who are interested in diverse areas of research such as general affect, specific emotions, mental accounting, and multi-method research.

Level of Completeness: For all four papers, the theorizing has been completed and multiple studies have already been conducted. Since all four papers are close to completion, we expect this to be an interesting and high quality session.

Plan for the Session: Our goal for the session is to give each presenter sufficient time to clearly present his or her findings, to encourage audience interaction with the presenters, and to facilitate a discussion about future research. We plan to allocate the session time in the following manner. Each paper will be presented for 15 minutes, followed by 2-3 minutes of question and answer.

Summary: In sum, while each of the papers examines the role that emotions play in consumers' reactions to prices and payment decisions, each provides different conceptual and methodological contributions. We believe that examining the range of affective, attributional, and physiological responses that consumers experience in response to purchase and payment decisions will not only appeal to a broad cross-section of ACR members, but also make an important contribution to theory. By highlighting the synergy in our research questions, we hope to provide significant insight and lay the foundation for future research on emotions, price, and payment.

Price Discounting For Emotional Impact

EXTENDED ABSTRACT

The process by which consumers respond to price promotions is generally thought to be a cognitive process (Inman, McAlister, and Hoyer 1990). Emotions are seldom considered, unless they are the outcome of a process that is still deliberate (Chandon, Wansink, and Laurent 2000) or evoked spontaneously without the mediation by cognitive processes (Naylor, Raghunathan, and Ramanathan 2006). We propose a more parsimonious view of consumer response to price promotions, acknowledging that consumer decisions are guided by

a combination of affective and deliberative processes (Loewenstein and O'Donoghue 2007).

We suggest that a price promotion is likely to influence the relative dominance of the two processes by lowering the stakes in the decision environment and therefore reducing the motivation of consumers to engage in effortful deliberation. As the relative influence of cognitions diminishes, affect takes control of behavior, and feelings are more relied on as inputs in judgments and decisions. This process produces a series of related effects, including shift in preferences towards goods with higher emotional content and valuations that are scope insensitive and more polarized.

In Experiment 1, participants were asked to purchase an affectively superior or a cognitively superior snack. These snacks were sold at full price or at a 50% discount. As predicted, the presence of a price discount shifted preference toward the former option. Importantly, participants in the discount condition performed worse on a recall task and reported relying more on their feelings when deciding. We tested for two plausible confounds, a mood and a justification mechanism, but found no evidence of these accounts.

In Experiment 2, we tested a promotional setting in which only one brand was discounted at a time. Participants were asked to indicate their preference between two brands, one that was affectively superior compared to the other brand, in three different product categories: cars, mobile phones and watches. The experiment manipulated a single between-subjects factor, price promotion, across three levels: baseline (no promotion), promotion on more emotional brand vs. promotion on less emotional brand. Participants' relative preferences were analyzed in a 3 X 3 mixed factorial ANOVA with price promotion as the between-subjects factor and product category as the repeated measure. Consistent with our prediction, we found that a price discount offered on the more emotional brand increased participants' preferences for it ($p < .000$), whereas the same promotion offered on the less emotional brand did not change participants' relative preferences ($p = .531$).

Experiment 3 expanded our investigation to consumer valuations by capitalizing on a judgmental correlate of feeling-based evaluations. Based on prior research that suggests that feeling-based evaluations are relatively insensitive to the scope of the target stimulus (Hsee and Rottenstreich 2004), we predicted that the scope insensitivity should be more pronounced in the presence of a price promotion than in its absence. Consistent with this prediction, we found that in their willingness to pay for a bundle of music CDs, participants were significantly less sensitive to the number of CDs in the box set when the box set was on promotion than when it was not on promotion.

In order to garner further process evidence, Experiment 4 examined whether an individual's need for cognition (NFC) moderates the proposed impact of a price promotion. Based on prior research suggesting that the NFC is a determinant of processing motivation and that reliance on feelings is greater when NFC is low, we proposed that a price promotion is likely to increase preference for the affectively superior option for low NFC individuals who are less motivated to think, while high NFC individuals' preferences are likely to be unaffected by the promotion. The experiment utilized a 2 (promotion) x 2 (NFC) mixed design. Participants were asked to indicate their preference between an affectively superior resort room and a cognitively superior resort room which were similar in price. The rooms were offered at full price or at a 30% discount. As predicted, the price promotion increased preference for the affectively superior room only for low NFC individuals ($p < .001$), while high NFC individuals' preferences were unaffected by the promotion ($p = .737$). A second objective of this experiment was to document another facet

of reliance on feelings (Ratner and Herbst 2005), testing the prediction that a price promotion would lead to more extreme and polarized evaluations of the target object. We found support for our prediction.

Finally, Experiment 5 manipulated the weight attached to feelings vs. cognitions. We examined whether our effect would be mitigated by instructing participants to use their cognitions as the basis for their decisions. Participants were instructed to use either feeling-based processing or reason-based processing as they were creating a list of DVDs from a sample of 'highbrow' and 'lowbrow' movies belonging to an online DVD rental service that either did or did not offer a price promotion. The experiment thus employed a 2 (price promotion) x 2 (judgment process) between-subjects factorial design. As expected, analyses revealed a 2-way interaction ($p < .03$). When instructed to rely on their feelings, participants preferred the affectively superior movies more strongly in the presence of a price promotion than in its absence ($p = .032$). However, when instructed to rely on their reason and logic, participants' relative preferences were not affected by the price promotion ($p = .260$).

Overall, these experiments demonstrate the impact of price promotions on consumers' reliance on affective vs. deliberative processes and how this would influence their preferences and valuations. Our findings highlight the importance of understanding the guts of consumers' reactions to price promotions.

Do Emotions Decrease or Increase Present Bias in Monetary Decisions?

EXTENDED ABSTRACT

For a long time, it has been argued that emotions are detrimental to rational decisions. However, the past few decades of research has provided support for the proponents of the other side of the debate. For example, patients with damage in the ventromedial prefrontal cortex (vmPFC) of the brain, who are not able to use emotions to aid in decision making, often engaged in behaviors that were detrimental to their well-being even though their reasoning and problem-solving abilities were unaffected by the brain damage (Damasio 1994). Furthermore, recent findings suggest that it is not only the excess of emotions but also the lack of emotions that is causing some of the most serious problems that mankind is facing.

The present research extends this debate in the context of the present bias – the propensity to focus on the present value of money rather than its future value. A typical study on the present bias employs a delay of gratification paradigm, wherein an individual has to choose between a smaller but immediate reward and larger but delayed reward. For example, a person might be asked to choose between $1000 a year later and $750 now. Generally, it has been found that most people tend to exhibit a preference for smaller present rewards than larger future rewards. Several scholars have argued that relying on emotions exacerbates the present bias (e.g., Van den Bergh, Dewitte, and Warlop 2008).

We challenge this view and argue that certain types of emotions – namely anticipated regret – can reduce the present bias. Therefore, people who are prone to anticipate regret are likely to benefit from relying on emotions when making financial decisions. Our conceptualization posits that the delay of gratification paradigm can be reframed as a battle between two different emotions: a positive visceral reaction to the immediate reward versus the anticipated regret from foregoing the larger delayed reward. Following other researchers, we assume that in terms of consequentiality and neurophysiological substrates, anticipation of regret is akin to the experience of regret (Camille, Coricelli, Sallet, Pradat-Diehl, Duhamel, and Sirigu 2004; Zeelenberg and Pieters 2007). Three studies demonstrate how dis-

positional traits and situational primes can interact to increase the anticipated regret that reduces the present bias. Across the studies, we find that when primed to rely on emotions, tightwads – who are predisposed to anticipate regret from spending money – become less present biased. This effect did not manifest for spendthrifts who are predisposed to experience less regret.

Study 1 tests the hypothesis that relying on emotions/feelings helps people to make loan prepayment decisions. Loan prepayment decision can be framed as a decision between keeping money to spend now versus prepaying money to save on interest payments and spend more in the future. 299 participants were randomly assigned to one of the three different priming conditions: feeling prime, calculation prime, or control. The priming task was adopted from Hsee and Rottenstreich (2004). After the priming task, participants were told to imagine that they had a loan and that the bank is considering giving them the option to prepay. All participants saw six different loan prepayment scenarios that varied in the prepayment amount and future interest. For each scenario, they indicated whether they want to prepay the amount given in the scenario to reduce their monthly payment amount or not to prepay and stay with the current monthly payment amount. After that, participants were administered a scale that captures dispositional propensity to be a tightwad or a spendthrift (Rick, Cryder, & Loewenstein 2008). Results show that priming participants to rely on their emotions reduced the present bias for tightwads but not for spendthrifts. Tightwads were most likely to prepay their loans when they were primed to rely on their emotions.

Study 2 tests the hypothesis using the standard present bias paradigm (Rachlin, Raineri, and Cross 1991). 131 participants went through the same priming procedure as in Study 1. Then they were asked to make a series of choices between smaller money delivered in the present and larger money delivered in the future. In line with the Study 1 results, priming participants to rely on their emotions reduced the present bias for tightwads but not for spendthrifts. Additionally, the effect was mediated by participants' anticipated regret such that when primed to rely on their emotions, tightwads anticipated strong regret but spendthrifts did not.

Study 3 was designed to provide additional support for the hypothesized role of emotions by using skin conductance response data, which have often been used as a measure of physiological arousal. 87 participants went through the same priming and choice tasks as in study 2 while wearing a sensor on their palm that measures their skin conductance responses. Results replicate the effects found in previous studies such that tightwads were less present biased and experienced greater arousal when primed to rely on emotions.

In sum, we argue that emotions can help in the financial decision and failure to anticipate regret can result in suboptimal financial decisions.

Emotional Effects of Purchase Price-Reference Price Divergence

EXTENDED ABSTRACT

Although the ability of price outcomes to elicit (un)happiness has long been postulated (Thaler 1985), empirical research on price affect (O'Neill and Lambert 2001) and particularly on the formation and impact of qualitatively different price-related emotions is relatively young (e.g., Gelbrich 2011). This research investigates consumers' discrete emotional responses to discrepancies between the actual market price of a product and (i) consumers' internal reference price (i.e., transaction utility), or (ii) their maximum willingness to pay (i.e., consumer surplus). Our results provide insight into how the

general happiness or pleasure of relative gains and the pain of losses (Thaler 1985) relates to specific emotional reactions to prices, which can have implications for long-term customer-seller relationships.

Consumer surplus has been defined as the difference between the actual market price and consumers' maximum willingness to pay (Frank and Bernanke 2001). Transaction utility incorporates a more psychological perspective. It depends on the difference between the actual market price and a consumer's reference price, that is, a consumer's conception of a fair or normal price the seller is expected to charge (Thaler 1985). The different standards considered (i.e., self-related vs. social norm-based) are expected to induce distinct evaluations in a purchasing context. Appraisal theories of emotion assume that such distinct appraisals about an event can elicit different discrete emotions (Lazarus 1991). Specifically, we expect that a consumer's surplus is evaluated in a self-attributional way ("I could beat the market!"), while a given transaction (dis)utility is appraised as related to the seller ("That was a really (un)fair price the seller charged me!"). This project focuses on consumers' emotional responses after having purchased a product (i.e., actual price ≤ maximum willingness to pay). Hence, we hypothesize that a positive consumer surplus will generate feelings of personal pride, while transaction (dis)utility is expected to trigger feelings of gratitude toward (anger about) the seller (Roseman, Spindel, and Jose 1990; Weiner 2000). Further, consumers are expected to cope with these emotions in specific ways (Lazarus 1991). Seller-related feelings of gratitude and anger are hypothesized to more strongly influence consumers' post-purchase behavioral intentions toward that seller than self-related feelings of pride about one's personal achievement (Soscia 2007; Nyer 1997).

We conducted three field surveys to test the hypotheses with consumers who had purchased a public transportation product (fare ticket, leisure product, etc.). In Study 1, a short online questionnaire was part of a diary study yielding 717 purchase observations. Maximum willingness to pay was measured by asking the respondents to indicate the highest price they would be willing to pay (Suri and Monroe 2001). The internal reference price was calculated based on the respondents' estimate of a fair price, normal market price, past price paid, as well as their highest and lowest price willing to pay (Chandrashekaran and Grewal 2003; Klein and Oglethorpe 1987; Suri and Monroe 2001). Multiple linear regression results indicate that transaction utility significantly triggers a consumer's attitude toward the price paid ($p < .001$) while consumer surplus does not ($p = .402$).

To further examine the role of discrete emotions, Study 2 was conducted online with 415 customers who were asked about their latest purchase of a public transportation product. As expected, multiple linear regressions revealed that a consumer's surplus triggers pride ($p = .013$), while gratitude (anger) toward the seller increases, the higher (lower) a consumer's transaction utility (ps < .01). 95% bootstrap confidence intervals on the significance of the specific indirect effects (Preacher and Hayes 2008) indicate that the effect of transaction utility on price attitude is mediated by gratitude and anger, while pride was not found to provide a significant indirect path from consumer surplus to price attitude.

Study 3 investigates the distinct behavioral coping responses associated with each discrete emotion. The sample included 803 consumers who just purchased a discounted ticket that was only available online and for specific fares. Again, transaction utility was found to trigger seller-related feelings of gratitude ($p < .001$) and anger ($p = .028$). However, it also had a positive effect on pride ($p = .001$), while the partial effect of consumer surplus on pride could not be replicated ($p = .309$). The latter may be due to using a newly in-

troduced product category for which consumers' might not yet have constructed a concise idea about the value. Nonetheless, 95% bootstrap confidence intervals indicate that anger, gratitude, and pride significantly mediate the effect from transaction utility on positive word-of-mouth and gratitude also explains repurchase intentions.

In sum, the results demonstrate that existing discrepancies in the actual price paid and various reference prices can elicit a portfolio of different emotional responses. Our findings emphasize the importance of investigating specific discrete price-related emotions beyond consumers' general (un)happiness as they distinctively impact consumers' behavioral responses to prices.

Beyond Clarity and Confusion: Affective Responses to Price Framing in the Airline Industry

EXTENDED ABSTRACT

Price framing ranges from the clear and simple (penny candy) to the opaque and confusing (many wireless service plans), with a wide range of effects on consumer judgment and decision-making. Prior research shows that price presentation affects price recall (Morwitz, Greenleaf, and Johnson 1998), purchase intention (Gilbride, Guiltinan, and Urbany 2008; Morwitz, Greenleaf and Johnson 1998), perceived deal value (Bertini and Wathieu 2008), perceived fairness (Sheng, Bao, and Pan 2007), and perceived savings (Krishna, Briesch, Lehmann, and Yuan 2002), just to name a few.

Our paper examines the effect of price presentation on consumers from a new perspective. We explore how consumers respond emotionally to different price presentation formats in the airline industry, and then predict post-purchase behavior based on the experienced emotion. This is a question of considerable public policy importance, as new regulations in both the U.S. and the UK require airlines to change how they display their prices to consumers. These price presentation requirements were imposed, in part, to increase clarity and transparency of pricing. However, our results show that they can also trigger emotional responses from consumers—an unforeseen consequence of this protective legislation.

We include three common pricing formats in our analysis—a la carte pricing, where sellers present a price for a basic product as well as a listing of fees or charges for optional add-ons; mixed bundle pricing, where an a la carte listing of prices for optional add-ons is presented alongside a bundle that includes some of the optional add-ons priced as a unit; and drip pricing, a pricing tactic related to partitioned pricing that has not been researched before. In drip pricing, consumers only see a portion of the total price up-front, with optional or mandatory fees revealed only as a consumer progresses through the buying process.

Our first study examined how consumers shopping for an airline ticket respond to a la carte pricing of optional fees relative to an all-inclusive combined price (control) and a partitioned price where the additional fees were for mandatory taxes and surcharges. The base price in the a la carte and partitioned conditions were the same, and the total price was kept constant across all conditions. We included the partitioned price condition to rule out the alternative explanation that consumers simply respond negatively to multiple fees versus one fee. A strict "pain of paying" view of consumer response would predict that, assuming each fee was mentally processed as a separate payment, negative affect in the a la carte and partitioned conditions should be comparable, and that both should be higher than that in the combined condition. However, our results did not confirm this prediction. A self-reported measure of anger with the total price and with surcharges (recorded post-purchase) was significantly higher in the a la carte condition than in either the partitioned or control con-

ditions (p < .001). Participants in the a la carte condition were also marginally more likely to complain after a mild service failure (p < .10) and were least likely to recommend the airline again (p < .01). Mediation analysis showed that these differences in post-purchase behavior across price presentation conditions were completely mediated by feelings of anger.

Our second study was designed to examine whether anger could be alleviated if the optional fees were offered in a mixed bundle. Thirty subjects shopping for an airline ticket were randomly assigned to either a mixed bundle fee condition or to an a la carte fee condition. The mixed bundle condition showed an a la carte listing of several optional fees as well as a bundle which included a subset of the same options. The bundle price was simply the sum of the a la carte fees for the included items (i.e., not discounted). As in Study 1, consumer anger about additional fees was significantly higher in the a la carte condition, but was reduced in the mixed bundle condition, even though the bundle price offered no discount (p < .05). Additionally, the additional fees were perceived to be fairer in the mixed bundle condition versus the a la carte condition (p < .05).

Our third study (in progress) examines consumers' emotional responses to drip pricing—an understudied pricing format, that is currently of much interest to government regulators in the U.S. and the UK. In this experiment we manipulate the timing (early versus late) and manner (drip versus combined) in which consumers are informed about additional fees during their purchase process. Preliminary results suggest that consumers exposed to drip pricing are more likely to purchase an airline ticket, are less accurate in price estimation and price recall tasks, and they experience higher negative emotional reactions than their combined price counterparts.

In summary, we show that the manner in which a price is presented affects consumers' emotions and their subsequent post-purchase behavior. Our findings also highlight how protective actions taken by government agencies should consider the affective as well as the cognitive impacts on consumers.

SESSION OVERVIEW

A large literature has established that people's preferences are often malleable and are influenced by context and environmental cues. Much of the research along these lines has provided "existence proofs" – demonstrating factors which can consistently have some effect on decisions. Therefore, a natural question is how to best structure the decision context (e.g., the "choice architecture", Thaler and Sunstein 2008) such that the impact on outcomes is maximal. Answering this question not only has immense practical implications, but also poses an important theoretical challenge to decision researchers. In most choice environments, there are multiple potential influences and existing theories often provide either no prediction or competing predictions of when contextual factors will be most impactful. Hence, to generate recommendations for designing "optimally effective" choice architecture, we need to pit all the competing forces against one another, identify the influences that yield differential effectiveness and come up with a deeper understanding that can generate simple principles to guide choice architecture decisions. This session is aimed both at providing some answers to such questions, but even more so, to demonstrate the usefulness of this approach for consumer research, both practically and theoretically, spurring related future research.

Pre-set defaults have very robust effects on choices, and have been used effectively in various consequential domains, such as organ donation and retirement savings. Different extant research, however, has implied that defaults that are either too high or too low might have detrimental consequences. Hence it is unclear how to maximize the impact of a default policy, and whether setting a default might sometimes have negative effects relative to no default. Across a range of domains (pricing, charitable donation, savings goals) that differ in the decision maker's motivations and implica-

tions of being amenable to the default, Goswami and Urminsky find that high defaults generally have a greater impact on increasing 'participation amount' than low defaults, without any difference in participation rate. Evidence for immediate downstream consequences of high versus low default on goal disengagement and rejection of subsequent defaults seem to be limited. These findings suggest an important principle of choice architecture, that setting low defaults might have negative consequences, but there is little risk of setting too high a default.

Another common approach to choice architecture is to provide (or mandate) detailed information for consumers. Research has indicated that consumers tend to undervalue the importance of long-term savings factors such as fuel economy, even when provided with detailed information about it in their car purchasing decisions. Ungemach, Camilleri, Johnson, Larrick and Weber show that a simple attribute decomposition intervention, communicating the fuel economy information multiple times and in different formats (e.g. miles per gallon, annual fuel cost etc.,) can increase the weight decision makers assign to this attribute irrespective of the purchase motivations. The efficacy is not driven by changing inferences about superiority on the most salient dimension, since even redundant information on the attribute influenced assigned weights. Rather, these findings suggest that optimizing choice architecture involves taking into account the weight and emphasis placed on information by considering the distribution of attributes across the key dimensions.

Along similar lines, recent attempts to improve consumers' food choices by providing calorie information have yielded largely disappointing results. In a large scale field study in a hospital cafeteria, Riis, Barraclough, Levy, Sonnenberg, and Thorndike demonstrate that labeling foods as red, yellow, or green, coupled with interventions to make the green food items more visible and accessible, had a dramatic impact. Specifically, the sale of bottled water increased 26%, seemingly driven by consumers' desire to make a healthy choice on a complimentary item in their meal without making sacrifices on the taste of focal component of the meal. These findings demonstrate that optimizing choice architecture may occur when information is made as easy to process and as accessible as possible, even at the expense of detail, and when it is offered on complementary items rather than focal items.

In another large scale field study, Bhargava and Manoli show how Earned Income Tax Credit (EITC) claims can be increased among eligible taxpayers (the working poor). They find that simplifying the program information meant to address issues like lack of awareness, misunderstanding of EITC rules including eligibility, and underestimation of benefit size substantially increases claims. More importantly, they test these interventions against competing interventions, including attempts to reduce perceived transaction cost and social stigma and risk of audit, which did not have any effect. Overall, the successful interventions reduced incomplete take-up from 25% to 22%, with a cumulative effect measured in millions of dollars. Their field study (and accompanying survey) findings further demonstrate that optimizing choice architecture involves maximizing comprehension and confidence with the information provided, rather than maximizing the quantity or detail of information.

Taken together, the four papers suggest that equally plausible interventions in the decision context can often have profoundly different effects, across many consequential domains. We expect that this

session would be of interest to a broad audience including consumer and decision researchers, economists, and policy practitioners. This session will also contribute to the diversity of types of research at ACR, by presenting data from two large scale field studies. We believe that our understanding of how to use choice architecture most effectively is under-developed, and that attempting to identify the conditions that yield optimal effectiveness is of crucial importance for both theoretical and practical reasons. We hope that this session will stimulate ideas and promote future research in the optimal effectiveness of choice architecture design.

In Search Of Optimally Effective Defaults

EXTENDED ABSTRACT

Pre-set default options are a key element of choice architecture. However, recommendations and defaults might yield a behavioral backlash if they are inconsistent with initial impressions (Fitzsimons and Lehmann 2004), invoke negative assessment of motives (Brown and Krishna 2004), or if the individual or group setting the default option is distrusted (Liersch and McKenzie 2011). Companies often set a fairly low default 401(k) contribution rate relative to chosen rates of saving, partly out of a concern that a higher default rate could reduce enrollment (WSJ, 7/2011). Thus, a critical unanswered question is how to set optimally effective defaults and whether setting defaults too low or too high is likely to have a greater impact.

In six completed studies, we set out to empirically test the potential for negative backlash effects of high defaults and anchoring effects of low defaults on active choices (i.e. not passive enrollment). To answer this question, we investigated the impact of default size on total amounts, as well as average 'amounts' among participants, participation rate, and immediate downstream consequences on goal disengagement and response to subsequent defaults. In order to generalize our findings, we use a range of domains, from savings to pricing, where the decision makers' motivations are very different and hence defaults are likely to be operating via different routes. In addition, we specifically investigate the effect of psychological reactance (Brehm 1966; Hong and Faedda 1996) and trust on different levels of default.

In Study 1 (n=502), we tested default policies on consumers' choices of savings goals (defaults of 7%, 5%, 3%, 1% or no default; b/w/s). The default was calculated from data attributed either to the U.S. Government (a well-known source) or U.S. Bureau of Economic Analysis (a lesser known source). Overall, the average savings goal increased monotonically with increasing default. When Government was the source, the savings rate was significantly increased by a high (7%) default and significantly decreased by a low (1%) default, relative to no default. Furthermore, high default did not increase drop-out rates (not setting any savings goal at all) relative to other conditions. Reactance reduced the overall efficacy of defaults, but did not differentially impact high defaults. In a follow-up study, Study 2 (n=443), we replicated our findings with unrealistically high default savings goals (defaults of 40%, 20%, 5%, 1% or no default; b/w/s). Even for these extreme rates, we found no evidence of backlash for high defaults (relative to no default), even among high reactance participants. In addition, non-participation rates, self-reported confidence and decision satisfaction did not differ.

In the next two studies, Study 3 (n=241) and Study 4 (n=453) we tested these results with participants facing real stakes. In study 3 we used a setting where 'higher' choice is not intrinsically desirable for the participants. Participants picked their own price to buy academic planners from a menu of prices with a default of $40, $5, $1, or no defaults b/w/s. Inexperienced participants, who did not

use planners in the previous year, valued the product significantly more when the default was higher. The effect could not be explained by increased attractiveness of the planners for inexperienced buyers, or default acting as a signal of information. Also, there was no difference in the participation rates across conditions. The high defaults ($40, $5) were effective in increasing willingness to pay, even though no one selected the defaults.

In Study 4, participants decided on how much they would be willing to donate from a real lottery award which every participant had an equal chance to win. High defaults (but now low defaults) significantly increased intended donations when participants had low information (resulting in low trust) about the charitable organization. Defaults did not have an effect on participants with high information. The pattern was true for participation rate as well. Therefore, in the absence of credibility bolstering information, high defaults helped to increase both average amounts as well as participation rates.

In two other hypothetical studies we tested people's response to defaults in a choice of how many promotional emails to allow a company to send them. In both Study 4 (n=192) and Study 5 (n=71), the average number of emails permitted did not vary significantly based on the default, and there were no negative consequences of high defaults. Also, across all studies we find very limited evidence of immediate downstream consequences of encountering high versus low defaults in a prior decision task.

Our findings suggest minimal potential for backlash against high defaults, particularly in multi-option choices. Even when a high default is rejected, it can influence choices by anchoring the participant on a high value. In contrast, we find that deviation from maximal defaults occurs primarily when defaults are too low, rather than too high. While psychological reactance reduces the impact of defaults, we find little evidence that high reactance leads to a backlash against high defaults. Trust is an important factor in the absence of defaults, but defaults can improve outcomes when trust is low.

Redundant Information as a Choice Architecture Tool: How Attribute Decomposition on Displays can be used to Highlight Important Dimensions for Consumers

EXTENDED ABSTRACT

Among the scientific community there is no doubt that climate change is a reality and that we must act immediately to reduce CO2 emissions (Karl, Melillo, & Peterson, 2009). While purely economic solutions have already been leveraged, it has been increasingly recognised that insights from psychology and behavioural economics are crucial to initiate and maintain the changes required to combat the threat (Johnson et al., 2012; Weber & Stern, 2011). One of the most promising psychology-based approaches to producing behavioural change is through the development of "choice architecture".

The choice architecture approach to behavioural change rests on the established finding that individuals often construct their preferences in the immediate choice context (Slovic, 1995; Lichtenstein & Slovic, 2006) and that decision context often influences the choice that is made (Thaler & Sunstein, 2008). A key principle of this approach is that there is no neutral choice context and any framing can and will affect what is chosen. Examples of nudges that have been shown to be effective include the selection of defaults (Johnson, Bellman, & Lohse, 2002), the number of alternatives presented (Payne, Bettman, & Johnson, 1993), the partitioning of options and attributes (Fox, Ratner, & Lieb, 2005), and rescaling (Burson, Larrick, & Lynch, 2009). A related observation with potential choice architecture implications is "attribute splitting", describing the phenomenon that decomposing an attribute into several sub-attributes

can increase the psychological weight assigned to that dimension (Jacobi & Hobbs, 2007; Weber, Eisenfuehr & von Winterfeldt, 1988). Attribute splitting has been demonstrated within weighting tasks but it remains unclear how the distribution of attribute values affects preferences.

The inherent goal of the presented series of experiments is to further understand the impact of and mechanisms behind attribute decomposition, and develop a new choice architecture tool within the domain of environmental decisions.

Experiment 1. A primary source of human-induced CO2 emissions is transportation, contributing approximately 27% of total U.S. greenhouse gas emissions in 2008 (http://www.epa.gov/otaq/climate/basicinfo.htm). However, prior research seems to indicate that consumers presented with relevant information undervalue fuel economy information in their car-purchasing decisions (e.g. German, 2002; Maples, 2003; Patterson, 2002). An interesting feature of the new fuel economy labels launched by the Environmental Protection Agency is that the fuel economy information is presented in a number of different, but highly correlated, metrics (e.g. MPG, GPM, annual fuel cost). In order to test whether repetition of the same attribute potentially reduces undervaluation of fuel cost information, as implied by the findings on attribute decomposition, we conducted a discrete choice experiment. 200 online respondents were asked to choose between pairs of cars for which EPA fuel economy labels (7 correlated metrics of fuel economy) and the prices of the car (one single price) were provided. The choice pairs were created using three MPG levels (High, Medium, Low) and three Price levels (High, Medium, Low). Each participant had to make 4 choices in 2 different scenarios: In the 'Capability' scenario, participants helped a friend select the car with the lowest overall cost (i.e, price and operating cost) given a fixed yearly mileage of 15,000 miles and 5 years before replacing the car; In the 'Preference' scenario, participants could choose the car they personally preferred assuming the same mileage and driving period. The label presentation format was also manipulated such that each pair of labels was either presented simultaneously or sequentially.

Discrete choice analysis showed that when using the label with multiple fuel efficiency metrics, participants tended to slightly overweight the fuel economy information relative to the car price. This tendency was observed in both scenarios and was not affected by the order the scenarios were presented in.

Experiment 2. In order to investigate whether people actually make use of all the highly correlated information on the label, we conducted a second experiment in the laboratory (n=10) where we tracked participant's eye movements while going through the same choice task as in Experiment 1. Although the calculation of the overall cost on the 'Capacity' task only required the combination of two numbers (one fuel economy metric and the price) the process tracing data revealed that most participants did indeed allocate attention to all of the available metrics, including the redundant information. Furthermore, the gaze paths show that redundant information was not merely scanned initially as part of the search process but participants repeatedly transitioned between similar attributes across labels, indicating that this information was used as part of the choice process itself.

Experiment 3. The observations made in Experiment 1 and 2 suggest that the presentation of multiple, highly correlated attributes may cause decision-makers to psychologically weigh this attribute more heavily. Our investigation is also related to the "majority rule" heuristic, which asserts that decision-makers tend to choose the option superior on most of the available cues (Zhang et al., 2005). However, this heuristic is applicable only to alternatives with more

than two attributes and it is unclear whether the heuristic can apply to multiple redundant attributes.

Our aim in Experiment 3 was to systematically manipulate the proportion of redundant attributes for a given dimension and observe the impact on the psychological weight assigned to that dimension. To fulfil this aim, we carried out a 2 (Upfront Cost Information: 1 metric vs. 4 metrics) x 2 (Running Cost Information: 1 metric vs. 4 metrics) x 3 (Upfront Cost: High, Medium, Low) x 3 (Running Cost: High, Medium, Low) between-subjects discrete choice experiment. 400 online respondents were presented with nine decision problems that each required a choice between two vehicles that varied in Upfront and Running costs, as in the 'Capability' scenario in Experiment 1 and 2. We found that, in general, presentation of multiple redundant attributes shifted the psychological weight assigned to that dimension.

Together, the results from these studies show that redundant information is utilized in the formation of preferences and that it might be overweighted. This observation offers choice architects a new tool to help decision-makers identify the important dimensions in a choice problem and nudge people towards buying more energy efficient cars.

Product Level and Segment Level Differences in the Effectiveness of a Longitudinal Labeling and Choice Architecture Intervention at a Large Hospital Cafeteria

EXTENDED ABSTRACT

Although many food retailers are trying to encourage their customers to make healthier choices, few of their interventions have been studied formally, and few are able to claim much success. The current study incorporated a two-phase retail intervention in a large hospital cafeteria. In the first phase, a simplified menu labeling system was applied throughout the cafeteria. Since calorie labeling interventions have shown limited success in changing customer purchase behavior, this study implements a simpler and more meaningful labeling scheme whereby all foods in the cafeteria were labeled as red, yellow, or green (with green being the healthiest). The second phase of the study altered the choice architecture of the food and beverages in the cafeteria, making it easier for customers to see and find the healthier food items. We compared the purchase patterns made during these two 3-month intervention phases with purchase patterns during a 3-month baseline period.

The setting for the study was the main cafeteria at large hospital in Massachusetts. More than 5000 individuals visit the cafeteria during a typical weekday and daily revenues exceed $30,000. Just over a quarter of the revenues come from employees who use a "meal card" which allows purchases to be directly deducted from their paychecks. The purchases of these individuals can hence be tracked over time.

The first phase of the intervention involved a point-of-purchase labeling intervention designed to educate the employees, patients, and visitors about the nutritional value of the foods and beverages of the cafeteria. All foods and beverages in the cafeteria were labeled as red, yellow, or green based on criteria that reflect USDA healthy eating recommendations. Displays around the cafeteria informed customers that Red items should be consumed rarely, as they are high in calories or unhealthy fat while Green items, which feature fresh fruits and vegetables, whole grains, and healthy proteins, should be consumed often. Yellow items are intermediate. The red-yellow-green categories were developed by a team of nutritionists at the hospital.

Following the three months of Phase 1, the second phase of the cafeteria intervention began. The labeling scheme did not change from Phase 1; food and beverages continued to be labeled red, yellow, and green; but choice architecture changes were made.

The intervention at Phase 2 involved a series of changes to the layout of the cafeteria and the standard servings of some items. These changes were designed to increase the purchase rates of green items by making them more salient and more convenient to select. Examples include the following: a) Bottled water and diet soda (both green items) appeared at many more locations around the cafeteria, including several prominent, easy-access baskets near each food service station; b) Pre-packaged side salads became available beside the pizza and grill stations, where previously customers who wanted a side salad must make a separate trip to the salad bar, and c) Healthier snack items and sandwiches were moved to the most visible and accessible shelves, while less healthy items in these categories were moved to less visible and less accessible shelves.

Cash register data recorded all purchases for the 9 month study period. In addition to analyzing cafeteria-wide purchase trends, we followed a cohort of 5000 meal card users. For each user in the cohort, we knew their age, sex, race/ethnicity, and job type, in addition to their purchase history.

The labeling intervention led to large reductions in the consumption of unhealthy foods and beverages, but this paper will focus on the choice architecture intervention. Some analyses of category effects and segment interactions are pending, but some results are clear. By far the largest single product category change due to choice architecture was for bottled water which showed a 26% increase in sales during the choice architecture period. Changes in other categories were less than half that. We believe that this is because beverages are complements to meals, and taste sacrifices here will seem relatively modest compared to taste sacrifices on a meal entrée or on a food favorite.

In terms of segment differences, there were very large differences in purchase patterns at baseline: For example, Black and Latino employees purchased 31% red items while, white employees consumed just 18%. Reductions of red item purchases and increases in green item purchases were however largely uniform across ethnic and income groups. All groups showed similarly substantial improvements in healthy purchasing. For example, the average reduction in calories per beverage was about 15% for each group, from baseline to Phase 2.

Finally, cafeteria revenues were consistent through the three periods, suggesting that such interventions may be sustainable. The interventions are ongoing at the hospital and we are currently looking at the second year of register and panel data.

Why are Benefits Left on the Table? Assessing the Role of Information, Complexity, and Stigma on Take-up with an IRS Field Experiment

EXTENDED ABSTRACT

A well-recognized, and perhaps surprising, feature of transfers to the economically and socially disadvantaged is that many targeted individuals fail to take-up their benefits (Currie 2006). The Earned Income Tax Credit (EITC), the nation's largest means-tested cash transfer program, is a prime example with an estimated 25 percent rate of incomplete take-up that amounts to 6.7 million non-claimants each year (Plueger 2009).

The policy consequences of incomplete take-up are significant. A typical EITC non-claimant forgoes credits equivalent to 33 days of income. Moreover, non-claimants forfeit other advantages, such as those related to family health, education, or consumption, that may be linked to transfers (Hoynes, Miller, and Simon 2011; Dahl and Lochner 2011; Smeeding, Phillips, and O'Connor 2001). The problem may be even more severe for other means-tested programs.

Several explanations are generally cited for incomplete take-up: lack of information, stigma, transaction costs, and complexity (Currie 2006). In this paper, we test the effect of a set of novel interventions on take-up with a unique field experiment administered in collaboration with the Internal Revenue Service (IRS). In addition to identifying strategies to improve take-up, our experiment allows us to evaluate leading theories as to its causes. Specifically, we test the role of information (regarding program benefits, costs, and rules), the complexity of such information, and program stigma on the take-up of the EITC.

We implement the experiment by modifying the informational content and complexity of IRS tax mailings and distributing these to the universe of over 35,000 tax filers from California who failed to claim their TY 2009 EITC despite presumed eligibility and the receipt of an initial reminder notice. Each mailing communicates likely eligibility for the program, and includes a worksheet which a recipient can complete and return to claim a credit. We use the differential response across mailings to adjudicate among the tested mechanisms. To maximize statistical efficiency, and to permit tests of treatment interactions, we assign and distribute the mailing elements---that is, the reminder notice, claiming worksheet, and an experimental envelope---with three independent randomizations to blocks defined by zip code and dependent status. The packets were published, assembled and mailed by the IRS in a single batch in mid-November of 2010. All told, we inform individuals of $26 million in unclaimed government benefits, of which about $4 million is ultimately claimed.
