Preface

The 44th Annual Conference of the Association for Consumer Research (ACR) was held at the Palmer House Hilton, Chicago, Illinois, October 3-6, 2013. This volume reports the presentations made in special sessions, competitive paper sessions, working paper session, roundtables and film festival.

The conference theme was “Making a Difference” and was inspired by Chicago, a bold city that is constantly reinventing itself through its architecture, restaurants, arts, nightlife, and music. Our hope was to channel this vibrancy into the conference in order to allow participants to discover, or re-discover, the joy of research that makes a difference. The conference attracted over 1230 participants, 104 special session proposals (51% accepted), 484 competitive papers (43% accepted), 254 working papers (64% accepted), 7 roundtables (100% accepted) and 13 films (81% accepted).

In keeping with the spirit of the conference, we introduced several inaugural events and innovations to further enhance the academic content of our program. These included:

- The keynote address, “David & Goliath” by Malcolm Gladwell. Over 1200 members attended and everyone received a complimentary copy of his newly released book
- The Mid-Career Mentorship Program, to connect mid-career faculty with senior mentors
- Perspectives Sessions, to integrate knowledge in specific research areas
- Workshops, to provide hands-on skills in research tools and methods
- Thematic organization of working papers into mini-sessions

All the academic and entertainment events made up for an energizing experience.

We thank our generous donors, especially our schools, the Kellogg School of Management, Northwestern University, USA, the London Business School, UK, and the Rotman School of Management, University of Toronto, Canada. Roger Martin, former Dean of Rotman, introduced us to Malcolm Gladwell and then flew in to open Malcom’s keynote speech. Thank you so much. Also supporting us was the American Marketing Association, the Journal of Consumer Psychology, the Journal of Marketing Research, the Journal of Consumer Research, and the Marketing Science Institute, and, from industry, Qualtrics, CBSIG, Fizz, and BrandOpus.

Many wonderful people worked tirelessly to help us. We thank our Program Committee, Competitive Paper Review Board Members, Competitive Paper Reviewers, Working Paper Reviewers, and Film Reviewers. Special thanks to Leonard Lee and Wendy Liu (Working Paper Chairs), Anirban Mukhopadhyay and David Wooten (Forums Chairs), Marylouise Caldwell and Paul Henry (Film Festival Chairs), Derek Rucker and Jaideep Sengupta (Doctoral Symposium Chairs), Nidhi Agrawal and Jonathan Levav (Mid-Career Mentorship Program Chairs), and Kelly Goldsmith, Tom Meyvis, Leif Nelson, Joachim Vosgerau (Entertainment Committee). David Bell, Robert Meyer, Keith Niedermeier, and Americus Reed II (*Brand Inequity* band members) and Ashesh Mukherjee (DJ Ash) rocked our closing gala at House of Blues. Special thanks also to ACR Executive Director Rajiv Vaidyanathan, Conference Manager Paula Rigling, website guru Aleksey Cherfas, Membership Executive Manager Praveen Aggarwal, Communication Executive Ekant Veer, administrative assistants Elisabeth Hajicek, Laura Nagle, Shira Conradi, Eliza Badoi, and Aaron Christen.

Our final thank you to colleagues who advised us throughout the year and helped in countless ways, to everyone who made our program stellar by submitting their best research, and to Angela Y. Lee, President ACR 2013, for this wonderful opportunity to organize the ACR conference.

Table of Contents

Preface	iii
Conference Committees & Reviewers	iv

2013 ACR Presidential Address

Making a Difference.	1
<i>Angela Y. Lee, Northwestern University</i>	

2013 ACR Fellows Address

Paper #1: Choice Architecture, Public Policy and Consumer Research	5
<i>Eric J. Johnson, Columbia University, USA</i>	
Paper #2: Consumer JDM Research in Search of Direction: What's Next for Consumer JDM-BDT Researchers? (My Take)	9
<i>Itamar Simonson, Stanford University, USA</i>	

Special Session Summaries

Consumer Behavior under Severe Restriction: A Look at Differences between Affluent and Impoverished People.	11
<i>Chair: Ronald Paul Hill, Villanova University, USA</i>	
Paper #1: Poverty and Materialism: Are Impoverished Children More Materialistic Than Affluent Children?	
<i>Lan Nguyen Chaplin, University of Illinois at Chicago, USA</i>	
<i>Debbie Roedder John, University of Minnesota, USA</i>	
Paper #2: Profiles of Consumer Saving: Societal Conditions and Individual Aspirations	
<i>Kelly D. Martin, Colorado State University, USA</i>	
<i>Ronald Paul Hill, Villanova University, USA</i>	
Paper #3: Consumer Negotiation and Acquisition at the Bottom-of-the-Pyramid: The Case of Women Market Traders	
<i>José Antonio Rosa, University of Wyoming, USA</i>	
<i>Madhu Viswanathan, University of Illinois, USA</i>	
<i>Shikha Upadhyaya, University of Wyoming, USA</i>	
<i>Srinivas Venugopal, University of Illinois, USA</i>	
<i>Susan Dewey, University of Wyoming, USA</i>	
Paper #4: Moral Identity and Competition in a Working Class Neighborhood	
<i>Bige Saatcioglu, Ozyegin University, Turkey</i>	
<i>Julie L. Ozanne, Virginia Tech, USA</i>	

How Audience Factors Influence Word-of-Mouth	16
<i>Chair: Alixandra Barasch, University of Pennsylvania, USA</i>	
Paper #1: Broadcasting and Narrowcasting: How Audience Size Impacts What People Share	
<i>Alixandra Barasch, University of Pennsylvania, USA</i>	
<i>Jonah Berger, University of Pennsylvania, USA</i>	
Paper #2: Compensatory Communication: Consumer Knowledge Discrepancies and Knowledge Signaling in Word-of-Mouth	
<i>Grant Packard, Wilfrid Laurier University, Canada</i>	
<i>David B. Wooten, University of Michigan, USA</i>	
Paper #3: Using Incentives to Encourage Word-of-Mouth Transmissions That Lead To Fast Information Diffusion	
<i>Andrew T. Stephen, University of Pittsburgh, USA</i>	
<i>Donald R. Lehmann, Columbia University, USA</i>	
Paper #4: Answering Why: Action and Reaction Explanations in Word of Mouth	
<i>Sarah G. Moore, University of Alberta, Canada</i>	
When the Choosing Gets Rough: Exploring Incidental Factors that Increase Choice Difficulty	21
<i>Chairs: Jordan Etkin, Duke University, USA</i>	
<i>Jennifer Savary, Yale University, USA</i>	
Paper #1: When Being Happy Makes Choosing Harder	
<i>Jordan Etkin, Duke University, USA</i>	
<i>Anastasiya Pocheptsova, University of Maryland, USA</i>	
Paper #2: The Cognitive and Behavioral Consequences of Considering Low-Fit Brand Extensions	
<i>Kelly Goldsmith, Northwestern University, USA</i>	
<i>Ryan Hamilton, Emory University, USA</i>	
Paper #3: Distractions: Friend or Foe in the Pursuit of Conscious and Nonconscious Goals?	
<i>Eunice Kim Cho, Pennsylvania State University, USA</i>	
<i>Andrew Mitchell, University of Toronto, Canada</i>	
<i>Ravi Dhar, Yale University, USA</i>	
Paper #4: The Positive Consequences of Conflict on Decision Making: When a Conflict Mindset Facilitates Choice	
<i>Jennifer Savary, Yale University, USA</i>	
<i>Tali Kleiman, New York University, USA</i>	
<i>Ran Hassin, The Hebrew University, Israel</i>	
<i>Ravi Dhar, Yale University, USA</i>	
Anthropomorphism: New Insights and Implications	27
<i>Chairs: Fangyuan Chen, Hong Kong University of Science and Technology, Hong Kong, China</i>	
<i>Rocky Peng Chen, University of Hong Kong, Hong Kong, China</i>	
Paper #1: The Effects of Anthropomorphization on Brand Personality Perceptions: A Motivational Account	
<i>Fangyuan Chen, Hong Kong University of Science and Technology, Hong Kong, China</i>	
<i>Jaideep Sengupta, Hong Kong University of Science and Technology, Hong Kong, China</i>	
<i>Rashmi Adaval, Hong Kong University of Science and Technology, Hong Kong, China</i>	
Paper #2: Is She My New Friend? The Effect of Social Exclusion on Consumer Preference for Anthropomorphized Products	
<i>Rocky Peng Chen, University of Hong Kong, Hong Kong, China</i>	
<i>Echo Wen Wan, University of Hong Kong, Hong Kong, China</i>	
<i>Eric Levy, University of Cambridge, UK</i>	
Paper #3: When Consumers Meet Humanized Brands: Effect of Self-construal on Brand Anthropomorphism	
<i>Meng-Hua Hsieh, University of Washington, USA</i>	
<i>Shailendra Pratap Jain, University of Washington, USA</i>	
<i>Xingbo Li, University of Washington, USA</i>	
<i>Vanitha Swaminathan, University of Pittsburgh, USA</i>	
Paper #4: When Temptations Come Alive: How Anthropomorphization Undermines Consumer Self-Control	
<i>Julia Hur, Northwestern University, USA</i>	
<i>Minjung Koo, Sungkyunkwan University, Republic of Korea</i>	
<i>Wilhelm Hofmann, University of Chicago, USA</i>	

Social Goals and Word of Mouth	33
<i>Chair: Hillary Wiener, Duke University, USA</i>	
Paper #1: Word-of-Mouth and Interpersonal Communication: An Organizing Framework and Directions for Future Research	
<i>Jonah Berger, University of Pennsylvania, USA</i>	
Paper #2: Talking About What You Did and What You Have: The Differential Story Utility of Experiential and Material Purchases	
<i>Amit Kumar, Cornell University, USA</i>	
<i>Thomas D. Gilovich, Cornell University, USA</i>	
Paper #3: Conversation Pieces	
<i>Hillary Wiener, Duke University, USA</i>	
<i>James R. Bettman, Duke University, USA</i>	
<i>Mary Francis Luce, Duke University, USA</i>	
Paper #4: You Gotta Try It! The Negative Side of Positive Word of Mouth	
<i>David L. Alexander, University of St. Thomas, USA</i>	
<i>Sarah G. Moore, University of Alberta, Canada</i>	
Look Who's Talking: Linguistic Signaling in C2C and B2C Communication	38
<i>Chairs: Gaby Schellekens, Radboud University Nijmegen, The Netherlands</i>	
<i>Ann Kronrod, Michigan State University, USA</i>	
Paper #1: A Negation Bias in Word of Mouth: How Negations Reveal and Maintain Expectancies about Brands and Products.	
<i>Peeter W.J. Verlegh, University of Amsterdam, The Netherlands</i>	
<i>Camiel Beukeboom, Vrije University Amsterdam, The Netherlands</i>	
<i>Christian Burgers, Vrije University Amsterdam, The Netherlands</i>	
Paper #2: Wii Will Rock You! The Role of Figurative Language in Word of Mouth.	
<i>Ann Kronrod, Michigan State University, USA</i>	
<i>Shai Danziger, Tel-Aviv University, Israel</i>	
Paper #3: How Language Signals Persuasion: Concrete and Abstract Language in Product Referrals from Consumers and Firms.	
<i>Gaby Schellekens, Radboud University Nijmegen, The Netherlands</i>	
<i>Peeter W.J. Verlegh, University of Amsterdam, The Netherlands</i>	
<i>Ale Smidts, Erasmus University Rotterdam, The Netherlands</i>	
Paper #4: Putting the Customer Second: Pronouns in Customer-Firm Interactions.	
<i>Grant Packard, Wilfrid Laurier University, Canada</i>	
<i>Sarah G. Moore, University of Alberta, Canada</i>	
<i>Brent McFerran, University of Michigan, USA</i>	
Transformative Consumer Neuroscience	43
<i>Chair: Martin Reimann, University of Arizona, USA</i>	
Paper #1: Scamming Depression Era Elders: Neuroanatomical Basis for Poor Decision Making Among Older Adults	
<i>Brian K. Koestner, University of Iowa, USA</i>	
<i>William M. Hedgcock, University of Iowa, USA</i>	
<i>Kameko Halfmann, University of Iowa, USA</i>	
<i>Natalie L. Denburg, University of Iowa, USA</i>	
Paper #2: Linking Individual Differences in Motivational and Executive Control Neurocognition to Real World Craving and Snacking Behavior: The Case of Restrained and Unrestrained Eaters	
<i>Ji Lu, Dalhousie, University, Canada</i>	
<i>Laurette Dubé, McGill University, Canada</i>	
Paper #3: Identifying Symbols of the Consumer Marketplace from Human Brain Activity	
<i>Yu-Ping Chen, University of California, Berkeley, USA</i>	
<i>Ming Hsu, University of California, Berkeley, USA</i>	
<i>Leif D. Nelson, University of California, Berkeley, USA</i>	
Paper #4: Reward Substitution: Incentivizing Consumers to Choose Smaller Portion Sizes	
<i>Martin Reimann, University of Arizona, USA</i>	
<i>Deborah MacInnis, University of Southern California, USA</i>	
<i>Antoine Bechara, University of Southern California, USA</i>	

Examining the “Me” in Emotion: How Emotion and Different Aspects of the Self Influence Self-Control 49
Chair: Anthony Salerno, University of Miami, USA
Paper #1: The Downstream Consequences of Incidental Emotions and Preference Inconsistent Information
DaHee Han, Indiana University, USA
Nidhi Agrawal, University of Washington, USA
Morgan Poor, University of San Diego, USA
Adam Duhachek, Indiana University, USA
Paper #2: Failing to Meet the Standards: How Guilt Triggers Preferences for Unrelated Self-Improvement Products
Thomas Allard, University of British Columbia, Canada
Katherine White, University of British Columbia, Canada
Paper #3: ‘I’ versus ‘You’: Self-focus as a Mediator of Emotion Effects on Self-control
Nitika Garg, University of New South Wales, Australia
Gergana Y. Nenkov, Boston College, USA
Paper #4: The Influence of Pride Diagnosticity on Self-Control
Anthony Salerno, University of Miami, USA
Juliano Laran, University of Miami, USA
Chris A. Janiszewski, University of Florida, USA

Making the Best of Uncertainty: The Role of Message Framing, Processing Style, and Risk Aggregation. 56
Chair: Alison Jing Xu, University of Toronto, Canada
Paper #1: The Influence of Framing on Willingness to Pay as an Explanation of the Uncertainty Effect
Yang Yang, Carnegie Mellon University, USA
Joachim Vosgerau, Tilburg University, The Netherlands
George Loewenstein, Carnegie Mellon University, USA
Paper #2: The Role of Cognition in Uncertainty Aversion: When Less Thought Leads to More Rational Choices
Kelly Goldsmith, Northwestern University, USA
On Amir, University of California, San Diego, USA
Paper #3: Psychological Risk Aggregation: Selling Products of Uncertain Qualities with Probabilistic Promotions
Mengze Shi, University of Toronto, Canada
Alison Jing Xu, University of Toronto, Canada

It’s Not Just About You: Social Influences on Creative Outcomes. 60
Chairs: Kelly Herd, Indiana University, USA
Ravi Mehta, University of Illinois at Urbana Champaign, USA
Paper #1: Heart Versus Head: Examining Differential Effects of Empathy Versus Perspective Taking on Creative Product Design
Kelly Herd, Indiana University, USA
Ravi Mehta, University of Illinois at Urbana Champaign, USA
Paper #2: The Light Side of Creativity: An Honesty Mindset Can Boost Creativity
Anne Laure Sellier, HEC Paris, France
Darren W. Dahl, University of British Columbia, Canada
Paper #3: Towards Understanding Creative Ingenuity in Dire Situations
Haiyang Yang, Johns Hopkins University, USA
Amitava Chattopadhyay, INSEAD, Singapore
Paper #4: The Impact of Comparisons with Others on Creativity Outcomes
Ke (Christy) Tu, University of Alberta, Canada
Jennifer J. Argo, University of Alberta, Canada

Associative Learning in Branding	66
<i>Chair: C. Miguel Brendl, Northwestern University, USA</i>	
Paper #1: Investigating Deliberative and Spontaneous Inferences as Outcomes of Associative Learning with High versus Low Contingency Awareness	
<i>Bryan Gibson, Central Michigan University, USA</i>	
<i>Chris T. Allen, University of Cincinnati, USA</i>	
<i>Douglas R. Ewing, Bowling Green State University, USA</i>	
<i>Frank R. Kardes, University of Cincinnati, USA</i>	
<i>Christopher Redker, Ferris State University, USA</i>	
Paper #2: On the Automatic Effects of Advertising: The Uncontrollability of Evaluative Conditioning Effects	
<i>Mandy Hütter, Ruprecht-Karls University of Heidelberg, Germany</i>	
<i>Steven Sweldens, INSEAD, France</i>	
Paper #3: Riding Coattails: When Co-branding Helps versus Hurts Less-known Brands	
<i>Marcus Cunha Jr., University of Georgia, USA</i>	
<i>Mark R. Forehand, University of Washington, USA</i>	
<i>Justin W. Angle, University of Montana, USA</i>	
Paper #4: Emotional Counter-Conditioning of Brand Attitudes	
<i>C. Miguel Brendl, Northwestern University, USA</i>	
<i>Vincent Nijs, University of California, San Diego, USA</i>	
<i>Eva Walther, University of Trier, Germany</i>	
<i>Jana Moeller, Free University of Berlin, Germany</i>	
Prosocial Choices and Consequences	71
<i>Chair: Michal Herzstein, University of Delaware, USA</i>	
Paper #1: Crowdfunding to Make a Difference: The Role of Choice in Funding Social Ventures	
<i>Scott Sonenshein, Rice University, USA</i>	
<i>Michal Herzstein, University of Delaware, USA</i>	
<i>Utpal M. Dholakia, Rice University, USA</i>	
Paper #2: Giving to What We Want Instead of to What We Should	
<i>Cynthia Cryder, Washington University at St. Louis, USA</i>	
<i>Simona Botti, London Business School, UK</i>	
<i>Yetta Simonyan, University of Birmingham, UK</i>	
Paper #3: Leave Them Smiling: How Concretely Framing a Prosocial Goal Creates More Happiness	
<i>Melanie Rudd, University of Houston, USA</i>	
<i>Jennifer Aaker, Stanford University, USA</i>	
<i>Michael I. Norton, Harvard Business School, USA</i>	
Paper #4: The Braggart's Dilemma: On the Social Rewards and Penalties of Advertising Prosocial Behavior	
<i>Jonathan Z. Berman, University of Pennsylvania, USA</i>	
<i>Emma E. Levine, University of Pennsylvania, USA</i>	
<i>Alixandra Barasch, University of Pennsylvania, USA</i>	
<i>Deborah A. Small, University of Pennsylvania, USA</i>	
Virtual Lives	77
<i>Chairs: Gia Nardini, University of Florida, USA</i>	
<i>Richard J. Lutz, University of Florida, USA</i>	
Paper #1: Virtual Learning about Alcohol through Narrative Transportation into Television Episodes	
<i>Cristel Antonia Russell, American University, USA</i>	
<i>Edward F. McQuarrie, Santa Clara University, USA</i>	
Paper #2: Coping with Stress in the Age of Warcraft: A Conceptual Framework for Consumer Escapism	
<i>Andrew Kuo, Louisiana State University, USA</i>	
Paper #3: When a Picture is Worth Less Than a Thousand Words	
<i>Gia Nardini, University of Florida, USA</i>	
<i>Robyn A. LeBoeuf, University of Florida, USA</i>	
<i>Richard J. Lutz, University of Florida, USA</i>	
Paper #4: Somewhere Out There: The Power of Brands to Act as Virtual Proxies Signifying Safety and Representing Home during Intense Risk-filled Separations	
<i>Hope Jensen Schau, University of Arizona, USA</i>	
<i>Mary C. Gilly, University of California, Irvine, USA</i>	
<i>Mary Wolfenbarger Celsi, California State University, Long Beach, USA</i>	

From the Bedroom to the Bank: Novel Insights into Sex and Consumer Choice.	83
<i>Chair: Kristina M. Durante, University of Texas at San Antonio, USA</i>	
Paper #1: Conspicuous Consumption, Relationships and Rivals: Women’s Luxury Products as Signals to Other Women	
<i>Yajin Wang, University of Minnesota, USA</i>	
<i>Vladas Griskevicius, University of Minnesota, USA</i>	
Paper #2: Playing the Field: The Effect of Fertility on Women’s Desire for Variety	
<i>Ashley Rae, University of Texas at San Antonio, USA</i>	
<i>Kristina M. Durante, University of Texas at San Antonio, USA</i>	
Paper #3: Sex as Power: Attractive Women Link Sexuality and Power for Personal Gain	
<i>Carlos J. Torelli, University of Minnesota, USA</i>	
<i>Chiraag Mittal, University of Minnesota, USA</i>	
<i>Kathleen D. Vohs, University of Minnesota, USA</i>	
Paper #4: Sex Hormones & Economic Decisions: The Effect of Testosterone on Financial Risk Depends on Social Context	
<i>Steven J. Stanton, Oakland University, USA</i>	
<i>O’Dhaniel Mullette-Gillman, National University of Singapore, Singapore</i>	
<i>Crystal Reeck, Columbia University, USA</i>	
<i>Charlotte Mabe, Duke University, USA</i>	
<i>Kevin S. LaBar, Duke University, USA</i>	
<i>Scott A. Huettel, Duke University, USA</i>	
Of Simple and Social Excuses to Indulge	89
<i>Chair: Michael L. Lowe, Texas A&M University, USA</i>	
Paper #1: “So Cute I Can Eat it Up”: Priming Effects of Cute Products on Indulgent Consumption	
<i>Maura Scott, Florida State University, USA</i>	
<i>Gergana Y. Nenkov, Boston College, USA</i>	
Paper #2: Consuming Functional Innovations: Are Utilitarian Behaviors Enhanced or Undermined?	
<i>Aaron M. Garvey, University of Kentucky, USA</i>	
<i>Lisa E. Bolton, Pennsylvania State University, USA</i>	
Paper #3: Anticipated Sharing and Preference for Hedonic Products	
<i>Peggy J. Liu, Duke University, USA</i>	
<i>Gavan J. Fitzsimons, Duke University, USA</i>	
<i>James R. Bettman, Duke University, USA</i>	
Paper #4: Camaraderie in Crime: Shared Self-Control Decisions and Affiliation	
<i>Michael L. Lowe, Texas A&M University, USA</i>	
<i>Kelly Haws, Vanderbilt University, USA</i>	
Expanding the Theoretical Boundaries of Consumer Acculturation: Investigating the Role of Institutional Forces and Nostalgic Consumption	94
<i>Chairs: Katja H. Brunk, ESMT, Germany</i>	
<i>Luca M. Visconti, ESCP Europe, France</i>	
<i>Ela Veresiu, Witten/Herdecke University, Germany</i>	
Paper #1: Fiddler on the Street: How Roma Refugees Enact Host Cultural Images of Nostalgic Otherness	
<i>Ela Veresiu, Witten/Herdecke University, Germany</i>	
<i>Markus Giesler, York University, Canada</i>	
Paper #2: Generations at the Mirror: First and Second Generation of Turkish Consumers’ Home Country Nostalgia	
<i>Luca M. Visconti, ESCP Europe, France</i>	
<i>Celina Stamboli-Rodriguez, Iseg Marketing and Communication School, France</i>	
Paper #3: Locals as Migrants in German Unification and Acculturation: How Nostalgia Enchants the Former East	
<i>Katja H. Brunk, ESMT, Germany</i>	
<i>Benjamin J. Hartmann, Jönköping University, Sweden</i>	
Paper #4: Asserting Integration through Nostalgic Discourses: Acculturation to the International Community	
<i>Julie Emontspool, University of Southern Denmark, Denmark</i>	
<i>Dannie Kjeldgaard, University of Southern Denmark, Denmark</i>	

Consumer Mindsets: Justifying, Comparing, and Competing	100
<i>Chairs: Alison Jing Xu, University of Toronto, Canada</i>	
<i>Aner Sela, University of Florida, USA</i>	
Paper #1: Justification Mindset: How Hedonic versus Utilitarian Purchase Influences Subsequent Choice	
<i>Uzma Khan, Stanford University, USA</i>	
<i>Qing Yao, University of Science and Technology Beijing, China</i>	
<i>Ravi Dhar, Yale University, USA</i>	
Paper #2: The Comparative Mindset and Managerial Decision Making: Theory Extensions and Boundary Conditions	
<i>Christine Moorman, Duke University, USA</i>	
<i>Alison Jing Xu, University of Toronto, Canada</i>	
<i>Vivian Yue Qin, Duke University, USA</i>	
Paper #3: Competitive Mindset: Does Scarcity Call for Selfishness?	
<i>Caroline Roux, Northwestern University, USA</i>	
<i>Kelly Goldsmith, Northwestern University, USA</i>	
<i>Andrea Bonezzi, New York University, USA</i>	
Paper #4: Beating the Market: Competitive Mindset and the Allure of Unintended Value	
<i>Aner Sela, University of Florida, USA</i>	
<i>Itamar Simonson, Stanford University, USA</i>	
<i>Ran Kivetz, Columbia University, USA</i>	
How Thinking About Money Changes Goal Pursuit	105
<i>Chair: Emily N. Garbinsky, Stanford University, USA</i>	
Paper #1: With Great Power Comes Financial Responsibility: The Effect of Power on Saving	
<i>Emily N. Garbinsky, Stanford University, USA</i>	
<i>Anne-Kathrin Klesse, Tilburg University, The Netherlands</i>	
<i>Jennifer Aaker, Stanford University, USA</i>	
Paper #2: Enhanced Desire for Product Choice in Response to Monetary Scarcity	
<i>Anneleen Van Kerckhove, Ghent University, Belgium</i>	
<i>Renaud Lunardo, Bordeaux School of Management, France</i>	
<i>Gavan J. Fitzsimons, Duke University, USA</i>	
Paper #3: Can Consumers Make Affordable Care Affordable? The Value of Choice Architecture	
<i>Eric J. Johnson, Columbia University, USA</i>	
<i>Ran Hassin, Hebrew University of Jerusalem, Israel</i>	
<i>Tom Baker, University of Pennsylvania, USA</i>	
<i>Allison T. Bajger, Columbia University, USA</i>	
<i>Galen Treuer, University of Miami, USA</i>	
Paper #4: Mere Exposure to Money Motivates Goal Attainment	
<i>Gülen Sarial-Abi, Bocconi University, Italy</i>	
<i>Kathleen D. Vohs, University of Minnesota, USA</i>	
Understanding Consumers' Perception of and Responses to Scarcity Cues	110
<i>Chairs: Chiraag Mittal, University of Minnesota, USA</i>	
<i>Caroline Roux, Northwestern University, USA</i>	
Paper #1: The Product to Space Ratio Effect: How Store Density Influences Perceptions of Scarcity and Product Preference	
<i>Julio Sevilla, University of Georgia, USA</i>	
<i>Claudia Townsend, University of Miami, USA</i>	
Paper #2: Planning Under Paucity: Responses to Resource Scarcity Threats Depend on Childhood Environments	
<i>Chiraag Mittal, University of Minnesota, USA</i>	
<i>Vladas Griskevicius, University of Minnesota, USA</i>	
Paper #3: The Effects of Resource Scarcity on the Ideal Female Body Size	
<i>Sarah E. Hill, Texas Christian University, USA</i>	
<i>Danielle DelPriore, Texas Christian University, USA</i>	
<i>Christopher D. Rodeheffer, Texas Christian University, USA</i>	
<i>Max Butterfield, Texas Christian University, USA</i>	
Paper #4: Understanding the Psychology of Scarcity: When Limited Resources Prompt Abstract Thinking	
<i>Caroline Roux, Northwestern University, USA</i>	
<i>Kelly Goldsmith, Northwestern University, USA</i>	

Let's Talk About It: Factors Influencing Word-of-Mouth Content	115
<i>Chairs: Yu-Jen Chen, Lingnan University, Hong Kong, China</i> <i>Rebecca Hamilton, University of Maryland, USA</i>	
Paper #1: Who's Driving This Conversation? Systematic Biases in the Content of Online Consumer Discussions	
<i>Rebecca Hamilton, University of Maryland, USA</i> <i>Ann E. Schlosser, University of Washington, USA</i> <i>Yu-Jen Chen, Lingnan University, Hong Kong, China</i>	
Paper #2: When Do People Talk About and Why?	
<i>Evan Weingarten, University of Pennsylvania, USA</i> <i>Jonah Berger, University of Pennsylvania, USA</i>	
Paper #3: The Content and Impact of Mobile Versus Desktop Reviews	
<i>Nicholas Lurie, University of Connecticut, USA</i> <i>Sam Ransbotham, Boston College, USA</i> <i>Hongju Liu, University of Connecticut, USA</i>	
Paper #4: Naive or Savvy: How Credible Are Online Reviews for Credence Services?	
<i>Shannon Lantzy, University of Maryland, USA</i> <i>Katherine Stewart, University of Maryland, USA</i> <i>Rebecca Hamilton, University of Maryland, USA</i>	
Emotion as Social Information: Insights Into the Interpersonal Effects of Pride, Embarrassment, and Sadness	120
<i>Chairs: Chen Wang, University of British Columbia, Canada</i> <i>Yanliu Huang, Drexel University, USA</i>	
Paper #1: Proud to Belong or Proudly Different? Contrasting Effects of Incidental Pride on Conformity	
<i>Xun (Irene) Huang, Sun Yat-sen University, China</i> <i>Ping Dong, University of Toronto, Canada</i> <i>Anirban Mukhopadhyay, Hong Kong University of Science and Technology, Hong Kong, China</i>	
Paper #2: The Interplay Effect of Embarrassment and Agentic-Communal Orientation on Consumer Behavior	
<i>Yanliu Huang, Drexel University, USA</i> <i>Chen Wang, University of British Columbia, Canada</i> <i>Rui (Juliet) Zhu, Cheung Kong Graduate School of Business, China</i>	
Paper #3: Empathy-Neglect in Embarrassment-Avoidance: Observations from an Outsider	
<i>Li Jiang, University of California, Los Angeles, USA</i> <i>Aimee Drolet Rossi, University of California, Los Angeles, USA</i> <i>Carol Scott, University of California, Los Angeles, USA</i>	
Paper #4: Hardening My Heart: Persuasion Knowledge and Emotion Regulation	
<i>Nicole Verrochi Coleman, University of Pittsburgh, USA</i> <i>Patti Williams, University of Pennsylvania, USA</i>	
Creating and Resolving Tensions: Exploring the Different Effects Materialism Has on Consumers and Society	126
<i>Chairs: Laurel Steinfeld, University of Oxford, UK</i> <i>Linda Scott, University of Oxford, UK</i>	
Paper #1: Materialism and Well-Being among Consumers of Three Asian Subcultures: The Effects of Religion and Ethnicity	
<i>Fon Sim Ong, The University of Nottingham Malaysia Campus, Malaysia</i> <i>George P. Moschis, Georgia State University, USA</i>	
Paper #2: Social Stratification and the Materialism Label: The Retention of Racial Inequities between Black and White Consumers in South Africa	
<i>Laurel Steinfeld, University of Oxford, UK</i> <i>Linda Scott, University of Oxford, UK</i>	
Paper #3: When the Going Gets Tough the Materialistic Go Shopping: Materialism and Consumption Response to Stress	
<i>Ayalla Ruvio, Michigan State University, USA</i> <i>Eli Somer, University of Haifa, Israel</i> <i>Aric Rindfleisch, University of Illinois at Urbana-Champaign, USA</i>	
Paper #4: Living in a Material World: The Role of Materialism in Consumer Confidence and Well-Being	
<i>Dee Warmath, University of Wisconsin-Madison, USA</i> <i>Nancy Wong, University of Wisconsin-Madison, USA</i>	

Choices and the Self from Cognition to Motivation to Physical Expression	132
<i>Chairs: Kathleen D. Vohs, University of Minnesota, USA</i>	
<i>Nicholas Olson, University of Minnesota, USA</i>	
Paper #1: Thinking That Choices Reflect the Self Leads to Maximizing Behavior	
<i>Kathleen D. Vohs, University of Minnesota, USA</i>	
<i>Nicholas Olson, University of Minnesota, USA</i>	
Paper #2: On Metacognition and Culture	
<i>Aner Sela, University of Florida, USA</i>	
<i>Jonah Berger, University of Pennsylvania, USA</i>	
Paper #3: One of Each: Variety Seeking to Avoid Choice Difficulty	
<i>Joseph K. Goodman, Washington University in St. Louis, USA</i>	
<i>Kathleen D. Vohs, University of Minnesota, USA</i>	
Paper #4: <i>Imago Animi Sermo Est</i> – Speech is the Mirror of the Mind: The Effect of Vocal Expression on Preferences	
<i>Anne-Kathrin Klesse, Tilburg University, The Netherlands</i>	
<i>Jonathan Levav, Stanford University, USA</i>	
<i>Caroline Goukens, Maastricht University, The Netherlands</i>	
A Play for Power: Exploring the Ways Consumption Marks Social Stratifications	137
<i>Chairs: Laurel Steinfeld, University of Oxford, UK</i>	
<i>Linda Scott, University of Oxford, UK</i>	
Paper #1: Effects of Geographic and Religious Stratification and Modernity in the Arab Gulf	
<i>Russell Belk, York University, Canada</i>	
<i>Rana Sobh, Qatar University, Qatar</i>	
Paper #2: Viewing the Creation and Reproduction of Racial Stratification through Consumption: Life Histories of the Black Middle-Class in America	
<i>David Crockett, University of South Carolina, USA</i>	
Paper #3: Controlling Consumption: The Illusiveness and Pervasiveness of Gender Norms in the Ugandan Marketplace	
<i>Laurel Steinfeld, University of Oxford, UK</i>	
<i>Linda Scott, University of Oxford, UK</i>	
Paper #4: The Consuming City: Economic and Health Stratification and the Glasgow Effect	
<i>Kathy Hamilton, University of Strathclyde, UK</i>	
<i>Katherine Trebeck, Oxfam, UK</i>	
Psychological Factors that Influence Healthiness Perceptions and Healthy Choices.	142
<i>Chair: Peggy J. Liu, Duke University, USA</i>	
Paper #1: “This Isn’t So Bad”: Assimilation, Contrast, and Self-Control on Healthiness Perceptions	
<i>Scott W. Davis, Texas A&M University, USA</i>	
<i>Kelly Haws, Vanderbilt University, USA</i>	
<i>Joseph P. Redden, University of Minnesota, USA</i>	
Paper #2: Avoiding Behavioral Resistance to Diet and Exercise Messages	
<i>Peggy J. Liu, Duke University, USA</i>	
<i>Gavan J. Fitzsimons, Duke University, USA</i>	
Paper #3: Is Self-Serving Self-Serving? Who Serves Food Shapes Self-Evaluation and Eating Decisions	
<i>Linda Hagen, University of Michigan, USA</i>	
<i>Aradhna Krishna, University of Michigan, USA</i>	
<i>Brent McFerran, University of Michigan, USA</i>	

Nudging Consumers in the Right Direction: Effective Interventions for Tackling Obesity 147
Chair: Hristina Dzhogleva, University of Pittsburgh, USA
Paper #1: ‘Does This Tax Make Me Look Fat?’: Using Stigma-Inducing Labels to Decrease Unhealthy Food Consumption
Avni Shah, Duke University, USA
James R. Bettman, Duke University, USA
Punam Anand Keller, Dartmouth College, USA
Peter Ubel, Duke University, USA
Paper #2: Does Reducing Nutritional Information Complexity Promote Healthier Food Choices?
Hristina Dzhogleva, University of Pittsburgh, USA
J. Jeffrey Inman, University of Pittsburgh, USA
Jim Maurer, Catalina Marketing Corporation, USA
Paper #3: Promoting Portion Downsizing by Improving Consumer Response to Percentage Cost vs. Percentage Benefit Offers
Bhavya Mohan, Harvard Business School, USA
Pierre Chandon, INSEAD, France
Jason Riis, Harvard Business School, USA
Paper #4: Choosing to Participate: The Effects of Message Type on Enrollment and Participation
Eleanor Putnam-Farr, Massachusetts Institute of Technology, USA
Jason Riis, Harvard Business School, USA

Making a Difference with Metal Pieces: New Findings on Seeing, Possessing, and Losing Money 152
Chairs: Yuwei Jiang, Hong Kong Polytechnic University, Hong Kong, China
Nicole L. Mead, Erasmus University Rotterdam, The Netherlands
Paper #1: Monetary Reminders Lead to Exchange Orientation and Emotion Suppression
Yuwei Jiang, Hong Kong Polytechnic University, Hong Kong, China
Zhansheng Chen, University of Hong Kong, Hong Kong, China
Robert S. Wyer, Jr., Chinese University of Hong Kong, Hong Kong
Paper #2: Monetary Cues Alter Interpersonal Harmony Because They Activate an Exchange-Oriented
Nicole L. Mead, Erasmus University Rotterdam, The Netherlands
Eugene M. Caruso, University of Chicago, USA
Kathleen D. Vohs, University of Minnesota, USA
Roy F. Baumeister, Florida State University, USA
Paper #3: To Tip or Not to Tip: Emotional and Monetary Tradeoffs in Tipping
Ayelet Gneezy, University of California, San Diego, USA
Nina Mazar, University of Toronto, Canada
Paper #4: Going, Going, Gone: Hidden Hormonal Influences on Loss Aversion
Ashley Rae, University of Texas – San Antonio, USA
Kristina M. Durante, University of Texas – San Antonio, USA
Vladas Griskevicius, University of Minnesota, USA
Stephanie M. Cantu, University of Minnesota, USA

Effects of Self-Affirmation on the Personal Self and the Interpersonal Self 157
Chairs: Ji Kyung Park, University of Delaware, USA
Kathleen D. Vohs, University of Minnesota, USA
Paper #1: Broadening Perspective, Changing Narratives, and Improving Academic Performance: The Effects of Values Affirmation Interventions
David K. Sherman, University of California, Santa Barbara, USA
Kimberly A. Hartson, University of California, Santa Barbara, USA
Kevin R. Binning, University of California, Santa Barbara, USA
Paper #2: The Multifaceted Role of Affect in Self-Affirmation Effects
William M. P. Klein, National Cancer Institute and University of Pittsburgh, USA
Peter R. Harris, University of Sussex, UK
Rebecca Ferrer, National Cancer Institute, USA
Paper #3: Less about Me, More about You: How Self-Affirmation Changes Word-of-Mouth Intentions for the Self versus Others
Sara Kim, Chinese University of Hong Kong, Hong Kong, China
Ann L. McGill, University of Chicago, USA
Paper #4: Self-Affirmation has the Power to Offset the Harmful Effects of Money Reminders
Ji Kyung Park, University of Delaware, USA
Kathleen D. Vohs, University of Minnesota, USA

Re-interpreting Culturally Construed Consumption and its Embodiment within the Female Body	163
<i>Chair: Andrew Lindridge, The Open University Business School, UK</i>	
Paper #1: Constructing Identity through Cultural and Ancient Interpretations of the Female Body	
<i>Anoop Bhogal-Nair, Coventry Business School, UK</i>	
Paper #2: The Halal Nail Polish: Religion and Body Politics in the Marketplace	
<i>Özlem Sandıkcı, Faculty of Business Administration, Bilkent University, Turkey</i>	
Paper #3: Religiosity and Acculturation through Apparel Consumption Amongst North African Migrant Women in France	
<i>Ranam Alkayyali, UPEC, ESCP Europe, Paris, France</i>	
Paper #4: Renegotiating the Patriarchal Bargain and The Embodiment of Womanhood	
<i>Andrew Lindridge, The Open University Business School, UK</i>	
<i>Lisa Peñaloza, Bordeaux Business School, France</i>	
<i>Omnipreye Worlu, The Open University Business School, UK</i>	
Unleashed Restraint: Feeding the Psychological Needs of Restrained Eaters	168
<i>Chair: Katherine E. Loveland, HEC Montréal, Canada</i>	
Paper #1: Do Restrained Eaters Identify as Dieters? Exploring the Role of Self-Concept in the Consumption of Restrained Eaters	
<i>Keri L. Kettle, University of Miami, USA</i>	
<i>Katherine E. Loveland, HEC Montréal, Canada</i>	
<i>Gerald Häubl, University of Alberta, Canada</i>	
Paper #2: Do Weight Watchers Want More Options? How Activating Self-Regulatory Concerns Triggers the Need for Variety	
<i>Anne-Kathrin Klesse, Tilburg University, the Netherlands</i>	
<i>Caroline Goukens, Maastricht University, the Netherlands</i>	
<i>Kelly Geyskens, Maastricht University, the Netherlands</i>	
<i>Ko de Ruyter, Maastricht University, the Netherlands</i>	
Paper #3: The Role of Reactance in Responses to One-Sided Advertisements: How Health-Related Appeals Backfire among Restrained Eaters	
<i>Nguyen Pham, Arizona State University, USA</i>	
<i>Naomi Mandel, Arizona State University, USA</i>	
<i>Andrea Morales, Arizona State University, USA</i>	
Paper #4: The Acuity of Vice: Goal Conflict Improves Visual Sensitivity to Portion Size Changes	
<i>Yann Cornil, INSEAD, France</i>	
<i>Nailya Ordabayeva, Erasmus, the Netherlands</i>	
<i>Pierre Chandon, INSEAD, France</i>	
Sharing Information: A Focus on the Sharer's Motives and Feelings	174
<i>Chair: Troy Campbell, Duke University, USA</i>	
Paper #1: The Selfish Side of Sharing: Effects of Need for Control on Advice Giving	
<i>Alessandro M. Peluso, University of Salento and LUISS University, Italy</i>	
<i>Andrea Bonezzi, New York University, USA</i>	
<i>Matteo De Angelis, LUISS University, Italy</i>	
<i>Derek D. Rucker, Northwestern University, USA</i>	
Paper #2: The Altruistic Side of Sharing: Giving Misery Company by Sharing Personal Negative Experiences	
<i>Troy Campbell, Duke University, USA</i>	
<i>Dan Ariely, Duke University, USA</i>	
Paper #3: La vie en Rose at the Top? Why Positive (Negative) Information goes Up (Down) in a Hierarchy	
<i>Christilene du Plessis, INSEAD, France</i>	
<i>David Dubois, INSEAD, France</i>	
Paper #4: The Negative Consequences of Empowering Consumers and Employees	
<i>Tami Kim, Harvard Business School, USA</i>	
<i>Leslie K. John, Harvard Business School, USA</i>	
<i>Todd Rogers, Harvard Business School, USA</i>	
<i>Michael I. Norton, Harvard Business School, USA</i>	

Pain or Gain: Comparative Thinking and Consumer Well-Being	181
<i>Chairs: Jingjing Ma, Northwestern University, USA</i>	
<i>Yangjie Gu, Tilburg University, The Netherlands</i>	
Paper #1: The Maximizing Mindset	
<i>Jingjing Ma, Northwestern University, USA</i>	
<i>Neal J. Roese, Northwestern University, USA</i>	
Paper #2: Unit Asking: A Method to Boost Donations and Beyond	
<i>Christopher K. Hsee, University of Chicago, USA</i>	
<i>Jiao Zhang, University of Miami, USA</i>	
<i>Zoe Y. Lu, Shanghai Jiao Tong University, China</i>	
<i>Fei Xu, Shanghai Jiao Tong University, China</i>	
Paper #3: When Choice Closure Reduces Satisfaction: The Moderating Role of Decision Outcome Valence	
<i>Yangjie Gu, Tilburg University, The Netherlands</i>	
<i>Simona Botti, London Business School, UK</i>	
<i>David Faro, London Business School, UK</i>	
Paper #4: Intelligence Predicts Choice of Absolute Versus Positional Income	
<i>Christopher F. Chabris, Union College, USA</i>	
<i>Bailey Rand, Union College, USA</i>	
<i>Najiba Keshwani, Union College, USA</i>	
<i>Shane Frederick, Yale School of Management, USA</i>	
Back to the Future: New Perspectives on Time	186
<i>Chairs: Ernest Baskin, Yale University, USA</i>	
<i>Jordan Etkin, Duke University, USA</i>	
Paper #1: Managing Motivation Over Time: How Focusing on the Present versus Future Influences Goal Pursuit	
<i>Jordan Etkin, Duke University, USA</i>	
<i>Rebecca Ratner, University of Maryland, USA</i>	
Paper #2: What was I Thinking? Effect of Construal on Memory-Based Choice	
<i>Ernest Baskin, Yale University, USA</i>	
<i>Cheryl Wakslak, University of Southern California, USA</i>	
<i>Nathan Novemsky, Yale University, USA</i>	
Paper #3: Philosophies of Happiness: Preferences for Experienced and Remembered Happiness	
<i>Cassie Mogilner, University of Pennsylvania, USA</i>	
<i>Michael I. Norton, Harvard Business School, USA</i>	
Paper #4: The Psychophysics of Humor	
<i>A. Peter McGraw, University of Colorado, USA</i>	
<i>Lawrence Williams, University of Colorado, USA</i>	
<i>Caleb Warren, Texas A&M University, USA</i>	
Beyond Reciprocity: Examining the Interplay Between Money and Relationships	191
<i>Chairs: Avni Shah, Duke University, USA</i>	
<i>Kathleen D. Vohs, University of Minnesota, USA</i>	
Paper #1: With Friends Like These Who Needs Money? Three Tests of the Substitutability Hypothesis of Money and Social Support	
<i>Kathleen D. Vohs, University of Minnesota, USA</i>	
<i>Jannine D. Lasaleta, University of Minnesota, USA</i>	
Paper #2: Money and Marriage? How Marital Dynamics and Gender Differences in Risk Affect Financial Portfolio Composition Choices	
<i>Avni Shah, Duke University, USA</i>	
<i>Howard Kung, University of British Columbia, Canada</i>	
<i>Jawad M. Addoum, University of Miami, USA</i>	
Paper #3: Friendship and Finance: The Psychology of Borrowing and Lending	
<i>Noah J. Goldstein, University of California, Los Angeles, USA</i>	
<i>Ashley N. Angulo, University of California, Los Angeles, USA</i>	
<i>Michael I. Norton, Harvard Business School, USA</i>	
Paper #4: Increasing Tax Compliance by Empowering Taxpayers	
<i>Cait Poynor Lamberton, University of Pittsburgh, USA</i>	
<i>Jan-Emmanuel De Neve, University College London, UK</i>	
<i>Michael I. Norton, Harvard Business School, USA</i>	

Redistribution and Social Justice in Consumer Behavior	196
<i>Chairs: Gabriele Paolacci, Erasmus University Rotterdam, The Netherlands</i>	
<i>Klaus Wertenbroch, INSEAD, France & University of Pennsylvania, USA</i>	
Paper #1: Deserved Fruits of Labor? Culture, Just-World Beliefs, and Preferences for Redistributive Incentive Schemes	
<i>William W. Maddux, INSEAD, France</i>	
<i>Douglas H. Frank, INSEAD, France</i>	
<i>Klaus Wertenbroch, INSEAD, France & University of Pennsylvania, USA</i>	
Paper #2: Spreading the Health: Americans' Estimated and Ideal Distributions of Death and Health(care)	
<i>Sorapop Kiatpongsan, Harvard Business School, USA</i>	
<i>Michael I. Norton, Harvard Business School, USA</i>	
Paper #3: The Effect of Income Tax on the Motivation to Work Depends on People's Cultural Philosophies	
<i>Scott Rick, University of Michigan, USA</i>	
<i>Gabriele Paolacci, Erasmus University Rotterdam, The Netherlands</i>	
<i>Katherine Burson, University of Michigan, USA</i>	
Paper #4: Conspicuous Consumption Reflects How Redistribution Influences Perceived Social Justice	
<i>Barbara Briers, Tilburg University, The Netherlands</i>	
<i>Klaus Wertenbroch, INSEAD, France & University of Pennsylvania, USA</i>	
<i>Breagin K. Riley, Syracuse University, USA</i>	
Consumer Engagement in Service Relationships: The Good, The Bad, and The Ugly.	201
<i>Chair: Nita Umashankar, Georgia State University, USA</i>	
Paper #1: Suffering in Silence: Close Customers' Reluctance to Complain Damages Service Relationships	
<i>Nita Umashankar, Georgia State University, USA</i>	
<i>Morgan Ward, Southern Methodist University, USA</i>	
Paper #2: Pour Oil on Troubled Water: The Effects of Mere-Measurement and Time on Customer Desire for Revenge	
<i>Mina Rohani, HEC Montréal, Canada</i>	
<i>Yany Grégoire, HEC Montréal, Canada</i>	
<i>Renaud Legoux, HEC Montréal, Canada</i>	
<i>Jean-Charles Chebat, HEC Montréal, Canada</i>	
Paper #3: The Effects of Consumer Vulnerability on Service Evaluations and Wellbeing Outcomes	
<i>Laurel Anderson, Arizona State University, USA</i>	
<i>Daniele Mathras, Arizona State University, USA</i>	
<i>Richard J. Caselli, Mayo Clinic, USA</i>	
<i>Denise M. Kennedy, Mayo Clinic, USA</i>	
<i>Amy L. Ostrom, Arizona State University, USA</i>	
Paper #4: Acknowledging Consumer Gratitude: Leveraging the Voice of the Consumer to Increase Loyalty	
<i>Paul W. Fombelle, Northeastern University, USA</i>	
<i>Clay Voorhees, Michigan State University, USA</i>	
<i>Sterling Bone, Utah State University, USA</i>	
<i>Alexis Allen, Florida State University, USA</i>	
What's Love Got to Do with It? Close Relationships and Consumer Behavior.	207
<i>Chair: Jordan Etkin, Duke University, USA</i>	
Paper #1: How do Friends and Strangers Interpret Shared Experiences? Synchrony as Relationship-Bolstering or Experience-Heightening	
<i>Suresh Ramanathan, Texas A&M University, USA</i>	
<i>Kathleen D. Vohs, University of Minnesota, USA</i>	
<i>Ann L. McGill, University of Chicago, USA</i>	
Paper #2: The Rewarding Nature of Matchmaking	
<i>Lalin Anik, Duke University, USA</i>	
<i>Michael I. Norton, Harvard Business School, USA</i>	
Paper #3: Power and Brand Compatibility in Close Relationships: A Dyadic Investigation	
<i>Grainne M. Fitzsimons, Duke University, USA</i>	
<i>Danielle J. Brick, Duke University, USA</i>	
<i>Tanya L. Chartrand, Duke University, USA</i>	
<i>Gavan J. Fitzsimons, Duke University, USA</i>	
Paper #4: Is Variety the Spice of Love?	
<i>Jordan Etkin, Duke University, USA</i>	

The Time of Our Lives: The Role of Time in Consumer Well-Being and Virtue	212
<i>Chair: Amit Bhattacharjee, Dartmouth College, USA</i>	
Paper #1: Too Impatient to Smell the Roses: Exposure to Fast Food Brands Impedes Happiness	
<i>Julian House, University of Toronto, Canada</i>	
<i>Sanford E. DeVoe, University of Toronto, Canada</i>	
<i>Chen-Bo Zhong, University of Toronto, Canada</i>	
Paper #2: Happiness from Ordinary and Extraordinary Experiences	
<i>Amit Bhattacharjee, Dartmouth College, USA</i>	
<i>Cassie Mogilner, University of Pennsylvania, USA</i>	
Paper #3: Time, Money, and Morality	
<i>Francesca Gino, Harvard Business School, USA</i>	
<i>Cassie Mogilner, University of Pennsylvania, USA</i>	
Paper #4: Temporal Decay, Reinstatement, and Debiasing of Self-Deception	
<i>Zoë Chance, Yale University, USA</i>	
<i>Francesca Gino, Harvard Business School, USA</i>	
<i>Michael I. Norton, Harvard Business School, USA</i>	
<i>Dan Ariely, Duke University, USA</i>	
Getting Out What You Put In: Drivers and Consequences of Consumer Effort	217
<i>Chairs: Keisha M. Cutright, University of Pennsylvania, USA</i>	
<i>Adriana Samper, Arizona State University, USA</i>	
Paper #1: Doing it the Hard Way: Low Personal Control Drives Preference for High-Effort Products	
<i>Keisha M. Cutright, University of Pennsylvania, USA</i>	
<i>Adriana Samper, Arizona State University, USA</i>	
Paper #2: Earning Luckiness: The Effect of Active Loyalty Program Membership on Consumer Predictions of Randomly-Determined Marketing Outcomes	
<i>Rebecca Walker Naylor, Ohio State University, USA</i>	
<i>Kelly Haws, Vanderbilt University, USA</i>	
<i>Chris Summers, Ohio State University, USA</i>	
Paper #3: Customized Assembly: How Does Effort Influence the Value of To-be-assembled Products?	
<i>Eva Buechel, University of Miami, USA</i>	
<i>Chris A. Janiszewski, University of Florida, USA</i>	
Paper #4: The Effect of Goal Progress Salience Cues in Effortful Consumer Domains: An Implicit Theory Perspective	
<i>Pragya Mathur, Baruch College, USA</i>	
<i>Lauren Block, Baruch College, USA</i>	
<i>Ozge Yucel-Aybat, Pennsylvania State University-Harrisburg, USA</i>	
The Techno Shopper: Consumer Interactions with Mobile and Digital Technologies	222
<i>Chairs: Michael R. Sciandra, University of Pittsburgh, USA</i>	
<i>J. Jeffrey Inman, University of Pittsburgh, USA</i>	
Paper #1: Smart Phones, Bad Decisions? The Impact of In-store Mobile Technology Use on Consumer Decisions	
<i>Michael R. Sciandra, University of Pittsburgh, USA</i>	
<i>J. Jeffrey Inman, University of Pittsburgh, USA</i>	
Paper #2: Close, Yet So Far Away: The Influence of Temporal Distance on Mobile Promotion Redemption during a Shopping Experience	
<i>Daniel Sheehan, Georgia Institute of Technology, USA</i>	
<i>Koert van Ittersum, University of Groningen, Netherlands</i>	
Paper #3: The Wireless Good Samaritan: Pro-social Behavior in Mobile Networks	
<i>Jayson S. Jia, Stanford University, USA</i>	
<i>Xianchi Dai, Chinese University of Hong Kong, Hong Kong, China</i>	
<i>Jianmin Jia, Chinese University of Hong Kong, Hong Kong, China</i>	
Paper #4: Digital Shopping: What You Need to Consider	
<i>Nikhil Sharma, V.P. of Shopper Insights, The Nielsen Company, USA</i>	

Indulgent or Industrious? How Seemingly Separate Events Influence Our Consumption Choices.	228
<i>Chair: Uma R. Karmarkar, Harvard Business School, USA</i>	
Paper #1: BYOB: How Bringing Your Own Shopping Bags Leads to Indulging Yourself and the Environment	
<i>Uma R. Karmarkar, Harvard Business School, USA</i>	
<i>Bryan K. Bollinger, New York University, USA</i>	
Paper #2: The Nearly Winning Effect	
<i>Monica Wadhwa, INSEAD, Singapore</i>	
<i>JeeHye Christine Kim, INSEAD, Singapore</i>	
Paper #3: From Fan to Fat?: Vicarious Losing Increases Unhealthy Eating, but Self-Affirmation Is an Effective Remedy	
<i>Yann Cornil, INSEAD, France</i>	
<i>Pierre Chandon, INSEAD, France</i>	
Paper #4: The Fresh Start Effect: Temporal Landmarks Motivate Aspirational Behavior	
<i>Hengchen Dai, University of Pennsylvania, USA</i>	
<i>Katherine L. Milkman, University of Pennsylvania, USA</i>	
<i>Jason Riis, Harvard Business School, USA</i>	
Understanding Intertemporal Preferences to Foster Consumer Well-Being: Increasing Patience and Goal Pursuit	233
<i>Chair: Selin A. Malkoc, Washington University in St Louis, USA</i>	
Paper #1: To Know and To Care: How Awareness and Valuation of the Future Jointly Shape Consumer Savings and Spending	
<i>Daniel Bartels, University of Chicago, USA</i>	
<i>Oleg Urminsky, University of Chicago, USA</i>	
<i>Shane Frederick, Yale University, USA</i>	
Paper #2: Making Decisions For the Future: Value of Delayed Durables and Shrinkage in Usage Duration	
<i>Kyu B. Kim, University of Southern California, USA</i>	
<i>Raghuram Iyengar, University of Pennsylvania, USA</i>	
Paper #3: Loosing vs. Gaining Control: Enhancing Feelings of Control Reduces Present Bias	
<i>Kelly (Kiyeon) Lee, Washington University in St. Louis, USA</i>	
<i>Selin A. Malkoc, Washington University in St. Louis, USA</i>	
<i>Derek D. Rucker, Northwestern University, USA</i>	
Paper #4: The Influence of Time-Interval Descriptions on Goal-Pursuit Decisions	
<i>Nira Munichor, Hebrew University of Jerusalem, Israel</i>	
<i>Robyn A. LeBoeuf, University of Florida, USA</i>	
Antecedents of, Predictions About, and Responses to Financial Constraints.	238
<i>Chairs: Stephanie M. Tully - New York University, USA</i>	
<i>Hal E. Hershfield - New York University, USA</i>	
Paper #1: From Intuition to Insolvency: Intuitive Decision Makers End up More Financially Constrained	
<i>Christopher Y. Olivola, Carnegie Mellon University, USA</i>	
<i>Jan-Emmanuel De Neve, University College London, USA</i>	
Paper #2: Expense Neglect in Forecasting Personal Finances	
<i>Jonathan Z. Berman, University of Pennsylvania, USA</i>	
<i>An T. Tran, University of Colorado, USA</i>	
<i>John G. Lynch, University of Colorado, USA</i>	
<i>Gal Zauberman, University of Pennsylvania, USA</i>	
Paper #3: Financial Constraint Induces a Shift Toward Material Versus Experiential Purchases Through Long Term Focus	
<i>Stephanie M. Tully, New York University, USA</i>	
<i>Hal E. Hershfield, New York University, USA</i>	
<i>Tom Meyvis, New York University, USA</i>	
Paper #4: Squeezed: Effects of Constraint on Consumer Planning	
<i>Philip M. Fernbach, University of Colorado, USA</i>	
<i>John G. Lynch, University of Colorado, USA</i>	
<i>Christina Kan, University of Colorado, USA</i>	

Exploring the Dynamics and Durability of Stigma	244
<i>Chair: Stephanie Feiereisen, Cass Business School, University City London, UK</i>	
Paper #1: Sexual Script Development in the Media	
<i>Elizabeth Crosby, University of Wisconsin La Crosse, USA</i>	
Paper #2: Stigma and Accommodation to Consumption Loss	
<i>Cristel Antonia Russell, American University DC, USA</i>	
<i>Hope Jensen Schau, University of Arizona, USA</i>	
Paper #3: The End of Stigma? Understanding the Dynamics of Legitimization in the Context of TV Series Consumption	
<i>Stephanie Feiereisen, Cass Business School, University City London, UK</i>	
<i>Dina Rasolofoarison, Aston Business School, UK</i>	
<i>Kristine de Valck, HEC Paris, France</i>	
<i>Julien Schmitt, Aston Business School, UK</i>	
Paper #4: Factionalized Fatshionistas: Dynamics within Collectives of Stigmatized Consumers Engaged in Marketplace Change Efforts	
<i>Eileen Fischer, York University, Canada</i>	
<i>Daiane Scaraboto, Pontificia Universidad Católica de Chile, Chile</i>	
How to Enhance Value and Motivate Action: New (Counterintuitive) Perspectives	250
<i>Chairs: Heather Barry Kappes, London School of Economics and Political Science, UK</i>	
<i>Sam Maglio, University of Toronto, Canada</i>	
Paper #1: Implementing Intuitive Decisions	
<i>Sam Maglio, University of Toronto, Canada</i>	
Paper #2: Weak > Strong: The Ironic Effect of Argument Strength on Supportive Advocacy	
<i>Omair Akhtar, Stanford University, USA</i>	
<i>David Paunesku, Stanford University, USA</i>	
<i>Zakary L. Tormala, Stanford University, USA</i>	
Paper #3: Feeling Entitled Because of Who You Are	
<i>Heather Barry Kappes, London School of Economics and Political Science, UK</i>	
<i>Emily Balcetis, New York University, USA</i>	
Paper #4: Wanting What Almost Wasn't: Counterfactual Reflection Heightens Valuation of Branded Products	
<i>Hal E. Hershfield, New York University, USA</i>	
<i>Adam D. Galinsky, Columbia Business School, USA</i>	
<i>Neal J. Roese, Northwestern University, USA</i>	
Exploring the Self in Self-Regulation: Unexpected Impacts on Goal Engagement	255
<i>Chairs: Kathleen D. Vohs, University of Minnesota, USA</i>	
<i>Yael Zemack-Rugar, Virginia Tech, USA</i>	
Paper #1: Making an Impact on the Self: How Sounds and Colors Increase Goal Engagement	
<i>Maferima Touré-Tillery, University of Chicago, USA</i>	
<i>Ayelet Fishbach, University of Chicago, USA</i>	
Paper #2: What I Haven't Done Can't Hurt Me: The Effects of Imagined Future Failure on Goal Disengagement	
<i>Yael Zemack-Rugar, Virginia Tech, USA</i>	
<i>Canan Corus, Pace University, USA</i>	
<i>David Brinberg, Virginia Tech, USA</i>	
Paper #3: The Role of Goal Engagement in Self-Regulation	
<i>Minjung Koo, Sungkyunkwan University, Republic of Korea</i>	
<i>Aparna A. Labroo, Northwestern University, Canada</i>	
<i>Angela Y. Lee, Northwestern University, USA</i>	
Paper #4: Self-Affirmation Can Enable Goal Disengagement	
<i>Kathleen D. Vohs, University of Minnesota, USA</i>	
<i>Ji Kyung Park, University of Delaware, USA</i>	
<i>Brandon J. Schmeichel, Texas A&M University, USA</i>	

The Psychology of Being Untrue: The Processes and Consequences of Consumer Dishonesty	260
<i>Chairs: Yajin Wang, University of Minnesota, USA</i>	
<i>Deborah Roedder-John, University of Minnesota, USA</i>	
Paper #1: What Hiding Reveals: Ironic Effects of Withholding Information	
<i>Leslie K. John, Harvard Business School, USA</i>	
<i>Michael I. Norton, Harvard Business School, USA</i>	
Paper #2: Faking It with Luxury Counterfeit Products: How Social Feedback Can Make Us More or Less Dishonest	
<i>Yajin Wang, University of Minnesota, USA</i>	
<i>Deborah Roedder-John, University of Minnesota, USA</i>	
Paper #3: The Effects of Construal Level on Consumers' Anticipations Involving Dishonest Behavior	
<i>Nelson Amaral, University of Minnesota, USA</i>	
<i>Joan Meyers-Levy, University of Minnesota, USA</i>	
Paper #4: Brand (In)fidelity: When Flirting with the Competition Strengthens Brand Relationships	
<i>Irene Consiglio, Erasmus University Rotterdam, The Netherlands</i>	
<i>Daniella Kupor, Stanford University, USA</i>	
<i>Michael I. Norton, Harvard Business School, USA</i>	
<i>Francesca Gino, Harvard Business School, USA</i>	
Choice Architecture in Consumer Contexts	265
<i>Chairs: Minah H. Jung, University of California, Berkeley, USA</i>	
<i>Leif D. Nelson, University of California, Berkeley, USA</i>	
Paper #1: Default Effects under Pay-What-You-Want: Evidence from the Field	
<i>Hannah Perfecto, University of California, Berkeley, USA</i>	
<i>Minah H. Jung, University of California, Berkeley, USA</i>	
<i>Leif D. Nelson, University of California, Berkeley, USA</i>	
<i>Ayelet Gneezy, University of California, San Diego, USA</i>	
<i>Uri Gneezy, University of California, San Diego, USA</i>	
Paper #2: Modeling Scale Attraction Effects: An Application to Charitable Donations and Optimal Laddering	
<i>Kee Yeun Lee, University of Michigan, USA</i>	
<i>Fred Feinberg, University of Michigan, USA</i>	
Paper #3: Working out Consumption: Designing a Robust Information Intervention for Healthful Eating	
<i>Indranil Goswami, University of Chicago, USA</i>	
<i>Oleg Urminsky, University of Chicago, USA</i>	
Paper #4: Single Option Aversion	
<i>Daniel Mochon, Tulane University, USA</i>	
What Thoughts Count? Some Ways in Which Gift Selection Affects the Giver	270
<i>Chair: Adam Duhachek, Indiana University, USA</i>	
Paper #1: Forgive by Remembering or Forgive by Forgetting: The Temporal Match Between Victim Motivation and Apology Gift Preferences	
<i>Christina I. Anthony, University of Sydney, Australia</i>	
<i>Elizabeth Cowley, University of Sydney, Australia</i>	
<i>Adam Duhachek, Indiana University, USA</i>	
Paper #2: Sweet Protection: Using Sweets to Manage Relationships	
<i>Ann E. Schlosser, University of Washington, USA</i>	
<i>Joshua Beck, University of Washington, USA</i>	
Paper #3: Ask and You Shall (Not) Receive: Close Friends Prioritize Relational Signalling Over Recipient Preferences in Their Gift Choices	
<i>Morgan Ward, Southern Methodist University, USA</i>	
<i>Susan Broniarczyk, University of Texas at Austin, USA</i>	
Paper #4: Mental Stealing Effects on Purchase Decisions for Others	
<i>Esta Denton, Northwestern University, USA</i>	
<i>Derek D. Rucker, Northwestern University, USA</i>	

From Encoding, to Protecting, to Retrieving: Understanding the Interplay between Social Identity and Consumer Memory 276

Chair: Amy N. Dalton, Hong Kong University of Science and Technology, Hong Kong, China

Paper #1: Memory for Advertising: When do Consumers Remember and When do they Forget Social-Identity-linked Ads?

Amy N. Dalton, Hong Kong University of Science and Technology, Hong Kong, China

Rod Duclos, Hong Kong University of Science and Technology, Hong Kong, China

Li Huang, City University of Hong Kong, Hong Kong, China

Paper #2: Savoring through Avoidance: Identity-based Strategic Memory Protection

Kathryn Mercurio, University of Oregon, USA

Americus Reed II, University of Pennsylvania, USA

Mark Forehand, University of Washington, USA

Paper #3: Identity Preservation: If I Can Remember It, You Can Have It

Karen Page Winterich, Pennsylvania State University, USA

Rebecca Walker Naylor, Ohio State University, USA

Julie R. Irwin, University of Texas at Austin, USA

Paper #4: Sentimental Social Roles and the Objects that Elicit Them

Lindsay R. L. Larson, Georgia Southern University, USA

T. Andrew Poehlman, Southern Methodist University, USA

The Uncertain Consumer 282

Chairs: Y. Charles Zhang, Boston College, USA

Gülden Ülkümen, University of Southern California, USA

Paper #1: Distinguishing Two Forms of Consumer Uncertainty

Gülden Ülkümen, University of Southern California, USA

David Tannenbaum, University of California, Los Angeles, USA

Craig R. Fox, University of California, Los Angeles, USA

Paper #2: Known Unknowns in Judgment and Choice

Daniel J. Walters, University of California, Los Angeles, USA

Craig R. Fox, University of California, Los Angeles, USA

Philip M. Fernbach, University of Colorado, USA

Steven A. Sloman, Brown University, USA

Paper #3: (Over-)Optimism in Two-stage Choice

Y. Charles Zhang, Boston College, USA

Rajesh Bhargava, University of Texas San Antonio, USA

Abhijit Guha, Wayne State University, USA

Amitav Chakravarti, London School of Economics, UK

Paper #4: The Unlikely Middle: Overestimation of Most and Least Likely Outcomes

Oleg Urminsky, University of Chicago, USA

Consumers' Prosocial Motives and Decision-Making 287

Chairs: Leif D. Nelson, University of California, Berkeley, USA

Minah H. Jung, University of California, Berkeley, USA

Paper #1: Powering Up with Indirect Reciprocity in a Large-Scale Field Experiment

Erez Yoeli, Federal Trade Commission, USA

Moshe Hoffman, University of California, San Diego, USA

David G. Rand, Yale University, USA

Martin A. Nowak, Harvard University, Program for Evolutionary Dynamics, USA

Paper #2: Signaling Virtue: Charitable Behaviors Under Consumer Elective Pricing

Minah H. Jung, University of California, Berkeley, USA

Leif D. Nelson, University of California, Berkeley, USA

Ayelet Gneezy, University of California, San Diego, USA

Uri Gneezy, University of California, San Diego, USA

Paper #3: Benefiting from Inequity Promotes Prosociality

Yoel Inbar, Tilburg University, The Netherlands

Emily Zitek, Cornell University, USA

Alexander Jordan, Dartmouth College, USA

Paper #4: Selfish or selfless? On the Signal Value of Emotion in Altruistic Behavior

Alixandra Barasch, University of Pennsylvania, USA

Emma E. Levine, University of Pennsylvania, USA

Jonathan Z. Berman, University of Pennsylvania, USA

Deborah Small, University of Pennsylvania, USA

2013 ACR Presidential Address

Making a Difference

Angela Y. Lee, Northwestern University

This year we come together to Chicago for ACR 2013. The theme of this year's conference is "Making a Difference."

The vision of the co-chairs when they were planning this conference was that we would be coming together to make a difference. But what does that mean? I think we all know what difference means. But it is one thing to know what it stands for, and another to try to explain it. So like what everyone does these days, I went online and looked up the word "difference" and found multiple definitions:

- The quality that makes one person or thing unlike another
- Something that people do not agree about – a disagreement, quarrel, dispute or controversy
- A point or way in which people or things are not the same
- A noticeable change or effect

Most of you would agree that "a noticeable change or effect" is what the co-chairs have in mind. But I also think that we could make a bigger difference as a field by leveraging our differences. Diversity is a good thing.

But is diversity really a good thing? Or is it just a politically correct stance to take? We all know the saying – birds of a feather flock together. Similar words of wisdom have been expressed by ancient philosophers starting with Aristotle (1934): "people love those who are like themselves" and Plato (1968) "similarity begets friendship;" as well as in Chinese proverbs: "the same kind gathers (物以類聚)."

Research as early as almost 100 years ago showed that school children who shared similar demographic characteristics such as age, sex, race or ethnicity were more likely to form playgroups or become good friends. We all know intuitively, as well as from research, that similarity attracts. People or things that are similar to us are aesthetically more pleasing. Similarity helps reduce uncertainty; and that is another reason why we like things that are familiar – as demonstrated by the robust mere exposure effect. Similarity facilitates communication; we can more easily communicate with others who share a common knowledge base, similar beliefs, or tastes. Similarity also engenders social cohesiveness. We can achieve greater consensus with people who are similar to us, and that makes us like them even more. It's an upward spiral.

Is similarity favored in academia? Does similarity work the same way in academia with finding co-authors? I did a mini survey with a small group of people from my cohort who were AMA Doctoral Consortium Fellows or MSI Young Scholars. I asked them to describe their most favorite co-author, what they thought of their co-author when they first met, and now. Not surprisingly, their attitude toward their favorite co-author grew over time. But the impression that they think alike and are not very different remained stable (Figure 1).

I also asked them to tell me where they met. The data suggest that favorite co-authors are likely ones who have the same training or share the same workplace culture (Figure 2).

In 1845, Samuel Morse sent the first electronic message "What had God wrought" from Washington DC to Baltimore, and declared putting an end to what he refers to as the "tyranny of distance." But it seems that even with the internet, email, and the dropbox that many of us use, the tyranny of distance still rules. And the conclusion one might draw from this very biased sample that "similarity attracts" provides more evidence to the "30-foot rule" phenomenon which says that people are most likely to work with others whose offices are within 30 feet of their own.

But while homophily is evident, there is also a need for heterophily – "love of the different." A co-author who is identical to us offers zero complementarity. There are good reasons that we like differences. Putting two different things together gives special ad-

2 / Making a Difference

vantage – a term known as hybrid vigor (heterosis). We see this advantage in the plant kingdom, such as the tea rose, or the rutabaga; we also see this advantage in the animal kingdom, like the Savannah cat. And amongst people, working with someone who is different from us sparks creativity, even when what makes them different is that they are wrong!

I would like to describe a free association study that researchers from Berkeley conducted. They asked subjects to freely associate with the word “blue” – and the most common answer is “sky”. But in another condition, they added another task before this free association task. They showed subjects and a confederate color patches and asked them to name the color. When the confederate sees the blue color patch and calls out “blue,” the free association is still “sky”. But when the confederate sees the blue color patch and says “green,” the free association became more interesting; participants might say blue jazz, or blueberry pie.

So just being different could lead to good outcomes. But what about difference as in “something that people do not agree about – a disagreement, quarrel, dispute or controversy?” How can disagreement or quarrel lead to something good?

Let me tell you something about Alex Osborn. He is the founder of BBDO, one of the major ad agencies with offices in many cities around the world, including Chicago. He is also the author of “Your Creative Power” published in 1948. What made this book so special was Chapter 33 – “How to organize a squad to create ideas.” According to Osborn, people should get together and use the brain to storm a creative problem; that is, they come together and engage in a “brainstorm”. And brainstorming was central to BBDO’s success. At one of these brainstorming sessions, ten advertising executives were reported to have generated a total of 87 ideas for a new drug-store in 90 minutes, at the rate of almost one idea per minute. The most important rule that they had to follow, one that distinguishes brainstorming from other types of group activity, was there should be NO criticism, and NO negative comments. The idea is that if people are worried that their ideas might be ridiculed, the whole process would fall apart. So the gist of the instruction was - “Forget quality. Aim for quantity.” Brainstorming was an instant hit and Osborn became an influential business guru.

Now business guru may know how to make money, but most of them don’t know how to do good research. More than 50 years later, in 2004, the same researchers from Berkeley conducted another study that took place in two countries – US and France. Fifty-two teams of 5 female undergrads each were given 20 minutes to come up with as many solutions as possible to reduce traffic congestion in the San Francisco Bay Area. At the same time, six teams of male undergrads and 15 teams of female undergrads were tasked with solving a similar traffic congestion problem in Paris. The teams in each country were randomly assigned to one of three conditions. All participants were told: “most research and advice suggest that the best way to come up with good solutions is to come up with many solutions. Freewheeling is welcome; don’t be afraid to say anything that comes to mind.” Then participants in the brainstorming condition were given the standard brainstorming instruction: “*However, in addition, most studies suggest that you should rule out criticism. You should NOT criticize anyone else’s ideas.*” And those in the debate condition were told: “*However, in addition, most studies suggest that you should debate and even criticize each other’s ideas.*” And participants in the control condition were not given any further instruction.

The results were quite surprising. The brainstorming group performed only slightly better than the no instructions control group. The debate group was by far the most creative, generating 20% more ideas than the other two groups. This study shows that

ideas are not inhibited by debates and criticisms; but are instead stimulated by them.

Other evidence also suggests when people who think differently come together, good things happen. A study examining what makes Broadway musicals successful shows that the best teams were those with a mix of old and new talents and relationships. West Side Story is a good example. It had really famous producers and directors and choreographers like Jerome Robbins, Leonard Bernstein, Arthur Laurents. It also had a 25-year old lyricist who had never worked on Broadway musical before – his name? Stephen Sondheim.

What I would like to advocate is that different ways of thinking can enrich research – there is a yin-yang complementarity. Let’s consider promotion and prevention focus. Both are essential for survival, and yet seldom can we adopt both orientations at the same time. Wouldn’t it be nice if someone has what we lack watching our back? It’s the same with abstract/concrete thinking, or analytical/holistic thinking. I’m sure you could come up with more examples.

So having a diverse team of researchers does have distinct pros and cons – while the team may lose out on social cohesiveness, they win big on creativity, innovativeness, and impact! Let me share with you the results of a paper published in *Science* a few years ago on research productivity and impact (Wuchty, Jones & Uzzi 2007). The authors examined web of science data on 19.9 million papers and 2.1 million worldwide patents published between 1945 and 2006 and found that teams increasingly dominate solo authors in the production of knowledge. Team efforts in research are on the rise across virtually all fields—science and engineering, social sciences, patents, except in arts and humanities where it is fairly stable. Teams also produce more highly cited research than individuals, with this team advantage increasing over time. The most frequently cited studies used to be the product of a lone genius, like Einstein, or Darwin. This is no longer the case. Today, papers by multiple authors receive more than twice as many citations as single-authored papers. And within teams, the diversity advantage continues: between-school collaborations have a significant advantage over within-school collaborations in terms of high impact papers. That is, UBC-Duke collaboration trumps UBC-UBC collaboration or Duke-Duke collaboration. And it is not just cross-school collaborations getting more citations, cross-border or international collaborations also receive more citations than within-nation collaborations.

What we are observing with these cross-school or international collaborations may be similar to what happens to a particular plant species - cucurbita pepo. The scallop squash, pumpkin, zucchini, these are all different varieties of the same species. Different farmers grow it for different characteristics they value – so after 7000 years, we have many different varieties from the same species. By the same token, we may start with one idea, and different researchers with different interests will take that idea into different directions, and we end up having a much richer set of findings for that construct, each with its unique contributions.

You may ask: where do ideas come from? Maybe we could take a lesson from Steve Jobs. When he was running Pixar, he thought the headquarters must have an airy atrium. But an airy atrium is not enough. He also thought “everyone has to run into each other.” So he needed to force people to go to the atrium. He started with mailboxes, then meeting rooms, cafeteria, coffee bar, gift shop... they were all in the atrium. He also had the only set of bathrooms in the entire building there, although he was later forced to compromise and had a second set of bathrooms elsewhere.

By now, we know all the ingredients for high impact work... different people, from different schools, preferably from different countries, a space for people to run into each other, time and venue

to listen, chat, debate, and to share personal experience. And when we put all the ingredients together, that's ACR2013 in Chicago!

Let's take a look at the membership of ACR. In 1973, ACR had 411 members from 8 different countries (Canada 25, Denmark 1, Finland 1, France 2, Germany 1, Japan 1, Norway 3, USA 3). Then membership went up to 789 members from 19 countries in 1983 (Australia 8, Brazil 2, Canada 53, Denmark 3, Finland 3, France 6, Germany 15, Greece 1, Japan 4, Netherlands 7, Norway 3, Saudi Arabia 1, Spain 2, Sweden 2, Switzerland 3, United Kingdom 3, USA 672, Yugoslavia 1), 1549 members from 33 countries in 1994 (Australia 28, Austria 3, Bahrain 1, Belgium 3, Brazil 3, Canada 78, Denmark 8, Finland 11, France 15, Germany 21, Hong Kong 3, India 1, Israel 3, Italy 2, Japan 16, Korea 11, Netherlands 22, New Zealand 2, N Ireland 1, Norway 2, Poland 1, Portugal 1, Saudi Arabia 2, Scotland 1, Singapore 8, South Africa 1, Spain 5, Sweden 4, Taiwan 3, Thailand 1, Turkey 4, UK 17, USA 1278). And this year in 2013, we have 1668 members from 51 countries (Table 1)—a diverse group of individuals, all with a shared goal.

I am proud to say that the profile of my co-authors looks somewhat like the ACR membership profile: 31 from North America, 10 from Asia, 2 from Australia, 2 from Europe, and 4 from the Middle East. They are the people who have taught me how to think differently to make a difference. I am thankful to every one of them.

Here's what I would like all of you to do. Before Saturday is over, talk to at least 3 people whom you did not know prior to this conference. You may find a collaborator for some exciting new research that you could submit to a new outlet.

Speaking of new outlet, let me take this opportunity to make an exciting announcement: The ACR Board has voted yesterday to launch a new journal. It is official. This decision was based on the findings and recommendations of three taskforces and many meetings and deliberate discussions. The focus of the ACR journal (name to be determined) is on substantive contributions. The issues will be themed – like special issues. Some of them will include commentaries. There are a lot of details that need to be ironed out, but please stay tuned for further announcements.

Before I leave this podium, I would like to acknowledge and express my gratitude to three special people who have made a difference in my life. In their different ways, they have guided me, supported me, and inspired me. Without them, I would not have been here today speaking to you. They are Andy Mitchell, my advisor, and Brian Sternthal and Alice Tybout, my colleagues at Northwestern. I thank them.

And I thank all of you. Have a great conference!

Table 1: ACR Membership in 2013

North America		Europe		Asia-Pacific	
Canada	121	Norway	10	Australia	36
Mexico	9	Poland	3	China	15

2013 ACR Fellows Address

Paper #1: Choice Architecture, Public Policy and Consumer Research

Eric J. Johnson, Columbia University, USA

Paper #2: Consumer JDM Research in Search of Direction: What's Next for Consumer JDM-BDT Researchers? (My Take)

Itamar Simonson, Stanford University, USA

Paper #1: Choice Architecture, Public Policy and Consumer Research

The dictionary definition of a fellow includes: “a member of a learned society.” Well, wow, what a learned society that I am joining. It has a history dating to the first large scale models of the field, in John Howard, distinguished colleagues like Paul Green, Peter Wright, Russ Belk, Sid Levy, Joe Alba and others, and includes friends like Jim Bettman, Hal Kassarian, John Lynch and now Itamar Simonson. I am deeply and truly honored to join this company.

I am also the fourth fellow from Columbia. This is neat, not only because we have twice as many as any other school, but also because it reflects a central merit of the school: a culture where doing research is valued above other things, something strongly advocated by my predecessors, like John Howard, and by my good friends and role models, Morris Holbrooke and Don Lehman.

I thought I would spend my time today looking backwards briefly, but as anyone who knows me well, I am more motivated by looking forward. I will divide this talk into two sections, the first I'll call an “unabashedly sentimental 5 minutes of thanks”, and in the remainder of the talk I will address something more forward looking, talking about how Choice Architecture can make consumer research more relevant.

For purposes of publication in the Proceedings, I've moved the gratitude section to an appendix, not because saying thank you is unimportant, but to let readers more interested in the future – as opposed to my idiosyncratic past – an easy entrance.

Consumer Research Should Matter More

As the economist David Laibson has observed, there is a council of economic advisors, but no Council of Psychological or Consumer Advisors. Yet if you study consumption you are obviously studying an important part of the economy:

- Consumers' decisions about mortgages helped lead to the worldwide 2008 financial crisis, yet their decisions were only of interest to consumer researchers in retrospect. Very little work looks at one of the most important choices that consumers make.
- Every day consumers make decisions about consumption that will exacerbate or mitigate climate change, including purchasing cars, houses, and appliances which, in the aggregate, will determine the amount of greenhouse gases released. Influencing these choices could have a major impact upon the future.
- While the information technology issues surrounding the launch of the health exchange may dominate short-term headlines, there is a more lasting and important question about the ability of people to select the right policy. Explicit in using a market to facilitate choice is the idea that

people will be able to choose the health insurance protection that will best fit their needs. People with interests in consumer behavior should be integral players in the design of the new marketplaces that are part of the Affordable Care Act, but so far have had very limited roles. Similar questions surround any government intervention that utilizes consumer choice, like Medicare Part D, a multi-billion dollar program providing subsidized prescription drug coverage to seniors.

Yet these topics are not prominent in the consumer research literature, and the voice of consumer researchers is not a major part of the discussion for any of these important debates. One could say that we are at best on the sidelines, or perhaps, to use an analogy, sitting at the kid's table at the public policy family gathering.

There are many diagnoses and potential cures. In this short talk, I will concentrate on one route to having influence on these important issues: Thinking hard and in a non-superficial way about how the options presented to people affect their choices. The phrase commonly used, and it's a brilliant coining by Dick Thaler and Cass Sunstein, is *choice architecture*.

Choice architecture is ubiquitous and inevitable: Either by accident or design every choice situation is presented in such a way that can influence choice. For example, I noticed that the conference organizers knew this and preselected the vegetarian option for us during this conference. And Sunstein and Thaler make this point in *Nudge*, using their ‘Cafeteria’ example: There is no neutral choice architecture. So, simply put, choice architecture is the set of decisions we make about what, how, and when options are presented to the decision-maker. It is important to realize that everyone, from a parent asking a child to go to bed, to a government presenting options to its citizens, is a choice architect. Remember, whenever you draft choice stimuli for an experiment, you are a practicing choice architect.

Let me describe some of the goals of choice architecture. These are ideas generated by a wonderful collection of colleagues at the 8th Invitational Choice Symposium published in a piece in *Marketing Letters* (Johnson et al., 2012). Choice architecture can:

- Make decisions easier.
- Make decisions more accurate reflections of consumers' preferences.
- Help consumers construct preferences to make more accurate hedonic forecasts.
- Make better tradeoffs between individual and societal goals.
- By improving consumers' decisions, make markets more competitive *and* efficient.

Now notice that only the fourth goal – that is making better tradeoffs between individual and societal goals – has anything to do with nudging. The simple fact of the matter is that there are no *No-Choice architecture* options. Just as every building has a design,

even a haphazard one, every choice has its own design. And just as the goal of architecture is not to control people’s behavior, but to produce a functional and aesthetically pleasant building, the goal of choice architecture is, for the most part, these first three goals.

Now that we have clarified that, let me suggest the challenges and benefits of incorporating choice architecture into the mainstream of consumer research.

These issues help address one critique, one our reviewers often raise:

What is new about this? After all, don’t most choice studies in consumer research try to change choices? What’s so special about that?

I would argue that choice architecture represents a fascinating blend of theoretical and applied issues, and that application helps focus theory on places it might have the most impact, which is in the world and not in our journals.

Let me illustrate the relationship between application and theory with three examples of important questions that central to choice architecture and that raise important and interesting theoretical connections.

What are the dynamics of Choice Architecture?

If choice architecture can change preferences, even in directions that are desired by the decision-maker, how long do those changes last? This is fundamental both theoretically and practically. It speaks to the enduring nature of value change and the relationship between preferences and behavior. Itamar Simonson, Jonathan Levav, and On Amir have explored this question and have different perspectives on this issue and obviously more work is being done in this area. However, early work on mere-measurement with Vicki Morwitz (Morwitz, Johnson, & Schmittlein, 1993) showed that measuring intentions changed behavior over a period of 6 months. Other work by Imai, Goldstein, Gürwitz and Gollwitzer (Imai, Goldstein, & Göritz, 2007) looks at changes in voting intentions and its effect on voting, and shows a wear out of a few weeks. Understanding when and why such effects decay will shed light on the fundamental nature of preferences.

Practically, if an intervention just has a short-term effect, and the decision is made often, then the intervention might wear out. Domains with this property include food consumption and saving decisions. Brian Wansink claims we make over a hundred decisions about food a day (Wansink, Just, & Payne, 2009) and we make decisions between tradeoffs between consumption and savings every time we pull out our wallet. I do worry that some interventions, like mindsets and priming, have strong effects, but are unlikely to be lasting. To the extent we want to influence reality, we need to consider these dynamics.

I think that in some cases we have been lucky: We have looked at areas where decision is made once, and tends to stick. This seems to be the case where the consideration of the decision is not particularly pleasant, for example Organ Donation, or retirement savings. But the relationship between the temporal nature of interventions, their effects on preferences and subsequent choice deserves much more theoretical consideration.

Are people aware of the effects of choice architecture?

There is a really theoretically important issue here about meta-cognition: Do people realize the effects of choice architecture? Do they attribute the effects of an intervention, such as a default, correctly, to the presence of the default, or do they attribute the choice they made to their own preferences? How much do they know about how well they have made choices in the absence of an intervention?

Do they believe that the choice environment improved or worsened their choices? Theoretically, we don’t know much about this, but it is worrisome. We do know that people are likely to adapt to whatever they chose and that suggests they are unlikely to learn.

Let me give you a brief example from some work we have done looking at how well people can make choices on the health exchanges generated by the Patient Protection and Affordable Care Act.

This work (Johnson, Hassin, Baker, Bajger, & Treur, 2013) shows that people have great difficulty choosing a cost effective health plan. Figure 1 shows the results of later experiments. The first bar, labeled Ex. 5, shows the performance of a set of Columbia MBA students. They do relatively well, choosing the most cost effective plan about 75% of the time (as shown by the ascending blue bar) and making an average mistake of about a \$100 dollars (as shown by the descending blue bar). However, even when we teach people the meaning of arcane terms like deductible and co-payment, ordinary people do not do well. As you can see in the next bar, they are making serious mistakes, choosing the most cost effective policy less than half the time, and making mistakes that average over \$500. Now we have tried several things to help people make better choices and have succeeded in doing so: The subsequent bars correspond to treatments in the study: providing significant incentives (which help very little), providing a summary of costs (termed a calculator), preselecting the best option as the default, or combining defaults and calculators. Obviously, these help, and in the paper, we explain how these savings can amount to billions of dollars.

But how well do people appreciate the effects of these choice architecture interventions? If they understood that calculators and defaults improved their choice, this would be very good news for choice architects: People would be drawn to web sites and vendors that helped them make better choices and avoid those that used unhelpful choice architecture. Public policies that improved their decisions would be supported. We have only started examining the question, but the results are discouraging. When given an incentive, which they should have in reality as these health plan decisions have real consequences, people worked harder and were more confident of their choices than in the default condition, but the reality, as can be seen in incentive bar in the figure, is that they did not do better. Providing defaults and calculators did not improve confidence even though the combination makes them as effective decision-makers as the Columbia MBA’s, as can be seen if you compare the first and last bars in figure 1.

Figure 1

From a practical perspective this has implications that are moral, ethical, and political. If people are unaware of the effects of a default, should they be warned of these effects? Who is responsible if a decision maker makes a wrong choice? These questions, focus-

ing on the relationship between choice architecture and awareness of choice quality seems a conceptually interesting and practically important question for future research.

Who is helped and is anyone hurt?

The concept of nudging seems seductive, but it hides the value of the first three functions of choice architecture that we have discussed, and raises important questions. We have been lucky that most of the ‘winning’ examples of choice architecture are in cases where the intervention helps almost everyone. Most people want to increase their savings rate but don’t, most want to become organ donors, but can’t bring themselves to think about their demise.

But people differ along two important dimensions: They have differing tastes and beliefs, and different sets of cognitive skills. Not everyone wants the same health insurance policy, not everyone wants the same kind of retirement plan. One concept that Dan Goldstein and I have talked about is that of ‘smart’ defaults (Goldstein, Johnson, Herrmann, & Heitmann, 2008). Instead of assigning people into a one-size-fits-all default, with a little bit of intelligence, you can default people into what you think is the best choice for them. They are still free to choose something different, but you have gotten them closer to an answer that should be right. Yet, again, questions about awareness of these effects come to mind.

Also, how do we identify these individual differences in cognitive ability or other determinants of the way we make decisions? This is not just as simple as incorporating individual difference variables to show moderation. I’m thinking of identifying the big effects in the real world, and looking at how different people are helped or hurt by different choice designs.

I’ll illustrate with an example from our lab’s current research. We are all getting older: a depressing consequence is that this means we lose our ability to process information quickly, an effect that has been termed by Salthouse and colleagues ‘cognitive collapse’ (Salthouse, 2010). The youngsters in this room have almost a full standard deviation of advantage on fluid intelligence, commonly measured by tasks like Ravens Progressive Matrices and the like. (Don’t get too smug; this is going to happen to you. Fluid intelligence peaks at 20). The good news for older people like myself is that we are improving in what is called crystallized intelligence, knowledge about the world. 60 year olds are much better crossword puzzle solvers than 20 year olds. Ye Li, Elke Weber and colleagues (Li, Baldassi, Johnson, & Weber, 2013) have been examining these effects on financial decisions across the life span. The basic result is that older people made decisions that are often better than those made by younger people, but they make them in different ways, relying on their knowledge of the world and not their brilliantly speedy ability to process new information. This suggests something very important: That the young and old have very different needs when it comes to providing information: That providing fewer alternatives might be more beneficial to elders than to the young, because it reduces the load on their fluid intelligence. In contrast, the young might benefit more from ‘just-in-time’ education about financial facts.

This suggests a different view of the role of individual differences in research; that we should not be concerned with those variables that are ‘theoretically’ interesting, but those that account for great variance in the real world.

How to be relevant

What are the benefits of consumer research? Why should we try to share what we know? I am absolutely convinced that we have quite a bit to offer, and despite the growth of the field and its great promise, it is underappreciated in many ways, not least of which is

its influence on public policy. To illustrate in an area of significant concern for me, look at consumer finance. The nascent Consumer Financial Protection Bureau has an Office of Research whose mission is to understand consumer behavior in the service of evidence-based regulation. You might ask how many consumer behavior researchers or psychologists work for the office. The answer is one, and she started last week.

I’ll modestly suggest focusing on some of the issues I have discussed, so focusing on choice architecture in general might bridge the gap between policy and our research. Finally, to increase impact, let me suggest three things:

A focus on the field

Field experiments are undervalued. A couple of years ago, at a preconference panel on having research with impact, I asked the panel about field research. The response was, to be polite, mixed, with many people saying things like: “there are always confounds in field research.” Well the simple reality is that there are always what John Lynch (Lynch, 1982) has called ‘background variables’ and that these confounds and background variables are a big part of reality.

Choice architecture research, more than others, needs to be done in the field, with the relevant population, with dependent variables that look like the actual choice, what Harrison and List (Harrison & List, 2004) call ‘framed field studies’.

This may sound like an impossible task, and I can imagine junior investigators, worried about tenure, asking ‘Who is that crazy man up there?’

Consider, however, that:

- Many real decisions are made on-line, that websites are used for many important policy decisions, like deciding when to collect social security, which health plan to pick, or what funds to select for a retirement portfolio.
- On-line participants, particularly if they come from the appropriate population can lend credibility to the research that will increase its impact.
- Field experimentation doesn’t mean field, it can mean on-line environments, and the world, more generally, is starting to look a lot like the lab.
- And by the way, if you are clever, you can establish causality in the field, even without controlling the manipulation, through instrumental variable regression.

One more observation: companies *are* running experiments now; it is part of what might be called making business more evidence-based, much like *Moneyball* made baseball more evidence-based. They get it. So we should take advantage of it too. The opportunities for field experimentation are many.

Worry about the size of the effect, the importance of the effect and not the elegance of the interaction

Often, we are satisfied with the fact that our results are statistically significant, and less sensitive to the effects of sample size. These effects tend to be less replicable and less likely to have impact, since, by definition, they suggest that applying the findings is tricky business. Contrast this to results that have several mediators, all of which pull in the same direction, making the results robust. A good example of this might be no-action defaults, which have at least three causes (Dinner, Johnson, Goldstein, & Liu, 2011).

Translate the results into numbers

It’s one thing to report a difference in means, it’s quite another to talk about dollars. In our work on the health exchanges, we could, and do, present the results as a percentage increase in performance.

But there is another measure. We can look at the size of the error *in dollars* represented by each decision, the descending bars in the figure. This dollar number, put in context, can be very persuasive. To say that choice architecture can reduce the errors made by consumers from \$533 dollars to \$77 is more concrete and vivid. Note that this simply applies principles that are part of the accepted wisdom in other fields about concreteness and vividness. But there is another trick: You can look at how those errors might scale up. Under the assumption that 20 million people will be buying insurance on the exchanges, that mistake multiplies, becoming, in the aggregate 9.12 billion dollars a year. Now that might get a policy maker's attention. Incidentally, some of the state exchanges are including calculators and other decision aids.

Conclusion

In closing, let me say that I am profoundly optimistic about the field.

- First, we are larger, more diverse and if the Flynn effect (Flynn, 1998) means anything the next generation is brighter (by several IQ points) than the preceding one.
- Second, the world is more interested and accepting of the social sciences and particularly input from decision research. This is true in both policy and business as witnessed by the Behavioral Insights team in Britain and its nascent equivalent in the US. The idea of a randomized control trial is rapidly gaining acceptance in business worldwide, and we can encourage that trend by incorporating a concern for experimentation into our teaching. Moreover, doing this will create research opportunities.
- Finally, the set of tools and toys you have is astounding. For those of us who started when surveys and punch-cards were mainstays, the alternatives are now staggering: Ubiquitous computing, eye-tracking in the supermarket – in fact, the super market is now your computer. It's time to abandon the survey: The lab is becoming reality. I envy the possibilities that you face.

Thanks for listening.

Appendix: The Unabashedly Sentimental 5 Minutes.

Now as I said, anyone who knows me well, knows that I don't look backwards a lot. To quote research terms invented by a friend who is a social psychologist, I am a promotion focus, high locomotion type. This can be a fault. I have forgotten old results from papers, and I'm much more likely to want to work on a new project than do the heavy lifting of getting an old one revised. But looking backwards is important.

There are many people to thank who have helped create the researcher who humbly talks to you today. Current and past graduate students, a particularly wonderful set of postdoctoral fellows, and some really superb research assistants and lab managers, particularly those involved in the Preferences as Memories Laboratory, or PAM-LAB, that I have been running jointly with Elke Weber for the last 10 years. It excites me to see them move up each rung on the ladder from RA to graduate student or postdoc to faculty member.

But I want to extend my particular thanks to people who made a difference early on, as a young working class kid from New Jersey came to realize the he could, perhaps, follow his crazy interests, first in science, and then in something he vaguely knew was something more relevant and interesting, social science and consumer decision-making. Excuse me if I tell you a little about my parents' background. My father grew up on a homestead in eastern Colorado, the first generation son of Swedish immigrants, and occasionally, but not

often, he would tell tales of burning corn cobs for fuel, and using the car battery to power the house's only radio, since electricity had not yet reached them. My mom was one of nine children born in Scranton, and my grandfather counted himself fortunate to be a supervisor in silk mills. While wonderfully encouraging, there were not a lot of role models for going to college or graduate school.

I'd like to focus on those most responsible for me choosing the career and research questions that I have. The tale starts with a couple of junior faculty, who were never tenured, in Human Communication at Rutgers, David 'Louie' Bender and David Davidson who gave a young RA something more to do than fetch coffee and who did me the great favor of giving me some things to read. Now I am sure you are thinking that Human Communication majors all were scholarship athletes or good-looking people who wanted to be news anchors, and I clearly fit neither role. I majored in this mostly because it had the least required courses, had something to do with social science and I really did not know what I wanted to do. The most important things given to me to read were work in attitude theory and Herb Simon's *Science of the Artificial*, a wonderful little book laying out the human information processing perspective. I applied to the Psychology PhD program at Carnegie-Mellon, which was pretty stupid. I had taken only taken two advanced psychology courses, and didn't get into some other programs because of this. I remember telling one of my letter writers in psychology thank you for his letter and that I had gotten into Carnegie-Mellon, to which he responded disbelievingly, "In Psychology?"

By an astounding accident, Jay Russo spent one year at CMU, making the transition from Psychology to Marketing. During this year I took a 6-week course called Buyer Behavior that used as a text Jim Bettman's *An Information Processing Theory of Consumer Choice* (a preprint in mimeo) and I was hooked. I then spent a year and a half at Chicago. There I admired and argued with Hilly EINHORN who offered great encouragement and was a great alto saxophonist. Playing bass for Hilly, Morris Holbrook and Paul Green was a ton of fun, but as they say, outside the scope of this talk.

Back to Jay who provided the right mix of encouragement and challenge. He also went way beyond what was necessary. I had written a paper and submitted to a conference in Sweden, and never heard back. When two weeks before the conference, Robin Hogarth told Jay I was on the program, he encouraged me to go, and lent me the money so I could make the trip. While I paid him back financially long ago, I really cannot pay Jay back for all the advice and encouragement he gave, but I can say thank you.

I should also mention Sarah Lichtenstein, who provided me with lots of encouragement, and was a huge role model for many people in the field.

I was then fortunate that Amos Tversky agreed to host me as a post-doctoral fellow on a National Science Foundation fellowship at Stanford. What followed was an enthralling, challenging, and intimidating intellectual experience. Oh, by the way, it was pretty productive. At this point, I was totally hooked on decision research, did two early papers on affect and risk with Amos, and was pretty schizophrenic: Enthrilled by two very different styles of research: The grand and clever demonstration experiment, a technique pioneered by Kahnemann and Tversky, and the careful and narrow information processing style of research, representing my Carnegie roots. I think I've never really reconciled the two.

About this time, I started to talk to John Payne. It would appear that I had chased John out of some of the best universities: He was a post-doc at Carnegie who had just left when I arrived, a faculty member at Chicago, who left when I got there, and when I received a job offer from Duke, I'm sure there was a sigh of relief when I didn't

take it: John was simply too valuable to them. Not long afterwards, John and I were developing production systems of strategies. Soon Jim Bettman joined us on this project. I felt a little like a rookie on the all-star team, but I was nonetheless amazingly comfortable: Our interaction was about the ideas, not egos. As a last bit of nostalgia, I remember that Jim and John would walk through the Fuqua School running our computer simulations on the administrator's IBM PCs inserting floppy disks at night and retrieving them in the morning. Little did they know they were inventing clustered computing.

In German you refer to your dissertation advisor as your doctor vater or doctor father, so while Jay played that role for me, Jim and John were my uncles, or since I'm from New Jersey, and have spent a lot of time in places used to film episodes of "The Sopranos", perhaps they were my godfathers.

Along the way, each of these folks saw something and said something that was encouraging, that made me feel that I could do something useful, that I had an interesting idea. This is in strong contrast to the kind of feedback we get so often from reviewers, or that we give each other in questions at conferences. Writing this, I come to feel that I've fallen short on this dimension, and hope we all realize how valuable this kind of encouragement can be. As Don Lehman said in his fellows address, it is important. Pass it on....

Paper #2: Consumer JDM Research in Search of Direction: What's Next for Consumer JDM-BDT Researchers? (My Take)

A primary goal of "Behavioral Decision Theory" (BDT), including the significant part of BDT research published in marketing journals, has been to introduce an alternative to economic, normative decision theory. More precisely, while not offering a comprehensive alternative decision theory, much of BDT has been devoted to showing that key assumptions underlying economic theory are violated and are inconsistent with the way decisions are actually made. BDT research consisted largely of "effects," many of which involved demonstrations of preference reversals. BDT research tended to have certain unique characteristics, including (a) avoiding "grand theories," such as those characterized by boxes and arrows; instead, BDT research led to some general conclusions such as the notion of the construction of preferences; (b) minimal, as required use of mediation analyses; (c) a preference for choice and behavior as dependent measures as opposed to ratings; (d) the introduction of various distinct effects, which are then appropriately named. Researchers have also tried to understand what underlies these effects and their moderators/boundaries. The consumer BDT community has been particularly diverse in terms of the educational background of researchers, many of whom have also been important contributors to the broader Judgment and Decision Making (JDM) field.

Consumers' BDT researchers have made important contributions to the consumer behavior literature and the broader JDM field. Although I have not conducted a systematic analysis, compared to other consumer research topics, it appears that BDT research published in marketing journals has had large impact on research in non-marketing fields as well as on quantitative researchers in marketing.

The primary objective of BDT has been largely accomplished – BDT research has persuasively demonstrated that the assumption of value maximization and, more broadly, assumptions underlying normative theories of decision making, are violated in systematic ways (such as various context and task effects). Accordingly, this is a good time to reevaluate possible directions for "ex-BDT" consumer researchers. Although each person will make his/her own choices, having a discussion about areas that present promising opportunities and might benefit from the skills and tendencies of consumer BDT researchers may help shape the direction of this large community.

A default option is to just let the chips fall where they may. As further demonstrations of violations of the assumptions economics are becoming less significant as contributions to the literature, various other topics have emerged. Though lacking one common purpose, they address a variety of interesting questions. In general, consumer JDM researchers have paid greater attention in recent years to topics that have particular implications for society, such as decisions concerning health, the environment, financial matters, and ethics. Consumer JDM researchers have also studied currently popular topics in psychology, such as embodiment. And long-standing topics such as intertemporal preferences and moderators of previously demonstrated effects have continued to be examined.

An important, emerging area for consumer JDM researchers is consumer decision making as a reflection and driver of the evolving information environment (Internet, etc.). The current information-rich, socially intensive environment can potentially fundamentally change many aspects of consumer behavior and marketing. Simonson and Rosen (2014) discuss the broad implications of a shift from relative evaluations to absolute evaluations of product quality. Briefly, in an age when consumers can readily obtain rather accurate

10 / Paper #2: Consumer JDM Research in Search of Direction: What's Next for Consumer JDM-BDT Researchers? (My Take)

information (based on reviews, demonstrations, and other information services) that allows them to predict experience quality, they are less dependent on relative comparisons. For example, consumers' product quality predictions are less likely to be driven by comparing the options in front of them (i.e., the local context), by prior brand evaluations, or based on prices and countries-of-origin. The current information environment might also change other aspects of consumer behavior such as basic purchase processes, adoption of innovation, and customer satisfaction.

Compared to the previous BDT field, this emerging area of research is less focused on anomalies and preference reversals. It calls for greater emphasis on external validity. Moreover, in addition to controlled experiments, studying consumer decision making in the new environment will involve greater reliance on secondary data. This may require researchers to improve their econometrics skills

and/or collaborate to a greater extent with empirical quantitative researchers in marketing.

Such a shift of focus raises other challenges. Because it is more marketing-focused than the previous more general purpose BDT/JDM field, it will require a greater commitment to marketing and consumer-specific research than the consumer BDT community has been accustomed to. Moreover, the general JDM community may find consumer-focused work of less interest. Considering that many researchers in the consumer BDT have strong ties to the psychology and general JDM field, it is unclear if they will be receptive to this direction.

SESSION OVERVIEW

The field of consumer behavior has a lengthy history of examination of the processes and nuances associated with the acquisition, consumption, and dispossession of goods and services. From its very inception as an academic field, substantive domains and methodologies have been explicitly interdisciplinary and include economics, psychology, sociology, anthropology, as well as other fields. However, despite this broad reach, most investigations have concentrated their attention on a rather small percentage of the entire world population and geographic locations (Martin and Hill 2012), emphasizing relatively elite portions of the economically developed west. Yet we assume our research is generalizable to the entirety of humankind.

This situation raises several distinct possibilities that have implications for consumer theory development. First, the 85 percent of the human population that has received only limited attention by scholars has the same needs and wants as the predominantly western elite consumers because of widespread exposure to media and other sources of information associated with the larger consumer culture (Alden et al. 1999). If this proposition is true, differences are a matter of scale rather than perspective or process. Such worthy research has influenced the Bottom-of-the-Pyramid movement in business that a multi-billion persons market exists, which requires similar products in smaller, more affordable portions and sizes (Prahalad and Hart 2002).

A second possibility is that the majority of consumers on our planet is truly distinct and demands all new ways of conceptualizing how they navigate their material world (Hill and Gaines 2007). Under this paradigmatic approach, cultural distinctions and individual differences may be so influential that a failure to take them into account leads to inappropriate theory and practice (for a fuller discussion see Okazaki and Taylor 2010). A third approach that is adopted in this session proposal suggests that restriction associated with im-

poverty supersedes most other factors and has a diverse impact upon consumer behavior. For instance, Hill, Martin, and Chaplin (2012) looked at consumption restriction, social comparison, and life satisfaction, finding that social comparisons are more powerful determinants of life satisfaction for people in poorer, developing societies than for people in affluent societies. Specifically, compared to their affluent counterparts, impoverished consumers experience greater decreases in life satisfaction when their access to goods and services is lower than others within their societies.

As a consequence of these and other results (Martin and Hill 2012), we propose a special session that presents four novel contexts where findings compare more affluent with more impoverished consumption environments and reveal the importance of poverty in our understanding of consumer behavior. The first examines how materialism manifests among poor children; the second looks at saving behavior in developing nations; the third studies consumer negotiation and acquisition processes in subsistence marketplaces, and the fourth presents working class consumer behavior in mobile-home parks. The central question asked in each of these new data sets is: Do impoverished consumers behave differently or the same when compared to more affluent counterparts?

Poverty and Materialism: Are Impoverished Children More Materialistic Than Affluent Children?

EXTENDED ABSTRACT

Our research is the first to examine consumer values for children and adolescents from impoverished backgrounds. In study 1, we found that older adolescents (ages 16-17) from impoverished families are more materialistic than adolescents from affluent backgrounds. In study 2, we found that differences in materialism among income groups emerge at the onset of early adolescence (ages 12-13). Prior to this stage, younger children (ages 8-11) from impoverished families exhibit a similar level of materialism as younger children from more affluent families. Across both studies, higher levels of materialism among impoverished adolescents is associated with low self-esteem, which has been identified as one of the negative impacts on youngsters living in families experiencing economic hardship. Below, we discuss the implications and contributions of these findings for consumer research on (1) poverty and materialism, and (2) young consumers and materialism.

The last decade has seen a resurgence of interest in issues related to consumers living in poverty as well as bottom-of-the-pyramid consumers in less developed countries (Martin and Hill 2012; Prahalad 2005; Viswanathan, Rosa, and Ruth 2010). However, even with this renewed interest, little is known about the role that material goods, consumption values, and desires for material wealth play in the lives of those living in poverty.

A naïve assumption would be that consumers living in poverty are focused on obtaining the bare necessities, leaving little room for strivings for material wealth and status. However, a recent study by Hill, Martin, and Chaplin (2012) questions this assumption. Using data across 38 countries, they show that social comparisons of mate-

rial wealth are more important for life satisfaction of consumers living in poorer developing nations versus consumers living in affluent Western nations. This work reveals that access to goods and services in the marketplace plays an even more important role in poverty-stricken societies. Our results show the same patterns for young consumers (adolescents) living in poverty within an affluent Western nation. Further research comparing these levels of analysis—poor versus affluent nations and poor versus affluent consumers within nations—may provide additional insights into the role of poverty in aspirations for material wealth.

The connection between poverty and materialism opens up several new areas for study. One topic of great importance is the effects of materialism on the well-being of consumers living in poverty. Higher levels of materialism are associated with a variety of negative consequences, such as lower life satisfaction, less successful interpersonal relationships, and less generosity toward others (Kasser 2002, 2005). Could higher levels of materialism exact an even greater toll on poor consumers? Believing that happiness and a more satisfying life depends on accumulating material wealth, which is beyond their grasp, individuals living in poverty may experience much greater negative consequences of materialism than the general population.

Preliminary data gathered during the course of our research lends credence to this view. In each of our two studies, we asked participants how happy they were on a scale from 1 to 5. Younger children from impoverished and more affluent families had similar levels of happiness (8-9 year-olds: 4.08 vs. 4.10; 10-11 year-olds: 4.07 vs. 4.22; all $p > .50$). Note that these children also had similar levels of materialism. However, adolescents from impoverished families were less happy than adolescents from more affluent families (12-13 year-olds: $M = 3.21$ vs. 3.64 , $t(1, 44) = 2.24$, $p = .01$; 16-17 year-olds: $M = 2.90$ vs. 3.91 , $t(1, 48) = 4.57$, $p < .01$). Recall that for both age groups, impoverished adolescents were also more materialistic than their affluent peers.

Another important consequence of materialism among impoverished adolescents may be a connection between materialism and juvenile delinquency. Our research shows that adolescents from impoverished families are more materialistic, yet they have fewer resources to fulfill their strivings for money and material goods. Crime provides one of few paths to material wealth. The link between materialism and crime among adolescents from poor neighborhoods is suggested by Ozanne, Hill, and Wright (1998) in their study of juvenile delinquents (ages 12-18) incarcerated for robbery, auto theft, and selling illegal drugs. These juveniles placed a high degree of importance on possessions and money as a way to obtain a sense of power and status among their peers. Possessions—such as cars, clothes, and guns—were seen as important to having the right image when “hanging out with friends” and competing for the attention of young women. Although crimes were sometimes committed for fun and excitement, many were committed to obtain money to spend on items to impress others and provide status among their peers.

Profiles of Consumer Saving: Societal Conditions and Individual Aspirations

EXTENDED ABSTRACT

We were interested in capturing the nuances of consumer saving behavior worldwide, among individuals in nations across a range of poverty and restriction. To do so we conducted two research investigations examining different facets of the poverty-saving relationship. Given the nascent stage of research in these areas, we proposed two different research questions to look at societal and individual

influences on consumer saving. In our first investigation, we used multilevel methods and analyses to understand how conditions of poverty and inequality at the societal level influenced individual saving likelihood. Using a broad worldwide sample and controlling for additional national and personal factors previously linked to saving, we found that societal poverty significantly influenced individual saving occurrence. Echoing research that highlights the resourcefulness and determination of the world's poorest citizens (Collins et al. 2009), we found that in conditions of greater poverty, saving likelihood also was greater. We were unable to confirm the impact of inequality on saving (versus spending), as inequality had no significant effect on these behaviors among consumers in our sample.

In our second investigation, we extracted two more narrow and focused samples of consumers in nations with the highest poverty and in nations with the lowest poverty, according to United Nations classifications. In each, we applied latent class nominal binary regression analysis to distinguish consumer profiles and understand the manner in which aspirations influence saving. As described above, we found differences among the consumers within each sample, as well as across the two samples. Specifically, theoretical perspectives of goal contents theory and the role of aspirations fit the high poverty sample well, demonstrating how both intrinsic and extrinsic aspirations influence saving for different profiles of consumers. The findings for the low poverty/ high affluence sample were in stark contrast, where a large number of consumers were not at all influenced by aspirations. When intrinsic or extrinsic aspirations were influential, they acted to promote spending rather than saving among these consumers.

Our findings challenge conventional wisdom about saving, and extend marketing and economics scholarship. Research involving materialism or conspicuous consumption accurately portrays the angst of consumers living in post-modern societies where identities are dependent on what we have and how it is displayed socially (Rindfleisch, Burroughs, and Wong 2007). Nonetheless, seven billion inhabitants live in diverse material environments characterized by varying levels of poverty, affluence, and equality. To suggest that these contexts may lead to similar beliefs, aspirations, and behaviors is fraught with difficulties, especially if investigations concentrate attention on the most impoverished people in the poorest developing nations (Hill, Felice, and Ainscough 2007). Our findings echo limited but emerging scholarship that examines large-scale samples of such populations and finds significant disparities in individual psychological interpretations as a result of societal poverty (Martin and Hill 2012).

The idea that consumers with less material access and goods might get caught up in the same needs and desires as their more affluent counterparts is a valid assumption as long as the context is a material world where the basic necessities of life are widely available (Martin and Hill 2012). When or if they are not, such as in subsistence marketplaces, heuristics employed in consumption versus saving may vary greatly, resulting in radically different behaviors for (potentially) radically different reasons. Consider our finding that greater poverty in the least developed parts of the world leads to increased saving. This outcome is not consistent with what happens in Western countries with more abundant marketplaces (Berger and Ward 2010), or in experimental settings with consumers who face restrictions for short time periods (Ordayeva and Chandon 2011). Yet an alternative logic is revealed that suggests the poorest citizens may recognize their lives are in greatest jeopardy in times of low to no resources, and saving during more abundant times could be viewed as necessary for basic survival (Collins et al. 2009).

Yet even these relationships are not so simple. As shown recently by Martin and Hill (2012), self-determination influences individual life satisfaction of BOP consumers. The present study moves significantly beyond their basic conceptualization of psychological need fulfillment to investigate nuances that enhance this theoretical paradigm; namely goal contents theory. Examination of consumer goals and aspirations is not new, as evidenced by the stream of work described in the paper's conceptual development. Although the findings of past research on goals are significant, we do see substantial value for life goals and aspirations as a differentiator of saving behavior between citizens in poor versus affluent nations. In particular, our finding that different forms of aspirations lead to greater saving in impoverished societies—but may have the opposite effect in wealthy countries—is theoretically compelling. Collectively, results suggest unique ways of understanding what it means to seek personal fulfillment and social status via consumer behavior if poverty abounds or if affluence abounds. Likewise, our results highlight the extent of these disparities and their relative importance across nations.

Expectations derived from goal contents theory are that intrinsic (Kasser and Ryan 1996) and extrinsic (Deci and Ryan 1985) aspirations help explain saving behavior. Yet again, we find important differences between the developed and developing worlds. For example, in the most impoverished societies, the vast majority of consumers experience one or the other form of aspirations, leading to increased saving. For individuals whose aspirations or goals are intrinsic in nature, greater numbers of children imply that they may be responding to desires to support their families' growing needs and promote their safety, security, and well-being. Such broader life goals also may be self-actualizing. For individuals whose aspirations are extrinsic in nature, low education and income levels may make them susceptible to negative social comparisons (Hill, Martin, and Chaplin 2012). Accordingly, financial, material, and success oriented goals may promote saving behaviors as a means to a desired end of status and other recognition. Future research could probe the characteristics and goal contents of high poverty consumers to understand how aspirations influence other important outcomes and aspects of their lives.

Consumer Negotiation and Acquisition at the Bottom-of-the-Pyramid: The Case of Women Market Traders

EXTENDED ABSTRACT

Fresh food markets, whether centrally organized by governments or ad hoc in nature, provide the world's market traders, the vast majority of whom are women, with a critical source of income. Simultaneously, these markets serve a critical social function by making possible the efficient aggregation and redistribution of foods to needy populations, and providing economically and ecologically sustainable alternatives to imported foods that have higher economic and environmental costs. Women market traders play a critical role in consumer access to fresh and low cost agricultural products. In addition, in some countries their market entrance fees serve as a significant source of local government revenue. Throughout Sub-Saharan Africa, Latin America, Asia, and Australasia, however, women traders are frequently dismissed as marginal, unskilled, and unimportant. Women market traders make substantial contributions to local and national economies by connecting consumers with agricultural producers, adding to local government funding, and sustaining countless households and communities. Their importance and contributions must be understood and acknowledged.

Women market traders in subsistence economies work in fragile socioeconomic and political environments. In some countries (e.g., Fiji), repeated military coups have led to policy instability that places additional pressure on market systems and social networks to preserve order and process, even when the rule of law is absent or unpredictable. In other countries (e.g., Tanzania), it has been economic shocks due to political upheaval in neighboring states that have introduced uncertainty into the market, and it has once again fallen to market traders to adjust and endure. In addition, markets are complicated by religious and ethnic diversity that constrains interaction between social groups, and by persistent pressure from civic leader to foster a sense of national identity that neutralizes such barriers. In environments made unpredictable by conflicting agendas at multiple levels, we study how women market traders create sustainable, multiethnic distribution networks that make markets possible and feed urban and rural residents while financing town and city operations.

In many emerging economies, residents engage in semi-subsistence agriculture to meet household food needs, but those who live in towns or urban areas rely upon fresh produce markets. Due to their popularity, and patronage by most urban residents, municipal markets are some of the few places where social interaction between individuals from different ethnic groups is normal and expected, and among traders such interethnic alliances constitute a critical aspect of their work. Key topics in this research are how capitalist markets create, reinforce, and subvert ethnic differences in a politically fraught environment, and the role of feminized market trade labor in these processes.

The research also explores how social justice and sustainable business practices come together in subsistence markets through women traders. It explores at a micro-level, for example, women's critical roles in creating and maintaining food security in the midst of climate change. Food security, broadly defined as people's abilities to access affordable and nutritious products, is a concern throughout the world. In Fiji, for example, climate change is a clear and present danger to sustainable livelihoods. Soil salinization caused by rising ocean levels is having widespread impact on crop production, and its influence is palpable in market trading activity. In Tanzania, it is record high temperatures and extreme weather events that are affecting growing seasons and food availability, with similar effects in local produce markets.

At the level of women traders, our research shows that they negotiate difficult circumstances and emerging problems created by climate change to make trade possible in spite of increasingly volatile supply and quality. The research further documents some of the labor environment challenges faced by women market traders and their innovative solutions to such challenges. Women market traders work long hours in conditions commonly seen as inadequate, unsanitary, and hazardous. They battle second-class status, pricing and access inequities, and the persistent threat of assault in order to fulfill market duties, and through impressive and creative management of their meager resources and distribution networks they preserve sufficient dignity to function. Their innovativeness and persistence are impressive, and worthy of being understood and emulated.

Moral Identity and Competition in a Working Class Neighborhood

EXTENDED ABSTRACT

An enduring finding in consumption communities and sociological research is that consumers socially stratify themselves (Veblen 1994/1899). Bourdieu (1977, 1984) theorizes society as made up of overlapping social fields where people compete for social dis-

inction by employing economic, cultural, and social resources. In particular, the cultural capital of the working classes is conceptualized as subordinate to the cultural capital of higher classes. The working classes lack resources so they create a culture of necessity where they develop a taste for the practical, passively accept popular culture, and are united in their conformity. Recent empirical work using survey data similarly portrays working class culture as deficit where poor consumers have little education, do not read books or attend cultural events, and have few preferences beyond consuming commercialized popular culture and visiting fast food restaurants (Bennett et al. 2009). Consumer researchers have extended this work on status consumption, challenging some of the initial assumptions and stressing the importance of consumption practices (Holt 1998; Ustuner and Holt 2007, 2010).

But the cultural capital prized within different social groups may be more nuanced and localized particularly when consumers have few resources. In a study of rural firefighters, they value their country competence, which is an embodied skill set that allows them to face life-and-death decisions; as members of the pickup-truck crowd, they see themselves as superior to the pretentious suburban Buick crowd (Desmond 2006). Consistent with other researchers who question the centrality of taste in status competition (Lamont 2000), we examine how moral dispositions guide the consumption practices of the working poor. Based on an ethnographic study and forty interviews in a mobile home park, we examine the home consumption practices of consumers in this marginalized and resource constrained environment.

Our research finds that different visions of morality lie at the heart of status negotiation for the working poor. Specifically, the trailer park residents' moral habitus shapes their evaluations of themselves and their neighbors, as well as their preferences, perceived capacities, hopes, and dreams. Habitus is a set of unconscious and enduring dispositions that are acquired in childhood and provide an implicit sense of how the world works and one's place in this world (Bourdieu 1984). Habitus is a forgotten history that is transferred to new contexts and helps explain why people reproduce existing social structures (Bourdieu and Wacquant 1992). This study extends this notion of habitus empirically to explore the moral habituses or dispositions that guide a working class neighborhood.

Five groups emerged in our study—Nesters, Reluctant Emigrants, Community Builders, Homesteaders, and Outcasts. Nesters enact a disciplined moral self that is based on hard work; they are critical of their neighbors who they see as lazy and instead align with middle class consumers. Reluctant Emigrants enact a caring moral self where family is privileged; yet they view the park as a hostile and chaotic place from which to escape. Community Builders affirm a communal self and work on projects to enhance the well-being of their neighborhood. Homesteaders are resigned to life in the park, which they see as a good place for poor people to live because they can leverage social support; their moral identity is fatalistic and they adopt a live-and-let-live approach. Finally, the Outsiders perform a spectacular self that is characterized by practices that are defiant and rule breaking.

The diversity of class habituses guided by different moral dispositions can explain the levels and intensity of class consciousness and agency within a social class. Why is class structure stable? Why do few working-class protests occur despite growing social inequalities? Part of this answer may lie in the co-existence of competing moral habituses within the same social class. For example, the Community Builders criticize the structural disadvantages facing the poor yet mobilize to take constructive actions. However, the Homesteaders are more passive and fatalistic. Within the trailer park, these two

groups interact socially more than any other groups. Yet given their differing moral dispositions, they do not work together in solidarity. Given the even greater differences among the other groups, class solidarity is unlikely. Nesters gain status by distancing themselves from the other trailer park residents, and consume symbolically to enact a middle class lifestyle. The Reluctant Emigrants see trailer life as a negative symbol of poverty and thus invest little energy in their home practices and seek to escape the community. All of these groups differ from the Outcasts for whom the home has little meaning except as a safe place to enact subcultural capital.

Paper #4: Answering Why: Action and Reaction Explanations in Word of Mouth

Sarah G. Moore, University of Alberta, Canada

SESSION OVERVIEW

How does the audience shape word of mouth? What audience characteristics influence what and how people communicate? Most research on word-of-mouth has focused on its consequences, or how it influences choice, diffusion, and sales (e.g., Godes and Mayzlin 2004; Chintagunta, Gopinath, and Venkataraman 2010). There has been less attention, however, to the processes underlying interpersonal communication, particularly how the recipient impacts what people talk about and share. The four papers in this session illustrate how various aspects of the audience might motivate the speaker to share different type of content, use different linguistic styles, or pass on product information in the face of incentives or knowledge discrepancies. All four presentations are working papers with at least four studies completed.

Barasch and Berger investigate how the mere number of people with whom consumers communicate impacts what people share through shifting sharer focus. They find that talking to a group leads people to focus on the self and share self-presentational content, while talking to one person leads people to focus on the audience and share useful content. Packard and Wooten examine how consumers compensate for knowledge deficiencies by sharing product information with psychologically close (but not distant) audiences. That is, people engage in compensatory self-enhancement with audiences that have self-concept relevance (i.e., friends) by sending close others positive signals of their consumer knowledge.

Stephen and Lehmann examine the use of incentives to encourage transmission of product information to higher-connectivity friends (i.e., social hubs). Moreover, the authors show that this mechanism of incentives based on positive externalities (increasing value with more audience members) can lead to faster information diffusion. Finally, Moore shows that the use of different explanations in WOM is determined by what speakers think would be most useful or helpful for their audience, such that they use more action explanations for utilitarian experiences and more reaction explanations for hedonic experiences.

Communication requires more than one party; indeed, people cannot share things without an audience. Together, these papers highlight the diverse ways in which the audience shapes what and how people communicate. Given the widespread applicability of the issues discussed, the session should attract researchers interested not only in word-of-mouth, communication, and persuasion, but also

self-presentation, utilitarian vs. hedonic experiences, and self-other trade-offs. In the spirit of the conference theme of “Making a Difference,” we hope that the practical implications of each presentation (how to improve social interactions, share more valuable content, or design effective WOM campaigns), and the diverse approaches to studying the audience’s influence on word-of-mouth, will generate a lively and fruitful discussion.

Broadcasting and Narrowcasting: How Audience Size Impacts What People Share

EXTENDED ABSTRACT

Does the mere number of people with whom consumers communicate impact what they talk about and share? Some conversations involve communicating with just one person (*narrowcasting*), whereas others involve communicating with many people (*broadcasting*). We suggest that audience size will impact communication by shifting the relative influence of two fundamental word-of-mouth drivers: self-presentation and helping others.

People disproportionately attend to their own opinions and interests (Kruger 1999), and it is intrinsically rewarding to talk about the self (Tamir and Mitchell 2012). Indeed, self-disclosure is the most common topic in human conversation (Emler 1990). Given that considering others requires time, effort, and motivation (Epley et al. 2004), broadcasting should do little to move people from their natural tendency for self-focus, which should boost self-presentation because people automatically associate themselves with favorable attributes (Paulhus and Levitt 1987).

Narrowcasting, however, should mitigate egocentrism and encourage people to focus on others. Thinking about a specific other makes others more concrete and promotes recognition of a person’s distinct identity (Alicke and Govorun 2005). Sharing with just one other person should make the audience more vivid, increasing the attention he or she receives. By increasing other-focus, narrowcasting should facilitate consideration of the audience member’s perspective, which should in turn encourage people to “tune” their messages (Higgins 1999) and share useful content.

Thus, we suggest that broadcasting will lead people to share more self-presenting content (because of increased self-focus), while narrowcasting will lead people to share content that is more useful (because of increased other-focus). The current research tests the causal impact of audience size by manipulating it directly across four experiments.

In Study 1, we gave participants a list of imaginary events and asked them to write a short description of their day for one person (narrowcasting) or a group of people (broadcasting). Since people often self-present through distancing the self from negative personal experiences (Sedikides 1993), we predicted and found that broadcasting led people to share fewer negative events ($t(90)=2.50, p=.01$) and reframe the negative events they mentioned in a positive light ($t(90)=-2.16, p<.04$).

In Study 2, we controlled for audience closeness by asking participants to have short, real conversations with other students in the lab, either a single partner (narrowcasting) or a small group (broadcasting). Then, we had 2 coders rate the conversations for negativity ($r=.9$). Building on Study 1, we found that broadcasting reduced negativity ($t(179)=-2.73, p<.01$). Further, as a preliminary test of self-focus and other-focus, we found that broadcasting increased the

usage of first-person singular pronouns (e.g., I, me, $t(179)=-2.14$, $p=.03$), while narrowcasting increased the usage of second-person pronouns (e.g., you, $t(179)=3.38$, $p<.01$).

Study 3 tested the underlying mechanism behind these effects. In addition to manipulating audience size, we asked half the participants to list the name(s) of the people with whom they are sharing, which should have a similar effect as narrowcasting by boosting other-focus and moderating the effect of audience size. Respondents were asked how likely they would be to share 8 useful items (e.g., “A coupon for a discount”), or 15 self-presentation items that were either acquisitive or protective (“Just got a good/bad grade on a test”). Because people are more motivated to avoid bad impressions than to pursue good ones (Baumeister et al. 2001), we expect the impact on self-presentation to reveal itself primarily in the avoidance of looking bad (protective self-presentation) rather than the approach of looking good (acquisitive self-presentation).

An ANOVA revealed a significant Audience Size x Other-focus interaction on usefulness ($F(1,138)=5.65$, $p<.03$), as well as an Audience Size x Other-focus x Self-presentation interaction, such that the effect on protective self-presentation was significant ($F(1,78)=6.90$, $p=.01$), but the effect on acquisitive self-presentation was not ($F<.1$, $p>.09$). As predicted, when participants did not list others’ names, narrowcasting boosted the sharing of useful content and broadcasting decreased willingness to share things that would make participants look bad. When participants listed names of the people with whom they were sharing, however, these differences disappeared. Making the audience more concrete had an analogous effect to narrowcasting, supporting the notion that audience size effects are driven by changes in sharer focus.

Study 4 tested this mechanism more directly. Respondents were randomly assigned according to a 2 (Audience size: narrow vs. broad) x 4 (Content type) between-within-subjects design. We simultaneously manipulated the usefulness and self-presenting nature of the content, asking participants how likely they would be to share each type of content and how much they were thinking about the self versus the audience (sharer focus).

As expected, people were always more willing to share useful content, but this tendency was stronger when people were narrowcasting ($F(1,141)=6.94$, $p<.01$). Similarly, people were always more willing to share content that made them look good rather than bad, but this tendency was stronger when broadcasting ($F(1,141)=23.97$, $p<.001$). Consistent with our previous results, while audience size did not impact participants willingness to share content that made them look good, broadcasting did reduce participants willingness to share content that made them look bad. The effects of audience size on self-presentation and usefulness were both mediated by sharer focus (95% CI [.03, .65]; 95% CI [-.39, -.03]).

By demonstrating the impact of audience size on communication and by articulating the underlying role of sender vs. receiver focus, this research integrates work on the drivers of word-of-mouth with work on self-other trade-offs to deepen our understanding of what people share and why. This work contributes to work on the behavioral drivers of word-of-mouth, interpersonal communication, and the role of sharer focus.

Compensatory Communication: Consumer Knowledge Discrepancies and Knowledge Signaling in Word-of-Mouth

EXTENDED ABSTRACT

People who believe they are knowledgeable about products tend to share this knowledge more with others. This tenet is central to research on word-of-mouth motivation (e.g. Engel et al. 1969; Feick and Price 1987; Wojnicki and Godes 2012) and consistent with Gricean maxims—those who believe they are more knowledgeable should make an appropriately weighted ‘conversational contribution’ by sharing their knowledge more with others (Grice 1991). A prediction that follows from this research is that a perceived shortcoming in consumer knowledge should constrain a person’s motivation to share product information.

While recognizing this possibility, we predict that perceived deficiencies in consumer knowledge sometimes lead to an increase rather than a decrease in word-of-mouth transmission. Why might this occur? Subjective consumer knowledge has been defined as what or how much a person thinks she presently knows about products (Park et al. 1994). Extending this definition, we propose that consumer knowledge consequences may be linked not only to a person’s beliefs about their present-state attributes or “actual self,” but also the “ideal self” they desire to be in the same domain (Markus and Wurf 1987).

A discrepancy between a person’s perception of their actual and ideal consumer knowledge (a *knowledge discrepancy*) may have significant behavioral consequences (Baumeister 1982). A common response to self-discrepancies is compensatory self-enhancement, whereby people work to promote more favorable impressions of themselves with self-concept relevant audiences (e.g. Swann et al. 1989). Building on prior research on compensatory self-enhancement (e.g. Rucker and Galinsky 2008) and self-concept motivation

in word-of-mouth (e.g. Berger and Schwartz 2011), we predict that the desire to produce compensatory signals of higher consumer knowledge sometimes leads knowledge discrepant individuals to share *more* (rather than less) product information. Four studies test our compensatory communication hypothesis.

Study 1 examined how a measured knowledge discrepancy impacts consumers' motivations to share product opinions with audiences that differ in self-concept relevance. The relevance of social relations with psychologically close individuals (i.e. friends) make them a primary target of self-enhancement, while distant (i.e. anonymous) others are likely to hold less self-concept relevance (Baumeister 1982; Tesser and Campbell 1982). Participants in this study (and all that follow) were told they would be testing the "Share" button feature of an online retailer, through which product reviews can be transmitted to either known or anonymous others. Our analysis revealed that given a psychologically close (but not distant) audience, a knowledge discrepancy increases the number of product reviews people intend to write and how many people they wished to share their reviews with during the study.

Study 2 explored the core effect using a manipulated rather than measured knowledge discrepancy, and tested for moderation by lay beliefs in the self-enhancement benefit of sharing word-of-mouth information (Hennig-Thurau et al 2004). A knowledge discrepancy in music was manipulated adapting an existing method (e.g. Higgins et al 1986). Three items captured lay beliefs in the self-enhancement benefit of sharing product knowledge. Analysis revealed that the effect of a knowledge discrepancy on the intention to write and share music reviews was greater for participants with higher beliefs in the self-enhancing benefits of sharing word-of-mouth.

Study 3 examined the effect in a different product category (movies) and with different dependent variables. Specifically, we analyzed the content of participant-written reviews using measures consistent with attempted audience impression management. We predicted that review content shared by participants with high (vs. low) knowledge discrepancies would indicate greater effort to write the review, include more self-centered content, utilize more complex language, and be more positive about the product (Schlenker 1980; Walther 2007). After the discrepancy manipulation, participants were to share their opinion about the last movie they had seen via email with a self-concept relevant audience. Multivariate ANOVA using 11 content-based measures supported all four predictions linking the compensatory communication effect to self-presentation in general or social displays of knowledge in particular.

In Study 4, we tested whether the compensatory communication effect was mediated by the negative emotion (dejection) found in prior examinations of actual:ideal self-discrepancies (e.g. Higgins 1987; Higgins et al. 1986). This study also provided an additional robustness test by examining discrepancies in consumer knowledge at a general as opposed to a category-specific level. A discrepancy in generalized consumer knowledge was manipulated using the same method as Studies 2-3 (except for dropping the product category name). Participants were then invited to share their knowledge about books, music or movies with a self-concept relevant audience in a manner identical to Study 2. The core compensatory communication effect was again replicated for both the number of reviews written and review sharing. Bootstrap analysis confirmed that the specific emotion linked by prior research to actual:ideal self-discrepancies mediated the effect of a knowledge discrepancy on intentions to transmit word-of-mouth.

Conventional wisdom regarding the relationship between word-of-mouth and consumer knowledge is that the people who talk more about products do so because they think they know more about them.

By identifying the motivational power of knowledge discrepancies, this research contributes a more nuanced understanding of how knowledge beliefs and audience factors motivate word-of-mouth transmission. We hope this research stimulates new inquiries leveraging a more dynamic conception of consumer knowledge, shedding new light on the link between these beliefs and consumer attitudes and behaviors.

Using Incentives to Encourage Word-of-Mouth Transmissions That Lead To Fast Information Diffusion

EXTENDED ABSTRACT

Unlike traditional advertising campaigns or sales promotions, word-of-mouth (WOM) marketing relies on consumer-to-consumer interactions to spread awareness, generate interest, and drive sales. Importantly, not only do marketers hope for positive WOM, they hope it spreads rapidly. Fast information diffusion is important in many marketing situations, particularly in competitive environments and when firms have limited timeframes in which to achieve objectives.

According to prior research, the best way to speed up WOM-based information diffusion is for firms to target consumers who are highly connected (i.e., social hubs). Extant research shows that once information (or a product) is passed on by a social hub diffusion speeds up because these WOM transmitters have access to more people than “normal” consumers (Goldenberg et al. 2009; Hinz et al. 2011). However, directly targeting social hubs is not always possible because they are, by definition, relatively limited in number. Further, outside of public online social networks such as Twitter, it is difficult to identify these types of consumers. In light of these problems, it may often be infeasible for marketers to base WOM marketing campaigns on directly targeting hubs.

The current research investigates an approach to WOM marketing that circumvents these concerns by not directly targeting higher-connectivity consumers. Instead, the proposed approach is based on targeting “normal” consumers who do not have abnormally high levels of connectivity and finding ways to encourage them to share the information with their high-connectivity “hub” friends. Five studies show that this can be achieved through the use of incentive mechanisms that increase the probability that a targeted consumer will transmit relevant information via WOM to a receiver friend who has a higher degree of social connectivity. We show that this leads to faster information diffusion. Our central hypothesis is that incentives based on positive externalities will increase the likelihood that a WOM-transmitting consumer will select a receiver with higher connectivity. When a piece of information has a positive externality, the value of the information to those who possess it increases with the number of others who possess it. For example, a positive-externality incentive would increase the amount of discount a transmitter received on a purchase if they spread WOM to more people. Conversely, a no-externality incentive would be fixed and not vary with the number of people who received WOM. Transmitting to more socially connected friends makes sense to a consumer who is presented with a positive-externality-based incentive because if their well-connected friend passes on the information more people will hear about it.

Study 1 tested this hypothesis by examining whether a positive-externality-based incentive increases the connectivity of a selected WOM receiver compared to a no-externality incentive in the context of a discount coupon for Amazon.com. In the positive-externality condition participants would receive a 50% discount only if the coupon was shared and redeemed by at least 7,500 people over three days. In the no-externality condition this requirement was removed. We found that participants were significantly more likely to transmit the offer information to a high-connectivity friend in the positive-externality condition than in the no-externality condition ($p < .001$).

Study 2 considered WOM transmissions in an online review advice-giving context. Amazon Mechanical Turk (AMT) “workers” who wrote reviews of AMT were asked to nominate a person with whom these reviews would be shared, and indicate how socially con-

nected their chosen receivers were. In the positive-externality condition a bonus payment was given if their reviews were shared over 100 times over a week. In addition to externality (positive vs. none) we manipulated how much effort participants put into the review-writing task (higher/longer task vs. lower/shorter task). We found that nominated receivers had higher connectivity ratings when a positive-externality incentive was used, but only when participants put in higher effort (i.e., were more intrinsically motivated). Thus, positive-externality incentives only work when transmitters are also sufficiently intrinsically motivated to see information spread among others.

Studies 3 and 4 were field experiments designed to replicate results from studies 1 and 2 in different contexts and with actual WOM transmissions. Study 3 used a context where transmitters did not stand to personally benefit from information diffusion. Instead, a third-party charitable organization stood to benefit by receiving a sizeable donation if participants’ actual WOM transmissions generated a large enough number of visits to the charity’s website in a specified period of time. Study 4 involved a social media startup that tried to recruit new users with messages designed to elicit a positive-externality or not. Both field experiments replicated the results from studies 1 and 2.

Study 5 sought to identify the macro-level outcomes of positive- versus no-externality incentives for WOM transmissions on information diffusion speed in a social network using simulations. The simulation experiment demonstrated that, as theorized, as the probability of transmitting to a higher-connectivity receiver increases, diffusion speed also increases.

Overall, these five studies demonstrate that positive information externalities can be successfully used to increase the likelihood that regular WOM-transmitting consumers will select their higher-connectivity friends as receivers and that this does indeed lead to faster diffusion processes at the macro level.

Answering Why: Action and Reaction Explanations in Word of Mouth

EXTENDED ABSTRACT

Word of mouth (WOM), where consumers share information about experiences with others, is an everyday occurrence that strongly influences consumers (Arndt 1967) and firms (Chevalier and Mayzlin 2006). However, prior work has overlooked a key component of WOM: its content. While prior work has focused on valence (Richins 1983), content is key to understanding the impact of WOM (Godes et al. 2005), as demonstrated in recent work (Schellekens et al. 2009; Moore 2012). The current paper focuses on when and why individuals use particular WOM content. We investigate explaining language as one important type of content; individuals often explain events and experiences, to reduce uncertainty and manage future utility (Gilbert, Wilson, and Centerbar 2003).

Prior work shows that the act of explaining influences consumers’ evaluations of their experiences. Due to their primarily emotional nature, explaining dampens evaluations of hedonic experiences, but, due to their primarily cognitive nature, explaining polarizes

evaluations of utilitarian experiences (Moore 2012). We extend this work by examining the role of two types of explanations—action and reaction explanations (Malle 2006)—in WOM. Action explanations outline why consumers chose experiences or behaved in certain ways (e.g., I bought the cookies for a friend). Reaction explanations outline why consumers felt the way a certain way about experiences (e.g., I liked the cookies because they were chewy). While prior work has identified actor/observer differences in using these types of explanations (Malle 2004), we focus on explanations in a WOM context.

We posit that explanation type in WOM may not be predicted by actor/observer differences—since the audience is salient, the use of different explanations may instead be determined by what speakers think would be most helpful for their audience (Grice 1957). This, in turn, may be determined by product type. For utilitarian experiences, which are instrumental and goal-oriented (cognitive), action explanations might be more useful and therefore more common; for hedonic experiences, which are affective and sensory (emotional; Dhar and Wertenbroch 2000), reaction explanations might be more useful and therefore more common. Further, we posit that providing these explanations will impact speakers (Moore 2012), such that for utilitarian experiences, only action explanations will polarize evaluations, but for hedonic experiences, only reaction explanations will dampen evaluations. We examine these predictions in seven studies.

In study 1, we tested audience preferences for different types of explanations. We provided individuals with constructed reviews that varied in valence (positive or negative), product type (pretested as hedonic or utilitarian), and explanation type (action, reaction, or none). Participants rated reaction explanations as more helpful for hedonic (restaurant) reviews and action explanations as more helpful for utilitarian (USB stick) reviews.

We next examined whether speakers (reviewers) were sensitive to these preferences. In study 2, we collected 200 Amazon.com reviews. We collected fiction and non-fiction book reviews to represent hedonic and utilitarian products (confirmed in a pre-test), and coded each review for its proportion of reaction and action explanations. More action than reaction explanations were provided for non-fiction (utilitarian) books (e.g., I bought this because it was a best seller), while more reaction than action explanations were provided for fiction (hedonic) books (e.g., I loved this book because it was well-written).

In study 3, we replicated this finding in the lab. Individuals recalled a recent utilitarian or hedonic purchase that was positive or negative. They imagined writing an online review or a diary entry, and rated how likely they were to include sentences that provided either no explanations, action explanations, or reaction explanations. Corroborating the Amazon data, regardless of valence, and only in the public (online review) conditions, individuals were more likely to include action (reaction) explanations for utilitarian (hedonic) products.

In studies 4 and 5, we examined how different types of explanations influence speakers. Individuals recalled and wrote about a recent purchase that varied by valence (positive or negative), product type (hedonic or utilitarian), and explanation type (action, reaction, or none). To manipulate explanation type, individuals completed fill in the blank sentences that varied in terms of the explanation re-

quested. In studies 4a and 4b, individuals wrote about dining out at a restaurant (hedonic) or purchasing a technology product (utilitarian). In studies 5a and 5b, to control for product tangibility, all individuals wrote about a technology product that was either hedonic or utilitarian. For positive and negative purchases across all three studies, compared to not explaining, action explanations polarized individuals' evaluations of utilitarian products, and reaction explanations dampened individuals' evaluations of hedonic products.

In sum, we examine WOM content, a critical but understudied issue in WOM. We focus on explanation type in WOM about hedonic and utilitarian products. We examine when action versus reaction explanations are preferred by audiences, and show that speakers are sensitive to these preferences—but sometimes to their detriment, as providing certain types of explanations can impact speakers' evaluations of their own purchases.

SESSION OVERVIEW

Much research has investigated how consumers make difficult choices (Luce 1998, Nowlis, Dhar and Simonson 2010). To date, choice difficulty is generally considered a fixed property of the choice set, determined by the configuration of alternatives and attribute values. Choices with many alternatives, for instance, are considered more difficult than those with less alternatives (Iyengar and Lepper 2000), and choices between alignable attributes are considered easier than choices between non-alignable attributes (Zhang and Markman 2001). More recent research has begun to explore the notion that choosing from the same choice set can be perceived as more or less difficult based on consumer or situation-specific characteristics (Schrift et al. 2011; Sela and Berger 2012). The papers in this session further this line of inquiry by examining incidental factors that affect choice difficulty and consequently choice incidence.

Paper 1 (Etkin and Pocheptsova) will open the discussion by exploring effects incidental positive mood on choice difficulty. While prior research has emphasized the benefits of positive mood for a wide range of outcomes, this research shows positive mood can actually make choice seem more difficult. The authors demonstrate that when choice evokes tradeoffs, positive mood increases perceived differences between choice options, which increases choice difficulty and the incidence of deferral.

Consumers' experience of choice difficulty also depends on the amount of cognitive effort expended prior to choice. Paper 2 (Goldsmith and Hamilton) shows that evaluating low (vs. high) fit brand extensions prior to choice actually decreases the incidence of deferral. The authors argue that reconciling low (vs. high) fit brand extensions requires more cognitive resources and promotes a more abstract style of thinking, thereby decreasing decision difficulty. Together with the results from paper 1, these findings expand understanding of how factors incidental to choice can nevertheless impact experiences of difficulty.

Papers 3 and 4 further enrich our understanding of how incidental factors influence choice difficulty by exploring novel pathways through which such difficulty may be resolved. Paper 3 (Cho et al.) explores the impact of distractions on choice difficulty. The authors

show being distracted while making a choice increases the likelihood that consumers choose consistently with their conscious focal goal. Distractions bolster the importance of the focal goal, thereby increasing adherence. Paper 4 (Danilowitz et al.) illustrates a final counter-intuitive relationship between incidental states and difficult decisions. Whereas previous literature has largely argued that feelings of conflict are associated with increased choice difficulty and greater choice deferral, this paper suggests that priming incidental conflict instead decreases choice deferral. The authors show priming conflict increases the systematic processing of choice information, which allows people to directly confront conflict and results in increased choice.

Together, four papers offer novel and surprising insights into how incidental factors influence consumers' experience of choice difficulty and choice deferral. In doing so, these papers demonstrate a series of important effects that will be of interest to a wide range of ACR attendees, including those interested in choice, mood, resource depletion, brands, and goals.

When Being Happy Makes Choice Harder

EXTENDED ABSTRACT

Being in a positive mood confers a wide range of benefits on consumers. Positive affect enhances creativity (Isen et al. 1985), promotes self-control (Aspinwall 1998; Ragunathan and Trope 2002), and generally leads to successful outcomes (Lyubomirsky et al. 2005). Based on these findings, one might expect positive mood to have beneficial impact on choice processes. In contrast, we propose that positive mood will at times make choice more difficult, increasing the incidence of choice deferral.

We base our propositions on prior work showing that positive mood increases context dependence, or adoption of situation-specific processing cues (Murray et al. 1990; Hunsinger, et al. 2011; Showers and Canter 1985). Although positive mood has been primarily shown to enhance focus on inter-item similarities (Isen and Daubman 1984; Isen et al. 1985; Lee and Sternthal 1999), in situations that cue consumers to focus on differences, positive mood instead increases perceived inter-item differences (Murray et al. 1999; Showers and Canter 1985). For example, Murray et al. (1990) demonstrated that participants in a positive mood identified more similarities between items when prompted to focus on similarities, but also identified more differences when prompted to focus on differences.

We posit that when choice involves tradeoffs, positive mood will spontaneously lead consumers to focus on differences between choice options. When consumers are faced with tradeoffs, they engage in comparison processes aimed at resolving this conflict (Brenner et al. 1999; Gilbert et al. 1995; Tversky 1977). Though choice options may be compared in terms of similarity or dissimilarity (Gati and Tversky 1984; Medin et al. 1993; Tversky 1977), an emphasis on unique or different features is the norm (Brenner et al. 1999; Dhar and Sherman 1996). We thus expect a differences cue to be salient when consumers make choices that involve tradeoffs. Positive mood, then, should lead consumers to more readily adopt this differences focus, increasing their perceptions of differences between choice options. Perceiving more differences between choice options, in turn, increases choice difficulty by making inter-item

comparisons more difficult (Iyengar and Lepper 2000). As a result, we expect positive mood will increase consumers' perceptions of choice difficulty for choices with tradeoffs, making them more likely to defer choice entirely.

We test our propositions in four studies. In a pilot study, we used a word-prime task to manipulate positive vs. neutral mood (adapted from Pyon and Isen 2011) and presented participants with a set of three physician options, designed in such a way as to require tradeoffs when making a choice (adapted from Schrift, et al. 2011). Half of participants chose a physician option while the remaining half rated the attractiveness of each physician option. Next, we asked all participants to rate their perceptions of differences between the three physician options [1-7]. As we predicted, positive mood increased perceived differences between the physician options when participants were confronted with tradeoffs (i.e., they had to make a choice; $M_{\text{pos}} = 4.89$, $M_{\text{neg}} = 4.26$; $F(1, 78) = 3.31$, $p = .07$), but not when they merely rated the options ($M_{\text{pos}} = 4.48$, $M_{\text{neg}} = 4.75$; $F < 1$). Consistent with prior findings, this reversal suggests in the absence of a cue to focus on differences, positive mood spontaneously leads individuals to focus on similarities.

Study 1 uses a different tradeoff manipulation to provide further support for our propositions. We manipulated positive vs. negative mood using pre-tested video clips and then asked participants to imagine they were taking a trip for work or for pleasure. We constructed a set of flight options such that choosing required tradeoffs when the trip was for pleasure but not for work. As expected, being in a positive mood increased perceived differences between the flight options when choosing required tradeoffs (i.e., when the trip was for fun; $M_{\text{pos}} = 4.80$, $M_{\text{neg}} = 4.26$; $F(1, 156) = 4.70$, $p < .05$), but decreased perceived differences when choosing did not require tradeoffs (i.e., the trip was for work; $M_{\text{pos}} = 4.33$, $M_{\text{neg}} = 4.88$; $F(1, 156) = 5.04$, $p < .05$).

Studies 2 and 3 extend our investigation by considering consequences of focusing on differences between choice options. In study 2 we manipulated mood as in the pilot study and asked participants to choose a task they would like to complete for pay. In one set (no tradeoffs), there was an asymmetrically dominating task option, whereas in the other set (tradeoffs required), there was not (adapted from Sela and Berger 2012). We measured participants' interest in deferring on a 7-point scale. As predicted, being in a positive mood increased interest in deferral when choosing required tradeoffs ($M_{\text{pos}} = 5.02$, $M_{\text{neg}} = 4.20$; $F(1, 180) = 3.87$, $p = .05$). The opposite occurred when participants chose from the set that did not require tradeoffs ($M_{\text{pos}} = 3.73$, $M_{\text{neg}} = 4.54$; $F(1, 180) = 4.02$, $p < .05$).

Study 3 replicated our findings in a field study. We intercepted students at a University food court, administered a word-prime mood manipulation (the alleged main study) and then in thanks, asked them to choose a \$10 gift-card to one of four local restaurants. This choice required participants to make tradeoffs among seven attributes (e.g., distance from campus, wait time for food, size of menu, etc.). We gave participants the option to defer immediate choice in favor of choosing later online. Results show being in a positive mood increased participants' propensity to defer choice ($M_{\text{pos}} = 11.54\%$, $M_{\text{neg}} = 0\%$; $\chi^2 = 3.89$, $p < .05$). That no participants in the negative mood condition chose to defer choice makes the higher incidence in the positive mood condition all the more remarkable.

In sum, we demonstrate positive mood can negatively influence choice, exacerbating consumers' perceptions of differences between choice options and increasing deferral. Our findings contribute to extant research on positive mood as well as choice difficulty, demonstrating mood is an important factor to consider when investigating choice processes.

The Cognitive and Behavioral Consequences of Considering Low-Fit Brand Extensions

EXTENDED ABSTRACT

Launching new products is a risky and expensive endeavor. Accordingly, many firms attempt to mitigate this risk by introducing new offerings under existing brand names. A great deal of academic research has explored the factors that affect consumers' likelihood of accepting these brand extensions, finding that the perceived "fit" between the extension and the brand is a critical factor in predicting consumer interest (Aaker and Keller 1990). However, in today's uncertain economy, many firms seek to maximize leverage from successful brands by broadening the scope of their product lines beyond exclusively high-fit extensions. This raises the question: How does having low-fit extensions in the marketplace affect consumers?

While recent research has begun to explore the factors that increase acceptance of low-fit extensions (e.g., Meyvis, Goldsmith and Dhar 2012), little work to date has explored the consequences that such brand extensions might have for consumers. For example, if Crest, an oral care brand, were to introduce a line of facial products (e.g., moisturizer), how might consumers' experience of evaluating such products differ as compared to evaluating products that were higher in fit (e.g., Crest gum)? Although one could argue that offering a wider array of brand extensions only benefits consumers by way of increasing variety (Kahneman, Wakker, and Sarin 1997), we propose that the presence of low-fit brand extensions may lead to unique consequences. Specifically, we predict that when the fit between the brand and the extension is low, evaluating such products will result in regulatory depletion as well as a shift towards more abstract processing. Further, we argue that these cognitive shifts have downstream implications for choice confidence, choice difficulty and choice deferral.

We draw from the literature on brand extensions (e.g., Peracchio and Tybout 1996) to propose that when there is a poor fit between a brand and an extension, evaluating such products requires expending more effort and can deplete consumers of the executive resources necessary for successful self-regulation (e.g., Baumeister et al. 1998). We test this prediction across a series of experiments. For example, in Experiment 1 all participants evaluated a series of brand extensions, which were either high in fit (e.g., McDonald's BBQ sauce) or low in fit (e.g., Mrs. Field's BBQ sauce) with the parent brand. Next all participants were given an unsolvable puzzle, as persistence on impossible tasks has previously been used to test depletion effects (Wan and Sternthal 2008). In line with our predictions, participants exerted less effort on the task (showing more depletion) after evaluating the low-fit brand extensions. Those in the low-fit condition spent less time on the task than those in the high-fit condition ($M_{\text{low fit}} = 174$ seconds vs. $M_{\text{high fit}} = 376$ seconds; $p < .05$). In subsequent experiments, we demonstrate boundary conditions for this effect that provide support for our process. Specifically, we show that when consumers are not motivated to reconcile the brand and the extension, these effects do not occur. We provide convergent evidence for the observed depletion effect by showing that decision confidence also erodes after consumers evaluate low-fit brand extensions (Hamilton et al. 2010; scale: 1-not at all confident to 9-extremely confident; $M_{\text{low fit}} = 5.9$ vs. $M_{\text{high fit}} = 6.5$; $p < .05$).

Having demonstrated that evaluating low-fit extensions leads to self-regulatory depletion across a series of experiments with convergent dependent measures, we argue that what makes the effect of evaluating low-fit brand extensions on self-regulatory depletion particularly interesting is that the same manipulation can also promote more abstract processing, a factor often shown to counteracts deple-

tion effects (e.g., Wan and Agrawal 2011). We base this prediction on findings from construal level theory, which demonstrate that higher-level, more abstract construals allow consumers to find connections between disparate stimuli (e.g., Trope and Liberman 2003). We add to this work by testing if this effect is bi-directional. Specifically, in Experiment 5 we explore if prompting consumers to find connections between disparate stimuli (e.g., by evaluating low-fit brand extensions) promotes more abstract construals. We have participants evaluate a series of extensions that are either high or low in fit, then having them complete a task traditionally used to assess differences in levels of construal (a modified behavioral identification task; Meyvis, Goldsmith and Dhar 2012). We find that those who first evaluated low-fit brand extensions were significantly more likely to identify behaviors in abstract terms than those who first evaluated high-fit extensions ($M_{\text{low fit}}=5.6$ vs. $M_{\text{high fit}}=4.8$; $p<.05$).

Having shown that evaluating low-fit brand extensions can promote more abstract processing, our final experiment tests for implications this might have on consumer choice. Prior work has suggested, although never directly demonstrated, that abstract processing should reduce choice deferral by decreasing decision difficulty (Kim and Dhar 2007). We test this by manipulating if consumers first evaluate high vs. low fit brand extensions then presenting them with an unrelated choice task that includes the option to defer choice (Dhar 1997). In line with our prediction, participants in the low-fit condition were significantly more likely to make a choice (less likely to defer choice) than those in the high-fit condition (choice deferral: $P_{\text{low fit}}=32\%$ vs. $P_{\text{high fit}}=48\%$, $p<.05$). In support of our process, we find this effect does not occur when consumers are not motivated to reconcile the brand with the extension.

Taken together, these results suggest that evaluating low fit brand extensions can have cognitive consequences for consumers both in terms of self-regulatory depletion (Experiments 1 – 4) and level of processing (Experiments 5 and 6). We discuss how these results extend the research on schema congruity, self-regulatory depletion and construal level theory. Because most if not all prior brand extension research has been from the perspective of the firm, we believe our findings offer novel insights into the effects that varying brand extension fit can have on consumers. We conclude with a discussion of the practical implications for these findings.

Distractions: Friend or Foe in the Pursuit of Conscious and Nonconscious Goals?

EXTENDED ABSTRACT

We have all had the experience of going to a coffee shop with the intent of working, but becoming distracted: the loud conversation at the next table, the music, the sunny weather outside, or even the desire to buy and eat a red velvet cupcake. How might these different types of distractions affect your goal to work? Will the consequences differ depending on whether your goal is conscious or nonconscious?

Conscious and nonconscious goals are generally believed to lead to similar processes and outcomes (e.g. Bargh et al. 2001; Chartrand and Bargh 1996). More recently, however, research is examining how the two types of goals may differ (Gollwitzer, Parks-Stamm, and Oettingen 2009). Our research posits that the pursuit of conscious and nonconscious goals diverges when faced with distractions. Consistent with the view that there is a limited pool of cognitive resources (Kruglanski et al. 2002), when a focal goal is faced with a distraction, the motivated response can be to protect the goal and protect the cognitive resources. We propose that because the activation and pursuit of conscious goals require cognitive resources

(Kruglanski et al. 2002), introducing a distraction that threatens to compete for those resources will increase the importance of the goal and as a result, increase goal adherence. The activation and pursuit of nonconscious goals, however, require very few cognitive resources (Bargh and Barndollar 1996), such that distractions are not perceived as a threat that requires a response. We hypothesize, therefore, that distractions will enhance the accessibility and pursuit of a conscious goal, but have no effect on a nonconscious goal. Furthermore, we examine the effect that different types of distractions will have on the pursuit of conscious and nonconscious goals. As a key component of our theorizing involves the consumption of cognitive resources by a goal, and the subsequent threat posed to those resources by a distraction, we expect that the increase in goal pursuit will be further moderated by the extent to which the distractions consume cognitive resources. More specifically, we hypothesize that the nature of the distraction will moderate the effect of distractions on goal pursuit. We test these hypotheses in a series of three experiments.

In Study 1, we demonstrate our main proposition that distractions can increase adherence to a conscious focal goal, but not to a nonconscious focal goal. The study was a 2 (Focal goal: conscious health goal vs. nonconscious health goal) X 2 (Distraction: travel goal prime vs. none) between-participants design. Participants first completed the focal goal prime task, then were presented with a distraction task or not. Next, they chose between two magazines: healthy living versus desserts. As expected, we find that among participants primed with the conscious health goal, those who faced a distraction were more likely to choose the healthy living magazine compared to those who did not (83% vs. 69%; $p = .05$). Choice share of the healthy living magazine did not differ among those primed with a nonconscious health goal (73% vs. 72%).

Study 2 measures the influence that distractions have on the accessibility of focal goals. Study 2 was a 2 (Focal goal: conscious academic goal vs. nonconscious academic goal) X 2 (Distraction: environment goal vs. filler task) between-participants design. As in Study 1, participants first completed the goal prime and then completed the distraction or filler task. Participants were then given a word search task and instructed to find 9 hidden words. Ten of the hidden words were academic goal-related words, while the other 10 were neutral words. The notion here is that the more (less) accessible the focal academic goal is, participants would find more (fewer) academic goal-related words. Consistent with our prediction, participants with the conscious academic goal found more goal-related words in the presence of a distraction (i.e. environment goal) than not (i.e. filler task; $M_{\text{distraction}} = 5.03$ vs. $M_{\text{filler}} = 4.46$, $p = .05$). There was no difference among the participants with the nonconscious academic goal ($M_{\text{distraction}} = 4.85$ vs. $M_{\text{filler}} = 4.69$). Taken together, these findings suggest that 1) conscious and nonconscious goals differ when faced with distractions such as alternative goals and 2) distractions not only activate shielding mechanisms of inhibition, which decrease the accessibility of alternative goals (Goschke and Dreisbach 2008; Shah, Friedman, and Kruglanski 2002), but also actually increase the pursuit and accessibility of conscious focal goals.

Study 3 tests the underlying process that distractions increase conscious focal goal pursuit by increasing goal importance. It also specifies the type of distraction that will produce this effect. In particular, we compare the effect that a resource consuming distraction—a conscious competing goal—would have against a distraction that is less resource consuming—a nonconscious competing goal on focal goal importance. We expect that a conscious competing goal will be perceived as a resource threatening distracter that will elicit a bolstering of the importance of the focal goal, while a nonconscious competing goal will not. As predicted, participants in the conscious

academic goal conditions reported higher importance of the goal to study when there was a threatening distracter (i.e. a conscious goal distracter) compared to when there was a non-threatening distracter (i.e. nonconscious goal distracter; $M_{\text{threat}} = 8.60$ vs. $M_{\text{non-threat}} = 7.60$, $p < .05$). There were no differences across the nonconscious academic goal conditions on importance of the goal to study ($M_{\text{threat}} = 7.22$ vs. $M_{\text{non-threat}} = 7.40$).

These findings contribute to the existing literature on goal pursuit by demonstrating that the pursuit of conscious and nonconscious goals diverge in the presence of distractions. Furthermore, our findings suggest that distractions can have the ironic effect of facilitating the pursuit of conscious goals.

The Positive Consequences of Conflict: When a Conflict Mindset Facilitates Choice

EXTENDED ABSTRACT

Conflict is generally thought of as aversive, associated with depression, neuroticism and illness (Emmons & King, 1988), decreased task performance (Shah & Kruglanski, 2002), and impaired decision making. In contrast to this modal and intuitive view, we propose that conflict can also be beneficial. We test our proposal by examining the effects of incidental conflict on people's willingness to make a decision. Extensive research on decision-making suggests that integral choice conflict increases deferral (Anderson, 2003; Iyengar & Lepper, 2000; Luce, 1998). In contrast we argue that incidental exposure to conflict activates a mindset that in turn facilitates decision making and increases choice likelihood. A conflict mindset brings with it the procedural benefits of coping with conflict without the associated costs such as negative affect (Luce, Bettman & Payne, 1999) or stress (Lazarus, 1993).

In the current paper we activate conflict outside of awareness by priming conflicting goals, and look for increased choice in domains unrelated to the primed conflict. Our main proposition is that exposure to conflict activates a conflict mindset, which leads to more systematic processing of subsequent, difficult choices. This assumption is in line with prior research indicating people who proactively work to resolve choice conflict systematically consider more available information (Janis & Mann, 1977) and take longer to decide (Bettman, Johnson, Luce & Payne, 1993). We propose that as a result of this systematic processing of choice information, people in a conflict mindset are more likely to resolve conflict and make choices. This is consistent with the notion that people choose more often when preference uncertainty is reduced (Dhar and Simonson 2003). Four experiments test our propositions.

In experiment 1, participants were randomly assigned to one of three conditions: Healthy/Indulge Conflict; Career/Socialize Conflict, or Control (no conflict). Our priming manipulation was a lexical decision task where participants indicated if the letters on the screen formed a word (21 trials) or a non-word (14 trials). In each of the Conflict conditions, 7 of the words related to one goal (e.g., fitness), 7 related to the conflicting goal (e.g., chocolate). Participants then made two choices (apartments, cell phones), which included a standard deferral option (Dhar 1997). Finally, participants were probed for awareness. As predicted, participants in the Conflict conditions were more likely to make a choice than those in Control ($M_{\text{conflict}} = 73\%$ vs. $M_{\text{control}} = 62\%$, $p < .04$). There were no differences between condition on any awareness measure, for any study reported here (all p 's > .1).

In experiment 2 we test our proposed process using two markers of systematic processing: longer decision times, and consideration of more information (Bettman et. al., 1993; Janis and Mann

1977). We capture these process measures using a program similar to Mouselab (Johnson et al., 1991) and test if systematic information processing mediates the effect of conflict on choice likelihood. Student participants were brought into the lab and primed with either a Study/Party Conflict or Control (no conflict) using the same lexical decision task as Experiment 1. They then made choices, which included a deferral option. The computer recorded the time spent on each choice and the amount of information viewed. Participants in the Conflict condition were more likely to choose one of the options than those in Control, $M_{\text{conflict}} = 82\%$ vs. $M_{\text{control}} = 71\%$, $p < .05$. Conflict primed participants tended to take more time to make their decision $F(1,78) = 3.4$, $p = .06$, and viewed more information $F(1, 394) = 4.5$, $p < .05$. To test our proposed process, decision time and information viewed were entered into a serial bootstrap model for multiple mediators (Preacher & Hayes, 2008). There was a significant and positive path indicating that conflict increases the amount of information searched, which increases decision time and results in greater choice (95%CI=.001, .088).

Experiment 3 tested a boundary condition and rules out an alternative explanation. Our mindset theory predicts that the conflict prime should facilitate resolution of subsequent difficult choices, but should not increase persistence on a non-choice task. In addition, we have proposed that it is the conflict mindset, and not the activation of a single goal, that brings about our effects. Using the same lexical decision task describe above, participants completed a Control, Conflict (career vs. socialize), or Single Goal (career only) priming manipulation. Half the participants made 2 choices identical to those in Experiment 2 (Album, Theater), while the other half completed a non-choice, persistence task in which they rated as many pictures as they liked before choosing to stop (adapted from Vohs & Heatherton, 2000). As before Conflict participants were more likely to make choices than Control participants, $M_{\text{conflict}} = 86\%$, $M_{\text{control}} = 75\%$, $p < .04$. However, as predicted, Conflict and Control participants persisted at a similar rate on a filler task, completing the same number of items, $M_{\text{conflict}} = 14.1$, $M_{\text{control}} = 12.8$, $p > .61$, interaction: $F(1, 200) = 4.3$, $p < .04$. Finally we do not find evidence to support a single goal priming explanation for the increase in choice resolution, as Conflict participants were more likely to make a choice than participants in Control and the participants who were primed with just a Single Goal, $M_{\text{conflict}} = 86\%$, $M_{\text{control}} = 75\%$, $M_{\text{singlegoal}} = 76\%$, $p < .05$.

In Experiment 4 we sought to conceptually replicate our findings using another common choice scenario: preference for an extreme option in a three item compromise choice set. We hypothesize people will be more likely to choose an extreme option after being primed with conflicting goals. As predicted, Conflict (vs. Control) participants were more likely to resolve the choice by selecting an extreme option, $M_{\text{conflict}} = 55.1\%$, $M_{\text{control}} = 41.1\%$, $p < .02$.

The negative consequences of choice conflict are well documented (Emmons and King 1988, Riediger and Freund 2004). This research examines whether a conflict mindset can have positive consequences, and suggests that the traditional view of conflict as causing a paralytic flight from difficult choices may not tell the whole story.

SESSION OVERVIEW

Anthropomorphism occurs when people imbue nonhuman agents (e.g. their pets) with humanlike characteristics, motivations, intentions, or emotions. In marketing, companies often aid this process of anthropomorphism by creating human-like representations of their brands (e.g., the Michelin Man). Consumers are also known to anthropomorphize brands (Delbaere, McQuarrie, and Phillips 2011; Puzakova, Kwak, and Rocereto 2012). However, the unique effect of each of these is unknown as is the interaction of the two. This special session attempts to answer this question. In doing so, it advances our understanding of anthropomorphism in the marketing context. The four papers offer new insights on the antecedents and consequences of product anthropomorphism, document novel effects of anthropomorphizing a product on consumer behavior, and examine the mechanisms underlying these effects. This session has implications for brand positioning, advertising, consumer well-being and self-control.

The four papers focus on how anthropomorphism influences consumer behavior and contribute to the literature from different perspectives. First, Chen, Sengupta and Adaval use a motivation-based framework to examine the antecedents of brand anthropomorphism. They show that sociality and effectance motivation prompt consumers to humanize brands and endow them with different personalities. The personality traits that brands are endowed with are often those that alleviate the underlying motivational needs. They also provide implications for brand positioning by showing that consumers with salient sociality (effectance) motivations indicate higher willingness to pay when a brand emphasizes a sociality (functionality) positioning. While the first paper documents the novel antecedents of brand anthropomorphism, the next two papers stress

the consequences of anthropomorphizing products on consumer preference. Chen, Wan and Levy examine how consumers respond to products communicated in an anthropomorphic manner as a function of their psychological state of being socially excluded or included. They show that experiencing social exclusion increases consumers' preference for anthropomorphized products, because these products are perceived to provide an opportunity for social re-affiliation. Their studies further demonstrate that this effect is diminished when the brand exhibits a tough personality, which signals higher chance of future rejection. Hsieh et al. take a different perspective to examine different types of anthropomorphism in marketing communication and their impact on consumer decision. Their studies reveal that consumers with an interdependent self-construal are more likely to purchase a brand that is anthropomorphized as a partner (vs. servant). This effect occurs because partner brands exhibit an intention to cooperate, which is consistent with the goals of the interdependent self. Finally, Hur, Koo and Hofmann document negative effects of anthropomorphizing products. They find that anthropomorphizing tempting products hampers consumer self-control, because consumers are less likely to identify self-control conflicts, leading to higher chance to indulge in temptations.

Despite the fact that anthropomorphism is pervasive in marketing communication, scholarly research about how anthropomorphism influences consumer behavior is still at an early stage. The proposed session will advance our understanding of the antecedents and consequences of product and brand anthropomorphism and the process by which consumers anthropomorphize products. By offering new insights and implications, we believe that the special session will stimulate discussion and future research on how to better understand the motivations underlying anthropomorphism and its consequences.

The Effects of Anthropomorphization on Brand Personality Perceptions: A Motivational Account

EXTENDED ABSTRACT

Anthropomorphism refers to the tendency that people have to imbue nonhuman agents with humanlike characteristics, motivations, intentions, or emotions (Epley, Waytz, and Cacioppo 2007). Past research suggests that consumers humanize objects such as brands when they have access to human-like knowledge structures while making brand judgments (Aggarwal and McGill 2007; Kim and McGill 2011). In contrast to the cognitive perspective (i.e., the influence of salient knowledge structures) that informs most of the extant consumer literature in this area, the present research draws on recent findings in psychology (Epley et al. 2007) to provide a motivational account of anthropomorphism. This perspective argues that the salience of certain motivations (e.g., a need for sociality and a need for control or effectance over one's environment) facilitates the process of anthropomorphism. We apply Epley et al.'s framework to a marketing context and, more importantly, advance the original conceptualization by merging it with relevant insights from the brand personality literature (e.g., Aaker 1997; Aaker, Vohs, and Mogilner 2010). Specifically, we argue that while sociality and effectance motives both lead consumers to humanize a brand, they differ in the *type* of human-like traits that the brand is endowed with. We further posit

that these different antecedents of brand humanizing have distinct consequences on the effectiveness of brand positioning strategies.

Our conceptualization is based on the idea that different underlying motivations (such as the desire for sociality arising out of feelings of loneliness or the desire for effectance arising out of feelings of not being in control) should yield different brand personality perceptions. Based on the idea of motivated perception (Balcells and Dunning 2006; Changizi and Hall 2001), we hypothesize that the specific motivation that causes consumers to humanize a brand should lead them to endow the brand with the particular human-like trait that can alleviate the underlying need. According to Aaker (1997; Aaker et al. 2010) consumers humanize brands along distinct personality dimensions, such as excitement, competence, sincerity, etc. Consider, for instance, two such brand personality traits: “warmth” and “dependability”. Our theorizing predicts that consumers for whom a sociality motivation has been made salient – e.g., via chronic or momentarily induced loneliness – will think of the brand as a “warm” person because doing so will help to alleviate loneliness. Therefore, when compared to a baseline condition in which no such motivation has been made salient, those with a sociality motivation should rate the brand higher on warmth but should show no difference in dependability perceptions. The reverse should be true for consumers with an effectance motivation, made salient either through chronic or momentarily induced need for control. By thinking of the brand as a “dependable” person, such consumers will be able to satisfy their need for control. Accordingly, compared to a baseline condition where no such motivation is salient, consumers with an effectance motivation should rate the target brand higher on dependability – but not on warmth.

Results from four studies provide convergent support for these arguments, and their implications. Study 1 examined the basic proposition that high sociality or effectance motivation can increase a person’s tendency to humanize a brand. Participants first recalled a personal experience that made them feel lonely (inducing a sociality motive) or helpless (inducing an effectance motive). A third, baseline condition, did not induce any such motive. Then, all participants were asked to draw a picture of an unknown brand. The brand was endowed with more human-like features given a salient sociality or effectance motivation relative to the baseline condition.

In Study 2, participants first went through the same motivation manipulation as in study 1. Next, they were exposed to an unknown brand and were asked to indicate their perception of brand personality along three dimensions – warmth, dependability, and outdoorsy (which was assessed as a control dimension). As predicted, lonely (helpless) participants perceived the unknown brand to be *warmer* (more *dependable*) than those in the baseline condition. No differences were obtained for the control “outdoorsy” dimension. Study 3 was identical to study 2 but replicated the above findings using an open-ended measure in which participants spontaneously listed human-like adjectives that best described the brand.

Finally, Study 4 both reinforced and built on our conceptualization to examine a key consequence of anthropomorphization, relating to the effectiveness of brand positioning. If an underlying motivational need is met by a brand humanizing exercise, it should remove the need to humanize a subsequent brand, rendering motivational appeals for that brand ineffective. To test this, participants’ salient motivation (sociality/effectance/baseline) was manipulated as before. Next, they were exposed to either a brand humanizing task, or a geography task. The former task offered an opportunity for participants to satisfy their salient motivational need through the brand humanization, but the latter task did not. For the latter participants therefore, the initial motivation task should remain salient. Next,

all participants were asked to evaluate a different product from the one that they had previously humanized – a smart phone calendar application called *MyCalendar*. This was described either as a great social (functional) app that facilitates the user’s social (work). The key dependent variable was willingness-to-pay (WTP) for this application. Results revealed a three-way interaction involving motivation, opportunity to humanize, and brand positioning on WTP. As expected, when participants had completed a brand humanization task prior to the calendar evaluation task, their sociality/effectance motivations were satisfied. Consequently, participants’ WTP estimates for *MyCalendar* were not influenced by brand positioning. In contrast, the geography task had presumably left participants’ sociality/effectance motivations unfulfilled and these should remain salient while performing the calendar evaluation task. In accord, lonely participants indicated higher WTP when the ad for *MyCalendar* emphasized a sociality vs. a functionality positioning, with a reverse pattern obtaining for helpless participants. All effects were significant at $p < .05$.

In sum, this research uses a motivational-based framework to provide a new look at both the antecedents and consequences of brand anthropomorphism. In doing so, we advance basic theoretical knowledge regarding the processes underlying brand anthropomorphism and offer insights into the brand personality literature.

Is She My New Friend? The Effect of Social Exclusion on Consumer Preference for Anthropomorphized Products

EXTENDED ABSTRACT

Anthropomorphism, defined as the tendency of seeing human characteristics in non-human agents (Epley, Waytz, and Cacioppo 2007), is often used in marketing communications. For example, marketers might create a human representation for its brand (e.g., the Energizer Man), or use human terms to describe products’ features in advertising. Past research has suggested that one major motivation for people to anthropomorphize is the desire for social affiliation (Epley et al. 2007). For instance, Epley et al. (2008) found that participants who were primed to feel lonely, compared with those in fear or control conditions, were more likely to describe their pets using supportive anthropomorphic traits. However, it is not clear how experiencing social exclusion, the state of being cut off, ignored, or isolated by other individuals or social groups (Baumeister et al. 2005; Williams 2007), will influence consumers’ preference for products communicated in an anthropomorphic manner. The current research examines this question.

Research in branding has suggested that people can form relationships with products in a similar way to how they form relationships with other people (Fournier 1998). Thus, when socially excluded consumers see human characteristics in the product, they may show more interest because connecting with the anthropomorphized product represents an opportunity for social affiliation. One’s interest in connecting with the product should be exhibited in their product attitudes. Therefore, we predict that socially excluded consumers, compared with socially included consumers, will exhibit greater preferences for anthropomorphized products, but not for non-anthropomorphized products.

However, excluded persons are needy but vulnerable (Maner et al. 2007). They desire new social affiliation, but also want to protect themselves from being rejected again. Downey and Feldman (1996) found that people highly sensitive to rejection tended to avoid social interactions and had more hostile intentions towards others who they believe might reject them. These findings suggest that excluded consumers may not exhibit greater preference for the

anthropomorphized products if the product is imbued with human characteristics that imply the possibility of rejection. Some brand personalities (Aaker 1997) may represent good opportunities for social affiliation while others may not. For example, a friendly personality depicts a kind and approachable image, whereas tough personality describes a less approachable image. Since excluded consumers would be reluctant to approach people with a tough personality due to the fear of being rejected again, we expect that these consumers would have similar reaction towards tough anthropomorphized products. Seeing the product with tough brand personality is expected to reduce their interest in having a relationship with the product. This prediction is consistent with Epley et al.'s (2008) finding that excluded participants did not describe their pets using non-supportive anthropomorphic traits (e.g., devious) more than participants in fear or control conditions. Therefore, we hypothesize that social exclusion will increase preferences for anthropomorphized brands that represent a friendly personality, but not a tough personality.

Empirical results from three studies support our hypotheses. Study 1 employs a 3 (social exclusion vs. social inclusion vs. control) x 2 (anthropomorphism: human vs. object) between-subjects design. Participants first recalled a recent experience in which they felt social excluded, socially included, or a control condition in which they were shopping in the supermarket. Then they were instructed to do an ostensibly unrelated product survey in which an energizer battery was presented for evaluation. The battery was communicated either in human form (i.e., the energizer man image with a first person introduction) or in object form (i.e., the pure object image with a third person introduction). As predicted, excluded participants, compared with those in inclusion and control conditions, provided more favorable evaluations of an anthropomorphized battery, but not a non-anthropomorphized battery.

Study 2 tested the moderating effect of brand personality on excluded consumers' attitude towards anthropomorphized products. A 2 (social exclusion: exclusion vs. inclusion) x 2 (anthropomorphism: human vs. object) x 2 (brand personality: friendly vs. tough) between-subjects design was employed. Participants first performed a ball-tossing game online (Williams, Cheung and Choi 2000) that manipulated social exclusion. Exclusion participants received far less ball tosses from their partners than included participants did. After completing the game, participants completed an ostensibly irrelevant product survey in which they were asked to evaluate a clock, which was presented either in first person with human facial features, or in third person without human facial features. The clock was described visually and verbally as either friendly or tough in its personality. As expected, results in friendly conditions replicate the finding in study 1, and this effect is diminished in tough conditions, supporting the moderating role of brand personality.

Study 3 examined the underlying mechanism in a 2 (social exclusion: exclusion vs. inclusion) x 2 (anthropomorphism: human vs. object) between-subjects design. The brand personality is manipulated within-subject in the choice task. Following manipulation of social exclusion (rejection or acceptance of a friend request in a social network website), participants provided thoughts about two sub-brands of Walker mint candy: bright princess and dark queen. The two sub-brands represent different personalities: friendly and easy to approach versus cold and difficult to approach. Participants were asked to describe what kind of person versus what kind of product the brands are (Aggarwal and McGill 2012), which manipulates anthropomorphism. Then participants were instructed to choose one between the two candies. To test the underlying mechanism, participants responded to a series of items including the

extent to which the candy can become their new friend. As expected, the choice share of friendly candy is significantly higher among excluded participants who humanized the candy, compared to all other three conditions. Results of mediation analysis supports that the perceived social re-affiliation opportunity drives this effect.

In sum, this research demonstrates novel effects of using anthropomorphism in marketing by showing when and what types of anthropomorphism are effective in influencing consumer response. We also identify new behavioral consequences of social exclusion, and contribute to the branding literature by documenting new antecedents of relationship building between consumers and brands.

When Consumers Meet Humanized Brands: Effect of Self-construal on Brand Anthropomorphism

EXTENDED ABSTRACT

Anthropomorphism is the attribution of humanlike characteristics, motivations, intentions, and emotions to nonhuman objects (Epley, Waytz, and Cacioppo 2007). It enables a brand to assume a social role as a relationship partner (Fournier 1998), as in a partnership, a fling (Aaker, Fournier, and Brasel 2004), an exchange, a communality (Aggarwal 2004), etc. Our research investigates how consumers with different self-construals exhibit differential purchase intentions towards brands that assume different social roles.

Further, we attempt to understand the underlying process by examining the different intentions underlying each social role brands assume. Some consumers feel entitled to their needs being met by brands and even demand special treatment thereof while others display flexibility and accommodation in dealing with brands when problems arise (Fournier 2009). In accord, we posit that anthropomorphized brands aim/intend to satisfy consumers' internal needs and/or cooperate with consumers. In particular, we further argue that a partner brand intends to cooperate with consumers as well as satisfy their internal needs, while a servant brand's intentions are geared more towards satisfying consumers' internal needs (Aaker et al. 2004; Braun and Zaltman 2000; Aggarwal and McGill 2012).

Self-construal literature offers insight on how consumers with different self-construals value different brand intentions. Self-construal has been viewed as the extent to which an individual perceives himself or herself as autonomous and independent of others or as embedded within a broader social network comprising of connection with others (Markus and Kitayama 1991). These different self-construals are labeled independent and interdependent respectively. Cooperating with others is an expression of and enhancing the interdependent self, as doing so is conducive to achieving the goal of fitting in. In contrast, expressing one's inner attributes and focusing on one's needs is conforming with the independent self, as doing so enables individuals to feel unique and autonomous (Markus and Kitayama 1991). Consequently, we predict that interdependents will prefer brands that exhibit a cooperation intention and independents will prefer brands that intend to satisfy consumers' internal needs. Since partner brands exhibit both intentions and servant brands intend to satisfy consumers' internal needs, we expect that consumers with an interdependent self-construal will express greater purchase intention for a partner than for a servant brand, while independent consumers' purchase intention will be similar for the two.

Study 1 which tested this prediction was 2 (brand anthropomorphism: servant vs. partner) x 2 (self-construal: independent vs. interdependent). 104 undergraduate participants (49 women, $M_{age} = 21$) from a US public university were randomly assigned them to one of two anthropomorphism conditions. In the

servant (vs. partner) condition, participants read that the HTC T5 brand (i.e. a fictitious brand under HTC) works for (vs. with) them and helps them perform many tasks (e.g. navigate the road; adapted from Aggarwal and McGill 2012). Purchase intention, the key dependent variable, was elicited using 3 items (“I would like to buy HTC T5,” “I would like to recommend HTC T5 to other people,” “I would like to switch to HTC T5 from other smartphones”; $\alpha = .88$). Covariates and control variables included affect. Self-construal was measured using the scale developed by Singelis (1994) towards the end of the questionnaire. We found a significant two-way interaction between anthropomorphized social role and self-construal ($\beta = .55$, $t = 2.11$, $p < .05$). Consumers with an interdependent self-construal (one standard deviation above the mean) were more likely to purchase the brand when the brand was described as a partner than when it was described as a servant ($M_{\text{partner}} = 3.87$ vs. $M_{\text{servant}} = 3.21$; $t = 2.06$, $p < .05$); independents (one standard deviation below the mean) were indifferent between a partner and a servant brand ($M_{\text{partner}} = 3.34$ vs. $M_{\text{servant}} = 3.68$; $t = -1.03$, $p > .30$).

We also investigate a boundary condition of the above effect. Self-brand connection refers to the extent to which individuals have incorporated a brand into their self-concept (Escalas 2003). Aaker et al. (2004) have documented that partner quality is associated with high self-connection. Thus, we theorize that when consumers strongly identify with a brand (i.e., their self-brand connection is high), the consumer-brand relationship resembles a partnership, regardless of the brand’s perceived intention. Under such circumstances, independents and interdependents will not display differential preferences toward a brand. Specifically, we hypothesize that the two-way interaction between self-construal and type of brand anthropomorphism observed in study 1 will be restricted to settings involving low, and not high, self-brand connection.

Study 2 tested this prediction and was a 2 (brand anthropomorphism: partner vs. servant) \times 2 (self-construal: independent vs. interdependent) \times 2 (self-brand connection: low vs. high) design. 142 participants recruited from an online panel (68 women, $M_{\text{age}} = 34$) were randomly assigned to an independent or interdependent self-construal condition (Trafimow et al. 1991), and one of two manipulations of anthropomorphized brand roles (partner vs. servant) based on participants’ a) listing a laptop brand that is like their partner (vs. servant), and b) explaining the partnership (vs. service; adapted from Aggarwal and McGill 2012). Subsequently, respondents indicated their purchase intention as earlier ($\alpha = .80$), responded to control and confounding measures, and finally to the self-brand connection items (Escalas and Bettman 2005). We found a three-way interaction between self-construal, anthropomorphized brand roles, and self-brand connection ($\beta = -.64$, $t = -2.93$, $p < .01$). Contrast analysis revealed that among consumers with a low self-brand connection, those with an interdependent self-construal were more likely to purchase the partner than the servant brand ($M_{\text{partner}} = 5.80$ vs. $M_{\text{servant}} = 4.60$; $t = 4.20$, $p < .001$), while those with an independent self-construal were equally likely to purchase the servant and the partner brands ($M_{\text{partner}} = 5.25$ vs. $M_{\text{servant}} = 5.68$; $t = -1.48$, $p > .13$); consumers with a high self-brand connection were equally likely to purchase the partner and the servant brands, regardless of self-construal ($ps > .3$).

When Temptations Come Alive: How Anthropomorphization Undermines Consumer Self-Control

EXTENDED ABSTRACT

Anthropomorphism is defined as imbuing the behavior of nonhuman agents with humanlike characteristics, motivations, intentions, or emotions (Epley, Waytz, and Cacioppo 2007). A major conclusion from the extant research on anthropomorphism is that anthropomorphizing non-human agents leads to more favorable attitudes toward those agents (Epley et al. 2008; Gong 2008). Moreover, previous consumer research has shown positive effects of anthropomorphism in consumer contexts (Delbaere, McQuarrie, and Phillips 2011); for example, consumers are less willing to replace a product when they think about it in anthropomorphic terms (Chandler and Schwarz 2010).

However, what if an anthropomorphized product is one’s temptation? None of the prior research has specifically looked at consumer self-control settings, that is, situations in which the anthropomorphized object may be both desirable and at the same time detrimental with regard to consumers’ self-control goals. For instance, how would dieters respond to anthropomorphized high-calorie cookies that hurt their long-term weight-loss goals?

We propose that anthropomorphization of temptation products hampers consumer self-control by decreasing identification of a self-control conflict. According to a number of formulations (Myrseth and Fishbach 2009; Hofmann et al. 2012), successful self-control rests on the concerted interplay of at least two internal processes: the detection of conflict and the recruitment of control to adjust thought, emotion, or behavior in accordance with one’s higher order goals. Consequently, there are two main reasons for self-control failure: a failure to detect motivational conflict in the first place; and, once conflict is detected, a failure to muster up enough control resources to resolve such motivational conflict. The focus of this work is on the primary problem of conflict identification, and we predict that anthropomorphizing temptation decreases the likelihood of conflict identification. Anthropomorphized temptation could be seen as having intentions to tempt people and as having more control over people’s decisions (Waytz et al. 2010). When faced with an anthropomorphized temptation, people may therefore undergo a certain shift in their attributional focus away from an internal attribution of responsibility towards an external attribution on the tempting product itself. As a consequence of losing an internal focus, people may become less likely to detect a self-control conflict and, consequently, less likely to engage in consumer self-control.

Four studies tested our predictions with diverse anthropomorphism manipulations and goal-contexts. Study 1 employed a 2 (temptation product: anthropomorphized (AM) versus control) between-subject design. Participants evaluated high-calorie cookies (tempting product) that were either in a humanlike shape (AM) or in a round shape (control) and reported the extent to which they identify self-control conflicts in consuming the cookies. As predicted, participants in the AM condition felt less conflicted toward eating cookies than those in the control condition.

Study 2 was designed to examine the effect of anthropomorphizing a tempting product on conflict identification and subsequent self-control behavior. The study employed a 2 (temptation product: AM versus control) between-subject design and we used a similar manipulation of anthropomorphism to Study 1. Participants were presented with photographs of the cookie products that were either anthropomorphized or not, and rated how conflicted they were about consuming the products. Upon completion of the

study, participants were offered to take candies (small chocolate bars) as many as they wanted, serving as a measure of self-control. As predicted, participants in the AM condition felt less conflicted toward consuming the products, and took more candies than those in the control condition.

As our theory assumes that the conflict people experience toward consuming the product is part of the self-control process, we predicted that anthropomorphism would not disrupt conflict identification if people do not hold a higher-order goal that conflicts with a target product. In Study 3, therefore, we manipulated the salience of a higher-order goal, and tested whether this goal salience moderates our effects. We employed a 2 (goal prime: focal versus control) \times 2 (temptation product: AM versus control) between-subject design. To gain more confidence in our effects, we also moved to a different goal context (academic goals for college students) and employed a different manipulation of anthropomorphism by naming the product and having it talk like a person. Participants were primed with either a focal (academic) or a control goal (health/diet). They then evaluated a temptation product (TV gadget) that was either anthropomorphized or not, and reported self-control conflicts and willingness to pay for the product. As predicted, when participants were primed with the focal goal, those in the AM condition identified less conflict and were willing to pay more for the product than those in the control condition. In contrast, when participants were primed with the control, unrelated goal, anthropomorphizing the product did not yield any effect on self-control conflicts or willingness to pay.

Study 4 tested the underlying mechanism of our effects: people make less internal attribution of their own possible behavior as they shift responsibility to the temptation agent. In addition, we assessed participants' chronic dieting goal strength and tested whether individual differences in goal strength would moderate the effect. Thus, the study employed a 2 (temptation product: AM versus control) between-subject design, with one self-report variable (dieting goal strength). Participants reported self-control conflicts and degrees of internal attribution toward consuming the cookie product, which was either anthropomorphized or not. Lastly, they reported how often they were on a diet. As predicted, we found a two-way interaction on both conflict and internal attribution: the stronger participants' dieting goals were, the less conflict they felt toward consuming the cookie, and the less internal attribution they made about their possible consumption, when the cookie was anthropomorphized versus not. The decrease in internal attribution also mediated the effect of anthropomorphism on conflict identification.

Taken together, four studies demonstrate that anthropomorphizing a tempting product decreases the likelihood of identifying the product as temptation, which conflicts with a goal that offers long-run benefits. Then, the decrease in conflict identification leads to more indulgence in temptations and greater willingness to purchase the product. So, what happens when your temptations come alive? It could significantly harm your self-control.

SESSION OVERVIEW

This session presents new research examining how people use and respond to word-of-mouth (WOM) in order to achieve their social goals. With the rise of written, online recommendations that function as word-of-mouth, we have the opportunity as a field to analyze massive amounts of word-of-mouth data. The data present exciting possibilities for new discoveries, but without a theoretical framework or understanding of the goals that motivate people to produce WOM and those that influence their responses to it, we are more likely to be overwhelmed than enlightened by such data. This session presents four papers, each of which looks at how people produce and respond to word-of-mouth to achieve their social goals.

The first paper, by Dr. Jonah Berger, presents a new goal directed theoretical framework for understanding WOM, and the three other papers each examine a different goal that can be achieved by either the speaker or listener in a conversation about a particular product or experience. By first presenting a theoretical framework in the same session as three empirical papers, we are able to immediately address some of the questions and gaps in the literature that the framework raises. In particular, Berger finds that there is a relative lack of research on the causes of WOM and why people talk about certain things rather than others.

Two of the three other papers examine the social goals of the speaker and the third examines the social goals of the receiver. Kumar and Gilovich and Wiener, Bettman, and Luce explicitly examine new motives for engaging in particular types of word-of-mouth behavior. Kumar and Gilovich find that talking about experiences fulfills the speaker's goal for happiness better than does talking about products, and so people talk about experiences more frequently than they talk about products. Wiener, Bettman, and Luce examine conversation pieces, or products that produce questions and interest from others, and find that people use unique, identity relevant and publically displayed products to encourage conversations that enable them to learn about their conversational partners, perhaps ultimately enabling them to find like-minded friends or partners. Presented together these papers suggest that conversation pieces blur the line between product and experience and suggest that a social goals approach has much to tell us about this distinction.

Of course not only do speakers have social goals, but recipients of word-of-mouth have social goals as well. Alexander and

Moore examine how listeners may interpret word-of-mouth as social pressure and how word-of-mouth may activate their goal to appear competent to others. This goal may negatively influence how they interact with a product and undermine new product usage.

Together these four papers suggest that the production of and responses to word-of-mouth are quite strategic in pursuit of their social objectives. Given the apparently utility of word-of-mouth for achieving social goals, is it possible that the desire to produce or have a good response to another's word-of-mouth may actually drive consumption behavior so that a consumer might have the "right" thing to say.

Word-of-Mouth and Interpersonal Communication: An Organizing Framework and Directions for Future Research

EXTENDED ABSTRACT

There is currently huge popular interest in word-of-mouth and social media more broadly (e.g., Facebook and Twitter). But while quantitative research has demonstrated the causal impact of word-of-mouth on diffusion and sales, less is known about what drives word-of-mouth and why people talk about certain things rather than others.

Why do certain products get more word-of-mouth? Why do certain rumors spread faster than others? And why does certain online content go viral? Further, how does the audience people are communicating with, as well as the channel they are communicating through, impact what gets shared?

This talk addresses these, and related questions, as it integrates various research perspectives to shed light on the behavioral drivers of word-of-mouth. It provides an integrative framework to organize research on the causes and consequences of word-of-mouth and outlines additional questions that deserve further study.

In particular, I argue that interpersonal communication is goal driven and serves five key functions. These include:

1. Self-Presentation,
2. Emotion Regulation
3. Information Acquisition
4. Social Bonding
5. Persuading Others

Self-presentation refers to the fact that people often share word of mouth to shape how others see them. This occurs through sharing self-enhancing things, things that signal desired identities, or even engaging in small talk to avoid sitting there in silence. Emotion regulation refers to the fact that people often share word of mouth to help manage or regulate their emotions. This includes venting, seeking social support, reducing dissonance, facilitating sense making, or encouraging rehearsal. Another important function of word of mouth is information acquisition. Talking and sharing to seek advice or figure out how to resolve problems. Word of mouth also serves a social bonding function, allowing people to connect or bond with others. Sharing can reduce feelings of loneliness and reinforce shared view. Finally, people use word of mouth to persuade others to their point of view.

It is worth noting that these goals are predominantly self-serving in nature. While communication almost always involves a recipient, I will argue that word of mouth is mostly self-serving rather other-serving. Though people certainly tune their message to their audience, and some acts of transmission can be interpreted as altru-

ism, these same behaviors can also be explained by self-serving motives (e.g., self-presentation or social bonding).

Finally, I will discuss how contextual factors, such as who people are talking to and what channel they are talking across, moderate these various motives. Talking to weak rather than strong ties, for example, should lead self-presentation motives to have a greater impact on transmission. But it is not only audience type that matters. Audience size may also play a role. Talking to larger audiences boosts self-presentation by encouraging people to focus on the self, while talking to smaller audiences may encourage sharing useful information by encouraging people to focus on others. Different channels should also play a role. Compared to oral communication (e.g., face-to-face discussion), for example, written communication (e.g., email or text) provides more time to construct and refine communication, and, as a result, leads self-presentation motives to play a greater role in transmission.

In sum, what we know about word of mouth is clearly dwarfed by what we don't know. That said, this talk will attempt to review what we do know, provide a framework to organize this existing research, and outline potential directions for future work in the area.

Talking About What You Did and What You Have: The Differential Story Utility of Experiential and Material Purchases

EXTENDED ABSTRACT

Imagine you just returned from a week in the Caribbean or sampling the restaurants in New York City. How likely would you be to tell others about your trip? Would the telling enhance your experience? Now imagine you spent a similar sum of money on a home theater or some new living room furniture you've been eyeing. How likely would you be to tell others about *these* purchases, and would the telling increase how much enjoyment you get from them?

The research presented in this paper investigates one explanation for the fact that experiential purchases bring us more happiness than material purchases (Van Boven & Gilovich, 2003): consumers talk more about their experiences than their possessions and derive more value from doing so. Such conversations facilitate the re-living of the experience in question, they encourage embellishment, and they foster social connection—all of which serve to enhance enjoyment of the original event. Seven studies demonstrate that people are more inclined to talk about their experiences than their material purchases and they derive more happiness from doing so; that taking away the ability to talk about experiences (but not material goods) would diminish the enjoyment they bring; and that being given the opportunity to talk about experiences (but not material goods) increases the satisfaction they bring.

In Study 1a, we examined whether consumers tend to talk more about experiential purchases than material purchases. Ninety-six participants were given a definition of either experiential or material purchases, and then asked to list their most significant purchase over the past five years in the category in question. Participants indicated that they had talked more about experiential purchases, $F(1, 94) = 12.54, p < 0.0001$, and also indicated that they would be more likely to talk about experiential purchases in a hypothetical situation in which they had to make small talk, $F(1, 94) = 15.46, p < 0.0001$. In Study 1b, we explored whether this difference could explain differences in purchase satisfaction. Accordingly, 102 participants answered the same questions as those in Study 1a, and also indicated how much happiness they derived from their purchase. After replicating our finding from Experiment 1a, $t(100) = 2.78, p < 0.01$, and replicating the satisfaction findings from Van Boven & Gilovich

(2003), $t(100) = 1.99, p = 0.05$, purchase satisfaction was regressed onto purchase condition and the talking composite. We found a significant mediational relationship, Sobel $Z = 2.42, p < 0.02$, suggesting that experiential purchases make consumers happier than material purchases, but this difference can be explained by the fact that experiential purchases are more likely to be talked about.

In Studies 2a and 2b, we looked into whether talking about experiential purchases boosts the teller's happiness more than talking about material purchases. One hundred four participants in Study 2a were given a list of material and experiential purchases and asked what portion of the happiness derived from each purchase came from being able to talk about it. Participants reported that talking was a more important element of the enjoyment of experiential purchases, matched pairs $t(103) = 4.80, p < 0.001$. Experiment 2b was a close replication of 2a, but instead of asking about the percentage of happiness that came from talking about each purchase, 109 participants rated on a Likert scale how much talking about the purchase added to their overall enjoyment. As predicted, participants reported that talking about purchases with others added more to their enjoyment of experiential purchases than material purchases, matched pairs $t(108) = 6.18, p < 0.0001$.

One way to gauge the importance consumers attach to talking about their purchases is to examine what happens when they don't have the opportunity to do so. That is, how much would not being able to talk about a purchase diminish the enjoyment of it, and is this amount different for experiential and material purchases? In Studies 3a and 3b, we hypothesized that consumers would be willing to accept a lesser experience rather than have a more enjoyable experience they couldn't talk about—but that they would be disinclined to accept such a trade-off when it comes to material goods. In Study 3a, 98 participants provided the two purchases they would most want to make within the categories of beach vacations (experiential) or electronic goods (material) and were then presented with a hypothetical choice dilemma: they could either have their first choice, but without being allowed to talk about it, or they could have their second choice and be free to tell others about their purchase. Participants were more likely to report wanting to switch to a lesser alternative that they could talk about in the experiential condition than in the material condition, $\chi^2(1, N=98) = 19.96, p < 0.001$. In Study 3b, we replicated this result, but instead of being restricted to the categories of vacation destinations and gadgets, 98 participants made judgments about purchases from their own lives, $\chi^2(1, N=98) = 3.86, p < 0.05$. Consumers seem willing to take a hedonic hit on the purchase itself in order to be able to enjoy talking about experiences, something they are less willing to do for material purchases.

In Study 4, we tested whether having participants talk about their experiential purchases would increase their remembered enjoyment of the purchases in question—but that talking about a material purchase would not have a similar benefit. We asked 204 participants to recall the most recent vacation they had taken or the most recent item of clothing or jewelry they had purchased. They spent five minutes simply thinking about their purchase, or five minutes talking to another participant about it. When then asked to rate how much they liked their purchase, we found a significant purchase type \times type of activity interaction, $F(1, 97) = 5.37, p < 0.03$, that indicated that participants given an opportunity to talk about their vacations reported higher levels of enjoyment than those who simply thought about them, while no such beneficial effect of storytelling was present for material purchases.

Conversation Pieces

EXTENDED ABSTRACT

People need people: they need people to talk to just for a moment—on a coffee break at work or at a party—and they need friends, people with whom they connect with more deeply (Baumeister & Leary, 1995). People invest time and effort in trying to create these short and long term relationships, but previous research has not examined how they may strategically enlist products to help them to create new social connections. This paper attempts to examine this behavior through examining conversation pieces, or products that produce questions and interest from others, literally ones that start conversations.

Previous research has found indirect ways that products can be used to achieve social goals. For example, excluded individuals may substitute products for people (Mead, et al., 2011) or use products to signal social status (Holt, 1998) or identity (Berger and Heath, 2007) to others. However, these articles have only looked at people using products for one-way communication rather than how products may facilitate interaction with another person. Given that conversation is a key way that people connect with each other, to study relationship development it is necessary to examine people talking about products, not just displaying them.

The word-of-mouth literature studies these conversations but focuses on their consequences for product liking or adoption rather than for social relationships. What research there is on the social motives for word-of-mouth suggests that it may not be motivated by social goals, but merely by what is accessible in the speaker's environment (Berger and Schwartz, 2011). Other research has suggested that they talk positively about products to self-enhance, to help others, or to create feelings of excitement (Sundaram, Mitra, and Webster, 1998). These goals may be rooted in a desire to have positive social interactions with people, but the ability of word-of-mouth to directly build relationships has not been studied. In this paper we examine how people use conversation pieces to create conversations and thus to facilitate the development of relationships.

Given the lack of previous research on conversation pieces, study 1 examines their basic characteristics and the characteristics of the people who frequently use them. In this study, participants were asked to describe a wearable conversation piece that they had and to rate it on a variety of different characteristics. This study and the subsequent ones asked about wearable conversation pieces (as opposed to furniture or art at a person's home) because the user has a choice of when to and when not to display the item, enabling us to understand the user's display motives.

In this study several common characteristics of conversation pieces emerged. Qualitative analysis revealed that conversation pieces tended to be souvenirs (a shirt from Cambodia), items related to media (a Super Mario leather jacket), or simply "interesting" pieces of clothing (a necklace mad out of zippers). Almost all of the conversation pieces described were considered by their owners to be noticeable, unusual, identity relevant, and well liked. Since conversation pieces only inspire conversation if others notice them and think that they are worth commenting on, it is not surprising that they are noticeable and unusual.

Study 1 also examined the personality characteristics of people who frequently use conversation pieces. We find that conversation piece usage was relatively across all participants, but people who are higher in extroversion, possession-self connection, and need for uniqueness were more likely to use conversation pieces than those lower in these characteristics. Despite the fact that almost all of the conversation pieces described were clothing, jewelry or accessories,

there were no differences in conversation piece usage between men and women.

In study 2A we investigated the motives behind displaying a conversation piece. In this study, participants answered open-ended questions about why they wore their conversation pieces. Participants identified both long and short term goals that they felt their conversation pieces helped them to achieve. Some conversation pieces make the wearer an easier target for another person to approach and initiate a conversation with—"I like your dress" is a very easy conversation starter. This enables the wearer to achieve a short term goal of not being ignored at a party.

Other participants described using their conversation pieces to achieve longer term goals, such as identifying which people they meet might be good friends. As found in study 1, conversation pieces frequently are identity-relevant and communicate a person's interests or values. Therefore wearers can use them to identify which other people share or approve of those interests and thus might be potential friends. Approximately one third of participants reported using their conversation pieces as a mechanism for deciding which individuals they were interested in getting to know better. This is exemplified by a quote from a 27 year old male who wears a Ninja Turtles t-shirt and says, "If someone says that a Ninja Turtle shirt is childish or stupid or lame I know that they don't have the same kind of sense of humor I do and we likely won't get along."

Study 2B followed up on the social motives behind conversation piece usage using an experimental design. Participants were first asked to think of a conversation piece they had and then were randomly assigned to have a goal to get to know new people or with a goal to talk to their friends. People were significantly more likely to wear their conversation piece when they had a relationship initiation goal than when they did not, suggesting that people may use conversation pieces to help them to cultivate relationships with new people. This study provides evidence that part of the function of conversation pieces is to create new social connections, and that when this motive is not active they are less useful and so less likely to be worn. In sum, in three studies we find evidence that people use products, specifically conversation pieces, to help them achieve both short and long term goals relevant to social connections.

You Gotta Try It! The Negative Side of Positive Word of Mouth

EXTENDED ABSTRACT

Word of mouth (WOM) is a fundamental process in the marketplace (Katz and Lazarsfeld 1955). Positive WOM can increase consumer attitudes (Bone 1995), switching behavior (Wangenheim and Bayon 2004), and trial and adoption of products (Arndt 1967); negative WOM does the opposite, with attendant consequences for firms (Chevalier and Mayzlin 2006). However, recent work has demonstrated that sharing positive WOM can have unintended negative consequences for the storyteller (Moore 2012). Building on this work, we examine the potential downside of positive WOM (PWOM) from the perspective of the receiver.

We ask whether receiving PWOM can ever be "bad" for consumers, and examine when and why this might be the case. We focus on the context of new products, where WOM is a key driver of diffusion (Arndt 1967; Mahajan, Muller, and Bass 1990), and where consumers might be particularly susceptible to the negative consequences of positive recommendations, given the risk and uncertainty surrounding new products (Taylor 1974; Herzenstein, Posavac, and Brokus 2007; Hirunyawipada and Paswan 2006).

Prior research shows that PWOM can elicit positive emotion by providing useful information and reducing risk (Arndt, 1967; Moldovan, Goldenberg, & Chattopadhyay, 2011; Murray, 1991; Söderlund & Rosengren, 2007). We make the novel prediction that PWOM might also be perceived as social pressure to use the adopted product competently and successfully, or else risk negative judgments from the recommender (Berger & Heath, 2008; Cialdini, Kallgren, & Reno, 1991; Schultz et al., 2007). Imagine a consumer who hears that the latest smartphone is the best yet. While this information should elicit positive emotion, we ask whether PWOM might also create social pressure for the consumer to have as positive an experience with the phone as the recommender. This PWOM-induced social pressure might elicit negative emotion such as worry or anxiety (Baumeister & Tice, 1990; Berthoz, Armony, Blair, & Dolan, 2002), with potential consequences for the consumer's intentions toward the recommended product (Alexander, 2013; Wood & Moreau, 2006).

We explore when PWOM might elicit both positive and negative emotions in adopters and investigate the consequences of these emotions for usage intentions. Since prior work suggests that PWOM should consistently elicit positive emotion, we focus on identifying conditions under which PWOM also elicits negative emotion. To do so, we examine four moderating variables that should increase the social pressure exerted by PWOM and thereby elicit negative emotion in adopters.

Across three studies, we examine 1) volume of PWOM received (study 1); 2) type of PWOM: whether PWOM is liking-based or performance-based (studies 2 and 3); 3) social distance: whether the recommender is close to or distant from the receiver (study 2); 4) product difficulty: whether the product is easy- or difficult-to-use (study 3). We predict that when these moderators exert social pressure to competently use a new product—when volume is high, PWOM is performance-based, the recommender is close, and products are difficult-to-use—adopters receiving PWOM will feel negative as well as positive emotion.

In study 1, we examined how PWOM influenced emotions in a sample of real consumers ($N = 299$) adopting one of 21 new technological products. We surveyed consumers within one week of acquiring the new product and measured their receipt of PWOM and their positive and negative emotions. We found that the more PWOM consumers received about the product they adopted, the more positive and the more negative emotions they felt about this newly acquired product. However, study 1 is correlational, and consumers do not always receive WOM in such quantities. Thus, our next two studies use a controlled lab setting to explore additional moderators that might elicit negative emotion in single episodes of PWOM.

In study 2, we examined how social pressure affects negative emotion after receiving PWOM from a single consumer. We held product difficulty constant and manipulated type of PWOM and social distance. Undergraduates imagined receiving liking-based (participants were told their friends were “addicted” to the product) or performance-based PWOM (participants were told their friends were “masters” at using the product) from a close or distant social other (a friend or an exchange student). To ensure that our results were due to the social pressure exerted by PWOM, rather than to receipt of new information, we also manipulated whether participants adopted the app because of the PWOM or on their own initiative. This resulted in a 2 (type of PWOM: liking or performance) by 2 (social distance: close or distant) by 2 (adoption influence: own or other) design. We predicted that only in the other-adoption condition would performance-based PWOM from close others exert social pressure and therefore elicit negative. As expected, there were no significant effects on negative emotion in the own-adoption or in the

liking-based PWOM conditions. However, as predicted, in the other-adoption conditions, participants who received performance-based PWOM felt more negative emotion when this recommendation came from a close compared to a distant other.

In study 3, undergraduate participants were informed that their school was adopting video editing software for use in class projects, and that the software was generally regarded as either easy- or difficult-to-use. They then imagined receiving PWOM from a close friend, who said the software was “incredibly cool”, and that they were either addicted to (liking-based PWOM) or masters at using it (performance-based PWOM). Thus, study 3 was a 2 (type of PWOM: liking or performance) by 2 (difficulty: easy or difficult) between-subjects design. We predicted that negative emotion would be elicited only when performance-based WOM was received about a difficult-to-use product. Consistent with this prediction, positive and negative emotions were simultaneously elicited only in the difficult-to-use conditions when participants received a performance-based WOM recommendation; type of PWOM did not influence emotions in the easy-to-use conditions. In this study, we also measured usage intentions. We found that positive emotion increased, while negative emotion decreased, usage intentions. We also found that negative emotion mediated the relationship between our social pressure variables (type of PWOM and difficulty) and usage intentions.

In sum, in one field survey and two lab studies, we find evidence of a downside of PWOM; PWOM can elicit negative as well as positive emotions in new product adopters, and negative emotions undermine adopters' usage intentions.

SESSION OVERVIEW

Consumers and firms communicate their intentions through a variety of language uses. Instances of such language uses may be pronoun use ('I/we will consider your complaint'), negation ('It wasn't expensive'), figurative language ('It's the Ferrari of vacuum cleaners'), or language abstraction ('That perfume smells fresh/is nice'). Recently emerging work on linguistic behavior in marketing (Kronrod, Grinstein and Wathieu 2012a, 2012b; Moore 2012; Patrick and Hagvedt, 2010; Schellekens, Verlegh and Smidts 2010) has directed a spotlight to questions of language use and its effect in marketing communication.

The current session is, figuratively speaking, a ray of this spotlight. In this session we intend to make a difference, bringing a new breeze of research to the attention of our research community. We will present works, all of which investigate phenomena in marketing linguistics, hoping the session will stimulate wide discussion of consumers' and firms' talk and what effects it has. The papers in this session are all closely tied around language use of consumers and firms. All four deal with the question: how do variations in language use affect consumers?

Verlegh and Beukeboom investigate the effect of negation in WOM and find that consumers use negation (e.g. 'it didn't take long') when they describe experiences inconsistent with their expectations; receivers of negation interpret this as a signal of unexpected product performance. Kronrod and Danziger examine the use of figurative language in communication originating from users (WOM) or firms (ads) and show how the source (WOM or ads) moderates the effect of figurative language on product evaluations and choice, for hedonic and utilitarian options. Schellekens, Verlegh and Smidts also compare WOM to firm communication and demonstrate that the use of

abstract (vs. concrete) language in product referrals from sales agents activates more persuasion knowledge than when it comes from other consumers. Finally, Packard, Moore and McFerran find that when firm service agents use "I" rather than "you" or "we" in responding to customer inquiries and complaints, customer purchases increase up to one year after the interaction, due to elevated perceptions of the employee's agency and empathy.

Together, the works in this session represent the growing interest in linguistic behavior of firms and consumers. The issues investigated in each of the papers have clear implications for consumers and marketers, as language is a natural component of almost any communication in marketing. Although these papers are tightly connected in their focus on language use in marketplace communication, they display variety of approaches and topics that will stimulate additional research into the role of language in marketing and consumer behavior. The combination of novel concept and a strongly increasing interest in linguistic issues in consumer behavior should warrant a wide interest for this session at ACR 2013.

A Negation Bias in Word of Mouth: How Negations Reveal and Maintain Expectancies about Brands and Products

EXTENDED ABSTRACT

Consumers like to talk about their product experiences with others. This word of mouth (WOM) can have a strong impact on product evaluations and sales (e.g., Chevalier & Mayzlin 2006), both practitioners and academics have great interest in understanding its effects and underlying mechanisms. Although research on WOM has a long history, dating back to the seminal work of Katz and Lazarsfeld (1955), academics have only recently begun to examine language use (Moore 2012; Schellekens, Verlegh & Smidts, 2010). Findings suggest that consumers implicitly reveal much information "in between the lines" of their WOM messages. Such formulation differences may for instance reveal speakers' a priori brand expectations when they describe a product experience. Of particular interest is the use of negations. The Negation Bias (Beukeboom, Finkenauer & Wigboldus, 2010) demonstrates that negations usage (e.g., *not stupid*, rather than *smart*) is more pronounced when (stereotypic) expectancies are violated, compared to when expectancies are confirmed. For instance, garbage men performing poorly on IQ-tests is stereotypically expected and likely described as "stupid", for professors this would be unexpected and described as "not smart". Importantly, negations lead message recipients to infer that the described experience was an exception, caused by situational circumstances (Beukeboom et al., 2010).

In two experiments, we examined the existence of a negation bias in WOM. We expect that negations are used more often in descriptions of expectancy inconsistent than consistent product experiences. We also expect that receivers can "decode" these implicit communications: a speaker's use of negations leads the receiver to infer that the described experience is an exception to the rule. The use of negations in inconsistent situations will dampen the impact of WOM on receivers, serving to maintain a brand's positive or negative reputation, even in the face of WOM disconfirming that reputation.

Experiment 1 examined whether people are more likely to use negations when they describe product experiences that are inconsistent (versus consistent) with their a priori brand expectations. Participants were presented with WOM vignettes that varied according to a mixed 2 (positive/negative brand expectation) x 2 (positive/negative experience) x 5 (vignettes) design. To manipulate expectations, we used pretested brands scoring either high or low on a focal attribute. For example, a customer received slow (versus fast) service in a Hilton (versus Ibis) Hotel. We created five vignettes for each condition. Each participant saw all five different vignettes within one condition. This was analyzed as a within-subjects factor.

Following Beukeboom et al. (2010), participants rated how well each experience was described by a negation or an affirmation (e.g., “the service was not fast/ slow”). After rating all five experiences, they were again presented on a separate page, and participants rated the expectedness of each experience.

A mixed model ANOVA revealed the predicted expectation x valence interaction, for both dependent variables ($F(1,115) > 9$; $p < .01$): for *positive* experiences, negations were rated *more* applicable when participants held low (versus high) expectations, and for *negative* experiences, negations were rated *less* applicable when participants held low expectations. Effects were mediated (Hayes, 2012) by perceived expectedness: the *less* expected an experience, the *more* applicable participants rated the negations, and the *less* applicable they rated affirmations.

Experiment 2 examined whether a speaker’s use of negations indeed leads receivers to infer that the experience was unexpected. Participants ($N=123$) read a scenario in which a friend commented on his suitcase. This comment was varied in a 2 (valence: positive/negative) x 2 (description: negation/affirmation) between-subjects design. We measured participants’ inferences about (1) the expectedness of the experience, (2) the speaker’s surprise with the experience (3) the speaker’s expectations before the experience, and (4) speaker evaluation of the experience.

As predicted, participants inferred that the experience was less expected and more surprising when the speaker used negations versus affirmations (both $F(1,119) > 4$, $p < .05$). Interactions with valence were non-significant. For inferences about the speaker’s a priori expectations we *do* predict an interaction: negations in descriptions of negative experiences (“not fast”) signal a positive a priori expectation, but the opposite is true for positive experiences (“not slow”). Indeed, we found a (marginally) significant interaction ($F(1,119)=3.55$, $p=.06$): the effect was significant ($p < .05$) for negative experiences, and directionally consistent for positive experiences.

Importantly, we found no significant effects of negations on inferences about the speaker’s evaluations. After all, negations do not communicate whether an experience was positive or negative. They do, however, communicate whether it was (un)expected, and whether it confirmed the speaker’s expectations. In this manner, negations provide a subtle mechanism for communicating and maintaining brand reputations.

Wii Will Rock You! The Role of Figurative Language in Word of Mouth

EXTENDED ABSTRACT

Research in advertising has studied the persuasive effect of figurative language. Figurative language is the use of words and expressions to convey an additional connotation beyond that of their lexical meaning (Fogelin 1988). Instances of figurative language may be, among others, metaphor (*The Ferrari of vacuum cleaners*),

word play (*Don’t leave without a good buy*), idiomatic expressions (*My car’s a lemon*), hyperbole (*the service person was a cell phone professor*) or imitating sounds (*This teacher is wrrruff*, meaning a tough teacher, or *ouch!*, meaning *I was offended*).

The common finding and general conviction is that figurative language evokes positive affect and attitudes across contexts (McQuarrie and Mick 1999, 2003; McQuarrie and Phillips 2005; Phillips and McQuarrie 2009). In contrast, we suggest that figurative language in user generated content is effective only in certain contexts. We propose that this context sensitivity results from a difference in the conversational norms regarding advertising and consumer generated content. For example, consumers often perceive ads to be biased, persuasive attempts (Sweldens, Van Osselaer, and Janiszewski, 2010). By contrast, user-generated content is generally perceived as an objective sharing of opinions (Moore 2012; Schellekens, Verlegh, and Smidts 2010; Sen and Lerman 2007). Thus, conversational norms regarding persuasive text may include expectations for linguistic tactics and artful word play. Conversely, the norms of using figures of speech in user generated content may not be governed by a general expectation of the text to be persuasive, but rather of it to reflect a sincere opinion.

Because of these differences we suggest consumers have a different set of conversational norms and expectations regarding advertising and user generated content. Namely, it is typical for, and expected of, advertising communication to be exaggerated and emotionally intensified. Therefore, figurative language is generally normative for advertising (Campbell and Kirmani 2000; Rotfeld and Torzoll 1980; Simonson and Holbrook 1993; Toncar and Fetscherin 2012; Xu and Wyer 2010). But user generated content is a form of natural language in interpersonal communication. Therefore language perception and language choice may be governed by considerations that differ from those in advertising, particularly in their crucial dependence on the context of conversation (Grice 1975; Schwarz 1996; Sperber and Wilson 1995).

We base our reasoning on psycholinguistic literature that demonstrates a positive link between emotional intensity and use of figurative language (Bryant and Gibbs 2002; Caillies and Butcher 2007; Fussell and Moss 1998; Zemanova 2007). We then suggest hedonic and utilitarian consumption as contexts commonly associated with emotional and rational attitudes, respectively (e.g. Alba and Williams 2013; Chaudhuri and Ligas 2006; Dhar and Wertenbroch 2000). Building on these literatures, we propose figurative language is more conversationally normative, and therefore more effective, in hedonic consumption than in utilitarian consumption. Following the reasoning whereby communication norms govern not only perception, but also language choice, we then test and find support for the prediction that consumers also use figurative language more in descriptions of hedonic consumption rather than utilitarian consumption.

In our studies we focus on the conditions that invoke the use of figurative language in consumption context and the conditions that increase the effectiveness of figurative language in WOM. In study 1 we contrast the effectiveness of figurative language in ads versus in WOM. Participants read a description of a hotel for either a business or a vacation purpose, which was presented as if taken from an ad or from a consumer review. The description was either figurative (e.g. The service is like on a king’s reception) or literal (e.g. The service is very professional). Results comparing ads to reviews suggest it is conversationally normative for figurative language to be used in advertisements for both hedonic and utilitarian product descriptions, and therefore the effectiveness of figurative language is similar for both types of product. However, figurative language is less norma-

tive, and therefore less effective, in utilitarian product descriptions provided by consumers ($F(1,334) = 4.2, p < .05$).

In study 2 we examined the effects of figurative language on real consequential consumer decisions. After reading figurative or literal reviews of the same store, which contained both hedonic and utilitarian products, participants were asked to choose hedonic or utilitarian products as a reward for participation in the experiment. Participants who read reviews containing figurative language chose more hedonic products as prizes than participants who read reviews that did not contain figurative language ($t = 5.0, p < .001$).

Study 3 involves natural data analysis. We analyzed product review headlines from www.Amazon.com. We find higher frequency of figurative language in hedonic product reviews, compared with utilitarian product reviews ($F(1,21) = 15.8, p < .05$). Our analysis also shows that in reviews of hedonic products more extreme product evaluations employ more figurative language, while in reviews of utilitarian products review extremity does not moderate use of figurative language ($F_{2,42} = 18.4, p < .001$).

Finally, in study 4 participants use liquid soap for either a utilitarian purpose (washing a spoon) or a hedonic purpose (blowing bubbles) and compose reviews of the products. Linguistic analysis of the reviews shows higher figurativeness of reviews for the soap when used to blow bubbles ($t(1,88) = 2.12, p < .05$).

This work contributes to consumer research by exploring an underrepresented aspect of online consumer communication – use and effects of language. This work also contributes to research of communication and psycholinguistics by being the first to investigate the *effect* of figurative language in natural communication. Finally, we propose a new theoretical explanation for the link between figurativeness and emotion, introducing conversational norms.

How Language Signals Persuasion: Concrete and Abstract Language in Product Referrals from Consumers and Firms

EXTENDED ABSTRACT

Nowadays it's becoming more difficult to detect if a product review or referral is made by another customer (without self-interest in advertising a product), or by someone with a commercial interest (advertisement, word-of-mouth marketing). Consider raving product reviews on Amazon.com or emails with product offerings from Facebook friends. What could be sincere word of mouth could also be a marketing scheme. One way to figure out the sincerity of the communication situation is to examine the language use in product referrals.

While psycholinguistics in marketing communication has received much attention from academics (for overview see Lowrey, 2007), language use in word of mouth only recently gained popularity (e.g., Moore 2012). Building on the linguistic category model (Semin & Fiedler 1988), Schellekens et al. (2010) have studied the use and effects of abstract versus concrete language in word of mouth. According to this model, an event can be described at different levels of abstraction. For example, the low fuel consumption of the Toyota Prius may be described as “the Prius use little gas” (concrete) or “the Prius is eco-friendly” (abstract). The use of abstract language describes the information as general and stable (“traitlike”), while concrete descriptions contain verifiable information on product functioning. Schellekens et al. (2010) showed that receivers of word of mouth are receptive to the use of abstract versus concrete language. They found that senders of positive (negative) word of mouth were perceived to be more positive (negative) about a brand if they use more abstract language, and that consumers who

receive word of mouth are persuaded more when the sender uses more abstract language. The current studies extend prior research on language abstraction and examine the role of communication setting (commercial vs. non commercial). The studies suggest that communication setting moderates the impact of language abstraction on consumers through the activation of persuasion knowledge. Persuasion knowledge refers to consumers' assumptions and beliefs about persuasion and marketers' motives, strategies, and tactics (Campbell & Kirmani, 2000; Friestad & Wright, 1994).

We argue that environmental cues in a communication setting can moderate the effect of language abstraction on persuasion knowledge of consumers, which in turn could affect product attitude and buying intention. More specifically, an environmental cue (e.g., advice giver has a sales motivation) could trigger consumers to be suspicious and attentive to persuasion cues. Since language can be used as a subtle mechanism to signal more information than the literal meaning of a message, suspicious consumers could scrutinize language use. Previous research showed that abstract (vs. concrete) descriptions are used more when trying to be persuasive (Schellekens, Verlegh & Smidts, 2012). Sales personnel is expected to try to convince customers to buy products and therefore might be expected to use more abstract (vs. concrete) language when describing products. Thus, positive product referrals framed abstractly (vs. concretely) from a sender with a commercial motive may be seen as more manipulative and incite more persuasion knowledge. On the contrary, without environmental cues indicating a commercial motive (i.e., word-of-mouth communication) we have no reason to expect a difference is the activated persuasion knowledge between abstract and concrete language use in referrals.

In Study 1, we manipulated the communication context (source of referral: commercial vs. non-commercial) and language abstraction of referral (concrete vs. abstract) between subject design. Participants read a scenario in which a person ('Sandra') was shopping in a perfumery when she heard a referral about a new perfume ('Spring'). Half of the participants were told that this referral was given by a sales person, while the other half were told it was given by another customer. The product referral was either described concretely as 'Spring smells fresh' or abstractly as 'Spring is a nice perfume'. The participants rated the goal of the communication from trying to (1) inform me about 'Spring' perfume to (9) persuade me into buying, and the interest of the speaker from (1) help Sandra to (9) own interest (Campbell, 1999; 2007). Next, participants indicated the speakers persuasion motives on four nine-point items ($\alpha = .816$): not manipulative/manipulative, sincere/insincere, honest/dishonest, and not pushy/pushy (Campbell & Kirmani, 2000).

As predicted, when a sales agent describes a product referral abstractly (vs. concretely), this leads to inferring the speaker as trying to sell a product (7.34 vs. 6.23, $t(130) = 6.04, p = .015$), serving his own interest (6.66 vs. 5.94, $t(130) = 2.86, p = .10$), and having persuasion motives (i.e., being seen as more manipulative and pushy and less sincere and honest) (5.61 vs. 4.89, $t(130) = 5.34, p = .022$). On the contrary, in line with our expectations the language abstraction of referrals from another customer has no effect on persuasion knowledge (all t 's < 1).

In study 2, we focused on the intervening construct, suspiciousness, which we activated by informing all participants that some of the product referrals of the study were written with a motive to be persuasive. We thus examined whether consumers who have a reason to be suspicious about the source of a referral associate the use of abstract (vs. concrete) language with a persuasion motive. We presented participants with five different product descriptions which were either abstract or concrete. For each description they were

asked to indicate on a nine-point scale whether they thought that the referral was given by (1) a friend or (9) a company agent. The concrete description of the household appliance was for example “this appliance works good” and the abstract version was “this appliance is good”. As expected, abstract (vs. concrete) statements were more strongly linked to salespersons than to friends (5.03 vs. 4.09, $F(1,46)=10.77, p<.01$).

The present studies extend the prior work by Schellekens and colleagues (2010), and show that the use of abstract language does not necessarily lead to more persuasive referrals. The two studies show that the use of abstract language may trigger persuasion knowledge, especially in commercial contexts. The findings add to the growing body of knowledge on the impact of language on persuasion, and help us understand how language abstraction affects consumers differently in different contexts. They also add the use of (abstract) language to the list of factors that are known to activate persuasion knowledge, which may provide fertile ground for future research in this area.

Putting the Customer Second: Pronouns in Customer-Firm Interactions

EXTENDED ABSTRACT

Recent work has demonstrated the importance of specific word use in influencing consumer behavior. This emerging body of work has examined the impact of language use on consumer senders and receivers of word of mouth (Moore 2012; Patrick and Hagvedt, 2010; Schellekens, Verlegh and Smidts 2010) and advertising (Sela, Wheeler and Sarial-Abi 2012). Yet there is little work examining the impact of firm employee language on consumers, particularly in the context of service interactions.

Firms, however, are starting to pay attention to interaction content, particularly when it comes to training and evaluating front-line employees. For example, Apple has “stop words” that employees are prohibited from saying to customers (Chen 2011). In contrast, online retailer Zappos does not have scripts for its agents, allowing each to create a “personal emotional connection” with customers (Hsieh 2010). Despite their different philosophies on language use, both Apple and Zappos recognize the importance of measuring and managing what is said between customers and employees. In this vein, we offer an empirical examination of the behavioral consequences of language use in service interactions. While prior research on service interactions often examines how *actions* taken by firm agents (e.g. apologies, compensation; e.g. DeMatos et al. 2007; Rust and Chung 2006) influence customer attitudes and/or behaviors, we are unaware of research assessing how their *words* might affect the same outcomes.

Our conceptual focus is on pronoun use, as pronouns are an important psychological indicator (Pennebaker 2011) and have been found to impact brand information processing (Bitner 1990; Sela et al. 2010). Further, it is not clear which pronouns firm agents should use in their interactions with customers. Managerial theory suggests that firm agents should talk about “you” (the customer) in interactions, thereby “putting the customer first” (Basch 2003, Evenson 2011). This tenet is corroborated by findings from linguistic psychology that demonstrate “you” pronouns can convey a focus on and desire to satisfy an interaction partner (e.g., Ickes, Reidhead and Patterson 1986).

In contrast, we predict that more self-centered firm agent language—represented by heavier use of “I” pronouns—may be particularly effective. Some support for this prediction comes from research suggesting that “I” pronouns indicate agency (e.g., Ahearn

2001; Pennebaker 2011) and socially-shared concerns (i.e., empathy; Campbell and Pennebaker 2003). Our research thus examines the impact of firm-agent use of “I” (vs. “you”) pronouns on customer attitudes and behaviors, with perceived firm-agent agency and empathy as potential mediators of this relationship. We leverage a linguistic analysis package (LIWC; Pennebaker, Booth, and Francis 2007) that identifies the proportion of words used in 70 linguistic and psychological categories, including pronoun sub-groups (e.g., the “I” sub-group includes “I’m”, “me”, “my”).

Study 1 examined which pronouns firms prioritize in practice. We constructed two emails—a customer question and a complaint—and sent these to a random sample ($N = 20$) of the top 100 Internet retailers (<https://www.internetretailer.com/top500>). Consistent with the tenet of “putting the customer first” we found, for example, that while “you” pronouns appeared in 100% of firm responses, “I” pronouns were present in only a minority (27%). It appears that firm agents indeed focus on the customer (vs. themselves) in these interactions. But is this necessarily ideal?

In Study 2, a controlled experiment examined the impact of firm agent pronoun use on customer satisfaction, with perceptions of firm agent agency and empathy as mediators. Participants ($N = 376$) imagined they had engaged in one of eight versions of a customer-firm interaction in a 2 (customer inquiry: complaint, question) \times 4 (firm response: I, we¹, you, control) between-subjects design. Versions of the firm response varied the preponderance of pronoun use only, with no change in meaning. After reading the interaction, participants reported their satisfaction with the interaction and their perceptions of firm agent agency and empathy. Regardless of interaction type (question or complaint), the “I” condition resulted in higher customer satisfaction than the “you”, “we”, or control conditions. Bootstrap tests confirmed parallel mediation of the “I” effect by participant perceptions of firm-agent agency and empathy.

In our third study, we leveraged a unique dataset from a large online retailer to examine whether firm agent pronoun use has real behavioral consequences. The data is comprised of over 1,100 unique interactions (6,500 emails) between customers and firm agents over a one-year period and includes each customer’s purchase data for a one year period pre/post their interactions. Similar to our Study 1 findings, firm agent use of “you” pronouns was higher than the use of “I” pronouns (91% vs. 28% of emails). More importantly, controlling for a large number of alternative explanations and covariates (e.g., customer pronoun use, pre-interaction purchases, complaint dummy, compensation dummy, # of emails in interaction, customer anger, demographics), we found that firm agent use of “I” pronouns (but not “you” or “we”) was linked to a significant increase in post-interaction purchases at one-year and shorter time intervals.

This research opens the door to further examinations of language use in customer-firm interactions. We show that while firms appear to prioritize the customer through the use of “you” pronouns, the use of “I” pronouns have a greater positive impact on customer satisfaction and purchase behavior. Our analysis sheds light on how firms might leverage the linguistic content of customer-firm communications (e.g. email, blogs, social networks, etc.) to improve their use of language in these interactions, thereby enhancing customer relationships.

¹ We also assessed “we” pronouns as a third relevant pronoun group, but refrain from extensive discussion of “we” here for brevity. Judge coding found that over 98% of firm agent use of “we” referred to “firm + agent”, not “firm + customer” or “agent + customer.” “We” was thus the primary non-customer pronoun used by firm agents. “We” pronouns were ineffective in relation to customer satisfaction (negative impact of “we” vs. “I”, null “we” vs. control) and purchases (null or negative impact for “we”).

Paper #4: Reward Substitution: Incentivizing Consumers to Choose Smaller Portion Sizes

Martin Reimann, University of Arizona, USA
Deborah MacInnis, University of Southern California, USA
Antoine Bechara, University of Southern California, USA

SESSION OVERVIEW

The purpose of this session is to integrate investigations on consumer neuroscience and neuromarketing—that is, the study of brain function associated with consumers' judgments and choices—(e.g., Plassmann, Yoon, Feinberg, & Shiv, 2011; Reimann, Schilke, Weber, Neuhaus, & Zaichkowsky, 2011; Smidts, 2002) with transformative consumer research—that is, research on how to increase consumers' welfare and quality of life (Ozanne, 2013). This session will highlight contemporary research in this new domain of transformative consumer neuroscience—which we define as “utilizing neuroscientific insights and methodologies to improve consumers' judgments, choices, and overall well-being”—and stimulate discussion on future research. The four papers in this session make important contributions in areas such as aging and decision making (Koestner, Hedgcock, Halfmann, & Denburg), craving and snacking behavior (Lu & Dubé), encoding of intangible characteristics of rewards (Chen, Hsu, & Nelson), and incentivizing consumers to choose less food (Reimann, MacInnis, & Bechara). In Paper 1, Koestner, Hedgcock, Halfmann, and Denburg study the neurobiology behind consumer vulnerability, particularly the brain activation patterns of older adults viewing deceptive and non-deceptive advertisements. The authors found that decreased activation in a region of the prefrontal cortex critical for complex decision making was associated with greater vulnerability. In Paper 2, Lu and Dubé link a lab measurement of neurocognition components involved in motivated behaviors with large-scale field observations of eating behavior. The authors found that snacking and the predictive power of craving on snacking vary between restrained and unrestrained eaters under the operation of different motivational and executive control processes. In Paper 3, Chen, Hsu, and Nelson advance current understanding of value representation by studying how the brain represents the intangible characteristics of goods, specifically branding. The authors found that by using machine learning techniques together with Aaker's brand personality scale, they can predict, from brain activity, pairs of previous-

ly unseen brands with accuracies significantly above chance. Finally, in Paper 4, Reimann, MacInnis, and Bechara establish that offering non-food rewards (lottery tickets, toys) bundled with smaller food portions as an alternative to full-portion meals can substantially decrease chosen portion sizes. The authors explain this effect by a “common reward currency” at the brain level. All four papers incorporate different neuroimaging and neuropsychological measurements to study imperative questions on consumers' decision making and well-being.

Scamming Depression Era Elders: Neuroanatomical Basis for Poor Decision Making Among Older Adults

EXTENDED ABSTRACT

Deceiving the elderly is not a new problem, but it is one that has been growing in prevalence. To illustrate, financial abuse of elders aged 65 and older has risen from a low of 8% in 1950 to an astounding 20% in 2010 (Infogroup / ORC, 2010; Kemp, 2005). These recent statistics may even underestimate the extent of the problem, with only 1 in 25 cases being reported (Wasik, 2000). Financial losses due to elder fraud are considerable. Estimates have placed losses at \$2.6 billion in 2008, rising to \$2.9 billion in 2011 (MetLife, 2011). Sadly, these numbers do not take into account the devastation fraud can have on the elderly and their families, often wiping out entire savings and years of work in a single action, not to mention the negative psychological effects.

The neurobiology behind elder fraud has received very little attention from researchers, but there is a sizeable literature in cognitive neuroscience that can be used to generate hypotheses. To illustrate, multiple studies have lent support to the idea of the “frontal aging hypothesis”, which states that the frontal lobe of the brain undergoes the greatest amount of age-related decline in the context of healthy aging (West, 1996). Also, lesion studies have demonstrated that the prefrontal cortex, and specifically the ventromedial prefrontal cortex, is crucial to real-world decision making (Bechara et al., 2000). Most directly, a recent study conducted by our research group demonstrated that patients with acquired ventromedial prefrontal cortex lesions displayed greater vulnerability to advertisements with misleading and deceptive content than both normal comparison and patients with brain damage outside the prefrontal sector (Asp, Manzel, Koestner, Denburg, & Tranel, 2012). Combined, these studies led us to hypothesize that older adults who were vulnerable to consumer fraud would have abnormal brain activation in ventromedial prefrontal cortex and insular cortex while viewing advertisements.

The older adult participants were recruited from a registry compiled in the Department of Neurology, University of Iowa College of Medicine. Thirty-two participants, age 62 to 88 years, participated; however, the data from one participant was excluded secondary to malfunction during the functional magnetic resonance imaging session, resulting in 31 final participants (52% female; $M_{\text{age}} = 76.8$, $SD = 7.0$ years). Participants were scanned using a Siemens 3T magnetic resonance imaging scanner with 12-channel head coil. Data analysis was completed using the Brain Voyager QX software package. Stimuli were created based on six advertisements deemed deceptive by the Federal Trade Commission (FTC, 1998). We created deceptive and non-deceptive versions of each advertisement. While in the scanner, participants were shown three deceptive and three non-deceptive advertisements. Outside of the scanner, each participant completed a questionnaire that assessed their comprehension of the

advertisement's content as well as their purchase intentions for each of the advertised products. During an earlier testing session, all participants completed a battery of neurocognitive evaluations and the Iowa Gambling Task (IGT; Bechara, 2007), a laboratory measure of decision making under uncertainty.

From the questionnaire data, we utilized participants' comprehension ratings of the three deceptive advertisements to create two groups based on their susceptibility to being deceived: "vulnerable" ($n = 16$) and "non-vulnerable" ($n = 15$). These two groups did not differ with regard to demographic variables (age, education, sex distribution) or cognitive variables (intellect, attention/working memory, language, visuospatial, anterograde memory, executive functioning) (all $ps > .05$). Vulnerable participants had less activation in the ventromedial prefrontal cortex when viewing both deceptive and non-deceptive advertisements than non-vulnerable participants ($p < .05$). We also observed that brain activation in the ventromedial prefrontal cortex was inversely correlated with personality trait Trustworthiness (a measure of "gullibility" from the NEO Five-Factor Inventory) ($p < .05$). Finally, brain activation in insular cortex correlated with Iowa Gambling Task performance such that laboratory decision making was positively associated with insular activation ($p < .01$). Interestingly, poorer laboratory decision making performance was predictive of greater activation for deceptive advertisements contrasted against non-deceptive advertisements ($p < .05$).

These findings provide some of the first evidence for differential neural patterns of brain activation to deceptive advertisements among older adults in relation to consumer vulnerability, personality traits, and decision making performance. Overall, older participants demonstrating greater susceptibility to deceptive advertising, higher gullibility, or lower financial decision making performance displayed less activation in brain regions crucial to decision making and emotional processing, suggesting that prefrontal brain regions, such as the ventromedial prefrontal cortex and insular cortex, may be integral to the protection of the older consumer from fraud.

Linking Individual Differences in Motivational and Executive Control Neurocognition to Real World Craving and Snacking Behavior: The Case of Restrained and Unrestrained Eaters

EXTENDED ABSTRACT

Background

Recent neuroscience research has generated detailed models of brain circuits involved in reward processing, decision-making, and self-control to understand may motivated behaviors, including eating (Dagher, 2012). However, research thus far has typically considered neurocognition components, one at a time (Vainik, Dagher, Dubé, & Fellows, 2013), divorced from the complexity of brain and real-life environment (Hammond et al., 2012). Thus, it is important to bridge the current knowledge of brain from neuroscience lab to real-world eating, sparking the transformation in individual behaviors, marketing practices, and public health policy (Dubé et al., 2008); Lab measurements of individual neurocognition should be empirically linked with field observations of eating to explore: which neurocognitive components are engaged in real-life eating; and how individual differences in neurocognition are related to eating as responses to internal (e.g., hunger or craving) and external cues (food cues).

Research Aims and Hypotheses

At any given point of time, eating is jointly determined by neurocognition components that combine homeostatic (e.g., hun-

ger), motivational (e.g., attentional bias to food cues and incentive salience in working memory) and executive control (e.g., inhibitory control and mental flexibility) processes (Dagher, 2012). Many but not all food consumptions result from yielding to craving, which has been attributed to a combination of inhibition over responses to rewarding cue, poor mental flexibility, and resulting incentive salience in working memory (Kavanagh, Andrade, & May, 2005). Individual differences in these motivational and executive control processes can be traced both at neurocognitive (Affective Shifting Task, AST; Murphy et al., 1999) and behavioral levels (restrained and unrestrained eating; Herman & Polivy, 1984).

Presuming individuals are constantly being exposed to high-caloric highly-rewarding food (HRF) cues, this study aims to examine the expectation that a person's likelihood of having HRF snacks, after hunger being controlled, will be predicted by the presence of craving. At individual level, we further expect that both snacking and the predictive power of craving on snacking vary between restrained and unrestrained eaters under the operation of different motivational and executive control processes. Restrained eaters are self-trained to heavily rely on their inhibitory control to regulate eating (Stroebe, Mensink, Aarts, Schut, & Kruglanski, 2008). As their goal is to resist the temptation of HRF, its related information persists and is elaborated in working memory resulting heightened craving (Polivy, Coleman, & Herman, 2005). Therefore, we expect restrained eaters with relatively better inhibitory control would be more vulnerable to HRF eating. Mental flexibility is the cognitive ability of intentionally directing attention to facilitate the switch between tasks with different cognitive rules (Cserjési, Molnár, Luminet, & Lénárd, 2007), and is one of the critical neurocognition components to resist the temptation of rewarding cues (Mobbs, Iglesias, Golay, & Van der Linden, 2011). Unrestrained eaters do not particularly intend to regulate eating beyond homeostatic processes (LeBel, Lu, & Dubé, 2008); while HRF cues catch their attention, they may or may not want to shift attention away depending on their contextual goal (e.g. whether they are hungry). But if they do, we expect that a stronger mental flexibility would contribute to resist HRF eating.

Method

In laboratory, 109 non-obese adult women performed AST. Restrained and unrestrained eaters were identified by restraint-scale (Polivy, Herman, & Warsh, 1978). They subsequently participated in an experience-sampling study (Reis & Gable, 2000) reporting their hunger feeling, HRF craving and snacking 6times/day in a ten-day period.

In AST, English words were presented, one for each trial, on a computer screen. In half of trials, participants were asked to quickly respond to positive English words (rewarding cues) and ignore neutral words; in the other half of trials, the rule was reversed. The rule-switches were structurally arranged. For each participant, AST indicators were obtained to assess her neurocognition components: Attentional bias was reflected in one's superior responsiveness to rewarding cues than to neutral stimuli. Inhibitory control was assessed by performance in the trials that responses to rewarding cues have to be stopped. And mental flexibility was assessed by the magnitude of decrement in task performance due to rule-switching.

To link individual AST indicators with HRF snacking reported in the experience-sampling study, data was analyzed by a generalized hierarchical linear model with two-level specification (see Appendix). At episode-level, HRF snacking (Yes/No) was explained by context variables (hunger and time) and HRF craving (Yes/No). At individual-level, the individual differences in HRF snacking likelihood and the predictive power of craving were further explained by

AST indicators, restraint-group (Restrained/Unrestrained eaters), and their interactions.

Major Findings

Consistent with our expectations, at episode-level, after controlling for hunger ($p < .001$), HRF craving was positively associated with snacking ($p = .04$). At individual level, both restrained and unrestrained eaters' HRF snacking likelihood was positively related to their AST indicator of attentional bias to rewarding stimuli ($ps < .02$).

Differences in both snacking likelihood and the predictive power of craving emerged in the neurocognitive processes that were expected to vary between restrained and unrestrained eaters. Specifically for unrestrained eaters, better mental flexibility was directly associated with lower HRF snacking likelihood ($p = .001$). In terms of the predictive power of craving, stronger attentional bias was associated with higher likelihood that snacking had been triggered by craving ($p = .03$), while better mental flexibility was associated with lower triggering power of craving ($p < .001$). These results suggest that unrestrained eaters' ability of directing attention helped them to attend to activities other than eating. As of restrained eaters, neither inhibitory control nor mental flexibility could directly account for HRF snacking likelihood. But the better restrained eaters were at inhibitory control, the more likely was it that snacking was triggered by craving. Neither difference in their attentional bias nor mental flexibility affected the triggering power of craving on eating.

The pattern of results suggests that it is possible to examine the pathways by which neurocognition components impact real-life motivated behavior. Results also highlight that mental flexibility is a natural contributor to healthier food choices for a large segment of population. Future research should not only bring these results back to neuro-imagery labs but also examine the possibility that restrained eaters could be trained to foster mental flexibility.

Appendix

Episode Level Model

$$\text{Snack (Y/N)} = P_0 + P_1 * (\text{Craving}) + P_2 * (\text{Hunger}_{t-1}) + P_3 * (\text{weekend}) + P_j * (T_j)$$

Where, Craving and Snack are dummy variables with HRF craving or snacking being denoted as 1, otherwise 0. Hunger ($t-1$) is a continuous variable (0-150), which is group centered. Weekend is a dummy variable indicating weekend and holidays as 1. T_j ($j=2-6$) are dummy variables indicating the time of the day.

Individual Level Model

$$P_0 = B_{00}(\text{Unrestrained}) + B_{01}(\text{Restrained}) + B_{0m}(\text{Unrestrained} * \text{AST indicators}) + B_{0n}(\text{Restrained} * \text{AST indicators}) + u_0$$

$$P_1 = B_{10}(\text{Unrestrained}) + B_{11}(\text{Restrained}) + B_{1m}(\text{Unrestrained} * \text{AST indicators}) + B_{1n}(\text{Restrained} * \text{AST indicators})$$

$$P_2 = B_{20}(\text{Unrestrained}) + B_{21}(\text{Restrained})$$

$$P_3 = B_{30}$$

Where, P_0 is the coefficient indicating an individual overall HRF snacking, that is, the probability to take HRF snack without craving being reported on the same episode. P_0 is further explained by Restrained (a dummy variable: restrained eater as 1, otherwise 0), a set of AST indicators, and the interaction between Restrained and AST indicators.

P_1 is the coefficient indicating how likely a participant followed her craving to take snack (the predictive power of HRF craving), which is further explained by Restrained, a set of AST indicators, and the interaction between Restrained and AST indicators.

Identifying Symbols of the Consumer Marketplace from Human Brain Activity

EXTENDED ABSTRACT

Consumer neuroscience seeks to understand how consumer decisions are shaped by marketing actions. Recent research, guided by formal economic models, has made rapid progress in understanding the neural basis of value representation. These idealized models, however, rely on well-defined and stable preferences in a human population that is famously fickle, and prone to influence from subtle signals like brands, which may be unrelated to intrinsic value. An understanding of these influences is therefore critical for both our understanding of consumer decision-making, as well as potential real-world applications.

The twin challenges in this work are the need to (1) capture, in controlled laboratory conditions, some tractable set of stimuli from consumer daily life, and (2) to characterize, using quantitative, theoretically-grounded measures, the underlying mental representations. Here we bring together research in consumer behavior and decision neuroscience to understand how these intangible characteristics are represented in the brain. Specifically, we investigated the neural basis of brand perception by building on the well established semantic associations related to brands, widely known as "brand personality." Brands are tractable and nearly inexhaustible. Frequently they are instantly recognizable, and emotionally and behaviorally evocative. Perhaps most importantly, brands have been nearly exhaustively studied. Research in consumer behavior in particular, has developed a rich framework for characterizing consumers' perceptions and attitudes toward brands, how they are formed, and factors that influence them (American Marketing Association 2012).

Historically, neuroimaging studies systematically map brain regions to experimental manipulations of cognitive states and/or behavior. In consumer neuroscience, for example, there have been several studies that have investigated brain regions that respond differentially to branded vs. unbranded items, or when making inferences about brands vs. about people (Yoon, Gutches, Feinberg, & Polk 2006; Schaefer & Rotte 2007). Our experiment, in contrast, asks the question, "What type of information about brands (or other aspects of the consumer experience) is contained in the brain regions that respond to brands?" We do so by studying the neural responses to brands by combining functional neuroimaging of brand perception with a quantitative model of an important aspect of brand perception—the brand's personality.

A total of 18 participants underwent functional magnetic resonance imaging (fMRI) while being shown a set of 45 of logos of well-known brands in a passive viewing task. Prior to the experiment, they were instructed to think about the characteristics and personalities of the brands. To access the latent perceptions of our participants, we used a measure of brand personality developed in Aaker (1997). Following the experiment, participants were asked to complete, for each brand, the 42 item brand personality scale, as well as familiarity and preference, for a total of 1,980 ratings per participant. The total time for completion of the experiment was approximately 3 hours, and they were paid \$70 upon completion of the experiment.

This widely used and validated factor analytic system, which has been cited more than 2,000 times, posits that brand personality can be described as a set of five orthogonal personality dimensions: sincerity, excitement, competence, sophistication and ruggedness. With the dimensions of brand personality, we decompose each brand as the composition of these factors, using them as the measure of the mental contents of brands.

We first found that activity in the striatum is correlated with brand preference ratings. This is a region of the brain known to respond to primary and secondary rewards, and is consistent with the idea that our brains respond to preferences of abstract objects such as brands. Then, we found that activity in the temporal-parietal junction (TPJ) is correlated with the brand personality index. This brain region has been hypothesized to be a general brain region of thinking about people and intentions (Saxe, 2006). This provides the first evidence that a significant proportion of variance in brain responses to brands can be captured by the brand personality construct.

Next, we used multi-voxel pattern analysis to predict the cognitive states of the participant using their neural responses to the brands and their latent associations (Haxby & Gobbini 2011; Naselaris, Pregner, Kay, Oliver, & Gallant 2009). To train the model, we reconstruct the relationship between the personality dimensions and the brain activation. With those we were able to predict the brain activations associated with the brands outside the training set. Once trained, we evaluated our model by comparing the predicted fMRI images and the actual data. Our model successfully distinguished pairs of previously unseen brands with accuracies significantly higher than chance. Similarly, we are able to test whether we can reconstruct which brands participants are viewing by using the physical feature of the logos, such as shape, color, and text, as well as using the brand personality model. This can be interpreted as a more stringent test of whether neural representation of brands is sufficiently captured by the brand personality construct.

Understanding the neural basis of consumer psychology and behavior has important managerial, financial, and ethical implications. Here we investigate whether and how the brain represents a specific construct—brand personality—that has excellent psychometric properties and is widely studied in consumer behavior. Beyond branding, this research represents a novel attempt to overcome the conceptual and technical challenges in bridging the mind and the brain, and how our brains deal with the astonishing diversity of goods and services afforded by the modern economy.

Reward Substitution: Incentivizing Consumers to Choose Smaller Portion Sizes

EXTENDED ABSTRACT

In many societies, food has become abundant and calorie-rich. A pandemic of obesity has ensued, with high costs to governments, businesses, and consumers. The medical sciences' remedy to this issue seems deceptively simple: Consumers should eat less (Lamberg, 2006). However, this advice is easier to give than to follow or enforce in societies that value having freedom and a variety of available options. One stream of research shows that—without altering satiation—smaller portion sizes can drastically decrease the overall quantity of food consumed (e.g., Geier, Rozin, & Doros, 2006; Rolls, Roe, & Meengs, 2006; Rozin, Kabnick, Pete, Fischler, & Shields, 2003). This notion of decreasing food intake by altering portion sizes has been investigated in several different yet related variants such as smaller assortment sizes (Kahn & Wansink, 2004; Redden & Hoch, 2009; Rolls et al., 1981), smaller package sizes (Scott, Nowlis, Mandel, & Morales, 2008; Wansink, 1996; Wansink & Kim, 2005; Wansink & Park, 2001), taller and more slender food containers (Wansink & Van Ittersum, 2003), and smaller bowls and plates (Van Ittersum & Wansink, 2012; Wansink & Cheney, 2005; Wansink, Van Ittersum, & Painter, 2006).

However, extant research has largely missed addressing the issue of how consumers can be incentivized to choose such smaller portions—a highly relevant question in a world of “family-sized”

cereal cartons (Wansink & Van Ittersum, 2007), all-you-can-eat buffets (Wansink & Payne, 2008), and restaurants where tempting “super-sized” meals are offered ubiquitously (e.g., Hill & Peters, 1998; Nestle, 2003; Nielsen & Popkin, 2003). Moreover, from a business perspective, recent marketing research has shown that some profit-maximizing firms have dropped smaller portion sizes from their portfolios and menus because of decreased demand (Sharpe, Staelin, & Huber, 2008) and that introducing smaller food packages to the marketplace may only be profitable for firms under specific circumstances (Jain, 2012). This raises the question whether firms should actively offer such smaller packages and risk losing profitability.

In order to answer these important questions and fill this unforeseen gap in the extant literature on food choice and consumption, the present research introduces a novel food offering that promotes eating less, possibly without hurting food manufacturers' and restaurants' profitability. This food offering entails half-sized meals paired with non-food rewards such as a lottery ticket or a small toy (at the same price than a full-sized meal). Four studies establish and validate a novel food choice effect, which we termed “reward substitution.” For the purpose of this research, we define reward substitution as the exchange of parts of a (food) reward with another (non-food) reward. As such, we follow the established definition of rewards being positive reinforcers, which are sometimes also referred to as incentive stimuli (Schultz, 2000).

In Study 1 of the present research, initial evidence for the reward substitution effect is provided in a children population. Study 2 replicated the effect among an adult sample and further shows that the effect does not wear-off over time, even as consumers became familiar with the product. Because self-reported satiety/hunger did not moderate the reward substitution effect in Studies 1 and 2, we manipulated consumers' satiety levels in Study 3 and found moderation of the reward substitution effect by manipulated satiety. In Study 4, we investigated the underlying neurophysiological process associated with choosing the half-sized meal with the non-food reward compared to choosing regular full-sized meals without such non-food rewards. Recent neuroimaging research has independently shown brain activation in the same brain system—the striatum—for distinct rewards such as food (Berridge, 1996), money (Knutson, Adams, Fong, & Hommer, 2001), beautiful faces (Aharon et al., 2001), and aesthetic packages (Reimann, Zaichkowsky, Neuhaus, Bender, & Weber, 2010). Our research builds on the idea of a common neural currency (Montague & Berns, 2002; Schultz, Dayan, & Montague, 1997; Wise, 1978) to see whether the combination of a small food portion and a non-food reward would attract activation in the striatum as does a large food portion alone.

Taken together, the findings from these four studies present a comprehensive examination of the reward substitution effect that contributes to the extant literature on consumer food choice by showing that attempts of promoting the choice of smaller food portions (1) can be behaviorally effective, (2) is moderated and even intensified by manipulated but not self-reported satiety, and thus, may be particularly effective in food-abundant societies in which consumers are generally satiated, and (3) attracts the same neurophysiological process, if non-food rewards are offered as partial substitutes for food.

SESSION OVERVIEW

In what ways are a consumer’s day to day emotional experiences and self-control dilemmas related to each other? Research has established that when consumers succeed (fail) at self-control, positive (negative) emotion is experienced in response (Carver and Scheier 1998). However, an overview of the literature shows that it is less clear when emotion will work to facilitate versus impede a consumer’s willingness to overcome a self-control dilemma (Winterich and Haws 2011). Understanding how emotion influences self-control requires focusing on the specific emotion experienced, as each discrete emotion activates unique cognitive and motivational properties that can change depending on the context (Tamir, Mitchell, and Gross 2008). In this session, we will focus specifically on how various discrete emotions influence *aspects of the self*, to then influence a consumer’s self-control.

The first paper, (Han, Agrawal, Poor, and Duhachek), shows how emotions create “situational selves” that shift preferences for certain types of information as a means of affirming one’s self. Specifically, they find that angry (versus shameful) people become more likely to exhibit increased counter-argumentation to inconsistent (consistent) information which affirms one’s self and leads to subsequent boosts in self-control. The second paper, (Allard and White), demonstrates that guilt (relative to sadness) leads to increased self-control by increasing the desire to engage in self-improvement rather than mood repair. This increased desire to self-improve is hypothesized to occur because guilt is experienced in response to violations of self-standards. The third paper, (Garg and Nenkov), suggests that sadness (relative to anger) leads to greater self-focus which decreases self-control efforts via indulgent consumption. In addition, they explore whether the increased indulgent consumption brought on by sadness attenuates if people are encouraged to shift their focus away from the self and towards others. The fourth and final paper, (Salerno, Laran, and Janiszewski), explores how certain experiences of pride are more likely to be perceived as a reliable experience which then influences self-control. Specifically, they find that in the absence of an active goal, pride that emerges from a stable behavioral pattern or

success at a high effort task is interpreted as diagnostic of a person’s self-concept and leads to increased self-control efforts.

Thus, the objective of this session is to address two key questions: (1) what are the ways in which various specific emotions effect aspects of the self and (2) what are the downstream consequences for a consumer’s ability to exert self-control? This research is important as it comes at a time in which the costs of self-control failure are higher than ever before, reflected in consumer overspending (Baumeister 2002), weight gain and obesity (Sharpe, Staelin, and Huber 2008), and addiction (Grant et al. 2010). We expect ACR attendees interested in the topics of emotion, the self, and self-control to be our primary audience with the session also being of general interest given the scope of theoretical constructs covered.

The Downstream Consequences of Incidental Emotions and Preference Inconsistent Information

EXTENDED ABSTRACT

Consumers are constantly exposed to information, which sometimes conflicts with current preferences. Research has shown that consumers typically resist preference-inconsistent information (e.g., Kunda 1990; Chen and Chaiken 1999) by discounting, ignoring, or selectively processing it in a way that reinforces pre-existing beliefs (e.g., Jain and Maheswaran 2000). Recent research has also highlighted the importance of consumers’ affective state, showing that emotions with differing valence and agency can influence decision-making after exposure to preference consistent versus inconsistent information (Agrawal, Han, and Duhachek 2012). The purpose of the present research is to tie together research on preference inconsistent information and emotional appraisals to explore the *downstream consequences* of emotions and appraisal (in)consistent messaging, specifically in terms of self-control. We employ the appraisal-tendency framework (e.g., Lerner and Keltner 2000; 2001; Lerner and Tiedens 2006) and self-affirmation theory (Sherman and Cohen 2006) to show that emotions of the same valence (e.g., shame and anger) can have different effects on self-control following confrontation with either preference consistent or inconsistent information.

According to self-affirmation theory, people are motivated to maintain the integrity of the self, where integrity is defined as a sense that one is a good and appropriate person (Sherman and Cohen 2006). We argue that incidental emotions create a situational self, such that the appraisal tendencies associated with an emotion can influence perceived “appropriateness” when presented with preference consistent or inconsistent information and this can activate the need to self-affirm. The appraisal tendency for shameful individuals is that they have transgressed an aspiration or ideal (Tangney 1991). Thus, to the extent that preference consistent information is considered a threat to this situational self (I’m wrong but you’re telling me I’m right), the individual will try to affirm the self by counter-arguing the message. The appraisal tendency for angry individuals is an offense against the self (Lazarus 1991); to the extent that preference inconsistent information is perceived as a threat to this situational self (I’m right, but you’re telling me I’m wrong), the individual will try to affirm the self by counter-arguing the message. Altogether, we predict that preference inconsistent (consistent) information is perceived as a threat to the situational self-identity of angry (shameful) individuals because it is at odds with the emotion’s respective appraisal. In an

act of self-affirmation, angry (shameful) individuals will exhibit increased counter-argumentation toward this inconsistent (consistent) information. Such self-affirmation should boost subsequent self-control (Schmeichel and Vohs 2009). We tested these predictions across three studies.

In study one, we tested the predicted interaction using a 2 (emotion: anger, shame) x 2 (preference consistency: consistent, inconsistent) between subjects design (N = 118). First, the target emotions were primed using an emotional recall task that induced either anger or shame (cf., Robinson and Clore 2001). Next, preference consistency was manipulated using a two-part procedure adapted from previous research (Jain and Maheswaran 2000). In part one, subjects read a description of two different products. To form a moderately strong preference for Product A, subjects were told that scientific testing showed that Product A was superior to Product B on five out of eight product attributes. In part two, subjects were shown evaluations from actual users of both products and randomly assigned to either a preference consistent or inconsistent condition. In the consistent (inconsistent) condition, subjects were told that the percentage of respondents who felt Product A (B) performed better than Product B (A) was much higher than those who felt Product B (A) performed better. Self-control was measured by asking subjects’ snack preference on a seven-point scale anchored by: 1 = chocolate cake, 7 = apple. As predicted, the results revealed that in the preference consistent condition, subjects exhibited more self-control when they felt shame versus anger ($p < .05$). In contrast, subjects in the preference inconsistent condition exhibited more self-control when they felt anger versus shame ($p < .05$).

In study two, we sought to replicate these results and also provide process evidence (N = 167). The design and procedure mirrored that of study one, except that subjects were asked to provide cognitive responses after exposure to the product evaluations in part two of the preference consistency manipulation. These cognitive responses were then coded to reflect the proposed mediator, counter-argumentation. The results replicated those found in study one: subjects in the preference consistent condition exhibited more self-control when they felt shame versus anger ($p < .05$), but subjects in the preference inconsistent condition exhibited more self-control when they felt anger versus shame ($p < .05$). Further, counter-argumentation was shown to mediate this relationship, such that angry (shameful) subjects expressed more counter-argumentation toward inconsistent (consistent) information, which in turn boosted subsequent self-control.

In study three, we sought converging evidence for our theory by including a trait measure of self-control. The design and procedure mirrored that of study one, with two exceptions. First, situational self-control was captured using a behavioral measure in which subjects were allowed to eat freely from a bowl of chocolates. Fewer chocolates consumed indicated greater self-control. Second, trait self-control was measured using Puri’s (1996) Consumer Impulsiveness Scale (CIS). Subjects that scored above (below) the median on the reverse-scored prudence subscale and on the hedonic subscale of the CIS were classified as prudents (hedonics) (N = 152). According to our theoretical model, we would expect that the effects found in studies one and two would be amplified (attenuated) among hedonics (prudents) because these individuals are chronically low (high) in self-control. The results were consistent with these predictions, revealing the predicted three-way interaction between emotion, preference consistency, and trait self-control ($p < .05$). Specifically, hedonics exposed to preference inconsistent information exhibited more self-control when they were angry versus shameful ($p < .05$), while hedonics exposed to preference consistent information exhib-

ited more self-control when they were shameful versus angry ($p < .05$). This pattern was attenuated among prudents.

Taken together, this research shows that emotions of the same valence (e.g., shame and anger) can have different effects on self-control following confrontation with preference consistent/inconsistent information. These results have implications for marketers and consumers alike.

Failing to Meet the Standards: How Guilt Triggers Preferences for Unrelated Self-Improvement Products

EXTENDED ABSTRACT

Guilt has traditionally been described as a self-conscious emotion stemming from some violation of normatively held standard of behavior (Basil, Ridgeway, and Basil 2006; Heidenreich 1968) and is often viewed as an interpersonal emotion arising from concerns over a transgression against others (Baumeister, Stillwell, and Heatherton 1994). This research examines a novel downstream consequence of guilt, namely, preferences for self-improvement products in domains unrelated to the source of the guilt.

Previous work on the downstream consequences of guilt has largely examined two types of outcomes. First, the experience of guilt leads individuals to engage in actions allowing for direct reparation of the wrong-doing (e.g., Dahl, Honea, and Manchanda 2005; Frijda, Kuipers, and ter Schure 1989). Second, guilt can lead to out-of-domain downstream consequences wherein the activation of guilt in one context can lead to prosocial behaviors in a second context (Konecni 1972; Regan et al. 1972). In other words, research suggests that people can take direct or indirect means of resolving guilt. Such behaviors have been attributed to resolving the negative emotions associated with guilt by repairing the mood or engaging in impression management (Cialdini et al. 1987).

We alternatively suggest that guilt can activate a desire for self-improvement. Drawing on past work suggesting that falling short of one’s own personal standards can activate guilt (Higgins 1987; Pelozo, White, and Shang 2013), we propose that guilt activation make salient one’s failure to meet important self-standards. As a result, consumers will exhibit self-improvement strivings. When options to engage in moral actions to directly or indirectly alleviate guilt in the prosocial domain are not available, we predict that activating guilt in one domain leads to increased preferences for consumption choices geared toward general self-improvement in subsequent unrelated domains.

Our approach draws from a recent body of literature focusing on improving our understanding of the distinct motivational outcomes of specific emotions (Griskevicius, Shiota, and Nowlis 2010; Wilcox, Kramer, and Sen 2011; Winterich and Haws 2011) to compare the effects of guilt with those of sadness – an emotion of similar valence, intensity, and certainty about its source – and of neutral emotional states on consumption preferences. More specifically, we compare two strategies for regulating negative emotional states, preferences for self-improvement and mood-management options. We thus compare the typically more effortful and future oriented process of making changes to the self with the process of regulating one’s mood. We present four experiments investigating this spillover effect.

Study 1 uses a 3(emotion: guilt vs. sadness vs. neutral) between x 2(goal type: self-improvement vs. mood-management vs. control) within, mixed-model design. Participants recalled an event that either made them feel particularly guilty, sad, or recalled a neutral event. In an ostensibly separate study, they were asked to help evaluating upcoming book titles in the “100 Tips to...” series. Par-

Participants evaluated the titles “Becoming Your Best Self” as the self-improvement option, “Improving Your Mood” as the mood-management option, and other control titles (e.g., “Exploring Italy”). Results support the predicted interaction between the emotion recalled and the goal associated with each title. Participants in the guilt condition rated the self-improvement title higher than participants in the sadness or control condition. No significant difference was observed for the other titles. Study 2 uses a 2(emotion: guilt vs. sadness) between x 2(social-comparison Type: upward vs. downward) within, mixed-model design. It provides additional support for the effect by testing how participants’ affective state influences agreement with alternative measures of self-improvement and mood-management desires. After performing a recall procedure similar to study 1, participants rated their agreement with both upward (self-improvement) and downward (mood-management) social-comparison behaviors. Participants in the guilt condition agreed more with upward social-comparison behaviors than those in the sadness condition. No difference was observed for downward social-comparison.

Study 3 uses a 2(emotion: guilt vs. sadness) between x 2(goal type: self-improvement vs. mood-management) within, mixed-model design. This study provides support for our theoretical framework by examining the mediating role of self-improvement motives. After engaging in a recall procedure similar to study 1, participants evaluated two functional music album titles. Participants in the guilt condition evaluated more positively than the ones in the sadness condition the self-improvement choice titled “Music to Improve Your Self,” which was recommended to “create the optimal environment for mastering new skills.” Ratings were not significantly different between conditions for the mood-management title “Music to Improve Your Mood,” which was recommended to “lift up mind, body, and spirit.” A difference score comparing participants’ ratings of each title also supported the notion of a relative preference for self-improvement over mood-management consumption. This relationship was mediated by participants’ self-improvement motivations.

Study 4 uses a 2(emotion: guilt vs. sadness) x 2(self-theory: incremental vs. entity) between-subjects design. It extends our understanding of the phenomenon by highlighting the importance of believing in one’s ability to change. We posit that individuals who view their self as being malleable and improvable will be particularly likely to pursue self-improvement products in another domain after experiencing guilt. We examined the impact of self-theory (Chiu, Hong, and Dweck 1997) or the extent to which participants believed the self to be stable (i.e., entity theory) or malleable (i.e., incremental theory) on subsequent product choices. Participants were asked to select three samples from two functional teas: the self-improvement “Get Smart” tea or the mood-management “Get Happy” tea. Results support the predicted interaction between emotion and self-theory on consumers’ choices of self-improvement over mood-management products. Among participants in the guilt condition, incremental theorists made more self-improvement choices than entity theorists. No such difference was observed in the sadness condition.

Taken together, the results of the four studies provide converging evidence that activation of guilt can subsequently lead to preferences for self-improvement consumption choices in unrelated domains. This relationship is driven by the activation of a general desire for self-improvement and contingent upon people’s belief that the self can be improved over time.

‘I’ versus ‘You’: Self-focus as a Mediator of Emotion Effects on Self-control

EXTENDED ABSTRACT

Anecdotal evidence has suggested that behavior and consumption are related with the emotion that a person is experiencing. Indeed, research on incidental or ambient emotions has discovered the pervasive tendency of emotions to carry over from one situation to another, coloring behavior in unrelated tasks (e.g., Keltner and Lerner 2010; Loewenstein and Lerner 2003). Among emotions, sadness is unique because of two important reasons. First, although negative, sadness does not conform to the standard predictions based on its emotional valence. Based on a valence-based model, one would predict that negative emotions, including sadness, will trigger generalized negative assessments of the environment and lead one to perceive the world in negative ways. In contrast, sadness actually triggers positive valuation of new products, as measured by willingness to pay (Lerner, Small, and Loewenstein 2004). Second, the carryover effect of sadness drives consumption behavior across diverse domains. In the domain of eating, for example, sadness (relative to happiness) leads to increased consumption of tasty, fattening food products, such as buttered popcorn and M&M candies (Garg, Wansink, and Inman 2007; Garg and Lerner 2013). In the domain of consumer transactions, sadness (relative to a neutral state) increases the amount people spend to purchase items (Lerner et al. 2004).

One of the factors implicated in the sadness-consumption relationship is the enhanced self-focus that sadness engenders. Cryder et al. (2008) found that this increased self-focus was tied to higher willingness to pay for a new product (water bottle). However, these authors focused on just acquisition of a new product rather than generalized indulgent (hedonic) consumption across domains.

In the present research, we hypothesize that the self- versus other-focus associated with emotions and its effect on consumption might hold more generally across emotions. In our studies we examine two specific, negative emotions – anger and sadness. We focus on the ‘self’ because based on the appraisal tendency framework it connects with one of the key dimensions - self-responsibility - differentiating emotions and their subsequent effects (Lerner and Keltner 2000; Smith and Ellsworth 1985). Self-responsibility refers to the degree to which one feels responsible for what is happening in the situation.

Understanding the differences in the effects of anger and sadness is important as they are two of the most common negative emotions associated with consumption experiences (Garg, Inman, and Mittal 2005). From a theoretical perspective as well, anger and sadness are very interesting, because even though both have a negative valence, they arise from different appraisal tendencies that lead to differential impact on a subject’s degree of self-responsibility (Smith and Ellsworth 1985). Whereas, a heightened sense of self-responsibility characterizes sadness, anger is associated with others being responsible for the situation (Lerner and Keltner 2000; Smith and Ellsworth 1985). Thus, whether anger and sadness lead to systematic differences in self-control relevant consumption becomes an important question to examine. The answers will broaden our understanding of the relationships between emotions and consumption in general; well beyond our current knowledge that is limited to the sadness-consumption links.

The current research also examines whether outcome elaboration moderates the emotion-consumption link. Extant research has established the beneficial effects of considering the potential future outcomes for effective self-control in the present (e.g., Baumeister and Heatherton 1996; Nenkov, Inman, and Hulland 2008). Prior re-

search, however, has not differentiated between different outcome elaboration approaches. We argue that elaborating on the potential outcomes of a behavior for the self versus others would moderate the relationship between emotions and consumption. We predict that since the self-focus associated with sadness drives its detrimental effects on self-control, switching the focus on others, rather than the self (e.g., by reminding participants about the potential effects of their behavior on others) could attenuate these effects.

To test our hypotheses, we conduct a series of three studies to examine whether anger and sadness are associated with varying levels of self-focus and whether this differential self-focus results in systematic shifts in preferences for hedonic options (Study 1); whether manipulating the focus of outcome elaboration (to emphasize the self vs. others) can alter the extent to which sad and angry individuals opt for hedonic options (Study 2); and finally whether self-focus and outcome elaboration can influence the amount of hedonic food product (M&Ms) consumed rather than simply shifting preferences for hedonic options, as in Studies 1 and 2 (Study 3).

Study 1 tested the hypothesis that sadness leads to a higher self-focus as compared to anger, and that this enhanced self-focus mediates the link between emotion and preference for hedonic options. We examined two consumer domains – preference for healthy versus hedonic food and preference for time spent on a utilitarian versus hedonic task. A 2 (emotion: sad, angry) x 2 (preference: food, time spent) between-subjects design was implemented to test the hypotheses of the study. Results find that sad individuals are significantly more self-focused than angry individuals and tend to prefer hedonic options across both domains. Also as predicted, this differential self-focus mediates the relationship between emotion and preference for hedonic options.

Study 2 aims to show that the focus of outcome elaboration – self vs. others – moderates the influence of emotions on preference for hedonic options. Study 2 uses a 3 (emotion: sad, angry, neutral) x 2 (outcome elaboration: self, others) between-subjects design. We expect that outcome elaboration would succeed in overriding the effect of sadness on preference for hedonic consumption only when it is focused on others (rather than self).

The final study seeks to replicate and extend the results of Studies 1 and 2 in the domain of actual food consumption (Garg et al. 2007; Garg and Lerner 2013). This study would test our predictions in a well-tested domain to bolster the reliability of our results and would move from examining simple preferences to actual behavior.

Overall, this research aims to provide critical insight into the theoretical moderators and mediators underlying the emotion-hedonic consumption relationship. This will have important implications for the strategies employed to attenuate the influence of contextual factors such as emotions because of the negative consequences of unbidden consumption.

The Influence of Pride Diagnosticity on Self-Control

EXTENDED ABSTRACT

Pride is a self-conscious emotion shown to generate appraisals of increased self-worth, which can have a diametric influence on self-control efforts. In some instances, pride’s increased self-worth can encourage people to exert self-control (Patrick, Chun, and MacInnis 2009; Williams and DeSteno 2008). In other instances, this same sense of self-worth can foster a “license to sin” and lead to self-control lapses (Wilcox, Kramer, and Sen 2011; Winterich and Haws 2011). Thus, understanding when pride assists versus impedes self-control may depend on the consideration of other moderating factors.

This research proposes that the influence of incidental pride on self-control is a function of (1) whether the experienced pride is perceived to provide diagnostic information about how to behave and, (2) a person’s present goal state. We find that two antecedents (i.e., the circumstances that were responsible for the pride) determine when pride is diagnostic: stability and effort. *Stability* is pride experienced as a function of how frequently an accomplishment is made within a domain. *Effort* is pride experienced as a function of the difficulty level of an accomplishment within a domain. When pride is high (versus low) in stability or effort in one domain, it should be perceived as diagnostic for what to do in other domains. This is because pride high in stability (effort) pertains to an accomplishment requiring persistence (overcoming difficulty). Such an accomplishment should be more trustworthy for what to do in other domains because persistence (overcoming difficulty) is applicable to attaining self-control success across all domains (Freund and Riediger 2006; Williams and DeSteno 2008).

We predicted that the effect diagnostic pride has on self-control will depend on one’s current goal state. When no regulatory goal is active, diagnostic pride should be used to make inferences about one’s self-concept (i.e., “The event that made me proud is part of who I am”). To the extent that opportunities (i.e., means) are available to pursue in other self-control domains important to an individual, diagnostic pride should increase self-control. However, when a regulatory goal is active, pride should become diagnostic to goal pursuit and supersede adjustments to the self-concept (Wheeler, DeMarree, and Petty 2007). Goal-pursuit relies on feedback for control; such that when progress is insufficient (sufficient), goal pursuit is increased (decreased) (Fishbach and Dhar 2005). Since the experience of diagnostic pride occurs in response to success in one’s long-term goals, pride should signal that the person is effective at regulatory behavior and to deemphasize the importance of the goal. Thus, diagnostic pride should lead to an inference that enough progress has been made toward the active goal (i.e., “The event that made me proud is enough of an accomplishment for now”) and decrease self-control.

We tested our hypotheses in three studies. Studies 1A and 1B used a two (regulatory goal: inactive vs. active) x two (pride experience: nondiagnostic vs. diagnostic) between-subjects design. The studies were identical in design and procedure except that each study manipulated one pride antecedent. Study 1A (1B) manipulated pride diagnosticity using the stability (effort) pride antecedent, where pride high in stability (effort) was diagnostic while pride low in stability (effort) was nondiagnostic. Participants first completed a lexical decision task that either primed the regulatory goal of being virtuous or no goal. Then participants responded to a hypothetical scenario that either evoked diagnostic or nondiagnostic pride. In study 1A (stability), participants in the nondiagnostic (diagnostic) pride condition were told to think about a single past experience (common past experiences) in which they were proud of eating healthy. In study 1B (effort), participants in the nondiagnostic (diagnostic) pride condition were told to think about a time in which they were proud of an A they received with very little effort (a great deal of effort) on their part. Lastly, participants completed a task purportedly related to everyday decisions but was actually our dependent measure for self-control. Participants made 15 total decisions, where each decision had two possible options, and one option was always more virtuous than the other. Results showed that when no regulatory goal was active, diagnostic pride led to a greater number of virtuous decisions made compared to nondiagnostic pride. However, when a regulatory goal was active, diagnostic pride led to a lower number of virtuous decisions made compared to nondiagnostic pride.

Study 2 builds upon studies 1A and 1B, showing that the perceived diagnosticity of pride is critical to predicting how pride will influence self-control. The study's design was modified to include a manipulation which made the concept of nondiagnosticity either salient or non-salient, using a two (nondiagnosticity salience: low vs. high) x two (regulatory goal: inactive vs. active) x two (pride experience: nondiagnostic vs. diagnostic) between-subjects design. First, participants completed the priming task from study 1, with the regulatory goal changed to savings. Next, participants completed the pride manipulation from study 1A. Then, participants completed a task supposedly related to reading comprehension but in truth manipulated nondiagnosticity salience. In the low salience condition, participants read about a new bird exhibit at the local zoo. In the high salience condition, participants read about a new book that highlighted the importance of "not using success in one area of their lives to infer what they should do in other areas." Lastly, participants completed a budgeting task and indicated how much they would save for the upcoming month, which served as our dependent measure for self-control. When nondiagnosticity salience was low, the pattern of saving intent replicated study 1. However, when nondiagnosticity salience was high, differences in pride experience attenuated, where only participants in the active regulatory goal condition exhibited greater saving intentions than those in the inactive regulatory goal condition.

Collectively, these studies show that the effect of pride on self-control is jointly determined by the diagnosticity of the pride experience and the presence (versus absence) of regulatory goals. As such, the findings contribute to our understanding of how emotions influence self-control, with important implications for consumer motivation and wellbeing.

Paper #3: Psychological Risk Aggregation: Selling Products of Uncertain Qualities with Probabilistic Promotions

Mengze Shi, University of Toronto, Canada
Alison Jing Xu, University of Toronto, Canada

SESSION OVERVIEW

The literature on judgment and decision making has long focused on the disutility of uncertainty. The certainty effect for example, first evidenced in the Allais paradox (Allias 1953), suggests that people overweight certain outcomes relative to probable outcomes (Kahneman and Tversky 2000). In general, people are risk averse in gains—they prefer a sure gain to a lottery of gains with the same expected value (Kahneman and Tversky 1979). In an extreme demonstration of risk aversion, Gneezy, List, and Wu (2006) showed that risky prospects are valued less than their worst outcome. Recently, however, researchers have begun to explore conditions under which consumers embrace uncertainty. For example, Goldsmith and Amir (2010) found that in the absence of thoughtful consideration, innate optimism drives consumers to respond to uncertain promotions and certain promotions with the best outcomes equally favorably, although the expected benefits of uncertain promotions are lower.

The current session brings together three papers each exploring a way to maximize the utility of uncertainty or minimize its disutility. Across the three papers, we discuss (a) how to frame risky prospects to increase willingness-to-pay; (b) which information processing strategy to use to decrease uncertainty aversion; and (c) how consumers aggregate promotion and product risk to minimize overall risk aversion.

The first paper by Yang, Vosgerau, and Loewenstein explores the influence of framing on consumers' valuation of a risky prospect. In particular, framing a risky prospect as "uncertain gift" compared to "lottery" substantially increases consumers' willingness to pay for the prospect. Although framing does not change consumers' subjective value of the risky prospect, the "uncertain gift" frame evokes a higher reference price than "lottery" frame which increases WTP. The second paper by Goldsmith and Amir compares effects of intuitive processing versus deliberative processing on people's tendency to avoid uncertainty. The results suggest that intuitive processing actually decreases uncertainty aversion, and thus increases one's likelihood of making a rational choice in contexts where uncertainty aversion usually biases choices. The first three papers focus on people's reactions to a single source risk. The final paper by Shi and Xu extends the scope of investigation by looking into how consumers make decisions when companies market products of uncertain qualities with probabilistic promotions. In this case, consumers aggregate two independent sources of risks (product and promotion risks) and evaluate them jointly. The results show that product risk and promo-

tion risk interact in determining joint risk evaluation – it is amplified when consumers perceive salient contrasts between the sizes of two risks.

Introductory remarks will briefly review the previous research on risk aversion and uncertainty aversion and emphasis will be placed on recent discoveries on the positive influence of uncertainty. Each speaker will discuss the theoretical perspective from which the findings are grounded. The last 10 minutes of the session will be devoted to summarizing the factors that have been examined in exploring the upside of uncertainty and encouraging the speakers and the audience to generate new theoretical perspectives that may highlight avenues for future research. In line with the theme of ACR of "making a difference," this session will aim to provide an overview of emerging findings that are built on previous work on risk aversion and uncertainty aversion but also make a difference by exploring the promises of uncertain environment.

We expect this session will be of interest to a broad audience at ACR. Given that risk aversion is one of the most prominent finding in consumer judgment and decision making, insights into when consumers embrace risk and uncertainty provides new opportunities for consumers, retailers, and manufacturers.

The Influence of Framing on Willingness to Pay as an Explanation of the Uncertainty Effect

EXTENDED ABSTRACT

Gneezy, List, and Wu (2006) documented the intriguing uncertainty effect (UE) where risky prospects are valued less than their worst outcome. For example, people are willing to pay an average of \$26 for a \$50 gift certificate, but only \$16 for a lottery that would pay either a \$50 or a \$100 gift certificate with equal probability. The psychological mechanism underlying this effect is still unknown. Keren and Willemssen (2009) claimed that participants simply misunderstood the instructions in the lottery condition. Simonsohn (2009) carefully ensured participants' correct understanding and reliably replicated the effect, proposing that the uncertainty effect denotes a direct form of risk aversion.

This extreme form of risk aversion appears even more peculiar given that in the marketing domain researchers have documented the opposite. Goldsmith and Amir (2010) examined the effect of uncertainty on promotions and found that risky prospects framed as a free gift could be more attractive than their expected value. Why do people exhibit extreme risk-aversion in the situations examined in the research documenting the UE, but extreme risk-seeking for seemingly closely equivalent risky choices in the domain of consumer research? In a series of 9 studies, we show that framing a risky prospect as a "lottery ticket" as opposed to an "uncertain gift certificate" substantially reduces WTP, because the lottery frame evokes a lower reference price, but people value the risky prospect equally under both frames.

In Experiments 1 and 2, we show that when a risky prospect is described as a "lottery" as opposed to an "uncertain gift", WTP is substantially reduced causing the UE. In Experiment 2, for example, we orthogonally manipulated framing (a lottery ticket vs. a gift certificate) and uncertainty (certain vs. uncertain). Framing a risky prospect as a lottery ticket—no matter whether it was certain or uncertain—substantially decreased WTP. Thus, the uncertainty effect

only occurred when the uncertain item was framed as a lottery ticket and the certain item was framed as a gift certificate.

In Experiments 3A and 3B we replicated the framing effect, and tested four possible explanations - subjective uncertainty, processing fluency, negative attitudes toward lottery tickets, and anchoring. The procedure in these studies was identical to that in the previous studies; additionally, participants also indicated how much uncertainty they felt in this offer (subjective uncertainty), how difficult the offer was to understand (fluency), and their attitude toward lotteries. Finally, we also asked participants to indicate the typical price of a lottery ticket either before or after they indicated their WTP to test whether WTP is anchored on typical lottery ticket prices. Neither subjective uncertainty, fluency, attitudes towards lotteries nor anchoring were related to WTP.

In Experiments 4-6 we manipulated aleatory uncertainty, mental representations of uncertainty, and anticipated disappointment. While we replicated the previously found framing effect in all three studies, none of the uncertainty and disappointment manipulations had an effect on WTP.

Experiments 7 and 8 test a reference price account of the UE that was inspired by Weaver and Frederick's (2012) reference price theory of the endowment effect. According to this account, the lottery frame may evoke a lower reference price than the gift certificate frame.

One prediction that follows from this account is that if the lottery ticket frame evokes a lower reference price than the uncertain gift certificate frame, setting an explicit reference price under both frames should lead to an assimilation of WTP to that reference price. In Experiment 7, we manipulated the presence of a reference price by telling half of the participants that the majority of participants in previous studies had been willing to pay \$35 for the risky prospect (\$35 is the median WTP across framing conditions in our experiments). In the *control* conditions no reference price was mentioned. As predicted, we found that the differences in willingness to pay (WTP) disappeared when the same reference price was set for both frames.

The reference price account also allows for another elegant prediction. According to Weaver and Frederick (2012), people are not willing to pay more than the reference price (r ; i.e., the market value) even when they subjectively value (v) the good more, because this would constitute a bad deal. Formally, $WTP = \min(r, v)$. WTA, however, is equal to the maximum of the reference price and valuations, and should not thus be affected by the low reference price under the lottery frame. Formally, $WTA = \max(r, v)$. This suggests: WTA, in contrast to WTP, should not be affected by the framing manipulation. In Experiment 8, we test this prediction by manipulating the frame (lottery vs. gift certificate) and endowment status buyer vs. seller. Consistent with the reference price account, results show that lottery framing reduces WTP but not WTA.

Experiment 9 and 10 examine whether our finding can be generalized to other frames, such as "raffle", "gamble", "coin flip" and "voucher". Consistent with the reference price account, we found that "raffle", "gamble", "coin flip" frames significantly reduced WTP compared to "voucher" frame. No UE effect was observed when the frame of the risky prospect and its worst outcome matched. We also found that framing had a greater impact on WTP than on WTA.

Concluding, in a series of 11 studies we demonstrate that framing influences WTP and thus explains the UE. We rule out a host of possible explanations for the framing effect on WTP, and find evidence consistent with a reference price account.

The Role of Cognition in Uncertainty Aversion: When Less Thought Leads to More Rational Choices

EXTENDED ABSTRACT

Human beings often strive to be rational and consistent in their decision making. As a result, a great deal of academic research has been devoted to understanding the decision strategies that promote rational choices across different contexts. Prior work has identified two distinct processing styles used in decision resolution: conscious deliberation, which draws attention to the decision, and intuitive responding, which relies more on "gut" responses. The belief that carefully considering one's decision should improve decision-outcomes has been advocated for centuries and some academic research supports the merits of such behavior; however, to our knowledge, no work to date has tested the implications that promoting (versus inhibiting) consideration of one's decision has for one's likelihood of making rational choices in contexts involving uncertainty.

A large body of academic work demonstrates that people prefer certain over uncertain benefits, even showing that a preference for certainty can lead to violations of expected utility theory. The seminal demonstration of such a violation is the Allais Paradox (Allais 1953). This paradox reveals that when individuals are presented with sequential choices between gambles, the majority violates the independence axiom, failing to treat the potential outcomes within the gambles as independent in part because uncertain gains are less tolerable when certain gains are available. We build on this work by testing the effect of processing style on this paradigm. In so doing, we are able to test if and how directing resources (e.g., cognitive focus) towards decisions involving uncertainty affects one's likelihood of making a rational choice.

Recent research suggests that careful consideration of one's decision may increase uncertainty aversion (Goldsmith and Amir 2010). If this is the case, manipulations that inhibit such considerations (e.g., by directing cognitive resources away from the decision) may increase rationality in contexts where uncertainty aversion has been shown to bias outcomes (e.g., the Allais Paradox). Experiment 1 tested this directly by manipulating cognitive load and testing individuals' likelihood of demonstrating the Allais Paradox and revealed that participants were less likely to demonstrate the Allais Paradox when under cognitive load ($P_{no-load} = 37\%$; $P_{load} = 27\%$; $p < .05$). If the Allais Paradox occurs in part because of uncertainty aversion, these results imply that under cognitive load, uncertainty aversion decreases, thus resulting in more rational choices in this context. If true, then when the decision context promotes consideration, participants should be more likely to demonstrate the paradox, as compared to when it does not. Prior research suggests that individuals naturally consider gambles with higher-stakes outcomes (e.g., higher in monetary value) more than those offering low-stakes rewards (Goldsmith and Amir 2010). We utilized this value manipulation in order to test for a conceptual replication of our effect and observed that participants were significantly less likely to demonstrate the Allais Paradox when the gambles were of low-value (21%) as compared to high-value (38%; $p < .001$). Experiment 3 replicates this pattern of results in a different domain by manipulating if participants were asked to "think carefully" about uncertain rewards prior to rating their attractiveness. In line with our predictions, we observe that directing attention towards the uncertain rewards made them less attractive ($p < .05$).

Decision making under risk and uncertainty has been at the forefront of social scientific investigation for five decades. We build on this work by shedding light on the relationship between processing style and uncertainty aversion. Our experiments offer convergent evidence demonstrating that consideration increases uncertainty

aversion, relative to more intuitive processing, which can decrease one's likelihood of making a rational choice in contexts where uncertainty aversion commonly biases choices (e.g., the Allais Paradox). We conclude with a discussion of the theoretical and practical implications for these findings.

Psychological Risk Aggregation: Selling Products of Uncertain Qualities with Probabilistic Promotions

EXTENDED ABSTRACT

Companies often market products of uncertain qualities with probabilistic promotions (e.g., 50% chance of getting 15% off; 50% chance of getting 45% off). A product provides uncertain qualities to consumers either because it is new to the market or because the product is inherently risky (e.g., investment products). When such products with uncertain qualities are promoted with probabilistic rewards, consumers need to aggregate two sources of risks (product and promotion risks) and evaluate them jointly to decide the attractiveness of the deal package. This paper studies consumers' psychological reactions to aggregated risks from independent sources. Our paper extends the existing literature on probabilistic promotions that has focused on consumer responses to the uncertain nature of the probabilistic promotions, comparing their performance relative to fixed promotions (Goldsmith and Amir 2010, Mazar, Shampanier, and Ariely 2012) or exploring the optimal design of reward structure (Kalra and Shi 2010). Most of the existing studies, by examining either established brands such as Nike athletic shoes, Amazon gift cards, and M&M's or hypothetical ones, have neglected the potential performance uncertainty in the products being promoted.

We develop a theoretical framework for joint risk evaluation that incorporates three factors: risk aversion, probability weighting, and contrast effects. First, risk aversion is the core concept in *normative economics theory*, which suggests that decision makers evaluate a two-risk prospect by computing the expected value of its outcomes. Assuming that people are risk averse, this model predicts that people should prefer fixed promotion over probabilistic promotions, and for any given product promoted by a probabilistic promotion, the joint evaluation of the two-risk prospect should monotonically decrease as the risk of the probabilistic promotion increases. *Second, prospect theory* assumes that people may overweight favorable outcomes and they are risk-averse. When probabilistic promotion involves low risk, since people may overweight the more favorable outcome in the reward package, the joint evaluation of the two-risk prospect can be greater than a fixed promotion with no risk. However, as promotion risk continues to increase, risk-aversion will overshadow positive-outcome-overweighting and lead to decrease in joint evaluation. Note that both frameworks assume that promotion risk and product risk *independently* influence joint evaluation. No direct interactive effect between two sources of risks is predicted. Finally, we extend above two frameworks with a *joint-risk evaluation model* to accommodate the contrast effect that may occur when aggregating two independent sources of risks (a promotion risk and a product risk). Specifically, when people perceive a large and a small risk prospect simultaneously, the larger risk is more salient and becomes the focus of attention. The smaller risk serves as the reference of comparison. Contrasting the large risk against the small risk amplifies the perceived size of the large risk. As a result, perception of joint risks is higher and joint evaluation is lower when the differences between the two risk prospects are sufficiently large to produce a contrast effect.

In two experiments, we manipulate the size of product risk (between-subject) as well as the size of promotion risk (within-subject)

and investigate how consumers make joint evaluations of the two-risk prospect in two diverse contexts. In the first experiment, product risk was manipulated by the variance of mutual funds' annual returns in the past (high vs. low). The size of promotion risk was manipulated through the spread between large and small rewards (7 levels from low to high): the larger the spread, the higher the promotion risk. The probability of getting either reward is 50%. Joint evaluation of this two-risk prospect was measured by the likelihood of choosing the mutual fund over a fixed-income fund with no promotion. The results revealed an interactive effect of product risk and promotion risk. First, inconsistent with the predictions of normative economic theory, the joint evaluation of the two-risk prospect did not decrease with reward spread monotonically. When the product risk was high, the joint evaluation dropped sharply when a low risk promotion was introduced, but then bounced as promotion risk increased to a higher level. Monotonic decreasing trend was observed when the promotion risk increased from the medium to high levels. This drop-bounce-drop trend was also in contradiction to the bounce-drop-drop trend predicted by single risk Prospect Theory. Second, when the product had low risks, introducing a small promotion risk had little impact on the joint evaluation. However, as the promotion risk increased from the medium level to high level, joint evaluation dropped dramatically.

The second experiment manipulated product risk by using three types – radically-new, incrementally-new, and established – of products in the airline industry (high vs. low vs. no risk; between-subject). The quality of a flight service would be uncertain when it is a new flight route offered by an established airline; and the uncertainty would be even higher when the new service route was offered by a newly founded airline. In contrast, the established product involves minimal quality uncertainty. Again, the size of promotion risk was manipulated through the spread between large and small rewards (7 levels from low to high). Joint evaluation of the target product was measured by indicating the matching price for a competing product that make the target and the competing products equally attractive. Again, the interactive effect of product risk and promotion risk supported the joint evaluation model.

Our results suggest that we should extend the commonly applied single-risk prospect theory models by explicitly accounting for psychological interactions between two sources of risks when they are evaluated jointly. The joint risk evaluation model developed in this paper offers one approach to incorporate such contrast effects between two risks.

SESSION OVERVIEW

Creativity has been defined as the generation of ideas, insights or problem solutions that are both new and useful (Amabile 1983; Sternberg and Lubart 1999). Consumers themselves engage in various problem solving activities and enjoy creative outputs in a wide range of contexts. In today's society, perhaps more than ever, creativity prevails as part of our everyday consumption environment. Whether sharing an idea in an online community, engaging in a craft project or creating a customized product, consumers value creative outcomes. It is no surprise then that over the past several decades, researchers have delved in understanding the antecedents and effects of consumer creativity. Recently however, most research in consumer creativity has focused on studying the effects of situational variables, such as external constraints (Moreau and Dahl 2005), involvement (Burroughs and Mick 2004), noise (Mehta et al. 2012), spaciousness (Meyers-Levy and Zhu 2007) on creativity.

The proposed session aims to diverge from this trend. This session brings together four papers that examine a more human side of creativity. First paper (Herd and Mehta) furthers current understanding of empathic design and teases apart the differential effects of empathy and perspective taking on creativity. Specifically, this paper demonstrates that empathy leads to higher levels of shared identity which then leads to more creative product outcomes. The second paper (Sellier and Dahl) examines the role of ethics in consumer creativity. Building upon recent research which demonstrates that higher creativity can lead to more unethical behavior, this work shows that an ethical (or a moral) mindset can lead to higher creativity. Hence, looking at things from a positive perspective this paper suggests that "good", can also boost creativity. The third paper in the session (Yang and Chattopadhyay) recognizes mortality salience and its influence on creativity. This research considers dire situations that can make death salient. The authors find that such thought processes can hamper divergent thinking, resulting in lower creativity of the generated ideas. Finally, the fourth paper (Tu and Argo) investigates the effect of consumers' social comparisons and evaluation expectations on creative outcomes. This paper shows that when consumers' creative outcomes are expected to be compared based on an individual's own ability level, it'll lead to higher level of creativity as it'll enhance competition and involvement in the given creativity task.

However, when the social comparison is based on the creativity outcome itself, it will negatively affect creative performance.

In sum, this proposed session examines a wide range of theoretical constructs (empathy, social comparison, morality, mortality) and their distinct influences on creative performance. All four paper papers in the session enhance current understanding of consumer creativity and provide cutting edge insights into how consumers' subtle psychological variables can either enhance or inhibit creativity. Thus, we believe that this session in itself presents a coherent theme that will appeal to a wide range of consumer behavior researchers.

Heart Versus Head: Examining Differential Effects of Empathy Versus Perspective Taking on Creative Product Design

EXTENDED ABSTRACT

The extant literature in product innovation and creativity has treated the constructs of empathy and perspective taking interchangeably (e.g., Dahl et al. 1999). Yet, recent literature suggests they are theoretically different processes (e.g., Davis et al. 1987; Galinsky et al. 2008).

Perspective taking is a cognitive process by which one imagines how another person thinks (Batson et al. 2007; Dahl et al. 1999). By taking another's perspective, consumers are able to "put themselves in the shoes" of a target. This process allows them to better anticipate the behavior and reactions of others (e.g., Davis 1983). Empathy, on the other hand, is an affective process that involves the adoption of another's feelings (e.g., Batson et al. 2007; Escalas and Stern 2003). Importantly, perspective taking and empathy have been shown to induce differences in the way the self is construed. Perspective taking involves taking another's perspective, but allows one to maintain an individual self-identity (e.g., Simon et al. 1997). An empathic connection on the other hand enhances shared identity, a redefinition in terms of others (e.g., Brewer et al. 1993; Simon et al. 1997).

This adaptation of shared identity as compared to maintaining one's self identity allows individuals to retrieve unconventional knowledge about others which then leads to enhanced creativity (e.g., Maddux and Galinsky 2009). We thus propose that in a product design context an affective process of empathic concern as compared to the cognitive process of perspective taking will lead to higher levels of shared identity, which in turn will lead to product designs that are more creative in nature. We test our hypothesis across three studies involving real design tasks and consistently find that empathy (vs. perspective taking) leads to more creative product designs. To pinpoint shared identity as the underlying process, we both measure and manipulate it across studies.

In study 1, all participants (N = 80) were prompted with either perspective taking or empathy strategy (manipulation adapted from Batson et al. 2007). In the perspective taking condition, participants were told to visualize a target consumer interacting with the product. In the empathy condition, participants are told to imagine how a target consumer would feel while using the product. Following the manipulation, all participants were directed to provide new creative ideas for a laptop that is specifically designed for consumers age 65+. Following the study, independent raters blind to condition evaluated each participant's ideas on the following dimensions: creativity, novelty, originality. These measures were averaged to create a mean objective

creativity score ($\alpha = .91$). Results revealed a main effect of empathy vs. perspective taking ($M_{PT} = 3.45$ vs. $M_{Emp} = 3.56$; $F(1, 79) = 4.65$, $p < .04$).

In the next study, all participants ($N = 45$) were again prompted with either a perspective taking or empathy strategy. Following the manipulation, each participant provided as many creative ideas as they could for a grocery cart for the elderly. Again, we found a main effect of strategy on objective creativity such that those prompted with empathy were more creative ($M_{PT} = 3.50$ vs. $M_{Emp} = 3.84$; $F(1, 44) = 4.12$, $p < .05$). In order to better understand the underlying process, we also captured shared identity measures of how similar they imagined themselves being to the elderly and how much they imagined themselves as a unique individual (reverse-coded). Mediation analysis using bootstrap approach showed a significant indirect effect of shared identity through which empathy (vs. perspective taking) influenced creativity (95% CI: .0455, 4.336).

Finally, in study 3, we manipulated shared identity to provide further evidence that this change in how participants identify with consumers influences creative output. All participants ($N = 180$) were provided with Lego-like toy pieces called Krinkles and were instructed to create a toy prototype for a 4-6 year old child. Strategy (empathy vs. perspective taking) was manipulated as in previous studies. Shared Identity was manipulated by asking participants to “imagine, as a product designer, if you were a 4-6 year old child *how you would interact (how you would feel)* while playing with the toy.” In Self Identity condition the participants were asked to “imagine, as a product designer, how this segment of 4-6 year old children will *interact (feel)* while playing with the toy.” Following the study, we took pictures of each design and asked moms of 4-6 year old children to evaluate each design’s creativity (creativity, novelty, originality). A significant two way interaction was observed ($F(1, 179) = 7.78$, $p < .01$) such that when the participants were primed with self identity empathy lead to lower creativity of the prototypes. However, when shared identity was primed no difference was observed between empathy and perspective taking conditions.

Taken together, these studies reconfirm that perspective taking and empathy are distinct constructs which differentially influence identification with consumers, driving differences in consumers’ abilities to develop new and creative ideas and designs.

The Light Side of Creativity: An Honesty Mindset Can Boost Creativity

EXTENDED ABSTRACT

Considerable consumer research has established that a critical area of study is the investigation of contextual factors that enable consumers to be creative (e.g., Moreau and Dahl 2005). Alarming-ly, recent research documented that creativity can negatively affect ethical behavior (e.g., Gino and Ariely, 2012). The present research flips this perspective to show that creators with an ethical mindset can enjoy greater creativity (study 1). We further show that a moral mindset can similarly serve as a creative boost (study 2). In sum, the activation of “good” can increase creativity.

What is a mindset? Engaging in certain tasks is known to activate a set of cognitive operations, which remain activated beyond the initial task, thereby influencing subsequent and unrelated tasks – the term “mindset” is used to refer to this global readiness (e.g., Gollwitzer, 1990). Following this research, we define an ethical mindset as a global readiness to have appropriate feelings in distinguishing between what is morally acceptable versus not (Crisp 2000). As such, an ethical mindset involves one’s justification of one’s actions as being appropriate (Gino & Ariely, 2012); it implies moral flexibility. A moral mindset is different in that it represents a global readiness to abide by an absolute set of rules allowing no internal justification – whether actions are appropriate is externally dictated.

We examine how an ethical mindset versus a moral mindset shapes subsequent creative cognitive processing. Prior research pinpointed constraints as a critical antecedent of creativity (e.g., Dahl & Moreau, 2007). Both an ethical and a moral mindset constrain the creative process in that they focus creators on ethical/moral creative solutions. Further, an ethical mindset provides autonomy, because it allows internal justification of one’s actions, whereas a moral mindset stifles autonomy. For these reasons, we expect that an ethical mindset will foster individual creativity more than a moral mindset and than a non-constraining, neutral mindset.

We tested this prediction in a first study in which 92 students (45 men, age = 20.1 years) completed creative tasks after having been primed with ethics-related, morals-related, or neutral words. They were told that they would take part in two studies. The first study was a word search task. Participants had to circle words hidden in a grid, from a list appearing below the grid. We varied the list of words, so that most of the words either related to ethics (e.g., “altruistic,” “generous”), morals (e.g., “abiding,” “imperative”) or were neutral (e.g., “armchair,” “telephone.”). Participants subsequently

reported how creative, original, novel, inspired, artistic, and innovative they perceived their alien to be (1-7; not at all/very), their mood, and other measures.

Next, participants participated in an ostensibly unrelated creativity study. They were instructed to imagine visiting a different planet, and encountering an alien there. Their task was to be as creative as possible in drawing this alien (Ward, 1994). Next, they were given a creative problem-solving task, the Duncker candle task, for which only one solution exists.

Once all data from creators were collected, 16 peers independently rated each alien's creativity, indicating how creative, original, novel, inspired, artistic, innovative (1-7; not at all/very; α for the averaged creativity score across peers = .99) the aliens were. Subsequently, they rated each alien's attractiveness (6 items, all α 's > .85).

Seven participants did not follow the study instructions, and were therefore excluded from the sample. We report our analyses for the remaining 85 participants. We computed a self-perceived creativity index by averaging creators' creativity ratings ($\alpha = .91$), and subjected this index to an ANOVA. We found a significant impact of Mindset, $F(1, 85) = 3.15, p < .05, r^2 = .04$, such that creators with an ethical mindset perceived their aliens to be significantly more creative than creators with a moral mindset ($M_{\text{ethical}} = 4.10$ vs. $M_{\text{moral}} = 3.44, t(82) = 1.94, p = .05, r^2 = .04$); and than creators with a neutral mindset ($M_{\text{neutral}} = 3.28, t(82) = 2.34, p < .03, r^2 = .06$). Moral and neutral creators rated themselves as equally creative, $t < 1$.

Next, we computed an objective creativity index by averaging peers' creativity ratings (all α 's > .85). An ANOVA using this index as the dependent variable showed a significant impact of Mindset, $F(1, 85) = 3.16, p < .05, r^2 = .04$, such that the ethical aliens were judged more creative than the moral aliens, $M_{\text{ethical}} = 4.34$ vs. $M_{\text{moral}} = 3.77, t(82) = 2.27, p < .03, r^2 = .06$; and than the neutral aliens, $M_{\text{neutral}} = 3.81, t(82) = 1.94, p = .05, r^2 = .04$. Moral and neutral aliens were rated equally creative, $t < 1$.

Focusing on the Duncker candle problem, we found that 54% of ethical participants found the correct answer, a greater performance than moral participants (29% solved correctly, $\chi^2 = 3.62$, one-tail $p < .03$), and than neutral participants (30%, $\chi^2 = 3.24$, one-tail $p < .04$). We found no influence of mood or peers' alien attractiveness ratings on our results, all p 's > .08.

A second study examines when a moral mindset can boost creativity above and beyond an ethical mindset. Following research in moral psychology (Haidt 2007), we suggest that a moral mindset (vs. an ethical mindset) will foster greater creativity when creators work in groups, because it activates group cohesion and facilitation processes during the creative process. In contrast, because it boosts autonomy, an ethical mindset compromises group cohesion.

We primed 90 participants with an ethical or a moral mindset as in study 1, before they worked on designing a toy for people eating behind the wheel, in groups of 3 or 4. Subsequently, they rated their creative process experience, in particular the extent to which they felt the group worked well and enjoyed cohesion. We found that moral groups produced more creative toys than ethical groups primed, $p < .05$. Further, we found that groups' ratings of how well they worked together mediated this effect.

Together, our results suggest that, if creativity can lead to dishonesty, honesty can also produce a creative advantage.

Towards Understanding Creative Ingenuity in Dire Situations

EXTENDED ABSTRACT

From deadly natural disasters to terrorism and wars to violent crimes, today's 24/7 media constantly exposes us to information that makes our own mortality salient. At times, we may even be quite close to such misfortunes (e.g., living in the areas ravaged by Superstorm Sandy or Hurricane Katrina). This research explores how mortality salience affects people's creative ability and what type of individuals are more sensitive to this effect.

Prior research suggests that mortality salience elicits existential anxiety and, to buffer against this paralyzing anxiety, people deploy terror management strategies to create a sense of meaning and order that can transcend death (e.g., Solomon et al. 1991; Greenberg et al. 1997). Because cultural values provide meaning and structure to one's world and represent permanence beyond an individual's demise, mortality salience intensifies people's adherence to their cultural values and worldviews (e.g., Greenberg et al. 1990; Rosenblatt et al. 1989). Supporting this theorization, a large number of studies show that the onset of mortality salience can alter evaluations of self and others (Burke et al. 2010). These effects have also been shown to be non-consciousness and unique to mortality salience (as opposed to other aversive situations; Greenberg et al. 1994).

Nonetheless, how mortality salience impacts creativity is not well understood. The current research proposes that mortality salience inhibits access to information outside of one's core conventional knowledge, as a means to protect the coherence and stability of one's core cultural values and worldviews. This inhibition occurs because access to peripheral information that may conflict or cast doubt on one's cultural values and worldviews, can make adherence to them more difficult, reducing the usefulness of this terror management strategy. Thus, mortality salience is likely to hamper access to divergent information in memory, impairing creative ingenuity.

Moreover, because death represents the ultimate form of loss of control (Becker 1973), mortality salience may impact people with different control beliefs differently. While individuals with high internal locus-of-control believe that event outcomes are primarily controlled by their own efforts and actions, those with moderate internal locus-of-control believe that they have control over only some events (Rotter 1966). The first group's beliefs are irreconcilable with the notion of death, which should lead to the elicitation of stronger terror-management behaviors under mortality salience. This, in turn, impairs their creative ability more. Consequently, while individuals with high internal locus-of-control can be more creative problem solvers in many situations (e.g., Burroughs and Mick 2004), their

creativity ability is likely to be inferior to those with moderate level of internal locus-of-control under mortality salience.

Our propositions were tested in the field and the lab. In study 1, we obtained consumers' new product suggestions ($n=44,864$) submitted to a major beverage company over a period of 174 weeks. Each of these ideas was evaluated by the firm's customers and the average quality of the ideas submitted was calculated for each of the weeks. We also obtained empirical data on the extent to which death was reported in the media during the same period. We ran a regression with the quality of the new product ideas as the dependent measure, the extent to which death was reported in the media as the independent measure, as well as variables controlling for consumer participation level and seasonality effects. Consistent with our proposition, the level of death reporting in the media had a significant negative effect on the quality of new product ideas ($\beta=-3.23$, $t=-2.18$, $p<.03$).

Study 2 examined whether mortality salience (MS) inhibits access to divergent knowledge. Participants ($n=221$) first responded to a locus-of-control scale (Rotter 1966). Following a most commonly used TMT paradigm (Burke et al. 2010), participants were then asked to write down thoughts regarding either their own death (MS condition) or viewing TV programs (control condition). Next, they completed the PANAS (Watson et al. 1988) that captured participants' affective states and served as a delay task (cf. Pyszczynski et al. 1999). Thereafter, participants in both conditions were asked to write down all the place names they could think of with "A" as the first letter. Consistent with the hypothesis that mortality salience inhibits access to divergent information in memory, participants in the MS condition wrote down significantly fewer foreign place names (e.g., Algeria, Aruba, Azerbaijan) than those who in the control condition ($M_{\text{control}}=3.98$, $M_{\text{MS}}=5.09$, $t=2.50$, $p=.01$). Further, a significant interaction effect between the locus of control measure and mortality salience manipulation was found ($\beta=-.86$, $t=2.95$, $p<.005$). To probe the interaction, we trichotomized participants based on their locus-of-control. Contrast analyses revealed that, in the MS condition, participants with high internal locus-of-control wrote down significantly fewer foreign place names than those with moderate internal locus-of-control ($M_{\text{moderate}}=4.96$, $M_{\text{high}}=3.56$, $F=4.96$, $p<.03$); however, the opposite was true in the control condition ($M_{\text{moderate}}=5.02$, $M_{\text{high}}=7.25$, $F=8.27$, $p<.005$).

In study 3, participants ($n=247$) were given a business decision making task—deciding what new business should go into a commercial property where a restaurant went bankrupt (adapted from Goncalo and Staw 2006); Whether participants followed the precedence—using the space for a restaurant again served the DV. The experimental procedure was similar to that of study 2. As expected, the same pattern of interaction effect and contrast comparison results emerged (p 's $<.04$). Finally, inconsistent with an affect-based account, including PANAS scores in the analyses did not affect the findings of study 2 and 3.

Overall, these results shed light on how mortality salience affects information accessibility and creative problem solving, add to the literature non-conscious processes underlying creativity (e.g., Yang et al. 2012; Zhong et al. 2008), and illuminate the role of control beliefs in terror management theories. Moreover, our findings contradict lay intuitions: A survey of mid to senior level executives ($n=30$) at one of the largest logistics firm in the world revealed that the majority (67%, $\chi^2=15.2$, $p<.01$) would put high locus-of-control managers in charge of problem solving, in crisis scenarios (e.g., natural disasters or terrorist attack that resulted in a major loss of life). Our results, however, suggest that those with moderate locus-of-control may be more creative problem solvers in those dire scenarios.

The Impact of Comparisons with Others on Creativity Outcomes

EXTENDED ABSTRACT

From scrapbooking to gift designing, from online co-creation (e.g., “My Starbucks Idea”) to customization (e.g., NikeID customization service), people often undertake the role of designer. The success of these activities requires participants to be creative. Also, these situations often entail a social environment where participants may interact with, and expect evaluation from similar others. While past research has investigated the impact of evaluation expectation from experts (people who are experienced in the domain under investigation) on creativity (for a review, see Amabile 1996), little research has examined the situation where evaluations are expected from similar others who are involved in either the same or a different creativity task. The present research attempts to fill this gap.

Building upon social comparison theory (Festinger 1954), we propose that in a creativity task (e.g., making a card), in order to assess their own abilities, people are likely to compare with others when they can easily see others’ creations, especially when evaluation is expected from others. Further, we hypothesize that comparisons with others occur at different levels depending on the type of creativity task in which others are involved. First, when people are involved in the same creativity task (i.e. people making scrapbook pages in a scrapbooking class), comparisons are likely to occur based on the creativity outcomes, focusing on the dimensions under evaluation (e.g., the theme of the creation and the materials used; Wood and Taylor 1990). We refer to such comparisons as outcome-oriented comparisons. Second, when people are involved in different creativity tasks (i.e. people working under different categories of the same co-creation platform) comparisons are expected to occur based on an individual’s own ability level, focusing on dimensions related to creativity ability (e.g., one’s occupation and experiences in the creativity task). We refer to such comparisons as individual ability-oriented comparisons. We propose a focus on outcome-oriented comparisons is detrimental to creativity because it constrains choice of what and how to create, while a focus on ability-oriented comparisons could leverage creativity because it enhances competition and involvement in the creativity task. Of note, while several early studies have found that constraints enhance creativity in a variety of creativity tasks (e.g., Costello and Keane 2000; Finke, Ward, and Smith 1992; Stokes 2001; Moreau and Dahl 2005), we argue it is unlikely the case in our context since people participating in the creativity task are not explicitly required to follow the creations of others. This argument is supported by Moreau and Dahl’s (2005) finding that only when constraints are both restricted and required, constraints enhance creativity.

Study 1 used a 2 (task type: same vs. different) x 2 (expected evaluation: yes vs. no) between-subjects design. A total of 65 females were run individually with one trained female confederate who was attending as another participant and did either the same creativity task (making a card) as the participants or a different task (sentence scrambling). To assess the creativity of the participants’ card designs, three experts with abundant experience in card-making who were blind to the study hypothesis and treatment evaluated the pictures of the participants’ card designs on six items, including “the card design is creative, distinct, unique, complex, neat, and the materials used are novel” (1 = not at all, 7 = to an extremely extent; items adapted from Amabile 1979). A creativity index was created by averaging the scores of these six items of the three coders ($\alpha = .92$). The results revealed a significant interaction of task type and expected evaluation ($F(1, 61) = 5.13, p < .05$), while both main effects were not signifi-

cant (p 's $> .05$). Planned contrasts indicated that participants were more creative when an evaluation was expected from a person who was doing a different task versus doing the same task ($t(57) = 2.23, p < .05$). No other contrasts were significant (all t 's < 1.6).

Study 2 seeks to obtain evidence that comparison levels drive the interactive effect of comparisons and evaluation expectation on creativity. We will adopt the same procedure of study 1 except: 1) evaluation expectation will always be present and 2) comparison necessity will be manipulated, yielding a 2 (task type: same vs. different) x 2 (comparison necessity: yes vs. no) between-subjects design. We expect that when comparison is necessary, participants will compare with the confederate intensively at the creativity outcome level/individual ability level in the same/different task condition, and hence, participants in the same task condition will be less creative than those in the different task condition. However, when comparison is unnecessary, there will be no comparison at either level, and hence, task type will not influence creativity differently.

Study 3 seeks to obtain support from a real-existing co-creation platform of a company. We will adopt a 2 (task type: same vs. different) x 2 (type of information available: creativity outcome vs. personal ability-related) between-subjects design. Specifically, participants will see creations (vs. personal ability related information) of others from the same (vs. different) contest. The personal ability-related information will include participants’ age, gender, occupation and experiences in the co-creation platform. We expect an interactive effect of the task type and information available on the participants’ creations.

Overall, the proposed research will make a number of contributions. Foremost, this research will add to work on creativity by investigating the impact of similar others on one’s creativity. Second, this research will extend social comparison theory by demonstrating that within the domain of creativity, people can make social comparisons at different levels (i.e. outcome vs. individual ability), and that the outcome of creativity depends on the level of such comparisons. Third, while traditionally, creativity research has focused on the importance of experts when studying expected evaluations, the present research found preliminary evidence that expectation of evaluation from similar others also has a significant influence on creativity. Finally, the expected findings will provide insights into the impact of others consumers on the outcome of creativity in co-creation community.

SESSION OVERVIEW

It appears obvious that marketers create associations between brands and attributes in consumers' minds. However, practitioners' knowledge of how to best do this does not seem to go beyond "pair the brand with an attribute and consumers will learn the association", even if they do not pay much attention (i.e., learning of associations flies under their radar). Not surprisingly, that simple rule does not do well at predicting when which associations will actually be learned. On the other hand, associative learning has not been a mainstream area in academic consumer behavior research. We hope that this session will contribute to increasing interest in this area.

The session addresses two main issues. First, when presenting a brand in conjunction with other stimuli (e.g., images within an ad, another brand, a design element, a product attribute) there are actually many different associations that could be learned, not just a single brand-stimulus association. Thus, we need theory about what the relevant types of associations are and which conditions favor or hinder their learning. Second, the question whether learning of associations does fly under the radar has proven to be difficult to answer. Two papers directly address this issue and all papers provide some perspective on it.

The first two papers ask whether associative learning occurs automatically. The first paper argues that in a conditioning context consumers do have to pay attention in order to learn, but that learning of the association kicks off two separate processes, one requiring attention, the other running off spontaneously without such attentional demands. So it argues that associative learning involves a deliberative stage (i.e., non-automatic) in the sense of requiring attention. The second paper argues that even at an early learning stage, associations can be learned against the will of consumers, that is, the learning is automatic in a sense of it being uncontrollable. These papers raise the question whether these positions are contradictory or complementary.

In the lab, learning is typically studied with brands that are artificially created to have minimal prior associations. However, in the real world, prior associations typically exist. The next two papers study systematic influences of pre-existing associations. Like the first paper, the third paper assumes that consumers draw spontaneous inferences during associative learning. This is studied in the context of co-branding an unknown brand with a known brand (the pre-existing associations). This paper argues that consumers learn more than a simple association between the two brands. Instead, they also infer associations between each brand and the benefits of these brands. The paper shows that when an unknown brand pairs up with a known one, the unknown brand could benefit or suffer, depending on how the brand-benefit associations are affected.

The fourth paper studies the real-world problem of a brand having pre-existing negative emotional associations. The paper assumes that learning positive emotional associations could work as anti-dote, but asks which type of positive emotions would be the most effective anti-dote.

Investigating Deliberative and Spontaneous Inferences as Outcomes of Associative Learning with High versus Low Contingency Awareness

EXTENDED ABSTRACT

In his insightful theoretical critique, De Houwer (2007) advocates an effects-based perspective regarding the meaning of evaluative conditioning (EC): *evaluative conditioning can be defined as an observed change in liking that is due to the pairing of stimuli* (p. 233). Embracing this effects-based perspective is stimulating a host of new research questions about associative learning. This perspective motivates competing theorizing about what causes the transfer of liking that takes place when stimuli co-occur (cf. De Houwer 2007; Jones, Olson & Fazio 2010). Additionally, recent studies featuring "non-evaluative" US's as part of a conditioning procedure are beginning to show effects more diverse than a simple transfer of liking (e.g., Forderer & Unkelbach 2011; Galli & Gorn 2011; Glaser & Walther 2013; Meersmans et al. 2005; Miller & Allen 2012). Said another way, conventional EC methods and procedures are now being utilized to examine a wide array of questions about associative learning beyond simple, direct affect transfer from US to CS.

Our research approaches associative learning as a formidable process that can include the spontaneous inferences people draw from co-occurring stimuli. Referring to the process as "formidable" reflects the theorizing of Kardes, Posavac & Cronley (2004), who assert that spontaneous inferences will have a significant impact on other judgments, yielding attitudes characteristic of the central/systematic route to persuasion rather than the peripheral/heuristic route. This challenges the longstanding view (e.g., Petty & Cacioppo 1981) that conditioning mechanisms only apply in the peripheral route to persuasion.

In the experiment described here we investigated the effects caused with conventional EC procedures on deliberative and spontaneous inferences and implicit and explicit attitudes. To probe subjects' self-generated inferences this experiment included several innovative features: 1) the US's used in this study were selected through extensive pre-testing to possess inference-provoking potential in one specific product domain; 2) spontaneous inferences are assessed through a unique Implicit Association Test (IAT); 3) con-

tingency awareness is treated as an experimental manipulation rather than being assessed post hoc.

The experiment was presented to subjects as a study in how they process visual information as consumers. The EC procedures follow Olson & Fazio (2001) with several alterations. Target stimuli (the CS's) were real but unfamiliar bottled water brands (not Pokemon characters). The US's were visual images of natural scenery chosen through pre-testing to evoke inferences of purity and freshness, rather than general positive words and pleasant pictures. The conditioning procedure had 5 blocks of trials with 86 images presented per block. Numerous filler images appeared in each block. In the conditioning treatment, the brand Isbre was paired with the natural images 8 times per block, for a total of 40 pairings across the 5 blocks. In the control group, Isbre bottled water was paired with neutral images 40 times across the 5 blocks. Contingency awareness (CA) was manipulated through instructions to subjects. For the high CA condition, subjects were told to identify any reoccurring patterns in the images presented and to press the spacebar when a red dot appeared on the screen. In the low CA condition, subjects were told to count backward by 3's from 300 and press the spacebar when a red dot appeared on the screen. The common spacebar task ensures consistent attentiveness in the two conditions (Gibson 2008). Following the conditioning procedure subjects completed separate IAT's to assess implicit beliefs and attitudes; and then measures for explicit beliefs and brand attitudes. A "strong measure" of CA (adapted from Field & Moore 2005) taken at the end of the study was used to validate a successful manipulation.

This experiment provides a test of a key assertion from Kardes et al. (2004) that spontaneous inference formation is more likely when one's motivation and ability to deliberate are high. Subjects' motivation and especially their ability to deliberate are influenced as a result of the contingency awareness manipulation. Moreover, deliberative and spontaneous inferences are tracked via measurement of explicit and implicit beliefs. The data show that with high CA, both deliberative and spontaneous inferences are present in the treatment versus the control group, but they are largely unrelated and each has unique downstream effects on explicit versus implicit attitudes, respectively. Simply stated, deliberative and spontaneous inferences appear to operate in separate systems. In the low CA condition no treatment effects were observed on any of the dependent measures. These findings regarding the necessity of contingency awareness to the observed outcomes are consistent with research on what has recently been labeled "non-evaluative" conditioning ((Forreder & Unkelbach 2011; Kim, Allen & Kardes 1996; Meersmans et al. 2005).

On the Automatic Effects of Advertising: The Uncontrollability of Evaluative Conditioning Effects

EXTENDED ABSTRACT

Changing brand attitudes by pairing brands with affective stimuli is called evaluative conditioning (EC). EC is defined as the change in liking of conditioned stimuli or brands (CS) caused by their pairing with valenced, unconditioned stimuli (US). This basic procedure of pairing brands with positive stimuli lies at the heart of branding and advertising strategies and is therefore of central importance to consumer research (Shimp, Stuart, & Engle, 1991; Stuart, Shimp, & Engle, 1987; Sweldens, van Osselaer, & Janiszewski, 2010). Whereas there is no doubt that EC effects can be established through conscious propositional reasoning, a long-standing disagreement in the literature concerns whether there can also be a contribution of an unconsciously operating automatic process in the attitude

acquisition (Hofmann, De Houwer, Perugini, Baeyens, & Crombez, 2010; Sweldens, et al., 2010). A process is defined as automatic if it occurs in the absence of awareness, is uncontrollable and is not influenced by intentionality or processing resources (Bargh, 1994).

In a recent contribution (Hütter, Sweldens, Stahl, Unkelbach, & Klauer, 2012) we showed that previous methods were biased towards the conclusion that EC effects require conscious awareness of the CS – US pairings. We developed a new method based on the process dissociation procedure (Jacoby, 1991), providing evidence that EC can, in fact, establish attitudinal effects without explicit memory for the pairings. In the current research, we present a new method to assess the automaticity of the learning process by focusing on the *controllability* of the EC effect. Specifically, we developed a process dissociation procedure that allows dissociating the effects of controlled processes from uncontrolled processes during the conditioning phase. In the *standard condition*, participants are informed that the USs are informative about the CSs. Participants thus believe that the valence of the USs can be trusted to form an attitude about the CSs. In order to separate controllable from uncontrollable processes involved in this task, a *reversal condition* was designed. The reversal instructions still stated that the valence of the USs is informative for the CS, but that it should actually be opposite in valence from what is presented. Participants thus believe that the valence of the US needs to be reversed to form accurate attitudes about the CS. To the extent that the valence transfer in an EC procedure is controllable, participants should be able to reverse the US valence in the generation of their CS attitudes. To the extent that the valence transfer is automatic and uncontrollable, participants will not be able to execute this reversal. Hence, the reversal condition is implemented so that controllable and uncontrollable processes lead to differential evaluations of the CSs.

We first conducted two experiments which implemented the standard and reversal conditions in a between-subjects (Experiment 1) and a within-subject (Experiment 2) design. A multinomial processing tree model was then applied to distinguish the relative contributions of controllable valence transfer (estimated by the *c*-parameter) from automatic uncontrollable valence transfer (estimated by the *u*-parameter). We used both types of designs as an opportunity for parameter validation. In Experiment 3, we increased participants' motivation to control the effects of affective stimuli on brand attitudes by offering financial rewards for complying with task instructions (i.e., successfully applying the valence of the affective stimuli in the standard condition and reversing it in the reversal condition). Experiment 4 features a cognitive load manipulation to validate the parameter estimates. A controllable process is hypothesized to be susceptible to cognitive load. An automatic, uncontrollable process on the other hand should not be affected by reductions in cognitive processing capacity.

In all experiments we found a significant *u*-parameter, which specifies an automatic uncontrollable EC effect on attitudes. Moreover, the *u*-parameter estimates did not differ between experiments, increasing confidence in their robustness. While the controllable (*c*) component was sensitive to the complexity of the conditioning phase, task experience, and the availability of cognitive resources, the automatic uncontrolled (*u*) component was insensitive to any of these procedural factors as well as participants' motivation to exert control over the acquisition process. Interestingly, the explicit evaluative ratings of the CSs do indicate a reversed EC effect in the reversal condition (albeit smaller in size than the normal EC effect in the standard condition). A researcher looking only at these evaluative ratings would have no means to distinguish the controllable from the uncontrollable components in the emergence of the total EC effect.

As these explicit evaluative ratings do indicate a reversed EC effect in the reversal condition, the researcher would probably – erroneously – conclude that EC effects are under conscious control.

Our demonstration of uncontrollable learning in EC has important implications for the study of branding and advertising in general, and for ethicality questions in marketing in particular. Our experiments show that even when consumers believe that a particular advertisement is misleading, they cannot help but be influenced by the affective stimuli included in the commercial. This raises a serious problem for the protection of consumers from unwanted influence. In addition, our research has important implications for dual process theories of learning, suggesting that associative and propositional processes are qualitatively distinct despite recent claims to the contrary (Kruglanski & Gigerenzer, 2011; Mitchell, De Houwer, & Lovibond, 2009).

Riding Coattails: When Co-branding Helps versus Hurts Less-known Brands

EXTENDED ABSTRACT

New brands often partner with established brands to leverage existing associations. Conventional wisdom holds that such partnerships disproportionately benefit the less-known (Aaker and Keller 1990; Boush and Loken 1991; Broniarczyk and Alba 1994; Levin and Levin 2000). A popular account for this is the Human Associative Memory (HAM) model, according to which an unknown brand is relatively devoid of associational content and is therefore a blank slate ready to receive the presumably positive associations from an established brand. Although there is intuitive appeal to this account, the HAM model presumes a static association between entities in which the consumer need only learn that the two brands are partnering together. Most consumer exposures to co-branding, however, are much more dynamic since the consumer learns not only of the existence of a partnership, but also of expected product benefits stemming from the partnership. When these dynamic effects are incorporated, research on consumer associative learning has found that the transfer of associations can deviate from the predictions of the HAM model.

Associative learning models predict that consumers will not simply strengthen the association between the component co-brands, but each component co-brand may also interact when forming associations with the outcome (e.g., the benefit the new co-branded product delivers). This cue interaction may lead the two brands to become asymmetrically associated with the benefit. Competitive cue interaction effects can bias consumers' predictions of which product features predict product performance for a given brand (e.g., Cunha, Janiszewski, and Laran 2008; Cunha and Laran 2009; van Osselaer and Alba 2000). In co-branding arrangements, competitive cue interaction could ironically cause the established brand to dominate associations with the benefit, thus undermining the advantage of co-branding for the less-known brand.

We draw upon the animal learning literature to propose that facilitative cue interaction effects are also possible (Urcelay and Miller 2009). In contrast with cue competition effects, facilitative effects would actually enhance the strength of association between a less-known brand and the outcome and thereby benefit the less-known brand. We propose that time delay between the presentation of cues (brands) and outcomes (product features) influences the breadth of stimulus generalization such that narrower (broader) generalization operates when time intervals are shorter (longer) time delays. When generalization is narrower, effects consistent with cue competition are predicted because little is generalized about the less-known

brand when it co-brands with a well-known brand. When generalization is broader, effects consistent with cue facilitation are expected because more is generalized about the less-known brand when it co-brands with a well-known brand.

In Experiment 1 participants were presented with a series of three learning trials. In the *compound condition*, an unknown breakfast cereal brand was paired with a well-known cereal brand (Kellogg's) as stimuli for the launch of three new co-branded cereals (one per learning trial), with each cereal delivering a different level of dietary fiber content per serving. The *elemental condition* replicated the *compound condition* with the key difference that the unknown cereal brand was presented alone in each of the three learning trials (i.e., no co-branding). In each trial, following presentation of the brand(s), subjects were given feedback about the amount dietary fiber each cereal delivered. In the *control condition*, no dietary fiber information was presented. Subjects were then asked to indicate the likelihood they would try a new cereal offered by the unknown brand. In the control condition, no differences in willingness to try the new brand were observed as a function of whether the new brand was presented in a co-branded format versus presented by itself. After receiving feedback about the cereals, however, subjects were less likely to try the new brand when it was presented in a co-branded format than when it was presented by itself, a cue competition effect.

Experiment 2 used time-delay as a moderator of stimulus generalization to demonstrate both cue competition and cue facilitation. When there was no delay between presentation of brand and outcome information, cue competition and its negative effects for the less-known brand were replicated. With a 5-second delay, however, participants reported greater willingness to try the less-known brand when it was partnered with the well-known brand, a facilitative cue interaction. Furthermore, this result suggests a single process account that can explain when co-branding helps versus hurts less known brands.

In Experiment 3, we verify that a focus on learning co-branding outcomes produces benefits for less-known brands owing to facilitative cue interaction effects and not to a HAM process. Experiment 3 manipulated whether the well-known brand has expertise in the product category, and the critical dependent measure was willingness to try a new product offered in a different category, a learning transfer task. Subjects learned information about the quality chocolate produced by an unknown and a well-known brand. They were then asked their willingness to try a sugar cookie produced by the less-known brand (a transfer task requiring stimulus generalization). In the no-delay condition, the negative effect of co-branding was again replicated. In the delay condition, however, the effect of co-branding was positive further supporting an underlying cue-interaction process.

From a theoretical standpoint, identifying the conditions under which cue interaction is competitive versus facilitative allows us to unify the diverging findings from the co-branding literature under a single theoretical model, rather than a dual-process account. From a practical standpoint, a better understanding of cue interaction effects will help marketers learn when to expect a less known-brand to strengthen (vs. weaken) its position after co-branding with a well-known brand.

Emotional Counter-Conditioning of Brand Attitudes

EXTENDED ABSTRACT

We investigate a situation when a brands' image suffers from negative emotional associations, such as for the Škoda car brand in the UK, which presumably was associated with embarrassment

(Srivastava & Malaviya 2003), or McDonald's, which might have been associated with disgust after a rumor that its hamburgers contained worm meat. How can such a brand improve its image? Fixing the deficiencies that initially gave rise to the negative emotional associations and communicating these objective improvements is often insufficient (Tybout, Calder, and Sternthal 1981), presumably because the emotional associations linger. Changing the brand name may at times solve the problem, but is often not feasible. From a psychological perspective, is there an alternative?

Building on psychotherapy, we propose emotional counter-conditioning as a "therapy" to improve brand image. Intuitively speaking, if a brand elicits negative feelings, eliciting positive feelings in the presence of the brand may result in "re-associating" the brand with these positive feelings, and that may be an effective way to improve attitudes toward the brand. Surprisingly, the experimental evidence that emotional meaning beyond valence can be conditioned focuses on just two negative emotions, fear and disgust (see Maren 2001; Mason and Richardson 2010; Mineka and Oehlberg 2008). Thus it is not clear whether emotional meaning in general can be transferred by means of conditioning, and for counter-conditioning there is even less evidence. Even more importantly, we are not aware of any research that develops a general theoretical position as to the type of emotion that would be most effective for counter-conditioning. Building on appraisal theories of emotions (cf. Clore, Schwarz, and Conway 1994), we develop such position. We introduce the concept of *specific counter-emotions*, emotions that differ in valence but share a similar appraisal structure. For example, the pleasure from eating food, i.e., sensory pleasure, shares a similar appraisal structure with the disgust one feels from tasting a spoiled food item. For instance, both attribute the negative feeling to a sensory event, here the taste of food. The joy one feels when experiencing a pleasurable event with friends, i.e., (social) joy, shares a similar appraisal structure with the sadness one feels when losing a friend. According to our *main hypothesis*, tainted brand attitudes can be more effectively improved through conditioning by pairing the brand with specific counter-emotions (specific counter-conditioning) rather than with other positive emotions (nonspecific counter-conditioning).

In a conditioning experiment we manipulated attitudes toward spring water bottles labeled with different brand names. In a first stage we initially paired these brands with images eliciting negative emotions (disgust, sadness). In a second stage, we counter-conditioned these brands with positive emotions (sensory pleasure, joy) and measured brand attitudes one week later. As predicted, specific counter-emotions were most effective at improving brand attitudes. That is, attitudes toward a "disgust brand" were improved more when counter-conditioned with sensory pleasure than with joy. Contrary, attitudes toward a "sadness brand" were improved more when counter-conditioned with joy than with sensory pleasure. Thus, the concept of specific counter-emotions provides a guideline managers can use to select a positive emotion as "anti-dote". They can then use specific counter-conditioning to complement objective improvements of deficiencies.

As an additional finding, the superiority of specific counter-conditioning replicated when we attempted to deteriorate positive brand attitudes with negative emotions (e.g., as in anti-smoking ads). If smoking is motivated by seeking a feeling of confidence or pride by associating with a respected group who smokes (e.g., peers, cool cowboys, actors), the common strategy of eliciting disgust or fear of disease is unlikely to counter feelings of pride. Our theorizing indicates that ads provoking embarrassment and shame may be more effective in undermining the motives behind teen smoking.

Emotions are multi-dimensional constructs, but respondents have difficulty articulating these dimensions. They also have difficulty articulating the extent to which they associate specific emotions with a brand. We addressed this difficulty by having our respondents provide similarity judgments of brands (counter)conditioned with different negative and positive emotions, which is easier for them. From these similarity judgments we derived perceptual maps and uncovered emotional dimensions, including brand attitude.

SESSION OVERVIEW

The objective of this session is to increase our understanding of prosocial behavior. About two thirds of all Americans engaged in prosocial behavior in 2012 by either giving money or volunteering their time to help others. However, this number might be a conservative estimate because a substantial number of prosocial behaviors are undocumented, such as giving money to homeless people or buying a particular brand from a company that donates some of the proceeds versus a company that does not. Opportunities to engage in prosocial behavior are ample but for most people resources are limited. In this session, the papers seek to address the following question: How do people choose among prosocial opportunities and how do they feel after the behavior was carried out?

Understanding prosocial behaviors and their consequences is important and can benefit both organizations and individuals in making better decisions. In a world where hunger, disease, and impoverishment are still prevalent, charities and other organizations should weave prosocial activities into their functioning and increase public appeal. Individuals, on the other hand, can engage in prosocial behavior with many charities and organizations, and therefore should learn how to best choose among these opportunities.

With four papers, this session addresses these issues as it integrates various research perspectives to identify factors affecting the entire decision making process, starting with how consumers choose where to give, through how consumers feel after they give, to how others perceive those who give. The papers complement each other in that they examine different aspect of prosocial behavior using different methodologies including analysis of archival data and laboratory studies with some innovative procedures.

Sonenshein, Herzenstein, and Dholakia show that social ventures posted on Kickstarter.com increase their likelihood of getting funded if they offer consumers very few or many donation choices, thus providing an alternative perspective to the "choice overload hypothesis". The authors show that backers of those ventures engage in intuitive, rather than rational, decision making. Cryder, Botti,

and Simonyan further examine donation choices and show that despite believing a cause to be low priority people prefer to give to that cause, over a more pressing cause, because the former is more appealing and personally satisfying to them. While the extent of a cause's neediness is valued as more important, actual donations reveal that the cause's attractiveness is actually more important. Rudd, Aaker, and Norton ask: How can we maximize the happiness experienced by people who engage in prosocial behaviors? These authors show that framing the goal of a prosocial act concretely rather than abstractly increases the giver's happiness because the giver focuses on the logistics of achieving the act versus the broader meaning of the act itself. Finally, Berman, Levine, Barasch, and Small show that when people engage in a prosocial behavior privately but then brag about it publicly (on Facebook), they are considered more generous, compared with those who do not brag. However when people engage in a prosocial behavior publicly and also brag about it, they are considered less generous, compared with those who do not brag.

Crowdfunding to Make a Difference: The Role of Choice in Funding Social Ventures

EXTENDED ABSTRACT

In recent years, the Internet has allowed individuals across the globe to contribute to and even actively participate in ventures influencing pressing social issues. The growing prevalence of online venues that support social issues is due in part to so-called crowdfunding organizations that use the Internet to bring together geographically dispersed individuals to make small contributions to ventures. By widening the pool of potential contributors and matching entrepreneurs with potential backers across the globe with minimal transaction costs, crowdfunding has altered the process of obtaining resources. But this model of resource acquisition comes with some significant challenges. For example, ventures must compete with numerous others from all over the world for attention. There is also greater potential for fraud because of limited regulation, a fact that makes the decision making process more difficult for potential contributors (Herzenstein, Sonenshein, and Dholakia 2011; Sonenshein, Herzenstein, and Dholakia 2011).

Given limited regulation but wider participation, a key question is how potential contributors decide which ventures to support, especially when most are developed and pitched by unknown and unproven organizers. Early analyses of this question (Edwards 1954; Harbaugh 1998) applied a rational utility maximizing framework supporting more choices ad infinitum, but research over the past decade has convincingly placed boundary conditions on this economic argument. Based on individuals' limited cognitive abilities, this growing body of research has found that an overload of choices can lead to diminishing returns (Iyengar and Lepper 2000; Schwartz 2005). Scholars embracing this "choice overload hypothesis" (Scheibehenne, Greifeneder, and Todd 2010) have found that decision making tends to follow an inverted U-shaped relationship such that initially more choices lead to favorable processes and outcomes up to an inflection point beyond which additional options lead to diminished outcomes for the decision maker.

Although the choice overload perspective offers an important qualification to the economic decision making paradigm, both perspectives assume that individuals rationally process information, and differ only on the role of cognitive limitations in decision making.

But for social ventures, it is not clear whether economic assumptions about rational decision making best explain how contributors allocate financial resources. Indeed, some research suggests that individuals are less prone to follow a calculative, rational mindset when considering support for social issues (Ashford and Barton 2007; Sonenshein 2007, 2011). Individuals may instead adopt a prosocial motivation in which they desire to have a positive impact on other people, groups, or organizations (Grant 2007). We argue that this focus on “the other” fundamentally alters how contributors make decisions about funding social ventures, thereby requiring new theory development beyond economic models of choice and the choice overload hypothesis.

To that end we develop and test theory we label “the intuitive leader impact hypothesis”. This hypothesis posits that individuals abandon the deliberate information processing approach, instead relying on intuitive judgments about a venture’s leader. We suggest that contributors focus less on maximizing their own utility and more on making a difference for others. Since most people who wish to help others do it through donations to organizations, charities, or ventures, the competency of the organization and its leaders is of utmost important. We hypothesize that organizers of social ventures offering potential donors few or too many donation choices will be viewed as more competent because they either carefully designed the collection of choices they offer or they exerted significant effort to offer something for everyone, respectively. As a result, these ventures are more likely to get funded and be successful in the longer term when compared to those offering a medium number of choices. This pattern represents a flipping of the choice overload hypothesis. We test these predictions in three studies.

In study 1, we used data scraped from Kickstarter.com, currently the largest online crowdfunding organization. Our dataset includes over a thousand ventures posted on kickstarter.com during July and August 2011 that were coded by trained RAs for whether they have a social mission or not. Controlling for the funding goal and other financial measures we show that ventures with a social mission are more likely to fund when they offer few or many funding choices—a U-shaped relationship between the number of choices and decision making outcomes—thus reversing the choice overload hypothesis. Projects that do not have a social mission follow the choice overload hypothesis—an inverted U-shaped relationship between the number of choices and the likelihood of funding. In study 2, we replicated and extended our field-based findings using a controlled laboratory experiment. Building on a real venture from kickstarter.com we described a band that wishes to raise money to record a new album. We manipulated whether the venture has a social mission (donating some of the proceeds to poor children) or not and the number of donation choices it offers (2, 4, 6, 8, or 10 choices), and asked participants to split \$500 between this venture and future ventures. We further asked participants a series of measures aiming to assess the competency of the venture’s leader. We replicate the results from study 1 and show that participants made more intuitive (faster) decisions for the social venture, and that perceptions of the venture leader’s competency mediate the effect of the number of donation choices on funding. Finally, in study 3, we surveyed Kickstarter venture leaders whose ventures have a social mission to examine the relationship between the number of choices leaders offered potential contributors and the venture’s success one year after launch. We find that leaders of ventures with few or many donation choices described the status of their ventures as being more successful than leaders of ventures with average number of choices.

To summarize, our mixed methods approach helps ground a new perspective on choice theory by showing how intuitive processes

prompted by concerns for others challenge traditional economic theory and invert the choice overload hypothesis.

Giving to What We Want Instead of to What We Should

EXTENDED ABSTRACT

There is a puzzling phenomenon in charitable giving that people give a lot of money to seemingly low-priority causes (e.g., sports fundraisers) while other highly pressing causes remain severely underfunded (e.g., water sanitation in destitute countries). In this project, we hypothesize that a fundamental reason why needy causes are ignored is because of a need to self-enhance via others’ positive attributes. Therefore, despite a strong and widespread belief that the neediest causes should receive priority, causes that are attractive or appealing can triumph over more needy alternatives.

Study 1 investigated people’s explicit preferences about the importance of neediness in resource allocation decisions. Two-hundred and twenty-eight participants generated an open-ended answer to the question: “If multiple individuals needed help and you were deciding which one to donate to, what would be the single most important thing you would consider when deciding which person to donate to?” Forty-six percent of participants spontaneously answered that neediness was the most important criterion. The next most popular criterion was the impact of the donation, receiving only 8% of responses; all other possible answers received a lower percentage of endorsement.

Study 2 investigated preferences for needy versus attractive alternatives in real allocation decisions. Participants viewed pictures of four girls who had received successful cleft palate surgery from the charity Smile Train. A pre-test verified that one of the girls, Angelica, was judged to be significantly more attractive or “cute” ($p < .0001$) and significantly less needy ($p < .0005$) than the other three girls.

In the experiment, participants were informed that each of the girls needed financial support to move on with their lives post-surgery. Participants selected one of the girls to support and were told that the researchers would send \$1 on their behalf to support the girl that the participant chose. The experiment included 3 conditions: 1) a control condition in which participants were simply asked to choose a girl to support, 2) an “Attractiveness” condition in which participants were asked to explicitly rate the cuteness of each girl before making their allocation decision, and 3) a “Neediness” condition in which participants were asked to explicitly rate the perceived neediness of each girl before making the allocation decision.

Participants exhibited a significant preference for allocating to Angelica, the cutest and least needy girl, over all other girls in the Control condition ($p < .05$) and the Attractiveness condition ($p < .01$). Results were significantly different, however, in the Neediness condition; in this condition, participants chose Angelica at a rate equal to that at which the other girls were chosen ($p = .30$) and were significantly less likely to choose Angelica than in the Control condition ($p < .05$).

Study 3 tested how self-involvement influences preferences for appealing options. Participants either indicated which child they would choose to sponsor themselves (self condition) or indicated which child they would advise an anonymous donor to sponsor (advisor condition). When participants chose for themselves, they exhibited a significantly greater preference for Angelica than when they advised others ($p < 0.01$).

Study 4 manipulated the presence of choice to further investigate the idea that self-enhancement underlies the preference for appealing options. Research has shown that choice is often used as a means to

express one's own self (Iyengar 2010) and, at least in the Western world, can be seen as a way to define oneself as an individual (Markus and Schwartz 2010). In a 2x2 experimental design, participants viewed either post-surgery (attractive) or pre-surgery (unattractive) photos of a mixed-gender group of Smile Train children. Participants then chose to allocate to a particular child (choice condition) or were randomly assigned to allocate to a particular child (no-choice condition). Subsequently, participants were asked how much they would donate to Smile Train. We observed an interaction such that participants in the no-choice condition reported giving equivalent amounts to Smile Train regardless of whether the children they allocated to were attractive or unattractive. However, participants in the choice condition, who had an opportunity to boost positive self associations via their choices, gave more when the children were attractive compared to unattractive.

Finally, because choices based on neediness may not satisfy donors' need for self-enhancement from their generous acts, we hypothesized in Study 5 that explicit reminders of neediness may have perverse consequences on generosity in the long run. Participants were randomly assigned to the Control and Neediness conditions from Study 2, and also completed a follow-up measure that asked participants how likely they would be to donate to the charity Smile Train in one year. We once again observed that while Angelica was preferred in the Control condition ($p < .0001$), this preference disappeared once participants explicitly considered neediness before the resource allocation choice ($p = .55$). When asked about donations in one year, however, participants indicated that they would donate significantly less if they had been in the Neediness condition compared to if they had been in the Control condition ($p < .05$). Considerations of neediness therefore appear to be a double edged sword—they increase evenhanded allocations in the short term but decrease overall kindness in response to future requests.

One of the most intense debates in the history of Social Psychology centered around the question of whether human generosity was altruistic or egoistic at its core (Batson, 1991; Cialdini et al., 1987). The current project sheds light on this issue. Although people carry with them an explicit belief that neediness *should* triumph all in resource allocation, actual judgments of resource allocation often are based on what we *want* to give to--appealing and attractive options. Although people can behave in a truly altruistic fashion, such as when focusing on others' neediness, doing so appears to squelch future generosity because it does not satisfy a primary motivation to self-enhance via appealing causes.

Leave Them Smiling: How Concretely Framing a Prosocial Goal Creates More Happiness

EXTENDED ABSTRACT

A growing body of research has demonstrated that behaving prosocially creates a "helper's high" (Luks, 1988) and increases subjective well-being (Anik et al., 2009; Lyubomirsky et al., 2004; Post, 2005; Thoits & Hewitt, 2001). But, do certain prosocial pursuits more effectively increase personal happiness? We explore this question, examining one factor linking prosocial acts and happiness: How the goal of the act is framed.

Goals can be framed at various abstraction levels (Emmons & Kaiser, 1996; Oettingen & Gollwitzer, 2001), and striving for concrete (versus abstract) goals has been correlated with less psychological distress and greater well-being (Carver et al., 1988; Carver & Scheier, 1990; Emmons, 1992). Building upon these results, we hypothesize that prosocial acts lead to greater giver happiness

when the act's goal is framed concretely (e.g., make someone smile) versus abstractly (e.g., make someone happy).

Why might a prosocial goal's abstraction level influence personal happiness? When a goal is concretely-framed (versus abstractly-framed), one's expectations of achieving the goal may be better calibrated (due to greater focus on the "how" and logistics versus the "why" and broader meaning of goal-directed actions; Torelli & Kaikati, 2009; Vallacher & Wegner, 1987, 1989). Moreover, the outcome of goal-directed actions may be perceived more favorably (due to concrete goals having clearer standards of success; Emmons, 1992; Locke & Latham, 1990). Importantly, these characteristics should enable concretely-framed (versus abstractly-framed) prosocial goals to shrink the gaps between people's expectations of success and reality (Kopalle & Lehmann, 2001; Ojasalo, 2001; Schwartz, 2005; Walker & Baker, 2000)—and smaller expectation-reality gaps are associated with greater satisfaction and well-being (Davis, 1981; Michalos, 1985; Schwartz, 2005; Thomas, 1981; Vermunt et al., 1989). Therefore, we predicted that concretely (versus abstractly) framing a prosocial goal increases personal happiness by reducing the gap between givers' expectations of accomplishing the goal and the actual outcome of their goal-directed acts. Because people routinely incorrectly predict how much happiness things in life will bring (Aknin et al., 2009; Brickman et al., 1978; Buehler & McFarland, 2001), including the hedonic benefits of performing prosocial acts (Dunn et al., 2008), we also predicted that people would not recognize that concretely-framed (versus abstractly-framed) prosocial goals cultivate more personal happiness.

Experiment 1 instructed participants to perform an act of kindness within 24 hours. Manipulating the abstraction of the prosocial goal of the act, participants randomly assigned to the concrete [abstract] condition were asked to do something to make someone else smile [happy]. Twenty-four hours later, in a follow-up survey, participants reported the extent their act created happiness in their own life, how well the outcome of their act met their expectations for accomplishing their assigned goal (i.e., their expectation-reality gap), and the specificity of the goal they had in mind when performing their act.

Manipulation checks confirmed concrete (versus abstract) condition participants had a more specific goal in mind when performing their act. Two ANOVAs then revealed concrete (versus abstract) condition participants felt the outcome of their act better met their goal achievement expectations and felt their act created more personal happiness. Importantly, a mediation analysis demonstrated that these shrunken expectation-reality gaps are what increased the personal happiness of those in the concrete (versus abstract) condition.

Experiment 2 ruled out several alternative accounts and began investigating the accuracy of people's prosocial goal predictions. Participants were pairs of friends—one friend served as the "giver," the other the "receiver." Placed in separate rooms, the friends answered questions about their friendship and were then told they would get a three-minute-long break (in a room with their friend) before completing another survey (in separate rooms). At this time, givers randomly assigned to the concrete [abstract] condition were asked to do something to make their friend (i.e., the receiver) smile [happy] during this break. After the break, the givers reported their current happiness, their beliefs (before the break) about their assigned (i.e., how challenging it would be, their ability to accomplish it, and their expectations for succeeding at it), how well their act actually met their expectations for accomplishing their assigned goal, and their perceptions of the size and concreteness of their act. The

receivers reported their current happiness and their happiness (and smiling) during the break.

Manipulation checks confirmed givers in the concrete (versus abstract) condition viewed their prosocial goal as more concrete (versus abstract). ANOVAs then revealed concrete (versus abstract) condition givers felt happier after performing their act and that the outcome of their act better met their expectations. As in Experiment 1, a mediation analysis demonstrated that their increased personal happiness was driven by these smaller expectation-reality gaps. Additional ANOVAs showed these effects could not be explained by differences in the type of receiver (e.g., a friend), closeness of the giver-receiver relationships, givers' perceptions of their act's size, or receivers' actual happiness (or smiling) during and after the break—as these factors did not differ across conditions. Three final ANOVAs revealed givers in both conditions had (before the break) viewed their goal as equally challenging, their ability to accomplish it equally great, and their expectations for success equally high—initial indications that people would not recognize the hedonic advantage of pursuing concretely-framed (versus abstractly-framed) prosocial goals.

Experiment 3 directly tested whether people would correctly predict which prosocial goal was better for personal happiness. Participants, assigned to the concrete or abstract condition, imagined taking part in Experiment 1 and predicted their responses to the follow-up survey. Subsequently, the two prosocial goals from Experiment 1 were described, and participants rated each goal (from 1-100) on how much personal happiness it would create.

An ANOVA revealed concrete (versus abstract) condition participants did not correctly predict their act would create more personal happiness. Furthermore, repeated measures ANOVAs, with the goal ratings as the within-subjects factor, revealed participants (within and across conditions) incorrectly rated the goal of making someone happy (versus smile) as able to create more personal happiness.

Conclusion. We extend the prosociality literature, showing that, contrary to people's intuitions, an act of kindness with a concretely-framed (versus abstractly-framed) goal leads to greater personal happiness—an effect driven by shrunken expectation-reality gaps.

The Braggart's Dilemma: On the Social Rewards and Penalties of Advertising Prosocial Behavior

EXTENDED ABSTRACT

Public displays of generosity are ubiquitous. People often signal their generosity to others by wearing t-shirts or announcing their good deeds to wide audiences on social networking sites. One reason it is surprising to see so many people advertise their good deeds is that there exists a strong norm to be modest about prosocial behavior. Further, individuals go to great lengths to communicate to that their good deeds are not motivated by self-interest (Ariely, Bracha & Meier, 2009). However, successfully demonstrating generosity has positive returns on reputation (Flynn, 2003), making it appealing to publicize one's good deeds to others.

We examine the role of bragging about prosocial behavior on attributions of generosity. We expect that bragging communicates that an actor has done a good deed, but also signals that the actor was motivated by selfish desires. Thus, an individual whose good deeds are unknown to others will be seen as more generous when he brags, because it informs others of his prosocial behavior. However, an individual whose good deeds are already known to others will be seen as less generous when he brags, because bragging no longer

provides new information about his behavior, and instead signals that his actions were motivated by reputation concerns.

In Study 1a, participants ($N = 201$) were asked to imagine running into a coworker named Jeff around town. During their walk, they passed by a group taking donations for a local children's hospital. We then manipulated (a) whether the participant saw Jeff donate to the charity and (a) whether Jeff later publicized his donation on Facebook. Participants then rated Jeff on a 12-item charitable credit measure, which included items such as how moral, nice, and altruistic is Jeff. A two-way ANOVA revealed a significant Donation Visibility X Facebook Post crossover interaction ($p < .001$). Participants in the Unknown condition gave Jeff more charitable credit when he bragged ($M = 5.38$) than when he did not brag ($M = 4.63$, $t(99) = 4.65$, $p < .001$). However, when the donation was Known to others, participants gave Jeff less credit when he bragged ($M = 5.24$) versus when he did not brag ($M = 5.72$, $t(98) = -2.66$, $p = .009$).

Study 1b tests the robustness of these results using a more subtle form of bragging. Specifically, we manipulated whether Jeff wore a button that advertised his donation to charity or one that supported his college basketball team. We replicate all results.

Studies 2 and 3 show why bragging about prosocial behavior is different from other forms of bragging. When prosocial behavior is already known, bragging becomes self-defeating: by telling others of their good deeds, a braggart is seen as having selfish motives which undermines the perception that he is generous. However, bragging about personal achievements and gains for the self do not undermine perceptions of motivation; for self-interested pursuits, image concerns are not directly at odds with perceptions about personal qualities. Thus, we expect that—unlike prosocial behavior—bragging about self-interested pursuits will have no effect on perceptions of the trait conveyed in a brag.

In Study 2, participants ($N = 203$) imagined running into a colleague named Jeff. We manipulated (a) whether Jeff just finished volunteering for charity or running a 10k race and (b) whether he bragged about his achievement on Facebook. Participants then rated (a) Jeff's intrinsic motivation for helping others [running in the race] and (b) how much charitable [athletic] credit Jeff deserved for his accomplishment. In order to compare credit across conditions, we first standardized our credit measure across the two activity types. A two-way ANOVA revealed a significant Activity Type X Facebook Post interaction, $p = .011$. In the Prosocial condition participants rated Jeff as being less charitable when he bragged ($M = -0.31$) than when he did not brag ($M = 0.33$), $t(100) = -3.38$, $p = .001$. However, in the Athletic condition, participants did not evaluate Jeff's athleticism differently when he bragged ($M = 0.04$) versus when he did not brag ($M = -0.04$), $t(96) = 0.72$, $p = .72$.

We also ran a moderated mediation analysis using the bootstrap procedure to test the process by which bragging affects credit. We predicted that in the Prosocial condition, a braggart will be seen as less intrinsically motivated to help which will reduce the credit he receives. However, in the Athletic condition, there will be no such mediation. Consistent with our hypothesis, we find a significant indirect effect for the Prosocial condition (Indirect Effect = -0.66 , $SE = 0.15$; 95% C.I. = $[-0.97, -0.39]$), but not for the Athletic condition (Indirect Effect = 0.00 , $SE = 0.14$; 95% C.I. = $[-0.26, 0.27]$).

It is possible that participants felt that running a 10k required more effort than volunteering, and bragging is more acceptable for high effort behaviors. In Study 3, ($N = 203$) we hold effort constant by comparing bragging about spending money on oneself versus bragging about spending money on the self. Specifically, we manipulated (a) whether Jeff donated \$60 to charity or purchased a \$60 tennis racket and (b) whether he bragged about it on Facebook.

We then proceeded in the same manner as in Study 2, and replicate our previous findings. Specifically, a two-way ANOVA revealed a significant Expenditure x Facebook Post interaction, $p = .041$. In the Spending on Others condition, participants rated Jeff as being less charitable when he bragged ($M = -0.23$) than when he did not brag ($M = 0.23$), $t(99) = -2.37$, $p = .02$. However, in the Spending on Self condition, participants did not evaluate Jeff's athleticism differently when he bragged ($M = 0.05$) versus when he did not brag ($M = -0.05$), $t(101) = 0.55$, $p = .59$. Additionally, we replicate the moderated mediation results from Study 2.

In sum, bragging communicates that an individual has acted generously, but also signals that the braggart was not motivated by pure intentions. For any prosocial behavior, this illuminates the fundamental tension between doing good and appearing good.

SESSION OVERVIEW

Consumers' lives are increasingly intertwined with technology (Evans 2003). As smartphones, tablet computers, and access to mobile broadband continue to diffuse throughout the population, constant connectivity has become a way of life.

The title of this session suggests that, as consumers spend more and more time with various forms of media, and as those media become more encompassing, interactive, and immersive, consumers' lives have an ever-greater virtual component. Consumers spend hours in massively multiplayer online games, sleep with their iPhones so as not to miss a single text, constantly manage their online identities via Facebook posts, and create avatars in online worlds like *Second Life*.

Clearly, consumers perceive multiple beneficial outcomes emanating from their virtual lives, or their participation would not be so intense. However, it is also apparent that the consumption of various forms of entertainment media that can nurture consumers' "virtual lives" also can sometimes have negative consequences in "real life". The mental health community, for example, is increasingly concerned with consumer addictions to videogames, devices such as smartphones, and social networking sites like Facebook.

The purpose of the session is to explore several instances of consumers' virtual lives broadly construed in order to gain more insights into the positive and negative consequences of this phenomenon. First, Russell and McQuarrie present the results of a series of experimental studies funded by NIAAA to investigate the role of narrative transportation (i.e., immersion into the story) in teens' reactions to TV programming featuring underage alcohol use. They find that narrative transportation is a powerful mediator of participants' attitudes toward drinking, beyond mere emotional reactions and identification with characters. Kuo reports the results of a qualitative depth interview study of escapism in the context of video games. He finds positive short-term consequences such as stress relief and self-esteem repair but also hints of long-term negative consequences of excessive and prolonged participation in escapist activities. Nardini, LeBoeuf & Lutz introduce the concept of "implicit distraction" to

explain the deleterious effect of excessive picture taking on enjoyment of an experience. Two experiments show that picture taking damages enjoyment, yet is not perceived by participants as a distraction. Finally, Schau, Gilly & Celsi use archival analysis and depth interviews to illuminate how consumers use brands as virtual connections during times of separation. Working with military families, they develop a typology of roles that brands can fulfill when serving as virtual proxies for safety and home.

Taken together, the papers in the session address the questions: How do consumers create and nurture their virtual lives? What are the tradeoffs between positive and negative outcomes of virtual lives? How can consumers manage their virtual lives more judiciously to enhance their "real life" wellbeing?

Virtual Learning about Alcohol through Narrative Transportation into Television Episodes

EXTENDED ABSTRACT

This research focuses on the health implications of immersing oneself into a virtual story, in our case, a fictional television episode. We pursue this research question in the context of a major public health problem: under-age drinking. Social policy research has established that depictions of alcohol and storylines that revolve around drinking are common in popular culture forms directed at a youthful audience. Alcohol consumption shows up in music lyrics and in music videos, and across a wide variety of movie and television genres (Dal Cin et al. 2008; Gunasekera, Chapman and Campbell 2005; Gruber et al. 2005; Russell and Russell 2009; Sargent et al. 2005; Sargent, Tanski, and Gibson 2007). In turn, exposure to media programming that features alcohol has been implicated as a causal factor in alcohol use and abuse by teens. The presentation reports the findings of an experimental program funded by the National Institute on Alcohol Abuse and Alcoholism (NIAAA) concerning the impact on teens of alcohol-related narratives. We constructed TV episodes to present these narratives. The episodes feature fictional characters' "virtual lives" whose experiences with alcohol could, based on narrative transportation (NT) theory, alter teen viewers' own beliefs about real life drinking and its consequences (Green and Brock 2000). The premise of NT theory is that transportation into the virtual world of the story causes dispositions to shift in a direction consistent with the story world (Gerrig 1993). So, if the story shows teenagers having fun drinking alcohol, and the teenage viewer is transported into that story, then that viewer's beliefs about the consequences of consuming alcohol should shift in the direction of perceiving more positive outcomes. Conversely, if the story shows realistic negative outcomes of alcohol, then a transported teen's dispositions toward alcohol should accordingly shift in a more negative direction. Because transportation into the story is usually induced through identification with the virtual characters that populate it, character identification is also a likely driver of the persuasiveness of the messages contained in the story.

We present a series of experiments to test the theoretical prediction that shifts in real life beliefs about alcohol will be mediated by the degree to which the teens immerse themselves into the virtual life presented in a TV episode. In other words, we assess the possibility that these virtual narratives can indirectly persuade teens through narrative transportation (Green and Brock 2000) and character iden-

tification. It is not known whether a personally consequential behavior, like under-age drinking, can be tacitly shaped by narrative exposure. The initial demonstrations of narrative persuasion focused on shifts in distal beliefs about the world, rather than personally consequential behavior.

The experiments were conducted with 14-17 year old teens whose parents were members of a nationally representative sample of the US population. For the manipulation, we produced original television episodes that varied based on the valence of the alcohol narrative. The narrative follows a male teenager, 'Tom', in a series of events leading up to a beach party where he and his friends are seen drinking heavily with other teenagers. In line with research about social marketing messages most likely to affect teenagers (Pechmann et al. 2003), both positive and negative versions of the film narrative emphasized the social consequences of the behavior. In one, Tom behaves charmingly, 'gets the girl', and wins entry to a competition: his drinking is part of a story that ends on a positive note. In the negative version, Tom behaves loutishly to the female romantic interest, she scorns him for his behavior while drinking, and he fails to advance to the competition.

The experiments followed a pre-post design: after obtaining parental consent and teen assent, the teen participants completed an initial online questionnaire that, amongst a series of lifestyle questions, included measures of media exposure and of their beliefs concerning the personal consequences of alcohol use. These were assessed using measures of outcome expectancies developed within alcohol research: these included sexual, social, physical, and cognitive outcomes that were either positive or negative (Grube and Agostinelli 1999; Jones, Corbin and Fromme 2001). Approximately 20 days later, the teens participated in another study focused on evaluating the pilot of a new TV series. This study began with viewing one version of the TV episode. Measures of narrative transportation (Busselle and Bilandzic 2009; de Graaf et al. 2009; Green and Brock 2000), identification with the characters of the story, positive and negative beliefs about alcohol consumption, and the manipulation checks were taken in that order.

The findings are discussed in terms of the mediating role played by narrative transportation, as opposed to simple exposure effects exerted by the negative (positive) narrative itself. We consider as well alternative formulations of mediators, such as emotional reactions, or identification with the characters in the narrative. Mediation is separately assessed for positive and negative beliefs about drinking and drinkers.

This presentation contributes to the broader discussion in the session about how virtual experiences—in this case, transportation into a story world presented via television—can be used in an education-entertainment fashion. Is it possible to shape alcohol beliefs by constructing a narrative that gives a realistic portrayal of the harm that can result? Or does the desired belief change only occur when the narrative is powerfully transporting? Conversely, how much should we worry about the plethora of alcohol narratives, often positive, to which teens are already exposed? Does mere exposure have an impact, or do these misleadingly positive stories only affect teens who are deeply transported into the narrative? In short, how powerful is the influence of virtual experience, when the subject matter is a personally consequential behavior that has important health and policy implications?

Coping with Stress in the Age of Warcraft: A Conceptual Framework for Consumer Escapism

EXTENDED ABSTRACT

This research explores the phenomenon of consumer escapism within the context of online gaming. While there exist many strategies for coping that involve the consumption of products, escapism through gaming is unique in its ability to immerse consumers in virtual realities where desires, wishes, and fantasies can come true. With continuing advances in media technology (e.g., online connectivity, photorealistic CGI, intuitive motion/touch controls), escaping into the digital worlds of video games and other such interactive platforms has become an increasingly common consumer behavior. In the current marketing literature, the escapism construct has been invoked in several consumption contexts. In their examination of online search behavior, Mathwick and Rigdon (2004) describe escapism as a state of psychological immersion. Within their framework of television connectedness, Russell, Norman, and Heckler (2004) define escapism as the process by which viewers immerse themselves in their favorite shows for the purpose of avoiding reality. These same themes are echoed in research examining other consumption contexts such as themed restaurants (Kozinets et al. 2002) and historical reenactments (Belk and Costa 1998). This research seeks to extend the current literature by examining the motivations and processes inherent to escapism through online gaming.

To accomplish this goal, in-depth interviews were conducted with two sets of participants: (1) four individuals who regularly participated in online sessions of *Warcraft III: Reign of Chaos*, and (2) four individuals who frequently engaged in non-gaming escape behaviors (e.g., watching TV). Following a methodology adapted from Mick and Buhl (1992), interviews were conducted over several sessions in participants' homes. The first session of each interview focused on uncovering relevant insights into the life themes and histories of each participant, and subsequent interviews obtained descriptive first-hand accounts of individual escape experiences. A general framework for escape was developed by analyzing the relationship between life themes, the interpretation of stress, and the escape behaviors that ensued.

There were several key findings that emerged from the qualitative analysis. The first stage of the analysis focused on understanding how the different stressors that motivate escape influence the gaming experience. Threats against self-esteem, for example, have been shown to trigger behaviors such as overeating (Mandel and Smeesters 2008) in an effort to cope. Within the context of gaming, threats against self-esteem (e.g., a poor job performance review) motivated respondents to adopt online avatars within *Warcraft* that allowed for a strong sense of affirmation. More specifically, such players tended to gravitate toward characters that represented ideal versions of their real life personas. One informant, for example, consistently chose elven characters because of their unique character traits (i.e., agile, chivalrous, intelligent). From the perspective of self-discrepancy theory (Higgins 1987), these respondents were given the opportunity to overcome perceived self-discrepancies by assuming the identities of their avatars within the *Warcraft* universe. Consequently, strong emotional attachments were formed with the avatars that persisted over long periods of time.

For other informants, threats against self-control (i.e., the inability to control interactions with the environment and other individuals) were the primary stressors motivating their gaming behavior. When faced with a loss of control in real life (e.g., lack of authority at work), such informants used *Warcraft* as means of re-establishing a sense of control within the confines of a virtual world. To achieve

maximum control of the in-game environment, these informants strategically chose avatars that possessed the power to dominate other players. Instead of forming a personal connection with their avatar, informants motivated by the need for control sought only the feelings of empowerment that come with in-game victory. One informant, for example, felt no attachment to his chosen avatar; rather, he repeatedly chose to use a specific character (i.e., the Death Knight) due to its ability to overcome the feelings of powerlessness he often experienced in the real world.

In contrast with the active role taken by consumers during a session of *Warcraft*, escapism through other forms of entertainment is often more passive in nature. When watching TV, for example, the viewer is generally a third-person observer, rather than a first-person participant. Consequently, informants engaging in non-gaming forms of escapism did not accrue the same benefits of affirmation and empowerment through their escape experiences. Instead, passive escapism functions as a coping mechanism through distraction and mental absorption. For example, one informant frequently used televised sporting events as a means of redirecting his thoughts away from stressful situations. The effectiveness of escape under such circumstances is contingent on the degree to which the stimulus can hold the attention of the viewer. Other informants reported similar experiences with magazines, music, and TV dramas.

As an emotion-focused style of coping (Lazarus 1999), active escapism through video games is particularly potent due to the feelings of affirmation and empowerment that emerge during the process. Although passive escapism may offer limited amounts of affirmation or empowerment through vicarious consumption, the element of role-play inherent to gaming allows for these feelings to be powerfully realized. For this reason, escapism through video games can become pathological; several informants, for example, reported that their gaming behaviors had negatively impacted their job performance and their relationships with family members. In this way, escapism through video games can become a vicious cycle whereby gaming leads to an increased amount of stress in the long-term. In extreme instances, addiction may occur when individuals see their existence in the virtual world of a game as preferable to their existence in the real world.

As gaming becomes increasingly prevalent across a broad range of consumers, this research contributes to the literature by creating a basic framework for understanding escapism in the gaming context. The insights gained through this research suggest that the unique stressors faced by individuals have a direct impact on the character of an escape experience. More specifically, threats against self-esteem lead to an escape experience that focuses on the affirmation of identity. In contrast, individuals who experience a loss of control in reality use the escape experience as a means of reestablishing a sense of control within the game.

When a Picture is Worth Less Than a Thousand Words

EXTENDED ABSTRACT

The use of technology, and particularly social media, has become exceedingly common, especially among young adult consumers. Consumers multitask; check Facebook while in meetings, tweet while watching TV, and text while partying with friends. Although consumers seemingly assume that these media add to their overall enjoyment and wellbeing, we contend that such media multitasking can detract from enjoyment in some consumption situations. Specifically, a consumer participating in a hedonic consumption experience (e.g., a visit to a national park) may inadvertently diminish his/her enjoyment of the experience by constantly taking photos intended

for Facebook. In essence, the desire to document the experience via pictures, tweets, or texts, distracts the consumer from the experience. However, because consumers take such activities for granted, they do not recognize them as distractions. Hence, we propose that the use of technology during a hedonic consumption episode becomes an *implicit distraction*, or a distraction that people fail to recognize. These implicit distractions may lead to unique effects not observed in response to more explicit distractions that people *are* aware of.

Past research on pain tolerance and on the enjoyment of positive experiences has found that distraction suppresses the effect of the informational component associated with an experience, thereby increasing dependence on the more automatic affective component (Leventhal, Brown, Shacham, and Engquist 1979; Shiv and Nowlis 2004). However, in this past research, the distraction (e.g., memorizing a number) was quite explicit to participants. We examine cases where the distraction is implicit or embedded within the experience, and we propose that the process is somewhat different. We suggest that with implicit distractions like taking pictures, the attention devoted towards the experience itself must be further divided, from simply enjoying the experience to also documenting it. This shift may lessen the amount of attention available for enjoying the experience itself.

We test this theory in two studies. Study 1 examined the effects of various types of distractions on the enjoyment and subsequent choice of a sampled experience. In the "High Implicit Distraction" condition, participants were asked to take as many pictures as possible during a 1-minute video of a private island in the Virgin Islands. In the "Low Implicit Distraction" condition, participants were told that they could take pictures if they wished, but that they weren't required to. In the "High Explicit Distraction" condition, participants memorized an 8-digit number while watching the video. Finally, in the "Low Explicit Distraction" condition, participants memorized a 2-digit number while watching the video. To gauge participants' enjoyment of the video, they were asked whether they would choose to watch a 5-minute version of the same video or instead watch an alternative (unsampled) 5-minute video, as well as rate their degree of enjoyment, involvement, and distraction while viewing the video.

The type and level of distraction significantly influenced both choice and rated enjoyment. Choice of the sampled video was significantly higher with high explicit distraction (memorizing an 8-digit number; 82%) than with high implicit distraction (taking many pictures; 50%; $\chi^2 = 4.77$, $p = .029$). When distraction was low, choice of the sampled video was marginally higher in the implicit (71%) than explicit condition (46%; $\chi^2 = 3.05$, $p = .081$). Planned contrasts also revealed that participants taking only a few pictures enjoyed the experience ($M = 13.42$) significantly more than participants taking many pictures ($M = 12.27$, $p = .05$). However, participants felt significantly more distracted in the high explicit condition than in each of the other conditions (all $p < .05$). Thus, taking many pictures (a high implicit distraction) did not feel particularly distracting but did reduce enjoyment of the experience.

Study 2 investigated consumers' lack of awareness of the detrimental consequences of taking too many pictures by looking into the lay theories people hold. Participants read a scenario about a person who vacationed at the Grand Canyon. We manipulated whether the vacationer took 10, 50, or 100 pictures during the 1-day trip.

The number of pictures taken significantly influenced predictions of enjoyment. Positive affect was predicted to be significantly lower when 10 pictures were taken ($M = 11.44$) than when 50 or 100 pictures were taken ($M = 13.65$ and $M = 14.08$ respectively, $p < .001$). Further, participants predicted marginally more regret when 10 pictures were taken ($M = 2.12$) than when 50 or 100 pictures were taken

($M = 1.54$ and $M = 1.44$ respectively, $p = .09$). Finally, participants predicted a significantly worse trip when 10 pictures were taken ($M = 1.76$) than when 50 or 100 pictures were taken ($M = 1.23$ and $M = 1.20$, $p = .03$). These results suggest that people believe that others enjoy experiences more, not less, when more pictures are taken. (We also found that when participants rated how much they themselves would enjoy the trip that they read about, the number of pictures taken by the vacationer did not affect the *participant's* own predicted enjoyment. Thus, our findings cannot be explained by participants judging the trip to be subpar when only a few pictures were taken.)

Our results thus far indicate that not all distractions have the same types of effects. The influence of distraction on the enjoyment of experiences depends on the nature of the distraction. While an explicit distraction at high levels (i.e. memorizing an 8-digit number) led to more enjoyment of an experience, an implicit distraction at high levels (i.e. taking many pictures) led to less enjoyment. Further, contrary to participants' lay theories, taking many pictures was significantly less enjoyable than taking only a few pictures.

Our findings have implications for consumers' use of technologies such as social media while engaged in hedonic experiences. Further research is underway to determine if the effects observed here hold for other common multitasking activities like texting and tweeting. In addition, we are working to develop a deeper process account of the effects.

Somewhere Out There: The Power of Brands to Act as Virtual Proxies Signifying Safety and Representing Home During Intense Risk-Filled Separations

EXTENDED ABSTRACT

There are about 1,400,000 active military personnel across all branches: 103,000 are "afloat" and 297,000 are installed in foreign countries (US Census 2012, Table 509). All are in a state of risk-filled separation. All communicate with families and friends. All seek to bridge the distance between themselves and loved ones. During separation, co-creating home and signaling proximity can bolster both deployed soldiers and family and friends who remain at home. Our research focuses on how home is enacted and consumed during family separation and how proximity is signaled. Our context heightens the importance of maintaining connections to home since deployment often involves the risk of bodily injury.

Fournier (1998) established that consumers create and maintain bonds with brands that in many ways resemble interpersonal relationships. Abundant literature has considered the manner in which these consumer-brand and consumer-company relationships are formed (c.f., Aggarwal 2004; Bhattacharya and Sen 2003), are enacted within specific consumer constituents (c.f., Kates 2000; Luedicke, Thompson and Giesler 2009), become intensified as in brand love (c.f., Carroll and Ahuvia 2006; Batra Ahuvia and Bagozzi 2012), and even eventually end (Fiona, Hall and Meamber 2012). Belk (1988) argues that relationships between consumers and objects are never truly dyadic (consumer-object), but rather are multi-pronged (consumer-object-consumer). Consumers' relationships with objects, like brands are most often social. Interestingly, Fournier's (1998) informants revealed that their consumer-brand bonds often originate in strong interpersonal relationships (a daughter engages in a relationship with a cleaning product her mother used). Schau and Gilly (2003) detail how consumers post brands in personal webspace as shorthand to communicate identity details to website visitors, engaging in conspicuous virtual materialism sharing identity projects with known and unknown others. Research on direct transitional objects show people actively use mementoes to transition from one identity

to another as in physical displacement and death (c.f., Gentry, Kennedy, Paul and Hill 1995; Hill 1991; Hill and Stamey 1990; Parkin 1999). The object sometimes stands in for a loved one or a special place. Research has examined how people create home away from home (Clapham 2012; Gorman-Murray 2007; Malone and Dooley 2006; McCracken 1989). While these studies elucidate many complexities surrounding consumers' relationships with objects and brands, they do not yet reveal how consumers use brands within their real life, active, interpersonal relationships, or specifically how brands connect consumers in virtualities. Our research seeks to understand the manner in which consumers undergoing intense risk-filled separations from family and friends use brands in their communication with distant loved ones. Specifically, we examine the manner in which deployed military and their family and friends utilize brands in their interpersonal communications.

Using historical documents (archived military personal correspondence), brand promotions that explicitly call upon patriotic military themes (especially separation), 26 interviews with families that have experienced a military deployment, and online forums for deployed military and their families, we uncover the strategic use of brands within personal communications during intense risk-filled separations.

We examined outward facing consumer-brand bonds that have a communicative function to an external set of constituents (family and friends not deployed to the same base). We find two broad categories: comfort brands and military-endorsed brands. For comfort brands and military-endorsed brands there are two consumer-brand relationship trajectories: continuing (once begun they are maintained in and out of military service) and contextual (only active during active military service).

Comfort Brands are consumed explicitly for comfort-oriented reasons. For example, brands are used to signify safety and proximity to friends and family in the U.S. or to represent locales like home. By function, we identify them as: proxies (brands that communicate proximity like being under the same sky as in *An American Tail* or singing the same song, watching the same show), cozies (brands that communicate that military personnel are safe and the situation is mundane rather than in peril, such as eating Dunkin Donuts), homies (brands that represent locales specifically home [US or regional] like McDonalds, Coca-Cola, or Alejandro tortillas specific to Tucson), and techies (brands that literally bring family and friends together technologically like Skype, iPhone/iPad, Google Chat, Gmail). Within comfort brand relationships we have two distinct types: legacy brand relationships, a form of continuing bonds (those that continue pre-military or extra-military consumer-brand bonds) and emergent brand relationships, a form of contextual bonds (those that emerge as comfort brands through military exposure on base).

Military Endorsed Brands are brands that military personnel first encountered in the military through defense-based contracts (e.g., Oakley) that then come to be trusted as high quality. Insiders who know military use of the brands and military grade standards come to mark these vetted high-quality brands as safe. In this research, we are specifically looking at family and friends of military. Within the military-endorsed brands we have two types: treasures and tools. Treasures are a form of continuing bonds where brands that are initially used within the confines of the job but then are exported or used outside of active military-related uses (e.g., used within families and friend sets). Tools are a form of contextual bonds where brands are used only within the confines of the job.

In essence, we find that consumers utilize brands as virtual proxies signifying safety and representing home during intense risk-filled separations. Both consumers at home and those deployed share

pictures and stories of shared brands to strengthen bonds and communicate shared safety and solidarity.

SESSION OVERVIEW

The idea that “sex sells” is commonplace in the marketing world. But, is it possible that sexual motives influence consumer choice far beyond the draw of explicit sexual cues? While sexual cues are an effective method for attracting consumers' attention, research has yet to consider how consumers' sexual and mating concerns influence decisions particularly within consumer domains that, on the surface, have little to do with sex. This special session features groundbreaking research that combines business science with the natural sciences. Each set of findings provide a unique window into the mating-related mechanisms that can underlie our consumer choices and challenge some existing views of the factors that influence consumption.

The first two papers offer a fresh take on women's conspicuous consumption and desire for variety. In the first paper, Wang and Griskevicius investigate the role sexual rivals play in driving women's consumption of luxury goods. Four experiments show that women's conspicuous consumption is triggered by a desire to signal to other rival women, and that flaunting expensive products is effective at deterring rivals from stealing a romantic partner. The second paper, by Rae and Durante, examines a previously unconsidered factor that influences consumer variety seeking: the hormones that regulate fertility. Four experiments show that ovulating women desire greater variety in product choice and that this increase in variety seeking is driven by an increase in desire for new men.

The final two papers provide new evidence for how sex and power impact economic and consumer choice. The third paper, by Torelli, Mittal, and Vohs, focuses on how attractiveness influences women's internalization of a link between sexuality and power. Four experiments show that more (vs. less) attractive women endorse sexual leveraging for acquiring/restoring power and – subsequently – attempt to boost their attractiveness via products that enhance sex appeal when feeling powerless. The fourth paper, by Stanton and colleagues, switches gears to also shine a light on men. Two studies

challenge the notion that testosterone – a hormone responsible for driving sexual behavior and status striving – is also responsible for risky financial decisions. Findings are the first to demonstrate that *how* testosterone influences financial risk depends greatly on whether the decision has social implications or only impacts the self.

This session aims to *make a difference* by introducing research lines that open an exciting new frontier for marketing research. Separately, each paper in this session provides a different insight into the role sex plays in consumer choice. Together, these papers provide an additional perspective on the idea that “sex sells” by showing how, when, and why the bedroom can often lead to the bank. As such, the session would be of interest to a breadth of consumer researchers, including those interested in materialism, sexual economics, motivation, social perception, nonconscious processes, romantic relationships, and biological and evolutionary approaches to consumer behavior.

Conspicuous Consumption, Relationships and Rivals: Women's Luxury Products as Signals to Other Women

EXTENDED ABSTRACT

A designer handbag found on the shelves of stores such as Neiman Marcus, Saks Fifth Avenue, or Nordstrom costs anywhere from several hundred to several thousand dollars. Yet an average American woman purchases three new handbags each year, prominently flaunting designer brands such as Fendi, Gucci, Louis Vuitton, Marc Jacobs, Christian Dior, Prada, and Chanel. Spending on luxury goods amounts to as much as \$525 billion per year in the United States alone, with women's products accounting for over half of this consumption. Given women's passion for pricey possessions, why do they desire luxury goods?

Considerable research has examined why people purchase luxury products. Past work finds that the reasons for why consumers seek such possessions include everything from pursuing happiness and boosting self-esteem to signaling one's status and identity (Belk 1985; Han, Nunes, and Dreze 2010; Richins 1987; Veblen 1899). But there is reason to believe that luxury goods play an important role in another ubiquitous part of life-relationships. Recent findings suggest that men's conspicuous consumption plays a vital role in relationship by serving as a “sexual signaling system” (Sundie et al. 2011). In the current research, we examine whether women's conspicuous consumption might have any function in relationships.

We propose that women's conspicuous consumption may function as a signal to romantic rivals. We hypothesize that a woman can use luxury products to signal to other women that her romantic partner is especially devoted to her. In turn, flaunting expensive handbags and designer shoes might help women deter romantic rivals from poaching her relationship partner. We investigate the idea of whether women's conspicuous consumption might function as a signaling system to guard mates in four studies.

Study 1 examined whether other women infer information about a woman's relationship based on the luxuriousness of her possessions. Sixty-nine women were randomly assigned to read one of the descriptions about a woman either wear designer products or non-designer products at a party with her romantic partner. Results indicate that a woman was perceived as having a more devoted partner when she had designer compared to non-designer outfit and accessories ($M_s=5.40$ vs. 4.82 , $t=2.01$, $p=.048$).

Study 2 examined if experimentally activating a motive to guard a mate triggers women's conspicuous consumption. Using guided visualization manipulations from previous research (Griskevicius et al. 2007; Maner et al. 2007), we activated either a (1) mate guarding motive, (2) mate attraction motive, or (3) control. Because the desire for conspicuous goods is related to the size of product brand logos (Lee and Shrum 2012; Nunes et al. 2010), women were then given the opportunity to draw luxury brand logos on a handbag, shoe, car, and T-shirt that they would want to purchase. The dependent measure was the size of the logo women drew for each product. Findings showed that only a mate guarding motive altered the size of logos ($t(134)=3.21, p = .002$), leading women to draw luxury brand logos that were about twice the size compared to those in the other conditions.

Study 3 sought to conceptually replicate and extended the mate guarding finding from Study 2 using different dependent measures including desire to spend for both conspicuous and non-conspicuous consumption products. The results suggest that mate guard motive, does not simply lead women to want to spend more on any products, but is instead specific to products used for conspicuous consumption. Study 3 also ruled out two possible alternatives, showing that this effect is not driven by threat to one's self-esteem or by the mere presence of another woman.

Study 4 examined the intended audience of women's conspicuous product displays. Because women's conspicuous consumption is hypothesized to ward off female rivals, we predicted that the intended audience of women's luxury possessions would specifically be women who are potential threats to the relationships. We activated a mate guarding motive, but the situation was manipulated so that the woman's conspicuous products could only be seen by either other women or men. Thus, the study had three between-subjects conditions: (1) mate guarding – male audience, (2) mate guarding – female audience, and (3) control.

To assess conspicuous consumption, all participants earned 5 extra dollars in the study, which they could either take home or use to purchase raffle tickets to win a \$200 gift card for a spending spree at a luxury store (e.g., Neiman Marcus, Tiffany & Co., etc.). Participants could spend as much or as little of the \$5, with higher spending increasing the likelihood of getting the card. Findings showed that activating a mate guarding only increased women's conspicuous consumption when the audience were other women ($t(72)=2.90, p=.04$).

Additional data suggest that when a woman had luxurious possessions paid by her partner, other women were less willing to romantically pursue her relationship partner if the opportunity arose. Therefore, women's luxurious possession is in fact effective signal to facilitate mate guarding.

Overall, this research makes a contribution by identifying a novel function of women's conspicuous consumption, showing the workings of how luxury products can function as signaling system to ward off romantic rivals, and revealing how products play an important and previously unknown role in relationships.

Playing the Field: The Effect of Fertility on Women's Desire for Variety

EXTENDED ABSTRACT

While considerable past research has examined variety seeking in consumer choice (e.g., Kahn 1995), the current research is the first to examine whether women's desire for variety is influenced by a universal biological factor – the monthly ovulatory cycle.

The ovulatory cycle spans, on average, 28 days, during which a woman can become pregnant on about one week – the *ovulatory* phase of the cycle. Although most women do not know when they are ovulating, research has shown that ovulation can non-consciously alter women's psychology and decision-making. For example, near ovulation women have more fantasies about other men that are especially different from their current partner (Sheldon et al. 2006) and have more extramarital affairs (Bellis and Baker 1990). Ovulating women are particularly attracted to men other than their current partner who display markers of genetic fitness (e.g., symmetry, masculinity, social dominance; Durante et al. 2012; Garver-Apgar et al. 2006). These findings suggest that the hormonal fluctuations associated with ovulation may increase women's openness to variety – at least in men. Here, we explore whether this ovulatory-induced shift in preference for different men translates to the marketplace.

Study 1 examined whether ovulation increases variety-seeking in consumer choice. Women made 15 choices about nail polish color (out of 20 colors). Participants were told to select a nail color for each day (1 – 15) and were told they could select as many or as few nail colors as they preferred. Results showed that women chose a greater variety of colors near ovulation compared to when not ovulating ($M_{ovulating} = 6.73$ vs. $M_{not-ovulating} = 5.46; p = .044$).

Because we propose that women's desire for variety in product choice is a reflection of an ovulatory increase in openness to different men, Study 2 examined whether openness to sex with a new man mediates women's variety seeking. Women made 15 choices of nail color as in Study 1 and reported the likelihood they would date, have sex with, or engage in a brief affair with a man other than their current partner. Ovulating women sought greater variety in nail choice compared to women who were not ovulating ($M_{ovulating} = 6.63$ vs. $M_{not-ovulating} = 5.52; p = .056$). Ovulating women also reported higher likelihood estimates for having a sexual affair with other men ($M_{ovulating} = .179$ vs. $M_{not-ovulating} = -.076; p = .014$). The effect of ovulation on women's variety seeking was mediated by women's openness to sex with other men (.21; $SE = .14$; 95% BCI .027 – .647).

Given that mating motives appear to underlie the effect of ovulation on women's variety seeking, Study 3 sought to suppress the ovulatory effect on desire for variety by manipulating women's mating goals. While ovulation leads women to be open to short-term sex with attractive men, an important moderator of this effect is the quality of a woman's current romantic partner. Research finds that ovulation *does not* lead women to be interested in other men when their current partner is high in sexual desirability (e.g., Larson et al. 2013). This suggests that ovulating women should be motivated to retain a current mate if he is someone who is physically attractive. Study 3 therefore investigated whether a motive to retain an attractive partner (vs. a control) would suppress the effect of ovulation on variety seeking. Study 3 also measured variety seeking in four different product categories: nails, high heel shoes, candy bars, and restaurants.

There was no influence of fertility on variety by product type so the four product categories were converted into a variety seeking composite ($\alpha = .77$). As predicted, there was no difference in variety seeking between ovulating and non-ovulating women in the mate retention condition ($M_{ovulating} = 8.50$ vs. $M_{not-ovulating} = 9.40, p = .13$). Replicating Studies 1 and 2, ovulating women in the control condition chose a greater variety of products near ovulation compared to when they were not ovulating ($M_{ovulating} = 10.35$ vs. $M_{not-ovulating} = 8.65; p = .016$).

To this point, we have examined the effect of ovulation on variety seeking for both single and married women. However, unlike single women, married women have made a significant commitment to one partner and they may have considerably more to lose from

the dissolution of their relationship. Further, married women often wear a symbol of their commitment to one man in the form of a wedding ring. Because a wedding ring is considered to be a strong and universal symbol of commitment to one's partner (Chesser 1980), we reasoned that the act of removing and putting on one's wedding ring should augment feelings of commitment. Drawing on the idea that sensorimotor stimulation translates to cognitions associated with that stimulus (Ackerman et al. 2010; Chandler et al. 2012), Study 4 examined how removing and replacing one's wedding ring would influence the effect of ovulation on variety seeking. We hypothesize that removing one's wedding ring should lead to cognitions associated with lower commitment (akin to a mate attraction motive) and, thus, bolster the effect of ovulation on variety seeking. Conversely, the act of putting one's wedding ring back on (akin to a mate retention motive) should suppress the effect of ovulation on variety seeking. There was a significant interaction between fertility and condition, $p = .03$. While there was no difference in variety seeking by condition for women who were not ovulating ($p = .37$), our key prediction concerned how removing and replacing a wedding ring would affect variety seeking in women who were ovulating. Near ovulation, women sought more variety in product choice after they removed their wedding ring and less variety when they put their wedding ring back on ($M_{\text{RingOff}} = 10.52$ vs. $M_{\text{RingOn}} = 8.48$; $p = .035$).

Four studies show that the hormones associated with ovulation influence women's desire for variety. This research adds to the literature on how hormones can influence consumption behavior (Durante et al. 2011) and is among the first to demonstrate the mediating role mating motives play in consumer choice.

Sex as Power: Attractive Women Link Sexuality and Power for Personal Gain

EXTENDED ABSTRACT

It is often believed that women and men differ in their approaches for exercising power, in that women in powerful positions seem more likely than men to mentor and coach (Eagly and Johannesen-Schmidt 2001). Although women and men tend to differ in their emphasis on the personal versus relational self (Cross and Madson 1997), women nonetheless possess a personal self complete with individualized goals, desires, and preferences (Gabriel and Gardner 1999). Knowing that women generally use power for mutual gain while acknowledging that women have inner goals that they seek to attain for their own personal gain suggests that there will be circumstances in which women seek personal gain through power. When and how women seek power for personal gain was the focus on the current research.

Our tack was to study women's views about the meaning and purpose of power, particularly as it relates to the use of sex and attractiveness. Social interactions with men can offer an opportunity for some women to gain personal power. Sexual Economics Theory (Baumeister and Vohs 2004) proposes that sex is a female resource that bestows upon women considerable negotiating power in the context of heterosexual relationships. This power enables women to be able to request valuable resources (e.g., respect or material gifts) in order for the sexual exchange to occur. Women's negotiating power is particularly strong in the case of more (versus less) attractive women. Because attractive women are more desirable than others, they have even more of an upper hand and thusly the power to demand more resources (Baumeister and Vohs 2004). Since men often see the world through sexual glasses and interpret their social interactions with women in sexual terms (Shotland and Craig 1988), men can become quite concerned about gaining the approval of attrac-

tive women (Van Vugt and Iredale 2012). As a consequence, there is spillover from the heterosexual negotiation script into mixed-sex social interactions, which also are especially favorable to attractive women (Dion and Stein 1978). To the extent that more attractive women successfully leverage their physical attractiveness for fulfilling their personal goals, these women could both develop a stronger belief that power can be useful for personal gain and that leveraging one's physical attractiveness is an acceptable and effective means for doing so (Darley and Fazio 1980). Therefore, we predicted that more (versus less) attractive women, who can use their physical attractiveness more often and effectively, would have a higher likelihood to conceptualize power in personalized terms (i.e., that the purpose of power is for personal gain, Winter 1973), as well as to endorse the use of sexual leveraging for achieving or restoring power.

Four studies tested these predictions by comparing the beliefs, reactions, choices, and behaviors among women who were (self- or other-rated as) more or less attractive. Study 1 used established scales to measure different facets of personalized power related to one's ability to control/influence others for personal gain, aspiration for gaining social status, and desire to dominate others, as well as participants' physical attractiveness. Findings suggested that more (versus less) attractive women expressed aspirations to achieve high social status, thought that assertive, forceful, and self-assured behaviors are good, and more confidently believed that they can influence others and satisfy their own desires.

Study 2 directly assessed the link between women's physical attractiveness and the use of sexuality to acquire/restore power. Participants first answered questions in response to four interpersonal situations including some contexts in which targets were portrayed exercising or reacting to power (Torelli & Shavitt, 2010). Two situations involved leveraging sex appeal for acquiring/restoring power, whereas the other two involved forceful, non-sexual actions in response to abuses of power. These latter situations were included for comparison purposes to explore the possibility that more (versus less) attractive women are simply more likely to react to the negative feelings triggered by misuses of power. Next, participants answered questions that measured their self-reported tendencies to leverage their sex appeal for gaining power. Last, we measured attractiveness in two ways as a robustness check. The results demonstrated that attractiveness was positively related with women's approval of the use of sexual leveraging for acquiring or restoring power. Furthermore, the higher approval of sexual leveraging actions for acquiring power among more (versus less) attractive women was mediated by their own self-reported tendencies to leverage their sex appeal. Findings also show that attractiveness seems to be unrelated with the likelihood that women would react to the negative feelings triggered by powerlessness.

Study 3 experimentally manipulated feelings of powerlessness in order to directly test the extent to which more (versus less) attractive women seek to amplify their sex appeal when feeling powerless. We assessed women's choices for products that can enhance sex appeal after inducing (versus not) a sense of being powerless. Results showed that feelings of powerlessness prompted more attractive women to choose products that could boost their sex appeal, compared to their choices in a neutral condition and compared to less attractive women. Less attractive women in contrast, showed no differences as a function of condition. Study 4 directly measured women's attempts to boost their physical attractiveness in response to feelings of powerlessness using a behavioral measure, and used others' ratings of participants' physical attractiveness as the measure of attractiveness. The findings demonstrated feelings of powerlessness made more attractive women become more interested

in products that are instrumental for boosting their attractiveness. These effects were specific to such products, and did not emerge for products that were described in sexually-appealing terms but were not instrumental for boosting attractiveness. This argues against the alternative account that power is linked to the general concept of sex in more attractive women, suggesting that they do not possess a global link between power and sex.

The combined results of the studies provided converging evidence for the notion that feelings of power and sexuality are linked for women high in attractiveness, which therefore make these women more likely to compensate for a lack of power by attempting to boost their sex appeal.

Sex Hormones & Economic Decisions: The Effect of Testosterone on Financial Risk Depends on Social Context

EXTENDED ABSTRACT

Does testosterone influence risky decisions in economic and social domains? There has been recent speculation in the media that testosterone drives risky decisions, and that the Great Recession started in 2008 because there was “Too Much Testosterone on Wall Street” (Hewlett 2009). In spite of those strong claims, there was scant empirical research to corroborate them, and generally little was known about physiological factors that might account for individual differences in our risk preferences. In two studies, the present research explored the extent to which testosterone predicts individuals’ willingness to take risks when making economic decisions alone and when making socially-interactive economic decisions.

Decades of research have shown that testosterone drives mating behavior and is associated with social dominance, the pursuit of status, and aggression (Archer 2006; Mazur and Booth 1998; Stanton and Schultheiss 2009). For example, individuals with high testosterone levels pursue high-status, risk-laden careers (Dabbs et al. 1990; 1998), and army soldiers with the highest levels of testosterone are the most likely to abuse drugs, be violent, and go AWOL (Mazur, 1995). These behaviors put one’s social relationships as well as one’s health and well-being at risk. While testosterone is associated with these and other risky social behaviors, it is unclear whether or not high levels of testosterone predispose individuals to pursue risk in other domains such as economic decision making. The present studies examine not just how testosterone may relate to risky economic decisions, but also the extent to which the social nature of the economic decision may influence the relationship between testosterone and economic decision-making behavior.

Across studies, testosterone was collected and measured from saliva using standard methods and radioimmunoassay techniques (Schultheiss and Stanton 2009). Testosterone levels were z-scored within sex and collapsed over gender (Mehta et al. 2008).

Study 1 investigated the relationship between individuals’ testosterone levels and their tolerance of unfair offers made in the ultimatum game. The ultimatum game is a dyadic social economic game that involves the exchange of money between participants within a constrained format that allows one to compare how often a participant is willing to accept fair versus unfair exchange offers. Participants’ ($N = 57$) testosterone levels were negatively related to their acceptance of unfair offers, $r(55) = -.27, p = 0.04$, meaning that high-testosterone individuals’ were less tolerant of unfair offers. The relationship persisted when controlling for gender $\beta = -.28, p = 0.04$. Moreover, there was no relationship between testosterone levels and acceptance of fair offers, $r(55) = .11, p = 0.43$, which demonstrates that testosterone selectively predicts behavior when confronted with

unfairness. Unfairness may be perceived as a challenge to one’s dominance. Accordingly, one would predict that testosterone should have selective effects on decisions regarding unfair offers as opposed to fair offers, which is what the data reflect.

But, does testosterone always lead individuals to make riskier decisions? Study 2 investigated the relationship between testosterone and aversion to risk in economic decisions that people make independently. In addition to interrogating the direct relationship between economic risk aversion and testosterone, the potential effects of participants’ relationship status were also considered. In the domain of power and sex hormones, relationship status is a critical factor, such that positive association between power and sex hormones is strongest in those who are single (Stanton and Schultheiss 2007; Stanton and Edelman, 2009). From an evolutionary perspective, testosterone may more robustly promote behaviors associated with the pursuit of power and economic gains in single individuals (Saad and Vongas 2009; Stanton and Edelman 2009).

Participants’ ($N = 390$) risk aversion was determined through 120 trials in which they chose between a certain outcome (a guaranteed win) and a risky gamble that could potentially pay more or less than the certain outcome. Across the 120 trials, the values of the certain outcome, probabilities of winning the gamble, and the ratio of the expected value of the gamble to the value of the certain option were varied and randomized. Participants’ payment was dependent on their choices, which ensured that their behavior was incentive compatible.

Across all subjects, testosterone levels were positively associated with risk aversion, $r(388) = .13, p = 0.01$. In other words, low-testosterone individuals were the most risk seeking, which stands in contrast to received wisdom. This effect persists when controlling for gender $\beta(387) = .13, p = .01$. Further exploration of the effects of participants’ relationship status revealed that testosterone and risk aversion were particularly strongly correlated amongst those participants who were single, $r(211) = .19, p = 0.005$. This effect was then tested independently for each gender, and both single men and single women showed a similar relationship between testosterone and risk aversion, Men: $r(80) = .27, p = .02$; Women: $r(128) = .15, p = .09$. In contrast, testosterone and risk aversion were not significantly associated for those who were coupled, $r(175) = .04, p = .56$, and independent of testosterone, those in a relationship were not riskier than those who were single $t(388) = .12, p = .90$. It may be that low-testosterone individuals desire to pursue risk, but feel inhibited in social domains, which leads them to pursue risk in domains that are socially isolated such as economic decisions that are made independently. The findings suggest that testosterone’s relationship with risk aversion may be both counterintuitive as well as more complex than previously assumed.

The present studies demonstrate that testosterone is uniquely associated with risky decision making depending on social context and social factors. For social decisions, higher levels of testosterone predict greater risk and less tolerance of unfairness, whereas for economic decisions made alone, higher levels of testosterone predicted greater risk aversion. Interestingly, in both studies, the relationship between individuals’ testosterone levels and behavior were the same in men and women, which suggests that the putative male-specific role of testosterone in promoting riskiness is ill-founded. These studies suggest that individual differences in testosterone levels are a potential physiological mechanism that accounts for heterogeneity in economic risk preferences.

Paper #4: Camaraderie in Crime: Shared Self-Control Decisions and Affiliation

Michael L. Lowe, Texas A&M University, USA

Kelly Haws, Vanderbilt University, USA

SESSION OVERVIEW

On its surface, exercising self-control would seem like a fairly simple proposition involving the decision to resist fleeting temptation and adhere to more important, long-term goals. In practice, however, choosing between indulgence and restraint is a daily convolution of emotions, aspirations, appetites, and rationalization, subject to a wide array of influences. Understanding the precursors and processes that lead a consumer to indulge or exercise restraint, and understanding the outcomes of these decisions, is of utmost interest to marketers, policy makers, and consumers alike. Consumers seem to be adept at generating justifications and excuses for lapses in self-control, contributing to a general propensity towards indulgence. Although most self-control research emphasizes the benefits of choosing virtues over vices (e.g., Wertenbroch 1998), consumers can clearly derive benefits from indulgent consumption experiences, and continually missing out on indulgence comes at a price (Haws and Poyner 2008; Kivetz and Keinan 2006). Still, indulgence as an intricate behavioral phenomenon has rarely itself been the focus of research.

The present set of papers offers intriguing and overlapping novel perspectives involving indulgent behaviors. These papers together illuminate a set of product- and situation-relevant conditions under which consumers become more likely to indulge and even receive enhanced benefits from indulgent consumption. For example, creating cuter versions of both hedonic and utilitarian products (Scott and Nenkov), adding functional innovation benefits to products (Garvey and Bolton), and sharing hedonic goods with others (Liu, Fitzsimons, and Bettman; Lowe and Haws) all enhance the likelihood of indulgence. In addition, sharing or co-indulgence is found to provide added benefits of engaging in more indulgent consumption (Lowe and Haws).

Specifically, the papers by Garvey and Bolton and Scott and Nenkov emphasize that the nature of the product itself matters—that is, the overall framing of the level of hedonic benefit associated with a product can be dramatically influenced by fairly simple changes to the core product. This may be through adding utilitarian functionality that in turn provides a license for indulging, or by priming concepts of fun and frivolity through making products “cute”. Next, the papers by Liu et al. and Lowe and Haws both explore the social aspects as-

sociated with indulgent experiences. Social interactions and experiences appear to be enhanced with hedonic consumption.

Overall, this session explores influences on indulgent consumption that are novel and not always immediately apparent. The papers illuminate previously unexplored product-level and situational factors, which lead consumers to indulge more readily and/or enhance the benefits of the indulgent experience. Important general questions emerge from this set of papers including: 1) how do we maximize the benefits we receive from choosing to indulge, while also minimizing the costs? And, 2) what can we learn by considering both the product level and social benefits provided by consuming indulgences? As such, this session embodies the “making a difference” theme of ACR 2013, and it should be of interest to a significant portion of ACR attendees including scholars studying self-control, indulgent consumption, and social interaction.

“So Cute I Can Eat it Up”: Priming Effects of Cute Products on Indulgent Consumption

EXTENDED ABSTRACT

This research examines exposure to cute products – a previously unexplored factor that might affect the extent to which consumers engage in indulgent consumption. Companies market cute products in various categories not only to children, but also to adult consumers. The marketplace is replete with cute clothes, utensils, appliances, foods, and even automobiles (e.g., Taylor 2011). Despite the abundance of cute products in the marketplace, however, academic research on their evaluation or their downstream effects on consumer decision-making and behavior is limited. This is the first research to examine how cute products available in the marketplace (e.g., cute cookies or cute ice cream scoops) may influence consumers’ consumption behavior.

In the current research we explore *cuteness*, which refers to products (and other objects) that are attractive in an adorable or endearing way and have a whimsical nature. Past research had shown that exposure to cute human stimuli (e.g., babies, baby-like facial features) triggers caretaking behavior and carefulness (Sherman, Haidt, and Coan 2009; Sherman et al. 2012), which should lead consumers to engage in more restrained and careful behavior. On the other hand, we put forward the possibility that cute products might have the opposite effect of triggering indulgent and frivolous behavior. We propose that exposure to cute products (i.e., evaluating, using, or consuming such products) would increase indulgent consumption, because cute products’ whimsical nature would prime mental representations of fun and frivolity.

Displaying behaviors of a primed concept or category has been replicated in a variety of contexts (e.g., Aggarwal and McGill 2012; Dijksterhuis and Bargh 2001). The activation of the construct also activates all the related features including behavioral tendencies associated with it, which increases the likelihood that these behavioral tendencies will be acted upon. The activation of a particular construct, in this case, fun and frivolity, should thus lead to a greater likelihood of nonconscious behavior associated with this construct. We predict that exposure to cute products will prime mental representations of fun and frivolity, leading consumers to display behaviors consistent with these representations, resulting in more indulgent consumption.

In a series of seven experiments we show that exposure to cute (vs. non-cute) products primes mental representations of fun and

frivolity, which leads to more indulgent consumption choices. Our results consistently show that when adult consumers are exposed to cute products, they tend to engage in more indulgent consumption. In one study ($n = 33$) consumers both scooped and ate more ice cream when serving with a cute (vs. neutral) ice cream scoop. In a series of three studies (total $n = 313$) when exposed to a cute (vs. different types of non-cute) cookie, they indicated a higher likelihood of eating the cookie, a greater desire to indulge in cookies, and ordered more cookies. These effects were strong enough to affect unrelated downstream consumption decisions as well – participants were more likely to choose a gift certificate that could be redeemed for indulgent groceries and to indulge in a rich entrée in a subsequent scenario. In these studies we also provide evidence of fun/frivolity priming by asking participants to list the first words that come to mind when seeing the cute (vs. neutral) product. Results across the three studies consistently revealed that a significantly greater proportion of participants mention the words fun or frivolous when presented with a cute versus a neutral product, providing evidence that cute products prime mental representations of fun and frivolity.

In two other studies (total $n = 174$) we tested whether consumers make more indulgent book and movie choices when they are shopping with a cute (vs. neutral) Barnes and Noble or Amazon gift cards. To assess indulgent choices, in we adapted an approach used by Read, Loewenstein, and Kalyanaraman (1999) in which participants selected among a set of highbrow (less indulgent, more virtuous) or lowbrow (more indulgent, less virtuous) movies. Results revealed that when shopping with a cute Barnes & Noble or Amazon gift card, participants chose to buy more lowbrow books and rent more lowbrow movies, respectively.

Finally, we uncovered an important boundary condition that illuminates when and how the effects of cute products on indulgent consumption are facilitated or inhibited ($n = 77$). We demonstrate that reminding consumers of the need to exert personal control may limit the ability of cute products to increase indulgent consumption, presumably because it primes mental representations of control and responsibility, which limits the effects of cute products' fun/frivolity priming.

Findings from this research have important implications for consumers, marketers, and policy makers. Based on our findings it seems that marketing cute products could not only lead to more indulgent choices, as shown in our experiments, but could also encourage impulsive buying, increase consumption rates, increase consumer spending, and further decrease the already low savings rates in the United States. Adult consumers may be increasingly stressed with responsibilities of daily life and may be attracted to cute products that prime mental concepts of fun, because it seems to allow them to let go of being restrained and responsible. Findings from the current research about the implications of such choices are important because consumers are likely unaware that exposure to cute products might have inadvertent negative effects on their choices in various important consumer domains.

This work helps scholars and practitioners better understand the underlying process and downstream effects of how cute products influence indulgent consumption. It also helps consumers make more informed decisions about the products they choose, and how these products may influence their consumption.

Consuming Functional Innovations: Are Utilitarian Behaviors Enhanced or Undermined?

EXTENDED ABSTRACT

A frequent practice in marketing is the introduction of products with new functionality; that is, a product is modified with attributes that afford consumers with additional opportunities for action (Dourish 2001; Ziamou and Ratneshwar 2003). Examples include functional foods (e.g. omega-3 ice cream) and green products (e.g. natural detergents) that provide benefits over their traditional counterparts, and which represent substantial portions of their respective consumer markets (Price Waterhouse Coopers 2009).

The present research examines how functional innovations may unexpectedly and ironically undermine the very outcomes their novel functionality is intended to support. Although prior research has deeply studied factors which influence preference for (Hirschman and Holbrook 1982, Naylor, Droms, and Haws 2009) and categorization of (Moreau, Markman and Lehmann 2001; Moreau, Lehmann, and Markman 2001) functional innovations, research is sparse examining the downstream consequences of consuming these products. Extant research has demonstrated that evaluative processing of novel innovations results in a heightened focus upon incremental benefits versus traditional products (Alexander, Lynch, and Wang 2008; Meyers-Levy and Tybout 1989). We propose that this “functional focus” may influence subsequent consumption patterns. Prior research has demonstrated that explicit self-perceptions of utilitarian behavior have the tendency to subsequently increase hedonic behaviors through a variety of mechanisms, including reducing perceived risk (Bolton, Cohen, and Bloom 2006), guilt reduction, (Wansink and Chandon 2006), executive resource depletion (Vohs and Heatherton 2000), and utilitarian goal-release (Laran, Janiszewski, and Cunha 2008).

Our research indicates that consumption of functional innovations subsequently increases hedonic-seeking behaviors which undermine utilitarian outcomes. Our results are consistent with a process of passive goal-guidance (Laran and Janiszewski 2009), in which consumption of a functional innovation releases relevant utilitarian goals, followed by involuntary emergence of conflicting hedonic desires (Carlson, Meloy, and Miller 2013) that subsequently guide perception and behavior. The result is a so-called hedonic “boomerang” that undermines overall utilitarian outcomes and the functional benefits of the innovation. Furthermore, we propose a method to interrupt this process and thereby mitigate the “boomerang” by priming a utilitarian goal beforehand—which shields (Chartrand et al. 2008) against the release of the functional goal.

A series of real behavior and scenario studies supports the proposed model and intervention, while ruling out alternative explanations. Study 1 examined the impact of consuming a functional innovation upon subsequent hedonic-utilitarian behavior. An environmental innovation in the technology domain (smartphones) was employed. Following purchase of a functionally innovative (“with Eco-Safe battery technology”) or non-innovative smartphone, participants indicated choice likelihoods for multiple phone application pairs containing one hedonically oriented and one utilitarian oriented option. As predicted, participants purchasing the functional innovation indicated a greater likelihood to purchase hedonic software apps.

Studies 2A-B were conducted to i) provide direct process evidence for a heightened hedonic and suppressed utilitarian state following consumption of a functional innovation distinct from conscious choice, and ii) demonstrate that a similar “hedonic boomerang” effect does not occur for traditional, non-innovative prod-

ucts that provide comparable utilitarian benefits, thereby ruling out conscious “justification” process explanations such as guilt reduction (Wansink and Chandon 2006), or conscious licensing due to inferences of goal progress (Fishbach and Dhar 2005). Study 2A directly measured involuntary activation of a heightened hedonic state due to functionality without soliciting conscious choice. In study 2A, participants first imagined purchasing either an environmentally responsible (washable cotton towel) or irresponsible (disposable paper towels) product that was either functional (“with Eco-Nurture additives”) or non-functional. To measure activation of a hedonic state, participants were next exposed to a 15x18 letter matrix containing an equal number of utilitarian (e.g. “responsible”) and hedonic (e.g. “exciting”) words. As predicted, functionality significantly increased (decreased) the number of hedonic (utilitarian) words found in the puzzle, regardless of the base product type or perceived environmental responsibility of the purchased product. These results are consistent with activation of a hedonic state that guides attention outside of conscious awareness. Furthermore, these results preclude explanations for behavioral shifts due to conscious guilt-reduction or “balancing” mechanisms, which propose that conscious justification of prior behavior is used as a “license” to engage in hedonic behaviors. Study 2B employed the same design and initial stimulus, but measured behavioral intentions through choice likelihood ratings of environmentally responsible and irresponsible options. Consistent with the process findings of 2A, functional innovations (regardless of base type) subsequently decreased preference for environmentally responsible options.

Study 3 explored in a real-behavior context whether consumption of a functional innovation undermines utilitarian behavior. As part of a “taste test” cover story, participants first consumed a real pre-packaged cookie labeled as functional (“with antioxidants”) or non-functional, then spent fifteen minutes viewing movie trailers and eating actual M&Ms. Consistent with our predictions, individuals consuming a functional innovation subsequently ate more grams of the candy. Study 4 replicated this effect with (non-) functional innovation versions of a “healthy” base product, yogurt.

Study 5 provided further evidence for the proposed process by demonstrating that prior activation of a utilitarian (vs. hedonic) goal mitigates the effect of functionality upon subsequent consumption. Thus prior utilitarian goal activation inoculates consumers and introduces a method for “undoing” the functional boomerang.

In summary, this research is, to our knowledge, the first effort to understand the downstream consequences of consuming functional innovations. Consumption of a functional innovation intended to support utilitarian outcomes is demonstrated to subsequently undermine these outcomes. This unintended consequence occurs because the functional innovation instigates a hedonic state resulting from the release of functionally-related goals.

Anticipating Sharing and Preference for Hedonic Products

EXTENDED ABSTRACT

Consumption situations in which people share products with others are common (Belk 2010). For example, people may share an appetizer at dinner with a friend or share household items with a roommate. We examine how sharing can alter consumers’ product preferences. Specifically, although products can differ along many dimensions, we focus on how anticipating sharing products shifts consumers’ preference for hedonic versus utilitarian products. Research has shown that there is an important distinction between hedonic and utilitarian products; hedonic products are desired for their

greater enjoyment but are more difficult to justify selecting, whereas utilitarian products are desired for their functionality and easier to justify selecting (Khan and Dhar 2006; Kivetz and Simonson 2002; Wertenbroch and Dhar 2000).

Prior research has shown that a variety of different factors can alter preferences for hedonic versus utilitarian products. For example, Okada (2005) found that in single evaluation (i.e., products presented separately), preference for hedonic products was higher than preference for utilitarian products, but that in joint evaluation (i.e., products presented together), preference for utilitarian products was higher than preference for hedonic products. Kivetz and Simonson (2002) found that expending greater effort in a frequency reward program shifted consumers’ preferences away from utilitarian rewards and towards hedonic rewards.

We examine how anticipating sharing versus not sharing a product affects hedonic product choice. We predict that anticipating sharing a product makes consumers more likely to select hedonic (versus utilitarian) products. Results from two studies support our hypothesis.

Study 1.

In study 1, we conduct a first test of our hypothesis, examining whether people are more likely to choose a hedonic food if they anticipate sharing (vs. not sharing) it. In addition, we identify shareability as a boundary condition, in that this effect does not apply to products that are not as easily shared. Participants were randomly assigned to one of four conditions in a 2 (shared, individual) x 2 (high shareability, low shareability) group between-subjects design. Participants read one of four scenarios, depending upon their assigned condition. All participants were told to imagine being at dinner with their best friend. Participants in the shared, high shareability condition were asked whether they would order twelve buffalo wings to share with their friend as an appetizer. Participants in the individual, high shareability condition were asked whether they would order six buffalo wings for themselves as an appetizer. Participants in the shared, low shareability condition were asked whether they would order two scoops of ice cream to share with their friend. Participants in the individual, low shareability condition were asked whether they would order one scoop of ice cream for themselves. All responses were on a scale from 1 (*definitely not*) to 5 (*definitely yes*). Analysis revealed a main effect of the shared/individual factor, qualified by a significant interaction between shared/individual and shareability. In the high shareability condition, participants were more likely to order the hedonic food if it was to be shared versus not shared. In the low shareability condition, participants were equally likely to order the hedonic food regardless of whether it was to be shared.

Study 2.

A potential alternative explanation for these results is that participants inferred that it would be cheaper for them to pay for half of a shared product than to pay for an entire non-shared product of half the size, thus leading them to be more likely to order the shared product than the non-shared product. Another potential alternative explanation is that sharing leads people to be more likely to purchase all products, not merely hedonic products as we propose. Study 2 addresses these alternative explanations by asking participants to allocate a store credit between hedonic and utilitarian goods. Participants were randomly assigned to one of two conditions in a 2 (shared, individual) group between-subjects design. Participants in both conditions were told that they would divide a store credit between digital entertainment (e.g., DVDs, digital music downloads,

Internet video streaming credits, movie tickets) and household supplies (e.g., floor cleaners, cleaning wipes, detergents, paper towels). Participants in the shared condition were told to imagine that they planned to spend a \$20 store credit on products to share with their roommate, and participants in the individual condition were told to imagine that they planned to spend the \$10 store credit on products for themselves. To measure preference for hedonic over utilitarian products, we calculated the percentage of total store credit allocated to digital entertainment. Thus, high values indicate greater preference for hedonic products, and low values indicate greater preference for utilitarian products. An analysis conducted on percentage allocated to digital entertainment revealed a significant main effect of shared/individual, such that participants allocated a significantly greater percentage of the store credit to digital entertainment in the shared versus the individual condition.

This research examines the choices that consumers make for themselves in situations in which they anticipate sharing versus not sharing products. First, we found that consumers are more likely to opt for a hedonic product if they anticipate sharing versus not sharing it. Second, we found that consumers allocate more money to hedonic versus utilitarian products if they anticipate sharing versus not sharing it. In doing so, we contribute to the literature on hedonic versus utilitarian choice while answering recent calls to examine how sharing shapes consumption choices (Belk 2010). Process mechanisms for this effect are being tested and will be presented and discussed.

Camaraderie in Crime: Shared Self-control Decisions and Affiliation

EXTENDED ABSTRACT

Self-control decisions very often involve an element of both social influence and social consequence, and consumers exhibiting high levels of self-control experience greater social acceptance for a number of reasons. For example, these individuals are more likely to display pro-social behavior (DeWall, Baumeister and Vohs 2008), appear trustworthy (Righetti and Finkenauer 2011), and self-monitor more effectively (Finkel et al. 2006). It has even been suggested that self-control exists for the very purpose of facilitating group membership (Baumeister, Schmeichel and Vohs 2007) by ensuring that our behavior that is coordinated with that of our peers.

However, previous research on the social outcomes of self-control decisions has generally employed actor-observer scenarios or actor-influencer scenarios (McFerran et al 2010, Ackerman et al. 2009, VanDellen and Hoyle 2010) and has very rarely examined *shared* self-control decisions or taken the perspective of a participating peer. However, no research that we are aware of has ever examined the potential *outcomes* of shared self-control decisions. As there are two key elements of a shared self-control decision – the peer(s) and the object of the decision itself – we offer a new conceptual framework to examine consumer self-control decisions in social settings and explore the outcomes of shared self-control decisions regarding 1) affiliation and 2) product experience.

In this paper we pay particular attention to shared self-control failure (co-indulgence). While it is true that socially coordinated behaviors lead to positive social outcomes, socially coordinated behavior may take various forms. Mutually indulging in a tempting consumption opportunity may offer a unique set of benefits that mutual restraint (co-abstinence) does not. Indulgence helps preserve cognitive resources that exercising self-control can deplete (Baumeister and Alquist 2009) and prevent feelings of regret associated with missing out on enjoyable experiences (Kivetz and Keinan 2006). Of most interest to us, however, is that co-indulgence seems to provide

a valuable bonding experience for those involved which in turn impacts the product experience. We examine the importance of perceived similarity and reduced anxiety in producing these co-indulgence effects. In three studies, we demonstrate that co-indulgence and co-abstinence both produce significant feelings of affiliation with peers with the effect being stronger for co-indulgence. Perceptions of similarity and reduced anxiety mediate this relationship. Product experience is also enhanced by co-indulgence because of this positive shared experience and a reduction of guilt.

In study 1, participants (N=155) imagined a dyadic shared self-control decision and were randomly assigned a choice condition (indulge vs. restrain) and a peer choice condition (peer indulge vs. peer restrain). Participants then indicated the impact this scenario would have on their feelings of affiliation for their peer, their product experience, and several other measures. The analysis resulted in a significant interaction between the two conditions such that shared indulgence and shared abstinence yielded much higher levels of felt affiliation. An increase in perceived similarity mediated this process. Contrast analyses also showed that co-indulgence led to higher levels of affiliation than co-abstinence and that this was mediated by reduced feelings of social anxiety. Among participants who indulged, co-indulgence also greatly enhanced the anticipated consumption experience. Co-indulgence led to significantly lower feelings of guilt which mediated the improved consumption experience.

In study 2, participants (N=172) were again asked to imagine a shared self-control decision with a peer. In this study, participants encountered a tempting purchase opportunity while on a tight budget. Participants imagined either a relatively expensive or inexpensive temptation (high-severity vs. low-severity, counterbalanced) and were randomly presented with one of two decision scenarios (co-indulgence vs. co-abstinence). An ANOVA was conducted on the measure of affiliation using co-indulgence vs. co-abstinence and indulgence severity as between-subjects factors. Analysis revealed a significant interaction such that co-indulgence resulted in higher feelings of affiliation when the indulgence severity was low, while the opposite was true when the severity was high. Examining the contrasts, the difference between co-indulgence and co-abstinence was significant in the low severity condition, while in the high severity (expensive) condition, the difference between co-abstinence and co-indulgence was marginally significant. A bootstrap analysis reveals that guilt significantly mediates the relationship between the interaction variable (co-indulgence vs. co-abstinence and cheap vs. expensive) and affiliation. The less guilt a consumer feels, or the more guilt a consumer avoids, the more socially beneficial a shared experience will be.

Study 3 (N=153) examines a three-way interaction between participant choice (indulge vs. restrain), peer choice (indulge vs. restrain), and peer familiarity (familiar vs. unfamiliar). A three-way ANOVA on affiliation using familiarity, participant choice and peer choice as factors was significant. Co-indulgence resulted in greater affiliation than even co-abstinence for familiar peers, whereas matched behaviors mattered for unfamiliar individuals, but there was no significant difference between co-indulgence and co-abstinence.

Our research demonstrates the effects of shared self-control decisions on interpersonal affiliation and product experience. We show social and experiential benefits to self-control failure and elucidate the conditions under which this applies. Self-control is not always a social positive. Consumers do at times seek for and appreciate moral support, but in the right circumstances they also value camaraderie in crime.

Dannie Kjeldgaard, University of Southern Denmark, Denmark

SESSION OVERVIEW

Consumer acculturation is on the rise and of interest to consumer researchers (Askegaard, Arnould, and Kjeldgaard 2005; Chytкова 2011; Dion, Sitz, and Remy 2011; Fernandez, Veer, and Lastovicka 2011; Oswald 1999; Peñaloza 1994; Vihalemm and Keller 2011). Although this research stream's overarching goal is "to understand and conceptualize the various forces that define, allow, facilitate, or complicate consumer acculturation under specific cultural conditions" (Luedicke 2011, 238), prior studies have predominantly focused on the micro-processes of individual migrants' cultural adaptation. A few notable exceptions include works on how migrants succumb to institutional domination (Üstüner and Holt 2007) or escape from it by using the market as a form of empowerment (Üstüner and Thompson 2012).

Hence, previous research has devoted surprisingly little attention to the role of macro-institutional variables. In line with this year's conference theme, this session aims to unpack various institutional forces that *make a difference* in migrants' market acculturation through four mature empirical studies (see Appendix 1 for project overview). The papers investigate how different institutional forces (market-mediated ethnic myths, market agents' imagined ethnic communities, political mergers, and multicultural environments) lead to different manifestations of nostalgia, commonly defined as "a sentimental longing for the past" (Holbrook and Schindler 1991). The authors then examine how these forms of context-driven nostalgia impact various migrant groups' market acculturation practices and experiences. Collectively, the projects show that different institutional conditions of acculturation 1) lead to distinct and previously unexplored manifestations of nostalgia, theorized here as performances, enchantments and discourses; 2) impact social networks with which to share nostalgic consumptions and feelings; and 3) result in unusual patterns of acculturation.

In detail, Veresiu and Giesler first conceptualize ethnic entrepreneurship as the strategic actions of migrant consumers to enact

and embody the host culture's market-mediated images of nostalgic otherness in order to ensure a smoother and speedier acculturation process, based on an ethnography of Roma refugees in Toronto, Canada. Second, Visconti and Stamboli focus on how institutional agents participate in the construction of an ethnic imagined community mediated by nostalgic market discourses in France's Turkish migrant community. Third, Brunk and Hartmann discuss how nostalgic enchantment for the former GDR's consumer culture may actually inhibit or even reverse acculturation of East-German consumers who have become migrants in their own country following Germany's political merger. Fourth, Emontspool and Kjeldgaard show that instead of exclusively promoting cosmopolitan detachment from home culture, multicultural environments, such as the one found in Brussels, can encourage displays of national belonging, expressed in nostalgic discourses about mundane and global products.

This session is relevant since it expands the theoretical boundaries of consumer acculturation by exploring macro-institutional forces and nostalgic sources. Secondly, it involves four empirical projects employing diverse data collection methods (depth-interviews, ethnography, netnography, and introspection). Thirdly, it has the potential to appeal to a broad audience interested in the interactions between macro (institutional variables and ethnicity) and micro (identity and personal emotions) dimensions in consumer research.

Fiddler on the Street: How Roma Refugees Enact Host Cultural Images of Nostalgic Otherness

EXTENDED ABSTRACT

It looks like there are two big reactions: the very exotic reaction like oh wow the Gypsies make their dreams, it's like the life of freedom and stuff or there is also the thing with us being thieves and you know like we take the chickens and steal the stuff. So you find the two same stories, but it looks like at some point we are accepted here [Toronto, Canada]. Here we can make a living, we are not living in extremely poor conditions or anything like that, maybe a bit like out of the society, but it looks like we have more power and we have more space and we don't have to live in camps. (Gabriela, 52, Roma Refugee, Freelance dancer, in Toronto for 4 years)

Gabriela's reflexive remark illustrates the important institutional influence of local stereotypes and attitudes about ethnic minorities on the lived experiences of migrant consumers. The Canadian host culture commonly defines "Gypsy" as either a lifestyle or a distinct nomadic ethnicity existing predominantly in Europe (Lee 1998a). More specifically, overview studies (e.g., Csepeli and Simon 2003; Liégeois 1994; Rehfish 1975) consistently distinguish between two main market-mediated myths of the Roma ethnicity that dominate popular opinion: one characterizing these individuals as passionate, mysterious, and talented "Gypsy" artisans and the other typecasting them as thieving, lazy, and dirty "Gypsies." Previous consumer acculturation research has explored in detail the processes and agents through which migrant individuals socialized into a different (mi-

nority) culture adapt to a new (dominant) consumer culture (e.g., Askegaard, Arnould, and Kjeldgaard 2005; Chytкова 2011; Dion, Sitz, and Remy 2011; Fernandez, Veer, and Lastovicka 2011; Luedicke 2011; Oswald 1999; Peñaloza 1994; Üstüner and Holt 2007; Vihalemm and Keller 2011).

How host cultural images about ethnic populations shape consumer acculturation experiences and practices has received much less attention, however. To redress this key theoretical oversight, as well as empirically engage Luedicke's recent (2011, 730) call for "consumer researchers to explore the reflexive interactions between local and migrant groups that compete for (or share) consumption spaces, services, objects, symbols, and natural resources," we conducted an in-depth ethnographic investigation of the interactions between Roma refugees (colloquially known as "Gypsies") and local residents in Toronto, Canada. Overall we found that Roma refugees, like Gabriela, are not only well aware of the two opposing ethnic stereotypes circulating throughout popular culture, but also strategically employ enactments of the market-mediated nostalgic image of the artisan "Gypsy" through everyday consumption-related activities in order to actively dispel the negative myth of the thieving "Gypsy."

To better understand this phenomenon, we draw on performance theory (e.g., Schechner 2006). According to performance theory scholars, ethnicity can be seen as a performance since it involves patterns of behavior that have been socially constructed, learned, practiced and revised by a certain group for a particular audience, over time. More specifically, this approach "underscores ethnicity as behavior, as a social skill of manipulating, masking, and assuming various cultural characteristics through innumerable symbolic activities. In this sense, one can view ethnicity as performance" (Staub 1989). Building on the idea that ethnicity is a type of performance, we develop the construct of ethnic entrepreneurship, which we define as the strategic actions of migrant consumers to enact and embody the positive images of nostalgic otherness from the host culture in order to ensure a smoother transition into the new consumer cultures. In particular, our findings section unpacks how Roma refugees in Toronto strategically employ enactments of the market-mediated nostalgic image of the artisan "Gypsy" to 1) dispel negative competing images of Roma as lazy, thieving, and dirty, 2) ensure ethnic acceptance is increased, 3) enable economic gains, and 4) allow for a smoother consumer acculturation process by resolving tensions between dominant and minority cultures.

Methodologically we used an ethnographic approach that combines both a discursive level (related historical documents and cultural materials from mass media channels and online), as well as a practical level (non-participant observation and in-depth, semi-structured interviews with 18 Roma refugees, aged 16-75, 56% female, 16 locals working in the immigration service industry, aged 25-65, 56% female, and 9 local residents, aged 25-61, 33% female). We analyzed the complete dataset (34 interviews, 1125 pages of historical and cultural data) using the hermeneutical analysis mode of tacking back and forth between data and theory (Thompson 1997).

This paper anticipates making two contributions. First, we expand the consumer acculturation literature by unpacking the important institutional role of the host culture's market-mediated ethnic stereotypes on migrant consumer acculturation practices and experiences. Second, this paper contributes to the literature on marketplace mythologies by exploring the impact of ethnic myths on the identity construction projects of migrants.

Generations at the Mirror: First and Second Generation of Turkish Consumers' Home Country Nostalgia

EXTENDED ABSTRACT

Migrants, as well as their children, typically live in a 'hyper-ethnicized' world. Institutional pressures coming from the outside—the dominant society as well as the ethnic communities (Zouaghi and Darpy's 'ideal us'; 2006)—and even from internal confrontations with family members—for example, across generations (Visconti and Napolitano 2009)—constantly reinvigorate the ethnic discourse. Hence, migrants are not allowed to overcome their often presumed ethnic diversity, and the way they behave and consume is permanently interpreted in the light of such (self)attributed difference. Elif, a Turkish second generation living in Lille, voices this institutional hurdle: "Look, have you seen how Turkish people are represented by French television? Think of what integration means. Are we willing to integrate by watching this stuff? No! We do on our own..."

Elaborating upon Benedict Anderson's (1983) idea of 'imagined community', we claim that ethnic discourses produced by institutional agents represent powerful imagined communities, invisible as much as immanent in the life of migrants and indigenous people. This idea complies with Jenkins' (2002) analysis of the 'imagined' but not the 'imaginary' nature of ethnicity. As Jenkins observes, ethnicity is constructed within an institutional scenario—thus, it represents its agents' 'imagination'—but its invisibility and immateriality do not make it 'imaginary', that is, without social consequences for the people producing and embodying that imagination. In a nutshell, fostered by increased mediatization and connectivity, imagination appears today as a form of 'organized social practice' (Appadurai 1990/2011).

By acknowledging a large array of institutional agents (dominant society, consumer culture, the mediascapes, ethnic communities, families, groups of peers, and marketers of different ethnicities), our paper attacks two main outcomes of these agents' imaginative production: 1) the broad category of ethnicity, here largely meant as 'Turkishness'; and 2) the more specific category of generational ethnicity, under the assumption that also different generations might constitute different 'imagined communities', which often receive specific juridical recognition within a nation. More precisely, we observe how first and second generations of Turkish in France refer to, elaborate, and use feelings of 'home country nostalgia—'the psychic suffering caused by expatriation' (Robert-Demontrond 2001, 319)—in the market. By home sickness we mean an obsession to be (back) to a different physical space, cultural context, social network, market, and institutional setting. As our data shows, these nested references combine factual as well as imaginary traits, and can be addressed specifically to migrants' country of origin or more broadly to a generic 'elsewhere'. Our aims are threefold. First, we want to relate home country nostalgia to institutional agents and unpack their interplay. Second, we wish to mark differences across first and second generations in terms of institutional forces at play and their impact on nostalgic discourses and consumption practices. Third, we contextualize former findings on migrants' acculturation in order to inspect the effects of home country nostalgia—as mediated by institutional agents—for first and second generations' acculturation.

Empirically, the work relies upon an ethnography on 18 Turkish informants (7 first generations and 11 second generations) around the city of Lille during a period of 18 months. Methods include depth interviews, participant observation and observation of indirect indicators (e.g., indicators of social and economic capital), collection of factual data, and photography. Interpretation is granted by iterative data analysis and field/theory alternation (Thompson 1997).

First, we demonstrate that nostalgia is seldom, if at all, possible in the absence of institutional pressures. Data reveals that nostalgia is often presentable as ‘imposed nostalgia’. Consistently with Emonstopool and Kjeldgaard in this session, we also observe that the dominant society expects Turkish people to be homesick (Matt 2007). We argue their expectation reflects both imaginative stereotyping about ‘enduring ethnicity’ and opportunities to consume Turkish difference made visible by nostalgic market behaviors in an attempt of ‘cross-over dreaming’ (Grier, Brumbaugh, and Thornton 2006). Second, we show that while the dominant society and the ethnic communities exert highest institutional pressures on the first generation, the first generation and the group of peers exert substantial pressures on the second generation. As such, Turkish parents’ nostalgic consumptions are more displayed beyond the family whereas children’s nostalgic consumptions are more domestic. Finally, by being institutionally stimulated, nostalgia and nostalgic-related consumptions play a major role in acculturation. In order to organize different effects of imposed home country nostalgia on first and second generations’ acculturation, we identify two conceptual dimensions: 1) individual versus social nostalgia; and 2) nostalgic consumptions having a defensive versus an offensive function against institutional pressures. By crossing these two dimensions, four different ends of nostalgic consumptions appear (cfr. Appendix 1).

Our contributions are threefold. First, we show that home country nostalgia is not only the consequence of hostile or favoring institutional agents (Stern 1992) that stimulate a ‘myth of return’ (Akhtar 1996) but that it can become an additional institutional force whenever external agents expect migrants to feel homesick: from an institutionally-led to an institutionally-leading nostalgia manifested via the market. Second, in its defensive manifestations, home country nostalgia is not an expression of ‘desire for a place’ (i.e. being there) but of ‘desire for a nonplace’ (i.e. being elsewhere) that are objectified through material possessions. Ideally, the home country becomes the context in which migrants are able to forget their ethnicity, and thus “subvert the imagined world of the official mind and of the entrepreneurial mentality that surround them” (Appadurai 1990/2011, 285). Third, we demonstrate that home country nostalgia is not only a side effect of acculturation but a force able to orient market acculturation effectively.

Locals as Migrants in German Unification and Acculturation: How Nostalgia Enchants the Former East

EXTENDED ABSTRACT

Consumer acculturation is commonly understood as a process of physical movement and the resulting adaptation to the cultural environment in one country by persons from another country (Peñaloza 1994). However, acculturation processes may take place even without migration. This project analyses such consumer acculturation instantiated in the specific institutional context of Germany’s political unification in 1989. With the fall of the wall, consumers in former East-Germany were—metaphorically—‘being crossed by the border’ becoming local migrants exposed to Western consumer culture and an inescapable process of cultural learning and adaptation.

This particular acculturation process is intertwined with a specific form of nostalgia. Emically glossed by the term ‘Ostalgie’—a combination of *Ost* (east) and *Nostalgie* (nostalgia); or Eastalgia—we witness an increasing nostalgic revival of East-German brands and consumptionscapes. Although East-Germans considered their products of low quality as well as unattractive back then and aspired Western brands as the ‘real things’ (Veenis 1999), today, many of these previously disliked commodities are cherished.

While public discourse has interpreted Eastalgia primarily as a longing for East-German life, anthropological literature suggests that the stereotypical image of the eastalgie East-German is an invention by West-German media to cope with Germany’s past (Boyer 2001; 2006). This suggests that Eastalgie consumption exceeds notions of being a mere retro phenomenon (Brown 1999; Brown, Sherry, and Kozinets 2003). Underneath its retro-coat, Eastalgia represents a resource for coping with acculturation processes in the institutional context of political re-unification. Given that we know surprisingly little about these deeper-routed cultural functions of nostalgia, this study explores and illustrates the sources, roles, and underlying functions of Eastalgia as a specific form of nostalgic consumption vis-à-vis acculturation processes for ‘local migrants’.

The current consumer cultural dynamics are rooted in the past and lived today, hence methodologically, the historical and contemporary context necessitates various materials. Our research starts with seven guided introspections (Wallendorf and Brucks 1993) of ‘local migrants’ reflecting upon the experienced changes and various aspects of their life before, during, and after the unification using a written essay format. Introspections were followed by long interviews (McCracken 1988) including photo elicitation and review of historical materials where possible. Moreover, netnography of facebook fanpages, blogs and commercial sites relating to Eastalgia, as well as newspaper articles and documentaries complement our material. This combination of methods allows a deeper understanding of the ‘then’ and ‘now’: the symptom, its manifestations, and its roots.

Our theoretical approach is inspired by literature on enchantment, disenchantment, and re-enchantment, discussing how consumers carry the burden of enchanting their lives (Ritzer 2005; Firat and Venkatesh 1995) and how they turn towards shelters of collective enchantment projects (Arnould, Price, and Otnes 1999). While enchantment has previously been portrayed as instantiated in religiosity (Muñiz and Schau 2005), magic (Arnould et al. 1999), utopia (Kozinets 2001), or pastoral myth (Press and Arnould 2011), there are explicit links between nostalgia and enchantment: Brown et al. (2003) observe that retro-brand meanings are channeled through enchantment as storied forms of nostalgic myths. Building on this, we frame nostalgia as a form of (re)enchantment that is collectively achieved and utilized by consumers to deal with various aspects of the acculturation process, and ultimately with dominated, modern cultural conditions in the context of (macro) institutional changes

Our findings contextualize Eastalgia across three cultural-historical phases of the re-unification process: (1) the ‘unification honeymoon phase,’ characterized by euphoria and hyper-consumption of Western brands experienced as enchanting, but also by eradication, discarding, and de-valuing anything East-German (Berdahl 1999; Veenis 1999); (2) the ‘hangover phase’ where Western consumer culture is no longer capable of enchanting, a realization facilitated by the dominated conditions under which political changes occurred, mass unemployment, and shattered dreams of ubiquitous prosperity; and (3) the ‘recovery phase’ during which Eastalgia emerges as a symptom of idealization and re-enchantment of the formerly despised products and consumption experiences through storied forms of myth about life and consumption in the former GDR. Thus, we reveal how Eastalgia mediates re-enchantment in three ways (ideological, re-enacted, re-appropriated) and unveil the different functions of eastalgie (re-)enchantment in acculturation processes: Eastalgia *inhibits, reverses, and facilitates* acculturation.

This paper aims to make the following contributions to existing literature. By investigating the novel context of ‘locals as migrants’, this study expands our understanding of consumer acculturation, the cultural functions of nostalgia in these adaptation processes, as well

as conceptually links nostalgia and (re)enchantment. We find that Eastalgia is both a symptom and coping strategy for dealing with problematic and contested acculturation and thus acts as a mediator for re-enchantment in dominated, modern cultural conditions. Our findings demonstrate how the sources for the manifestation of nostalgic enchantment are multiple, as are the consequences for acculturation. Nostalgic consumer projects can play a central role in facilitating, inhibiting or even reversing acculturation processes. By offering evidence for reverse acculturation, our study supports Luedicke's paper (2011) in that acculturation should no longer be seen as a progressive, directed process but rather as a complex recursive system of adaptation by migrants and local consumers.

Asserting Integration through Nostalgic Discourses: Acculturation to an International Community

EXTENDED ABSTRACT

The concept of nostalgia has played an important role in consumer research for the last decades. Its main conceptualization is one of "bitter-sweet" feelings of longing for a past considered as better than the current situation, which leads consumers to prefer products reminding them of these happy times (Holak and Havlena 1998; Schindler and Holbrook 2003). In the migration context, recent research points to its beneficial side, for instance in easing migrants' adaptation to a new (consumption) culture (Stamboli-Rodriguez 2011), nuancing nostalgia's initial link to negative experiences of homesickness (Matt 2007).

Increased migration around the world due to globalization has led to a diversification of migrants' socio-economic and geographical profiles, which diversifies the cultural influences during acculturation. As a large share of research has however focused mainly on permanent, low-skilled labor migration between two cultures, investigating the role of nostalgia in consumer acculturation of more diversified types of migrants is therefore timely. Hence, the aim of this paper is to investigate individuals' recourse to nostalgic consumption discourses during multicultural encounters.

In this context, the discursive side of nostalgia is particularly important; migrants resort to different discourses about food consumption as indicator of social identity in one context or the other (Luna, Ringberg, and Peracchio 2008; Oswald 1999). In particular, cultural reflexivity, that is, conscious reflection on one's culture, impacts consumption practices (Askegaard, Kjeldgaard, and Arnould 2009). As Emontspool and Kjeldgaard (2012) indicate, consumption discourses in multicultural communities can exacerbate this cultural reflexivity, which then becomes a "conscious consideration and enactment of a cultural identity in order to comprehensively and adequately represent cultural affiliation" (Emontspool and Kjeldgaard 2012, 229). The authors show how nostalgic discourses can then illustrate migrants' cross-cultural consumption experiences.

What has not been discussed until now, is how institutional discourses may induce this behavior. Indeed, as Luedicke (2011) indicates, more focus is needed on the role of host cultural institutions in order to fully investigate migrant consumers' relationship to markets, as well as different outcomes of their adaptation to these new consumption environments (Askegaard, Arnould, and Kjeldgaard 2005; Peñaloza 1994). Acculturation is not only an individual, psychological change; individuals' surroundings greatly impact it. In this paper, we therefore propose an exploration of nostalgic acculturation discourses, asking how consumers integrate institutional expectations in those discourses.

To address this issue, the paper firstly analyses 17 in-depth interviews (McCracken 1988) with migrants of different socioeco-

nomie and ethnic origins, and investigates consumer acculturation and nostalgia in this population. Secondly, this study draws on interviews undertaken with young migrants living in shared an apartment in Brussels, to focus on cross-cultural discourses, as well as on perceptions of institutionalized discourses within these communities. The chosen sample is particularly representative of multicultural environments of higher cultural capital, as Brussels welcomes large numbers of migrants due to the presence of the European institutions, which provide strong institutional discourses about cultural identity.

The findings of this study illustrate the emergence of nostalgic discourses that are less due to the acculturation process in itself, but rather follow upon migrants' impression that nostalgic discourses are expected from them. The respondents relate that during social contact, other migrants express curiosity as to the respondents' country of origin. In consequence, they feel required to express national pride and longing to their culture of origin, although they don't necessarily feel nostalgic themselves. Nonetheless, they adopt nostalgic discourses about a large range of consumption items.

In an international community as exists in Brussels, nostalgia discourses can thus display integration in multicultural societies rather than longing for a lost past. This finding finds an explanation in the differentiation made by Cannon and Yaprak (2002) between local and global cosmopolitans. While global cosmopolitans, who have no attachment to particular places, consider nostalgia a failure (Thompson and Tambyah 1999), our findings show the compatibility of attachment to the country of origin with multiculturalism as promoted by supranational organizations such as the EU, influencing local cosmopolitans' consumption discourses and encouraging nostalgic discourse in multicultural settings.

APPENDIX 1

Project overview: forces, contexts and conceptual contributions

	Institutional forces	Acculturation context	Type of Nostalgia	Manifestations of nostalgia and impact on acculturation
Veresiu and Giesler	Dominant market-mediated ethnic stereotypes	Strategic Acculturation	Performed Nostalgia	Nostalgic performances as a survival tactic and type of ethnic entrepreneurship
Visconti and Stamboli	Pull forces of migration (migrants for job or family rejoining)	Assimilation, acculturation, resistance, swapping	(Imposed) home country nostalgia	Nostalgia as survival; sewing; contestation of the imaginary community; and nurturing
	Generational forces (first vs second generations)	Reculturation	Inherited and imposed home country nostalgia	Nostalgia as sewing; and nurturing
Brunk and Hartmann	Political merger (acculturation in absence of immigration or displacement)	Non-migratory acculturation	Nostalgia as enchantment	Ideological, re-enacted and re-appropriated meanings of enchanted nostalgia can facilitate, inhibit or even reverse acculturation
Emontspool and Kjeldgaard	Multicultural environment	Reflexive acculturation	Discursive nostalgia	Reverse process: Reflexive acculturation leads to developing nostalgic discourses (something expected by others)

Consumer Mindsets: Justifying, Comparing, and Competing

SESSION OVERVIEW

Mindsets are cognitive schemas (Oyserman et al. 2009), activated in one situation, which persist and impact subsequent behaviors, judgments, and decisions. Despite the pervasive impact of mindsets, consumer researchers have only recently started to investigate their antecedents and consequences for consumers, integrate new findings with existing ones, and explore how mindsets affect the interaction among different actors in the marketplace.

How might purchasing different types of products activate different mindsets that impact subsequent decisions? Can activated mindsets change managers' decisions and consumers' interactions with others? And what is the role of mindsets in people's perceptions of bargains? The current session addresses these and related questions, and offers cutting-edge insights into the causes and role of mindsets in judgment and decision making.

The first paper, by Khan et al., makes an important contribution by identifying a novel mindset that consumers develop while making purchases. It compares the cognitive consequences of making hedonic versus utilitarian purchases and shows that purchasing hedonic products induces a justification mindset, which increases choice of easy-to-justify options in a subsequent situation. The second paper, by Moorman et al., demonstrates that activating a comparative mindset not only increases managers' likelihood of making hypothetical purchases but also elevates their spending levels in real business decisions. Thus, it generalizes the comparative mindset effect to manager decision making and extends the effect from choice to spending level.

The next two papers explore different antecedents of a competitive mindset and show the consequences of such a mindset in decision contexts that involve an interaction between consumers or between consumers and marketers. The paper by Roux et al. shows that a scarcity prime activates a competitive mindset that motivates people to pursue self-focused goals when interacting with others. The paper by Sela et al. suggests that the interactions between marketers and consumers activate a competitive mindset, which leads

consumers to attach higher value to offers that seem to fit them by coincidence, without the marketer's intent, than to offers that were designed to fit their preferences.

Considering the fundamental role of mindsets in consumer behavior and the variety of topics these talks cover, the session should be of interest to a broad set of audiences. Not only should it appeal to researchers working on judgment and decision making, choice, and cognition, but also to those who study social interactions, goals, and motivation more broadly.

Justification Mindset: How Hedonic versus Utilitarian Purchase Influences Subsequent Choice

EXTENDED ABSTRACT

Consumers make both hedonic and utilitarian choices. Generally, hedonic choices are guided by pleasure-seeking goals and are more pleasurable than utilitarian ones, which are often guided by functional needs (Alba and Williams 2013). Most literature in the hedonic-utilitarian paradigm has focused on the decision processes by which consumers choose between such products (Dahl et al. 2003; Dhar and Wertenbroch 2000; Kivetz and Simonson 2002; Okada 2005; Strahilevitz and Myers 1998). However, whether choosing a hedonic or utilitarian item guides consumers' subsequent preferences differently has remained under-studied (Mukhopadhyay and Johar 2009; Dholakia et al. 2005). The question is important as growing research has documented sequential influences in decision-making (Novemsky and Dhar 2005; Dhar et al. 2007; Dhar and Simonson 1999). In the current research, we examine how choosing a hedonic versus a utilitarian option affects subsequent choices by changing the reasoning process applied to the subsequent decisions.

We propose that buying a hedonic (vs. utilitarian) item induces a justification mindset. The proposition rests on findings that hedonic items often evoke guilt and are harder to justify (Okada 2005; Khan et al. 2005). Once a justification mindset is activated it may shift consumers' focus in subsequent decisions from the attributes of the choice alternatives to the reasons that best support each alternative thereby encouraging easier-to-justify actions. A carryover effect of justification mindset is consistent with findings that when a mindset is evoked, it persists, guiding thought and behavior, even in unrelated tasks (Gollwitzer & Bayer 1999; Chandran and Morwitz 2005; Dhar et al. 2007). The framework of a justification mindset allows us to predict how a hedonic (vs. utilitarian) initial purchase (driver) can influence subsequent choices (target) in a seemingly diverse set of contexts.

We start by examining how hedonic (vs. utilitarian) driver affects WTB (willingness-to-buy) of a target. Past research has shown that an initial purchase can increase the purchase likelihood of unrelated subsequent items (Dhar et al. 2007). If hedonic purchases induce a justification mindset, then we predict that a hedonic (versus utilitarian) driver should attenuate purchase acceleration. Study 1 tested this prediction by offering participants an opportunity to purchase either a hedonic (potato chips), a utilitarian (notebook), or no driver item and noting the differences in WTB of a utilitarian target (Keychain) across these groups. As predicted, a utilitarian driver significantly increased (55.3%_{utilitarian} vs. 35.7%_{control}), and a hedonic driver directionally decreased (22.7%_{hedonic} vs. 35.7%_{control}) purchase of the target keychain compared to the control. Note that the reduc-

tion in the subsequent purchases may be even more pronounced when the target is hedonic.

Study 2 tested a justification mindset account for the above findings by eliciting reasons for purchase of a target. In a justification mindset people are likely to focus on the best reasons for their choice, hence asking for reasons should have no further effect. Thus, while asking for reasons should reduce purchase likelihood of the target after a utilitarian driver, it should have no significant impact after a hedonic driver, which is predicted to induce a justification mindset. As predicted, eliciting reasons had an effect when the driver was utilitarian (59%_{no-reasons} vs. 25%_{reasons}) but not when it was hedonic (20%_{no-reasons} vs. 17%_{reasons}).

Besides WTB, a justification mindset should also affect the relative attractiveness of hedonic versus utilitarian options: consumers in justification mindset should be more likely to choose easier-to-justify utilitarian items. We first examine this prediction for choice of the compromise option. A need to justify a choice should increase the share of a compromise option (Simonson 1989). Thus, we predict that the compromise effect would be more pronounced after a hedonic (vs. utilitarian) purchase. Study 3 participants were asked to choose between three digital cameras (target choice) involving a price-quality tradeoff. Participants either viewed choice-set ABC where B was the compromise option or BCD where B was a non-compromise option. Prior to this choice, participants were either offered to purchase a bag of potato chips (hedonic driver) or a notebook (utilitarian driver) or nothing (control). As predicted, compromise effect was not significantly different in the control and utilitarian driver conditions (32%_{no-driver} vs. 27%_{utilitarian-driver}) but almost doubled in the hedonic driver condition (32%_{no-driver} vs. 53%_{hedonic-driver}).

Study 4 examined implications of a justification-mindset for a choice-set that contains only hedonic options. Goldsmith and Dhar (2009) show that extreme hedonic options may sometimes be easier to justify than moderately indulgent options as they offer a justification of maximum goal attainment. Building on this, we predict that a hedonic (vs. utilitarian) driver would result in greater share of the most indulgent item from an all-hedonic choice-set. To provide further support for the justification-mindset account we also examined an important individual difference relevant to purchase behavior. Rick et al. (2008) have shown that spendthrifts and tightwads differ significantly in their experience of pain-of-paying. Differences in pain-of-paying may partly determine the level of guilt people experience from hedonic purchases, such that spendthrifts may experience less guilt than tightwads. Hence, we predict that hedonic (vs. utilitarian) drivers may affect the subsequent behavior of tightwads more than spendthrifts. To test this idea we asked participants to imagine purchasing an expensive pair of shoes either for work-wear (utilitarian driver) or for party-wear (hedonic driver). Next, they chose between two luxury vacations, one of which was relatively more indulgent. Finally, we measured spendthrift vs. tightwad tendencies. In addition to a main effect of driver-type (higher purchase of more indulgent resort after hedonic driver (50%_{hedonic-driver} vs. 38%_{utilitarian-driver}), and a main effect of consumer-type: higher purchase of the more indulgent resort by spendthrifts than tightwads (61%_{spendthrifts} vs. 26%_{tightwads}), an interaction between driver-type and consumer-type emerged revealing higher choice of the more indulgent resort for tightwads after a hedonic driver (33%_{hedonic-driver} vs. 15.9%_{utilitarian-driver}) but no significant difference for the spendthrifts (62.2%_{hedonic-driver} vs. 58.3%_{utilitarian-driver}).

Our research contributes to hedonic-utilitarian literature and to the growing work on mindsets and their influences in sequential decision-making and stresses the importance of understanding consumer purchases in the context of their consumption journey rather than as isolated decisions.

The Comparative Mindset and Managerial Decision Making: Theory Extensions and Boundary Conditions

EXTENDED ABSTRACT

Previous research on the comparative mindset effect suggests that consumer purchases often involve three sequential steps (Xu and Wyer 2007; 2008). First, they decide whether-to-choose, then they decide which-to-choose, and finally, they implement the purchase. This sequence of steps also occurs in many managerial decisions involving company purchase of products or services as well as in decisions to spend on advertising or strategic initiatives. Extending previous framework in consumer research, we suggest that after making whether-to-choose and which-to-choose decisions, managers often need to decide how much money to spend (i.e., deciding spending level). Because these steps are often pursued sequentially, activating a comparative mindset, which disposes managers to engage in the which-to-choose stage without first considering whether-to-choose, could not only increase managers' choice likelihood (H1) but also elevate their spending levels (H3). Moreover, this effect is mediated by reduced weighting of negative product information at the decision stage (H2).

Study 1 manipulated *comparative mindset* by asking participants to state a preference for one animal from twenty pairs of animals (elephants vs. hippos, kangaroos vs. zebras, etc.). In the *control* condition, they solved twenty word-completion problems about animal names (e.g., _ u _ _ _ er _ _ ly, H _ p _ _ _ , etc.). Then, participants were asked to imagine that they were the Vice President for a company and were planning to buy computers for their company. Based on information about two computers, participants decided whether they would "Purchase Computer A," "Purchase Computer B," or "Defer Choice and Search for Other Models." As predicted, participants in the mindset condition were more likely to purchase one of the computers rather than deferring choice than those in the control condition.

Study 2 explores the processes through which a comparative mind-set influences choice. In the *mindset* condition, participants compared six pairs of ads on a range of criteria (e.g., "Which picture is more likely to prompt consumers to click through on a website?"). In the *control* condition, participants rated six ads on the same criteria (e.g., "Is this picture likely to prompt the consumer to click through on a website?"). Then, participants made purchase decisions about computers as in study 1. In addition, they reported how much they thought about the computers' strengths, weaknesses, pluses, minuses, strong points, weak points, etc., when making their decisions. The results replicated the findings in study 1, and show that reduced thinking about the negative aspects, but not increased thinking about the positive aspects, mediated the mindset effect.

Study 3 used the same manipulations as study 2 did. In the dependent task, all participants were asked to play the role of Vice President of a computer manufacturing company and make next-year advertising spending decisions for the company. Based on the descriptions of two computers that their company was selling, participants decided among three options: "Advertise Model A," "Advertise Model B," or "Advertise Neither Model and Save the Budget." Contingent on their choice, those who chose to advertise either Model A or Model B were asked to decide the percentage of budget they wanted to spend to advertise the chosen model and the percentage that they wanted to save. Results indicated that participants in the comparative mind-set condition not only were more likely to choose to advertise one of the models, but also committed a greater percentage of the budget to spending than their counterparts did in the control condition.

Two quasi-experiments examine the comparative mindset effect on real business decisions and the moderating conditions surrounding this effect. We select presidential election years as a context that should stimulate a comparative mindset among managers because the primaries and general election create an intensive period of comparing political candidates. We hypothesize that activating a comparative mindset during presidential election years increases marketers' advertising spending levels relative to a control group (H4). Moreover, this effect will be weakened when the economy is in a recession (H5), and will be amplified when the manager's company has higher profits (H6). Both economic recession and company profits are operationalizations of *decision scrutiny*, which defines the extent to which people make cost/benefit tradeoffs in decisions. Finally, this effect will be amplified when the manager's company is located in a swing state (H7) because political campaigns are more intensive in these states, and therefore, should enhance the *accessibility* of the comparative mindset.

The first quasi-experiment tests H4 by using a multiple time series quasi-experimental control group design in which we compare a sample of firms headquartered in the U.S. to a control group of firms headquartered outside the U.S., assuming that managers of non-U.S. firms are influenced less by the comparative mind-set induced by the presidential election. The dependent variable is the advertising spending data pulled from Compustat during the period 1950-2011. The results show that only managers from U.S. firms, but not managers from international firms, spent more on advertising in presidential election years.

The second quasi-experiment tests a set of moderating variables among firms in the U.S. This result indicates a main effect of the presidential election effect. Consistent with H5, we observe that the interaction of *Election*Recession* is negative and significant, indicating that the comparative mind-set effect associated with the presidential election weakens during tough economic times. The interaction of *Election*Firm_Profit*, on the other hand, is positive and significant, indicating that when managers' companies are more profitable, the effect of the comparative mind-set strengthens. This supports H6. We also found a two-way interaction of *Election*Swing_State*, showing that the effect of the comparative mind-set associated with the presidential election strengthens when the state associated with the manager's company headquarter is a swing state. This supports H7. We exclude the alternative explanation that these effects are driven by increased ad price in election years.

In sum, this research extends the influence of comparative mindset to spending level decisions among managers, explores the underlying mechanism, and identifies the boundary conditions. In addition, this study shows that the comparative mindset influences not only hypothetical purchase and advertising decisions, but also business spending decisions in the real world.

Competitive Mindset: Does Scarcity Call for Selfishness?

EXTENDED ABSTRACT

Scarcity is a prevalent condition that characterizes human existence. Mankind has regularly experienced periods of famine and draught (Chakravarthy and Booth 2004), modern economies often must cope with economic recessions (Griskevicius et al. 2013) and even in resource-rich environments it is common to encounter cues that emphasize the limited nature of products and resources (Cialdini 2009; Gitlin 2007). As a consequence, consumers often think about, worry about and discuss scarcity-related concerns (Twist and Barker 2006). However, in spite of the prevalence of cues and cognitions related to scarcity, little is known about the psychological processes

that result when the concept of scarcity is activated in the mind of the consumer, and further what implications those processes might have for decision making (Shah et al., 2011).

This research investigates how activating the concept of scarcity affects consumers' propensity to behave selfishly in subsequent, unrelated tasks. We draw from research in social and evolutionary psychology (Hill et al. 2012; Griskevicius et al. 2013) to predict that when the concept of scarcity is activated, people's decision making will be guided by a focus on advancing their own welfare, relative to that of others. We argue that this occurs due to an underlying shift towards a competitive mindset. Our theoretical framework also predicts that activating the concept of scarcity can cause people to become more generous with others, but only in settings where the associated benefits to the self are highlighted (e.g., charitable giving in order to gain status, Griskevicius, Tybur, and van den Bergh 2010).

We test these predictions in five studies. In all studies, participants are first randomly assigned to either a scarcity prime or a neutral prime condition. We employ three different manipulations to prime the concept of scarcity (a listing task, episodic recall and a semantic priming task) and find convergent results supporting our predictions. Study 1 tested for the proposed main effect of priming scarcity on selfish behavior. After the priming task, participants were asked to evaluate the acceptability of an immoral behavior that benefited the self, yet came at a detriment to society (tax fraud). In line with our predictions, participants primed with scarcity rated tax fraud more acceptable ($M_{\text{control}}=3.10$ vs. $M_{\text{scarcity}}=4.23$; $F(1, 88)=4.79$; $p=.034$).

Study 2 tested whether a competitive mindset mediates the effect of scarcity on selfish behavior. After the priming task, participants were given a real donation choice: the option to keep vs. donate \$1 of their compensation to a charity. Next, among several filler scales, participants were given the Hypercompetitive Attitude Scale (Ryckmam et al. 1990), which was included as a measure of a competitive mindset. In line with our predictions, participants primed with scarcity were more likely to keep the money ($\beta=-1.21$; $p=.054$). They were also more competitive ($\beta=.58$; $p=.009$) and this competitive tendency had a negative effect on donation rate ($\beta=-1.04$; $p=.035$). Most importantly, the direct effect of scarcity on self-profitable behavior was not significant when an agentic orientation was added to the model ($p=.29$; 95% CI [-2.03;-.03]; Preacher & Hayes, 2008).

In order to provide convergent evidence that activating the concept of scarcity makes individuals more focused on the self and, hence, more selfish, study 3 also tested whether it made them less focused on others, and thus reduced their communal orientation (Frimer et al., 2011). After the priming task, participants completed the Communion Management scale (Paulhus and Trapnell, 2008), which assesses dissimulation on communal attributes. In line with our prediction, activating the concept of scarcity significantly decreased participants' communal tendencies as compared to the control ($M_{\text{control}}=6.9$ vs. $M_{\text{scarcity}}=5.6$; $F(1, 263)=5.11$; $p=.025$).

Studies 4 and 5 tested for boundary conditions to the observed effects. Specifically, study 4 tested whether exposure to scarcity-related cues promotes a strategic response, by increasing selfish behavior only when the behavior is directly self-profitable, instead of simply leading to a generalized, irrational desire to hoard resources. To test this, after the priming task, participants played either a dictator or an ultimatum game. The interaction between the scarcity and the game manipulations was significant ($F(1, 187)=6.56$; $p=.011$). In the context of the dictator game, wherein retaining more money leads to more self-profit, scarcity significantly increased the amount of money participants retained for themselves ($M_{\text{control}}=\$6.17$ vs. M_{s}

$=\$7.06$; $F(1, 187)=4.78$; $p=.030$). However, in the context of the ultimatum game, wherein retaining more money can lead to reductions in self-profit, scarcity had no effect on the amount of money retained ($M_{\text{control}}=\$5.96$ vs. $M_{\text{scarcity}}=\$5.47$; $F(1, 187)=2.09$; $p=.150$).

Study 5 tested whether priming scarcity can promote other-profitable behavior when such behavior is framed as directly benefiting the self. After the priming task, participants indicated their gift giving intention and their willingness to pay for a gift designed to thank a helpful friend, which were standardized and averaged to form a composite measure of generosity. The interaction between the scarcity and the self-benefit manipulations was significant ($F(1, 141)=5.55$; $p=.02$). When gift giving was not framed as providing any clear benefit to the self, participants' generosity did not differ between the scarcity and the control condition ($M_{\text{scarcity}}=-.18$; $M_{\text{neutral}}=.01$; $F(1, 138)=.89$; $p>.3$). However, when gift giving was framed as providing a clear benefit to the self, scarcity increased participants' generosity ($M_{\text{scarcity}}=.29$; $M_{\text{neutral}}=-.15$; $F(1, 141)=5.87$; $p=.017$).

This paper sheds light on the heretofore unknown consequences of priming the concept of scarcity on selfishness. Across five studies, we demonstrate that scarcity activates a competitive mindset, which in turn motivates people to pursue self-focused goals through selfish means. This suggests that desperate times may indeed call for selfish measures.

Beating the Market: Competitive Mindset and the Allure of Unintended Value

EXTENDED ABSTRACT

Consumers often encounter marketing offers that can potentially be construed as valuable opportunities, such as products on sale, loyalty programs, rebate offers, and various promotions. However, the mere fact that an offer is presented or framed as a bargain is often not sufficient to generate consumers' subjective belief that the offer actually represents superior value for them. While a great deal of research has examined factors that influence value assessment, the factors that produce subjective perceptions of bargain have remained rather elusive.

We propose that one important determinant of deal perception is the degree to which an offer appears more valuable than presumably intended by the marketer. In particular, consumers' belief that the marketer has not fully factored-in their willingness-to-pay or the utility they derive from the promoted product tends to create the (mis) perception of unintended consumer surplus; this, in turn, enhances the likelihood that the offer will be seen as valuable. We further propose that the tendency to act on such perceived bargains reflects in large part a competitive mindset where consumers are driven by a desire to outsmart the market and obtain a better value than intended by the marketer (Ratner and Miller 2001; Wright 1986).

Thus, subjective perceptions of bargain and the action tendencies they invoke depend on consumers' belief that the offer is valuable for them without the marketer's intent. We test these propositions primarily in the important marketing context of offer customization and targeted promotions. Specifically, we contrast cases in which a marketing offer appears to fit the consumer's preferences better than presumably intended, thereby providing unintended utility or value, with cases in which the offer is explicitly tailored by the marketer to fit the consumer's preferences. Importantly, we examine the effect of incidental versus tailored fit while holding constant both the actual and the perceived fit between the offer and the consumer's preferences, and examining both cases of idiosyncratic (Kivetz and Simonson 2003) and non-idiosyncratic fit.

Experiment 1 shows that consumers are more likely to pursue a marketing offer when certain cues lead them to believe the offer fits them better (and is therefore more valuable for them) than intended, than when such cues are absent or when the offer is explicitly designed to fit the consumer. After measuring participants' idiosyncratic preferences in an unrelated task, we offered participants with a special interest in economics and world news to take advantage of a special promotion for *The Economist* magazine – an offer that strongly matches their individual preferences. One third of participants were told that the offer was targeted at the average person, thereby providing them with seemingly unintended fit. Another third were told that the offer was designed “for the classic reader of *The Economist*”. The last third did not get any information about whom the offer was designed for. The offers were otherwise identical. In addition to the offer framing manipulation, half of the participants were primed with a competitive mindset whereas the others were primed with a neutral mindset. Consistent with our propositions, participants interested in economics and world news were more likely to take advantage of the offer when it was framed as designed for the average person than when it was designed “for the classic reader” or when no targeting information was provided. Moreover, the tendency to take advantage of the offer in the average person framing condition increased in the competition mindset priming condition, compared to the control prime.

In Experiment 2, we offered people to take advantage of a Hollywood Hits TV channel for \$50 a year instead of a Hollywood Hits + Ballet channel package for \$90 per year (almost all our participants favored Hollywood hits and had no interest in ballet). We told half of the participants that the Hollywood Hits offer was available instead of the enhanced Hollywood + Ballet package due to a local infrastructure capacity constraint. The other half were told that the company conducted market research which suggested people were not interested in ballet. In addition, half of the participants were primed with a competitive mindset whereas the others were primed with a neutral mindset. As predicted, people were more likely to take advantage of the Hollywood-only (but better value) offer when it was due to the company's infrastructure constraints than to market research. Moreover, the tendency to take advantage of the offer increased following the competitive mindset prime, compared to the neutral prime.

Experiment 3 extended these findings and provided direct evidence that offers that seem to provide unintended fit are seen as more valuable than intended by the marketer, compared to equivalent offers that fit the consumer by design.

Experiment 4 bolsters our proposition that the effect of unintended fit/value reflects consumers' perception of marketers as counterparts in a competitive, zero-sum game. Specifically, we predicted that the competitive motivation to obtain a bargain at the marketer's expense would be attenuated when it comes at the expense of a not-for-profit entity (McGraw, Schwartz, and Tetlock 2012). Thus, in addition to varying whether the offer seemed to provide unintended versus intended fit/value, we also varied whether the offer was made by a for-profit marketer or a not-for-profit entity. Consistent with our theory, the tendency to pursue the offer providing seemingly unintended value was pronounced when the seller was framed as a for-profit marketer, but it was attenuated when the seller was framed as a not-for-profit entity.

Taken together, the findings show that offers are particularly attractive when their value to the consumer (e.g., through fit) appears unintended rather than premeditated. The findings provide novel insights into factors that lead consumers to perceive offers as subjectively valuable and underscore the hitherto unexplored role of the

adversarial, competitive motivation to outsmart the market by taking advantage of unintended opportunities. The findings also show that explicit offer customization can boomerang by lowering bargain perceptions.

SESSION OVERVIEW

Reminders of money are ubiquitous. Every purchase we make, bill we pay, and check we receive forces us to think about how much money we have. Additionally, we encounter many subtle reminders of money in our daily lives, such as passing by a bank, ATM, or billboard displaying dollar signs. With this in mind, researchers have examined how thinking about money affects attitudes and behavior. For example, individuals who are primed with money, rather than time, feel less connected to products that they have purchased (Mogilner and Aaker 2009) and are less willing to donate money to charity (Liu and Aaker 2008). However, research in the area of money has largely ignored how priming this concept affects goal pursuit. As activating the idea of money makes people more self-sufficient (Vohs, Mead and Goode 2006), thus changing people's aspirations, this raises the important question: How does the activation of the idea of money in people's minds change goal pursuit?

With four papers, this session addresses this question as it integrates various ways to activate the concept of money to examine how these thoughts affect a host of goal-related behaviors. Garbinsky, Klesse, and Aaker prime thoughts of money by influencing one's subjective level of wealth, via manipulating scale anchors. The authors find that making people feel less wealthy ironically causes them to save less money. They attribute these findings to feelings of powerlessness that are induced by feeling relatively poor, thus making individuals feel like their savings goal cannot be attained. Van Kerckhove, Lunardo, and Fitzsimons manipulate thoughts of money in an alternative fashion by having participants make lists of things they would be unable to do without money or by asking participants to indicate the amount of money in their bank account. They find that priming money scarcity leads consumers to place greater value on option choice as they are willing to invest more resources to keep options open. Johnson et al. manipulate monetary thoughts in a more generalizable way by providing participants with a cost calculator similar to those found on existing websites. They find that these calculation aids, in union with other interventions, cause participants to make better health coverage choices that could ultimately save

10 billion dollars each year. Finally, Sarial-Abi and Vohs show that even subtle reminders are sufficient to activate the concept of money by having participants sit in front of a computer with a screensaver displaying one hundred dollar bills. They find that activating the concept of money enables participants to better achieve a range of goals, from financial to health and problem-solving.

Although this session is designed to be of substantial interest to those who study the psychological consequences of money (as all four papers share a common focus on deepening a theoretical understanding of ways in which thinking about money affects goal pursuit, we also expect this session to have broader appeal. For instance, this session will focus on various ways to prime the concept of money in people's minds, making it relevant to researchers interested in priming tactics more generally. Additionally, as three of the four papers examine the effects of money on financial decisions (saving, spending, and choosing health insurance), this session should also attract those interested in financial decision making. We hope that attracting a diverse audience will help facilitate a lively and fruitful discussion. In addition to creating connections between research areas, this session should also build connections between academia and industry because of its direct managerial implications; not only do the researchers focus on advancing our theoretical understanding of the consequences of money, but they also identify techniques that could potentially be manipulated by marketers in order to activate thoughts about money and thus change how much people ultimately decide to save, spend, or invest.

With Great Power Comes Financial Responsibility: The Effect of Power on Saving

EXTENDED ABSTRACT

The savings rate among the poor is very low. Approximately 10% of all U.S. households, most of which live in poverty, lack formal saving tools (Bertrand, Mullainathan and Shafir 2006). Without banks, they must rely on alternative financial means such as check cashers, payday loans, or borrowing from friends, which can have serious ramifications for spending and savings issues. With this in mind, we sought to investigate why people who feel poor tend not to save as well as ways to encourage saving behavior. In doing so, we shed light on a new mechanism that explains the link between wealth and saving: feeling powerful.

Experiment 1—Subjective Wealth and Saving

This experiment sought to establish that feelings of power drive the relationship between subjective wealth and saving. Subjective wealth was manipulated by asking participants to indicate their annual household income on a scale that ranged from \$0 – over \$420,000 (low subjective wealth manipulation) or on a scale that ranged from \$0 – over \$44,000 (high subjective wealth manipulation) (Nelson and Morrison 2005). Then, participants imagined that they just received \$100 and indicated how much of this money they would put in a savings account. Participants then indicated the extent to which they felt powerful (1 = not at all, 7 = very much).

Results showed that among those willing to save ($N = 68$), there was a significant difference in subjective wealth condition such that participants in the high subjective wealth condition ($M = \$50.86$, $SD = \$29.81$) were willing to save more money than those in the low subjective wealth condition ($M = \$37.12$, $SD = \$26.16$), $t(66) = 2.02$,

$p = .05$. Additionally, participants in the high subjective wealth condition indicated feeling significantly more powerful ($M = 4.40$, $SD = 1.67$) than those in the low subjective wealth condition ($M = 3.06$, $SD = 1.62$), $t(66) = 3.36$, $p < .001$. Finally, these feelings of power mediated the relationship between subjective wealth condition and amount that participants were willing to save (95% CI: .96, 14.00).

Experiment 2—Power Poses and Saving

This experiment sought to manipulate power in a way unrelated to money in order to establish that power is indeed driving the effect on saving. Feelings of power were manipulated by having participants imitate poses associated with feelings of high power or low power (Carney, Cuddy and Yap 2010). After being shown pictures they had to imitate, participants made two high power poses or two lower poses for one minute each. Then, they imagined that they just received \$100 and indicated how much of this money they would put in a savings account. Results showed that among those willing to save ($N = 66$), there was a significant difference in power condition such participants in the high power condition ($M = \$76.72$, $SD = \$20.81$) were willing to save more money than those in the low power condition ($M = \$64.26$, $SD = \$22.77$), $t(64) = 2.32$, $p = .03$.

Experiment 3—Why Power Increases Saving

This experiment sought to establish why feeling powerful increases the amount of money one is willing to save. Because power promotes an action orientation (Galinsky, Gruenfeld and Magee 2003), we hypothesized that feeling powerful makes people feel like their savings goals can indeed be achieved, thereby increasing the amount of money one is willing to save. An additional benefit of experiment 3 was the inclusion of a control condition, allowing us to examine whether differences in saving are driven by feelings of high or low power. Feelings of power were manipulated by having participants write about a time when they had power over someone else (high power condition), a time when someone else had power over them (low power condition), or they were not given a writing assignment (control condition) (Galinsky et al. 2003). Then, they imagined that they just received \$100 and indicated how much of this money they would put in a savings account. Participants then indicated the extent to which they agreed with following two statements: “Right now, I feel like I am able to work effectively toward my long-term saving goal,” and “Right now, I feel confident that I will be able to achieve my long-term saving goal” (adapted from Klesse et al. 2012).

Results showed that among those willing to save ($N = 117$), there was a significant difference in power condition, $F(2, 114) 3.55$, $p = .03$, such that participants in the high power condition ($M = \$78.15$, $SD = \$23.48$) were willing to save more money than those in the control condition ($M = \$65.29$, $SD = \$33.40$), $t(114) = 1.96$, $p = .05$, and low power condition ($M = \$61.55$, $SD = \$30.16$), $t(114) = 2.53$, $p = .01$. Additionally, the aforementioned items were averaged to create a goal attainability index ($r = .68$, $p < .001$), revealing that participants in the high power condition ($M = 5.48$, $SD = 1.13$) felt significantly more able to work effectively toward their saving goal than those in the control condition ($M = 4.82$, $SD = 1.57$), $t(114) = 2.16$, $p = .03$, and low power condition ($M = 4.83$, $SD = 1.35$), $t(114) = 2.11$, $p = .04$. Finally, feeling like one’s saving goal could be achieved mediated the relationship between power condition and amount that participants were willing to save (95% CI: .37, 5.77).

General Discussion

We suggest that the low savings rate among the poor can be attributed to feelings of powerlessness (experiment 1) by showing

that feelings of power drive increases in saving. This pattern was observed by having participants imitate power postures (experiment 2) or write about a past experience in which they felt powerful (experiment 3). Additionally, these results suggest that power causes individuals to save more money by making them feel like their savings goal can indeed be achieved.

Enhanced Desire for Product Choice in Response to Monetary Scarcity

EXTENDED ABSTRACT

While consumers are well-accustomed to having the freedom to choose among alternatives, they often find themselves in situations in which their choice freedom is restricted. A theory apt to deal with people’s reactions to threatened freedoms is ‘reactance theory’ (Brehm 1966), which proposes that perceived threats to freedom motivate people to reassert that freedom. Though abundant, reactance research has been limited as it has exclusively focused on how making a specific option unavailable affects consumers’ behavior with respect to that specific object. The current research, however, focuses on a situation that people may experience as a generalized threat to choice freedom, and as such may have a broader effect on consumer behavior.

As money is generally seen as giving people options in life and yielding feelings of freedom (Mitchell and Mickel 1999; Vohs and Baumeister 2011), we posit that monetary scarcity may be experienced as a general threat to freedom of choice. Hence, monetary scarcity may be experienced as a restriction of choice, resulting in an increased valuation of option choice. Moreover, as people high (vs. low) in trait reactance are more motivated to reestablish threatened freedoms, monetary scarcity may lead people higher in reactance to value option choice.

To study whether monetary scarcity has a more generalized effect on the valuation of option choice than the scarcity of specific products (especially for those higher in trait reactance), participants first completed a reactance questionnaire (Hong and Faedda 1996). Next, they were randomly assigned to one of three scarcity conditions. In each condition, scarcity was activated by having participants list three things they would not be able to do anymore when either gasoline, sugar, or money was unavailable to them (Roux, Goldsmith and Bonezzi). Finally, participants were presented with three pairs of assortments, each comprising a small and a large assortment. Participants indicated from which assortment they would be most happy to choose (Inesi et al. 2011). Three products, namely water, candy, and detergent, were included in the assortment choice task. Results show that while participants in the sugar (vs. gasoline) scarcity condition prefer a larger assortment size for candy only, participants in the monetary (vs. gasoline) scarcity condition prefer a larger assortment size for all three products. Moreover, we find an interaction effect: The preference for a large assortment in the monetary scarcity condition is larger for highly reactant participants.

Experiment 2 replicates this finding by assigning participants to a monetary scarcity or monetary abundance condition, rather than focusing on different types of scarcity. After completing the reactance scale, participants indicated the amount of money in their bank accounts, either on a response scale with large (monetary scarcity) or small (monetary abundance) increments. Next, participants chose three chocolates out of an assortment of five. Finally, participants evaluated the size of the assortment they chose from and indicated their satisfaction with their choices. Two regressions both reveal a significant interaction: Monetary scarcity (vs. abundance) leads to lower assortment size evaluations and lower satisfaction with a

choice from a small assortment, especially for people high in trait reactance.

Experiment 3 replicates this finding incorporating a clear measure of people's striving for option choice. After completing the reactance scale, participants were randomly assigned to a money condition (monetary scarcity vs. control; Zhou, Vohs and Baumeister 2009). Next, participants played a 'door game' (Shin and Ariely 2004), in which participants could click on three depicted doors. The game was designed as such that switching between doors was costly, though necessary to keep doors/options available. People who like to keep options open may be inclined to switch more than others. As anticipated, an interaction occurred whereby monetary scarcity leads people to switch more, especially when their reactance level is high.

Prior research showed that when a resource becomes scarce, people will value it more (Brock and Brannon 1992; Lynn 1991). Hence, as money becomes scarce, people should value money more. The reported studies indicate that under conditions of monetary scarcity, people also value option choice more. Using a 2 (money: scarcity, abundance) \times 2 (resource: money, time) mixed-model design with resource serving as a within-participants factor, Experiment 4 focuses on how people trade-off money and option choice under conditions of monetary scarcity.

After measuring reactance, monetary scarcity was manipulated by an episodic recall task (Roux, Goldsmith and Bonezzi). Next, participants were presented with two scenarios; each scenario involved deciding whether to make the purchase from a store offering a small or a store offering a large assortment. In the first scenario the prices of eyeglasses were lower in the small versus large assortment store, while in the second scenario, the small-assortment store was open, and the large assortment store was closed. Desire for a larger choice set was measured, by, respectively, the amount of money participants were willing to spend additionally and the number of minutes they were willing to wait to access the larger choice set. Results show that in the monetary scarcity condition, participants are willing to wait longer to choose from a large assortment, especially when reactance is high, replicating the findings of the previous studies. However, when considering the amount of money people are willing to additionally spend to choose from a large assortment, we find that there is no effect of monetary scarcity, nor an interaction with reactance. This finding indicates that, even though lacking money triggers a greater desire for choice, people do not value option choice more than money. Hence, having choice options cannot substitute for a lack of money.

Overall, these studies suggest that monetary scarcity can lead people to exhibit reactance and to look for freedom. Whereas financially threatening situations generally redirect people's focus on extrinsic goals such as financial success and social popularity (Sheldon and Kasser 2008), we show that this may also instigate an increased valuation of a 'higher-order' goal like freedom of choice. Our research extends the scope of reactance theory, but also sheds new light on the desires of people living under conditions of monetary scarcity.

Can Consumers Make Affordable Care Affordable? The Value of Choice Architecture

EXTENDED ABSTRACT

In less than a year, on January 1, 2014, tens of millions of Americans, along with members of Congress, will participate in a grand experiment in consumer choice: They will select health insurance using a marketplace or *health insurance exchange* operated by states and federal governments as part of the Patient Protection and

Affordable Care and Act. The success of these exchanges depends upon two related premises: First that consumers will be able to select the best policy for their needs, and second that price competition, driven by effective consumer choice, will lower prices

These premises are critical not only to the new exchanges, but also for all government administered health insurance markets and for the efficiency of privately provided benefit choices. Yet, a large literature in psychology suggests that this may not be the case, since, as we shall see, these exchanges may not provide a helpful *choice architecture* to support decision making. In this paper, we examine three related questions: Can people select the best policies? Do they know how well they are doing? Does the design of the sites change their performance?

Our results suggest there is significant room to improve these decisions. Without any intervention, respondents perform at near chance levels and show a significant bias, overweighting out-of-pocket costs and deductibles. Financial incentives do not improve performance, and decision-makers do not realize that they are performing badly. However, performance can be improved quite markedly by providing calculation aids, and by choosing a "smart" default, raising the performance of ordinary respondents to that of the MBA students.

Experiment 1 provides a baseline, examining the proportion of people choosing the most cost-effective policy from 4 or 8 options. Fig. 1 shows the outcomes from all experiments. The top half of each bar, in blue, represents the proportion of correct choices, and the bottom half, in red, plots the average dollar error, across respondents. The dashed line represents expected choice quality by a random chooser. Panel A of Fig. 1 shows a rather dramatic outcome: With 4 choice options, respondents select the best option only 42 percent of the time, and make an average mistake of over \$200 dollars. With eight options, they select the correct option 21 percent of the time, a figure not different than chance ($p < .05$). Experiment 2 added monetary incentives. As can be seen in the next two bars of Fig. 1 (A), incentives did not improve outcomes, and performance was close to chance.

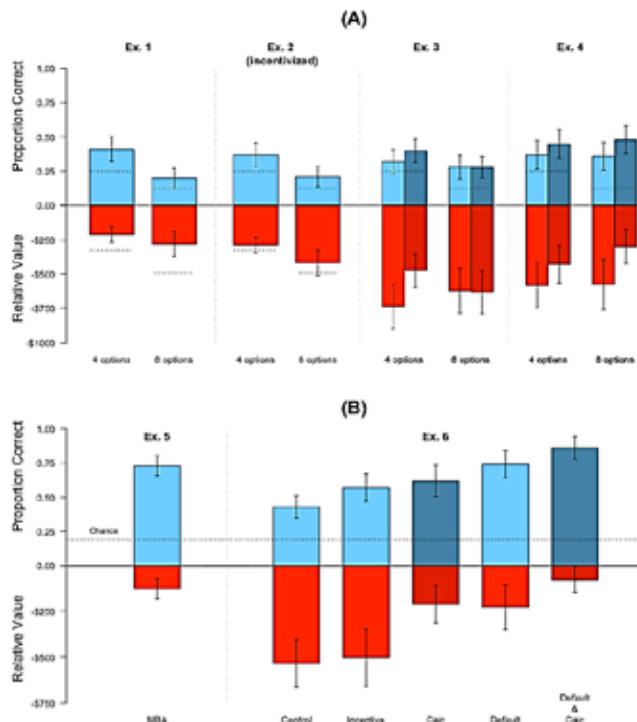

One obvious intervention, used in Experiments 3 and 4, provides a cost-calculator stating the annual total cost. This is done on several existing web sites including Medicare.gov. In addition, Experiment 4 also simplified the choice by removing quality information for half the respondents.

The results, shown in the third and fourth columns of Fig. 1(A) are not markedly different. Again respondents chose the most cost effective option less than half the time, and make large financial errors. The unaided decisions makers averaged errors of \$611 in Experiment 3 and chose the correct option 32% of the time. Providing the calculators did marginally help but only in Experiment 4: Respondents provided with calculators chose the correct option 10.1% more often, and reduced the size of errors by \$216, but still were only correct 47% of the time and made mean errors of \$364.

Is this task simply impossible? Experiment 5, used a very different population to see how highly trained, financially literate individuals might do. We presented MBA students enrolled in a class on consumer finance with the same task as in Experiment 4.

As seen in the first column of Fig. 1(B), they perform appreciably better, choosing the right option 73% of the time, and making an average mistake of \$126. Their self-reports of how they accomplished the task are interesting: Forty percent reported using excel. This suggests that having *both* the right mental model *and* the ability to execute these calculations may be a basic requirement to make good choices.

Figure 1: Performance across experiments

In Experiment 6, we explored the possibility that mental models plus different possible interventions would produce good performance by those who will be using the exchange. We compared a control condition to four different manipulations. An incentive group received a more extreme and sophisticated incentive regime. We contrasted this to three choice architecture interventions. The first provided a *calculator*; explained what the calculator did, and tested that understanding. The second provided a *smart default* that preselected the most cost effective options given that individual's usage. Individuals could, and did, change that selection if they wanted. Finally, we combined *defaults and calculators*. The presence of incentives and our choice architecture manipulations allows comparing the cost effectiveness of these interventions.

The last four bars in Fig. 2(B) show that the treatments vary widely in effectiveness. The controls, despite having received instruction and tests of understanding, choose about as well as respondents in prior experiments. The second bar indicates that incentives do not have a significant effect on outcomes, even though individuals in the incentive condition did take 38% longer to make their decisions, a significant increase relative to controls. Calculators (with education), in contrast, produce better decisions, with a significant decrease in the size of the loss and an increase in the proportion correct. The smart default option has a similar effect, reducing losses and increasing the percentage correct. Finally, when combined, the defaults and calculators seem to complement each other, leading to performance levels that are comparable to those of the highly trained MBA students. This last result suggests, perhaps, that the use of calculators justifies the selection of the default, increasing the transparency of their selection. It also suggests that providing just-in-time education along with calculation and choice aids produces better performance.

We close by showing that respondents were overconfident, and that these choice architecture interventions could save purchasers and taxpayers 10 billion dollars a year.

Mere Exposure to Money Motivates Goal Attainment

EXTENDED ABSTRACT

How do people achieve their goals? Goal performance has been linked to goal setting, dedication to achieving the goal, self-perceptions of being able to achieve the goal, and the goal's value to the individual (Heath et al., 1999; Vroom, 1964). Being motivated (i.e., feeling energized toward pursuing the goal) helps too (Locke & Latham, 1990). The current article offers the idea of money, as a simple environmental cue, can aid goal pursuit.

The use of money is intimately tied to goal pursuit. When people use money, they do so to close a gap between a current and desired end-point, the definition of goal pursuit (Baumeister, 1998; Carver & Scheier, 1990). Money is also linked to goal attainment in another manner. The largest source of money gain is earnings, which means that people apply persistence, skill, or other behaviors to perform jobs that meet an acceptable standard.

Hence, there are two distinct ways that money and goal pursuit are intertwined – through spending and earning it. Due to their frequent pairing, the very concepts of money and a goal might stimulate energetic and motivated reactions. We predicted an interaction between being reminded of money and the presence of goal in determining motivated behavior.

Experiment 1: Finances. Participants in money (vs. nonmoney) reminder condition saw 20 images of one hundred dollar bills (vs. shells) arranged onscreen randomly and provided a quick and accurate account. Next, participants in the no-goal condition read a second-person paragraph that described how they had not been good at managing their finances. Participants in the goal condition read the same paragraph, but they also read that they had adopted a goal of being frugal and not spending much money. The next screen displayed and described 11 products (e.g., a CD that includes an additional CD as promotion). They reported the likelihood of buying each item. Ratings were averaged to form an overall spending likelihood measure.

An ANOVA with money reminder and goal condition as predictors of spending intentions revealed the predicted interaction effect, $F(1, 104) = 5.21, p < .03$. Participants in the money reminder condition who were given an explicit goal versus no goal reported lower spending intentions, $F(1, 104) = 7.17, p < .01$. Participants in the no money reminder condition, however, did not differ in their spending intentions as a function of goal and no goal condition, $F < 1$.

Experiment 2: Health. Participants randomly received the money versus non-money reminder manipulation as in Experiment 1. Next, participants read text written in second person to describe a person's realization of eating too much lately and gaining weight. In the goal condition participants read, "You tell yourself, I must stop eating so much, and this becomes an important goal that you want to reach." Then participants rated a series of words on their aesthetics using three 5-point scales anchored with: unattractive / attractive, unpleasant / pleasant, and negative / positive. We averaged the health-related items (e.g., apple) to create a healthy attitude score.

An ANOVA with money reminder and goal condition as predictors of healthy attitude scores revealed the predicted interaction effect, $F(1, 86) = 4.68, p < .04$. Participants in the money reminder condition who were presented with a goal reported more favorable attitudes toward the health words than did participants who were not reminded of money ($F(1, 86) = 13.81, p < .01$). In the absence of a goal, whether participants earlier had been reminded of money or not did not affect their attitudes toward the health words, $F < 1$.

Experiment 3: Problem Solving Performance. Participants were handed a stack of questionnaires. Computers nearby had a screen-

saver on, which depending on condition, showed either money versus fish floating underwater. Next, participants in the goal condition read they should adopt the goal of completing as many problems as they can. In the no goal condition, participants read that they would be performing math problems.

An ANOVA with money reminder and goal condition as predictors revealed the predicted significant interaction effect on duration, $F(1, 104) = 18.85, p < .01$. When given a goal, participants who had been reminded of money, relative to their non-money counterparts, spent more time trying to solve the math problems, $F(1, 104) = 17.20, p < .01$. Without being given a goal, duration was equivalent between participants who were or were not reminded of money, $p > .05$.

Experiment 4: Having Fun. We last sought to test whether money reminders would help people achieve goals that were not explicitly given to them by us. Participants' first task was to complete paper forms of questionnaires while a nearby computer's screensaver showed either pictures of money or fish underwater. Next, participants in the fun (versus no frame) condition were instructed to complete four puzzles that were described as "enjoyable games and puzzles" versus "verbal tasks." Four items measured participants' experience: the task was fun/enjoyable; I enjoyed/had fun doing the task."

An ANOVA on experience of fun during the task revealed the predicted significant interaction, $F(1, 92) = 4.32, p < .05$. When participants in the money reminder condition were given a task framed as fun, they experienced more fun compared to those who were in the nonmoney reminder condition, $F(1, 92) = 12.30, p < .01$. There was no difference between money and nonmoney reminder condition participants' experience of fun when the task was not framed as fun, $p > .57$.

General Discussion. Four experiments showed that reminders of money influences goal pursuit. The findings of this research contribute to the literature in several ways. First, we demonstrate money as a tool for goal-pursuit. Second, we integrate the literature in psychology of money and self-regulation to highlight the underlying mechanism under the influence of money on goal-pursuit. In sum, our data, for the first time, shows that money can be used as a facilitator for goal-pursuit.

Paper #4: Understanding the Psychology of Scarcity: When Limited Resources Prompt Abstract Thinking

Caroline Roux, Northwestern University, USA
Kelly Goldsmith, Northwestern University, USA

SESSION OVERVIEW

Modern life is rife with inconsistencies in product and resource availability. Not only does the economy continue to be characterized by periods of recessions, but there is considerable inequality among people for access to products and resources. Consequently, how do consumers perceive and react to cues of scarcity in their everyday lives? Despite increasing interest in this research topic, there are still many open questions regarding the antecedents and consequences of scarcity. For example, it is unclear what environmental cues lead consumers to perceive resources as more or less scarce. Moreover, the influence scarcity exerts on consumers' cognition, judgment and behavior still remain vastly unexplored. This session provides a step forward in this direction by considering various ways in which scarcity shapes consumer behavior.

All four papers in this session provide new insights into how different cues of scarcity, from store atmospherics to news articles indicative of recession, influence consumers' cognitions and behaviors. Two of the papers also identify important person variables, such as childhood environments, that may affect people's responses to such cues.

The first paper, by Sevilla and Townsend, investigates how environmental cues influence perceptions of scarcity. Specifically, they demonstrate how the product-to-space ratio in a retail setting leads consumers to perceive products as more or less scarce. Results from three experiments suggest that consumers perceive products to be scarcer when they are surrounded by more empty space, holding the product assortment constant. In turn, scarcity perceptions translate into higher purchase intention and increased price estimates.

The second paper, by Mittal and Griskevicius, draw from Life History Theory to explore whether consumers' response to scarcity cues depends on their childhood environments. Specifically, the authors investigate how resource scarcity cues differentially influence financial planning. Across three experiments, the authors present evidence suggesting that consumers who grew up with relatively lower levels of family support value financial planning more less when exposed to resource scarcity cues.

The third paper, by Hill, DelPriore, Rodeheffer and Butterfield, also draw from Life History Theory to investigate how resource scarcity influences women's ideal body sizes. Three experiments demonstrate that exposure to scarcity cues leads women who experienced relatively stressful (benign) childhoods to prefer heavier (thinner) body sizes.

Finally, the fourth paper by Roux and Goldsmith explores how being exposed to scarcity-related cues influences people's level of processing. Specifically, they show that activating the concept of scarcity induces people to adopt an abstract (vs. concrete) mindset, which broadens one's consideration, thus leading them to categorize objects into fewer, more general, superordinate groups and to be more likely to include atypical exemplars into a given category.

Taken together, these four papers advance our understanding of how scarcity influences consumer behavior. Overall, this session offers a coherent set of innovative perspectives that enhance the breath of our knowledge in a growing area of research. We expect this session to appeal to a broad audience, including researchers interested in resource scarcity, store atmospherics, financial planning, family environments, physical appearance, and cognitive processing.

The Product to Space Ratio Effect: How Store Density Influences Perceptions of Scarcity and Product Preference

EXTENDED ABSTRACT

Past research has shown that consumers use cues in the retail environment when making inferences about the properties of a product (Zeithaml 1988). In this work, we investigate an important aspect of a store environment, product density, which is the amount of space devoted to a constant number of items. Despite the importance of this factor as a potential determinant of store and product perception, this component of the retail environment has been widely understudied. Unlike past research on store density, which has focused on human or overall crowding (e.g. Eroglu and Harrell 1986; Machleit et al. 1994; Machleit et al. 2000), the present research considers how varying the density of *products* affects consumer preferences towards them.

In our studies we keep the number and characteristics of a set of products constant and manipulate the amount of space devoted to their display. Our results systematically show that a lower product-to-space-ratio (more space per product) has a positive effect on product preference, valuation, and likelihood of purchase. These findings are consistent with research on the use of white space in advertising (Pracejus et al. 2006), which suggests that this visual trope is effective due to its socio-historical meaning. However in contrast, we show that the effect of product to space ratio in the retail environment is due to a less deliberative process, that of increased perceptions of product scarcity. Past research has shown that scarce products are highly desirable (Cialdini 2009; Inman, Peter and Raghubir 1997; Verhallen 1982), mostly because people believe that limited opportunities are more valuable (Cialdini 2009). In this work, we show support for this notion and document a new manner of manipulating perceptions of product scarcity in a retail place, through varying the amount of space surrounding each product. Moreover, we rule out alternative explanations for the effect based on perceptions of store messiness or consumer difficulty in observing product assortments

as well as address the automatic versus deliberative components of the phenomenon.

Study 1 was a field study that established our proposed effect revealing that consumers spent more money in the store when a constant product assortment was displayed across a larger rather than smaller amount of space ($M_{large\ space} = 6.73$ vs. $M_{small\ space} = 3.67$; $t(195) = 2.24$, $p < .04$). Moreover, a survey of store visitors revealed more favorable evaluations of products in the low product to space ratio condition ($M_{large\ space} = 5.27$) than in the high product to space ratio group ($M_{small\ space} = 4.73$; $t(84) = 2.29$, $p < .03$).

Study 2 used a laboratory controlled environment to provide evidence for the display density effect by asking participants to select a choice set from which to make a hypothetical purchase. Specifically, participants considered two sets of men's neckties that differed on the designs of the ties and on the product-to-space-ratio of the display. The display space and product design factors were counter-balanced and yet significantly more than half of participants selected the assortment with more space as the one from which they would prefer to purchase (59.1%, $\chi = 6.32$, $p < .02$), which they liked more (59.1%; $\chi = 6.32$, $p < .02$), found more attractive (61.1%; $\chi = 8.00$, $p < .01$) and more luxurious and exclusive (59.1%; $\chi = 6.32$, $p < .02$).

Study 3 considered the underlying mechanism behind this effect by examining potential mediators for the phenomenon. In contrast to study 1, study 2 used a between- rather within- subject design, used estimated price of the featured products rather than choice set selection as a dependent measure, and considered a female-centric product category, that of women's shoes, as opposed to men's neckties. As expected, participants in the larger space condition estimated the price of the shoes as higher than did those in the smaller space condition ($M_{large} = \$97.51$ vs. $M_{small} = \$70.20$; $F(1, 97) = 6.61$, $p < .02$). Moreover, both perceptions of scarcity associated with the store ($M_{large} = 3.69$ vs. $M_{small} = 2.98$; $t(99) = 2.10$, $p < .04$, CI: 16.36 to -1.14) and with the product ($M_{large} = 3.74$ vs. $M_{small} = 1.22$; $t(99) = 9.06$, $p < .0001$, CI: -38.63 to -1.01-) mediated the effect.

In a set-up similar to study 2, study 4 provided further support for the underlying scarcity mechanism revealing the effect to be deactivated when participants' beliefs about how scarce a product is are directly manipulated ($\chi = 1.61$, $p > .20$). Additionally, in this study we found that the effect held under conditions of cognitive load, which suggests predominantly automatic and non-deliberative processing. This is a novel finding when we contrast this work to past research on scarcity effects, which are usually triggered through rational claims or explicit amounts shown (e.g. Fromkin 1970; Verhallen 1982).

We believe this presentation is consistent with the theme of the conference and would "make a difference" as this topic has direct theoretical consumer behavior and managerial implications. Specifically, we have shown that the effect of product-to-space-ratio plays a positive role in increasing product preference and valuation, and yet this finding may be at odds with cost efficiency concerns that suggest a denser store maximizes retail rent utility. The present research could encourage researchers from these different fields to work together to determine the conditions and situations in which the display density effect can best be employed to maximize profits.

Planning Under Paucity: Responses to Resource Scarcity Threats Depend on Childhood Environments

EXTENDED ABSTRACT

Financial planning is pervasive in consumers' lives. Not only does it impact how we spend money in our everyday lives, but it also has a profound effect on wealth accumulation and retirement

satisfaction (Ameriks, Caplan, and Leahy 2003; Elder and Rudolph 1999). Because a principal reason to plan is to have a better and more comfortable future, might uncertainties about the future change people's planning psychologies? For example, can cues indicating looming resource scarcity such as those related to economic recessions lead people to change their financial planning? Would such cues lead them to plan more or plan less?

Recent work suggests that the answer depends. Research indicates that people respond in divergent ways when faced with threats of resource scarcity based on their childhood resource conditions (Griskevicius et al., 2013, White et al., 2013). For example, adults raised in relatively resource-rich environments took fewer risks and became less impulsive under cues of resource scarcity, whereas those from relatively resource-deprived backgrounds responded to the same cues by taking more risks and becoming more impulsive (Griskevicius et al., 2013). In the present work, we draw on the cost-benefit framework of life history theory to investigate the effects of resource scarcity on people's financial planning behavior.

In Study 1, we experimentally manipulated resource scarcity cues by having people read a news article about the recent economic recession or having them read a control article. We then examined their beliefs about the importance of financial planning by using an adapted version of the propensity to plan scale (Lynch et al., 2009). Results revealed that for people growing up with relatively higher levels of family resources, the recession news article did not significantly affect their valuation of financial planning. However, among individuals growing up with relatively lower levels of family resources, recession cues *decreased* their valuation of financial planning.

In Study 2, we sought to replicate the results of Study 1 by using a behavioral measure of the value of planning. Resource scarcity was manipulated by having participants recall an incident when they felt financially deprived compared to their peers (Sharma & Alter, 2012). In the neutral condition, people simply responded to the measure of financial planning. Then, in an ostensibly unrelated task, respondents were informed that the experimenters were interested in knowing the kinds of information people are interested in learning in the context of retirement planning. They were then provided with a list of topics pertaining to retirement finances that they could choose to learn about. Importantly, they were informed that they could read as many or as few of the topics they were interested in. The dependent measure was the amount of time respondents spent on learning about retirement planning. Findings conceptually replicated the results of Study 1. Specifically, respondents who grew up with relatively higher levels of family resources did not differ significantly on learning about retirement planning under scarcity manipulation. In contrast, among those growing up with relatively lower levels of family resources, scarcity thoughts significantly decreased the amount of time they spent on learning about retirement planning.

Study 3 had two goals. First, to ensure the robustness of the experimental findings in Studies 1 and 2, we sought to conceptually replicate the results using a third methodology to prime resource scarcity—a photo slideshow (Griskevicius et al., 2013, Hill et al., 2012). Second, to test whether people's perceptions of personal control could be potential mediator of the relationship between resource scarcity cues and planning beliefs. Resource scarcity cues were manipulated by having participants view a slideshow with visual images suggestive of economic recession or control images. Next, participants rated their beliefs about the importance of planning and their perceptions of control over their financial behavior. Consistent with the results from Studies 1 and 2, Study 3 found that for people growing with relatively lower levels of family resources, recession

cues significantly *decreased* their rated importance of financial planning. Additionally, the changes in the importance of planning were found to be mediated by the changes in perceptions of personal control over financial behaviors.

These studies provide important new insights into the complex relationship between resource scarcity and people's financial behaviors. It draws on life history theory to explore why people from different childhood backgrounds might respond differently to modern stressors such as resource scarcity and uncertainty. It also identifies perceptions of personal control as an important variable that guides people's subsequent beliefs and behaviors pertaining to financial planning. This work has important implications for public policy professionals and others who wish to foster better financial planning behaviors in people from underprivileged backgrounds.

The Effects of Resource Scarcity on the Ideal Female Body Size

EXTENDED ABSTRACT

When it comes to women's body ideals, is it true that thin is in? Or is shapely sexy? The answer to this question varies considerably across cultures. Although ultra-thin female models are idealized in Western nations like the United States, individuals living in nations where resources are scarce, tend to prefer women with a heavier body size (see e.g., Swami et al., 2010). This pattern repeats itself within nations, communities, and across the sexes. People living in relatively safe, affluent regions idealize thinner female bodies than those residing in more dangerous, lower SES communities (Swami et al., 2010). Resource scarcity and stress also increase the heaviness of the body that men most desire in their romantic partners (Swami & Tovée, 2012), but not necessarily themselves (Sobal & Stunkard, 1989).

Why do researchers regularly observe a relationship between resource scarcity and preference for a heavier female body ideal? Here, we use insights from two theoretical models in evolutionary biology – life history theory and the critical fat hypothesis – to examine whether this relationship might emerge from the different life history strategies typically adopted by individuals living in resource scarce versus resource plentiful environments. Female body fat plays a key role in women's fertility regulation, with thinness being related to suboptimal fertility (Frisch, 1985). Accordingly, we predicted that resource scarcity cues – which promote the contingent expression of a faster life history strategy and more immediate reproduction – would produce a preference shift away from the very thin, sub-fertile female ideal typically chosen by Western women toward a heavier, more fertile female form.

In Study 1, we experimentally manipulated cues of resource scarcity by having men and women read a news article about the recent economic recession. We then asked them about their developmental history and measured their perceptions of the ideal body size using the contour drawing figure rating scale CDFRS (Swami et al., 2010). We predicted that women who experienced earlier pubertal development – a physiological indicator of sensitization to a faster life history strategy – would respond to scarcity cues by shifting away from the very thin, sub-fertile body ideal typically favored by western women, toward a heavier, more fertile female ideal. Because body fat does not influence men's fertility, we predicted that no such effects would be found for men. The results of Study 1 supported these predictions.

In study 2, we used a similar priming methodology to explore whether we could conceptually replicate these results using a second cue to resource scarcity – cues to heightened environmental stress

and uncertainty. Participants read a news article about increasing stress and unpredictability in the modern world or a control article. Next, they reported on their pubertal timing and indicated the ideal female body size. As predicted, women who experienced earlier pubertal development chose a heavier female body ideal after readings a news article about increasing rates of violent crime compared to comparable controls.

Study 3 was designed to extend our findings in two ways. First, we sought to examine whether resource scarcity cues have implications for men's perceptions of the ideal *female* body size. Because successful enactment of faster life history strategies is critically dependent on female body fat, both men and women sensitized to faster reproductive strategies should respond to harshness by idealizing a heavier, more fertile female body size. Second, because pubertal timing is not the only developmental marker of life history strategies, Study 3 was also designed to test whether we could conceptually replicate the specific pattern of results found in Studies 1–3 using a different index of developmental history – childhood SES (see e.g., Griskevicius et al., 2011). We predicted that resource scarcity cues would interact with both men's and women's childhood SES, such that individuals growing up in lower SES environments would idealize a heavier female body size relative to individuals growing up in higher SES environments. As predicted, we found that men and women growing up in lower SES environments responded to resource scarcity cues by favoring a heavier, more fertile female body ideal.

The results of our three studies provide some of the first experimental evidence regarding how and why people living in relatively safe, affluent regions prefer a thinner female body ideal than those residing in more dangerous, lower SES communities. Specifically, the results of our studies lend support for the hypothesis that this variability might reflect the different life history strategies adopted by those living in resource scarce versus resource plentiful environments. Although this variability is often attributed to differences in exposure to Western media and the thinness of fashion models used in magazines and advertisements, the current research provides evidence that these findings may also reflect fundamental differences in people's psychologies based on the level of resources present in men's and women's childhood and adult environments. This work has important implications for researchers interested in various areas including physical appearances, food consumption, individual differences, and mating behaviors.

Understanding the Psychology of Scarcity: When Limited Resources Prompt Abstract Thinking

EXTENDED ABSTRACT

Scarcity is a prevalent condition that characterizes human existence. Mankind has regularly experienced periods of famine and draught (Chakravarthy and Booth 2004), modern economies often must cope with economic recessions (Griskevicius et al. 2013), and even in resource-rich environments people routinely encounter cues that emphasize the limited nature of products and resources (Cialdini 2009; Gitlin 2007). As a consequence, people often think about, worry about, and discuss scarcity-related concerns (Twist and Barker 2006). However, in spite of the frequency of cues and cognitions related to scarcity, our understanding of the psychological processes that result when the concept of scarcity is activated remains limited. In this research, we investigate how activating the concept of scarcity influences the way people process information. Specifically, we posit that scarcity-related cues can affect people's level of processing through the activation of an abstract mindset (Liberman and Trope 2008).

Construal level theory (CLT; Liberman and Trope 1998) posits that psychological distance affects the way in which individuals mentally represent objects or events (Trope and Liberman 2003). More specifically, when events are psychologically distant, people represent them at a higher level, focusing on their superordinate, central, and general features, whereas when events are psychologically proximal, people represent them at a lower level, focusing on their subordinate, peripheral, and concrete features. Research has also shown that unrelated cues can promote these more abstract versus concrete levels of processing (Fujita et al. 2006; Freitas, Gollwitzer, and Trope 2004; Förster, Friedman, and Liberman 2004) and have carry-over effects on decision processes (Khan, Zhu, and Kalra 2011; Kim, Zhang, and Li 2008; Meyvis, Goldsmith, and Dhar 2012).

We add to this work by testing how exposure to scarcity-related cues affects consumers' level of construal. Prior work has shown that exposure to threat-related cues can narrow one's scope of attention to a more local (vs. global) level (Friedman and Förster 2010). Because exposure to scarcity-related cues might trigger cognitions related to threat, one thus might expect such cues to promote concrete levels of construal (Liberman and Trope 2008; Marguc, Förster, and Van Kleef 2011). This prediction is supported by research showing that being raised or put in an environment where resources are scarce changes how people allocate attention, specifically by shifting focus towards the scarcity-related problem and away from other problems or future considerations (Griskevicius et al. 2013; Shah, Shafir, and Mullainathan 2011).

However, we draw from research on resource constraints and goal pursuit to argue that exposure to scarcity-related cues induces people to adopt an abstract mindset. Indeed, research has shown that interfering forces (Higgins 2006) encountered during goal pursuit induce a more global, higher-level perspective in order to improve problem solving through the detection of alternative means or strategies, and that this shift in processing can carry over to tasks unrelated to one's goal pursuit (Marguc et al. 2011). Related research has also shown that constraints put on a creative process can improve creative thinking (Burroughs et al. 2011; Moreau and Dahl 2005). Therefore, in resource-rich environments, being exposed to scarcity-related cues may not be interpreted as a threat, but instead as an interfering force that induces taking a step back and processing information from a more abstract perspective. We test this prediction in three studies and find convergent results supporting our prediction.

First, to test whether activating the concept of scarcity induces people to adopt an abstract mindset, study 1 manipulated the activation of scarcity (episodic recall, adapted from Fischhoff et al. 2003) prior to having participants complete the Behavior Identification Form (BIF; Vallacher and Wegner 1989), which assesses people's level of representation (abstract "why" vs. concrete "how") of 25 different activities. In line with our prediction, participants primed with scarcity were more likely to select higher-level representations of behaviors ($M = 17.05$) than participants exposed to a neutral prime ($M = 14.81$; $p = .054$).

Studies 2 and 3 demonstrate conceptual support for this effect, showing that activating the concept of scarcity broadens one's considerations. Prior work has shown that when individuals process information abstractly, they tend to categorize objects into fewer, more general, superordinate groups (Liberman and Trope 2008; Marguc et al. 2011; Waslak et al. 2006). Study 2 thus manipulated the activation of scarcity with a listing task (Roux, Goldsmith, and Bonezzi 2012), where participants had to list three things they "cannot do" (vs. "can do") when different resources are unavailable (vs. available). Participants then completed a categorization task (Waslak et

al. 2006), where they had to categorize three different lists of items (camping trip, household, and yard sale items) into groups. In line with our prediction, participants primed with scarcity classified the items into fewer categories overall ($M = 6.12$) than those in the neutral prime condition ($M = 6.64$; $p = .057$).

Prior research has also shown that abstract thinking expands the boundaries of conceptual categories and increases the inclusion of atypical exemplars into a given category (Liberman and Trope 2008). Study 3 thus manipulated the activation of scarcity (listing task) prior to having participants complete a category inclusiveness task (Huang and Galinsky 2011, Isen and Daubman 1984), where they had to rate the extent to which strong, intermediate, and weak exemplars belonged in a given category. In line with our prediction, participants primed with scarcity demonstrated greater category inclusiveness for medium ($M = 8.14$) exemplars than participants exposed to a neutral prime ($M = 7.75$; $p = .04$). A similar pattern of results emerged for the weak exemplars ($M_{\text{scarcity}} = 5.90$; $M_{\text{neutral}} = 5.48$; $p = .07$), but not for the strong exemplars ($M_{\text{scarcity}} = 9.87$; $M_{\text{neutral}} = 9.77$; $p = .13$), consistent with prior work (Huang and Galinsky 2010).

In summary, the findings presented here advance our understanding of how being exposed to scarcity-related cues affects one's psychological orientation. Across three studies, we demonstrate that exposure to scarcity-related cues promotes more abstract construals. Although further research is necessary to fully understand the boundaries of these effects, this research provides an important step towards a better understanding of the psychology of scarcity.

Paper #4: Naive or Savvy: How Credible Are Online Reviews for Credence Services?

Shannon Lantzy, University of Maryland, USA
Katherine Stewart, University of Maryland, USA
Rebecca Hamilton, University of Maryland, USA

SESSION OVERVIEW

Consumers often share information about their consumption experiences and discuss products and services with others online (e.g., by reviewing a service provider or participating in a discussion forum). Although previous research has provided insight about why consumers post content (e.g., Schlosser 2005) and how quantitative metrics such as review volume and ratings change over time (e.g., Moe and Schweidel 2012), we know much less about the factors that influence the qualitative content consumers share. An understanding of online content is critical because decades of research on social influence show that what consumers say influences others (e.g., strong vs. weak arguments: Petty and Cacioppo 1986; vividness effect: Herr, Kardes and Kim 1991).

The four papers in this session, all at an advanced stage, leverage both large datasets from online forums and controlled experiments to examine factors that influence word of mouth (WOM) content. Specifically, they examine whether **what consumers say** differs when they are:

- the first to post a response vs. the second or third?
- posting about the past or future instead of the present?
- posting a review on a mobile device vs. on their desktop computer?
- reviewing a provider whose services are harder vs. easier to evaluate?

Hamilton, Schlosser and Chen show that early responses to a post affect later responses to the post, suggesting that the first people to respond play a crucial role in driving the content of the discussion. **Weingarten** and **Berger** demonstrate that there is a strong present bias in what people talk about but that people tend to talk about the near future and distant past. This suggests that accessibility and emotional intensity affect *when* people talk about. The next two papers examine the effects of sharing devices and the type of experience. Lurie, Ransbotham and Liu find that restaurant reviews written on mobile devices are more affective and more negative than those written by the same reviewer on desktops. Notably, mobile reviews tend to be rated by others as less useful, perhaps because they are shorter and more emotional. Finally, Lantzy, Stewart and Hamilton also ex-

amine reviews of service providers and find that negative reviews contain higher-quality arguments and more information than positive reviews for the same types of service providers. They show that reviews of credence service providers (e.g., doctors, auto mechanics) include more claims about easier-to-evaluate experience attributes than claims about harder-to-evaluate credence attributes.

Consumers rely on online content to make important decisions. We aim to "*Make a Difference*" by identifying systematic biases that affect the information being shared online. We expect this session to generate discussion about the emotional and affective nature of online content, the influence of previous posts (either by the same person or by others) on subsequent posts, and the various methods that can be used to study WOM. This session will appeal to researchers interested in the antecedents and consequences of WOM and social media marketing as well as those interested in social influence and communication.

Who's Driving This Conversation? Systematic Biases in the Content of Online Consumer Discussions

EXTENDED ABSTRACT

Consumers rely on online word of mouth to make consumption decisions partly because they believe the information provided helps them make better-informed decisions. However, participants in online discussion forums may have multiple goals, only one of which is to provide others with accurate information. For example, participants may want to signal expertise (Schlosser 2005; Wojnicki and Godes 2012), convey uniqueness (Schlosser 2009) or build connections with others (e.g., Hennig-Thurau et al. 2004; Schlosser 2009). Because online posting is context-dependent communication in which participants read previous posts within a thread before offering their own opinions (Moe and Schweidel 2012), the information shared in online forums will be influenced by previous posts. Therefore, it's likely that early responses would drive the discussion towards or away from the information requested in the initial post.

We closely examine the role of early responses on later responses in online discussion threads in which the consumer seeking information explicitly tells other participants which decision criteria are important. For example, a consumer posting on TripAdvisor.com might describe an upcoming trip and ask for hotel recommendations, noting her preferences for location, price level and other services such as parking. Despite the objective value of the information that has been requested, we predict that the discussion content will show systematic biases. For example, we expect already mentioned attributes to be more rather than less likely to be mentioned in subsequent responses. Research on social influence has shown that group members tend to repeat shared information (Larson, Foster-Fishman and Keys 1994; Mojzisch et al. 2010; Stewart and Stasser 1995). Thus, we expect information provided in online discussion forums to be driven by early responses to the query: instead of equally reflecting attributes mentioned in the query, we expect the content to focus more on attributes already mentioned. We suggested that this is because consumers exhibit conformity to express affiliation toward others.

We test our predictions by analyzing public data from online discussion forums and conducting controlled experiments. Our analysis of discussion threads from three online discussion forums (on

Tripadvisor.com and DISboards.com) provides empirical evidence that early responses to a query drive the subsequent discussion. We examined two different consumption categories (hotels and restaurants) in three cities (Seattle, Washington DC, and Orlando). Our sample included 324 posts from 85 discussion threads with at least three participants and the goal of seeking advice about a specific decision (e.g., Should I stay at hotel A or B?) between January 2011 and January 2013. After identifying the attributes most frequently mentioned for each product category (e.g., location, price), two raters coded each response to indicate whether each attribute was mentioned. Because each response could mention multiple attributes, we used a Generalized Estimating Equations approach (GEE; Liang and Zeger 1986) to analyze the data. Controlling for the importance of the product attributes, we find that whether previous responses mention an attribute is more predictive of whether subsequent responses mention the attribute than whether the initial post mentions the attribute. This finding suggests that previous responses to a post play a critical role in influencing the attributes discussed in subsequent responses.

In Study 2, participants were given information about the attributes of two restaurants. Using this information, participants were asked to respond to a posted question asking about the appropriateness of the two restaurants for an occasion involving a large group of friends. The number of previous responses to the question was varied so that participants were either providing the first, second or third response. The content of the previous responses was also varied so that previous posts either mentioned the critical attribute (the suitability of the restaurant for groups) or did not (and mentioned the atmosphere of the restaurant instead). Consistent with our manipulation of the importance of the critical attribute, when there were no previous responses, more participants mentioned the restaurants' suitability for groups ($M = 70\%$) and fewer mentioned atmosphere ($M = 43\%$). Importantly, more participants mentioned the restaurants' suitability when *all* other previous posts mentioned suitability for groups ($M = 71\%$) than when no previous posts mentioned suitability for groups ($M = 48\%$). Notably, when some responses mentioned suitability for groups and others did not, participants were also less likely to mention the important attribute ($M = 52\%$). As in the real discussion threads we analyzed, participants in this study seem to be more strongly influenced by the initial responses to the post than to the query.

Study 3 allowed participants to communicate their own knowledge in their response to a post about a real event in which they were familiar. All participants read an inquiry post and a first response about the event. We manipulated the content of the first response in terms of the attribute being mentioned. The results were consistent with Study 2 such that participants were more likely to be influenced by the first response on attribute that is critical ($M_{\text{mention}} = 50\%$ vs. $M_{\text{not mention}} = 13\%$). However, when the attribute is not critical, whether the first response mentioned did not change participants' response ($M_{\text{mention}} = 45\%$ vs. $M_{\text{not mention}} = 49\%$).

Study 4 examined whether the perceived expertise of the first responder moderates the effect. The procedure was identical to study 2 except that we manipulated expertise by describing the first responder as a frequent or first-time traveler to the Boston area. Although we replicated the key finding of our first lab study, showing that whether the first response mentions the key attribute has a significant effect on whether the participant mentions it ($M = 79\%$ vs. 46%), we did not observe an attenuation of the effect when the first responder was perceived to be less expert. This suggests that the influence of the first responder derives not from his or her expertise

but from social incentives to focus on shared rather than unshared information.

In our last study, we manipulate the participant's goals to provide accurate information in response to the query or form relationships with group members. The procedure was similar to study 2 except that participants were encouraged to adopt either a group goal or an accuracy goal. As predicted, we replicated the early response effect only in the group goal condition, suggesting that participants' goals moderate the effect, suggesting that participants are responding to normative influence within the group setting.

When Do People Talk About and Why?

EXTENDED ABSTRACT

People talk about things that occur over various time horizons into the past, present, and future. They talk about the television show they are currently watching, the groceries they bought yesterday, and the restaurant they are going to tomorrow.

But, *when* are people more likely to talk about, and why? That is, how does the likelihood people talk about something vary based on its temporal position from the present, and how does this pattern inform us about the drivers of interpersonal communication?

We suggest two key factors shape *when* people talk about. The first is accessibility. People are more likely to talk about things that are accessible (Berger and Schwartz 2011). Temporally distant events are less accessible than temporally close events (D'Argembeau and Van der Linden 2004). In the context of when people talk about, that suggests that (1) individuals should share more about the present than the past and future, (2) that temporally close events should be shared more frequently than temporally distant events, (3) that people should talk more about the future later in the week when they get closer to the weekend, and (4) that people should talk more about the past 24 hours later in a given day. Second, arousal impacts sharing (Berger 2011; Berger and Milkman 2012) and emotional arousal should also shape when people talk about. Past research has found the future to be more emotionally intense than the past (D'Argembeau and Van der Linden 2004; Van Boven and Ashworth 2007), more positive (Newby-Clark and Ross 2003), and less constrained (Van Boven, Kane, and McGraw 2008). Consequently, while people may talk about the near past than near future (because it is more accessible), they may talk about the distant future rather than distant past (because it is more emotionally intense).

To provide a naturalistic examination of *when* people talk about, we collected a large sample of everyday conversations. We randomly selected about 3,000 tweets posted in the public twitter stream, 3,000 Facebook posts taken from an online database of Facebook data (Kosinski and Stillwell 2011), and hundreds of pages of transcribed in-person conversations from a written corpus. Next, two research assistants removed spam posts from the Twitter and Facebook data set. Then, three research assistants individually coded each message in Excel on a continuous scale in terms of fraction of a day from the present ($-7 =$ a week ago, $-1/24 =$ an hour ago, $0 =$ now, $1 =$ a day from now, $365 =$ a year from now), and resolved disputes together. The intraclass correlation coefficient for the datasets was high ($>.95$).

Four key results emerged. First, as predicted, interpersonal communication is very focused on the present. Approximately 43% of all rated posts were about exactly now, 29% were about the past, and 28% were about the future ($\chi^2(2, N = 3812) = 165.64, p < .001$). The past and future did not differ significantly overall in their frequencies ($\chi^2(1, N = 2169) = 2.324, p = .13$). If the range that counted as "present" was expanded (from 0) to include posts within a half

hour into the past and future, 60% of posts were about the present. This number grows to 64% if broadened to an hour into the past or future. This result shows that many online social media posts, if not focused on the very instant of posting, are focused heavily on the present, which is the most accessible.

Second, as predicted, time of day affects when people talk about. As the day progresses, individuals talk more about what happened within the previous twenty-four hours (excluding the past hour). This result holds in terms of hours ($B = .015$, Wald = 4.032, $p = .045$) and minutes ($B = .000217$, Wald = 3.171, $p = .075$) since midnight. Overall, this result is consistent with the accessibility explanation: individuals have and share more accessible material from earlier in the day as it progresses.

Third, as predicted, day of week also affects when people talk about. As people move further into the week (and away from the weekend), people talk more about the upcoming twenty-four hours. This progression holds for days since Saturday ($B = .054$, Wald = 7.131, $p = .008$) and trends in the right direction for hours since Saturday ($B = .00134$, Wald = 2.476, $p = .12$), and holds when reviewing days ($B = .055$, Wald = 7.113, $p = .008$) and hours ($B = .00195$, Wald = 4.854, $p = .028$) since Sunday. This result is also consistent with the accessibility mechanism if the future becomes more accessible as Friday gets closer.

Fourth, people talk more about the near past and distant future. In other words, the relative frequency of past and future fluctuates based on temporal distance ($\chi^2(1, N = 2169) = 63.041$, $p < .001$). Looking at nearby time periods, people share more about the previous twenty-four hours than the next twenty-four hours ($\chi^2(1, N = 1823) = 20.858$, $p < .001$), but for distant time periods (i.e., greater than a day away), people talk more about the future than the past ($\chi^2(1, N = 346) = 44.439$, $p < .001$). Whereas people talk more about the recent past than near future, they talk more about the distant future than the distant past. This latter finding is in line with the emotional intensity explanation inasmuch as the more evocative, distant future is shared more than the distant past.

Overall, these results are consistent with our predictions about the impact of accessibility and emotional intensity on the sharing from temporally close and distant time frames. People share more nearby events, and more distant future than distant past events. We are currently conducting various lab studies to further explore and provide evidence for our proposed mechanisms as drivers of these effects.

The Content and Impact of Mobile Versus Desktop Reviews

EXTENDED ABSTRACT

Although there is a growing body of research on the content and impact of word-of-mouth on consumer behavior, little is known about differences between mobile and traditional desktop reviews. Recent empirical research shows that desktop reviews are generally positive (Chevalier and Mayzlin 2006), that product ratings in online reviews increase over time but decline as the number of reviews increases (Godes and Silva 2012), and that later reviewers are influenced by earlier ones (Moe and Trusov 2011). Other research shows that the valence, dispersion, and volume of consumer reviews predict sales in traditional (i.e., desktop) online environments (Chevalier and Mayzlin 2006; Duan, Gu, and Whinston 2008; Godes and Mayzlin 2004). Other research suggests that the perceived value of consumer-created content depends on characteristics such as contribution length, contributors' prior posting behavior, contributor expertise, and the perceived similarity of the creators to the readers

of this content (Forman, Ghose, and Wiesenfeld 2008; Weiss, Lurie, and MacInnis 2008). However little is known about differences in the characteristics and relative influence of consumer content created in mobile versus traditional settings. In addition, there is substantial debate over the pros and cons of allowing consumers to write real time reviews with some fearing that mobile reviews will not benefit from reflection and that consumers will affectively (and negatively) respond to their current experiences. This has led some review sites (e.g., Yelp) to allow consumers to start reviews on their mobile devices but require them to use a desktop computer to finish them. This research addresses these issues by 1) identifying potential differences in content created on mobile versus non-mobile devices and 2) assessing how these factors affect the relative influence of mobile versus desktop reviews.

Given that mobile reviews are more likely to be written during or immediately after service experiences, they should be more accurate, and less optimistically biased, than retrospective (i.e., desktop) evaluations (e.g., the rosy view; Mitchell et al. 1997; Novemsky and Ratner 2003; Wirtz et al. 2003). This means that mobile reviews will be more negative than desktop reviews. However, because they are likely to be written in real-time, and therefore reflect "hot" reasoning (Ariely and Loewenstein 2006), mobile reviews may be more emotional and heuristic decreasing their perceived usefulness relative to desktop reviews. Further, time pressure and tradeoffs between physical and cognitive effort on mobile devices (Lurie, Song, and Narasimhan 2009) means that mobile reviews should be shorter; potentially also reducing their perceived usefulness (Weiss et al. 2008).

To gain initial insights into these issues, we collected 299,806 reviews from 125,147 users on 144,231 restaurants on the website Urban Spoon. Of these, 136,306 reviews (45%) were written on mobile devices and 163,500 (55%) were written on non-mobile devices. To control for user characteristics that might drive differences between mobile and non-mobile reviews, we focused on 4,449 users who wrote both mobile and non-mobile reviews providing a sample of 48,610 (20,616 mobile and 27,994 non-mobile) reviews. Review text was analyzed using the LIWC program (Pennebaker, Booth, and Francis 2007). To measure influence we examined differences in the number of people that "liked" a review. Results show that mobile reviews are shorter (as expected), more negative, involve a greater percentage of words expressing positive emotion, are less cognitive, and more affective. Mobile reviews are also less influential (i.e., fewer readers "like" these reviews) even after controlling for differences between mobile and desktop reviews.

Naive or Savvy: How Credible Are Online Reviews for Credence Services?

EXTENDED ABSTRACT

Online reviews allow consumers to share information about their service experiences with other consumers. Theoretically, sharing this information should reduce market information asymmetries between potential consumers and service providers because many attributes of a service experience cannot be evaluated prior to consumption (i.e., they are credence or experience attributes rather than search attributes; Huang, Lurie, and Mitra 2009). For example, although a consumer might be able to evaluate the prices of entrees (a search attribute) prior to eating at a restaurant, it is very difficult to evaluate their tastiness (an experience attribute) without having consumed a meal, and even after eating them, a consumer cannot verify the claim that they are made with organic ingredients (a credence attribute). Because consumers cannot assess the quality of credence attributes, consumer reviews of services that are dominated by cre-

dence attributes (e.g., doctors, auto mechanics) are of dubious credibility. Indeed, many doctors have strongly resisted the legitimacy of consumer reviews (Andrews 2008; Jain 2010), in some cases even requiring patients to sign documents promising never to review their doctors (ElBoghdady 2012).

Although consumers have numerous forums to review credence services (e.g., RateMDs.com, Angie's List, Yelp.com), extant research has focused only on reviews of search and experience goods (Huang et al. 2009; Mudambi and Schuff 2010; Park, Kim, and Han 2008). We address this gap by examining the claims typically included in reviews of credence service providers and whether consumers rationally discount claims about credence attributes within reviews. We pose three interrelated research questions: 1) Do the claims made in reviews of credence services on forums such as Angie's List and Yelp.com substantively differ from the claims made in reviews of experience services, and if so, how? 2) Which attributes do consumers believe are most important for evaluating credence service providers? and 3) When evaluating credence service providers, do consumers weigh credence claims more heavily than experience claims because credence attributes are more important for these services, or do they weigh experience claims more heavily because these claims are more credible?

We address these questions by conducting a content analysis of real online reviews and a series of lab experiments. First, we design and test a rigorous classification method for identifying credence and experience services based on their core and peripheral attributes. The economics of information literature categorizes goods and services into search, experience and credence categories, but does not discuss the possibility that credence services may have search, experience and credence attributes (e.g., a doctor's office location is a search attribute, bedside manner is an experience attribute, and accurate diagnosis is a credence attribute). Our categorization method fills a gap in the literature by explicitly linking a product's relevant search, experience, and credence attributes (Ford, Smith, and Swasy 1988) to the categorization of the product as a search, experience, or credence good (Dulleck and Kerschbamer 2006). Previous work has simply assumed the classification of goods as search, experience, or credence a priori, which has led to conflicting classifications. For example, in Nelson's original work (1970) and in subsequent papers a camera was classified as a search good, but other authors have argued that cameras should be labeled experience goods (Huang et al. 2009). We propose a replicable and rigorous method for classifying services based on their core and peripheral attributes.

Next, we content analyze online reviews of service providers to compare their content and structure across services that are dominated by credence vs. experience attributes. Using Toulmin's (1958) theoretical framework for evaluating arguments and claims, we compare the structure of claims made in reviews of experience vs. credence service providers. We find that negative reviews contain higher-quality arguments as well as more information than positive reviews for the same types of service providers. This finding provides an alternative explanation for the greater impact of negative reviews in online word of mouth that has been demonstrated in earlier work (Cao, Duan, and Gan 2011; Laczniak 2001). This pattern of results also may explain why review length seems to mediate the effect of review valence on helpfulness ratings (Wu, van der Heijden, and Korfiatis 2011).

Further, we code claims about specific service provider attributes that are mentioned in reviews. Our results indicate that reviews of credence services include a mix of claims about both credence and experience attributes, but claims about experience attributes appear more frequently than claims about credence attributes. Thus, we

find that although reviews of credence services contain claims about experience attributes (e.g., a doctor's bedside manner), they also contain claims about credence attributes that consumers cannot accurately evaluate (e.g., whether the doctor's diagnosis was accurate).

Finally, we are conducting a series of experimental studies to explore consumers' perceptions of reviews, manipulating factors such as the type of service provider (experience or credence), the type of attribute in the review (experience or credence), and the valence of the review (positive or negative). We expect to find that although consumers reading reviews may acknowledge the low credibility of credence claims when they are explicitly asked to evaluate the claims, claims about credence attributes significantly influence their evaluations of credence service providers.

SESSION OVERVIEW

All emotions arise from events that have relevancy to oneself. Certain emotions such as pride and embarrassment are particularly self-relevant, since they involve self-reflection and self-evaluation (Tangney and Tracy 2012). It is thus not surprising that a large body of research has examined the *intrapersonal* effects of emotions. For example, previous research has investigated the impact of pride on self-control (Wilcox, Kramer, and Sen 2011) and self-efficacy (Passyn and Sujana 2012), the antecedents underlying the self-appraisal elements of embarrassment (Dahl, Manchanda, and Argo 2001), and the impact of sadness on evaluative judgment (Schwarz and Clore 1983) and affect regulation (Andrade 2005). In addition to the intrapersonal impacts, emotion also plays a central role in our interpersonal life (Fisher and Manstead 2008; Van Kleef 2010). However, the *interpersonal* effects of emotions, particularly those self-conscious emotions (e.g., pride), have received little attention in consumer research.

In an attempt to advance our understanding of the interpersonal effects of emotion, this session brings together four papers, which particularly focus on pride, embarrassment, and sadness, to provide insights into how these emotions influence consumers' interpersonal encounters. Specifically, this session investigates the following questions: How would pride influence consumers' tendency to conform to others? How would embarrassment impact consumers' impression management concerns in a social setting? How would taking other's perspective affect consumers' embarrassment avoidant behaviors? How would sadness influence consumers' reactions towards interpersonal persuasions?

In the first paper, Huang, Dong, and Mukhopadhyay investigate the impact of pride on consumers' conformity behavior. They show that pride can either increase or decrease conformity depending on

lay theories of achievement (entity/incremental). Specifically, those who attribute achievement to personal traits (entity theorists) are less likely to conform than those who attribute achievement to effort (incremental theorists).

In the second paper, Huang, Wang, and Zhu examine the effect of embarrassment on consumers' impression management concerns in product selection and donation behavior. They show that when feeling embarrassed, consumers demonstrate behaviors to create a positive self-impression and at the same time to be consistent with their agentic-communal orientations.

In the third paper, Rossi and Scott also explore embarrassment by focusing on how taking other's perspective influences embarrassment-avoidant behavior. They suggest that perspective-taking prompts consumers to engage in less embarrassment-avoidant behavior. But this only occurs for consumers with high public self-consciousness.

In the fourth paper, Coleman and Williams investigate the impact of sadness on consumers' reactions to interpersonal persuasion. They show that consumers are naturally suspicious of sad (vs. happy) appeals by engaging in emotion regulation. This effect could be strengthened when persuasion knowledge is made accessible.

We believe that this session will appeal to a wide audience at ACR. There has been a limited understanding on emotions, particularly those self-conscious emotions, in an interpersonal setting. This session advances the literature by investigating certain important yet less studied emotions that range from cognitively differentiated affects (e.g., pride and embarrassment) to more global affects (e.g., sadness), and by providing insights into how each emotion may affect consumers' interpersonal behaviors (e.g., conformity, donation). Twelve studies were included in total with three studies in each paper. Also, this session echoes the conference mission of making a difference by reinventing established perspectives in theory and by providing socially impactful insights in practice.

Proud to Belong or Proudly Different? Contrasting Effects of Incidental Pride on Conformity

EXTENDED ABSTRACT

Pride is as an emotional response to success or achievement (Lazarus 1991; MacInnis and Patrick 2006; Mukhopadhyay and Johar 2007), in which the self is attributed as having achieved an important goal (Tracy and Robins 2004). It is a common response to important life events (e.g., graduation) as well as everyday occurrences (e.g., get praised by teacher). Previous research on pride has mainly focused on how incidental pride influences one's *own* behavior in a personal setting. For example, pride can influence consumers' self-control (Wilcox, Kramer, and Sen 2011), and is linked to self-efficacy (Passyn and Sujana 2012), and motivation for future achievement (Fredrickson 2001; Louro, Pieters, and Zeelenberg 2005). In contrast, the current research aims to explore whether and how incidental pride can influence consumers' preferences given *social* influence, specifically, their tendency to conform.

We propose that the effect of pride in such situations depends on the lay theories that consumers hold about their achievements. Lay theories influence how people interpret and predict their social worlds (Wyer 2004). Given that our domain of interest is the pride

that people feel in response to achievement, we draw on Dweck and Leggett's (1988) seminal concepts of lay theories of achievement. In this model, "entity theorists" believe that intelligence and ability are fixed quantities and cannot be changed, whereas "incremental theorists" believe that intelligence and ability are malleable resources and thus can be improved through effort. Hence success is attributed differently depending on one's lay theories – either to traits (for entity theorists), or to efforts (for incremental theorists; Molden and Dweck 2006).

How do these lay theories influence the effect of pride on conformity? The key insight here is that pride is not a unitary construct, but rather two different types of pride – hubristic and authentic (Tracy and Robins 2007). Hubristic pride results from achievement that is attributed to internal, stable, and uncontrollable causes ("I did well because I'm great."), whereas authentic pride results from achievement that is attributed to internal, unstable and controllable causes ("I did well because I tried."). Importantly, the distinct patterns of attributions for hubristic versus authentic pride are parallel to those made by entity versus incremental theorists.

Now, hubristic and authentic pride can lead to different interpersonal relationship goals. Hubristic pride is associated with superiority (Tracy and Robins 2007) and narcissism (Lewis 2000; Tracy and Robins 2007). People feeling hubristic pride are motivated to "get ahead" at the expense of others (Cheng et al. 2010). In contrast, authentic pride is associated with feelings of self-worth and authenticity (Tracy et al. 2009), and activates the interpersonal goal of "getting along with others" (Cheng et al. 2010). People feeling authentic pride are more likely to feel similarity with others (Batson et al. 1997; Cialdini et al. 1997).

Because perceptions of similarity are an important predictor of conformity (Castelli et al. 2001; Cialdini 2001), we hypothesize that authentic pride will increase conformity, whereas hubristic pride will enhance uniqueness preference. More generally, incremental theorists who feel proud will make effort-based attributions and thus conform, similar to those experiencing authentic pride. In contrast, entity theorists who feel proud will make trait-based attributions and not conform, similar to those experiencing hubristic pride.

Three studies investigated these possibilities. In study 1, we examined if participants who experience effort-based pride (i.e., incremental theorists) express greater conformity than those who experience trait-based pride (i.e., entity theorists). We first asked participants to recall an event when they felt pride due to their efforts versus due to their own traits. Participants then performed an ostensibly unrelated on-line shopping task in which they chose one T-shirt from a set of four options, which were identical except that three of them were white and one was red. A significantly greater percentage of participants in the trait-based (versus effort-based) pride condition chose the uniquely-colored T-shirt.

The procedure of study 2 was essentially the same, except for two differences. First, instead of using manipulating two types of pride, we manipulated entity versus incremental lay theory by presenting participants with a Psychology-Today type article describing the lay theory of achievement (Chiu, Hong, and Dweck 1997), and then asked participants to recall either a pride experience or a typical school day experience (control condition). Second, we used four different product categories to measure conformity. Results showed that proud participants who believed in the entity (vs. incremental) theory showed less conformity. There was no effect in the control condition, meaning lay theory itself did not influence conformity.

Study 3 extended the previous results in the following ways. First, we measured participants' lay theories, instead of manipulating them. Second, we generalized our findings using a different product

category and a different measure of conformity. Participants first recalled either a pride experience or a typical school day experience, and then indicated their evaluations of a popular brand of hiking GPS and a unique one. The difference between the two evaluations served as an index for conformity. In the third task, participants indicated their belief toward implicit theory (entity vs. incremental). Regression analyses with pride condition, mean centered lay theory, and their interaction as independent variables and the conformity tendency as the dependent variable revealed a significant main effect of lay theory and a significant interaction effect. Spotlight analyses (Aiken and West 1991) revealed entity (vs. incremental) theorists evaluated the popular hiking GPS less favorably when they were feeling proud. However, no significant effects were obtained among incremental theorists.

This research demonstrates a novel effect of incidental pride on consumers' conformity preference. The distinction between the two types of pride is new to consumer research, and the underlying mechanism represents a synthesis of the literatures on emotions and lay theories.

The Interplay Effect of Embarrassment and Agentic-Communal Orientation on Consumer Behavior

EXTENDED ABSTRACT

Embarrassment is an experience that nearly everyone is familiar with. It occurs "whenever an individual is felt or have projected incompatible definitions of himself before those present" (Goffman 1956), such as when people purchase embarrassing products or when they do not have enough money to pay at the register. Despite its prevalence, little research has been done looking at how embarrassment influences consumer behavior. Hence, this research seeks to investigate how embarrassment impacts consumers' product selection and donation behavior.

According to typical psychological models of embarrassment (e.g., Edelman 1981; Keltner and Buswell 1997), behavior inconsistent with social rules in the presence of real or imagined others leads to arousal. The arousal gives rise to nonverbal behavior that provides information to the self and the observer to label the arousal as embarrassment. There is a need of "face-saving" after embarrassing interchange to honor, maintain, and restore the desired public identity (Goffman 1956, 1959). The need motivates people to develop strategies to alleviate distress and create a favorable impression (Brown and Garland 1971; Keltner and Buswell 1997).

We argue that this face-saving need interacts with agentic-communal orientation to influence consumers' product selection and donation behavior differently. Individuals with agentic orientation are self-centered and tend to be independent from other people, whereas individuals with communal orientation are other-oriented and tend to focus on interpersonal affiliation (Eagly 1978, 1987; Carlson 1972). Therefore, we hypothesize that when feeling embarrassed, people will follow strategies that are consistent with their orientation and at the same time try to create a positive self-impression. Specifically, for product selection which is self-focused, when feeling embarrassed, communal individuals (e.g., females) will prefer in-group options to enhance affiliation with others, while agentic individuals (e.g., males) will prefer non in-group options to reflect their individuality. Both strategies create a positive self-impression. In the domain of donation which is other-focused (Eagly 1987), the results will reverse (i.e., favor in-group) for agentic individuals. This is because agentic individuals normally favor out-group charity, but when feeling embarrassed, favoring in-group charity helps them cre-

ate favorable self image and at the same time allows their agentic goals still to be met (Winterich, Mittal, and Ross 2009).

We tested these hypotheses in three studies. In Study 1, we used participants' gender as a proxy of agentic/communal orientation. Participants came in groups of three, and were asked to choose and evaluate products in a hypothetical shopping task. The products contain either embarrassing products (e.g., adult diapers) or regular products (e.g., paper towel), depending on the condition. The experimenter verbalized each participant's choice loudly and ensured other participants to hear it. Embarrassment was successfully induced in this way, as the awareness of social presence is critical in creating embarrassment (Dahl, Manchanda, and Argo 2001). After the embarrassment manipulation, participants chose between two pens as a thank-you gift, one with a university logo and the other with no logo (i.e., in-group vs. non in-group). Their pen choice served as our dependent variable. Consistent with our hypothesis, there was a significant interaction between emotion (embarrassing vs. control) and gender, such that females preferred the logo pen whereas males preferred the no-logo pen when feeling embarrassed.

In study 2, we tested our hypothesis in the donation domain. After a similar embarrassment manipulation with study 1, participants indicated how much they were willing to donate out of their \$10 compensation towards either an in-group or an out-group charity. Their agentic-communal orientation was also assessed at the end. As predicted, we found a three-way interaction between gender, emotion, and charity type. Specifically, for females, there was only a main effect of charity such that females preferred in-group (vs. out-group) charity regardless of the emotion. However, for males, there was an interaction between emotion and charity type, such that males donated more to in-group charity in the embarrassing condition, but donated more to out-group charity in the control condition. The pattern maintained the same when we replaced gender with agentic/communal scores, which further supported our proposition.

In Study 3, we manipulated agentic-communal orientation and looked at both donation and product evaluation. We adopted a sentence-scrambled task from Kurt, Inman, and Argo (2011) to prime agentic/communal orientation at the beginning. Embarrassment was induced as per previous studies. After the same donation task as that in study 2, participants were asked to evaluate a hypothetical vacuum that was made either domestically (i.e., in-group) or internationally (i.e., out-group). For donation task, we replicated our previous results. For product evaluation, there was a three-way interaction between priming, country of origin, and emotion, such that agency-primed individuals showed more favorable attitudes towards the out-group vacuum when feeling embarrassed (vs. neutral), whereas communally-primed individuals had more favorable attitudes toward the in-group vacuum in the embarrassing condition.

Results from three studies show that embarrassment and agentic-communal orientation jointly influence consumers' behaviors. Embarrassed individuals tend to engage in behavior consistent with their orientation and creating a positive self to "save face".

Empathy-Neglect in Embarrassment-Avoidance: Observations from an Outsider

EXTENDED ABSTRACT

As consumers, we often forgo opportunities to help ourselves and others in order to avoid embarrassment. Our fear of embarrassment prevents us from admitting we do not know how a product works such as a mortgage or birth control, and from asking advice about what we should do such as our mounting mortgage bills and unplanned pregnancies. In many cases, if we are to help ourselves

and others, we must overcome our fear of embarrassment. This research offers advice on how to curb consumers' embarrassment-avoidant behavior.

Recent research should bring comfort to those who worry about others witnessing our embarrassing blunders. First, our blunders often go unnoticed by others (Gilovich, Medvec, and Savitsky 2000). Nevertheless, we overestimate how much others pay attention to us; a tendency termed the 'spotlight effect'. Second, when others do notice our embarrassing blunders, they tend to make kinder judgments than we expect (Savitsky, Epley, and Gilovich 2001). Still, we fail to take others' empathy into account, a tendency termed 'empathy-neglect' (Epley, Savitsky, and Gilovich 2002). Both of these tendencies—the spotlight effect and empathy-neglect—underlie embarrassment-avoidance. However, no studies to date have examined how these two factors interact to increase or decrease embarrassment avoidance.

A main goal of our research is to investigate the roles that both the spotlight effect and empathy-neglect play in influencing embarrassment-avoidance. For example, if empathy-neglect was reduced, would a spotlight still cause embarrassment-avoidant behavior? This is an important issue since it may often be impossible for consumers to avoid being in the spotlight (e.g. when purchase of a product is public knowledge). Alternatively, would empathy-neglect cause embarrassment-avoidance absent a spotlight? This is also an important issue since it would imply an influence on consumer behavior regardless of whether it occurs in public or private. For example, do consumers who avoid public opportunities to learn about a product, such as a mortgage or birth control, avoid private opportunities as well? An understanding of the separate and combined effects of the spotlight effect and empathy-neglect could provide a basis for effective strategies to manage embarrassment-avoidance. To this end, we must investigate the role of one individual-difference variable, namely public self-consciousness (PUBSC), since it determines whether one or both of these tendencies are at play.

Experiment 1 tested the initial hypothesis that although high (vs. low) PUBSC consumers have higher expectations of being embarrassed and thus engage in embarrassment-avoidance, all consumers regardless of PUBSC suffer from empathy-neglect and persist in embarrassment-avoidant ways. Three ads for an embarrassing but well-paying job were created: control, spotlight disclaimer, and empathy reminder. Analysis found that PUBSC moderated embarrassment-avoidant behavior due to the spotlight effect but not due to empathy-neglect. Specifically, the significant interaction between ad type and PUBSC arose from the control ad, which simply provided details about the job opportunity. High PUBSC was associated with lower application intentions. However, there was no relationship between PUBSC and application intentions in response to either the spotlight disclaimer or the empathy-reminder ad.

We next investigated a process by which empathy-neglect can be countered. Experiment 2 demonstrated in the healthcare context that perspective-taking is a helpful (hurtful) tool to correct for empathy-neglect among high (low) PUBSC consumers. Participants were prompted to take the perspective of either the interviewer or the interviewee, depending on the condition, and indicated their intentions to be interviewed about sensitive issues relating to their sex lives. In a control condition there were no perspective-taking prompts. In addition, half of participants received a cognitive load manipulation. We predicted that cognitive load would inhibit the presumably effortful empathy-transfer. Analysis revealed a three-way interaction among PUBSC, perspective-taking, and cognitive load, such that empathy-transfer (and reduction of empathy-neglect among high PUBSC consumers) could be triggered by adopting the perspective

of the interviewer (but not the interviewee), and required psychological effort (no load).

Experiment 3 tested our theorizing in another important consumer context, advertising embarrassing products. After exposure to a real-world flatulence prevention brand, participants' purchase intention was assessed and open-ended responses were collected to examine the proposed empathy-transfer process. Analysis found the predicted three-way interaction among PUBSC, ad type, and cognitive load on purchase intentions. A two-way interaction emerged between PUBSC and load for the control ad conditions, whereby higher PUBSC levels were associated with more embarrassment avoidance under no load. Load exacerbated the PUBSC effect. Further, analysis of the thought protocols in terms of self-related versus other-related thoughts under load and no load provided ancillary evidence as to the effortful nature of the empathy-transfer process, as well as chronic differences in how high versus low PUBSC consumers respond to embarrassing ads and perspective-taking prompts.

Together, these three experiments demonstrate the power of our theory to explain, predict, and modify embarrassment-avoidant consumer behavior, even when the consequences are financially and socially significant.

Hardening My Heart: Persuasion Knowledge and Emotion Regulation

EXTENDED ABSTRACT

Consumers do not passively process marketing influence attempts, but rather use persuasion schemas to interpret, resist, and reject persuasion (Campbell and Kirmani 2000; Friestad and Wright 1994). The "Persuasion Knowledge Model" (PKM) proposes that consumers develop knowledge structures about persuasion, influence agents, and selling tactics, and they use this knowledge to cope with persuasion episodes. Researchers propose an assortment of persuasion tactics; invoking social norms, "battering up" the target, bargaining, and more (Friestad and Wright 1994; Rule, Bisanz, and Kohn 1985). While many of these have been investigated, a repeatedly mentioned but rarely examined tactic is emotions. In fact, using emotional appeals was one of the most common interpersonal persuasion techniques (Rule, Bisanz, and Kohn 1985). Given this, understanding whether consumers recognize emotional appeals as persuasive tactics and how they respond to these attempts is needed.

We specifically focus upon emotion appeals that use sadness to motivate consumers. Sadness results from experiences of loss that cannot be avoided (Frijda 1986), and prompts actions to change the situation (Frijda, Kuipers, and ter Schure 1989). Expressions of sadness indicate a need for help (Izard 1977) and promote feelings of sympathy (Small and Verrochi 2009), leading to enhanced prosocial behaviors (Small and Verrochi 2009). We draw upon emotion regulation theories—how individuals manage the emotion antecedents and emotional responses (Gross 1998)—to propose that when consumers recognize an emotional appeal as an influence attempt, they regulate their emotions to resist persuasion.

Study 1 examined whether consumers spontaneously regulated their emotions when they encountered emotional advertisements, and whether this would differ for happy versus sad appeals. This was a three-group design, where participants saw either a happy, sad, or neutral commercial. Emotional content was manipulated through pictures and music with identical information. After the commercial, participants reported attitude toward the ad, the degree of emotion regulation, and beliefs about manipulative intent (to measure persuasion knowledge). Attitude toward the ad was the highest for the happy commercial compared to both the neutral and sad commercials.

The amount of emotion regulation was highest for the sad commercial, whereas no difference occurred for the neutral and the happy commercials. Also, the sad commercial prompted beliefs of manipulative intent, but the happy and neutral commercials were seen as only mildly manipulative. And indeed, serial mediation found that sad appeals prompted inferences of manipulative intent, which in turn induced emotion regulation, which finally predicted attitude toward the ad. Once the indirect effects were accounted for, the direct effect of emotion appeal was no longer significant in predicting attitude toward the ad, implying full mediation through both manipulative intent and emotion regulation (Preacher and Hayes 2008). These results suggest that consumers naturally see sad appeals as manipulative, triggering an emotion regulating response. However, happy commercials "fly under the radar" and do not prompt the activation of persuasion knowledge and its concomitant rejection.

Study 2 manipulated the accessibility of consumers' persuasion knowledge. The design was 3 emotions (happy, sad, neutral) x 2 accessibility (high, low); accessibility was manipulated by reading an article about persuasive tactics (high) or about superstitious beliefs (low) prior to the commercial. As before, participants rated their attitude toward the ad, emotion regulation, and manipulative intent. In the low accessibility conditions, the results from study 1 were replicated: emotion regulation and manipulative intent were only high for participants viewing the sad commercial. However, results in the high accessibility conditions showed a different pattern. Specifically, those who viewed the happy or the sad commercials both increased emotion regulation and manipulative intent inferences. Results suggested that when persuasion knowledge was accessible, consumers relied on it to interpret the persuasive messages; happy appeals were also seen as utilizing persuasion, leading to consumers' emotion regulation.

Study 3 replicated study 2 in the context of donation. Specifically, participants first read the article from study 2 to manipulate accessibility. Then participants were exposed to one of three advertisements for a children's cancer charity, where the child in the ad was expressing either happiness, sadness, or a neutral expression (Small and Verrochi 2009). Previous work has shown that individuals who view the sad child experience sadness themselves, via emotion contagion, and this experience of sadness then increases sympathy and prosocial behaviors. We predicted that the accessibility of persuasion knowledge would moderate these effects. A significant interaction of persuasion knowledge accessibility and emotion emerged: for those with low persuasion knowledge accessibility, sympathy toward the child was the greatest for the sad ad, replicating earlier work. However, for those with high persuasion knowledge accessibility, the pattern reversed that sympathy for the child was the lowest for the sad ad (no difference occurred between the happy and the neutral ads).

Three studies demonstrate that individuals resist emotion-based persuasive attempts through emotion regulation; however the natural response is only toward sad appeals. When persuasion knowledge is made accessible, individuals recognize that happy appeals are also influence attempts and regulate those as well. Our findings certify that emotion regulation can be used to resist persuasion, suggesting new directions for studying emotion regulation.

SESSION OVERVIEW

Who is materialistic, and why, and whether materialism has positive or negative implications, fluctuates pending the social context. Such fluidity suggests that it may be time to reevaluate the basic concept, which has been formulated as an individual construct, to consider encompassing the social milieu—religious influences, group tensions, and socio-economic context.

This special session creates such an opportunity, allowing researchers to explore the meaning of materialism and to move the construct from a deeply rooted personal value to one shaped by social conditions and tensions. To do so, it demonstrates how the concept can have widely different results even when all the studies pull from the same scale (Richins and Dawson 1992). The studies stretch the concept across diverse geographical regions—Malaysia, South Africa, Israel and America—and across divergent groups of consumers and social settings. Some pull at the social tensions and consumer stress associated with materialism, others demonstrate how it can be used as a positive force to rejuvenate the economy. This session would open up the constructed scale to expose its inherent biases, to explain what aspects of the scales give rise to the varied findings and how the social context influences these findings, and ultimately, provide a starting ground where cultural biases that shape our understanding and study of the general concept of materialism can be brought to the fore.

Fon Sim Ong and George P. Moschis open the session with evidence that may help explain the contradictory outcomes that have often plagued materialism and well-being studies. Using a large survey of Malaysians, their study finds adherents of Islam, who tend to place material possessions in direct philosophical conflict with pious living, experience higher levels of stress if they are materialistic, which in turn will lower their level of life satisfaction. In contrast, these results differ from Hindus and Buddhists, who conceptualize the relationship between the material and spiritual in a different way.

Consequently, the effects of materialism are strongly moderated by both religion and the level of religiosity.

Laurel Steinfield and Linda Scott similarly build from the moral tensions materialism creates around consumption, but view “materialism” as an epithet that is used in South Africa to protect racial stratifications. They demonstrate that “materialism” is a local racial slur, intended to discredit the consumption behavior of blacks when they purchase goods formerly available only to whites. Hurling an insult about black “materialism” thus acts as a moral restriction to protect the demarcating power of goods.

Ayalla Ruvio, Eli Somer, and Aric Rindfleisch discuss how materialism influences coping in extreme stress situations. When traumatic stress increases, materialistic people react more adversely, often by engaging in maladaptive consumption behaviors such as impulsive buying and shopping escapism.

Dee Warmath and Nancy Wong end by discussing how materialism can help a society navigate economic downturns through triggering consumer spending. They break apart the materialism scale to note how the different sub-categories affect consumer behavior. Two dimensions of materialism (success and centrality) combined with hope bolsters consumer confidence about the economy, while the happiness dimension of materialism combined with hope influences personal confidence and leads to higher spending expectations.

Each of the studies points to a different way of viewing materialism and offers potentially fruitful avenues for future research, yet the sum of these approaches may also help us to imagine how a better understanding of the social dimensions of materialism can guide policies, even in high stress situations and among diverse groups, toward more humane tactics. This session should be of relevance to researchers interested in materialism, cross-cultural studies, consumption and wellbeing, and moral versus immoral consumption.

Materialism and Well-Being among Consumers of Three Asian Subcultures: The Effects of Religion and Ethnicity

EXTENDED ABSTRACT

Studies on the relationship between materialism and life satisfaction have produced contradictory findings across cultural settings. There is little theory to suggest the reason(s) materialism is associated (positively or negatively) with well-being in some countries and not in others, the processes that link materialism to life satisfaction, and the variables that moderate this relationship. Furthermore, it is not clear whether materialism is the cause or the consequence of well-being, whether the two variables are causally related, or even whether the previously reported relationships between them represent the effects of third variables.

This paper explores the impact of the socio-cultural context on materialism. It presents the results of a government funded large-scale study that seeks to explain the relationship between materialism and well-being by assuming that materialism 1) affects well-being, 2) is a consequence of a person's well-being, or 3) its relationship with well-being is the result of third variables, especially ethnic and religious differences among consumers of a culturally diverse Asian society. By confining the present study to a sample of consumers drawn from Malaysia—a country of diverse subcultures who share similar cultural values (collectivistic), we attempt to control the ef-

fects the other possible reasons that generate these differences, ranging from broad macro-environmental factors (e.g., country-related) to mediating processes, as well as ways people in different countries respond to questions and measurement instruments.

The study involved a survey using face-to-face interviews with 1,025 adult Malaysian consumers who lived in five major cities/towns. Non-probability quota sampling was employed to ensure equal representation of the three ethnic groups, Malays, Chinese, and Indians. All of the respondents were age 20 or older, and the average (mean) age of the sample was 48.08 years old, with a standard deviation of 16.58 years. The percentages of female and male respondents were almost equal: 51.4% of the respondents were female and 48.6% were male. The respondents' ethnic backgrounds were: 52.9% Malay, 29.4% Chinese, 15.6% Indian, and 2.1% were of other ethnic backgrounds.

The items in the questionnaires were designed to collect data on the variables related to the hypotheses of this study. The constructs: materialism, well-being (measured using life satisfaction and self-esteem), stress, and religiosity were measured by using established scales. All of the scales had a Cronbach's alpha greater than .70. A measure of social desirability was also used.

In this study, we first assumed that materialism is a causal variable that adversely affects well-being, as this is the implicit assumption of most studies (e.g., Burroughs and Rindfleisch 2002). We then, however, tested a second explanation for the observed negative relationship between well-being and materialism, assuming a reverse causality - i.e., well-being leads to materialism. Because well-being is defined by psychologists in several ways, including self-esteem and strength of aversive feelings (e.g., depression, anxiety, stress) (Burroughs and Rindfleisch 2002), it has been shown that materialism helps consumers alleviate negative feelings and low self-worth (e.g. Belk 1988; Chaplin and John 2007). We use structural equations modeling with instrumental variables to decompose the possible reciprocal effects of the two constructs, but our instruments turn out to be weak predictors of their respective variables.

In using conventional methods of data analysis to test our hypotheses, we find that stress mediates the effects of materialism on life satisfaction, and religiosity moderates the relationship between materialism and stress, which has negative effects on well-being. However, this finding holds among the most religious Malays (Muslims). These findings suggest that it is the specific values of the Islam religion that might be in direct conflict with material possessions, not those promoted by Hinduism or Buddhism; and they help clarify the conflicting values perspective (Burroughs and Rindfleisch 2002) because they suggest that religiosity is a necessary but not a sufficient condition (i.e., religious beliefs matter).

In viewing materialism as a consequence of well-being, we find that only lower degree of stress significantly moderates the effects of self-esteem on materialism. These findings suggest that self-esteem is a coping resource, as suggested by Thoits (1995). During stressful times, material possessions may be viewed as means to reducing stress—i.e., medicating one's adverse emotions, rather than serving as means of enhancing one's self in the eyes of others. In contrast, in the absence of stress, Malays may value material possessions as a way of "showing face" to others, a motivation commonly noticed in Asian countries (Wong and Ahuvia 1998).

The study findings suggest that consumers in different Asian ethnic subcultures are affected unequally by their religions and religiosity. Religion may constitute one of the main factors that affect each subculture's belief system regarding life in general and consumption in particular. As shown in this study, religiosity significantly and directly affects the life satisfaction of all three ethnic

groups. However, in terms of consumption behavior, other factors may also influence each subculture differently. Specifically, the study findings suggest that because the materialistic values of the Indians cannot be predicted by either religiosity or life satisfaction. When comparing the three ethnic subcultures, the Malays, who are Muslims, appear to be affected by religiosity the most, both in terms of life satisfaction and materialism. Although the Chinese are less religious than the Indians, their levels of religiosity have a greater effect on their life satisfaction and materialism.

These findings could be explained by other factors that relate to different social structures in which these subcultures are embedded. The results, for example, also demonstrate how different ethnic sub-cultural groups have different predictors of life satisfaction (Diener and Diener, 1995). Diener et al (1998) have found that causes of subjective well-being reflect people's values. Thus, in a collectivist culture, differences in subjective well-being could be due to culturally defined norms that lead to different emotional reactions depending on what the subculture defines as acceptable (Suh and Koo, 2008).

This study offers evidence to help explain the socio-cultural context and mechanisms that account for the negative relationship between materialism and life satisfaction reported in previous studies conducted in many countries.

Social Stratification and the Materialism Label: The Retention of Racial Inequities between Black and White Consumers in South Africa

EXTENDED ABSTRACT

We begin from the observation that, in English-speaking societies, "materialistic" is an epithet. The moral polarity that results – materialism (sin) versus spirituality (virtue) – is clearly reflected in the early CB literature on the topic (Belk 1983; Pollay 1986). Indeed, the word's status as an insult is apparent in socially desirable responding (Mick 1996) among research subjects.

In this research, therefore, we focus on the circumstances in which one group labels another "materialistic": we ask why they are using that particular label and question whether the people being thus labeled view themselves as "materialistic." Using Goffman's (1951) work on status symbols, we look at how the application of this pejorative protects the demarcating power of goods when a threat of misappropriation occurs. Status symbols hold expressive powers (they express the cultural values, lifestyles, privileges or duties a person holds) and categorical powers (they visibly divide the social world), and so their misappropriation threatens the social distinctions that maintain hierarchy. The accusation that someone is "materialistic" exemplifies a set of interested moral restrictions designed to keep outgroups from acquiring the symbols of the established elite. Such moral restrictions are often disguised as "religious scruple, cultural disdain, ethnic and racial loyalty, economic and civic propriety, or undisguised 'sense of one's place'" (Goffman 1951: 297). In this study, we consider how materialism acts to restrict consumption by social grouping, as well as the power agenda that the rhetoric of morality conceals.

We look at the social context surrounding the use of materialism, not to discern how the meaning of materialism changes with differing value structures, but to look at whether it acts to produce judgments that protect the hierarchy. Using the luxury goods market in South Africa, we show how the term is imbued with power that maintains race-based social stratifications. We assess the reasons "materialistic" people consume and show how personal justifications illuminate stratification.

In South Africa, through government and business initiatives focused on empowerment and wealth creation (such as Black Economic Empowerment (BEE)), there is an emerging black middle class starting to challenge one of the significant legacies of apartheid - the racial segmentation of class and consumption. Studies being conducted on this group, popularly labeled "Black Diamonds," show an increase in the proportion of black households in the upper quartile income segment. In 2006, 78.8% of white households, compared to only 8.6% of black households, were in the upper quartile (Statistics South Africa 2008). Yet by 2011, black households represented 40% of South Africa's richest 10%. In demonstrating their new wealth, Black Diamonds often "trade-up" and emulate the respectable life of the elite White through living in White-majority posh areas, sending their children to prominent English or Afrikaans schools, and procuring the status symbols once definitive of the white elites (UCT Unilever Institute 2011).

Our study focuses on luxury consumption in South Africa, focusing on an observable status symbol with expressive potential, but with previously limited availability for blacks. Media coverage and speeches by prominent South Africans were first analyzed to understand the local discourse around luxury consumption and race. Participant observations were conducted at the boutiques where the line under study was sold. We then conducted forty interviews with luxury goods consumers and sales personnel, using pictorial stimuli and adjective checklists. We administered Richins and Dawson's (1992) scales, but afterward showed respondents their scores and asked them whether they agreed with the outcome.

As we expected, pejorative terms of "ostentatious," "flashy," and "materialistic," were often applied to describe the luxury consumption of blacks, which did not exist to the same extent for whites. Local terms that emerged during interviews to describe "materialistic" consumers, such as "fat BEE cats" and "tenderpreneurs," are applied *only* to black people. Our analysis of media and speeches explain how these terms linked the origins of black wealth with corruption and government nepotism, and are used to taint the legitimacy of blacks' wealth and luxury consumption. Blacks are believed to consume luxury goods for less appropriate reasons than whites: blacks purchased products for status or brand labels, versus the white elite who are believed to purchase and truly appreciate luxury goods for their quality and craftsmanship. These beliefs were accepted and internalized by both blacks and whites, and reflected in their justifications for their own materialistic tendencies. When asked about their own "materialism" scores, blacks would often accept that they could be considered materialistic because they wanted to achieve and demonstrate their new wealth. For them, status symbols were "game changers" in business meetings, in wedding proposals, and for their own personal sense of accomplishment. In contrast, white consumers would downplay the applicability of their materialism scores, saying they merely appreciated the finer things in life.

Thus, we argue that the social dislocations resulting from the post-apartheid power shifts have given rise to moral polarities describing luxury consumption of different races. From this perspective, "materialism" is not a consumer value or trait, but instead a word with a social use: to maintain racial stratifications. These findings suggest that "materialism" is used by people as a moral restriction, and as such, these findings may have relevance for other contexts with intense social dislocations or for other stratifications (gender, class, religion) in which the threat of status deprivation exists.

When the Going Gets Tough the Materialistic Go Shopping: Materialism and Consumption Response to Stress

EXTENDED ABSTRACT

Recent consumer research has examined the influence of existential insecurity on a variety of consumption-related behaviors. Drawing upon Terror Management Theory, this research suggests that in times of upheaval and stress people often seek relief via shopping and consumption (Arndt, et al., 2004; Mathwick, et al. 2001 Rindfleisch et al., 2009). Unfortunately, research indicates that consumption provides little benefit to materialistic individuals (Belk, 1985; Burroughs & Rindfleisch 2002; Richins & Dawson 1992). Thus, it might be the case that materialism may actually make bad events even worse. Our research explores this question.

Specifically, we suggest that highly stressful life events (such as a terrorist attack) will generate higher levels of post-traumatic stress (PTS) among materialistic individuals compared to their less materialistic counterparts. Furthermore, we theorize that materialistic individuals will also exhibit higher levels of maladaptive consumption behavior such as compulsive consumption and impulsive buying. In other words, we focus on the moderating effect of materialism on the relationships between PTS and the maladaptive consumption behavior. As such, we extend previous research that largely centers on *direct* negative outcomes of materialism, by examining the *indirect* (moderated) effect materialism, which makes negative outcomes even worse.

We conducted a field study that consists of 139 participants in the extreme-stress group who experienced ongoing terrorist attacks and 179 individuals in the low-stress group who were exposed to these events via the media only. Our measures include scales for materialism (Richins and Dawson 1992), PTS Symptom Scale (Foa et al. 1993), compulsive (Babin et al. 1994) and impulsive buying (Beatty & Ferrell 1998).

The results of our hierarchical regressions show that threat condition (0 = non-mortal-threat, 1 = mortal-threat) is positively associated with PTS ($b = .44, p < .01$). The mean level of stress in the mortal-threat condition was 17.4 (range: 0-51) compared to 6.5 (range: 0-40) in the non-mortal-threat condition ($t(310) = -8.30, p = .001$), indicating that participants from the mortal-threat condition experienced higher PTS than participants from the non-mortal-threat condition. In addition a significant interaction between threat condition and materialism ($b = .10; p < .05$) was established, which indicates that stress associated with a mortal threat is greater among highly materialistic individuals than their less materialistic counterparts.

We tested the effect of PTS as a mediator of maladaptive consumption, compulsive consumption and impulsive buying, and materialism as a moderator of these relationships.

Compulsive Consumption. Threat condition has a significant effect upon compulsive buying ($b = .06; p < .05$). In addition, PTS (the mediator) also exhibits a significant effect upon this outcome ($b = .21; p < .05$). Moreover, when this mediator is accounted for, the effect of the threat condition is reduced to non-significance ($b = .02; ns$). In addition, the interaction between PTS and materialism (the moderator) is also significant ($b = .17; p < .01$). These results indicate that PTS mediates the association between threat condition and compulsive buying and that materialism moderates the effect of PTS upon this outcome. Specifically, it appears that the use of compulsive consumption as a means of coping with the stress associated with a mortal threat is much more prominent among individuals high in materialism than those low in materialism.

Impulsive Buying. Threat condition has a significant effect upon impulsive buying ($b = .02; p < .05$). In addition, PTS (the mediator) also exhibits a significant effect upon this outcome ($b = .27; p < .01$). Moreover, when this mediator is accounted for, the effect of the threat condition is reduced to non-significance ($b = -.01; ns$). In addition, the interaction between PTS and materialism (the moderator) is also significant ($b = .13; p < .05$). These findings indicate that PTS mediates the association between threat condition and impulsive buying and that materialism moderates the effect of PTS upon this outcome. Specifically, it appears that the use of impulsive buying as a means of coping with the stress associated with a mortal threat is considerably more prominent among individuals high in materialism than those low in materialism.

Our results reveal that, in addition to its well-documented harmful direct effect on psychological well-being, materialism also exerts an indirect negative effect by making bad events even worse. Our findings contribute to this school of thought by offering a more comprehensive view of the relationship between materialism and stress. Going beyond the simple association between materialism and higher levels of stress (in the form of PTS), our study suggest that materialism also shapes the manner in which individuals cope with this stress. Specifically, our results indicate that, materialistic individuals are more likely to respond to traumatic stress via impulsive and out of control consumption activities. Thus, materialism's relationship with stress may be even more pernicious than commonly thought.

Living in a Material World: The Role of Materialism in Consumer Confidence & Well-Being

EXTENDED ABSTRACT

In 2008, America entered its worst recession since the Great Depression. Two perspectives were offered as the proper response to lead the country out of that state: the recovery perspective and the reset perspective. The recovery perspective suggests that we awaken the materialism of Americans and get consumers spending again (Posner 2009). In contrast, the reset perspective suggests that materialism is what got us into this mess and that the current circumstances offer a perfect opportunity to seek alternative belief and value systems that promote greater health and well-being (Arndt et al. 2004). These perspectives fundamentally differ in their views on the impact of materialism on well-being, recovery assuming a positive impact and reset assuming a negative one.

Despite our cultural inclination toward materialism, there is meaningful variation in the levels of materialism from one individual to another, due to biological, personal and social circumstances (Giddens, Schermer and Vernon 2009). Numerous studies have examined the relationship between materialism and such consequences as quality of life (Roberts and Clement 2006), life satisfaction (Burroughs and Rindfleisch 2002), pro-social behavior (Briggs et al. 2007), and racism (Roets et al. 2006) and generally find that negative effects of materialism outweigh the positive ones; thus suggesting that we should find ways to reduce our materialistic tendencies.

However, notwithstanding its negative consequences, materialism has also led to increased standard of living, productivity and technological advances (Inglehart and Welzel 2005). More recently, Gardarsottir, Dittmar and Aspinall (2009) suggest that it is not necessarily the pursuit of acquisition, but the motives for that pursuit that determine whether the welfare results are negative. Ingrid, Majda and Dubravka also suggest that "materialistic aspirations will not decrease people's well-being if they help them to achieve basic financial security of some intrinsic goals" (2009, p. 317). Therefore, motives for acquisition play an important role in determining wheth-

er materialistic values produce positive or negative welfare results. "Materialism has often been blamed for consumers' overspending and excessive debt levels, but there is little understanding of how materialism influences these practices" (Richins 2013).

This study embeds materialism in a broader decision context to examine the process by which materialism triggers consumer spending. Materialism, or possession-defined success and the centrality of acquisition (Richins and Dawson 1992), is shown to bolster general confidence while possession as happiness increases one's personal level of confidence toward the economy, thus leading to increased expected spending. Another psychological factor, hope (Snyder et al. 1991) provides the motivation, which is conceptualized as "a positive motivational state that is based on an interactively derived sense of successful (1) agency (goal-directed energy) and (2) pathways (planning to meet goals)" (p. 287). Based on this psychological representation, consumers who are more materialistic and who have higher levels of hope will have higher expectations for future consumption.

Past research on consumer confidence indicators has found that consumer attitudes about the future predict future consumption over and above changes in future economic resources (Carroll, Fuhrer and Wilcox 1994; Ludvigson 2004). More recently, researchers are advocating that marketing and psychological variables that bridge the gap between production and consumption (Bovi 2009) could also play a role in predicting consumer spending. For example, Fornell, Rust and DeKimpe (2010) find that aggregate customer satisfaction (ACSI) predicts 23 percent of the variation in future consumer spending growth. However, these studies tend to use time-lagged indices as predictors of current period consumption whereas the current study links individual material values to personal confidence and future consumption behavior.

This paper uses the November and December waves of The Economy Tracker (2009) from The NPD Group, Inc. to provide an empirical assessment of materialism and hope and to observe its combined impact on consumer confidence and buying behavior. We examined the joint effects of materialism (Richins and Dawson 1992) and hope (Snyder et al. 1991) on consumer confidence and purchase intention using structural equations modeling. Confidence/concern regarding the U.S. economy in general and personal economic perception were measured using a weighted score of a series of questions relating to the near-term outlook for the U.S. economy in general. Since all these scales have been extensively validated, they demonstrated strong composite reliabilities (Materialism = .97, Hope = .95, General Confidence = .96, Personal Confidence = .96). Spending behavior was measured by the retail response indicator developed by The NPD Group, Inc.

The results in Study 1 (N=1620) showed that two materialism dimensions (success and centrality) and hope bolsters confidence toward the economy while happiness and hope positively influence personal confidence leading to higher spending expectations. Study 2 (N=1420) replicated the findings from Study 1 at a special time of the year (December, 2009) when consumer confidence was influenced by the Christmas shopping season and consumers became more susceptible to the impact of materialism and hope. Study 3 (monthly surveys from January 2010-September 2011) further explores the relationship between monthly measures of materialism, consumer confidence, purchase intentions and subjective wellbeing (as measured by Diener's Life Satisfaction scale (Diener et al., 1985)). Findings from this paper will not only explore the role of materialism as a key indicator of consumer confidence and spending during economic uncertainty, but also its impact on consumer wellbeing over time.

SESSION OVERVIEW

What does it mean to make a choice? From exerting agency, to drawing conclusions about the self's values, to wanting to produce a normatively right outcome, to expressing one's preferences, choice is a fundamental route by which the self is empowered to "make a difference" (as per the theme of ACR 2013).

Theorists (e.g., Baumeister 1998) depict the self as housing three processes that drive behavior: executive functioning, which is comprised of self-regulation and decision making, interpersonal processes, and self-evaluation (e.g., self-esteem). The executive functioning aspect of the self is that which makes humans unique among animals (Baumeister 2005). Hence, there is a special relationship between the self and decision making, one with practical implications for everyday choices as well as ramifications for big decisions about well-being.

The first paper offers a new connection between the self and decision making via maximization tendencies. Vohs and Olson wondered why people would elect to engage in maximization, given its associations with regret, uncertainty, and decision stress. They predicted and found such tendencies arise from the belief that choices represent the self, which explains why and to what degree people exhibit maximizing tendencies.

The second paper builds on the first by overlaying the notion of attribution to choices and the self. Sela and Berger predicted and found that the interpretation of unexpectedly difficult decisions varied by culture. The authors demonstrated that priming American and Indian consumers with the notion that choices represent the inner-self versus societal roles leads to different interpretations about what choice difficulty means for the self.

The third paper tackles the motivational side of the choice-self connection. When people are faced with a consumption decision with a host of options, how might they decide? In a further instantiation of constructed preferences, Goodman and Vohs demonstrated people with limited mental resources tend to seek variety. Furthermore, this effect is especially strong in people who often rely on System 1 processing, compared to those who generally rely on System 2 processing. These results suggest a variety-seeking heuristic exists, which helps consumers with a constrained capacity for decision processing.

The fourth paper takes a physical tack on the issue of the self and choices. One would think humans' sophisticated capacity for self-expression would render all forms psychologically equivalent, but that is not what Klesse, Levav, and Goukens found. They found that when choice is expressed vocally (that is, through speech), consumers make decisions that are more consistent with their automatic, emotional reactions (i.e., choosing unhealthy foods) compared to those who express choices non-vocally (such as by pushing a button).

With new and counterintuitive findings that nonetheless follow from established theories, this session will be of interest to a host of consumer behavior scholars. Most centrally, scholars interested in the self, choice, and choice processes, as well as those interested in expressiveness, self-regulation, ego depletion, and meta-cognition will find a home in this session, as will policy makers seeking to nudge consumers toward making decisions that 'make a difference' on the self and society.

Thinking That Choices Reflect the Self Leads to Maximizing Behavior

EXTENDED ABSTRACT

Consumers must often employ one of two goals when making choices. They can satisfice and seek any option that meets some minimum standard, or they can maximize and attempt to find the best possible option available. Research suggests that while consumers' tendency to maximize may vary depending on characteristics of the decision (Simon 1956; Levav, Reinholtz, and Lin 2012), maximizing is also an individual difference (Schwartz, Ward, Monterosso, Lyubomirsky, White, and Lehman 2002). Certain people, known as maximizers, display high chronic levels of maximizing behavior and often endeavor to make the optimal choice for every decision. They engage in this behavior despite the many negative effects caused by maximization, such as less decision satisfaction, higher regret, and longer decision times compared to those who chronically satisfice (Schwartz et al. 2002; Levav et al. 2012). Furthermore, even when maximizing creates objectively better outcomes than satisficing, maximizers are subjectively less happy with the outcome than are satisficers (Iyengar, Wells, and Schwartz 2006).

In light of these findings, one could reasonably wonder why consumers would ever be motivated to maximize. We hypothesized that one possible cause of maximization is the belief that one's choices reflect the self, which is to say that choices are a representation of one's identity. We specifically predicted that those who strongly believe that one's choices reflect the self will be more likely to maximize compared to those who only weakly believe this notion. Three experiments provided support for this hypothesis.

Experiment 1 tested whether people who generally think that their choices are representative of the self also tend to exhibit maximizing behaviors. Participants completed a scale that measured the extent to which they believed that choices reflect the self (Choices Reflect the Self scale). They then completed two additional scales that measured their tendency to maximize and experience regret. Previous research suggests that in addition to maximizing more frequently, chronic maximizers also experience more regret than those who maximize less (Schwartz et al. 2002). Based on these results, we expected that Choices Reflect the Self scores would have a positive relationship with maximizing and regret scores.

On Metacognition and Culture

EXTENDED ABSTRACT

Metacognitive experiences have an important impact on judgment and decision-making. How difficult information is to process, for example, influences liking (Reber, Winkielman, and Schwarz, 1998), perceived distance (Alter and Oppenheimer, 2008), perceived uniqueness (Pocheptsova, Labroo, and Dhar, 2010), and frequency estimates (Tversky and Kahneman, 1973).

Based on existing research, one might assume metacognitive effects are universal. But could they differ by culture? We suggest this possibility based on the notion that metacognitive effects on judgment are largely inference-based (Schwarz 2004) and that there are cultural differences in the lay theories that give rise to such inferences (Markus and Kitayama, 2003). What people infer from metacognitive experiences depends on their lay theory regarding what makes information easy or difficult to process in a particular situation (Winkielman and Schwarz, 2001). Given culture's ability to shape people's lay theories in general (Briley, Morris, and Simonson 2010), it should also impact the inferences people draw from metacognitive experiences.

Consider the act of choice. A European-American cultural context is characterized by independent self-construal and a disjoint model of agency, where people see choice as reflecting or corresponding to the inner-self (Markus and Kitayama, 2003). An Indian cultural context, however, is characterized by interdependent self-construal and a conjoint model of agency, in which, choice is seen less as self-expression and more as reflecting contextual influences such as social roles (Kim and Drolet, 2003; Kim and Markus, 1999; Savani, Markus, and Conner 2008). Building on these two streams of research, we suggest the inferences people draw from the cognitive experience of choice difficulty should depend on cultural differences in self-construal and related models of agency.

We test this possibility by examining how culture moderates the tendency to infer decision importance from decision difficulty. Prior research (Sela and Berger, 2012) has shown people perceive unexpectedly difficult decisions as more important and therefore deserving of increased deliberation. Ironically, such a metacognitive inference is more likely to happen for decisions that initially seemed unimportant, because people expect them to be easy, whereas important decisions are expected to be difficult to begin with (Schwarz 2004; Wänke, Schwarz, and Bless 1995).

Importantly, inferring decision importance from difficulty is based on the lay-theory that a difficult decision is likely to also be of personal/inner importance. We hypothesize that this lay-theory is more salient in cultures characterized by independent self-construal and a disjoint agency model and less salient in cultural contexts characterized by interdependent self-construal and a conjoint agency model.

In Study 1, we presented American and Indian participants with a choice between two university courses and manipulated decision importance framing (important versus unimportant) and processing difficulty (fluent versus disfluent). We measured how long participants spent deciding (Sela and Berger 2012, experiment 4). We predicted processing difficulty under unimportant framing to increase perceptions of decision importance and consequently the amount of time spent deciding, but only among American participants. To examine the mediating role of perceived decision importance, participants also rated the extent to which it was important to make a good decision.

A 2(importance framing) x 2(processing difficulty) x 2(culture) ANOVA on time spent revealed the predicted 3-way interaction.

The results were consistent with predictions. Choices Reflect the Self scores were positively and significantly correlated with both maximizing and regret scores. The more participants thought their choices reflected them, the more they tended to maximize and experience regret.

Experiment 2 tested whether a situational manipulation could induce participants to think that choices either reflect the self or do not reflect the self. Participants were asked to write an essay that purportedly would be used to help middle schoolers who were having trouble making choices. Participants were randomly assigned to one of two groups for this essay: the *choices are the self* group and the *choices are not the self* group. They were then instructed to complete the Choices Reflect the Self scale.

In the choices are the self condition, participants were told middle schoolers today were underestimating how much their choices say about who they are, an attitude that leads them to make decisions that reflect poorly on them. Participants were instructed to help middle schoolers with their supposed problem by writing an essay to make kids realize that choices reflect them. The choices are not the self condition used an identical procedure, except in this condition participants were told middle schoolers cared too much about what their choices said about them. Participants were instructed to help middle schoolers with this purported issue by writing an essay to let the kids know they are more than just the choices they make. After writing the essays, participants in both conditions completed the Choices Reflect the Self scale. Results show that those in the choices are the self condition had significantly higher Choices Reflect the Self scores than those in the choices are not the self condition, indicating the manipulation.

Experiment 3 replicated and extended experiment 2 in that in addition to manipulating the idea that choices do or do not reflect the self, experiment 3 tested whether these beliefs would influence maximizing tendencies. Participants were again instructed to help middle schoolers who, it was reported, were bringing about negative consequences for themselves either because they underestimate how much their choices reflect them (choices are the self condition) or overestimate how much their choices reflect them (choices are not the self condition). Participants then wrote an essay that purportedly would be used to help these middle schoolers who were having trouble making choices. They were then instructed to complete the Choices Reflect the Self scale. Finally, participants indicated their tendency to maximize.

As predicted, the results from experiment 3 show that those in the choices are the self condition (vs. choices are not the self condition) indicated significantly stronger beliefs that choices reflect the self, suggesting our manipulation was effective. This condition also reported stronger maximizer tendencies. Furthermore, the extent to which participants believed that choices reflect the self mediated the effect of condition on maximizer scores. This experiment showed that manipulating the idea of choices signifying individuals was effective in eliciting maximizer behavior insofar as the manipulation caused participants to actually believe choices represent the self, which further supports our hypothesis that it is specifically the thought that choices reflect individuals that is leading to maximizer behavior.

Summary: With all of the choices afforded to consumers in society today, it is no wonder that those who frequently attempt the daunting task of maximizing each decision often end up less satisfied than those who merely satisfice. By recognizing why certain consumers feel compelled to strive to select the best option, people can better comprehend the merits of such behavior and ways of counteracting its adverse effects.

Consistent with prior research, American participants spent more time deciding in the disfluent than in the fluent condition, but only in the unimportant framing condition. However, Indian participants spent slightly less time in the disfluent compared with the fluent condition when the decision was framed as unimportant. Processing difficulty did not influence decision time in the important framing conditions.

A moderated-mediated-moderation analysis suggested that the effect of processing difficulty on time spent, through perceived decision importance, was significant among Americans under unimportant framing but not among Indian participants or under important framing.

Studies 2 and 3 examine whether manipulating the salience of disjoint versus conjoint agency models can reverse the effect of culture on metacognitive inferences. In study 2, we expected priming Indian participants with the notion that choice reflected their inner-self would lead them to spend more time on unexpectedly difficult decisions. We first asked half the participants to describe a choice they had made that strongly expressed who they were, their individual preferences, beliefs, emotions, or goals (e.g., an item they bought because they felt it communicated their identity as individuals). In the control prime condition, we asked participants to list all the food items they consumed that day.

In the next task (borrowed from Sela and Berger 2012), participants chose between two flight options. All the participants chose a flight option and the decision was framed as unimportant. We manipulated decision difficulty (fluent versus disfluent). The dependent variable was the amount of time participants spent deciding.

A 2(prime) x 2(processing difficulty) ANOVA on time revealed the predicted prime x difficulty interaction. Disfluency had no effect on time in the control prime condition. However, in the choice-as-self-expression prime condition, participants spent more time deciding in the disfluent than the fluent condition.

In Study 3, American participants completed a similar sequence of tasks as in Study 2, but this time half of them described a choice they had made that was strongly influenced by a societal imperative (e.g., an item they bought because they were expected to). The other half listed foods they consumed that day, as in Study 2. The remainder of the procedure was identical to Study 2.

We expected the social-imperative prime to eliminate American participants' baseline tendency to spend more time on unexpectedly

difficult decisions. A 2(prime) x 2(difficulty) ANOVA on time revealed the predicted prime x difficulty interaction. As expected, in the control prime condition, participants spent more time deciding in the disfluent than the fluent condition. However, in the social-imperative prime condition, disfluency had no effect on time spent. See Table 1.

This research makes an important contribution by showing that susceptibility to metacognitive influences may differ by culture and that these differences may reflect cultural differences in the lay-theories people recruit to interpret their metacognitive experiences. The findings suggest limitations to the idea that metacognitive effects are universal.

One of Each: Variety Seeking to Avoid Choice Difficulty

EXTENDED ABSTRACT

When consumers are faced with a choice conflict from information overload, they use heuristics and non-compensatory choice processes, such as elimination-by-aspects and conjunctive models, to reduce the consideration set and come to a choice (Broniarczyk 2008; Payne 1976; Payne, Bettman, and Johnson 1993). Yet in so many modern-day choice situations, consumers are able to choose multiple options. Moreover, decision difficulty seems to propel consumers to purchase more options (Goodman, Broniarczyk, Griffin, and McAlister 2013). Consumers may seek variety as a way to minimize the conflict and difficulty associated with choice. Consumers seek variety due to actual or anticipated satiation (McAlister 1982), a desire to reduce preference uncertainty (Kahn and Lehman 1991), anticipated satiation (Simonson 1990).

We propose that consumers possess and use a variety-seeking heuristic to relieve choice conflict and information overload, and provide evidence that variety seeking increases when consumers' mental resources are taxed. We tested our hypotheses by both manipulating participant's mental resources (via ego depletion) and measuring consumer's decision-making processing tendencies (by measuring System 2 processing via a Cognitive Reflection Test). Depletion served as a unique test of our theory because it does not create conflict, per se, but rather reduces the resources available to deal with the existing conflict and difficulty. Three studies tested and found support for our hypotheses.

In study 1, we used a traditional ego depletion manipulation (Vohs et al. 2008). We asked 186 undergraduate participants to watch a video of a woman being interviewed for 4 minutes, with random words flashed on the side of the video. Participants in the depletion condition were instructed to not look at the words. The nondepletion condition was not instructed to control their attention. Participants then completed an unrelated study to measure variety-seeking. Participants imagined that they were purchasing ice cream and asked to choose how many of each flavor (chocolate, vanilla, and strawberry) and size (small, medium, large) they would buy. As expected, the results showed that depleted participants chose more variety ($M = 3.27$) compared to nondepleted participants ($M = 2.45$). This effect was not driven by a difference in quantity, as the depletion condition did not increase quantity purchased ($F < 1$).

In study 2 we examined a common method by which consumers become depleted in the shopping environment by manipulating consumption decisions. We also tested whether the use of the variety-seeking heuristic can be reduced after resources are replenished. We paid 88 participants \$7 as part of a longer 40-minute study. Participants in the depletion condition made 24 choices and received one of the products that they chose at the end of the study (Vohs et al. 2008). Participants in the control condition indicated whether they

Table 1: Results for these studies

SUMMARY OF FINDINGS

Study 1 (N = 258)				
Culture	Importance Framing	Difficulty	Mean	Std. Error
Americans (N = 123)	Unimportant	Fluent	21.090	4.072
		Disfluent	31.192	3.761
	Important	Fluent	31.094	3.817
		Disfluent	26.300	4.144
Indians (N = 135)	Unimportant	Fluent	41.353	4.220
		Disfluent	26.175	3.511
	Important	Fluent	32.997	3.511
		Disfluent	36.541	4.004
Study 2 – Indians (N = 113)				
Prime		Difficulty	Mean	Std. Error
Food and drink		Fluent	26.570	3.594
		Disfluent	30.751	3.960
Choice as Self-Expression		Fluent	26.711	4.277
		Disfluent	47.341	4.033
Study 3 – Americans (N = 144)				
Prime		Difficulty	Mean	Std. Error
Food and drink		Fluent	17.150	1.370
		Disfluent	21.710	1.407
Choice by Social Imperative		Fluent	19.722	1.335
		Disfluent	17.911	1.516

had used each specific product. Participants were then instructed to take a break and choose four snacks, in any combination. This choice task served as our dependent measure, and the snack and break also served to replenish participants' resources. As expected, depleted participants chose more variety ($M = 2.81$) compared to the nondepleted participants ($M = 2.40$, $t(87) = 2.10$, $p < .05$). After replenishing their resources, participants responded to the same ice cream choices as in study 1. As expected, there was no longer any difference in variety seeking after replenishment ($M = 2.35$ vs. $M = 2.40$, $t < 1$).

In study 3 we measured individual differences in System 1 versus 2 processing by administering the Cognitive Reflection Test (CRT, Frederick 2005) after the choice task. We also manipulated depletion as in Study 2. If variety is used as a heuristic, then low CRT participants should exhibit more variety seeking. As in study 2, depleted participants showed more variety seeking ($M = 4.52$) than nondepleted participants ($M = 4.25$, $t(513) = 2.05$, $p < .05$), and participants that scored low on the CRT chose more variety ($M = 4.57$) than those high on CRT ($M = 4.11$, $t(513) = 2.61$, $p < .01$).

These results support the presence and use of a consumer variety-seeking heuristic. Furthermore, they suggest that consumers use variety seeking as a shortcut to manage the decision process. Further, the results have important implications for the myriad decision situations that evoke depletion, such as long shopping trips or multi-stage product customizations.

At a theoretical level, these findings imply that consumers who have limited executive resources might variety seek in order to mitigate the potential for future losses, which could be a boon to overall well-being. Yet a contrary view suggests that variety seeking can be a recipe for dissatisfaction. Future work will unravel the consequences of heuristic-driven variety seeking, drawing a pathway from documenting the prevalence of this new heuristic to its implications for consumer welfare.

***Imago Animi Sermo Est* – Speech is the Mirror of the Mind: The Effect of Vocal Expression on Preferences**

EXTENDED ABSTRACT

The marketplace affords consumers different modes by which to express their preference. These include, but are not limited to, pressing a button, noting something on paper, and vocal expressions. New technologies enable consumers to interact with vending machines and even kitchen devices. Normatively these different modes of expression should not yield different choices, as there is nothing about the option (or the consumer) that differs as a function of expression mode. Yet, we find in our research that mode of expression has a substantial effect on people's choices.

The study of response mode effects is not new; four decades of research on decision-making show that preference construction can be influenced by the form in which these preferences are elicited (Lichtenstein and Slovic 1971; Tversky, Slovic, and Kahneman 1990; Nowlis and Simonson 1997). However, to date no studies have tested the effect of response modality—that is, the form in which the preference is expressed—on people's choices. Previous research hints at the possibility of differences due to modality. In particular, vocal and non-vocal preference elicitation modes differ in what is required to translate one's preference into the desired outcome. Most non-vocal preference elicitation modes—such as pushing a button at a vending machine—require the translation of one's choice (e.g., Snickers) into another medium (e.g., button B4) to obtain the desired outcome. Speech, on the other hand, is directly connected to emotionality: During a child's emotional development, speech serves as a main

vehicle for emotional expression (Chen, Kennedy, and Zhou 2012). Numerous studies have shown that speech and emotionality are indeed strongly interlinked (e.g., Pavlenko 2002). We conjecture that translating one's choice into another medium might therefore reduce emotional resonance, which suggests that the more that the situation calls for explicitly vocalizing one's preferences, the more that emotional, automatic preferences will guide choice outcomes. This would imply that speech, more than non-vocal expressions, would produce decisions reflective of automatic emotional reactions, a prediction that was confirmed in three experiments.

We tested this conjecture in three lab studies. In Study 1 ($N = 101$), we let participants choose between vices and virtues. Generally, individuals prefer vices because they are inferred to be tastier, but this initial impulsive response can be overridden if more cognitive evaluation takes place (Shiv and Fedorikhin 1999). In this study, participants chose a snack from a vending machine with healthy (e.g., apple slices, cereal bar, etc.) and unhealthy snacks (e.g., M&Ms, Kit Kat, etc.). Depending on condition, participants expressed their choice non-vocally (i.e., by pushing a button) or vocally (i.e., by speaking in a microphone attached to vending machine).

Based on participants' choices, we computed the average calorie content of the snack selected in each condition. Participants who expressed their choice vocally chose snacks significantly higher in calorie content ($M_v = 239.56$) than participants who expressed their choice by pushing the button ($M_b = 209.04$; $F(1,99) = 5.81$, $p < .05$). A logistic regression with choice of snack as a dichotomous variable (i.e., unhealthy vs. healthy) revealed a significant effect of condition ($b = -1.06$, $p < .05$). Participants that expressed their choice vocally were less likely to choose a healthy snack.

In Study 2 ($N = 59$), we let participants choose between regular and low-fat ice cream. Based on research that shows that perceived healthiness and inferred tastiness are negatively correlated (Raghunathan, Naylor, and Hoyer 2006), we assumed that participants' initial impulsive reaction would be to go for the regular version. During the study, participants were asked to choose an ice cream flavor among three different flavors available in a regular or a non-fat version. Participants expressed their choice either by using the computer mouse or by expressing it vocally into a microphone that was connected to voice recognition software. We conducted a logistic regression with ice cream flavor as the outcome and preference elicitation mode as the predictor. The results revealed an effect of condition, such that participants who expressed their choice vocally were less likely to choose a low-fat ice cream.

Study 3 ($N = 132$) was designed to provide evidence that expressing one's choice vocally fosters choices that are more in line with an individual's automatic emotional reactions. We therefore focused on the special situation of dieting. For dieters, high calorie food is implicitly associated with positive affect, even though at an explicit level they endeavor to override this natural response (Strack and Deutsch 2004). We therefore measured individuals' dieting status (e.g., 'I am on a diet') and expected an interaction effect with preference elicitation mode so that dieting increases the likelihood of choosing a snack higher in calorie content when expressing one's preferences vocally. An ANOVA conducted on calorie content of the chosen snack revealed a (marginally) significant main effect of condition ($F(1,130) = 3.02$, $p < .09$): Participants who expressed their choice vocally chose snacks higher in calorie content ($M_v = 220.64$) than participants who expressed their choice by pushing the button ($M_b = 196.397$). A logistic regression with choice of snack (i.e., unhealthy vs. healthy) revealed a significant effect of condition ($b = -.691$, $p < .05$): Participants who expressed their choice vocally were less likely to choose a healthy snack. Further, we find a

(marginally) significant interaction effect between preference elicitation mode and being on a diet ($p < .09$). Using ‘floodlight’ analysis (Spiller, Fitzsimons, Lynch and McClelland, forthcoming) to probe the interaction we find that the region of significance for preference elicitation mode is all values of being on a diet equal to or higher than 1.696. This indicates that dieters choose snacks higher in calorie content.

Our findings highlight that consumer preferences differ depending on whether they are expressed in spoken word or otherwise. Spoken choices appear to be more congruent with initial emotional reactions, while the translation into another medium (e.g., button B4) acts as a distancing function, promoting more reflective decision-making.

SESSION OVERVIEW

This special session examines how power shapes consumption and limits policies or economic actions that attempt to bring about societal change through challenging social hierarchies. We bring together four papers that consider different types of stratification: geographical, religious, racial, generational, gender, and class. We demonstrate how consumption norms and practices that reinforce the stratifications are perpetuated or contested in the marketplace. We start by considering the different ways power dynamics and stratifications intersect and are experienced in the marketplace and build toward recognizing how these dynamics shape and influence the implementation of policies. Each of these presentations use different methods, and thus extend our awareness of tools researchers can use to study normative and socio-economic forces.

Russell Belk and Rana Sobh open the session with vignettes that reflect the intersectionality of geographical, religious, generational and gender stratifications occurring in the prosperous Islamic countries of Qatar and United Arab Emirates. Through cases that emerged in their three years of fieldwork, these scholars examine how consumers navigate the traditional structures and stratifications when Western popular culture starts to influence traditional family life.

David Crockett investigates the racial stratification of America through an historical analysis of postwar black middle-class consumers. He discusses the historical transitions from legislated racial segregation to stratifications maintained through structural and symbolic systems. Using life histories of black middle-class families, he documents how race and class stratifications are maintained through myths about consumption while their reproduction is being contested by generational differences.

Laurel Steinfield and Linda Scott explore the gender stratifications perpetuated by consumption practices in rural and urban Uganda. Policy and legislative protocols are encouraging women to become more educated and employed in the private and public sectors, yet the effectiveness of these changes is hampered by gender biases that affect the consumption of women. Using projective techniques and armed with a shopping bag of goods, Steinfield and Scott conduct interviews that unearth the normative prejudices and

pejorative labels that limit the consumption choices that can be made by women and observe the flow of these ideologies to urban areas.

Kathy Hamilton and Katherine Trebeck close with a presentation that demonstrates how economic stratifications are intensified by regeneration strategies. They call into question policies that attempt to spur economic investments and a culture of consumption, noting how too much emphasis on the marketplace can lead to an increase in poverty, inequality and health problems. Presenting the work they have done on the “Glasgow effect”, they remind us that the consumer marketplace is only one of many places in which the effects of stratifications are felt and experienced.

Our session asks how social stratifications are institutionalized and contested through the marketplace, but also reflects on the reasons why such stratifications should matter to policy-makers and should be accommodated in planning and interventions. It explores the tension that exists in market-based solutions to societal change, asking: in what instances does the marketplace perpetuate vulnerabilities and when does it enable empowerment and societal transitions? This session should be of interest to researchers interested in social stratifications, power, religion, race, gender, class, emerging economies and transformative consumer research.

Effects of Geographic and Religious Stratification and Modernity in the Arab Gulf

EXTENDED ABSTRACT

Stratification in Qatar and UAE occurs both within these nations and between these nations as well as between the countries of origin of its non-citizen residents who make up 80 to 85 percent of local populations. Religion, location, citizenship, age, income, ethnicity, country of origin, and gender all play a role in the status of those living in these Arab Gulf countries. These stratifications are embedded within one another and in order to appreciate their impact on consumption, it is necessary to consider their intersections. Illustrations of the importance of local intersectionalities include contrasts such as the following:

1. A male Hindu worker from Kerala working in UAE for two years versus the same man when he returns to India.
2. A female Muslim Qatari married to a Bedu Qatari man (a Bedouin Arab of Qatari tribal origin) versus another Muslim Qatari woman married to an Ajam Qatari man whose heritage is Iranian and who may speak Farsi rather than Arabic.
3. A 45-year-old Qatari Muslim woman versus her 20-year-old daughter in university.
4. An expatriate Christian British businessman living in UAE versus an expatriate Muslim Indonesian cleaning woman for an Emirati family.
5. A 20-year-old Sri Lankan Muslim non-citizen born and raised in UAE versus his Emirati university friends.

These illustrations, based on a three-year ethnography, demonstrate how the recent petro-wealth and Western popular culture has affected social status and consumption patterns.

In the first case the guest worker in the UAE lives in a “labor camp” in Dubai and is bused daily between the camp and a high rise construction site. He has one day off a week and his employer holds his passport and sponsors his visa. He is near the bottom of the social hierarchy in UAE. He repatriates his money to his family

in Kerala where he will build a house and become a nouveau riche “king” when he returns home.

In the second case the woman married to the Bedu man has higher social status than the one married to the Ajam man, even though they are both citizens of Qatar and thereby entitled to benefits such as higher salaries, free education, water, and electricity, low cost housing loans, and free land for building a house. There is a further status hierarchy depending on the prominence of the Bedu couple’s clan. Although there are virtually no poor Qataris (or Emiratis), clan and heritage are stratification variables within these societies, with Abd Muslims who originate from North Africa being lower status than either Bedu or Ajam.

In the third case the mother and daughter occupy the same social status (unless the woman gained citizenship by marrying a Qatari man, in which case her daughter would not be a citizen). But the influence of modernity is likely to be strikingly different between the two. Both are likely to wear the traditional black abaya (gown) and shayla (head covering), but the daughter’s is more form-fitting, covers Western designer clothes including tight fitting jeans, red high heels, and accessories from Gucci, Prada, and Louis Vuitton, and is left partly unbuttoned with her hair peeking out from her shayla, also revealing her heavy makeup. Her abaya may be covered in Swarovski jewels and may even have a rock star insignia on the back. It costs hundreds or thousands of dollars and may be out of fashion in two months.

The fourth case involves a relatively wealthy businessman who lives in a high rise apartment and enjoys a high salary, but not enough to keep up with Emirates who have one of the highest per capita incomes in the world (along with Qataris). Unlike the businessman who lives far from the palatial homes of local Emirates, the cleaning woman lives with an Emirati family in a separate quarters. Like the guest workers she repatriates most of her money to her home country. She learns some Arabic and may be able to make the Hajj to Mecca.

Like the Brit, the Sri Lankan man may have a wealthy family, but they enjoy none of the privileges of citizenship and he can never become a citizen, even if he were to get permission to marry an Emirati woman. Since citizens have 20 percent of the jobs set aside for them and earn considerably higher salaries than non-citizens doing the same job in the same establishment, he is at a considerable economic disadvantage.

We draw on our ethnographic data to demonstrate the inadequacy of singular analyses of location, nationality, citizenship, age, gender, ethnicity, education, income, or religion alone in order to understand the status hierarchies of the Gulf States. Rather the structural inequalities that begin with religion and location, are entangled with the intersectionality of other characteristics that must be considered jointly in order to understand the role of consumption in the daily lives and statuses of those living in these newly rich nations.

Viewing the Creation and Reproduction of Racial Stratification through Consumption: Life Histories of the Black Middle-Class in America

EXTENDED ABSTRACT

This research documents the racial stratification that occurs in the marketplace of America as consumer culture attains dominance in the mid-twentieth century. The history of consumer culture in the West can best be characterized as a social formation that shifts commodity consumption from a peripheral activity in social life to the quintessential activity of social life. The insights generated herein

are intended to highlight the critical role played by consumption practices, and consumer culture more broadly, in the creation and maintenance of the Black middle-class.

Any broad-reaching investigation of black middle class family life must place consumption practices and consumer culture at its center. Unfortunately, such a perspective has been either largely absent or marginalized in scholarship found in the humanities as well as the social sciences. Traditionally, scholars in the US study Black life largely by looking at labor and income inequality in isolation or in tandem with critical social institutions like family, school, and church. This traditional approach is very limiting insofar as it ignores or marginalizes consumption’s centrality to identity formation as well as its role in the reproduction of culture. Fortunately, contemporary scholarship has begun to include consumption as part of the analysis of the black experience. Unfortunately, consumption still lurks at the margins.

This research addresses this imbalance by moving consumption to the center of the analysis of the Black middle-class experience. It views the construction of personal and social identity in the Black middle-class as well as upward and downward social mobility through the lens of consumption. It forms part of a larger project that studies consumption at the intersection of race-, class-, and gender stratification under historical conditions specific to late capitalism.

The Black middle-class (typically inclusive of African, Afro-Caribbean, and other immigrants designated as “black” in the U.S.) emerges in recognizable form at roughly the same historical moment that a culture of mass consumption emerges to supplement and then replace a culture of mass production at the very center of U.S. social life. Although the emergence of a black middle class began in the Reconstruction period immediately following the U.S. Civil War (DuBois 1935), the focus of this study is on the post-World War II black middle class, which is qualitative different from its pre-war counterpart (Patillo-McCoy 1999). The post-war black middle class emerges in a consumer culture that is simultaneously a “democracy of goods” yet rife with racial stratification: African Americans are initially the object of legalized racial stratification in markets and the state (Drake and Cayton 1962). Following the collapse of the Jim Crow regime in the U.S., access to markets (and certainly to the cultural capital thought to flow from full participation in them) is at times attenuated even for high income African Americans. Structural features (e.g., high levels of residential segregation) and symbolic representation (e.g., widely-held stigmatization) continue to stratify the market. At the same time consumption serves as a primary means by which the black middle class distinguishes itself from the black working class and poor (Patillo-McCoy 1999). But, even more disconcerting for what Lacy (2007) describes as the “elite” black middle class, in an intergenerational boundary: evident feelings of alienation separate black middle class informants from their children. This interconnection and interplay between consumer culture and black middle class status comes to the fore through the life histories interviews of these informants. Using boundary theory, I show how their histories demonstrate two broad categories of consumption-focused strategies for configuring ethno-racial identity.

In the first category, actors seek to change boundary topography. That is, they try to expand boundaries to incorporate out-group members into an identity group, or, they contract boundaries to expel in-group members. These strategies are on the whole unavailable to Blacks in the US. Thus, I focus on the second category, where actors seek to change their affiliation with particular boundary-created identity groups or alter a boundary’s meaning. Following Wimmer (2008), I show how informants implement consumption-focused strategies (inverting the racial hierarchy, equalization, boundary-

crossing and collective repositioning) to attenuate the impact of stratification with varying degrees of success. Part of this success is determined by the destruction of myths by generational changes; that is, I find that racial stratification in the marketplace is maintained through myths yet these myths, and thus the stratification, lose meaning and power over consumption as they become challenged by generational divergences.

Controlling Consumption: The Illusiveness and Pervasiveness of Gender Stratifications in the Ugandan Marketplace

EXTENDED ABSTRACT

In Uganda, as women become more educated and employed, and as laws are enacted to protect their rights, male economic power might be expected to erode. Ideologies, however, continue to uphold the gender hierarchies in this traditional patriarchal society. In rural communities, where traditional tribal laws are still practiced, women continue to be treated like property, traded for a bride-price as soon as they can bear children, or, if a widow, being inherited by her husband's family and forced to marry his male relative should she have no male children to provide for her. Women continue to submit to these laws for fear that they will be outcasts of society. The local model of domestic virtue continues to restrict a woman's role in the economy even in urban areas (Kyomuhendo and McIntosh (2006).

Our research investigated the way such gender restrictions are perpetuated through family consumption decisions. We frame our analysis using two of Lukes (2005) faces of power: decisions and preferences. In rural Uganda, a woman is limited in her ability to keep her own money or to get to the shops to buy needed goods. If she works with her husband, the money goes directly to him. Any money she earns through selling small amounts of produce can easily be taken by her husband who, culturally, is allowed to beat her. She becomes trapped at home, burdened with the responsibility of childcare, kept from travelling the miles between her homestead and the trading center by cultural beliefs that make female mobility on a motorcycle immoral. Although norms are less openly restrictive in urban areas, the other face of power – power over preferences – does exist in judgments of appropriate versus inappropriate consumption, with pejorative terms applied to women who challenge gender norms for consumption.

It is infamously difficult for respondents to articulate these kinds of gender issues. To study the influences of power over preferences, therefore, we devised techniques that could be used in spite of language differences and low literacy rates. For instance, we researched typical purchasing habits in remote areas in order to create a typical "shopping bag" of groceries and augmented that set of goods with objects said to have strongly gendered identities in local habits. The final "bag" held a broad array of items, including common foods and everyday "necessities," as well as gender specific items for both females and males (e.g., hair extensions versus alcohol and phone time). We took the actual collection of objects into remote areas and asked participants to group the goods into piles of items (1) for which they pay and for which their spouse pays, (2) that the household often buys or never buys, and (3) items that men/women think are necessary versus unnecessary. The results made visible the social norms that elevate the consumption habits of men and place limits on the consumption of women. The items men denoted as necessary but said their wives would see as unnecessary (batteries, airtime, and alcohol) nevertheless were frequently purchased staples of the household; in contrast, goods women thought were necessities

(sanitary pads, hair extensions, and skin-whitening lotion), but were not thought important by men, were rarely, if ever, bought.

Men were expected to be the main providers for the house, but once they have fulfilled a basic commitment they were allowed to spend their money as they wished – with no social stigma even for flashy purchases or frequent drinking. Women, on the other hand, were not only to grow the food and provide for the other needs of the family (clothes, education, etc), but were always expected to put their family needs before their own. They will buy their daughters sanitary pads, but will not buy sanitary pads for themselves. There is a strong moral suasion held over women to put their families first and to not buy things for themselves, which does not exist to the same level for men.

We used a projective technique based on Haire's (1950) coffee study to elicit judgments of consumption. We grouped together four goods: sanitary pads, hair extensions, lipstick, and skin-whitening cream, and asked respondents to describe a woman who purchases these items for herself, on a regular basis. In rural Uganda, this woman was often labeled as a "malaya" – a prostitute. To indulge in "inappropriate" consumption habits earns a woman a much stronger social stigma than a man. These moral restrictions protect a man's money, and thus his freedom to consume, on two accounts: they ensure that a woman will restrict her personal consumption and use her own money, instead of her husband's money, towards family expenses (thus allowing him more disposable income for his personal consumption) and they prevent her from asking her husband for money for personal items for fear that she will be suspected of prostitution. Even among university students in urban Uganda, a woman who buys self-indulgences on a regular basis was assumed to be engaging in exchange sex. Thus, the myth of the "malaya" transfers from rural to urban settings, applied specifically to women who challenge the social norm of limiting their personal consumption. However, the gender norms that limit economic opportunities, thus causing women to be dependent on men as providers of goods and potentially driving them to engage in prostitution, are seldom recognized.

We see further through this study how gender stratifications in consumption limit the effectiveness of policies and legislation. Our research in rural Uganda, which forms part of a bigger study on girl's education and sanitary pads, demonstrates how gender biases in household decisions can place limits on a girl's ability to continue in school, despite government and civil society programs designed to further female education. For instance, families consistently place a man's social drinking needs ahead of his daughter's need for sanitary pads, thus limiting the girl's ability to stay in school. In turn, the next generation of women fails to escape the ideologically-imposed restriction on her economic autonomy, is traded in marriage, and the whole cycle begins again.

The Consuming City: Economic Stratification and the Glasgow Effect

EXTENDED ABSTRACT

This presentation will focus on the city of Glasgow (located within the central belt of Scotland) and explore the way its economic development is influenced by ideological, socio-cultural and historical forces. Images, discourse and media representations associated with Glasgow offer opposing views regarding the success, prosperity and identity of the city. On the one hand, Glasgow is proclaimed to be a city of retail and following London is the UK's second largest shopping destination. On the other hand, Glasgow has high levels of deprivation. With this in mind, we will consider the

following research questions: Is the focus on consumption making the citizens of Glasgow vulnerable? Are regeneration strategies that centre on consumption effective both for economic development and individual consumers? Or are they counter-productive and instead harming the social assets of citizens already vulnerable due to decades of deindustrialisation?

The development of consumer culture in Glasgow has been a central strategy in response to the identity crisis caused by de-industrialisation and the decline of traditional employment opportunities, particularly that offered by the ship-building industry. Similar to Miles (2010), the consuming city has become central to urban life to the extent that policy-makers and urban planners focus on consumption at the expense of anything else. Since the early 1980s, place marketing campaigns have drawn on sophisticated lifestyle concepts to position Glasgow as a high class destination. One of the most prominent, the 'Glasgow: Scotland with Style' marketing slogan was launched in 2005 in an effort to enhance the city's reputation, increase visitor numbers and increase the economic value of tourism. Proclaimed as the 'Style Mile,' Glasgow's city centre is presented as a destination filled with what Ritzer (2010, p.7) would term 'cathedrals of consumption:'

"Everyone knows that Glaswegians live, breathe, eat and sleep style. Little wonder that, in the very heart of the marvellous city they call home, one square mile houses the most extraordinary concentration of inspirational shopping, atmospheric cafés, fine restaurants, and decadent late night haunts." (<http://www.glasgowstylemile.com/>)

The assumption is decades of regeneration policies that focus on physical improvements and the construction of luxury shops will address growing inequalities through increased employment opportunities and other benefits created by economic growth. Some point towards Glasgow being awarded European City of Culture in 1990 and the hosting of the Commonwealth Games in 2014 as evidence of success. However, poverty persists and inequalities have widened. Recent statistics indicated that the percentage of Scots living in relative poverty is 17 per cent, while income inequality has increased since 2004/5 (Scottish Government, 2011). In Glasgow, there are particular concerns related to poor health and high mortality rates. Walsh et al. (2010) undertook a detailed comparison of Glasgow and two other UK cities (Liverpool and Manchester) which have almost identical levels of deprivation and have similar experiences of deindustrialisation. Findings highlighted that Glasgow suffers from excess mortality beyond that attributable to the city's high levels of socio-economic deprivation, a phenomenon known as the "Glasgow Effect."

In this presentation we draw on data from Oxfam's Humankind Index for Scotland which was built following consultation with Scottish people about what aspects of life make a real difference to the prosperity, resilience and sustainability of their households and communities. Particular effort was made to ensure that the consultation was inclusive, especially with regard to seldom heard groups and data collection included focus groups, community workshops, street stalls and an online survey. The results are a set of weighted priorities that describe what Scottish people identify as important to living well in their communities. Findings point to health, security, time with friends and family, access to green spaces and satisfaction in work as priorities. Such priorities are dramatically different from how Glasgow has been marketed – competitive, stylish, imaged-focused. They are also unlikely to be outcomes

flowing from the current mode of economic development being pursued in the city.

Although we focus on Glasgow, the trend towards more entrepreneurial governance means that increasingly cities across the world are being marketed as shopping destinations (Kavaratzis, 2004). The danger with such an approach is that the city becomes 'less a place for and of the people and more a unit for the efficient maximisation of consumption' (Miles, 2010, p2). We demonstrate that beneath idealised marketing images, this approach to regeneration is not conducive to the reduction of poverty and inequality. This has important implications for both city planners and city marketers as a more multidimensional focus on the planning and branding of cities would provide a better fit with the priorities of citizens and also ensure greater sustainability. By considering goals beyond economic growth and elevating policies which contribute to better distribution of that growth and growth of what matters to communities in the first place, policy makers would be in a better position to really make a difference to local residents.

Paper #3: Is Self-Serving Self-Serving? Who Serves Food Shapes Self-Evaluation and Eating Decisions

Linda Hagen, University of Michigan, USA
Aradhna Krishna, University of Michigan, USA
Brent McFerran, University of Michigan, USA

SESSION OVERVIEW

Excess unhealthy food intake and inadequate exercise are major contributors to the obesity epidemic, such that understanding and increasing healthy choices is a major issue of interest to researchers and policymakers. This session features three papers that use psychological theories to inform our understanding of important factors that influence eating and exercise choices. Collectively, these papers raise and begin to address the following questions: 1) How can we leverage existing psychological research insights to understand and improve eating and exercise choices, and 2) How can studying psychological theories in the eating and exercise domains lead to new theoretical insights?

The first paper builds upon assimilation and contrast research and demonstrates that these effects can manifest differently in food consumption contexts. In three studies, assimilation and contrast effects on healthiness judgments were moderated by individual differences in self-control, such that people higher (lower) in self-control made healthiness judgments that facilitate healthier (unhealthier) eating patterns.

The second paper builds on reactance research to show that highly reactant people resist the influence of direct self-control messages. Three studies show that exposing people to words directly related to a target healthy behavior (e.g., exposure to diet-related words to promote healthier food choices) can be less effective than exposing them to words indirectly related to the target behavior (e.g., exposure to exercise-related words to promote healthier food choices). This effect occurs among highly reactant people and indicates that indirect health messages can be more effective than direct ones at promoting healthier behavior.

The third paper builds upon research on agency and self-serving attributions to examine how perceptions of agency in food serving shape post-eating feelings and how anticipation of such feelings shapes eating decisions. Four studies demonstrate that people feel better when unhealthy food is served to them as opposed to when they self-serve it, that people have intuitions about ramifications of different serving arrangements, and that people adjust their unhealthy food portion selections based upon whom they expect to be the server.

These three papers are in advanced stages and collectively leverage psychological theories to investigate important factors that influence healthiness perceptions and healthy choices. Moreover, two papers examine interactions between experimental manipula-

tions and individual differences (self-control, reactance), providing a nuanced understanding of how different consumers may respond to environmental cues, messages, and potential interventions. This session will appeal to an audience interested in self-control, healthy choices, and food psychology. This work relates to the “making a difference” theme because it sheds light on factors influencing consumer welfare.

“This Isn’t So Bad”: Assimilation, Contrast, and Self-Control on Healthiness Perceptions

EXTENDED ABSTRACT

Assimilation and contrast effects play an important role in the way consumers make judgments (Parducci 1992; Schwarz and Bless 1992b). The order of information, in particular, may have a contextual influence on the way we evaluate (Schwarz and Bless 1992a). In the present research, we examine how assimilation and contrast effects might manifest differently in food consumption related situations. Across three studies, we examine contextual order effects and test our hypothesis that these effects are moderated by self-control, facilitating better overall patterns of consumption for individuals higher in self-control. We show that prior exposure to healthy or indulgent food options impacts consumer evaluations of healthiness for subsequent options differently at varying levels of self-control.

Comparative evaluations and order effects are critical to our understanding of consumer judgments and choice. Our research contributes to this knowledge by examining the role of self-control in goal contexts with sequential exposure to different foods. Research on order effects has identified highlighting and balancing behaviors toward pursuit of self-regulation goals (Dhar and Simonson 1999). For example, a dieter may balance an unhealthy lunch by eating a healthy dinner or vice versa. The present research examines judgments about the ambiguously healthy foods that may lead individuals with low self-control to use strategies such as highlighting and balancing ineffectively or categorizing alternatives in a manner that negatively impacts the pursuit of health goals (Poynor and Haws 2009). Specifically, we hypothesize that people with lower self-control will assimilate their perceptions of healthiness for ambiguously healthy options following exposure to healthy foods and contrast after unhealthy foods. This behavior broadens the number of acceptably healthy choices available. For those high in self-control, we expect the opposite pattern to emerge and impede goal-inconsistent choices.

In Experiment 1, participants were shown food images one at a time and asked to rate the healthiness of each. Participants were shown either a healthy (an apple) or unhealthy food (potato chips) followed by an ambiguously healthy food (Goldfish® Crackers). Separately, participants completed the 13-item self-control scale (Tangney et al. 2004). Analysis revealed a significant interaction ($p = 0.05$) between the order condition and trait self-control. A spotlight analysis confirmed that individuals with lower self-control evaluated the neutral Goldfish option as more healthy subsequent to exposure to a healthier item (an apple) relative to people with higher self-control ($p = 0.01$). Consistent with our hypothesis, these results indicate that after seeing a healthy item, low self-control individuals assimilate judgments about a subsequent ambiguously healthy item whereas high self-control individuals contrast. In the condition be-

ginning with an unhealthy item (potato chips), there was no significant difference between low and high self-control participants.

In Experiment 2, we tested whether our effects extend to calorie estimates, which are related to consumers' perceptions of healthiness. Participants were shown Teddy Grahams® as a neutral food following a healthy (apple slices) or unhealthy (chocolates) item. After being presented with the snacks, participants were asked to estimate the number of calories in the Teddy Grahams. The interaction between health condition and trait self-control was again significant ($p < .001$). Participants lower in self-control estimated fewer calories in the Teddy Grahams after exposure to apple slices ($p < .001$) relative to participants higher in self-control, supporting the pattern of assimilation and contrast found in Experiment 1. After exposure to healthy foods, this pattern of assimilation for people with low self-control effectively broadens the category of healthy foods and makes the pursuit of health goals easier, but less effective. Conversely, contrasting healthiness narrows categorization to protect high self-control people from threats to goal-pursuit. Consistent with Experiment 1, there was no significant difference based on self-control in the unhealthy first condition, possibly because seeing the indulgent food first does not activate a health goal.

In Experiment 3, we extended our study of order effects by presenting healthiness information for the first snack to half of the participants. We expected to find that conscious processing of health information would attenuate the tendency for people low in self-control to assimilate to healthy items. As in Experiment 1, participants were first shown either a healthy (apple slices) or unhealthy (potato chips) snack. Health grades (A for apple slices and D for potato chips) were provided to participants in the health information condition. Brief information about the algorithm for the health grade was also presented to indicate USDA guidelines and nutrient content as key determinants of the grade. All participants were then shown ambiguously healthy Goldfish and asked to estimate the number of calories in a serving. We find a significant 3-way interaction ($p < .05$) among order condition, health information condition, and trait self-control. A spotlight analysis on the healthy-first condition revealed a significant difference between the health information conditions for individuals with low self-control ($p < .01$). Consistent with our hypothesis, low self-controllers estimated significantly more calories for the ambiguous Goldfish when health information was provided.

Our findings contribute to literature on context effects as part of a goal pursuit process by exploring the role of assimilation and contrast effects in self-control decision-making through the impact on healthiness perceptions. Prior research revealed the importance of categorizations of alternatives in goal pursuit (Poynor and Haws 2009). Here, we identify trait self-control as a factor that moderates order effects, showing that low self-control individuals tend to assimilate their healthiness judgments to prior healthy food choices, whereas high self-control individuals tend to contrast. This effect can lead to suboptimal decisions for people with low self-control. However, we find that presenting health information can reverse the effect and lead to contrasting judgments among low self-control individuals. These findings may help explain why people high in self-control are more successful at pursuing self-control goals.

Avoiding Behavioral Resistance to Diet and Exercise Messages

EXTENDED ABSTRACT

People are exposed to many persuasive health messages that encourage them to become healthy in different ways. For instance, some messages encourage people to eat healthy and diet, and other

messages encourage people to get active and exercise. How do consumers respond to the constant bombardment by these messages? Some consumers may respond by developing an automatic tendency to behave in line with the content of the persuasive health messages (Bargh and Chartrand 1999; 2000; Berger and Fitzsimons 2008; Fitzsimons, Chartrand, and Fitzsimons 2008). However, other consumers may respond by developing an automatic resistance to performing the promoted behavior, such that the original message has no effect on them at all (Laran, Dalton, and Andrade 2011). We propose that this automatic resistance happens for some people in response to direct health messages (e.g., diet-related words to promote healthier eating) and that this resistance can be avoided by using indirect health messages (e.g., exercise-related words to promote healthier eating).

To establish more clearly what we mean by direct versus indirect health messages, we borrow an analogy from the goal structure literature (Shah and Kruglanski 2003). In this framework, different subgoals (e.g., diet; exercise) are linked to the same superordinate goal (e.g., self-control). Therefore, if attempting to increase healthy food choice, direct messaging refers to activating concepts related to diet, whereas indirect messaging refers to activating concepts related to exercise. Thus, we argue that increasing healthy food choice can be brought about either directly (activating diet concepts) or indirectly (through activating exercise concepts, which relate to the same superordinate goal).

Intuitively, one might expect direct messaging to be equally or more effective at promoting a desired behavior compared to indirect messaging. Indeed, past research has shown that exposing people to words directly related to the target behavior affects behavior. For instance, exposing people to words related to cooperation leads them to engage in greater cooperation in a resource management game (Bargh, Lee-Chai, Barndollar, Gollwitzer, and Trötschel 2001), and exposing people to words related to thriftiness leads them to make thriftier product choices (Chartrand, Huber, Shiv, and Tanner 2008). However, for some persuasive messages, we propose that a subset of people frequently and consistently experience a feeling of resistance upon encountering the message and facing the choice of whether to follow through on performing the target behavior. For these people, indirect messaging may be more effective than direct messaging at promoting the target behavior, because these automatic pairings of resistance do not arise for words that compose the indirect messages.

Our hypothesis that a subset of people may develop automatic resistance to some direct messages draws from the theory of reactance, or the psychological tendency to resist restrictions on one's freedom to choose (Brehm 1966). Prior research by Chartrand, Dalton, and Fitzsimons (2007) found that people high in reactance display a different pattern of responses to a stimulus compared to people low in reactance. They argued that reactance to a stimulus can become automatized when people frequently and consistently experience a feeling of resistance paired with a stimulus. We propose that people who have habitually experienced reactance while encountering similar persuasion messages will come to experience automatic resistance to performing the behavior upon encountering the words often contained in such persuasion messages. For instance, external events (e.g., "eat healthy" diet message) may have been paired with a feeling of resistance ("I won't eat healthy") frequently and consistently for people high on reactance. For these people, we hypothesize that indirect messages can be more effective than direct messages at promoting the target behavior because automatic resistance to performing the target behavior has not developed for indirect messages, yet such indirect messages are still strong enough to activate the target behavior. We tested our hypotheses in three studies.

Study 1 had a one-way between-subjects design with three levels (message: direct (diet), indirect (exercise), control). Participants completed a scrambled sentences task that exposed them to words related to diet, exercise, or neutral words. Then, they chose five snacks from a selection of five unhealthy and five healthy snacks. Results showed that the direct message and the indirect message led to more healthy snacks chosen compared to the control condition. More importantly, the indirect message led to more healthy snacks chosen than the direct message.

Study 2 had a 2 (message: direct (diet), indirect (exercise)) \times continuous measured reactance between-subjects design. Participants completed a scrambled sentences task that exposed them to words related to diet or exercise. Then, they chose five snacks from a selection of five unhealthy and five healthy snacks. Finally, they completed an individual difference measure of reactance (Hong 1992; Hong and Faedda 1996). Results showed that the indirect message again led to healthier snack choices than the direct message. This effect was moderated by reactance, such that high reactance participants displayed this effect, whereas low reactance participants did not.

Study 3 had a 3 (message: direct (exercise), indirect (diet), control) \times continuous measured reactance between-subjects design, which aimed to replicate the conceptual finding of study 2 in the exercise domain. Participants first completed a scrambled sentence task that exposed them to words that were diet-related, exercise-related, or neutral. Then, they chose three activities from a selection of three sedentary and three exercise activities. Finally, they completed a reactance scale (Hong 1992; Hong and Faedda 1996). Results revealed a significant two-way interaction, such that participants high in reactance resisted the direct message but not the indirect message or the neutral words in the control condition.

In sum, in the diet and exercise domains, an indirect message is more effective than a direct message at promoting the direct message's target behavior for people high in reactance.

Is Self-Serving Self-Serving? Who Serves Food Shapes Self-evaluation and Eating Decisions

EXTENDED ABSTRACT

Eating meals that are served by someone else is commonplace: 50% of all meals are consumed away from the home, and two-thirds of Americans eat out at least every other day (Stewart, Blisard, and Jolliffe 2006). Being served offers convenience – but does it come at a cost for health? Indeed, consumers are aware of making more unhealthy choices when eating out (Gregory, Smith and Wendt 2011). In this research, we explore this phenomenon and investigate how one predominant feature of eating out, being served by someone else instead of serving oneself, might drive it. Based on the literatures of agency and self-serving attributions, we theorize that being more versus less physically involved in the act of serving food differentially affords self-serving attributions of responsibility for one's food choices. Thereby, it may shape how consumers feel about themselves after eating, and even alter their portion-size choices beforehand.

A variety of consumer research has shown that consumption experiences and behavior can be significantly altered by the degree to which the consumer is active in the process (Botti and McGill 2006; Norton, Mochon, and Ariely 2012). Agency – the sense of controlling one's actions – considerably influences judgment and decision-making, particularly by intensifying affective reactions (Botti and McGill 2011; Landman 1987). Accordingly, agency attributions are consequential and are often distorted in self-serving ways to protect a positive self-view (Campbell and Sedikides 1999; Miller and

Ross 1975). People attribute responsibility for favorable outcomes to themselves but attribute responsibility for unfavorable outcomes to others (Arkin, Gleason, and Johnston 1976; Blaine and Crocker 1993). They also self-penalize less when they can explain away responsibility to other factors (Bandura, 1990), something especially pronounced in goal-domains (Dunning, Perie, and Story 1991).

One such important goal-domain for today's consumer is healthy eating. Most people want to eat healthily, and eating is intricately linked with self-conscious feelings (e.g., many experience shame for eating indulgent foods) (Ramanathan and Williams 2007). We propose that being served unhealthy food by someone else (versus self-serving) affords an opportunity to reject responsibility and have more positive self-evaluative feelings as a result. Four studies show that (1) self-evaluative feelings following consumption are influenced jointly by the food's healthiness and who served it; (2) this effect is mediated by feelings of responsibility; and (3–4) people adjust their food consumption in anticipation of this effect.

Study 1 established that healthiness and who serves interactively affect self-evaluative feelings. In a 2 (server: self/other) \times 2 (healthiness: healthy/unhealthy) between-subjects design, participants imagined lunch in a cafeteria where they either served themselves or were served, and saw a photograph of their healthy or unhealthy dish. Subsequently, participants indicated how good, justified, guilty, and shameful they would feel after eating this meal, yielding an index for positive self-evaluative feelings. The analysis yielded a main effect for healthiness, with participants reporting significantly more positive self-evaluative feelings when they imagined eating healthy food versus unhealthy food. More important, however, this effect was qualified by the predicted interaction between healthiness and server. For healthy food, people had directionally more positive self-evaluative feelings when they imagined self-serving than being served by another person. Conversely, for unhealthy food, people had more positive self-evaluative feelings when they imagined being served by others compared to self-serving.

Study 2 tested if this effect is mediated by attributions of responsibility for the plate of food as a function of who served and the food's healthiness, based on the idea that self-serving may force consumers to accept, but being served may offer an opportunity to reject, responsibility. In a 2 (server) \times 2 (healthiness) between-subjects design, participants imagined eating with friends who had cooked dinner where they served themselves [their friend served them], and saw a photograph of their healthy [unhealthy] dish. Lastly, they reported their self-evaluative feelings and indicated how much responsibility they felt for their food. For positive self-evaluative feelings, the data fully replicated study 1. Importantly, these patterns were fully mediated by feeling responsibility ($CI=4.03-40.50$). When people thought about eating healthy food, those who imagined being served assumed just as much responsibility as those who imagined serving themselves. Conversely, when people thought about eating unhealthy food, those who imagined being served accepted significantly less responsibility than those who imagined serving themselves.

Together, studies 1–2 demonstrated that people feel better about themselves when unhealthy food is served to them (as opposed to when they self-serve the same food) because they can reject responsibility for it. Studies 3–4 sought to extend these findings to downstream effects on consumers' food-related decision-making.

Study 3 explored whether people's preferences for who should serve food change as a function of the food's healthiness. Participants imagined getting a healthy [unhealthy] snack and indicated their preference for serving themselves versus being served by their friend. The analysis revealed that for the unhealthy snack, preference shifted towards being served by the friend, compared to the healthy

snack. Consumers appear to have an intuition about the consequences of serving themselves unhealthy food.

Study 4 tested to what extent this intuition causes consumers to adjust how much food they allow themselves in a given context, depending on the food's healthiness and the serving-arrangement. In a 2 (server) × 2 (healthiness) between-subjects design, participants envisioned purchasing a healthy [unhealthy] dessert at an establishment where they would self-serve [be served by a clerk]. They then selected one of eight serving-cup sizes. For portion-size choice, the analysis showed a main effect of server, such that those who expected to be served selected significantly larger portions than those who expected to self-serve. More important, this effect was qualified by the predicted interaction with healthiness. Consistent with our other studies, for a healthy dessert, people selected equal portion-sizes irrespective of who would serve. Contrastingly, for an unhealthy dessert, people selected a significantly larger portion when they expected to be served than when they expected to self-serve the dessert.

In combination, studies 3 and 4 showed that people have an intuition of the ramifications of different serving-arrangements and adjust their consumption of unhealthy food accordingly.

Paper #4: Choosing to Participate: The Effects of Message Type on Enrollment and Participation

Eleanor Putnam-Farr, Massachusetts Institute of Technology, USA

Jason Riis, Harvard Business School, USA

SESSION OVERVIEW

The United States is the most obese country in the developed world, with obesity rates already reaching epidemic proportions. About two thirds of adults and one third of children in the US are either overweight or obese. Moreover, obesity is considered to be one of the costliest plagues of the 21st century since it contributes significantly to the already high healthcare costs of the nation - obesity-related healthcare costs are expected to exceed \$300B by 2018.

Past efforts to address the problem of obesity have been largely unsuccessful and public policy makers are looking for new initiatives that could prove helpful in curbing the obesity epidemic. Therefore, the four papers in this session (all in advanced stages of completion) offer interventions that have the potential to solve the obesity problem by tackling two of its leading causes – the increased consumption of unhealthy foods and the lack of physical activity.

The first three papers focus on ways in which consumers could be encouraged to make healthier food choices. Specifically, Shah, Bettman, Keller, and Ubel assess the effectiveness of economic and stigma-inducing interventions in reducing unhealthy food choice and consumption and show that stigma-inducing signals prove superior to economic interventions alone (‘unhealthy’ label versus 17.5% tax). The second paper by Dzhogleva, Inman, and Maurer examines how the ease-of-processing of nutritional information at the point of purchase impacts consumers’ food choices. The authors reveal that facilitating the understanding of nutritional information by disclosing nutritional facts in a simple manner helps consumers make healthier food decisions. Mohan, Chandon, and Riis study the moderating role of cognitive ability on consumers’ ability to objectively assess the value of percentage-based promotions. Importantly, the authors demonstrate that providing ratio-based rates nudges consumers away from obesogenic, higher-calorie percentage benefit offers (33% bonus size) in favor of healthier, lower-calorie percentage cost offers (33% price discount) that are also superior from a unit-price perspective. Finally, Putnam-Farr and Riis seek to combat the lack of physical activity part of the obesity problem and evaluate the effectiveness

of different recruitment messages on enrollment and participation in a physical activity tracking program. Results show that active choice leads to higher enrollment and equally strong participation as opt-in; moreover, messages focused on intangible health benefits and non-quantified rewards lead to higher duration of participation than those emphasizing quantifiable rewards.

Using diverse methods (lab and field experiments, household shopping data) and offering the perspectives of diverse researchers and a practitioner, all papers in this session aim to make a difference in consumers’ lives by answering collectively the following question: How should we structure consumers’ choice environments such that they promote healthier choices? Thus, all papers converge around the common theme of nudging consumers in the right direction and helping them make decisions that would benefit their long-term wellbeing. We expect this session to be of great interest to a broad audience of researchers, consumers, public policy makers, and health practitioners interested not only in combating obesity but also in improving consumer welfare in general.

‘Does This Tax Make Me Look Fat?’: Using Stigma-Inducing Labels to Decrease Unhealthy Food Consumption

EXTENDED ABSTRACT

Obesity and unhealthy food consumption are two of the largest public health concerns nationwide. Obesity rates have more than doubled in the past few decades. While there is debate regarding the cause of obesity, most research has argued that increased consumption of unhealthy food and beverages is a major driver of obesity (Chandon and Wansink 2007, 2011; Young and Nestle 2002). Many public health advocates have suggested that large-scale interventions are necessary to combat the epidemic. While there are proponents of increased nutrition education, others have suggested the use of a tax on unhealthy food and drinks.

Although an economic approach is one possible way to attenuate consumption of unhealthy food, will consumers even notice a price change? Are there other approaches that may be equally, if not more so effective? For example, an intervention that explicitly associates unhealthy food choices to an undesirable social identity may actually be more effective at reducing consumption. Consumer research has shown that individuals attribute a wide array of traits and characteristics such as social appeal, morality, and gender roles to others based on their food choices and consumption habits (Rozin et al. 2012). As a result, what one chooses to eat can have important implications for not only one’s sense of self but also impression management, social judgment, and status (Vartanian, Herman, and Polivy 2007). One of the most devalued and negative identities in social contexts is stigma, which Goffman (1963) characterized as one of the greatest social risks that reduces the stigma bearer “from a whole and usual person to a tainted, discounted one” (p. 3). Given that individuals are conscious of their social identity and strongly seek to avoid social stigmatization from engaging in negative or deviant behavior, it is surprising how little research has examined the influence of explicit stigma-inducing signals on how individuals make food choices, a major area of interest in public health. Using the context of food choice and consumption in a real-world social setting and in controlled lab experiments, we examined the unique and combined effect of economic and stigma-inducing interventions on food choice and consumption. We also investigated

whether gender and social context (i.e., whether one dines with a friend or alone) moderated the effectiveness of these interventions. Finally, we examined whether self-construal differences between men and women, specifically independent self-construal versus interdependent self-construal, mediated the effectiveness of these interventions on unhealthy food choices.

In Experiment 1, we used a real-world restaurant context to test our initial hypotheses. Over a 16-day span we measured entrée choice and consumption (measured in grams) at a local, mid-priced tapas restaurant open from 4pm-midnight. We ran the study from Monday-Thursday for 4 weeks counterbalancing conditions ($N=464$ tables, 1063 people, 669 women). We used four different menus containing the same entrée items: *Control* (no unhealthy food tax or stigma label), *Food Tax* (17.5% price increase on unhealthy food items, no stigma label), *Stigma Label* (marked unhealthy items with an asterisk and an explicit ‘Unhealthy’ label, no food tax), *Combined* (unhealthy food tax plus stigma label). Stigma labels significantly reduced unhealthy entrée choice ($p<0.01$) and unhealthy food consumption ($p<0.01$) more than the food tax alone or the control group. The effect of unhealthy stigma labels was moderated by gender, where higher proportions of men at the table significantly increased unhealthy choices and consumption of unhealthy food ($p<0.01$).

In Experiments 2 and 3, we used a hypothetical food choice scenario to examine whether we could replicate our findings from the field in a more controlled laboratory setting. Experiment 2 tested whether gender moderated the effect of economic and stigma-inducing signals on food choices. An MTurk sample ($N=1800$) of men and women selected an entrée items from a hypothetical menu with six items (2 beef, 2 chicken, 2 fish, with 1 healthy and 1 unhealthy item within each food group). We used the same four menu conditions as Experiment 1. Replicating the field study, stigma labels are significantly more effective at reducing unhealthy food choices than an unhealthy tax alone or the control group ($p=0.007$). There was also a significant Gender X Food Tax X Stigma Label interaction ($p=0.05$): women chose healthier dishes when unhealthy items had a stigma label ($p<0.01$). Men and women selected more healthy items when unhealthy food was taxed and there was a stigma label ($p<0.01$).

In Experiment 3, we examined how dining with a same-sex friend influenced the interaction between gender and economic and stigma-inducing interventions on the proportion of individuals choosing an unhealthy menu option. In addition, Experiment 3 sought to investigate a potential mechanism for these effects. Specifically, using the same food choice scenario as Experiment 2, we examined whether self-construal differences between men and women mediated the effectiveness of economic and stigma-inducing interventions on unhealthy food choices. Men eating with other men chose more unhealthy options ($p<0.01$) while women eating with other women chose healthier options ($p<0.01$) in comparison to dining alone. Self-construal differences among men and women fully mediate the effects of the stigma label: Men chose more *unhealthy* items when there was an ‘Unhealthy’ label, the more they were concerned that others would think they were wimpy and less masculine, a more interdependent mindset. In contrast, women chose more *healthy* items when there was an ‘Unhealthy’ label, the more they felt uncomfortable by others and wanted distance from unhealthy individuals, a more independent mindset.

In the field and lab setting we demonstrate that increasing the tax on unhealthy items alone, even substantially by 17.5% is insufficient for reducing the proportion of individuals choosing an unhealthy entrée. A combination of food tax and a stigma label such

as marking items as ‘Unhealthy’, significantly reduced unhealthy choice, regardless of gender and dining partner. We also demonstrate that interdependent/independent self-construal differences among men and women drive these effects. These studies have important practical implications and also demonstrate that social constructs such as stigma may moderate previous notions of gender and self-construal mindsets.

Does Reducing Nutritional Information Complexity Promote Healthier Food Choices?

EXTENDED ABSTRACT

The Nutritional Labeling and Education Act (NLEA) was one of the biggest efforts by policy makers to promote healthy eating among Americans. Unfortunately, it has failed to curb the obesity epidemic, so policy makers and marketers are seeking new ways to impact consumers’ dietary decisions. A recent trend among food retailers is to implement in-store nutrition scoring systems that communicate the nutritional value of foods in a simplified manner (e.g., Guiding Stars, NuVal). Our research examines whether facilitating the understanding of nutritional information through such nutrition scoring systems at the point of purchase helps consumers make healthier food choices.

Past research demonstrates that the complexity of understanding nutritional information has impeded consumers from making smarter food choices. Cohn et al. (2012) report that point-of-purchase calorie postings in restaurants are not effective in encouraging consumers to embrace healthier eating because consumers find it difficult to comprehend and use the provided information. This suggests that in order for nutritional information to be incorporated into consumers’ decisions, it does not have to be only available at the point of purchase but also easily “processable” (Bettman 1975; Russo 1975). Russo et al. (1986) argue that consumers face three types of costs in incorporating nutritional information into their food decisions: collection costs (time and efforts to acquire the information), computation costs (efforts in combining the gathered information into an overall evaluation), and comprehension costs (efforts to understand the nutritional information). Reducing all three costs leads to greater reliance on products’ nutritional content in making food choices (Russo et al. 1986).

Although the NLEA largely eliminated consumers’ collection costs, it had less impact on their computation and comprehension costs. Therefore, we propose that providing simpler and easy-to-process nutritional information which reduces all three types of costs will prove helpful in prompting consumers to purchase healthier foods. In other words, we anticipate that the nutrition content of shoppers’ purchases will be higher after the introduction of the nutritional scoring system than before the scores were available at the store (H1). We further predict that this effect will be stronger in categories with greater variability in the healthiness of the offered products (H2). In such categories consumers have a wider variety of products to switch to. Moreover, purchasing a healthy product from a mixed set of both relatively healthy and unhealthy alternatives provides consumers with greater utility than when such a purchase is made from a homogeneous opportunity set (Dhar and Wertenbroch 2012). We also propose that the effect in H1 will be stronger in healthier product categories (H3) because past research suggests that consumers are more likely to use nutritional information in categories which are perceived to be more nutritious (Brucks, Mitchell, and Staelin 1984). Finally, we anticipate that consumers who do not switch away from unhealthy foods after the introduction of the scoring system at the store will buy fewer items of those foods (H4).

We test our predictions using 12-months of individual shopper sales data for over 528K shoppers of a Northeast grocery chain. The data consists of 40.2M purchases in eight product categories: frozen pizza, ice-cream, salad dressing, soup, spaghetti sauce, tomatoes, granola bars, and yogurt. In early 2009, the grocery chain implemented the NuVal Nutritional Scoring System, which assigns each SKU a 1-100 score based on its nutritional value. Since the NuVal scores were displayed on the shelf tags, after their introduction, consumers could easily determine and understand the nutritional value of all foods. Our data contains information about consumers' purchases before and after the NuVal introduction in the chain, allowing us to use the first 6 months as the baseline and assess its impact on consumers' food choices using a quasi-experiment.

To test H1-H3, we estimate a hierarchical linear model in which shoppers' purchases (level 1) are nested within the categories (level 2). The dependent variable is the average volume-weighted NuVal score of each shopper's purchases (i.e., the nutrition content of shoppers' purchases), which is predicted by the period (contrast coded: -1=pre-NuVal introduction; 1=post-NuVal introduction). We allow both the intercept and the slope of period to vary randomly across the eight different product categories (the level-2 units); moreover, the slope of period is specified as a function of two category-level variables – the perceived category healthiness and the variability in the healthiness of the offered products in each category. The perceived healthiness was obtained from a separate survey in which shoppers from an online panel were asked to rate the healthiness of the eight product categories on a 7-point scale (1="Very Unhealthy," 7="Very Healthy"). The variability in the healthiness of the offered products is operationalized using the standard deviation of the NuVal scores of all products in the category. Both level-2 predictors are grand-mean centered.

Results support H1, revealing that the nutritious content of shoppers' purchases in the post-NuVal introduction period was significantly higher than in the pre-NuVal period ($p < .0001$). Furthermore, in line with H2 and H3, the cross-level interactions of period with the two category-level predictors are significant (both $p < .0001$), suggesting that the effect of the nutrition scoring system on shoppers' food choices was stronger in healthier categories and those with greater variability in the healthiness of the offered products.

To test H4, we estimate a separate two-level random-intercept, random-slope hierarchical linear model in which the change in total units purchased by each shopper (post – pre) is predicted by the change in the nutrition content (NuVal score) of the shopper's purchases (post – pre). Results demonstrate that shoppers who did not improve the nutritious content of their purchases after the introduction of the scoring system at the store reduced the number of units they bought ($p < .0001$), thus supporting H4.

In sum, our work reveals that facilitating consumers' understanding of nutritional information by disclosing nutritional facts in a simple and easy-to-process format can help them make healthier food decisions. Our findings have important practical implications for consumers, food manufacturers, grocery retailers, and public policy makers interested in combating obesity.

Promoting Portion Downsizing by Improving Consumer Response to Percentage Cost vs. Percentage Benefit Offers

EXTENDED ABSTRACT

Marketing communication, particularly in the domain of food, frequently contains percentage information about benefit changes

(e.g., 50% larger food packages) or about cost changes (e.g., 50% price reduction). Nominally equivalent percentage changes to the cost versus the benefit associated with an offer are not economically equivalent in terms of cost/benefit or benefit/cost ratio. To compare two percentage changes in cost and benefit requires knowing whether $x\%$ is bigger or smaller than $-x/(1+x)\%$; this comparison involves multiple arithmetic operations and is very difficult to do mentally, even in the simplest cases (e.g., +50% vs. -33%). Chen, Marmorstein, Tsiros, and Rao (2012) have shown that, when comparing offers with percentage information (e.g., a 50% quantity increase vs. a 33% price reduction, which has the same unit price consequence), consumers focus on the nominal percentage and fail to take into account the base levels of these percentages, a phenomenon that they called "base value neglect".

Across four studies, we examine the robustness of the effect found for bonus packs vs. price changes by Chen, et al. (2012), and demonstrate the moderating roles of consumer goals (minimize cost, maximize benefit, or maximize value), cognitive reflection (Frederick, 2005), and provision of a cost/benefit vs benefit/cost ratio (such as unit price) (Manning, Sprott, & Miyazaki, 2003; Larrick & Soll 2008).

Study 1 asked participants to choose between a 33% quantity increase and a 33% price decrease (or a 33% quantity decrease and a 33% price increase) for their favorite brand of yogurt or ice cream. Overall, consumers were indifferent between the % price and % quantity offers, regardless of category and whether people were choosing between two gains or two losses. However, there was a strongly statistically significant interaction between outcome valence (gain or loss) and consumer goal ($p < .001$). For example, consumers who were seeking to minimize cost strongly preferred the 33% price decrease over the 33% quantity increase in the gain condition and strongly preferred the 33% quantity decrease to the 33% price decrease in the loss condition. We also find that the Cognitive Reflection Test (Frederick, 2005) is a particularly good predictor of base value neglect because it captures the tendency to follow the intuitive (but wrong) answer instead of engaging in more effortful system-2 computation. Participants who scored above a 0 on the CRT test strongly preferred the economically-superior 33% price change over the 33% quantity change. Finally, we show that providing rate information such as price per unit reduces consumer errors when comparing percentage offers, regardless of CRT score. Participants who were exposed to the unit price were no longer indifferent, and strongly preferred the 33% price change over the 33% quantity change.

In the subsequent 3 studies, we demonstrate the moderating role of CRT, and the corrective effect of providing a ratio, across a variety of tasks and domains. In Study 2, we asked participants to rank printers by speed after taking account either a % change in pages per minutes (benefit) or a % change in the minutes (cost) needed to print a page. Once again, we find that those scoring high on the CRT made better choices. Providing a ratio, in the form of pages per minute, also has a significant effect on participant accuracy ($p < .01$). Next, we examined whether the way a ratio is presented (cost/benefit vs. benefit/cost) influences a consumer's likelihood of responding to the unit price implications of a cost versus a benefit percentage change. In Study 3, we asked participants to assess percent changes when comparing wireless plans, and manipulated the ratio type by providing either seconds/cents or cents/seconds. We find that people fail to realize that a percentage cost change is better than the opposite percentage benefit change, even when the cost and benefit base values are identical. Moreover, in the presence of a ratio, significantly more participants correctly chose the economically-

superior cost change when the ratio was framed as a cost/benefit as opposed to a benefit/cost, particularly when choosing between 2 losses. Finally, in Study 4 participants completed a word search puzzle at a given wage (6 cents/word), and subsequently chose between the following two payment options for completing a bonus puzzle: a 50% increase in the wage paid per word (9 cents/word), or a 50% decrease in the number of words needed to make the same wage (12 cents/word). Participants with a CRT score greater than zero, as well as participants given the unit wage, were more likely to make the economically optimal choice in this incentive compatible field experiment.

Our results suggest that marketers should frame their offers as a percentage benefit change, which produces the largest nominal percentage, rather than by the equivalent percentage cost change. In general however, framing offers as a percentage benefit change rather than a percentage cost change will lead consumers to sub-optimal choices. There are practical implications for consumers making food choices when faced with percentage promotions without accompanying unit prices. If a consumer fails to comprehend that 35% price reduction is better than a 50% quantity bonus from a unit price perspective, they will tend to choose the larger portion, thus increasing the likelihood of overeating (Wansink, 1996; Young & Nestle, 2002). Conversely, consumers are less likely to choose a healthier but smaller portion (e.g., pastry made from real butter instead of palm oil) if someone points out that it is 50% smaller than the regular portion than if the comparison highlights that it is 35% more expensive. At the moment, unit prices are not mandatory for retail distribution in all US states and are never mandatory when accompanying percentage price promotions and in non-retail domains (U.S. Department of Commerce, 2013). Thus, our findings have important implications for public policy. They reaffirm the effectiveness of providing unit price information, which is currently only mandatory in brick-and-mortar retailers (and not in restaurants, for example). We think that rate information, in particular unit prices, should be made mandatory everywhere and not just for brick and mortar retailers.

Choosing to Participate: The Effects of Message Type on Enrollment and Participation

EXTENDED ABSTRACT

As more services (including health services) move online, the development of communication strategies to maximize enrollment and engagement has become increasingly important. Programs like Boost (activity tracking) are increasingly used as relatively low cost ways to engage consumers and employees in activities that can improve healthy behaviors and reduce problems related to obesity and its associated diseases. While some research has shown that message framing and choice architecture can affect enrollment, these studies have usually taken place in a forced choice environment where the consumer's attention is high. The reality is that most recruitment for most online services comes through email or other cluttered channels where attention is lower. Furthermore, engagement (or participation after enrollment) has rarely been examined, yet engagement is a major objective of services that require renewal, or for services that are designed specifically to help consumers manage their own behavior, particularly in the domain of health.

We address both of these issues in a large scale field experiment where over 17,000 employees of a large American company were invited to enroll and participate in an activity tracking program (Boost) and find strong benefits to active choice along with significant differences in participation resulting from the different message

frames. Focusing on a high quantified reward is most effective for getting people's attention, but it does not yield the best outcomes for participation. Thus, marketers who want to involve participants for the long term, such as in diet and exercise programs, would be best served by using an active choice frame which emphasizes a non-quantified reward.

While research on choice architecture has focused initially on the differences between opt-in and opt-out, a number of recent studies (e.g., Carroll et al. 2009; Keller et al. 2011) have started to include an active choice component, where participants are forced to choose between enrolling or not enrolling rather than being presented with a default. Active choice has generally been used synonymously with forced choice because the scenarios have forced participants to choose one or the other option (usually a yes/no for enrollment), yet forced choice opportunities are relatively rare under most recruitment situations.

Despite the knowledge among researchers that expected rewards can have a deleterious effect on intrinsic motivation (Deci, Koestner, and Ryan 1999), practitioners continue to use rewards as a means of attracting participants due to their strong immediate impact. We contrast the effects of rewards (both quantified and non-quantified) on enrollment and participation to demonstrate the differing short term and long term effects and to highlight the potentially negative consequences of quantifying rewards when aiming to promote long term engagement.

Participants (N=17,093) were recruited for participation in an activity tracking program run by RedBrick Health and were assigned to one of seven message conditions in a randomized field experiment. All participants were given the same introductory text with basic information about the health and rewards benefits of participating in the activity tracking program. All participants were eligible for \$2 per day that they tracked at least 30 minutes of activity, with a quarterly maximum of \$125 (other programs also provided rewards). All participants had previously completed a health assessment survey as the basis for program eligibility.

Participants in the control condition were given a standard opt-in message with a link to the enrollment page. The 6 treatment conditions were constructed by crossing two between subject factors pertaining to the yes/no response options. The first factor was message type (3 conditions) whereby different benefits of the program were emphasized. One message focused on health benefits (health), the second focused on the rewards (non-quantified rewards), and the third quantified the rewards (quantified rewards). The second factor was the strength of the "no" option (strong versus weak – 2 conditions). The strong "no" option included a reference to the lost benefit, while the weak "no" condition did not. For example, participants in the health condition all saw the following "yes" text: "Yes, I would like to participate in the Boost tracking program. I want to track my activities to help improve my health" and one of the following "no" options: [STRONG] No, I do not want to participate in the Boost tracking program because tracking my activities to improve my health is not important to me at this time. [WEAK] No, I do not want to participate in the Boost tracking program.

We found that all six active choice messages prompted higher enrollment than opt-in. Despite the expectation that the repetition of benefits in the strong no would increase loss aversion, we found no difference between the strong and weak no. Once enrolled, we found that there were no significant overall differences between opt-in and active choice in terms of their duration or frequency of participation, leading to an overall strongly positive relationship between receiving an active choice email and participation in the program.

Looking at the messages by type, we found that rewards and health were both equally effective in terms of duration of participation, but quantification of the rewards message resulted in lower average duration of participation. This lower average duration is driven by a substantially higher proportion of participants who drop out in the first two weeks after enrollment (25% versus 15% in the non-quantified reward condition). We hypothesize that the \$125 message sets a high target and that a lower than expected rate of rewards accumulation in the first two weeks results in demoralization and abandonment. Further work (analysis and follow up experiments) is underway to determine the exact mechanism.

This paper provides insights to managers interested in recruiting participants to programs where their active engagement is an important objective. Involving participants by means of an active choice makes them more aware of the potential benefits of a program that they might otherwise ignore, but marketers should beware that setting a high target for achievement might result in abandonment of the program if participants do not see early success.

SESSION OVERVIEW

Consumption is constituted as the final purchase of goods or services by individuals. Money, as an extremely efficient medium of exchange, is probably the most common consumption tool. And yet, despite its everyday use as a tool, consumers' representation and reaction to money extends far beyond what one would expect from a tool. Instead, money is deeply embedded and intertwined in consumers' minds, so much so that it produces dramatic changes in people's thoughts, feelings, and behavior. Although recent research has greatly advanced the field's understanding of money, two large and very important theoretical questions linger: 1) through what psychological mechanisms does money operate and 2) how does every day uses of money change human behavior and society? This special session brings together a novel and diverse set of findings that, collectively, provide fresh insight into these questions by examining various manners of interacting with money: seeing, possessing, and losing money.

The first two papers focus on the first question and show that subtle monetary cues trigger an exchange relationship-style, which in turn accounts for some of the downstream consequences of monetary reminders. The first paper, by Jiang, Chen, and Wyer, investigates the relationship between monetary reminder and people's emotional expression. Five experiments show that the concept of money activates an exchange relationship orientation, and consequently leads to increased negative attitudes toward expressing emotions, decreased expression of emotion when describing events, exaggerated perceptions of others' emotions, and decreased willingness to interact with people who express strong emotions. The second paper, by Mead,

Caruso, Vohs, and Baumeister, builds on the first paper by examining how monetary reminders affect interpersonal interactions. Three experiments provide novel evidence that merely being exposed to monetary cues drives people to apply money-market norms to social relationships, regardless of the situational norm. And this heightened exchange orientation can hamper interpersonal relationships when situations call for communal norms.

The third and fourth papers address the second major question. The third paper, by Gneezy and Mazar, focuses on the influence of monetary possession on the way consumers tip. Three experiments show that under some circumstances, when not having enough cash to reciprocate the quality of the received service, customers ironically end up tipping bad service (to punish) but not good service (to not insult). The last paper, by Rae, Durante, Griskevicius, and Cantu, studies the fear of losing money from an evolutionary perspective. Four studies reveal that hormonal fluctuations associated with ovulation lead women to become less loss averse but only when a product does not serve to enhance attractiveness.

Together, these papers shed light on how the mere exposure to money, possession of money, and aversion of losing money affect human behavior. We believe this symposium will advance the field's understanding of the psychology of money and, as such, will be of interest to a broad audience at the ACR conference.

Monetary Reminders Lead to Exchange Orientation and Emotion Suppression

EXTENDED ABSTRACT

The mere exposure to money, independently of the context of any goal to which it might be relevant, increases individuals' motivation to be socially independent and decreases their sensitivity to others' needs (Vohs, Mead and Goode 2006; 2008). Thus thinking about money may dispose individuals to view themselves as being more in an exchange relationship with others (Clark and Mills 1979) in which interpersonal interactions are considered in impersonal, transactional terms. Transactions in such a relationship are governed by *quid pro quo* without regard for idiosyncratic needs of the parties involved. Given that emotions are used to convey information about needs of the senders (Ekman 1993), the expression of emotion is likely to be considered irrelevant and even inappropriate in such a relationship and, therefore, is likely to be suppressed. Our research evaluated implications of this general hypothesis. Five experiments showed that subtle reminders of money can influence people's disposition toward exchange versus communal relationships, their willingness to express emotion, and their reactions to others' expression of emotions.

Experiment 1 was conducted online through Amazon's mTurk website. After exposure to money- vs. control-themed pictures, participants finished items concerned the desirability of expressing emotions and the exchange and communal relationship orientation scale (Mills and Clark 1994). Data showed that activating the concept of money decreases participants' favorability towards expressing emotions, and this effect is mediated by the increased exchange (vs. communal) relationship orientation of money-primed participants.

Experiment 2 investigated more directly the hypothesis that reminding individuals of money would lead them to suppress their emotions. Participants were first primed with either money or control

concept through a sentence unscrambling task (Vohs et al. 2006). Next, in an ostensibly unrelated task, participants were instructed to imagine that their newly purchased laptop had broken down and they were dissatisfied with how this issue was handled by the company. They further imagined that they had decided to write a negative product review to complain about the incident on a popular online forum. After participants wrote the reviews, independent raters who were blind to our hypothesis read the reviews and rated the emotions expressed in the review. As expected, the complaints participants in the money-primed conditions wrote were less angry and less negative, than those of participants in control conditions.

Experiment 3 extended our findings to the suppression of positive emotions. In addition, if priming money really leads people to suppress their emotions, they should have relatively poorer performance on a subsequent task that requires cognitive resources than control participants should (Heatherton and Vohs 2000). We also tested this possibility. After performing the money vs. control priming task as in Experiment 1, participants watched a funny movie clip and then they were asked to describe the movie in writing to future audience. After finishing this writing task, participants performed an anagrams task similar to that used by Vohs (2006) to assess resource depletion. Specifically, participants were given five unsolvable anagrams and the time they spent on the task before giving up was assessed. Results are consistent with our predictions. Participants had significantly less intense emotional reactions to the movie (measured by both self-reports and independent ratings of their writing) when they had been primed with money than when they had not. More importantly, participants also persisted less long on the unsolvable anagrams task if they had been primed with money than if they had not, suggesting that they were suppressing their emotions (thus resource depleted) in the former condition.

People tend to believe that others are likely to behave the same way they personally behave under similar circumstances (Marks and Miller 1987). If people who have been primed with money suppress their emotions, they are likely to expect others to do so as well, and they are likely to perceive persons who do not conform to these expectations as conveying more extreme emotions than they otherwise would. Experiment 4 confirmed this prediction. After completed the sentence unscrambling task as we used in Experiment 2, participants were shown pictures portraying people with happy or sad expressions and they were asked to judge the intensity of the emotion conveyed by each picture. Results showed that money-primed participants rated the emotional expressions shown in the pictures as more intense than control participants did.

If being reminded of money decreases individuals' belief that personally expressing emotion is desirable, it is also likely to affect their belief about others' emotional expressions in a similar way. Thus it should decrease individuals' willingness to interact with others who display intense emotions. In Experiment 5, after completed the sentence unscrambling task to prime money or control concept, undergraduate participants were shown faces with happiness, anger, or neutral emotions. Participants were told that each picture portrayed an incoming foreign exchange student and were asked to indicate the extent to which they would want (a) know more about the person, (b) to meet the person, and (c) to make friends with the person. As expected, money-primed participants were less inclined than control participants to interact with both the person who expressed happiness and the person who expressed anger, but not the person who had a neutral expression.

In sum, our findings suggest that, as the major medium of exchange, the concept of money activates an exchange relationship orientation, in which people view both their own and others' expres-

sions of emotion less favorably. Consequently it led them to have more negative attitudes toward expressing emotions themselves (Experiment 1), decreased their expressions of emotion when describing both a negative event and a positive one (Experiments 2 and 3), led them to interpret others' emotional expressions as more extreme (Experiment 4) and decreased their willingness to interact with person who express strong emotions (Experiment 5).

Monetary Cues Alter Interpersonal Harmony Because They Activate an Exchange-Oriented

EXTENDED ABSTRACT

Consumers coordinate their interactions with others – be it salesclerks, supervisors, or spouses – by drawing from a small set of psychological scripts that serve to guide social interactions (e.g., Clark and Mills 1979; Fiske 1991). Throughout human history, communal relationships were the basis of social life (e.g., Fiske 1991). However, the introduction of money ushered in a new relational style that is characterized by a desire to track and optimize the ratio between costs and benefits. This relational style is called market-pricing mode (Fiske 1991) or exchange orientation (Clark and Mills 1979) and it may be unique to humans. Theoretically, communal and exchange orientations are diametrically opposed to one another (Fiske 1991), which led us to hypothesize that the previously unexplained link between money and hampered social harmony could be explained by exchange orientation. We tested this hypothesis in three experiments by varying whether participants were exposed to the concept of money; subsequent changes in relational-style and interpersonal harmony were measured.

Experiment 1 served as a basic test of the hypothesis that the mere reminder of money activates a preference for exchange relationships (vs. communal relationships). After completing a set of filler questionnaires in front of a money or neutral poster (green lettuce), participants were led to believe they would complete a workload-sharing task with another participant. When participants received this task (a number search task), it had been half completed in red ink, ostensibly by the partner. The dependent measure was the pen color that participants chose to complete the task (red and blue were both available on their desk in counterbalanced order). Because using a different color pen makes each person's work distinct and accountable, choosing a blue pen would be reflective of an exchange orientation. In contrast, because using the same pen color would lead to the sharing of the work and rewards, choosing the red (same) color of pen would reflect a desire for a communal relationship (cf. Clark and Mills 1979). As predicted, participants reminded of money were more likely to choose a different color pen than participants not reminded of money. Hence, the results of experiment 1 suggest that the mere reminder of money is sufficient to activate an exchange orientation.

It is possible that participants reminded of money chose a different pen color for reasons other than a desire to track each person's contribution, such as a desire for uniqueness or a curiosity about one's own performance. To rule out these alternative accounts we conducted a follow-up experiment. An additional goal of experiment 2 was to test the hypothesis that money reminders cause people to misapply market-norms to the social relationships. In other words, activating a money market can trump a social market (see also Heyman and Ariely 2004).

The design of Experiment 2 was a 2 (money descramble task vs. neutral descramble task) X 2 (money market vs. social market) between-subjects design. Participants thought they would complete a number search task with a partner, and that performance would gar-

ner rewards. In the social-market condition, participants were told that each answer would result in the donation of 25grams of rice to malnourished children. In the money-market condition, each answer would result in 25cents. As predicted, a significant money X market interaction emerged. Participants reminded of money reported a stronger desire to track performance relative to neutral participants, but only in the social market condition. In the money-market condition, there was no effect of the money manipulation. Hence, neutral participants were generally sensitive to the situational market norm, and they altered their behavior accordingly. However, people reminded of money preferred a money-market orientation, and they applied these money-market norms regardless of the overarching context. As expected, no significant effects emerged when predicting desire for uniqueness or desire for knowledge about one's performance.

Experiment 3 tested the full theoretical model: money reminders strain interpersonal harmony because they conjure up an exchange orientation. Additionally, experiment 3 sought to rule out the possible alternative explanation that money is operating through a change in power. As in experiment 2, we varied the situational norm. After completing a money or neutral descramble task, participants completed measures of exchange orientation (Mills and Clark 1994) and a power subscale (Cassidy and Lynn 1989). The dependent measure was willingness to engage in conversation topics that were pre-rated to be positive for interacting with a new friend (communal relationship) and supervisor (exchange relationship). Overall, results supported predictions. When chatting with a new friend, reminders of money reduced willingness to engage in conversation topics that facilitate the growth and intimacy of a new friendship. Additionally, this effect was fully mediated by exchange orientation. Also consistent with hypotheses, in the exchange context, there was no effect of the money manipulation on willingness to engage in positive conversation topics. Consistent with previous work (Vohs, Mead, and Goode 2008) feelings of power did not shift as a function of the money reminder. Hence, power cannot account for the current findings.

In sum, three experiments provide novel evidence that merely being exposed to monetary cues evokes a shift in people's relational style. More specifically, having money on the mind caused people to apply money-market norms to social relationships, regardless of the situational norm. Thus, when situations call for exchange norms, people with money on the mind may be fine. However, when situations call for communal norms, people with money on the mind may go awry.

To Tip or Not to Tip: Emotional and Monetary Tradeoffs in Tipping

EXTENDED ABSTRACT

Imagine experiencing great service in a cash-only tipping environment, following which you realize you don't have enough cash to reciprocate the quality of the service. What do you do?

Although tipping norms vary by culture, they are commonly used to promote efficiency by allowing consumers to reciprocate service workers', such as waiters' and taxicab drivers', efforts. The rule of thumb is that the better the service the higher the tip. Consequently, very low tips are more likely to be associated with poor service.

This paper investigates a tipping paradox and shows that consumers that experience good service would rather not tip at all when the only other alternative is to tip very low. Thus, when not having enough cash, good service providers can end up economically "punished." We present evidence from three experiments.

Experiment 1

Participants (N=552) were asked to imagine having dinner in a nice restaurant that only accepts cash tips. Using a between-participants design, we manipulated the described behavior of the waiter (3 levels: rude, control, nice) and the tipping options available to the participants (2 levels: \$0.25 vs. \$0; \$7 vs. \$0). Participants reported their tipping decision, how they felt about it, the extent to which they cared not to offend the waiter, whether they thought that tipping something was better than nothing, and indicated which of the two tipping alternatives (tip the available cash vs. not tip) they considered more offensive to the waiter and more embarrassing to themselves.

Not surprisingly, when having \$7 (an amount considered more appropriate for the tip), participants were significantly more likely to tip the nice (96%) and control (89%) waiter than the rude waiter (52%). Interestingly, when having only 25 cents in their wallet, participants were as likely to tip the nice (49%) and control (41%) waiters as they were to tip the rude waiter (40%). Furthermore, while participants in the \$7 conditions felt relatively good about their tipping decisions, for those in the \$0.25 conditions, only participants in the rude condition felt good about their decision but those in the nice and control conditions felt significantly worse. A follow up analysis revealed that those with only 25 cents in their pockets did not feel that tipping something was better than nothing. In fact, particularly those in the nice and control conditions were concerned that a 25 cents tip would be offensive to the waiter and indicated feeling embarrassed about leaving such a tip.

Together, these results contradict the general social norm that the better the service level the more tipping and is also in contradiction of the standard economic assumption that some money is better than none.

Experiment 2

In Experiment 2, we tested whether we could reverse participants' decision not to tip a good service provider by providing them information regarding that person's expectations. We asked participants (N=126) to imagine using complimentary transportation offered by their car dealership and that their driver was nice and courteous. Participants were then asked to choose one of three tipping options: \$1 Tip (very low), \$20 tip (very high), or No Tip. Using a four condition between-participants design we manipulated the driver's tipping expectations to be high (\$6-\$10), low (\$1-\$5), asked the participants to deliberate on the drivers tipping expectations (Own Reference) or did not provide any instructions/information with regards to the driver's tipping expectations (No Reference).

As predicted, our expectation manipulation had a significant effect on participants' decisions ($\chi^2(3)=12.21$, $p<.01$). Specifically, participants in the Low Reference condition were more likely (67.7%) to tip \$1 relative to the High Reference (27.3%), No Reference (39.4%), and Own Reference (34.5%) participants. Participants in the later three groups did not differ in their likelihood to tip \$1.

These results add another layer to our investigation by showing that when the social norms are changed, by making a low tip acceptable, participants were more likely to tip \$1. Experiment 3 was designed to test if we could replicate our findings if we restricted participants' tipping alternatives to tipping a low amount versus not tipping at all and to see if we could find more direct evidence for the underlying psychological process.

Experiment 3

Participants (N=305) were randomly assigned to one of three experimental conditions: High Reference, Low reference, and Con-

trol (i.e. No Reference). The first part of the scenario was identical to the one used in Experiment 2. Following the scenario participants were asked to choose between two options: Tip \$1 or Not Tip and then answered a battery of questions that tapped into the underlying process.

Similar to participants in Experiment 2, participants' tipping decisions were affected by the driver's expectation, $\chi^2(2)=8.99$, $p=.01$. Participants were more likely to tip the driver \$1 when the tip expectation was low (92.1%) than when it was high (77.5%), and when there was no tipping expectation information (82.4%). A critical component in our framework is the notion that the tipping decision might be mediated by beliefs about economic value, offensiveness to the service provider, or embarrassment to oneself when tipping \$1 versus nothing. Our analyses revealed that the reference condition only had a significant effect on beliefs about economic value and the offensiveness of tipping \$1 (versus nothing) to the service provider (all other measures were non-significant). Follow-up analyses revealed that regressing the decision to tip on both, the tipping reference condition and as potential mediators, the belief about economic value and the offensiveness to the service provider, respectively, each of the two potential mediator variables had a significant effect on the decision to tip and rendered the effect of the tipping reference condition insignificant. Finally, none of our measures, except for gender, moderated the effect of the tipping reference condition on the decision to tip \$1 or nothing.

Together our findings are important to our understanding of social preferences and the way they are affected by individuals' concerns for others'. Considered at a broader perspective, these results propose our concern for others' emotions may triumph basic norms and conventions.

Going, Going, Gone: Hidden Hormonal Influences on Loss Aversion

EXTENDED ABSTRACT

Loss aversion is the tendency to be more sensitive to losses than comparable gains. Research has converged on the robustness of loss aversion in human psychology (Kahneman and Tversky 1979; Tversky and Kahneman 1991), yet little research has investigated how biological factors influence intra-individual differences in loss aversion. The current research examined whether women's sensitivity to loss aversion is influenced by a universal biological factor – the monthly ovulatory cycle.

The ovulatory cycle spans, on average, 28 days, during which a woman can become pregnant only during the week long ovulatory phase of the cycle. Research has shown that ovulation can non-consciously alter women's psychology. For instance, ovulating women report less commitment to their current romantic partner (Durante and Li 2009; Gangestad, Thornhill, and Garver 2002) and are particularly attracted to men other than their partner who display markers of genetic fitness (e.g., physical attractiveness, masculinity, social dominance; Durante et al. 2012). Consequently, women are more likely to cheat on their partner near ovulation (Bellis and Baker 1990; Garver-Apgar et al. 2006). Because ovulating women become less committed to their current partner and are more likely to engage in behaviors that could threaten their relationship, we predicted that women might exhibit less loss aversion near ovulation. Thus, we investigated whether ovulating women's decreased commitment to their current partner translates to the marketplace.

Study 1 tested ovulating women's response to losing hypothetical amounts of money and consumer products. Ovulating and non-ovulating women were asked to indicate how unpleasant losing

money in increments of \$5, \$10, \$15, \$20, and \$25, as well a pair of running shoes and a laptop ($\alpha=.74$). Results revealed that ovulating women were significantly less loss averse than women who were not ovulating ($M_{\text{ovulating}} = 3.07$ vs. $M_{\text{not ovulating}} = 5.55$).

Study 2 examined how ovulation influenced selling price in an actual marketplace exchange. A high selling price indicates that a consumer places a higher value on the product and greater upset associated with losing that product (Aggarwal and Zhang 2006). In Study 2, women came into the lab once on a high fertility day (near ovulation) and again on a low fertility day. The sessions were counterbalanced and ovulation was confirmed via urinalysis. This methodology provides the most precise measure of ovulation and also allows us to examine behavioral change within the same woman across the cycle. At each session, women were given a coffee mug or a picture frame to keep. Women were told the mug (or frame) retailed for \$5.00. Later in the testing session women were told that another participant in the same study was interested in buying the mug (or frame), and the participants were asked to indicate at what price they would be willing to sell the mug to the other participant. Results showed that women had a significantly lower selling price when they were ovulating compared to when they were not ovulating ($M_{\text{ovulating}} = \$6.59$ vs. $M_{\text{not ovulating}} = \8.46). This suggests that women are less loss averse near ovulation.

Study 3 examined the mechanism responsible for the effect of ovulation on loss aversion. Because ovulation leads women to become less committed to their current partner to facilitate greater sexual receptivity to men with markers of genetic fitness (Garver-Apgar et al. 2006), Study 3 attempted to suppress the effect of ovulation on loss aversion by manipulating a mating goal. To do this, women imagined they were on a date with a boyfriend who was described as handsome, confident, affectionate, and loving. The manipulation was designed to endow women with a partner who met the criteria of a man high in genetic fitness and effectively increase women's desire to commit to one partner. After exposure to either the mate retention or a control condition, women were asked to indicate the price they would be willing to pay for a hypothetical gym membership and the price they would be willing to sell the membership. We predicted that the mate retention condition would suppress the effect of ovulation by reinstating loss aversion for ovulating women. As predicted, there was a larger discrepancy between the sell price and buy price for ovulating women in the mate retention prime condition ($M_{\text{sell-buy}} = \$40$) compared to ovulating women in the control condition ($M_{\text{sell-buy}} = \$6$). There was no difference in sell and buy prices across conditions for women who were not ovulating. Results suggest that women's decreased level of commitment to a romantic partner near ovulation is the psychological mechanism that underlies the effect of ovulation on loss aversion. Increasing women's desire to commit to one man in the mate retention condition effectively suppressed the effect of ovulation on loss aversion.

Will ovulation always lead women to become less loss averse? Previous research finds that ovulating women desire to look more attractive and choose clothing and accessories that are sexier (Durante et al. 2008; Durante et al. 2011; Haselton et al. 2007). Thus, ovulating women might display increased loss aversion if the product serves an attractiveness-enhancement function. To investigate this possibility, in Study 4, women were given a coffee mug and lipstick palette and asked to indicate their selling price. Results replicated Study 2, and showed that ovulating women had a significantly lower selling price for the coffee mug compared to women who were not ovulating ($M_{\text{ovulating}} = \$6.09$ vs. $M_{\text{not ovulating}} = \8.89). However, when women were asked to indicate at what price they would be willing to sell the lipstick palette, ovulating women had a significantly higher

selling price compared to women who were not ovulating ($M_{\text{ovulating}} = \$11.54$ vs. $M_{\text{not ovulating}} = \9.10). This suggests that women are less loss averse near ovulation only for products that do not serve an attractiveness-enhancement function.

This research adds to the literature on loss aversion and provides further evidence of how biological factors such as hormones can influence robust psychological phenomena commonly studied in marketing and decision research.

SESSION OVERVIEW

The theme of ACR 2013 is “Making a Difference.” One of the most functional approaches to making a difference in the self is to incorporate feedback from the environment in a healthy, instructive manner and modify the self accordingly. Nevertheless, all too often dismissiveness and defensiveness get in the way of such personal growth.

One process that repeatedly and robustly has been shown to open people up to unflattering feedback and turn their attention toward others’ wants and needs is self-affirmation. The papers in this session delve into the promise for self-affirmation to bring about positive self-change.

Self-affirmation refers to processes that bolster a global sense of self-integrity (Steele 1988). Self-affirmation manipulations remind people of important aspects of the self, enabling them to view events from a reasonable, considered, rational view (Sherman and Hartson 2011). By enhancing the psychological resources of self-integrity, self-affirmation reduces defensive responses to threatening information and events, leading to positive outcomes in various areas such as psychological and physical health, education, prejudice and discrimination, and social conflicts (Sherman and Cohen 2006).

Although studied extensively by social psychologists, self-affirmation has only just begun to receive attention from consumer researchers. This session provides an overview of self-affirmation theory, and discusses why self-affirmation is beneficial to consumers’ personal and interpersonal well-being. The first two papers provide new evidence and insights on underlying processes that help explain how self-affirmation benefits the self under threat. The next two papers propose that self-affirmation enables people to transcend concerns about the self in order to care about others.

First, Sherman, Hartson, and Binning report results from a longitudinal field experiment involving minority students and the experience of academic threat. The authors find that self-affirmation alters the students’ narrative explanations about events and in doing so changes their perspective about threats. Self-affirmed (vs. not affirmed) students viewed threatening events within a larger view of the self and construed events at a more abstract level, with the result being that they were less undermined by identity threat. This new model has the potential to change the way that scholars think about self-affirmation in offering new mechanisms for how it works – while elucidating one of the most powerful and straightforward ways that consumers can ‘make a difference’ in themselves.

Second, Klein, Harris, and Ferrer examine how self-affirmation influences and is moderated by negative affect. They show that self-affirmation when combined with the experience of health related threats increases the negative emotions of *worry and anxiety* (about getting breast cancer after reading an article linking alcohol consumption with breast cancer risk). These specific negative emotions consequently promote behavioral changes. Further, the authors find that affect moderates the effects of self-affirmation. Negative affect such as *anger and sadness* impairs the effectiveness of self-affirmation, whereas general positive affect enhances the effects of self-affirmation. In tying self-affirmation to specific and theoretically-derived forms of affect, this paper opens up new avenues for understanding how health-related messages should be constructed.

Third, in continuing with the theme of negative emotions and affirmation, Kim and McGill propose that self-affirmation enhances caring about others’ negative feelings. They find that self-affirmation increases people’s willingness to spread negative word of mouth (WOM) on behalf of others who are angry about product failures. Yet, affirmation decreases willingness to spread negative WOM about one’s own negative experiences. These outcomes occur because a broader view resulting from self-affirmation reinforces social connections, enhancing the importance of others’ negative feelings. However, such a broad self-view uncouples the self from threat, mitigating the importance of one’s own negative feelings.

Finally, Park and Vohs show that self-affirmation offsets the harmful effect of money priming on the interpersonal self. Money priming, which enhances the self-sufficiency orientation, has been found to reduce helpfulness toward others and requests for help, and to enhance tendencies to separate the self from others. The authors show that self-affirmation reduces such adverse money priming effects, and helps people become more sensitive to interpersonal needs. This work points to the power of self-affirmation while raising fresh and invigorating questions about the psychology of money as well.

These four presentations propose different effects of self-affirmation under various contexts such as identity threats, health threats, product failures, and money priming, which can significantly affect consumers’ well-being. By focusing on the effect of self-affirmation on the personal self (Sherman, Hartson and Binning; Klein and Harris) and the interpersonal self (Kim and McGill; Park and Vohs), the presentations proposed here paint a picture of how affirming the self impacts consumers. This presentation will be of interest to researchers studying goal-attainment, self-regulation, information processing, word of mouth, and prosocial behavior — and anyone interested in one of the most effective ways that consumers can “Make a Difference.”

Broadening Perspective, Changing Narratives, and Improving Academic Performance: The Effects of Values Affirmation Interventions

EXTENDED ABSTRACT

Research on self-affirmation theory has repeatedly shown that brief interventions designed to affirm the self-concept can produce lasting benefits on a variety of behavioral outcomes, including academic performance. However, the question of what causes these effects is the topic of continued research attention. The purpose of the present talk is to summarize self-affirmation theory, to present a general model to explain the effects of values affirmations (Sherman & Hartson, 2011), and to introduce new evidence from two values affirmation intervention studies that supports this model.

Self-affirmation theory evolved from an alternative explanation for cognitive dissonance phenomena (Steele, 1988; see also Aronson, Cohen, & Nail, 2009; Stone & Cooper, 2001) to an intervention strategy employed in a wide range of settings (see Harris & Epton, 2009; Garcia & Cohen, 2012 for reviews). Its core idea is that people have a general motivation to maintain self-integrity – that is, the perception of one’s self as efficacious, consistent, and good (Sherman & Cohen, 2006; Steele, 1988). In the face of threats to one’s self-integrity, people behave in ways that serve to protect the self-concept. For example, when faced with the threat of confirming negative stereotypes about one’s group (i.e., stereotype threat), people may defensively disengage from the domain rather than risk confirming the stereotype. However, when global perceptions of self-integrity are affirmed, for example, via a writing task that reminds people of an important personal value, otherwise threatening information may lose its capacity to threaten the self. After completing values affirmations, individuals feel, both to themselves and to others, as though the task of maintaining self-integrity is settled. Consequently, they can focus on other demands in the situation beyond ego protection—for example—the academic tasks at hand in a school environment.

Sherman and Hartson (2011) proposed a model that seeks to explain the cognitive processes by which affirmation exercises may exert their influence. Specifically, affirming important values is proposed to augment the psychological resources available to an individual to confront a threat. That is, self-affirmation allows people to experience threatening events and information within a broader, larger view of the self. Self-threats, when viewed in the context of this enhanced perception of self-resources, can be seen from a broader perspective. This broader perspective changes people’s narrative of their ongoing experience, such that the threat does not affect, to the same extent, their overall evaluations of themselves. In the context of a focal threat, the general attenuation of concern about self-evaluation can lead to attenuated stress responses, and improved performance. And to the extent that these effects shape enduring narratives of experience and initiate (or interrupt) recursive processes, they can lead to long-term psychological changes.

Evidence supporting this model comes from recent investigations in other laboratories (e.g., Schmeichel & Vohs, 2009; Wakslak & Trope, 2009; Logel & Cohen, 2011) and two recent studies we have conducted, each featuring a longitudinal field experiment in a mixed-ethnicity middle school. These studies examined the achievement gap between Latino American and European American students and whether a values affirmation writing exercise could attenuate this gap, and the processes by which this attenuation occurs.

In Study 1, students completed multiple self-affirmation (or control) activities as part of their regular class assignments (in procedures modified from Cohen et al., 2006; 2009). The manipulation did not affect the grades of White students, but Latino American stu-

dents, the identity threatened group, had higher grades in the affirmation than control condition as assessed by core course GPA over the academic year. Examination of quarter by quarter performance indicates that the affirmation elevated Latino American students’ trajectory. The results persisted for three years, the period of examination, and persisted despite approximately 2/3 of the sample moving on to high school. The long-term effects of Study 1 suggest that students’ narratives of their ongoing experiences changed, and that they took this new “story” with them into the new environment (cf. Wilson, 2011).

To provide more direct evidence as to how affirmation shaped students’ narratives of their ongoing academic experience, Study 2 featured daily diaries where participants reported their daily adversity, perceptions of identity threat, and feelings of academic fit. In addition, Study 2 included multiple assessments of construal level (the Behavioral Identification Form; Vallacher & Wegner, 1989) to examine participants’ perspective. We predicted that affirmation would broaden construals and prevent daily adversity from being experienced as identity threat. We also predicted that affirmation would insulate academic motivation from identity threat.

Study 2 replicated the effects of values affirmation on academic performance, as affirmed Latino American students earned higher grades in their core courses than non-affirmed Latino American students. Evidence supporting the general model of affirmation effects (Sherman & Hartson, 2011) was also obtained, as the affirmed Latino American students also construed events at a more abstract (broader) rather than concrete level and were less likely to have their daily feelings of academic fit and motivation undermined by identity threat. More specifically, affirmed Latino American participants saw events and situations at a broader level of construal than Latino American students in the control condition. The measures of construal focused on general topics, and not just academics, and were separated from the affirmation manipulation by weeks to months, and thus, the effects seemed quite general. Being under identity threat may lead individuals to experience a narrowing of perspective. Providing value affirming experiences and thereby reminding them of their important self-resources may broaden this perspective.

The diary findings also suggest that when affirmed, and with self-worth perhaps more secure, identity-threatened students did not experience daily adversity as indicative of identity threat. Further, to the extent that they perceived threat in their environment, these negative experiences did not spread into and affect academic motivation. Rather, the Latino American students sustained motivation independently of the perceived threat in the environment. Together, these findings suggest that affirmation can change psychological experience and instigate lasting changes in how people create narrative experiences over time.

In sum, these two experiments provide evidence to support the general model of affirmation effects—that values affirmations exert their effects, in part, by bolstering resources, broadening perspective, and changing the narrative of ongoing experience under threat.

The Multifaceted Role of Affect in Self-Affirmation Effects

EXTENDED ABSTRACT

Self-affirmation theory holds that threats to the self can be reduced by focusing on cherished values unrelated to the content of the threat (Steele, 1988). Because threat often leads to defensiveness (Lieberman & Chaikin, 1992), self-affirmation can be a useful technique to promote even-handed, non-defensive responding. Indeed, several studies show that people are more accepting of a threatening

health message – and more likely to change behavior in accordance with the message – if given the opportunity to focus on personal values prior to reading it (for review, see Harris & Epton, 2009). Self-affirmation can also alleviate the negative effects of threat on task performance and academic achievement, ostensibly because it uncouples performance success from the self-concept (Sherman & Hartson, 2011).

Although the body of evidence illustrating beneficial effects of self-affirmation continues to grow, little is known about how self-affirmation opportunities influence affective processes or how the effects of self-affirmation might vary with affective state. Early research found that there was little or no effect of self-affirmation on general mood, reducing the likelihood that self-affirmation effects were a proxy for the effects of positive affect or that positive affect mediated those effects. Instead, we propose that the relationship between self-affirmation and affect is much more nuanced. In particular, we contend that (1) self-affirmation influences more specific affective experiences such as worry and feelings of vulnerability (in contrast to more general affect), (2) rather than being a direct consequence of self-affirmation, general incidental emotions – that is, discrete emotions (e.g., sadness, anger) minimally related to the self-affirmation experience – will moderate effects of self-affirmation, and (3) self-affirmation can alleviate the impairment of performance elicited by negative affective states such as stress.

We first consider the effects of self-affirmation on specific affective experiences rather than general affect. In one study, female undergraduates who consumed moderate to large amounts of alcohol read an article linking alcohol consumption with breast cancer risk. Prior to reading the article, participants were randomly assigned to a self-affirmation condition (in which they wrote an essay about a value important to them) or a standard no-affirmation control condition (in which they wrote about how a value unimportant to them might be important to someone else). We found that participants in the self-affirmation condition expressed more worry and anxiety about getting breast cancer – specific affective experiences that promote behavior change (Klein, Harris, Ferrer, & Zajac, 2011). Moreover, self-affirmation was found to strengthen the relationship between affective responses and intentions. Two additional studies demonstrated that these effects on message-specific affect mediated subsequent effects on

Finally, as a complement to our overarching investigation of how affect moderates the beneficial effects of self-affirmation, we explored how self-affirmation might offset the influence of negative affect – in this case, chronic stress. Much work suggests that chronic stress can impair performance on difficult tasks (Liston, McEwen, & Casey, 2009). We hypothesized that self-affirmation can ameliorate such effects. Undergraduate students varying in chronic stress were given 30 difficult Remote Associate Test (RAT) items and asked to complete them in front of an evaluator. This experience was stressful as demonstrated by increased heart rate and blood pressure. Importantly, self-affirmed individuals performed better on the RAT task than controls, particularly among participants who were chronically stressed.

As a group, these seven studies demonstrate a multifaceted relationship between affect and self-affirmation, building on previous research showing no direct effects of self-affirmation on general measures of affect. Self-affirmation appears to have effects on more precise threat-relevant affective experiences such as worry, and there are important interactive effects between self-affirmation and affect on message processing, behavioral intentions, and task performance.

Less about Me, More about You: How Self-Affirmation Changes Word-of-Mouth Intentions for the Self versus Others

EXTENDED ABSTRACT

Previous literature on WOM has focused on consumers' communications about their own experiences (Berger and Schwartz 2011; Dichter 1966; Dye 2000), however, consumers may also talk about others' consumption experiences, sometimes when jointly experiencing a product or service (e.g., dining companions) or when another consumer reports an experience and the target consumer must consider whether to pass that story on. The present research shows that self-affirmation decreases the tendency for consumers to complain about their own, but to increase the tendency to talk about others' negative experiences, the "Consumer Champion Effect." We trace this effect to the broader perspective adopted by affirmed individuals, which mutes the extremity of their own emotional responses to events while it concurrently produces a more accurate understanding and deeper appreciation of the intensity of others' emotions. These responses thereby lead to an ironic effect of self-affirmation in which very calm consumers, who are not upset about their own negative experiences, may nevertheless be vocal critics of a firm on behalf of others.

Prior research has shown that the "self-affirmation task," that is, reflecting on core values, reminds people of their broader identity (Sherman and Cohen 2006). Within this broader perspective, people feel more secure in their self-integrity and less pressure to defend a particular aspect of the self. As a consequence, affirmed consumers are more likely to process potentially threatening messages, for example, reports that favored products might have negative health consequences, in an open-minded way (Sherman, Nelson, & Steele, 2000). We build on this prior research to explore additional consequences of a broadened self-view. First, in a direct extension of prior work, we posit that a broader view of self may mute the intensity of people's own feelings about a product or services failure because each event is "just one thing" in a broader view of the self. That is, the affirmed individual is not whipsawed about by each individual passing event because the broader view incorporates other, more stabilizing influences (thoughts and feelings about the rest of one's life). This theorizing leads to the hypothesis that affirmed consumers will be less angry after experiencing product or service failures, and, in turn, when they have a chance to spread negative WOM, they will be less likely to do so.

However, we also propose a novel influence of a broader perspective resulting from self-affirmation, specifically, that a broader view incorporates the feelings of others to a greater extent, leading affirmed individuals to be more attentive toward others' affective reactions. Supporting our argument Crocker et al. (2008) showed that self-affirmation increased other-directed positive feelings such as love. However, moving beyond Crocker et al. (2008) who focused on positive emotions expressed toward others, we show that affirmed consumers more deeply appreciate the intensity of others' positive as well as negative emotions. Further, we suggest affirmed consumers estimate more extreme (and accurate) emotional profiles in others' affective reactions. After self-affirmation, others' positive emotions seem to be more positive, while negative emotions seem to be more negative. As a consequence, affirmed consumers will be more willing to complain on behalf of those others, an effect we term, the "Consumer Champion Effect."

The first experiment, consisting of two studies, examines the influence of self-affirmation on estimation of others' emotions. In experiment 1a, self-affirmation was manipulated using an essay writ-

ing task, commonly employed in this literature (Sherman and Cohen 2006). Participants in the high self-affirmation condition wrote an essay about their most important value while those in the low self-affirmation condition wrote an essay about the least important value. Then, participants listened to moderately annoying sounds (e.g., electric drill, squeaking door) then indicated either what they felt about the sounds or what they thought another person felt about the sounds. The results show that self-affirmation reduced the intensity of one's felt emotions while it amplified the estimated intensity of others' emotions. We also provide evidence that affirmed consumers more accurately estimate others' emotions while projecting less of their own emotional states.

Experiment 1b further examines consumers' assessments of others' emotions through their interpretation of posted user reviews. In addition, in this experiment, instead of manipulating self-affirmation through an essay writing task, we measured individual differences in self-affirmation tendency, specifically, their self-concept clarity. We observed that participants with high self-concept clarity estimated more intense emotions from both positive and negative reviews, seeing positive reviews as more positive and negative reviews as more negative.

In experiment 2, which was a scenario study, participants were asked to imagine various situations involving product or service failure, for example, poor restaurant service during a celebratory dinner, and then to estimate either their own or the other person's emotional reactions. Self-affirmation was manipulated as in study 1a using an essay writing task. We found self-affirmation led to lower willingness to generate negative WOM for the self but greater willingness to generate negative WOM on behalf of the other person.

Experiment 3 was intended to probe the process underlying the effect further by exploring the effects of a theoretically motivated moderator, specifically, anonymity of the communication. If self-affirmation produces the Consumer Champion Effect by reducing narrow and defensive processing, it should be less prevalent when such processing is already limited, such as when one's comments are anonymous. Consistent with this view, when participants had to identify themselves, we again found that self-affirmation lessened participants' tendency to report their own concerns but more likely to champion the concerns of others. When anonymity was guaranteed, self-affirmation was less effective.

Self-Affirmation has the Power to Offset the Harmful Effects of Money Reminders

EXTENDED ABSTRACT

Self-affirmation, which encourages people to ponder why their core values are important to them, promotes a broad-minded, big picture perspective of the self, and enhances psychological resources of self-integrity (Sherman and Cohen 2006). Prior research has provided ample evidence that self-affirmation positively affects interpersonal aspects of the self by making people be more open to those holding opposite opinions who accordingly are judged favorably (Cohen, Aronson and Steele 2000; Sherman and Cohen 2002), reducing within-relationship threats (Lockwood et al. 2004), and enhancing a key other-directed feeling—love (Crocker, Niiya, and Mischkowski 2008)

In this paper, we asked the question: Given its impressive ability to promote prosocial responses, could self-affirmation reduce the negative effects of money on the interpersonal self? Money, a social resource, makes people feel self-sufficient and behave accordingly (Vohs, Mead and Goode 2006, 2008). When reminded of money, people pursue personal goals and prefer to be separate from others.

Thus, people prefer that others do not depend on them, and want to be free from dependency (e.g., reduced helpfulness toward others and reduced requests for help) (Vohs et al. 2006, 2008). Further, money leads people to prefer to be separate from others, and to be less distressed about social exclusion (Zhou, Vohs and Baumeister 2009). In sum, prior research has consistently found that money negatively affects the interpersonal self. We proposed that affirming important values will help people be less affected by money. Within the broader and abstract perspective of the self, money should lose its symbolic power.

In the first experiment, we tested whether self-affirmation reduces tendencies to be free of dependents and dependency that money brings about. First, participants received the self-affirmation (vs. control) manipulation. In the self-affirmation condition, participants wrote an essay on a paper explaining why their core value is important to them, whereas those in the control condition explained why a less important value would be important to the average person. In the middle of writing about values, one of two screensavers appeared. Participants in the money (vs. control) condition saw a screensaver depicting various denominations of currency floating underwater (vs. white dots on a black background).

Next, to measure the tendency to be free of dependents, we used willingness to help others in need. Participants were asked to read about a non-profit organization—Operation Smile, which is an international children's medical charity that provides reconstructive surgery for children born with facial deformities, such as cleft lip and cleft palate. Then, they were told that in this experiment, five participants would be randomly selected to win a bonus payment of \$50. If they were chosen as a winner, they could donate all or part of the \$50 to Operation Smile. They were asked to write down the amount of money they would donate to Operation Smile.

Finally, as an indicator of dependency, we used a request for help during a difficult task. Participants were asked to outline all segments of a geometric figure without lifting their pencil or retracing any segments. Unbeknownst to the participants, the figure was unsolvable. Participants were told that it was not a matter of how many tries it took or how long it took them to solve the puzzle. They were instructed work on it until they either solved it or decided to get help from the administrator. After 10 minutes, they were asked to stop.

Consistent with prior research, money priming led to self-sufficiency orientations, reducing helpfulness toward others in need and dependency on others while attempting a difficult task (Vohs et al. 2006, 2008). In the no self-affirmation condition, participants primed with money (vs. not primed) donated less money and were less likely to request help. However, self-affirmation reduced such an adverse money prime effect. Participants who self-affirmed and received the money prime donated more money, and were more likely to ask for help while solving a difficult task, as opposed to those who did not self-affirm prior to the money prime.

In the second experiment, we tested if self-affirmation reduces different effects of money priming—tendencies to reduce social contact and to feel less distressed under social exclusion. First, participants received the self-affirmation manipulation and the money priming, as in study 1. Then, participants were asked to choose between two activities. Within each item, one option was an activity for one person (e.g., planning your own vacation) and the other option was for two people or more (e.g., planning a family vacation).

Next, we manipulated social exclusion by asking all participants to play a computerized ball-tossing game (Cyberball; Eisenberger et al. 2003). Participants were led to believe they played with 3 live participants, but in fact, the computer simulated the other play-

ers. Initially, the ball was tossed equally among the 4 players. In the normal-play condition, this equal play continued throughout the game. In the social-exclusion condition, the simulated confederates stopped throwing the ball to the live participants after 10 throws. Afterward, participants rated the social distress they felt about the game using the Southampton Social Self-Esteem Scale (Sedikides 2008). Sample items on this scale included, "I feel devalued," and, "I feel rejected."

Consistent with prior research, money priming led to social separateness (Vohs et al. 2006, 2008). In the no self-affirmation condition, participants primed with money (vs. not primed with money) chose more individually focused leisure experiences and were less likely to feel distressed after social exclusion. However, self-affirmation reduced the adverse money prime effect. Participants who self-affirmed and received the money prime were less likely to choose individually focused leisure experiences, and were more likely to feel distressed after social exclusion, as opposed to those who did not self-affirm prior to the money prime.

Conclusion: Self-affirmation and money are both simple but powerful motivators of behavior change. Past work has documented the deleterious effects that even small and subtle reminders of money can have on interpersonal outcomes. The current work found that self-affirmation can not only nullify such troubling negative outcomes but in some cases actually reverse them. By understanding how self-affirmation alters the typical effects of money priming, the field is in a better position to understand more about the psychology of money as well as how self-affirmation works – seemingly to instigate the interpersonal self over the personal self.

SESSION OVERVIEW

In an increasingly globalized world, where images are disseminated around the world in mini-seconds and economic changes challenge the fundamental principles of what we want and expect from society the role of women within this remains a contentious issue. Indeed events from ranging from the role of women in the Arab spring revolutions to a series of news reports from India on female rape cases serves to remind us that the cultural and societal embodiment of what constitutes being a woman remains a site to be contested. Contested by the women who feel they have ownership over their bodies and how they are perceived, versus how others, typically men, perceived the role of women and their bodies. In the middle of this field lies the market, adapting, creating and nurturing change in an effort to open new market segments, opportunities and profit possibilities. How then do women use consumption in these changing environments – as an opportunity to thrive, resist or conform?

Perhaps central to this cultural understanding is religion, where women feature prominently in various roles. From the Hindu scriptures where women, presented as gods, are revered and worshiped as a form of perfection, to Christian and Islamic teachings on women's modesty, religion determines how men, society, and women themselves are perceived. Yet religion's role, both from a cultural and societal, perspective has become the embodiment of why women's bodies are a site to be contested. In India, the sexualization of the female body has recently increased not only in Bollywood films but wider Indian society, especially amongst the middle classes. Economic growth has led to get feelings of female empowerment and consumption opportunities to dress in a more Western style. Yet this consumption act challenges and embodies wider societal changes, as traditional male roles are usurped by newly empowered women. The consequences of this form the basis for our first paper.

Whilst India represents implied state control, critics of France's recent laws on religious symbolism argue that the state now has implicit legal powers to arrest any women wearing a hijab, burka or any other symbolic piece of religious clothing. As women are often the bearers of a religion's tangible values, such laws inherent discrimination is targeted then at women. Yet it is not just France that views women's bodies and their representation as a site for state control. How women respond to this is discussed in our second paper.

The market itself continues to play an important role in cultural and symbolic meaning embodied within women's bodies. Our third paper, explores how enterprising organizations now see the female consumer, their body and religion as a marketing opportunity. Consequently, the market actively works with religion to find new ways of redefining women's bodies, whilst challenging and renegotiating wider cultural and societal norms. Yet, the market itself may not lead to such renegotiation. Indeed, in our last paper, market produced goods are shown as tools to be wielded within the acculturation process. Consumption then is used to redefine migrant women's identities and bodily meanings, asserting greater independence and equality, often against the husband's wishes.

The four papers in this special session offer insights then into the contradictory themes of state and individual, male and female, consumption and ownership roles in women's lives and their bodies. From these themes two questions emerge:

1. To what extent does consumption represent a contested site for the state and gender differences towards women and their bodies be acted out, and
2. Are women merely victims of consumption that aims to directly or indirectly reinforce their oppressed position?

Constructing Identity through Cultural and Ancient Interpretations of the Female Body

EXTENDED ABSTRACT

In societies undergoing modernity, how do women use consumption to negotiate the contrasting cultural values of tradition and modernity when their own bodies are held to be sacred (Agnew, 1997; Mukherjee, 1983; Wadley, 1977)? This paper explores the nuances surrounding consuming the female body in India through the material/spiritual dichotomy that manifests in the discourses of nationalistic modernity (Chatterjee, 1989). Women are defined and located through social and moral parameters which serve as prominent markers of control and surveillance over their consumption choices for 'clothing' their body. Through changes in family and household structures (Sardamoni, 1992), an increasing female workforce (Venkatesh and Swamy, 1994) and changes in media representations of women (Mankekar, 1999), women are encouraged to reconstruct their identity.

Indian womanhood has been characterized as an ambivalent state, wherein women are both revered and subjugated, worshiped and molested, free to express themselves in different domains and yet voiceless. The Indian woman's body then becomes the embodiment of Hindu religious texts, such as the Vedic and Dharmic literature, with the female body as a contrasting site of power and destruction, needing to be controlled.

Yet within India contrasting female imagery in media and society consolidates a form of sexual, cultural and religious worship, women in the social sphere are still deemed the atavistic and authentic 'body' of national traditions (McClintock, 1992). In this position women simultaneously function as the living archive of the national archaic (Reuben, 1994), becoming a standard to construct around a modernizing nation. Indian women then embody the spiritual qualities that characterize a nationalistic form of modernity (Mukhopadhyay, 1969), whilst embodying the social and familial embodiment. Effectively Indian women are juxtaposed between contrasting and

opposing forces; revered and subjugated, worshiped and molested, free to express themselves in different domains, and yet voiceless (Altekar, 1987; Olivelle, 2004). Within this ambivalence, modernity has created a consumer culture empowering women to challenge, subvert or re-negotiate societal patriarchy in material world once reserved for men. Women are portrayed not as passive but as active, assertive and visible agents vivaciously participating 'body projects'. The tension created here becomes one between the self as individual and as a collective object. It is within this fissure that women negotiate their sense of self through their consumption activities.

Shilling (2006) noted that the rise of the body within consumer culture was a bearer of symbolic value where the "body provides a firm foundation on which to reconstruct a reliable sense of self in the modern world" (p.2). The young Indian women in my study had modified their consumption choices in light of what was socially acceptable and they were also seen to "skillfully resolve the tension between being faithful and comfortable and creating, modifying, and vigorously legitimizing their clothing choices" (Ger and Sandıkcı, 2010, p. 26). Consumption at the level of the body, then, becomes a metaphor for an unraveling Indian modernity, one which is fraught with the contradictions of Indian womanhood. If, as Puri (2002) notes, women's bodies are used to articulate discourses of modernity and development, then these are also the sites where fear of loss of national tradition are expressed. Consumption, in this vein, illustrates how performing identities at the level of the body creates tensions between an autonomous and collective sense of self.

A three month multi-method interpretive research study involving 23 young urban and rural women was undertaken in New Delhi. A mixture of focus groups and one-to-one interviews were conducted, with each interview lasting up to ninety minutes. Respondents were also asked to create posters and take photographs of their consumer experiences.

The findings showed how participants considered the role of the body as central to negotiating both consumption activities and notions of modernity. Conclusions were drawn about the centrality of consumption for the young women in being able to forge alternative identities which have not been socially scripted. However, the attempts made at constructing this alternative (through rebellion, seeking loopholes and testing boundaries) was constrained through forms of control and surveillance from the familial and social spheres respectively, presenting an ongoing tug-of-war between traditional, social narratives of the conduct of women, and an individually ascribed notion.

The 'self' emerged as an ontological dilemma where the preoccupation with the 'self' was looked down upon by rural respondents who felt that the loss of collectivity would result in a loss of tradition. The self in terms of grooming and maintaining trends was a project of necessity for the urban respondents; the rural girls on the other hand critiqued this expression of self-indulgence as unnecessary, especially before marriage. Control and surveillance were of particular importance as they operated as mechanisms to curb and control not only women as their physical selves, but formed to protect the 'morality' of the nation. The most palpable effects of the markers of distinction were held between the urban and rural girls, in that the appropriation of Western clothing, Western music, hybrid linguistic forms, emphasis upon professional achievement and personal grooming deemed the urban girls as directly involved with the project of modernity. For rural consumers, the global flows served to hinder and problematize the status quo and they believed that the erosion of village sentiment was in part attributed to the attainment of new global symbols of prosperity which encompassed characteristics deemed as "modern". Ultimately, as material and discursive sites where tradition is performed (Oza, 2001), the body poses

a number of complex and often contradictory negotiations for the young women in light of their constructions of identity.

This paper develops an understanding of the body through its cultural frame, however, as noted by Shilling (2006), contemporary analyses of the body as socially constructed phenomena, refer to the body as a theoretical space, but the body often remains relatively neglected as an actual object of analysis. This paper aims to address this shortcoming. Tracing through history, it can be concluded that the body project itself is tempered through both nationalistic and ancient ideals of womanhood in India. Consumption choices amongst the young women express a system of values which reflect an ethos of modernity where the clothing of the body demonstrates prevailing socio-cultural processes which condition respondents' daily lives.

The Halal Nail Polish: Religion and Body Politics in the Marketplace

EXTENDED ABSTRACT

In January 2013 the Polish cosmetic company Inglot introduced the first ever halal nail polish, the O2M line of breathable nail enamel. Wearing nail polish is a contentious issue for pious Muslim women, both symbolically and materially. While some religious scholars emphasize that looking beautiful is a requirement in Islam, others call for a refrain from any action that would attract the male gaze. Moreover, wearing nail polish interferes with ablution, a ritualized body cleansing process that every Muslim should undertake before prayer. Because nail polish sets a permanent barrier between water and nail, ablution cannot be performed without first removing the nail polish. Inglot claims to have devised a formula of breathable nail polish, which allows water to penetrate nail, hence is suitable for prayer. In this paper, I use halal nail polish as a case to interrogate the complex ways through which social, cultural, material and religious interpretations of body intersect with marketplace dynamics and in-form identities.

The perception and evaluation of one's own body and physical appearance contribute significantly to self-concept (Thompson and Hirschman 1995). Within the logic of consumer culture, body turns into a site of endless choice and possibility. However, the relationship between body and choice becomes complicated in the context Muslim identities. As substantial amount of research has shown the concept of modesty plays an important role in shaping Muslim identities and practices related to body. While modesty requirement applies both men and women, it is the female body that modesty becomes embodied, most prominently in the form of Islamic veiling (Ahmed 1992; El Guindi, 1999; Mahmood, 2005; Sandıkcı and Ger, 2010). Increasingly, the discussions of a modest body take place in the marketplace. The veiling industry and related Muslim lifestyle media promote products and images that promise women fashionable yet modest looks (Sandıkcı and Ger 2007). Underlying these is an understanding that modest dressing, like other body management practices, is a choice for individual women. This emphasis on choice resonates with the construction of the neoliberal consumer subject and aligns religious norms with market logic. The introduction of halal nail polish exemplifies this mutually informing relationship between Islam and neoliberal consumerism. However, what is interesting in this case is the product's capacity to invoke internal debates about female body and concepts of modesty.

I explore these debates through netnographic and ethnographic methods. Blog entries, news stories and forum discussions on social media sites as well as interviews with women selling and using the product constitute the data set. As the nail polish has been recently introduced, data collection still continues. Preliminary analysis sug-

gests three main themes. First, there is a debate about the ‘necessity’ of a halal nail polish that revokes on the one side the notion of market opportunism and on the other side the notion of consumer freedom. Second, there is a tension between religious and material conceptions of body. While references to scriptural texts and norms seek to define boundaries of Muslim female body and situate nail polish within this normative framework, testaments based on the physical experience of the product attempt to expand the very boundaries of religiously appropriate and inappropriate forms of bodily consumption. Third, the debate about the nail polish brings forefront the question of who has authority to speak on behalf of women and what defines being a pious and modern Muslim woman today.

Overall, reactions toward the halal nail polish underlie the question of what Muslim looks like, or what looks Muslim. Body features predominantly in these interrogations, but not only at the symbolic level. The nail polish draws attention to the material understandings of body and highlights how products shape women’s relationships to their bodies by enabling or preventing performance of certain practices and contribute to their sense of being a “good” Muslim. While introduction of halal nail polish appears to be yet another example of the growth of modest fashion and lifestyle sector (Lewis, 2010), it also shows the increasingly instrumental role market actors play in the construction and maintenance of pious consumer identities.

Religiosity and acculturation through apparel consumption amongst North African migrant women in France

EXTENDED ABSTRACT

Migration challenges the cultural, religious and social values associated with consumption for both the migrant and the recipient society. Previous studies have tended to focus on multi-cultural societies that take a melting pot perspective that recognizes and accepts difference, such as the USA and UK (Peñaloza, 1994; Gbadamosi, 2012). However what happens when migrants are faced with a society that openly rejects cultural and religious differences? And how is this rejection acted through consumption? This paper mobilize post-colonial theory which shows a perspective of the subordinated and marginalized (Brace-Govan and Burgh Woodman, 2008) to explore these themes through the role of Islam amongst North African female migrants living in France. A strongly secular country that legally prohibits public displays of religious symbolism (Tahran, 2011) and views ethnic marketing as an irrelevance (Héran, 2007). How female migrants and their daughters, who represent the most visible cultural difference, resolve potential conflict between personal religious and societal beliefs forms the focus of this paper. In doing so we address calls for further research into inter-generational influences (IGI) amongst immigrant family settings (O’guinn et al, 1986) and religiosity within consumer research (Cleveland and Chang, 2009; Sandicki, 2006). We also explore how stigmatized consumers differentiate themselves through customizing their traditional ethnic dress in an established market (Sandicki and Ger, 2010).

Acculturation, describing the level of individual and community attachment to the values of the original culture or host culture, has been extensively applied to consumer research (Peñaloza, 1994; Askegaard et al, 2005). Whilst some studies drawing upon Berry’s (1997) categories, such as Üstüner and Holt’s (2007) reflect upon acculturation as a range of outcomes, others have viewed migrants as constantly changing their identities and related consumption depending upon the context (Lindridge et al, 2006). However, these studies assumed that migrants actively want to assimilate, whilst retaining their own ethnic identity. In countries where the nation culture is

deemed to be superior, cultural and religious differences are seen as subservient. Such as Islamic women wearing the Hijab (head scarf) in public, in France, is an illegal act. Yet, research into the role of religion in consumption in secular countries reflects wider tensions. For example Sandicki (2006) found that religion influenced poor female migrants’ acculturation into life in Turkey’s cities conflicted with secular demands to change their bodily representation through clothing. The city’s cultural codes of wearing body hugging clothes were viewed as an act of resistance to God. In a similar vein, Gbadamosi (2012) found that Black African migrant women in London viewed religious beliefs as sufficient to resist societal pressure to acculturate to wearing body revealing clothes. These findings suggest that the women’s body, her ownership over it, and how it is represented becomes a site for acculturation conflict (Sandicki, 2006)

Our paper explores these themes by researching North African Muslim migrant women living in Paris, France, where 70% of migrants originate from North and West Africa constituting 8% of the 5 million ethnic minority population (Héran, 2010). France was chosen following its legal ban on all religious symbolism in Government spaces, such as wearing the Hijab. Forty-one participants’ interviews were undertaken from women born in Algeria, Tunisia, and Morocco living in Paris. Participants were categorized as either highly religious (HR) faithful to Islamic values in their life and were recruited from mosques. Casually religious women (CR) who practice Islam occasionally were recruited through a snowballing technique. Interviews lasted between 30 minutes to two hours supported by researcher observation of participants in their daily lives.

Our analysis revealed conflicting behaviors regarding the role of religion within acculturation. CR migrant women favored French stores that sold western style clothing, demonstrating little reverence for clothing that met with Islamic principles, due to their weak Islamic beliefs and their strong identification with France. HR migrant women, in contrast, resisted French secular clothing styles by rejecting clothing patterns that were considered against Islamic teachings. For example, French clothing brands were rejected as too fashionable, body revealing and symbolic of legal system that outlawed religious clothing. In term of (IGI) whilst HR / CR mothers had HR/CR daughters respectfully, in some instances this was not always true. When HR mothers had CR daughters acculturation tensions arose when CR daughters left the traditional family house to gain individual freedoms and to engage with secular consumption. Daughters’ rejection of their HR mothers manifested through consumption, such as buying / renting their own apartments, living with their boyfriend, attending night clubs, wearing revealing apparel and rejecting ethnic meals.

CR mothers who had HR daughters experienced tensions around food preparation, with their HR daughters’ preferring Halal meat. Consequently these mothers found their daughter’s extreme Islamic behavior manifested through refusing to shop with their mothers, eat from their meals, and not exchanging ideas around purchases items. Our analysis locates religion then as a central variable within acculturation, manifesting through contesting how the female body should be presented. Consumption then provided the means to construct a project that communicated acceptance or resistance to society, as well as a sense of ownership and belonging to society.

Renegotiating the patriarchal bargain and the embodiment of womanhood

EXTENDED ABSTRACT

This research explores how migrant women use consumption to renegotiate their culturally construed gendered identity and related

bodily representations. Central to this renegotiation is the embodiment of the migrant female identity embodied within the patriarchal bargain, representing a set of pre-existing rules and scripts that regulate gender identity and related roles (Kandiyoti, 1988). For example, duties the wife is expected to perform, such as mother, cook etc. As migrant women's roles transition from a wife within a consanguine, traditional, family based around patriarchy to a nuclear family that encourages equality, the cultural values embodied in these women are challenged and renegotiated. This research then addresses previous research gender bias towards male immigrants, with female immigrants either invisible or stereotyped (Dona and Ferguson, 2004; Reid and Comas-Diaz, 1990). Consequently, although the process of immigration offers opportunities for culturally determined gender roles to be reconstructed in the new host society (Dona and Ferguson, 2004), the extent that immigration improves or undermines a women's ability to renegotiate her sense of identity remains unclear (Moon, 2003).

Patriarchal bargaining exerts a powerful influence on shaping a woman's gendered subjectivity and determines her sense of gender ideology and embodiment in different contexts, for example in the family, as an employee etc. Previous research has shown that men and women, within the family, have unequal power and, hence, ability to change the thoughts and/ or actions of each other (Olson and Cromwell, 1975). Consequently, the man is widely perceived as having greater purposeful influence over his spouse and, therefore, ability to exert his decisions and his gendered expectations (Kranichfeld, 1987). Whilst both men and women accept and collude with these rules and scripts, they may also challenge, redefine or renegotiate them.

Acculturation's emphasis on cultural change presents an interesting perspective to explore how women's gender embodiment is renegotiated. This cultural re-negotiation we argue can either be undertaken with mutual acceptance between husband and wife, or resisted and subversively created by another. Drawing upon the work of McCracken (1986) we argue that consumption with its related meanings becomes a contested area, offering opportunities for migrant women to construct and mediate their own sense of gendered identity and renegotiate culturally laden meanings embodied upon them.

10 first-generation Nigerian married couples and 10 British white couples (20 husbands and 20 wives) living in Britain were recruited, exceeding theoretical saturation (McCracken, 1988). This then provided a comparison group. Interviews were conducted on a sequential basis, with each female participant interviewed twice; first with the husband and then separately. Interviews ranged from ninety to one hundred and eighty minutes.

Our findings revealed that gender embodiment and cultural interpretations represented a nexus of shifting patriarchal power, driven by context and opportunity. Opportunities to embody traditional female cultural roles through consumption reflected a desire for equality; a desire often resisted by their husbands. Sometimes this arose from necessity but other times female participants used market construed products to intentionally assert and renegotiate their role. Whilst these women actively cooked and cleaned the family home, embodying the feminine body demanded in the patriarchal bargain, they also undertook roles reminiscent of the man. For example, the woman purchasing products for family members against the husband's wishes, refusing to embody cultural roles of womanhood at community events, and publicly renouncing the husband's position through consumption opportunities. At other times the women actively supported their husband's position, even though they had previously undermined it. For example, the wife would empower

the husband to fulfil cultural duties such as purchasing meat (even though they women were capable of doing so).

In conclusion, whilst these women actively sought and achieved a sense of equality through consumption, renegotiating their gender roles and physical sense of self, these acts were undertaken with a wider cultural recognition. Acculturation then represented a means of renegotiating the patriarchal bargain within Nigerian cultural parameters, rather than a bid to acculturate into British White culture. Our findings then indicate the role and embodiment of cultural boundaries within the acculturation process.

SESSION OVERVIEW

The purpose of this session is to better understand the psychological needs that drive the often seemingly irrational consumption of restrained eaters. Restrained eaters tend to chronically experience two conflicting motives when making daily food decisions: hedonic enjoyment and weight control (c.f. Stroebe et al. 2008). This conflict leads restrained eaters to be hyper sensitive to food cues in the environment, often resulting in disinhibited consumption. This disinhibited consumption tends to be interpreted as a self-regulatory failure; however, the papers in this session take a different perspective. Rather than condemning the failures of restrained eaters, the papers in this session each seek to answer the question, “What are the psychological needs that restrained eaters are addressing through their consumption?”

As the obesity epidemic continues to grow, at great physical, emotional and economic cost to both individuals and society at large, it is becoming clear that the efforts of chronic dieters (a.k.a. restrained eaters) to lose weight are not working. In order to find a solution to this problem, it is important to understand why restrained eaters are so prone to disinhibiting their consumption, and what needs, beyond momentary pleasure, disinhibited consumption serves.

The first paper of this session, “Do Restrained Eaters Identify as Dieters? Exploring the Role of Self-Concept in the Consumption of Restrained Eaters,” explores how a general self-concept prime impacts the consumption of restrained eaters. These authors find that among restrained eaters a general self-concept prime suppresses diet related thoughts resulting in increased consumption, suggesting that dieting is inconsistent with their self-concept. Thus, one driver of disinhibited consumption is the enactment of identity consistent behavior.

The next two papers, “Do Weight Watchers Want More Options? How Activating Self-Regulatory Concerns Triggers the Need

for Variety,” and “The Role of Reactance in Responses to One-Sided Advertisements: How Health-Related Appeals Backfire among Restrained Eaters,” both explore how restrained eaters use their consumption to create a greater sense of psychological freedom. Because restrained eaters are constantly imposing limits on their consumption, they are particularly sensitive to feeling trapped by additional restrictions. Thus, these papers highlight that restrained eating fosters a greater need for behavior aimed at regaining their freedom.

The final paper of this session, “The Acuity of Vice: Goal Conflict Improves Visual Sensitivity to Portion Size Changes,” explores how the food related ambivalence experienced by restrained eaters can actually improve their perceptions of portion size. A series of studies shows that consumers experiencing ambivalence towards a food, such as the chronic ambivalence experienced by restrained eaters for hedonic foods, are more sensitive to changes in portion size. It is worth noting that restrained eaters were not more accurate for estimating portion size for low ambivalence “diet” foods, which have been associated with disinhibited consumption in past research (e.g. Scott et al 2008). Thus, another driver of disinhibited consumption is release from the hyper-vigilance of food cues.

Do Restrained Eaters Identify as Dieters? Exploring the Role of Self-Concept in the Consumption of Restrained Eaters

EXTENDED ABSTRACT

Prior research views restrained eaters’ self-regulation of food consumption as an effortful, conscious desire to limit their food consumption, and thus control their physiological urges to consume food (Herman and Polivy 1980; Stroebe et al. 2008). In support of this perspective, research has shown that restrained eaters consistently think more about dieting and weight-related issues (Boon, Stroebe, and Schut 1997; van Koningsbruggen, Stroebe and Aarts 2012), and that the chronic accessibility of dieting and weight-control thoughts enables restrained eaters to successfully regulate their food consumption (Stroebe et al. 2008). Consequently, situational variables that inhibit conscious self-regulation lead restrained eaters to consume more food. Although research has provided much insight into how situational influences can lead to increased or decreased food consumption among restrained eaters (e.g., McFarlane et al. 1998; Herman, Roth, and Polivy 2003), less is known about the role that the self-concept plays in the self-regulatory efforts of restrained eaters. Research suggests that restrained eaters are more concerned about their weight and physical appearance than non-restrained eaters (Laessle et al. 1989; Wilksch and Wade 2004), and that restrained eaters are more self-aware and self-conscious about how they are viewed by others than non-restrained eaters (Blanchard and Frost 1983; Heatherton and Baumeister 1991). These differences are frequently attributed to societal pressures on individuals to be thin (Herman et al. 2003; Strauman et al. 1991). Yet, it is unclear the extent to which restrained eaters’ chronic concern about weight control and dieting is purely a social phenomenon, or has been internalized to become a part of their self-concept.

We examine the role of the self-concept in the consumption behavior of restrained eaters. To do so, we use a general self-concept prime – signing one’s name – that has been shown to activate the aspect of one’s self-concept that is afforded in the present situation

(Kettle and Häubl 2011). This simple intervention enables us to investigate how activating the self-concept of restrained eaters influences their self-regulatory efforts in controlling their food consumption. In particular, our research seeks to better understand the extent to which restrained eaters' urge to regulate consumption has been internalized and incorporated into their self-concept, versus remaining an essentially external force. In other words, as restrained eaters engage in that never ending battle between their "love of food and not wanting to get fat," which side of the battle is more closely linked to the self-concept? In answering this question, our research takes an important step toward better understanding the self-concept of restrained eaters.

In studies 1A and 1B we explore whether a general self-concept prime leads to increased or decreased consumption among restrained eaters. Based on finding by Kettle and Häubl (2011), we theorized that since food is relevant to the self concept of restrained eaters that a general self-concept prime should impact the food consumption of restrained, but not unrestrained eaters. What was less clear was whether a general self-concept prime would lead to increased or decreased consumption. We reasoned that if restrained eaters identify as dieters then a general self-concept prime in the presence of food would activate that aspect of the self, resulting in decreased consumption. If, on the other hand, restrained eaters do not identify as dieters and the desire to restrict consumption remains an essentially social construct, then a general self-concept prime should result in increased consumption. In study 1A we find that restrained eaters who engage in a general self-concept prime (signing their name) purchase more chocolates with money earned in an unrelated task than restrained eaters in a control condition (printing their name). As predicted, the general self-concept prime has no effect on the chocolate consumption of unrestrained eaters. In study 1B we replicate the same pattern of results with non-hedonic foods finding that after a general self-concept prime restrained eaters eat more carrots and more pretzels compared to a control condition, while the consumption of unrestrained eaters is unaffected by the general self-concept prime.

In study 2 we sought initial evidence for our proposition that the increased consumption exhibited by restrained eaters in response to a general self-concept prime is caused by decreased accessibility of the dieting construct. Participants signed (did not sign) their name in the presence (absence) of food and then engaged in implicit measure of thought accessibility (DeMarree, Wheeler, and Petty 2005) in which the target words were diet related (e.g. overeat, indulge). Among restrained eaters in the general self-concept prime, food present condition, diet related words were significantly less accessible compared to the control condition, providing initial evidence that dieting is not part of the self-concept of restrained eaters.

In study 3 participants received a bag of pretzels and engaged (did not engage) in a general self-concept prime. Participants then listed 5 thoughts about the pretzels and rated each thought in terms of how relevant it was to food, dieting, and themselves. Among restrained eaters, fewer diet related thoughts were reported after the general self-concept prime compared to the control. Additionally, restrained eaters were more likely to consume the pretzels after the general self-concept prime compared to the control. No effects were found for either D.V. among unrestrained eaters. Furthermore, among restrained eaters, the number of diet related thoughts mediated pretzel consumption only in the control condition, while in the general self-concept prime condition there was no relationship between diet thoughts and consumption. These results provide additional support for our proposition that dieting is not consistent with

the self-concept of restrained eaters and it is this inconsistency that leads to increased consumption after a general-self-concept prime.

Do Weight Watchers Want More Options? How Activating Self-Regulatory Concerns Triggers the Need for Variety

EXTENDED ABSTRACT

In daily life food variety has become omnipresent. When dining out or grocery shopping consumers can select between a variety of different dishes and products. On the upside, these strategies correspond with individuals' preference for variety in food consumption and provide them with higher consumption utility (Kahn & Wansink, 2004). On the downside, food variety fosters increased consumption (Rolls et al., 1981). Parallel to this trend, weight watching has become a recurring theme in present-day life. When reading magazines or watching TV, one is bombarded with information on dieting programs, creating the impression that watching one's weight is the status quo. Considering these recent developments in combination, the question that presents itself is whether weight concerns, in general, and restricting one's food intake, in particular, could influence individuals' need for variety: Do individuals who restrict their food intake seek more or less variety than individuals free from self-regulatory concerns?

When individuals are concerned about their weight, they restrict their food intake and adhere to self-imposed demands instead of listening to physiologically determined satiety boundaries (Herman & Polivy, 1984). This brings about stronger hedonic responses to highly tempting food (Hofmann, et al., 2009). In fact, when individuals restrict their food intake, they constantly ruminate about food and evaluate food stimuli in terms of pleasure that can be derived from eating. Accordingly, restricting one's food intake provokes a struggle between adhering to self-imposed demands and the desire to maximize pleasure from eating. Consuming the same kind of food easily results in habituation and decreases enjoyment of that particular food (Epstein et al., 2009) while eating a variety of different food is expected to bring about higher anticipated levels of consumption utility (Kahn & Wansink, 2004).

Taking these findings together, we predict that restricting one's food intake potentially increases variety seeking since it provides a means to compensate for the decreased pleasure that comes with adhering to these self-imposed demands. Specifically, we argue, first, that dieters seek more variety than non-dieters and, second, that non-dieters engage in higher variety seeking if self-regulatory concerns are activated. In study 1 we utilized a 2 (mental budget vs. no mental budget) x 2 (dieter vs. non-dieter¹) between-subject design. Participants took part in two seemingly unrelated studies. The first part served to manipulate the mental budget activation. In line with Krishnamurthy and Prokopec (2009) participants in the treatment condition read that people try to limit their snack consumption to 2.13 snacks a day and were asked to type in the number of snacks they would allow themselves today. Subsequently, all participants took part in a taste test and were randomly assigned to either taste a small piece of chocolate cake or chocolate. At the end participants could choose another piece of waffle or cake as an additional reward. We measured variety seeking as switching away from the food item just eaten². A direct logistic regression with our manipulation (mental budget vs. no mental budget) and dieting status (dieter vs. non-dieter) and their interaction effect on the likelihood to seek va-

1 Using the restrained scale (Herman & Polivy, 1980) we categorized participants as dieters (i.e., a score > 16) and non-dieters (i.e., a score ≤ 16).

2 Because product type (i.e., waffle or cake) eaten during the taste test did not influence individuals' likelihood to seek variety, we collapsed the data across product types.

riety (no vs. yes) revealed dieting status ($p < .05$, $\beta = 1.30$) and mental budget as significant positive predictor ($p < .05$, $\beta = .79$). Dieters as well as non-dieters with a mental budget were more likely to choose a different snack than non-dieters or participants without a mental budget. The interaction effect is insignificant ($\beta = -.71$). This study provides initial evidence that self-regulatory concerns increases variety seeking.

In study 2 we exclusively focused on non-dieters. Again, we activated self-regulatory concerns by means of asking half of the participants to generate a mental budget of how many snacks they want to allow themselves. Afterward, all participants were allowed to customize their own chocolate bar by choosing any six toppings out of a six-item choice set (e.g., cappuccino chocolate chips, or nougat piece). The results show that participants who imposed a mental budget chose significantly more different toppings ($M_{MB} = 3.52$, $SD = .14$) than those who did not impose a mental budget ($M_C = 3.12$, $SD = .15$), $F(1, 53) = 3.93$, $p < .06^3$. In study 3, we manipulate self-regulatory concerns by asking half of the participants to respond to the restrained scale (Herman & Polivy, 1980) and by assessing their weight. Afterward, participants obtained a cake covered with whipped cream and were told to customize it by choosing among seven different toppings (e.g., Smarties®, chocolate flakes, or small almond cookies). Participants for whom self-regulatory concerns were activated chose significantly more different toppings ($M_{MB} = 3.73$, $SD = .27$) than participants without activate self-regulatory concerns ($M_C = 3.0$, $SD = .25$, $F(1, 30) = 3.90$, $p < .06$).

By means of three studies we establish a relationship between self-regulatory concerns and variety seeking. In doing so, our findings suggest that particularly those individuals who are watching their weight are most susceptible to the negative consequences of variety, i.e., increased food intake: When confronted with varied product assortments individuals with self-regulatory concerns are most likely to seek variety and, thereby, run the risk of overeating.

The Role of Reactance in Responses to One-Sided Advertisements: How Health-Related Appeals Backfire among Restrained Eaters

EXTENDED ABSTRACT

In this research we explore consumer attitudes toward one-sided appeals that present only the negative aspects of consuming indulgent food and determine how these attitudes influence subsequent food preferences. Public service announcements (PSAs) often use one-sided messages (e.g., “All dessert is bad”) to encourage healthy behaviors and to discourage unhealthy behaviors, such as overeating indulgent food. These kinds of messages can backfire, however, because consumers perceive them to be biased since they only mention the negative aspects of dessert and disregard anything positive. Since the intended purpose of the message is to convince consumers that they should eat fewer desserts, consumers may rightly feel that such one-sided messages are trying to limit and constrain their choices. Reactance theory (Brehm 1966, 1989) suggests that when individuals feel that someone else is constraining their freedom to choose or act, they will initiate a motivational state of reactance to regain that freedom. We propose that under certain conditions, one-sided messages will cause reactance, leading consumers to pursue goals that run opposite to those intended by the message, such as increasing consumption of indulgent food.

More specifically, we propose that consumers’ dietary restraint status (Herman and Polivy 1980) will determine whether one-sided

messages produce reactance rather than compliance. Because restrained eaters (or dieters) have a greater concern for their figure and/or weight, and exhibit a strong desire to be thin, they are highly involved in and emotional about issues of indulgent consumption. Thus, their reactance is high because it comes from the motivation to be cognitively engaged with one-sided messages about indulgent food. In line with reactance theory (Brehm 1989) which emphasized the motivational construct of reactance, we posit that dieters (versus non-dieters) are more motivated to react to the one-sided message related to indulgent consumption. Particularly, dieters who see the message “all dessert is bad” are likely to feel their food choices are being constrained, thereby activating a goal to reassert their freedom of choice by consuming more (rather than less) indulgent food. Conversely, dieters who see the message that “all dessert is good” are unlikely to feel their food choices are being constrained, and thus do not need to respond with reactance to the message. Moreover, because reactance is motivational in nature, any reactance induced by a one-sided message should get stronger after a delay since it activates a goal to pursue the opposite behavior (Chartrand et al. 2008).

In a pilot study, participants ($n=66$) received a one-sided message (“All dessert is bad”) or a neutral message (“Tortola is the main island of the British Virgin Islands”) and performed a lexical decision task, where they decided whether each string (14 unhealthy food words, 56 neutral words, and 70 non-words) was a word by pressing the “Y” or “N” key. A regression analysis revealed a significant message by dietary restraint interaction effect on the speed of word recognition ($b=-164.014$, $p<0.01$). Dieters who received the one-sided message were faster at recognizing the unhealthy food words than dieters who received the neutral message ($b=-222.086$, $p<0.01$). This effect was not significant among non-dieters. Results provide preliminary evidence that exposure to a one-sided message focusing on the negatives of indulgence increases dieters’ interest in indulgent foods. However, an alternative explanation is that the one-sided manipulation simply activated thoughts of food whereas the control manipulation did not, particularly among dieters for whom food concepts are more top-of-mind. We addressed this limitation in Study 1 by activating thoughts of food in all experimental conditions.

Study 1 was similar to that of the pilot, except for the following changes: (1) Participants ($n=397$) randomly saw one of three messages: “All dessert is bad” (one-sided negative message), “All dessert is good” (one-sided positive message), and “All dessert is food” (neutral message), (2) In place of a word recognition task participants pressed the “F” and “J” keys (labeled “pos” and “neg”) to indicate whether they thought a word (20 healthy food, 20 unhealthy food and 20 neutral words) was positive or negative. (3) We measured participants’ situational reactance (Hong and Faedda 1996). Dieters who saw a one-sided negative message scored higher on reactance ($b=0.364$, $p<0.05$) and generated a higher number of positive thoughts about unhealthy food ($b=2.116$, $p<0.01$) than dieters who received a neutral message. This effect was not significant among non-dieters. There was no effect of the one-sided positive message on the number of positive thoughts about unhealthy food or reactance for either dieters or non-dieters.

The purpose of study 2 was to investigate the process underlying our findings. Specifically, does a one-sided message activate a goal in dieters’ minds, such as the goal to choose whatever foods they desire? The procedure was similar to that of Study 1, except for the following changes: (1) We added a manipulation of delay/no-delay to test whether the effects get stronger after a delay, and (2) Participants ($n=414$) chose snacks for the next two weeks from a list of seven snacks pretested as unhealthy (Oreo cookies) and seven snacks pretested as healthy (Whole wheat crackers). Dieters who received

3 We excluded one outlier on the variety-seeking measure ($SD > 2.5$).

the one-sided negative message scored higher on reactance and made more unhealthy choices than dieters who received the neutral message ($b=1.055$, $p<0.01$) and ($b=2.844$, $p<0.01$). Further, these effects were stronger after a delay ($b=1.294$, $p<0.01$ and $b=4.530$, $p<0.01$) and were not significant among non-dieters, suggesting that the one-sided negative message activated a reactance goal among dieters. There was no significant difference in the number of unhealthy choices made by dieters who received the one-sided positive message and dieters who received the neutral message.

Studies 1 and 2 showed dieters' reactance to the one-sided appeal reflected in their faster recognition of unhealthy food words, and increased positive thoughts and choice of unhealthy snacks. Further research will explore the effects of consumer reactance to one-sided messages about healthy food, examining whether dieters react to biased, negative appeals about healthy food (e.g., vegetables) the same way they react to biased, negative appeals about indulgent foods. We expect that the effects for healthy food will be symmetric to the ones we have already observed for unhealthy food.

The Acuity of Vice: Goal Conflict Improves Visual Sensitivity to Increasing Portion Sizes

EXTENDED ABSTRACT

There is a broad consensus that the rise in the obesity epidemic in the past several decades has been driven more by overeating (increased calorie intake) than by expending fewer calories (Ludwig & Nestle, 2008; Swinburn, et al., 2011). These effects are compounded by today's oversized food portions (Chandon & Wansink, 2007; Rolls, Roe, & Meengs, 2007).

Supersized portions increase food intake partly because people rarely read the size information on the labels and instead rely on their visual impressions to estimate portion size. However, visual perception is biased, and consumers tend to underestimate the changes in food portions, more so for large portions than for small portions. As a result, consumers overeat because they fail to realize just how large supersized portions really are (Chandon & Wansink, 2007). These findings have brought the biases in portion size perception and their remedies to the forefront of the research and the policy agenda.

Previous research on this issue focused on the effects of physical properties of packages such as size and shape, and on solutions to design packages that do not bias visual perception (Chandon & Ordabayeva, 2009; Folkes & Matta, 2004; Raghuram & Krishna, 1999; Wansink & Van Ittersum, 2003). In this research, we examine how higher-order factors, namely, ambivalent attitudes towards food (perceiving the food as desirable but harmful) influence size perceptions. Our results propose strategies that can effectively reduce biases in portion size perception without requiring any changes in physical package attributes such as size or shape (which may be costly, time-consuming, and difficult to enforce through policy).

We draw on two sets of findings in the motivated perception literature to formulate our hypothesis. One group of findings has shown that people are more sensitive to changes in the physical properties (e.g., quantity, distance) of desirable (vs. undesirable) objects (Balci et al., 2010a). For example, coins look larger to people with low financial means and with low power (Bruner & Goodman, 1947; Dubois, Rucker, & Galinsky, 2010). Another set of studies has found that undesirable stimuli, too, can enhance visual sensitivity, when they pose an imminent threat (e.g., a pointed gun; (Van Ulzen et al 2008)), although these effects should arguably also occur with more common and less imminent threats such as temptations and objects detrimental to a goal (Balci et al., 2010b).

Building on these findings, we predict that desiring a food item and perceiving it as harmful should enhance visual sensitivity to changing portions. Since in food decisions desire and harm perceptions reinforce each other (Raghunathan, Naylor, & Hoyer, 2006), we expect that ambivalence (or conflict) between these two attitudes will influence impressions of food portions more than each attitude individually. In three studies we show that this effect occurs when ambivalent attitudes are chronic (e.g., among restrained eaters) and when ambivalence is induced through external interventions (e.g., through ambivalence primes).

In Study 1 we examined the effects of ambivalent attitudes towards food on portion perceptions of children. We showed six portions (which doubled in size from one portion to the next) of chocolate chunks or baby carrots to eight-year old schoolchildren, who are an important population to study from a public policy perspective. Provided the size of the smallest portion (in units), we asked the respondents to estimate the number of units contained in the remaining portions. Afterwards we measured their ambivalence toward the food by asking them to rate their desire for the food item and their anticipations of being scolded by parents for eating the food item. The results indicated that children who felt ambivalent towards chocolate were more sensitive to the increasing portions of chocolate than children who did not experience ambivalence (because they perceived it as delicious but likely to be scolded by parents). Ambivalence did not influence perceptions of carrots.

In Study 2 we tested whether inducing ambivalence through separate manipulations of desire and perceived harm would improve portion size perceptions of adults. Participants saw four portions of gummy candies (which increased in size by 75% from one portion to the next). Provided the size of the smallest portion (in grams), the participants estimated the remaining three portions. We described the stimuli as "Omega 3 nutrition chews" (low harm condition) or as "gummy candies" (high harm condition). We manipulated desire by either asking the participants to consume either one gummy (high desire condition) or no gummy (low desire condition) (Wadhwa, Shiv, & Nowlis, 2008). The results revealed that portion size perceptions were the most accurate when ambivalence (perceptions of food desirability and harmfulness) was manipulated to be high. Similar patterns were observed with the implicit measure of ambivalence (as captured by implicit association tests of participants' desire and danger perceptions associated with hedonic foods).

In Study 3, we sought to extend the findings to a consumer group that naturally holds ambivalent attitudes towards hedonic foods. We therefore approached a sample of dieting and non-dieting individuals at a gym. The participants saw six portions of potato chips as in Study 3. The chips had a regular label for half of the participants and a low-fat label for the other half. Consistent with our predictions, restrained eaters (who hold naturally ambivalent attitudes toward hedonic foods) had more accurate portion size estimates than unrestrained eaters for regular chips, but not for low-fat chips.

Our findings contribute to the literature on motivated misperception by examining the interplay of wanting and liking in driving portion size perceptions. They also propose ambivalence as a useful tool for improving consumers' portion size perceptions.

SESSION OVERVIEW

Sharing information goes by many names: word of mouth, recommendations, information transmission, voting, gossiping, or in modern times "tweeting." Acts of sharing are one of (if not *the*) strongest influences on many consumer behaviors, influencing both the sharer and recipient of the information. Accordingly, many businesses have sought to drive and guide sharing behavior.

However, both businesses and academics remain blind to many of the underlying factors that surrounding sharing, particularly issues surrounding the sharer. Although academics have extensively examined how recipients respond to sharers' recommendations and general social influences, much less is known about the sharer. Particularly what motivates the sharer? And how does the sharer feel about transmitting different types information, to different types of people, in different types of situations?

The first paper by Peluso, Bonezzi, and De Angelis begins by examining a selfish side of advice giving, specifically examining how a motive to gain a sense of personal control leads people to share advice (even advice that may hurt recipients) to fulfill this motive. Campbell and Ariely complement the first paper by presenting an altruistic side of sharing, finding people share personal negative experiences they wish not to share in order to provide others with beneficial social comparison. The second paper also examines the influence of differences in valence of shared content and personal relationship with the recipient. Du Plessis and Dubois pick up on the topics of valence and relation to the recipient in the case of hierarchies, finding that people tend to share positive information up the hierarchy ladder and negative information down the ladder. The authors propose that arousal underlies these patterns. Kim and colleagues finish the session by examining a specific case of communication in ahierarchy: that between stakeholders (e.g. consumers, employees) and the larger firm. The authors critically examine the popular trend of firms (e.g. Facebook) inviting stakeholders to share opinions and vote on issues. Though seeming a positive step toward

giving stakeholders a feeling of influence and autonomy, the authors find many negative consequences for both firms and stakeholders.

In addition to the theme of feelings and motives, many of the papers tackle other overlapping themes, specifically: the trading off of sharer and recipient welfare (paper 1 and 2), the valence of transmitted information (paper 2 and 3), recipient characteristics (paper 2 and 3), hierarchies (paper 3 and 4), and feelings of control (paper 1 and 4).

In sum, this session seeks to reaffirm how basic consumer research can make a big difference in a modern world of increasingly sharing behavior. All the benefits of sharing, tweeting, and word of mouth hinge on a potential sharer actually choosing to share. Accordingly, understanding what motivates the sharer and how the sharer feels about sharing is fundamentally important if one wishes to promote any type of sharing from peer-to-peer tweeting to good ol' fashioned face-to-face word of mouth.

The Selfish Side of Sharing: Effects of Need for Control on Advice Giving

EXTENDED ABSTRACT

Consumers' purchasing decisions are often influenced by information provided by others in the form of advice (Cheema and Kaikati 2010; De Bruyn and Lilien 2008; Fitzsimons and Lehmann 2004). Previous literature has often conceptualized advice giving as an altruistic behavior driven by empathic concern for others (Goldsmith and Fitch 1997; Liu and Gal 2011). From this perspective, consumers provide advice to improve or protect others' well-being (Hennig-Thurau et al. 2004; Sundaram, Mitra, and Webster 1998).

Despite the intuitive validity of this argument, we suggest that a self-serving motive, and not empathic concern, sometimes drives advice giving. We argue that consumers sometimes provide advice to fulfill a self-serving motive to restore a lost sense of personal control. Building on the notion that consumers experiencing a threat to their sense of control seek means to restore control (Kay et al. 2008; Whitson and Galinsky 2008), we suggest that giving advice can provide one means of accomplishing such an objective. Thus, we propose that individuals with a need to restore control are more likely to give advice than individuals who do not have such a need.

Experiment 1 tested whether individuals who experience a temporary need to restore control are more likely to give advice than individuals without this need. Moreover, we also tested whether this tendency is stronger for individuals with a higher chronic desire for control (Burger and Cooper 1979; Gebhardt and Brosschot 2002). Eighty-two participants were assigned to either a need to restore control condition or a no need to restore control condition of a between-participants design, with chronic desire for control serving as a continuous measured variable. We manipulated personal control via threat, using an episodic recall task (Whitson and Galinsky 2008). We then asked respondents to recall a positive consumption experience, and write about it as if they were writing an email to a friend. Messages were then coded based on whether or not they contained an explicit advice or recommendation for the recipient. A logistic regression revealed a significant effect of need to restore control ($p = .05$), indicating that respondents who had a need to restore control gave advice more than respondents who did not have such a need. Moreover, this main effect was qualified by a significant interaction between need to restore control and chronic desire for control ($p = .05$), indicating that the tendency to give

advice when feeling out of control was stronger for individuals with a higher chronic desire for control ($p < .01$) compared to those with a low chronic desire for control ($p > .10$).

Experiment 2 directly tested for a differential effect of empathy and need to restore control on advice giving. We reasoned that, in situations in which providing advice may be potentially detrimental to the receiver, empathy vis-à-vis need to restore control should produce opposite effects. Specifically, individuals motivated by empathy should be more likely to refrain from giving advice, to avoid potentially hurting the recipient. In contrast, individuals motivated by a self-serving need to restore control should be more likely to give advice, as worry less about potential negative consequences for the recipient. One hundred and sixty five participants were assigned to three conditions of a between-participants design. We used an episodic recall task to activate across conditions either empathy, a need to restore control, or a neutral state (baseline). Next, respondents were asked to read a scenario describing a consumer in need of advice about applying for a fixed versus adjustable-rate mortgage. In particular, the scenario was characterized by ambiguity about the best course of action and potential for harm to the receiver if the wrong advice is provided. Respondents were asked to indicate whether or not they would provide advice to the person involved in that situation. A logistic regression revealed a positive effect of need to restore control on advice giving, indicating that respondents in this condition were more likely to give advice than respondents in the baseline condition (72.2% versus 53.4%, $p = .04$). In contrast, the results showed a negative effect of empathy, indicating that respondents in this condition were less likely to give advice than respondents in the baseline condition (34% versus 53.4%, $p = .04$).

Experiment 3 tested whether the desire to engage in advice giving is attenuated when an alternative way to restore one's threatened sense of control is provided beforehand. One hundred and sixty participants were assigned to a 2 (need to restore control: present versus absent) \times 2 (opportunity for self-recovery: present versus absent) between-participants design. We manipulated personal control using an anticipatory thinking task (Rutjens et al. 2010). Half of the participants then engaged in a choice task that provided an opportunity to restore their threatened sense of control (Inesi et al. 2011). Finally, respondents were asked to recall and write about a positive experience they had with a product and indicate their propensity to advise others to buy that product ("I am definitely going to suggest to others to buy this product"; 1 = strongly disagree, 9 = strongly agree). There was a significant need to restore control by opportunity for self-recovery interaction, $p = .03$. Contrasts revealed that when no intervening opportunity for self-recovery was present, participants with a need to restore control expressed a higher intent to give advice ($M = 8.66$) than participants with no need to restore control ($M = 7.60$), $p < .001$. In contrast, when an intervening opportunity for self-recovery was present, participants' intent to give advice did not differ as a function of need to restore control, $p > .10$.

Overall, this research furthers our understanding of the motives that drive advice giving. Contrary to prior research, we show that advice giving can be motivated by a self-serving desire to restore a lost sense of control. Attesting to the compensatory role of advice giving as a means to regain a temporary threatened sense of control, our results suggest that advice giving might in fact be attenuated when an alternative way to restore control is provided.

The Altruistic Side of Sharing: Giving Misery Company by Sharing Personal Negative Experiences

EXTENDED ABSTRACT

"The world needs people like you and me who've been knocked around by fate. 'Cause when people see us, they don't want to be us, and that makes them feel great. We provide a vital service to society!"-Avenue Q the Musical

Why do people so often share negative personal information (e.g. a fight with a spouse, a miserable product experience) when research shows focusing on one's own or another's negative personal experiences produces undesirable outcomes? (Neuman & Strack, 2000; Schwarz & Strack, 1999; Tiedens & Linton, 2001) In this paper we attempt to shed light on this puzzle. Building upon the altruism (Batson & Shaw, 1991; Monroe, 1994; Small, Loewenstein, & Slovic, 2007) and social comparison theory literatures (Corcoran et al., 2011; Wills 1981), we propose that the sharing of personal negative experiences is often motivated by social altruism such that people willingly trade off personal costs to provide benefit to target-persons through the process of downward social comparison. Thus, people (who we call "supporters") share negative personal information not because they are unaware of the costs associated with focusing on negative information. Instead, supporters tell target-persons about their own negative experiences because of a conscious intention to aid target-persons based on a lay understanding of social comparison (Exline & Lobel, 1999).

In sum, the findings paint a picture of people as daily social altruists who engage in a sophisticated cost-benefit analysis of two competing forces. The first force, the *salient negative force* entails a cost for both supporter and target-person. This force focuses both parties on negative experiences, leading both parties to feel negative emotions and dissatisfaction. In contrast, the second force, a downward *social comparison force*, may benefit the target-person. When considering the combination of the two forces involved in sharing personal negative information, supporters consistently predict a personal cost for sharing such information. However, supporters predict the effect on the target-person will vary depending on whether the cost of the salient negative force or the benefit of the downward social comparison force looms larger for target-persons. Importantly, by speaking about their own negative experiences, people believe they can literally give "misery" beneficial company and are willing to become such company.

In the current project we conducted five scenario experiments to test this social altruism sharing hypothesis, assess the intuitions people have about the effects of sharing negative personal information, and understand the factors that intensify and dampen the likelihood of sharing personal negative information for socially altruistic purposes.

In the first two experiments we found supporters shared more negative (and separately less positive) personal information with a target-person who had recently experienced negative experiences and that this pattern was stronger when the target-person's negative experiences was unchangeable. In the third experiment we found the above pattern significantly occurred for targets that were and were not friends with the supporter, however the pattern was notably stronger for friends.

Experiments 4 and 5 revealed more direct evidence that this sharing behavior is intended to benefit target-persons through downward social comparison. In Experiment 4, when sharing experiences with target-persons, we found supporters not only selectively choose

to share more personal negative experiences to benefit bad feeling target-persons, but that supporters also lie about their personal experiences, portraying their experiences as more negative when target-persons would benefit from a downward social comparison. Thus supporters may incur the moral cost of lying (Grover, 1993) for the benefit of target-persons. The tendency to more negatively portray one's experiences with target-persons who had recently experienced negative rather than positive events was completely mediated by intentions to benefit the target-person. Further, we found that when target-persons had recent negative experiences, supporters reported a much higher intention to benefit the target through personal sharing. This finding suggests that it is when others are suffering that socially altruistic processes in personal sharing are most often triggered.

Finally, Experiment 5 documented how in interpersonal conversation situations like those explored in the first four studies, people predict sharing negative experiences would be A) costly for supporters' general feelings and worsen supporters' own satisfaction with their personal experiences and B) beneficial for targets' general feelings and improve targets' satisfaction with their own experiences. Together the experiments also rule out alternative behavioral patterns and hypotheses, such as taking advantage of situations to vent, matching the conversation tone of a conversation partner, or a mean reduction in personal sharing with negative feelings others.

We began with the puzzling observation that although research has demonstrated negative consequences of focusing on one's own or others' personal negative experiences and people have a general preference against sharing and being exposed to negative personal experiences (De Angelis et al., 2012; Kowalski, 2002), people often choose to complain and share negative personal experiences. Though previous research has observed such behavior to occasionally be motivated by selfish desire (Taylor, Wayment, & Carrillo, 1996; Kowalski, 1996, Smith, 1983), here we propose a different (though not exclusive) motivation for this behavior: social altruism. We found that at times, supporters will incur a personal cost and share negative personal experiences when they believe doing so will benefit a target-person. We explain our findings by theorizing people hold a lay intuition of social comparison theory (Corcoran, et al., 2011; Mussweiler & Strack, 2000; Wills, 1981), such that supporters seek to deliberately construct downward social comparisons for target-persons by sharing their own negative experiences. Future research should explore under what circumstances sharers' strategies are effective and if sharers can anticipate when sharing personal negative information is most likely to provide target-persons with beneficial social comparison, though past research suggests this would be in general a beneficial strategy (Jordan et al., 2011). We discuss implications for consumer behavior, social welfare, and word of mouth.

La vie en Rose at the top? Why Positive (Negative) Information goes Up (Down) in a Hierarchy

EXTENDED ABSTRACT

A key concern for marketers, both in academia and practice, is understanding when and why positive and negative product information spreads through word-of-mouth (WOM). Indeed, positive WOM often leads to an increase in sales (Chen, Wang and Xie

2011) or value (Villanueva, Yoo and Hanssens 2008) whereas negative WOM may decrease brand evaluations (Amdt 1967; Haywood 1989) or even spark damaging rumors about a brand (Dubois, Rucker and Tormala 2011). While some research suggests that consumers are more likely to share negative WOM (e.g., Kamins, Folkes and Pernes 1997), other studies show that consumers can, at times, share positive rather than negative WOM (e.g., East, Hammond and Wright 2007). Regardless of the valence of information shared, consumers tend to share information that is more psychologically arousing to them (Berger and Milkman 2012). This is because arousal is a state of excitement which leads to mobilization (Berger and Milkman 2012). Extant research shows that consumers' likelihood to share a stimuli (e.g. a WOM message or a video) increases when the content evokes arousing emotions such as anxiety or amusement, relative to content that evokes emotions which are less arousing, such as sadness or contentment (Gross and Levenson 1995). Accordingly, even incidental arousal unrelated to the message content (e.g., whether a sender is physically aroused when sharing information) can boost sharing (Berger 2011).

We aim to shed light on *when* consumers will share more positive or negative WOM as a function of arousal. Our reasoning builds on the premise that information is not arousing per se. Rather, information *becomes* more or less arousing depending on the context of the information sharing (Berger 2011) or the sender and recipient's characteristics.

In particular, we propose that the hierarchical relationship between a sender and a recipient of a WOM message can dramatically shift the information's arousing properties. Specifically, we hypothesize that sending a message to someone lower in the hierarchy will increase the arousal of negative information. In contrast, we hypothesize that sending a message to someone higher in the hierarchy will increase the arousal of positive information. This is because low hierarchical positions are typically associated with negative information in the form of stereotypes or negative affect, while high hierarchical positions are often viewed more positively (Cozzarelli, Tagler and Wilkinson 2002). In turn, we expect that this differential focus will make positive or negative information more arousing, depending on the recipient's position in the hierarchy. Thus, we predict that the increased arousal, elicited by an expected sharing of information with a recipient higher or lower in the hierarchy will result in differential sharing of positive and negative information. These ideas are tested across two experiments.

In Experiment 1, undergraduates were presented with a review for a car, which has an equal number of pros and cons. After reading the review, participants were asked to send a WOM message as if they were to send an email. Key to the experiment, they were either instructed to send a WOM message to someone higher (high hierarchy condition) or lower (low hierarchy condition) in their company structure. To communicate this difference, participants were told that their task was to share a message to Paul, presented as their boss (HH) or employee (LH). To increase the hierarchical divide between the sender and the recipient, participants were presented with a graphical representation (i.e., a tree graph) representing Paul as either immediately above (HH) or below (LH) them in the tree. Next, participants wrote their messages. We counted the number of pros and cons in the message, and computed a valenced index (number of pros less the number of cons and divided by the total number of thoughts). Results indicated that participants' message was significantly more positive when they addressed a recipient higher in the company hierarchy than when they addressed someone lower, $p < .01$.

In Experiment 2 we specifically manipulated recipient's relative standing based on their own actual perceived standing, once again through a graphical ladder representing social hierarchy (see Piff et al. 2012). To do so, senders (participants) first indicated their position on the ladder. Next, a research assistant told them they would be randomly assigned to another participant to whom they will send a WOM message, and were given an information sheet about this participant. Key to the experiment, the information sheet was staged. In the high hierarchy condition, the information sheet mentioned that the assigned recipient had indicated being two steps *higher* on the ladder. In contrast, in the low hierarchy condition, the information sheet mentioned that the assigned recipient had indicated being two steps *lower* on the ladder. Next, participants shared a WOM message about a car. We coded participants' messages as in experiment 1. Consistent with our hypotheses, messages were more positive when respondents wrote an email description to a recipient higher in the social hierarchy than when they were asked to email someone lower in the social hierarchy, $p < .05$.

Overall, this research contributes to our understanding of when and why valenced information is shared by demonstrating how psychological arousal arising from the hierarchical relationship between the recipient and sender of the WOM message impacts the sharing of positive vs. negative information and are consistent with arousal-hierarchy hypothesis.

These findings also have important practical implications for understanding how information might be distorted across multiple successive transmissions in an organization: the same situation might be seen in rosy hues by those at the top but through gloomy lens for those at the bottom. In turn, this discrepancy in perception might explain why leaders can be unrealistically optimistic and ignore warning signs regarding the health of their organizations, and why individuals lower in the hierarchy might show more distress or anxiety about the future—because they've received different information.

The Negative Consequences of Empowering Consumers and Employees

EXTENDED ABSTRACT

Gone are the days of managers acting as sole decision-makers in strategic choices. Increasingly, managers "outsource" some decisions - from creating advertisements to deciding on mission statements - to both internal and external stakeholders: employees and customers. While delegation of agency is often a strategic move to dodge responsibility for potential missteps or avoid being perceived as lacking transparency (Bowen and Lawler, 1992), collecting information through shared decision-making also allows companies to induce positive effects by empowering those who participate. In workplace settings, for instance, empowering employees leads to increases in job satisfaction and performance (Kirkman, 1999; Spreitzer, 1995). Similarly, research on consumer empowerment - such as allowing consumers to personalize products and services - points to the benefits of involving consumers (Fuchs, Prandelli, and Schreier, 2010; Prahalad and Ramaswamy, 2004; Wind and Rangaswamy, 2001). In contrast, we explore the possible negative consequences of such empowerment, examining how opening the Pandora's box of empowerment can prove problematic when companies wish to close the lid and revert to making their own consequential decisions.

Our research focuses the consequences of empowering stakeholders to vote, with three goals, each of which contributes to a broader understanding of the negative consequences of empowerment over time. First, we explore whether allowing people to vote leads them to want to continue voting on subsequent decisions, even when the "vote giver" may no longer desire such input. Indeed, research in political science shows that political participation (including voting) engenders future participation (Finkel, 1978; Putnam, 2000). As in the previous literature, we expected stakeholders to be satisfied when empowered; in addition, however, we expected empowerment to lead to stakeholders' demand to continue voting. Second, we examine whether stakeholders who are allowed to vote on one issue and then have the vote taken away for a second issue are more upset than those who are not allowed to vote on the first issue and then given the vote for the second: while in each case stakeholders will have voted once, we suggest that having the vote taken away is so aversive that stakeholders are as dissatisfied as they are with never being allowed to vote at all. Finally, we explore whether all voting is good voting. In particular, we explore issues of voting on trivial issues.

Study 1 tests the idea that once empowered to vote, people will express the desire to vote more and more in the future. Participants ($N=106$) acted as consumers of a breakfast products company called Cereal Central. The study employed one between-subjects manipulation, where participants either voted six times on company-related

issues with one filler task in the middle, or were simply told about the choices the company was considering. They were then given a list of ten company issues and were asked whether each should be put up to a vote. As predicted, voting begets more voting: those in the vote condition indicated that they wanted to vote for more issues ($M=2.98$) than those in the no vote condition ($M=2.43$), $t(104)=2.32$, $p<.05$.

Study 2 explored whether voting and then having the vote taken away can be worse than not voting and then being given the vote - and even as bad as never being able to vote at all. In a 2 (vote vs. no vote on the first issue) x 2 (vote vs. no vote on the second issue) between-subjects design, participants ($N=243$) acted as employees of a local firm whose management team decides to let employees vote or not vote on each of two company-related issues (revising bonus scheme and promotion policies). A 2x2 ANOVA revealed no significant effect of voting on the first issue on satisfaction, $F(1, 239)=1.80$, $p=.18$, but a significant main effect of being able to vote on the second issue, $F(1, 239)=78.37$, $p<.001$, such that participants who could vote the second time were more satisfied ($M=4.00$) than those who could not ($M=2.79$). Most importantly, we observed the predicted interaction, $F(1, 239)=7.65$, $p<.001$. Follow-up tests indicated that participants who did not vote the first time and were given a chance to vote for the second issue reported significantly higher satisfaction ($M=4.29$) than those who voted both times ($M=3.72$); $t(122)=3.32$, $p=.001$: being given the vote feels better than having had the vote all along. In contrast, once empowered to vote, having that ability taken away for the second issue made people feel less satisfied ($M=2.89$) than those who did not vote and then voted ($M=4.29$), $t(122)=7.96$, $p<.001$, despite the fact that in both cases participants voted once. Indeed, having the vote taken away made participants feel as dissatisfied as if they had never gotten to vote at all ($M=2.69$), $t(117)=.90$, $p=.34$.

Finally, Study 3 explored whether empowerment can backfire in a different way: when stakeholders are repeatedly asked to vote on issues that they deem trivial. Using the same workplace paradigm from Study 2, participants ($N=480$) were randomly assigned to one condition of a 2 (the first issue is important vs. trivial) x 2 (the second issue is important vs. trivial) x 2 (vote vs. no vote on the second issue) between-subjects design. An ANOVA revealed that being able to vote the second time significantly increases people's level of satisfaction overall, $F(1,472)=33.44$, $p<.001$. This main effect, however, was qualified by the predicted three-way interaction, $F(1, 472)=53.12$, $p<.001$. In contrast to all other conditions - in which being disempowered on the second issue led to decreased satisfaction - employees who considered trivial issues at both times were actually more satisfied when the vote was taken away on the second issue ($M=4.05$) than those "empowered" to keep voting on trivial matters ($M=2.84$), $t(121)=7.73$, $p<.01$.

These results suggest that while empowering stakeholders by giving them the vote generally increases satisfaction, such empowerment can come with downstream costs: stakeholders demanding to vote in the future (Study 1), stakeholders becoming angry when the vote is taken away (Study 2), and stakeholders becoming irritated when repeatedly forced to vote on issues about which they do not care (Study 3).

SESSION OVERVIEW

The comparisons are ubiquitous in consumers' everyday life. Research shows that comparisons play a key role in areas such as similarity (Medin, Goldstone, & Gentner, 1993), categorization (Nosofsky, 1986), stereotyping (Biernat, 2003), attitudes (Sherif & Hovland, 1961), person perception (Higgins & Lurie, 1983), decision making (Tversky & Kahneman, 1974), affect (Higgins, 1987), and the self (Festinger, 1954). In the consumer context, individuals' tendency to compare plays a crucial role in a wide range of substantively important phenomena. As the papers in this session show, comparative thinking can influence decisions in domains of goal and mindset, consumption satisfaction, charity donations, as well as relative income and consumption.

The thread linking the four papers in this special session proposal is a focus on the prevalence of comparative thinking and on its consequences for consumers' welfare. Overall, these papers include 13 completed studies across a variety of methods, research areas, and substantive settings.

The first paper, by Ma and Roese, shows that comparative tasks in non-consumption domains can activate a maximizing mindset, and that this mindset can have a cross-domain impact on consumption satisfaction by amplifying regret and dissatisfaction, increasing likelihoods of returning products and switching brands, and even negatively impacting sensory experiences. This research demonstrates the potential psychological pain and adverse behavioral consequences that comparative thinking can bring about.

On the other hand, the second paper by Hsee and Zhang, demonstrates a potential gain of comparative thinking in the context of charity donations. The authors introduce a virtually costless method for boosting charitable donations: unit-asking. Unit-asking entails that donors are asked to indicate a hypothetical willingness-to-donate for one needy person before being asked to decide willingness-to-donate for N needy persons. This method makes salient the comparison between one and N needy persons, increasing individuals' scope-sensitivity and thus boosting donations.

The third paper by Gu, Botti and Faro, identifies conditions in which the pain (vs. gain) of comparative thinking is more likely to occur. Specifically, they show that choice closure, the psychological process by which consumers come to perceive a decision to be final, increases satisfaction when the chosen option compares unfavorably with the forgone options, but reduces satisfaction when the chosen option compares favorably with the forgone options.

Lastly, Chabris et al. find that the preference for *absolute* over *positional* income levels (e.g., preferring a society in which you earn \$100K while others earn \$200K over one in which you earn \$50K while others earn \$25K) is significantly predicted by three different measures of intellectual abilities (vocabulary, CRT, WPT), but is not predicted by sex, in contradiction to most evolutionary theories.

Our proposed session can contribute to the theme of ACR 2013—making a difference. The research papers in this session extend, refine, and challenge prior research on comparative thinking and consumer well-being, and contribute to both basic theory development and marketing strategy.

The Maximizing Mindset

EXTENDED ABSTRACT

Getting the best is great. It has been advocated as ideal in almost every domain of life. In business, companies strive to become the most competitive in the market. In education, students are encouraged to get as many "A"s as possible. Even in entertainment, the most popular TV shows, such as "American Idol," "Dancing with the Stars," and "X Factor" center on the crowning of the best performer. Although maximizing outcomes might be considered a goal, here we suggest that it may also be a mindset, that is, a way of thinking that carries over across different judgment domains.

If there is such a maximizing mindset, how does it influence satisfaction with various outcomes in life? Moreover, most people do not always achieve the best outcome, and another key question is the consequences of a maximizing mindset after failure as well as success. For example, does looking for the most suitable city in which to live have a carry-over influence on consumers' regret level when they miss product promotions? Does trying to get "A"s in school have a cross-domain impact on satisfaction with computers or smart phones? Does seeking an ideal mate make consumers more likely to switch brands?

Past research on maximizing has centered on individual differences in chronic behavioral patterns, such that some people consistently try to get the "best" (maximizers) whereas others tend to "satisfice" and settle for "good enough" outcomes (Simon 1955). It has been proposed that maximizers have two key features: the goal to get the best out of any situation and the tendency to compare and search for alternatives (Iyengar, Wells, and Schwartz 2006; Schwartz et al. 2002). Moreover, it has been found that maximizers tend to experience greater regret and lower satisfaction than satisficers (Nenkov et al. 2008; Schwartz et al. 2002). Beyond this pattern of correlation, it remains unclear what causal impact a temporarily activated maximizing mindset might have on various affective responses to particular outcomes.

The present research experimentally activated individuals' tendency to maximize (i.e., mindset priming) via tasks involving comparing and getting the best (e.g., a choice task). In conjunction

with this mindset priming, we manipulated different consumption outcomes and measured participants' consumption satisfaction (e.g., regret, satisfaction, likelihood of returning the product). We assumed that this experimentally activated maximizing mindset in non-consumption domains would have a carry-over effect on subsequent consumption satisfaction. This assumption is based on the extant literature on procedural and mindset priming, which specifies that a cognitive process that is activated in the pursuing of one task remains active and is shifted to subsequent tasks, affecting responses in these tasks as well (Förster and Liberman 2007; Kray, Galinsky, and Wong 2006; Gollwitzer 1990; Gollwitzer, Heckhausen, and Steller 1990; Schooler 2002; Xu and Wyer 2007).

We showed that constantly trying to get the best in non-consumption domains can induce a maximizing mindset which features an elevated tendency to compare and a salient goal to get the best. This mindset can have a cross-domain impact on consumption domain, amplifying regret and dissatisfaction, increasing the likelihood of returning products, and dampening sensory experiences, such as taste.

Across six experiments, we examined the impact of the maximizing mindset activated in non-consumption domains on consumer satisfaction (e.g., regret and satisfaction) in various consumption scenarios, such as missing the best deal, product malfunction, and an imperfect vacation. Experiments 1a demonstrated the basic effect by showing that the maximizing mindset activated in non-consumption domains magnified regret in a consumption domain when participants did not get the best product deal. In a different consumption scenario, Experiment 1b further demonstrated that the maximizing mindset activated in non-consumption domains magnified regret, dissatisfaction, and likelihood of returning a product when the product malfunctioned. To probe the effect in Experiment 1 further, Experiment 2 sought to validate our proposed definition of the maximizing mindset by showing directly that this mindset indeed involves a heightened tendency to conduct upward comparisons. Experiment 3 further showed that even the sensory experience of a product (i.e., the taste of a snack) was hurt by the maximizing mindset when this product was not participants' best choice. Moreover, this experiment also showed that although the maximizing mindset decreased satisfaction when the outcome is not the best, when the outcome is the best individuals in the maximizing mindset condition were as satisfied as individuals in the control condition.

To support our theory that the cross-domain impact of the maximizing mindset is a carry-over effect of procedure priming which is not context specific, Experiment 4 manipulated the maximizing mindset in the consumption domain (i.e., choosing brands) and then examined its impact on individuals' satisfaction in a non-consumption domain (i.e., satisfaction about performance on an IQ test). We found that individuals' regret and dissatisfaction about their IQ task performance were magnified after their maximizing mindset was activated in the consumption domain. Finally, Experiment 5 was designed to show the maximizing mindset is different from the comparative mindset in earlier research. Specifically, this experiment showed that the maximizing mindset and the comparative mindset both improved task performance, but only the maximizing mindset amplified regret and dissatisfaction.

The present research documents a new kind of mindset that has not been articulated in prior research yet which has unique effects on consumption satisfaction. The maximizing mindset is distinguishable from other mindsets (e.g., comparative mindset; counterfactual mindset, etc.) that have been examined in earlier research. Future research may explore further the unexpected impact of mundane daily tasks on well-being. For example, choosing the tastiest dish from

a long menu in a restaurant, watching American Idol, and grading students' assignments may all involve temporary activation of the maximizing mindset, which may in turn amplify regrets and dissatisfaction in unrelated life domains.

Unit Asking: A Method to Boost Donations and Beyond

EXTENDED ABSTRACT

Raising charitable donations requires considerable time and effort. In the U.S., for example, it costs over \$50 billion each year to raise roughly \$300 billion in individual donations (Greenfield, 1999; National Philanthropic Fund, 2012). In this research, we introduce a simple and virtually costless method for boosting donations.

To illustrate, consider a web-based fundraiser that solicits donations to help N needy persons. Imagine two alternative versions of the website: One version asks the donors to decide how much to donate for all of the N persons. The other version first asks the respondents a hypothetical question—how much they would donate for one of the N persons—and then asks them to decide how much to donate for all of the N persons. Notice that the second version merely adds a hypothetical question that carries no additional external information. Yet we propose that this hypothetical question will considerably boost donations. We refer to this effect as the unit-asking effect.

The unit-asking effect occurs because donors are initially scope-insensitive (Hsee, 1996; Hsee & Zhang, 2010); thus, the willingness-to-donate (WTD) donors in the unit-asking condition indicate for one needy person would be similar to the WTD donors in the control condition indicate for all of the N needy persons. When the donors in the unit-asking condition are subsequently asked to decide on their WTD for all of the N needy persons after having indicated their WTD for one needy person, their desire for consistency will compel them to contribute more for the N persons than for one person. Thus, donors in the unit-asking condition will donate more money than will those in the control condition, resulting in a unit-asking effect.

We tested the unit-asking effect in three studies involving both real fundraisers and hypothetical fundraisers. In one study testing the unit-asking effect in a real fundraiser, a company in China sent a mass email to its employees announcing a fundraiser aimed to help 40 students from low-income families at an elementary school in rural Sichuan, a school the company had sponsored following the region's 2008 earthquakes. The email encouraged each employee to make a donation on a designated Web site within one week. The Web site had two versions, control and unit-asking. Within one week of the announcement, 320 employees visited the Web site and were randomly directed to one of the two versions. Consistent with our prediction, the unit-asking version solicited significantly more donations than did the control version.

In another study, we replicated the unit-asking effect in a different context and showed that the unit-asking effect is distinct from the well-known identifiable victim effect. One hundred and thirty-one participants recruited from Amazon's Mechanical Turk were asked to imagine that they received a letter from the head of a trustworthy local orphanage soliciting donations for 30 new orphans. We manipulated two factors between-participants. One was the soliciting method, control vs. unit-asking. The other was victim identifiability: Half of the participants received no identification information about any of the orphans; the other half were provided with the name and a picture of one of the orphans. A 2 x 2 ANOVA found both a significant main effect of method, replicating the unit-asking effect, and a significant main effect of victim identifiability, replicating the identifiable-victim effect. The interaction effect was not significant,

suggesting that the unit-asking and the identifiable victim effects are orthogonal.

In a third study we further replicated the unit-asking effect and addressed two questions. One is whether unit-asking worked because it increased the salience of the number of needy persons. To address this, we included a number-recalling condition in which respondents were asked to recall the number of the needy persons before indicating their WTD. Another question is whether asking the donors to write down their unit-WTD is necessary. To address this, we included a thinking-only condition in which respondents were asked to merely think about how much they would donate for one of the needy persons without writing down a unit-WTD. A one-way ANOVA revealed a significant effect. Post hoc Duncan comparisons showed that WTD was significantly higher in the unit-asking condition than in any of the other three conditions, the control condition, the number-recalling condition, and the thinking-only condition. No other effects were significant. These results replicated the unit-asking effect. They also suggested that unit-asking worked not because it increased the salience of the number of needy persons, and that asking the donors to write down their unit-WTD was necessary; what was written down was concrete, and hence more likely to compel the donors to be consistent.

In sum, our studies show that a subtle manipulation based on psychological science can make a substantial difference in real life. Even if only a small fraction of fundraisers adopt the unit-asking method, it can considerably increase total donations.

When Choice Closure Reduces Satisfaction: The Moderating Role of Decision Outcome Valence

EXTENDED ABSTRACT

Previous research has shown that choice closure, defined as the psychological process by which consumers come to perceive a decision to be final, increases satisfaction with difficult decisions (Gu, Botti, and Faro forthcoming). This positive effect is explained by the fact that the sense of completion associated with choice closure inhibits comparisons between the chosen and the forgone options after the decision has been made. As comparisons tend to reduce an option's attractiveness (Brenner, Rottenstreich, and Sood 1999), choice closure enhances satisfaction with the selected option. However, research has also found that comparisons do not always decrease the evaluation of the option being compared (Hsee and Leclerc 1998; Simonson 1989), suggesting that choice closure may, under some conditions, be detrimental to satisfaction.

In this paper, we examine the role of decision outcome valence in moderating the effect of choice closure on satisfaction. Literature has shown that a negative outcome causes individuals to engage in upward counterfactuals, resulting in lower satisfaction with the outcome, whereas a positive outcome elicits downward counterfactuals, leading to greater satisfaction (Markman et al. 1993). As choice closure works through the inhibition of these comparisons, we predict that consumers experiencing closure will be more satisfied than those not experiencing closure when the outcome is negative, but less satisfied when the outcome is positive. We also predict that consumers may not anticipate the effects of choice closure, and therefore act contrary to what may enhance their satisfaction. Prior research shows that negative, as opposed to positive, affect is more prone to activate counterfactual comparisons (Roese 1997). As negative (positive) outcome is likely to be accompanied with negative (positive) affect, we argue that when given the opportunity of reaching choice closure, consumers may avoid it and engage in more comparisons

when the outcome is negative, and instead look for closure when the decision outcome is positive.

We tested these two predictions in three studies. Based on literature showing that sensations can metaphorically activate a related abstract concept (Landau et al. 2010), in these studies we triggered choice closure using visual cues as signals to the decision maker that a decision is final and the rejected alternatives should not be further compared.

Study 1 was a computer-based study involving a hypothetical choice of chocolate, with a 2 (choice-closure trigger: closure vs. no-closure) \times 2 (feedback: positive vs. negative) between-subjects design. On the first screen, participants were asked to choose one chocolate from a selection of 12 chocolates. After choosing, participants moved onto the next screen where they encountered both the choice-closure-trigger and the feedback manipulations. Choice closure was triggered via visual alterations in the assortment presentation format. Specifically, the chosen chocolate was framed in yellow and shown together with the other 11 forgone chocolates. Each forgone chocolate was either labeled with a "rejected" tag (closure condition) or not (no-closure condition). Outcome valence was manipulated through providing feedback about the quality of the selected option relative to the average quality of the assortment—either above (positive-feedback condition) or below (negative-feedback condition) the average. As predicted, in the negative-feedback (positive-feedback) condition participants exposed to the "rejected" labels were more (less) satisfied than those who were not.

Study 2 aimed to test the process underlying the observed effect by directly manipulating either negative or positive comparisons. This study was a 2 (choice-closure trigger: closure vs. no-closure) \times 2 (feedback: positive vs. negative) \times 2 (comparison: replication vs. comparison) between-subjects design, involving a real experience with the choice outcome. The study procedure and the manipulation of choice-closure trigger and feedback were similar to study 1. In addition, participants were submitted to a comparison manipulation while tasting the chocolate. In the comparison condition, participants were instructed to describe how the selected chocolate might be better (worse) than other chocolates in the selection, if they had previously received positive (negative) feedback. In the replication condition, participants wrote anything that came to their mind. The results in the replication condition replicated those of study 1: when receiving negative (positive) feedback, participants in the closure condition were more (less) satisfied than those in the no-closure condition. Consistent with our hypothesized process, in the positive-feedback condition, positive comparison enhanced satisfaction in the closure condition, but had no effect in the no-closure condition. In contrast, in the negative-feedback condition, the negative comparison reduced satisfaction in the label condition, but had no effect in the no-label condition. These results support the theory that comparisons, favorable or unfavorable depending on outcome valence, drive the effect of closure on satisfaction.

Study 3 tested whether consumers have an intuition of when choice closure can help and when it can hurt their satisfaction. Participants were asked to imagine buying a flavor of coffee online from 12 different coffees. They were told that, after the purchase, they found an independent report showing that their selected coffee was rated either among the top three (positive-feedback condition) or last three (negative-feedback condition) coffees among the same set of 12 coffees. In the control condition, no feedback was provided. Next, participants were directed to two purchase history webpages that concluded their purchase. These two webpages differed in presentation formats: webpage A showed the chosen along with the rejected coffees, but separated by a solid line (closure design) whereas

webpage B displayed the chosen and the forgone options without any separation line (no-closure design). Participants were asked to choose which of these two webpages might enhance their satisfaction with the selected coffee. Results showed that participants in the positive-feedback condition were more likely to select the closure-design webpage than those in the control condition. However, participants in the negative-feedback condition were less likely to select the closure-design webpage than those in the control condition. As predicted, consumers do not seem to have an intuition for when they should and when they should not seek closure, and when given the opportunity to choose between experiencing choice closure or not they act in ways that could be detrimental to their satisfaction.

Intelligence Predicts Choice of Absolute Versus Positional Income

EXTENDED ABSTRACT

Positional goods are those whose valuation depends, in part, on the levels held by others. For example, if the productivity of all PhD students doubles, the rising tide of publications would not necessarily increase anybody's job prospects, since publication records are evaluated relative to each other. Other goods, such as the amount of food at a picnic, are *non-positional*. A picnic feast can be relished by all, and the satiated are not made better if some go hungry.

Many goods lie in between. Indoor plumbing reduced the inconvenience of bathroom visits, but before it was universal, its value came partly from having it when one's neighbors did not. Since income can be used to purchase indoor plumbing, swimming pools and other things in this intermediate category, we can presume that income, itself, is a positional good to some extent.

A study by Solnick and Hemenway (1998), offers a pertinent data point on this issue. They posed the following question to 257 students, faculty, and staff at the Harvard School of Public Health:

Which of these two worlds would you prefer to live in?

A. Your current yearly income is \$50,000; others earn \$25,000.

B. Your current yearly income is \$100,000; others earn \$200,000.

Note: Prices are what they are currently and prices (therefore the purchasing power of money) are the same in states A and B.

Respondents were roughly evenly split. Thus, if taken at face value, the data suggest that roughly half of these participants would be willing to have their real income cut in half to reduce others' income by a factor of eight. (Or, equivalently, would forego an opportunity to double their income if it meant that they would lose their positional status they enjoy in world A.)

The rationality of preferring A over B (or vice versa) presumably depends on individual differences in the uses of money and in the intensity of feelings of inequity. Without knowing more, it would be hard to label either preference a mistake. One can, however, ask whether intellectual abilities predict such preferences. And we did. Our participants included undergraduate students at a selective liberal arts college and people recruited from other sources such as Amazon Mechanical Turk. Each participant completed one of several different measures of cognitive ability, including a 10-item vocabulary test (adapted from the General Social Survey), a 3 or 5-item version of the Cognitive Reflection Test (CRT; Frederick, 2005), or the Wonderlic Personnel Test (WPT).

Three results are noteworthy: First, income appears to be less of a positional good than Solnick and Hemenway's data suggest: 70% of our participants chose world B, in which they sacrifice relative position for more purchasing power. Second, the preference for B was predicted by intellect. For each of the three tests of cognitive ability,

those who preferred B scored significantly higher. The vocabulary and WPT tests were as predictive as the CRT, which suggests that a preference for world A is not necessarily a product of some compelling intuition that is rejected upon second thought (though the test results do indicate that cognitive ability affects the considerations brought to bear or the construal of the "tradeoff" between absolute and positional standing). Third, preference between regimes was unrelated to sex. This contradicts a prediction evolutionary theorists would likely aver: that men would be more attuned to relative standing, as this would determine mating opportunities and number of offspring.

SESSION OVERVIEW

Time is a pervasive theme in modern day consumer culture that unites a variety of scholars, themes and methodologies. Behaviors such as forming plans for the present and future, making decisions now or postponing them to later, and recalling past experiences all require consumers to consider time. Whether people focus on the present or the future also changes the way events are mentally represented and the meaning subsequently derived from those events (Bartels and Rips 2010; Day and Bartels 2008; Liberman and Trope 1998; Mogilner 2010; Mogilner and Aaker 2009; Trope and Liberman 2000; 2003; Zauberman et al. 2009). Our proposed session builds on prior work by exploring new directions in time research, offering novel insights into how temporal perspectives affect consumer decisions and experiences.

Each of the papers included in this session adopts a unique perspective on time research, drawing on diverse methodology and theory. We will discuss, for instance, how time and temporal cues impact motivation, influence information encoding and retrieval, make people happier, and make certain events funnier.

Paper 1 (Etkin and Ratner) will begin the session by discussing how cuing consumers to focus on pursuing ongoing goals in the near future (e.g., this week) versus far future (e.g., this year) impacts goal-directed motivation. Though prior work finds a focus on the future to improve goal-related performance, these authors demonstrate that in certain situations, focusing on the present (vs. future) is actually more motivating. Next, paper 2 (Baskin, Wakslak, and Novemsky) will discuss issues regarding differences in level of construal from when consumers first encounter and encode information (e.g., in an advertisement) to when they recall it at the time of choice. Results suggest construal level at time of choice plays a major role in decisions, relative to construal at time of encoding particularly in circumstances when construal is incidental to the stimulus.

Papers 3 and 4 examine emotional consequences of time. In paper 3, Mogilner and Norton show consumers tend to prefer experienced happiness to remembered happiness, except when the focal time period is short (minutes, hours). Thus, though people may generally prefer experienced happiness, in minute-to-minute decisions they instead behave in ways that maximize remembered happiness.

Finally, paper 4 (McGraw, Williams, and Warren) demonstrates consumers' humorous response to tragedies depends on their distance from the event. Moderately distant tragedies are more humorous than both close and far tragedies, consistent with predictions made by benign violation theory.

This session aims to bridge researchers who are looking at a variety of consumer research

issues through the lens of time and temporal distance. Through that lens, it raises several interesting questions such as how meaning evolves over the course of time and how focusing on the present versus the future impacts behavior. It will also stimulate discussion on the effects of time across multiple areas in one's life, both in the consumer and the personal realms. More specifically, several of the papers have implications that show marketers how to better position their products in ways in which people can make themselves happier. As such, the session aims to make a difference for people in terms of their overall well-being and raises questions about the implications of time in other related consumer domains.

In sum, our session integrates research on a wide range of consumer issues through the shared lens of time. Adopting such a perspective offers unique insights for consumer well-being and marketing practice. We expect the session to be of broad interest to ACR attendees, particularly to scholars interested in issues pertaining to goals, information processing, happiness, humor, and of course, time. We also hope the session will stimulate discussion of other ways in which time and temporal perspectives shape behavior, raising interesting questions for future research.

All research is in advanced stages, each with substantial empirical support (e.g., from field and laboratory studies).

Managing Motivation Over Time: How Focusing on the Present versus Future Influences Goal Pursuit.

EXTENDED ABSTRACT

Many of consumers' goals persist over long periods of time. Saving for retirement and being healthy, for instance, cannot be achieved in one night. These and other 'ongoing' goals (e.g., being successful in one's line of work, having close relationships with family) require that consumers behave consistently with their goal in the present but also well into the future, and potentially for a lifetime.

Given the long-term nature of ongoing goals, one might expect looking ahead to the future (rather than simply focusing on the present) would be critical for achieving successful outcomes. Indeed, consumers' propensity to plan for the future predicts wealth accumulation (Ameriks, Caplan, and Leahy 2003) and satisfaction upon retirement (Elder and Rudolph 1999). Alternatively, focusing on goal pursuit in the future might make the goal 'loom large', or seem broader in scope. If consumers feel overwhelmed by goal pursuit, they may be more likely to disengage. When will focusing on goal pursuit in the present versus future be motivating versus demotivating?

In this research we suggest that how focusing on present versus future goal pursuit impacts motivation critically depends on whether consumers perceive they are in early or later stages of goal pursuit. Recent work suggests what drives goal-directed motivation evolves as consumers progress toward their goal (Etkin and Ratner 2012; Fishbach and Dhar 2005; Zhang and Huang 2010). When perceived

progress is low, consumers tend to be more concerned about the attainability of their goal, whereas when perceived progress is high, consumers tend to be more concerned about the value of their goal (Huang and Zhang 2011; Zhang and Huang 2010). Thus, factors that make one's goal seem more attainable should be motivating at early stages of goal pursuit, whereas factors that make one's goal seem valuable (i.e., important) should be more motivating at later stages of goal pursuit.

We suggest whether consumers adopt a present versus future focus for goal pursuit will mitigate (vs. exacerbate) their attainability and value concerns. Thinking about pursuing a goal over the next few days (i.e., present) should make the goal seem smaller in scope, and goal pursuit more manageable. Conversely, thinking about pursuing the same goal over the next few months or years (i.e., future), should make the goal seem larger in scope, and goal pursuit less manageable. Thus, focusing on goal pursuit in the present (future) should mitigate (exacerbate) goal attainability concerns, but exacerbate (mitigate) goal value concerns. Because consumers who perceive low goal progress to-date are attuned to fluctuations in goal attainability, we predict present (vs. future) temporal cues will increase motivation when perceived progress is low. In contrast, because consumers who perceive high goal progress to-date are attuned to fluctuations in goal value, we predict future (vs. present) temporal cues will increase motivation when perceived progress is high.

A series of studies supports our predictions. In study 1, we manipulated perceptions of progress (low vs. high) towards a fitness goal and asked participants to think about pursuing their goal over the next seven days (present) or over the next seven weeks (future). We find focusing on goal pursuit in the next seven days (vs. weeks) increased motivation among participants who perceived low goal progress ($M_{\text{days}} = 5.58$, $M_{\text{weeks}} = 4.65$; $F(1, 72) = 4.24$, $p < .05$), but decreased motivation among participants who perceived high goal progress ($M_{\text{present}} = 5.05$, $M_{\text{future}} = 6.18$; $F(1, 72) = 6.39$, $p < .001$). Consistent with our theorizing, focusing on the present (this week) boosted motivation for those who perceived they were in early stages of goal pursuit, whereas focusing on the future (the next two months) boosted motivation for those who perceived they were in later stages of goal pursuit.

Study 2 replicates this interaction pattern in a different goal domain: savings goals. We measured participants' perceptions of progress towards their savings goal and then introduced them to a real website (SaveUp.com) designed to facilitate saving money. We asked participants to think of SaveUp as a tool to help people save money 'right now' (present) versus 'over the next year' (future), and recorded whether they signed up for an account as a measure of motivation. We found the present (vs. future) cue increased sign-ups among participants who perceived low goal progress, but decreased sign-ups among participants who perceived high goal progress toward their own savings goals.

Our subsequent studies investigate moderators and mediators of these effects. For example, two studies demonstrate that self-efficacy (measured in one study and manipulated in another) moderates the impact of temporal cues on motivation for low-progress consumers. Results suggest low-progress consumers differ in the extent to which they are concerned about goal attainability, and therefore the extent to which focusing on the present (future) is motivating (demotivating). Consumers high in self-efficacy (Jerusalem and Schwarz 1992) feel confident in their ability to achieve their goals, despite being in a (temporary) state of low progress. Consistent with our prior studies, near (vs. far) future temporal cues increase motivation for low-progress consumers low in chronic (or situationally-induced) self-efficacy. Among low-progress consumers high in self-efficacy,

in contrast, far (vs. near) future temporal cues increase motivation, similar to high-progress consumers.

Many of consumers' most important goals are ongoing quests that require persistence over time. Understanding factors that enable (or detract from) consumers' ability to stay motivated to pursue ongoing goals thus has important implications for consumers and marketers alike. Our results suggest maintaining a high level of motivation may require strategic management of whether consumers look to the future, or instead, focus on goal pursuit in the present.

What was I Thinking? Effect of Construal on Memory-Based Choice.

EXTENDED ABSTRACT

Construal Level Theory (CLT) argues that one's construal level, or the degree to which one represents information concretely vs. abstractly, has a broad influence on attitudes, choice, and related behavior (Trope and Liberman, 2010). Despite the theory's wide impact, a fundamental aspect of the theory's mechanism is still unclear. Consider a situation where information is encountered long before a decision relevant to that information will be made. For example, consumers encounter most advertisements far from the moment of choice. This type of situation raises an important question about how construal operates: does abstract construal at the time of encountering a stimulus determine the effect of that stimulus on a later choice or does the concrete construal at the time of choice determine the effect of the previously encountered stimulus? In other words, does construal operate at encoding, causing the memory representation to reflect the encoding level of construal or does construal operate at the time of retrieval via differential weighting of information from a construal-free memory representation? In our research, we examine decisions where all the information has been learned before the moment of choice to discriminate an encoding and a retrieval account of CLT effects.

Across all studies, we use a single paradigm in which participants learn information at one point in time (with or without making a choice) and later make a choice based on their memory of the information they saw before. Construal level at exposure and final choice were independently manipulated. In order to remove potential ceiling effects, all studies involved choices between 2 vacation destinations that had 4 feasibility attributes and 4 desirability attributes. One of the vacations was high on desirability and one was high on feasibility.

In Study 1, participants were asked to choose between 2 vacation destinations that involved desirability/feasibility tradeoffs at time 1 using a superordinate/subordinate categories manipulation where participants were asked questions that required them to identify either the superordinate or the subordinate category of an item. After completing a series of unrelated tasks for 10 minutes, participants were asked to choose between the same vacation destinations under either the same or a different temporal construal. This time no information about the vacations was presented, leaving participants to rely on their memory of the vacations. An attentional mechanism would produce a main effect of time 1 construal on time 2 choice or an interaction while a weighting mechanism would predict only a main effect of time 2 construal. Only a main effect of time 2 construal was found suggesting that construal level does not influence memory representations, but rather operates through an attribute weighting mechanism.

Memory of attributes was also tested. Even though participants remembered about half of the attributes, on average, the ratio of feasibility to desirability attributes remembered did not differ by con-

dition suggesting that memory was not affected by construal at the time of encoding even though construal at the time of encoding did affect choice at encoding.

Finally, this study also included a mouselab type measure that allowed us to record which attributes participants were viewing and for how long. These measures also showed that while time 1 preferences were consistent with the construal level at that time, there were no differences in the number of feasibility/desirability attributes viewed or the amount of time spent viewing them.

While study 1 asked for a choice at time 1 as well as time 2, study 2 did not ask for a choice at time 1 in order to show that choice is not required to establish product memory. Also, we used different types of construal manipulations at time 1 and time 2 to avoid artificial dominance of the time 2 construal manipulation. Construal at time 1 was manipulated using the how?/why? manipulation that has been shown to reliably change construal level (Freitas, Gollwitzer, and Trope, 2004) while construal at time 2 was manipulated using a temporal distance manipulation similar to those used in the earlier experiments. The results showed only a main effect of time 2 construal consistent with the idea that construal operates only at retrieval. Study 2 memory results were consistent with Study 1.

Finally, to generalize our results to a longer time span, Study 3 used vacation choices with 48 hours between information exposure and choice. Results were consistent with our previous studies. This study also reconciled our results with somewhat differing results found by Kim, Park, and Wyer (2009). In their study, they found effects of construal level at encoding after using temporal construal manipulations at Time 1. Study 3 replicates their study and compares their temporal manipulations, integral to the stimulus itself, to our manipulations, which are more priming based and incidental, suggesting that there is a difference in the way that these two forms of construal affect encoding in memory. Study 3 results suggest that integral manipulations do affect attention and memory while incidental manipulations do not.

In sum, across a series of 3 studies manipulating the construal level under which participants learned information as well as retrieved it to make choices, we find that construal level at final choice is a major factor in decisions, for both long and short delays. Furthermore, these findings have theoretical implications for CLT suggesting that construal does not seem to influence attention or memory representations unless the construal level is integral to the stimulus itself.

Philosophies of Happiness: Preferences for Experienced and Remembered Happiness

EXTENDED ABSTRACT

Which life would you prefer: a life where you experience happiness on a moment-to-moment basis such that you feel happy during your life; or a life that you reflect back on and feel happy thinking about and remembering? Now, imagine answering this same question for just your next hour, rather than for your life overall – would you choose an hour of experienced happiness or remembered happiness? We explore not only people's preferences for happiness, but also examine how these different philosophies of happiness play out in how people spend their hours – and ultimately how they live their lives.

Blaise Pascal observed, "All men seek happiness. Whatever different means they employ, they all tend to this end." Although everyone wants to be happy and research has begun informing this universal pursuit, the factors shown to be associated with happiness seem to be largely dependent on how happiness is assessed (Kahen-

man and Deaton 2010; Nelson et al. 2012; Stone et al. 2010). While some of the research treats happiness as a moment-to-moment state, where the goal is to optimize the happiness people experience over the course of their daily lives (Csikszentmihaly and Hunter 2003; Kahneman et al. 2004; Killingsworth and Gilbert 2010; Mogilner 2010; White and Dolan 2009), other research asks people to evaluate their happiness by reflecting back on their lives more generally (Diener, Emmons, Larsen, and Griffin 1985; Easterlin 1995; Lyubomirsky and Lepper 1999). Kahneman (2011) describes this distinction as experienced happiness (being happy *in* your life) versus remembered happiness (being happy *about* your life). Although there has been considerable research identifying factors that are associated with each kind of happiness, researchers have not asked people which form of happiness they would prefer. In short, we ask the question: which happiness are people looking to optimize?

We asked 398 individuals from across the United States to choose which of these two forms of happiness they would prefer, and we varied the time frame under consideration such that participants chose between experienced and remembered happiness for their life, the decade, the year, the month, the week, that day, that hour, or that minute. Overall, most people (67%) chose a life experienced as happy over a life remembered as happy (33%). This preference held irrespective of gender, age, income-level, marital status, having children, and reported life satisfaction; indeed, the only individual difference that had an effect was impulsivity, with highly impulsive people being even more likely to choose an experienced happy life (88%) over a remembered happy life (12%). Most interestingly, this preference for experienced happiness persisted for all of the time frames except the minute and the hour. When choosing for these shorter time frames, individuals preferred remembered happiness (58%) over experienced happiness (42%). Because minutes and hours necessarily add up to days and weeks, these results suggest a possible mismatch between short-term and long-term preferences: overall, people want a life of experienced happiness, yet in any given minute they choose remembered happiness.

We tested the robustness of these preferences in a different sample of 203 Americans who were presented with this choice of happiness for all seven time frames in a within subjects design. The results persisted: 74% chose a life experienced as happy over a life remembered as happy (26%). Again, this preference reversed for shorter time frames, with 73% choosing a minute remembered as happy over a minute experienced as happy (27%). Interestingly, this preference reversal did not occur among participants who were first presented with the choice for their life (rather than for the minute). Among these participants, preference for experienced happiness persisted through to the smaller time frames, suggesting that starting in an "experienced" mind frame in the long-term may help people choose experienced happiness in the shorter-term as well.

Thus, it appears that there is a general preference for experienced happiness over remembered happiness; however, when considering smaller time frames, people are generally more likely to prefer remembered happiness. Indeed, when we manipulated a week-long vacation to be perceived as shorter in another study, we saw the preference for experienced happiness decrease. Specifically, we asked a sample of university students to choose between experiencing or remembering happiness for their upcoming Spring Break, which was highlighted on either a year calendar (making the break seem relatively short) or on a month calendar (making the break seem relatively long). There was also a control condition with no calendar shown, for which the results looked very much like the long break condition, in which most (77%) chose a vacation experienced as happy over a vacation remembered as happy (23%). However,

when led to view their Spring Break as shorter, students' preferences for experienced happiness significantly decreased (to 60%).

Not only is one's philosophy of happiness malleable, but the philosophy one adopts manifests in distinct behaviors. For instance, Spring Breakers who chose experienced happiness were more likely to spend their vacation relaxing on the beach, whereas those who chose remembered happiness were more likely to spend their vacation days volunteering. Similarly, individuals whom we instructed to maximize their experienced happiness reported being more likely to spend the next hour relaxing, whereas those whom we instructed to maximize remembered happiness reported to be more likely to spend that hour working or volunteering.

Although people's lives are the sum of the minutes and hours they spend, our results demonstrate that individuals seek to maximize different versions of happiness when considering these different time frames. And if people decide how to spend their next hour in pursuit of remembering happiness (as our results suggest), they might miss out on their preferred life of experienced happiness.

The Psychophysics of Humor

EXTENDED ABSTRACT

Psychological distance (due to the passage of time, degree of social familiarity, differences between geographical locations, or degree of reality) is an important factor in transforming tragedy into comedy (McGraw et al. 2012; Morreall 2009). Understanding how psychological distance influences humor perceptions has implications for happiness (enjoying life), advertising (knowing who to target with humorous ads, and when), coping (transforming pain into pleasure), and sensitivity (avoiding "too soon" comedy fails).

In contrast to theories that explain why distance linearly increases perceptions of humor (McGraw et al. 2012), we draw from the benign violation theory to predict a curvilinear relationship. There is a sweet spot to comedy in which humor in response to a tragedy will rise and subsequently fall with distance.

The benign violation theory proposes that humor occurs when something that seems wrong, threatening, or unsettling (i.e., a violation) simultaneously seems okay or acceptable (i.e. benign; McGraw and Warren 2010). For example, tickling is physical attack that does not cause true harm (Koestler 1964; Veatch 1998). The theory suggests two ways that something may fail to elicit humor: it can be purely benign (tickling oneself) or purely violating (a stranger does the tickling; McGraw and Warren 2010; Veatch 1998). Humor requires the right balance of threat. Too much threat reduces humor by making it difficult to see things as benign, whereas too little threat reduces humor by making it difficult to see a violation.

Psychological distance reduces threat (Mobbs et al. 2007; Williams and Bargh 2008). Thus, the benign violation theory predicts that increased psychological distance (e.g., passing time) alters whether an event seems purely violating (insufficient distance), a benign violation (the right amount of distance), or purely benign (too much distance). We thus expect that a tragic event (a severe violation) can be transformed by passing time (or other forms of distance) into something that is humorous (a benign violation) and then into something that is boring (a benign situation) producing a curvilinear relationship between distance and humor.

Hurricanes are anticipated tragedies, providing a unique opportunity to examine the influence of distance on humor found in social media content. As Hurricane Sandy approached the New York metropolitan area, people were already joking about it. @AHurricaneSandy tweeted, "It's RAINING men. Literally. I just picked up a bunch of dudes and threw them." To illustrate the dynamic inter-

play between the passage of time and humor, we presented online samples of participants potentially humorous tweets about Hurricane Sandy before, during and after the hurricane hit the northeastern US. We recruited participants at nine time points: one day before the hurricane hit the northeastern United States, the day the hurricane made landfall there, and again numerous days and weeks following the natural disaster. At each point, participants evaluated the humor in three tweets related to Hurricane Sandy.

Humor is highest at wave 0 (the day before the storm hits), then drops to its lowest point at wave 4 soon after the storm hit (16 days), goes back up to a second peak at wave 7 after more time has passed (36 days), and drops again at wave 8 (64 days) as the event starts to become a distant memory. These data suggest that (1) in the immediate wake of the storm, it is "too soon" to find humor in jokes about it, (2) with distance, it becomes "okay" to find humor in such jokes, but (3) with too much passage of time, jokes about the tragedy lose their punch. In a one-way ANOVA treating wave as a random factor, we find that humor significantly varies across time, $F(8, 908) = 2.60$, $p = .008$, partial eta-squared = .02. Contrast tests support a non-linear view of time on humor, as the linear contrast was not significant, but the quadratic ($p = .004$) and cubic contrasts ($p = .003$) were reliable.

We suggest that psychological distance creates a sweet spot in which one is most likely to find humor in tragic events. The sweet spot should vary as a function of the degree of tragedy or threat. More severe violations (vs. less severe violations) should stay longer in the "too soon" category, thus taking longer to get to the "just right" sweet spot. They should also take longer to become benign and fall into the "too late" category. To illustrate we asked an online panel to provide examples of tragedies (severe violations) and mishaps (mild violations). First, participants described an event that, "observers would generally agree is so bad that it is a tragedy, but can be joked about" (e.g., "a piano falling on one's head"). Next, participants described an event that, "observers would agree is bad, but falls well short of being a tragedy, and can be joked about" (e.g., "breaking a leg"). Participants then indicated either when it is "too soon" to find humor, or "too late" to find humor, in jokes about the previously listed events.

Participants indicated that it takes longer for it to become "okay" to joke about severe tragedies (median = 30.4 days) compared to milder negative events (median = .04 days). It also takes longer for it to become "too late" to joke about severe tragedies (median = 547.5 days) compared to milder negative events (median = 182.5 days). Hence, when it comes to finding humor in tragic events, the severity of the event determines the best time to joke about it. We conducted a 2 (severity) X 2 (timing) repeated measures ANOVA, with severity (tragedy vs. mishap) serving as the within subjects variable and timing (too soon vs. too late) serving as the between subjects variable. Most critically, the analysis revealed a main effect of severity, $F(1, 93) = 18.9$, $p < .001$.

Human history is rife with tragedy, and triumph over tragedy. Psychological distance is an important factor in triumphing over tragedy, first through humor and next through irrelevance. The dynamic nature of humor challenges the leading theories of humor and psychological distance, but it is supportive of a benign violation approach to humor and a threat reduction approach to psychological distance.

SESSION OVERVIEW

If one could wish for two gifts that would substantially improve life, having money and strong close relationships would be ideal candidates. Money and relationships, while being able to improve life's outcomes, do so by dramatically different routes and mechanisms—and yet have significant overlap too. This session peers into the consequences that money and close relationships have for one another—and in doing so reveals some thought-provoking patterns for scientific understanding and consumer welfare.

This session features cutting-edge research in the psychology of money and relationships, and seeks to answer two important questions: 1) How can individuals' close relationships influence their perceptions of and decision-making with money? 2) Conversely, how can decisions about money influence the behavior and perceptions within relationships? This session explores two fundamental areas of research in consumer research and seeks to understand the theoretical and practical implications to aid consumer well-being.

The first two talks investigate how close relationships can influence perceptions of money and decision-making with financial assets. Vohs starts the session by examining how social support and money can be treated as interchangeable resources. Vohs and Lasaleta demonstrate the *substitutability hypothesis*: when people have strong close relationships and feel supported by others, individuals have less desire to obtain and hold onto money. Shah investigates the interaction between social support and money by exploring how marital status can affect financial portfolio compositions. Women make safer asset choices when they are single, divorced, or when they receive an income shock while married as compared to men.

The last two papers examine how money can influence perceptions and attitudes towards relationships. Goldstein discusses how perceptions and attitudes within relationships change when lending or borrowing money. The researchers show that there is a unique exchange expectation in lending relationships in comparison to gift-giving for example, regarding what types of goods or services the

recipient is expected to consume with the borrowed money. Lenders believe that they are entitled to a certain level of control over the borrowers financial decisions, reporting frustration and anger when they feel money has been misused. At a system level, these results help explain why American taxpayers were so outraged by seeing their money being used by the government to fund indulgences such as bonuses, resulting in subsequent tax avoidance and evasion. The final talk by Lambertson examines how to reverse this result and increase satisfaction and compliance. The authors demonstrate that providing consumers with an opportunity to voice their opinions about spending priorities increases tax compliance.

In summary, this session investigates the interactive nature of money and relationships. Using a diverse set of methodologies these papers have incredible implications for policy and societal well-being, as well as basic scientific understandings of the psychology of money and relationships. This session will appeal to researchers interested in the self, interpersonal relationships, judgment and decision-making, as well as those interested in policy or managerial decision-making. As a consequence we expect that a diverse set of scientists, policymakers, and scholars will find value in the session.

With Friends Like These, Who Needs Money? Three Tests of the Substitutability Hypothesis of Money and Social Support

EXTENDED ABSTRACT

Rich people have fewer friends than the rest, according to a Gallup poll (2004). Respondents whose income was at the top of the scale reported having the fewest friends, while those making the least money reported having the most friends.

There are many possible explanations for these stylized facts. One is that having or being around money creates a preference to be alone or an inability to make friends. Another is that having many friends weakens the desire or ability to obtain money. (Of course, there are third-variable explanations too.)

Our theory is that there is something correct about the two direct association explanations. People seem to treat money and social support as interchangeable resources, a claim that we have termed the *substitutability hypothesis*. This hypothesis predicts that to the extent that one resource is seen as plentiful, people will act as if there is little need to pursue the other. There already exists evidence supporting one form of the substitutability hypothesis, that money can substitute for relationships with others (e.g., Vohs et al. 2006; Zhou et al. 2009). Therefore, our investigation tested the novel hypothesis that when people feel that they have ample support from others, defined as the perception that one is cared for by others (Wills, 1991), they have less desire for money, defined as the motivation to obtain and hold onto money. Three experiments supported this hypothesis.

Aim: Experiment 1 was the initial test of the substitutability hypothesis. *Method:* Participants (n=39) were instructed to recall instances of social support or the number of facts they had learned throughout their lives. Next, participants ranked a list of twelve life values and traits in order of personal importance (adapted from self-affirmation research). This list included business skills and financial success, both related to the acquisition of money. *Results:* In an initial show of our hypothesized effect, participants who recalled in-

stances of social support ranked business skills and financial success as less important than those who recalled number of facts learned.

Aim: Experiment 2 provided a conceptual replication of the effect using different measures of desire for money: worry over money and willingness to pay. We reasoned that as desire for money weakens, people would be less worried about it, and more willing to give it up for goods and services. Experiment 2 also aimed to address an alternative explanation for the proposed effect. It is possible that recalling instances of social support heightens positive affect, which could affect how much people care about money. *Method:* Participants ($n=119$) rated the number of friends they talked to every day on scales that cued a social network that was small (low social support condition) or large (high social support condition). Next, participants completed a worry over money scale and indicated their willingness to pay for twenty-two items. *Results:* As predicted, participants who were cued to see themselves as having a more expansive network reported less worry over money and greater willingness to pay for goods than those cued by a smaller social network. As expected, there was no effect of condition on positive or negative mood reports. This rules out an alternate explanation of our effects based on changes in mood.

Aim: Experiment 3 further tested our theory using a face valid measure of desire for money and provided process evidence. *Method:* Participants completed the same manipulation from Experiment 1, recalling either number of facts learned or friends made throughout their lives. Participants then completed a standard measure of social support (Social Connectedness Scale – Revised; Lee, Draper, and Lee, 1991) to provide process evidence. Next participants completed a money importance scale as an indicator of desire for money (sample item: “Frankly speaking, having money is something that I value”). *Results:* As predicted, participants who were reminded of their friends expressed less money importance than those reminded of facts. Process evidence revealed that the effect was mediated by increased perceptions of social support.

Conclusion: Three experiments demonstrated evidence in support of the novel hypothesis that feeling socially supported weakens the desire for money. More broadly, this work supports the *substitutability hypothesis*, which states that people treat money and social support as interchangeable resources. Both money and help from others can enable people to obtain what they want and need from society and culture, and the apparent substitutability of these resources translates into a diminished motivation to attain one when feeling flush with the other.

The current work connects two large literatures whose focus bears significantly on the daily lives of people worldwide, and yet do not connect much with one another. Close relationships constitutes a fundamental part of psychology, an entire field, economics, is devoted to the study of money, whereas marketing has interests in both relationships and money. What is therefore surprising is how little research there is on how these two motivations relate, which the current work seeks to rectify.

We opened the paper by noting that a Gallup poll (2004) presented an interesting association. Respondents with the highest incomes said that they had on average the fewest friends, whereas those with the lowest incomes said that they had the most friends. While wanting to be popular can drive people to engage in unhealthy behaviors and enter dangerous situations, a putatively bigger problem (perhaps especially today) is the powerful drive to have money, lots and lots of money. Our research suggests a way to offset its power — stoke a sense of social support and people’s motivation for money should wane.

Money and Marriage? How Marital Dynamics and Gender Differences in Risk Affect Financial Portfolio Composition Choices

EXTENDED ABSTRACT

Disagreements over money are widely believed to be one of the leading causes of divorce and separation in the developed world. Hence, it is perhaps unsurprising that examination of transitions in and out of marriages reveal large differences in financial portfolio decisions. Women invest a significantly smaller proportion of their portfolios in stocks when single. In contrast, men tend to significantly increase their stockholdings when single (e.g., Hinz et al., 1997; Barber and Odean, 2001). However, what remains unclear is how these gender differences manifest themselves in financial portfolio allocations.

We examine how portfolio compositions are altered when single individuals transition to marriage, or conversely when married individuals transition to divorce. We ask how varying income levels or sudden income shocks amongst men and women within marriage affect bargaining power and subsequent financial portfolio decisions? Finally, what psychological mechanisms account for these differences in financial risk-taking and changes in bargaining power in marital dyads? We suggest that gender differences in risk, specifically that women are more risk averse while men are risk seeking, can substantially influence how financial portfolios are composed within and out of marriage. We argue that wanting to ensure financial certainty for the future will mediate this gender and safer portfolio choice relationship.

We first used field data from the Panel Study of Income Dynamics (PSID), a nationally representative longitudinal survey of nearly 9,000 U.S. families to investigate whether intra-household frictions are significant predictors for explaining life-cycle portfolio choice. We found significant evidence that women, both individually and in dyads are more risk averse than men. This was reflected in stock allocation differences. Furthermore, our results were robust to alternative risky asset definitions, including investments in stocks, real estate, and holdings in private businesses. Also, the proportion of safer to risky assets was shifted towards safer holdings when women had sudden income shocks, such as a raise or inheritance, in comparison to men. We sought to dig deeper into this relationship across three experiments.

In Study 1, we investigated whether differences in risk was actually moderated by gender. We gave participants a series of twenty gambles to choose from varying the probability of winning and amount of money earned if won. Participants were given \$5 with each gamble costing \$1 to play. Individuals could choose to play up to five gambles at most or could choose to play none and keep the \$5. Women significantly ($p < 0.01$) chose less gambles to play overall than men and chose gambles with higher probabilities of winning in comparison to men demonstrating the gender disparity in risky decision-making with money ($p < 0.01$).

In Study 2, we sought to investigate how perceived marital status (i.e., single, married, divorced) influenced the relationship between gender and risky financial choices. We repeated the study design from experiment 1, but asked individuals to imagine that they were either single, married, or divorced during the decision-making process. We replicated the finding that women were more risk averse than men, but we found significant evidence that women made riskier choices when they were in the marriage stage as opposed to single and divorce. In

In Study 3, we wanted to investigate the potential mechanism of why women and men acted differently regarding financial decisions

within and outside of marriage. We repeated the same study design as the first two experiments but told participants that in addition to their \$5 they were given for gambling, they would be given an additional either \$1 or \$5 in order to mimic a sudden income shock. Women made safer asset choices when single or divorced, and also made safer choices when they received larger income shocks. This effect was mediated by wanting to ensure future financial certainty, especially for their family. Thus, it is clear that relationship stage can influence decisions with assets. Also, it seems that the need for financial certainty for the future, or in other words wanting to protect resources for one's future family also influences safer or riskier choices with money.

Such differences are interesting in documenting a potential mechanism for better understanding how and why marital status, gender, and intra-household bargaining can affect financial portfolio decisions over time.

The Psychology of Borrowing and Lending

EXTENDED ABSTRACT

How do we feel when other people – like our friends and family – spend our money? A great deal of research explores the factors that influence our satisfaction with the goods and services that we consume with our own money (Bearden and Teel 1983; Spreng et al. 1996; Van Boven and Gilovich 2003). However, there is surprisingly little research on the factors that influence our satisfaction with the goods and services that *other people* consume with our money. In particular, we explore the case in which one person loans another a sum of money and then must watch (uncomfortably) as that borrower spends that cash before paying it back to the lender. We suggest that this mixing of friendship and finance can quickly go awry, harming relationships in the process.

Researchers have drawn distinctions between market and communal relationships (Fiske 1992) and the unique currency (i.e., financial and social, respectively) that is acceptable for exchange within each (Heyman and Arieli 2004). Situations that blend the two types of exchanges – like close friends loaning money to each other in the manner of a bank – often have unexpected consequences.

Exchange relationships between lenders and borrowers are unique but prevalent; the implications can be small, ranging from a cup of sugar lent to one's neighbor, to monumental in the 2008 example of the federal government loaning A.I.G. money in the largest bailout in American history (Walsh 2008). Due to the everyday and large-scale implications of lending relationships, it is important for researchers to understand how the details of the exchange, the purchase, and different expectations influence satisfaction with the various dimensions of the lending and borrowing experience.

In our research, we demonstrate that lenders and borrowers differ in both (a) how they mentally account for the loaned funds (Thaler 1985) and (b) the expectations they have for how the money should be spent. We argue that this asymmetry between lenders and borrowers contributes to the dissatisfaction with the lending experience, affecting the relationship and influencing whether lending will occur again.

Our first study demonstrates that *what* the borrower purchases influences the lenders' satisfaction. Participants read a scenario in which they imagined they had loaned a certain amount of money to an acquaintance. Some participants learned that the borrower made a utilitarian purchase with the money (a textbook), whereas other participants learned the borrower made a hedonic purchase (music from iTunes). Participants reported more anger towards borrowers who made the hedonic purchase than borrowers who made the utilitarian

purchase. Participants also viewed borrowers that made the hedonic purchase as more selfish and ungrateful than borrowers who made a utilitarian purchase.

Study 2 explored whether these different reactions to borrowers buying hedonic or utilitarian products was unique to lending experiences – experiences that mix market and communal relationships. We compared three types of exchanges: one where a gift was given to a recipient (communal), one where a payment was made to a recipient (market), and one where a loan was made (mixing the two). As in Study 1, we also manipulated whether the recipient spent the money on a hedonic or utilitarian good. Consistent with predictions, participants reported more anger if the borrower purchased a hedonic item (versus a utilitarian one), but those who had loaned the money (versus gifted or paid) reported the most anger. These results suggest that there is a unique exchange expectation in lending relationships regarding what goods or services the recipient is expected to consume with the money they borrowed.

In Study 3, we explored whether these effects were limited to loaning *money* to borrowers, as opposed to lending other tangible resources, such as products. Specifically, whereas money is fungible, a tangible good like a video game is not. Participants read a scenario where they either lent a friend a video game worth \$50 or loaned the friend \$50 cash. Participants again reported being angrier with the borrower who purchased iTunes (versus textbook) whether they had lent them a game or loaned them money; those who loaned money (versus lent the game), however, reported the most anger.

In our last study we aimed to investigate whether the driver for lenders' anger was the expectation that they should be able to control what the borrower purchases. Through a sense of endowment for the loaned money, the lender might expect more influence over what the borrower purchases than what the borrower expects of the lender. We asked participants how much control borrowers (versus lenders) believe that lenders should have over what the borrower does with the money. Our results revealed that lenders believe they are entitled to far more control over what the borrower purchases than borrowers believe lenders to be. This result sheds light on the possible root of the anger that lenders feel when borrowers seem to "misappropriate" their loan (Studies 1-3).

Taken together, these findings provide insights into the psychology of interpersonal lending and borrowing. More broadly, the results help to explain the "outrage" (Reddy and Bendavid 2009) American taxpayers felt after discovering that much of the money the federal government loaned to companies such as A.I.G. went to employee retention bonuses (a luxury purpose). In this example – as with lending between friends – lenders (in this case taxpayers) believed that borrowers should use the loaned money for utilitarian purchases, and were enraged when borrowers seemed to indulge.

Increasing Tax Compliance by Empowering Taxpayers

EXTENDED ABSTRACT

Consumers would prefer to spend their money on nearly anything but taxes (Sussman and Olivola 2011). Given this deep-seated hatred of taxes, achieving tax compliance remains a challenge. In fact, as a result of tax avoidance or tax evasion, major public programs in the US are subject to funding shortfalls amounting to over \$300 billion per year. Despite the increased attention paid to financial decision-making by consumer behavior researchers, research has not yet documented interventions that increase tax compliance – behavior that can have hugely positive effects on public well-being.

We suggest that consumers' tax compliance can be significantly increased simply by providing them a structured opportunity to voice

their opinions about spending priorities. This voice opportunity is offered in a simple advisory allocation process, where consumers provide non-binding input regarding the way their tax dollars are spent. In addition, increased compliance appears to increase satisfaction with payment, suggesting that such an intervention could benefit not only the institutions that depend on tax dollars, but decrease the irritation that taxpayers experience when paying taxes.

Two experiments support these conclusions. In study 1, two-hundred and fifty-seven English speaking US citizens recruited via Amazon's Mechanical Turk panel received a nominal payment in return for their participation. Participants first provided basic demographic information, reported their tax filing status, and stated their gross household income. Some participants were then given the opportunity to provide input about the way that 10%, 25% or 50% of their tax dollars would be allocated across various categories currently used by the US government to describe tax spending (www.whitehouse.gov), while others were given no allocation opportunity. Then participants were asked to imagine that they became aware of a tax loophole that enabled them to avoid paying 10% of their income tax bill, and were asked if they would take the loophole.

When not given the opportunity to allocate, approximately 64% of participants indicated that they would take the questionable loophole. Allowing 10% allocation led to a significant decrease in likelihood of taking the questionable loophole (45%) relative to non-allocation (chi-square = 4.00, $p = .05$). This effect was larger when 25% allocation was offered, dropping to 39% (chi-square = 7.74, $p = .005$). However, allocating 50% of one's tax dollars did not decrease likelihood of taking the questionable loophole (51.5%, chi-square = 1.83, $p = .18$).

Study 2 sought to replicate this pattern of effects in a laboratory setting, using actual payment and introducing the possibility of audit. One hundred eighty-nine participants (40% male, age range: 23-40) attended a paid lab session, and were told that they could earn an additional \$10 for completing a task. However, they were informed that this additional payment would be subject to a 30% lab tax; they would leave \$3 in an envelope placed on their desk when they left the session. Participants were also told that approximately 1 in every 8 participants would be "audited," meaning that the experimenter would check the amount they had put in their envelope before they left the session. (This proportion reflects most US taxpayers' beliefs about audit likelihood). Non-compliant participants who were audited would be asked to both pay their overdue taxes and an additional penalty of \$2.00. Participants then completed the task and were given their \$10 payment. Participants were then randomly assigned to either the allocation or no allocation conditions. Participants in the no allocation simply put as much tax as they wished to pay in the envelope. By contrast, before continuing, participants in the allocation condition were told they could provide input as to how a portion of the lab tax dollars would be spent in the future, allocating their taxes across three categories: beverages for study participants, snacks for study participants, and enhanced incentives for future study participants. They then put as much tax as they wished to pay in the envelope on the desk in the same way as the no allocation participants had. Then all participants answered a number of questions about their satisfaction with paying taxes, demographic items, and beliefs about how taxes would be used. When all studies in the session were complete, lab administrators collected the envelopes and recorded the amount of money paid by each participant. Lab administrators also audited 1 in 8 participants, consistent with the instructions read by participants.

Analysis revealed a bi-modal distribution of compliance, such that most individuals either fully complied (\$3 in the envelope) or

did not pay any tax (\$0 in the envelope). This finding is consistent with patterns among actual taxpayers (Alm, Bloomquist and McKee 2012). An ANOVA using advisory allocation or no allocation to predict the amount of tax paid, using a negative binomial distribution, showed that individuals who were not offered an opportunity to allocate opinions paid significantly less in tax (\$1.58) than did individuals who provided advisory allocation (\$2.11, Wald chi-square = 4.18, $p = .04$). Further, we find that effects on compliance are mediated by participants' beliefs that taxes will support something they value (95% CI for indirect effect of allocation via value use: 0.01 to 0.14). This finding is consistent with Frey and Stutzer's (2000) suggestion that higher subjective well-being associated with other direct democracy actions can be attributed to "political outcomes closer to voters' preferences, as well as to the procedural utility of political participation possibilities."

In contrast, beliefs about audit likelihood did not explain compliance ($p > .5$), consistent with a large body of literature showing the relative ineffectiveness of stringent penalties in this domain (Isaac, Schmidt and Walker 1989). Most interestingly, we find that higher compliance also mediated participants' satisfaction with paying the lab tax (95% CI for indirect effect of allocation via amount paid: .01 to .13); this mediation does not however hold if causality is reversed. This finding is consistent with recent work suggesting that tax payment may create, rather than result from, satisfaction (Akay et al. 2012).

Future work will explore allocation's effectiveness relative to other interventions designed to increase compliance, examining their interplay and documenting their relative effects.

SESSION OVERVIEW

The financial crisis of 2008 that originated in the U.S. and the subsequent, ongoing economic crisis across the industrialized economies of Western Europe have focused societal attention on the importance of consumer preferences for (in)equality and social justice. This session sheds light on two questions that are at the core of the current political and public debate on inequality in many countries: How much (in)equality do consumers prefer, and what effects do different redistribution regimes designed to reduce income inequality have on consumer behavior and motivation?

Maddux, Frank, and Wertenbroch examine preferences for income (in)equality. They observe cultural differences in preferences for economic redistribution, both via individual incentive schemes as well as fiscal redistribution via income taxation, and demonstrate that these cultural differences are due to cultural variations in consumer just-world beliefs about the sources and deservedness of individual success. Kiatpongsan and Norton examine preferences for income-based health (in)equality. They assess Americans' perceptions of (in)equality of health-related outcomes along with their ideal distributions of these outcomes, showing not only that respondents underestimate the concentration of gains in life expectancy among the wealthy and overestimate gains in life expectancy among the poor but also that respondents prefer greater health equality among the rich and the poor than is currently the case. Rick, Paolacci, and Burson examine how income redistribution affects motivation to work. Contrary to normative predictions, they show that the mere presence of taxes decreases effort and accuracy in a repeated labor task. However, people who favor both redistribution and government intervention are actually motivated by the presence of a tax, resulting in increased productivity and earnings. Briers, Wertenbroch, and Riley examine how people's redistribution preferences affect consumption behavior. Specifically, they posit that people who favor less rather than more fiscal redistribution are more inclined to perceive

and display status consumption as a meaningful signal because they consider income to be more deserved, that is, because they have a stronger belief in a just world.

The objective of the session is to broaden the scope of consumer research into the political and macroeconomic realm, by linking theories from economics and social psychology to derive implications for consumer behavior in its social context. Because the papers in the session address key questions in the current political, public, and academic debate of (in)equality and social justice, we expect it draw a large and diverse audience of consumer researchers. In turn, we hope this session will foster further scientific efforts that will contribute to such debate with novel angles. The papers have experienced consumer researchers as authors and/or presenters, which may also help increase the visibility of the session. All empirical studies described in this session proposal are complete.

Deserved Fruits of Labor? Culture, Just-World Beliefs, and Preferences for Redistributive Incentive Schemes

EXTENDED ABSTRACT

Until recently, managers and business leaders have tended to assume that organizational reward systems are equally acceptable around the world. However, several recent high-profile failures highlight the potential hazards of applying a "one-size-fits-all" reward system around the world. For example, the failure of Wal-Mart's entry into Germany has been attributed in part to its unwillingness to embrace egalitarian German wage-setting practices (Knorr and Arndt 2003). Similarly, the Lincoln Electric Company, the subject of the best-selling Harvard Business School case study, failed initially when it tried to expand abroad from the U.S. The CEO said executives had mistakenly assumed that all cultures would be equally receptive to the company's performance pay system (Hastings 1999). The cultural acceptability of these systems, especially of "high-powered," individual performance incentives (Lazear 2000), is also of increasing relevance in the context of growing income inequality (Plender 2012). Thus, the French government recently discussed limiting top executive salaries in state-controlled companies from exceeding those of the lowest-paid employees to a ratio of 20:1. What makes different incentive schemes more or less preferable in different cultures?

We identify a particular psychological mechanism, linking cultural variations in social preferences for egalitarian versus performance-based compensation schemes to beliefs about the relationship between effort and success. Building on recent economic research on preferences for fiscal redistribution, we propose that cultural differences in preferences for compensation schemes are at least partly driven by cultural differences in "just-world beliefs" (JWBs, e.g., Lerner 1980). JWBs refer to individuals' general beliefs about whether the world is a fair place where people largely get what they deserve. In cultures where JWBs are relatively strong and the typical individual is seen to generally get what s/he deserves, performance-based compensation should be seen as fair and compensation schemes should be relatively motivating and desirable for employees. Thus, Lincoln Electric's reward system in the United States, a country relatively high in JWBs (e.g., Bénabou and Tirole, 2006), reflects James Lincoln's philosophy that each worker "must have a reward that he feels is commensurate with his contribution" (Lincoln 1951, p. 33),

which is consistent with the country's dominant cultural ethos. In contrast, in cultures where JWBs are weaker and the link between effort and performance is generally believed to be more tenuous, more equal payment schemes should be seen as fairer and thus be more preferred. Thus, in Europe, where JWBs are lower overall and where Lincoln stumbled, performance-based incentives were less successful. There, compensation practices are more regimented due to widespread collective bargaining (e.g., Flanagan 1999), which leads to wage compression (e.g., Kahn, 2000). This wage compression weakens the link between an individual's reward and her contribution and makes compensation inherently more redistributive than a system that aims to match wages and productivity.

An impact of JWBs on cultural differences in organizational reward systems and preferences for incentive schemes has not been noted in the literature. In hypothesizing an effect of JWBs on these preferences, we leverage recent cross-national analyses in economics of a link between JWBs and attitudes towards redistribution in the context of taxation and social spending (e.g., Alesina and Angeletos, 2005; Bénabou and Tirole, 2006). We build on the structural similarity between tax-based, fiscal redistribution and organizational incentive schemes, both of which can be designed to reward the results of individual performance (by taxing higher incomes at relatively low rates or by paying performance-based wages) or to redistribute them across group members (by taxing higher incomes at relatively high rates or by paying more equal wages for different degrees of performance). Based on this similarity between tax- and wage-based redistribution, we propose that cultural differences in JWBs impact preferences for more or less redistributive individual compensation schemes much like they impact preferences for more or less fiscal redistributive tax policies. Study 1 demonstrated a general correlation between the JWBs of a culturally diverse sample of former managers (measured with items from Rubin and Peplau 1975) and their preferences for performance pay on an individual task, controlling for expected task performance. Study 2 showed that American participants had stronger preferences for individual performance pay in an experimental task (controlling for task performance) and for lower general tax rates than French participants and that these differences were mediated by JWBs. Study 3 held culture constant in a moderation-of-process design and replicated these effects by experimentally manipulating instead of measuring JWBs, demonstrating the causal effect of JWBs on preferences for performance based reward systems while controlling for possible differences in cultural value systems (e.g., Siegel and Larson, 2009, on the role of egalitarian value systems; Tosi and Greckhamer, 2004, on the role of Hofstede's, 1980, power-distance and individualism).

In the current political and social debate about growing income inequality in countries around the world, our research provides guidance to policy makers and executives in gauging the cultural acceptability of different tax regimes and pay practices. We demonstrate that cultural variations in fundamental social beliefs about the causes of individual performance and success—about “how the world works”—are responsible not only for cultural variations in preferences for fiscal redistribution but also for redistributive reward systems.

Spreading the Health: Americans' Estimated and Ideal Distributions of Death and Health(care)

EXTENDED ABSTRACT

Recent debates in the United States about universal health care – with some viewing the 2010 Patient Protection and Affordable Care Act (or “Obamacare”) as a moral imperative but others viewing

it a government intrusion – have highlighted differences in opinion about how the costs and benefits of health care should be distributed among poor and rich Americans. Using two metrics – life expectancy and access to healthcare – we sought to measure people's understanding of how health is currently distributed among Americans, as well as assess their preferences for how health should be distributed. We then compared these estimates to the actual distribution. Importantly, we also explored whether Americans from across the political and income spectrums (rich and poor, liberal and conservative) showed consensus in their ideals.

415 Americans (58% female; age range: 18 to 74) estimated the distribution of outcomes for Americans in each of the five income quintiles in two domains: a) unmet need for prescription medications (unable to obtain prescription medication due to cost in the previous year) and b) gains in life expectancy (average increase in the number of months people lived over the previous 20 years). Respondents also reported their ideal distributions of death and healthcare – how they thought each should be distributed among Americans. These estimated and ideal distributions were then compared with the actual distributions.

Respondents' estimated distributions of unmet need for prescription medications as a function of income were fairly accurate. However, respondents underestimated the extent to which gains in life expectancy were concentrated among the wealthy and overestimated the extent to which gains in life expectancy were shared by the poor. Most importantly, estimated and ideal distributions differed significantly on both dimensions – unmet need for prescription medications and gains in life expectancy – such that respondents wanted these health outcomes to be spread more evenly among the rich and poor than they estimated them to be. Female, Democrats and lower income respondents preferred more equal health distributions compared to Male, Republicans and higher income respondents, respectively ($p < 0.05$ for all the comparisons). However, all respondents – male and female, rich and poor, conservative and liberal – desired more equal distributions of health outcomes than the current actual distributions in the United States.

In sum, estimated and ideal distributions of health and healthcare differ significantly, suggesting that Americans across the political and economic spectrum would prefer health and healthcare to be more equally distributed among the rich and poor.

The Effect of Income Tax on the Motivation to Work Depends on People's Cultural Philosophies

EXTENDED ABSTRACT

When income is based on effort and performance, daily decisions about how much and how hard to work can add up to influence one's financial well-being. We investigate how income tax influences the decision to work. Some have famously promised to exit the labor force in response to income tax. For example, many Tea Party enthusiasts have considered “going Galt” (quitting their jobs to reduce the amount of income tax the government can collect), inspired by *Atlas Shrugged* protagonist John Galt. However, despite decades of empirical research, economists have yet to reach a consensus on how income taxes influence labor force participation (Keane 2011). The lack of a definitive answer may be due to the conflicting effects of income tax posed by neoclassical economic theory. Income taxes make leisure relatively less expensive (substitution effects), but also make people poorer, producing a greater need to work (income effects).

Beyond income and substitution effects, income tax may impose psychological costs that influence labor force participation. Although people across the political spectrum prefer a more equi-

table distribution of wealth than currently exists in the United States (Norton and Ariely 2011), the interventions required to achieve that more equitable distribution (e.g., income tax) may be psychologically aversive to many.

To examine the psychology of taxation, some previous experimental research has investigated the effects of the mere presence of taxation (taxation that did not reduce net wages or increase consumer prices, and thus, from an economic perspective, should not influence behavior). Some studies have found that taxes are more aversive than comparable non-tax price increases (Hardisty, Johnson, and Weber 2010; Sussman and Olivola 2011), whereas others have found that people respond positively to taxes (e.g., Djanali and Sheehan-Connor 2012).

We propose that an important source of the mixed results is heterogeneity in what Kahan (2012) and colleagues refer to as “cultural philosophies.” Taxes involve both redistribution and government intervention, and thus the extent to which people find inequality aversive and endorse government intervention are likely to be influential. Such cultural philosophies are separable (correlated but distinct), stable, and differ widely across individuals. Regarding inequality, “Egalitarians” find it distressing, whereas “Hierarchists” are comfortable with existing levels of inequality. Regarding government intervention, “Communitarians” believe that it is needed to protect citizens, whereas “Individualists” object to government intervention.

To examine whether cultural philosophies influence reactions to income tax, we conducted a multi-round, incentive-compatible labor experiment in which we controlled for net wages. From a normative perspective, the presence of taxation that does not affect net wages should not influence productivity (persistence and accuracy). Psychologically, however, taxes may be irritating enough to forgo income unless people favor both redistribution and government intervention. As a result, the mere presence of taxation may reduce productivity among everyone except Egalitarian-Communitarians, who may actually be motivated by income taxes.

In our experiment, participants were given the opportunity to earn money by performing a tedious task. In each round, participants counted the number of zeros that appeared in a matrix of zeros and ones (cf. Abeler et al. 2011). Participants were assigned to a No Tax or Tax condition. In the No Tax condition, participants were paid 20 cents per acceptable response (a response within ± 1 of the correct response). In the Tax condition, participants were paid 40 cents per acceptable response, and 20 cents in tax was immediately deducted. The tax was redistributive: participants were told that their taxes would go to “students who participate in different studies with different tasks that do not allow participants to earn money themselves.” A paycheck, indicating their pay-rate and net pay for that round, appeared at the end of each round. Participants were told they could stop working at any time, and (unbeknownst to participants), they could complete up to 20 rounds. At the end of the study, following several filler items, participants completed the short form of the Cultural Cognition Worldview scales (Kahan et al. 2011). Our manipulation did not influence responses to these trait scales.

Overall, we found that taxed participants earned significantly less than non-taxed participants (even though taxes, by design, did not influence net wages). This was driven by taxed participants’ greater tendency to make more mistakes and to quit sooner. However, as predicted, we also found a three-way interaction between condition, communitarianism, and egalitarianism. Among Egalitarian-Communitarians, the mere presence of tax increased persistence, accuracy, and earnings.

The results raise the possibility that populations that include a high proportion of Egalitarian-Communitarians may be less resistant

to income tax. To address this question, we compared state-by-state responses to the 2010-2012 ANES Evaluations of Government and Society Study (EGSS) with state income tax rates (a proxy for resistance to income tax). The EGSS uses a representative U.S. sample and measures respondents’ state of residence. The EGSS includes nine items that capture Egalitarian/Hierarchical philosophies (e.g., “When women demand equality these days, they are actually seeking special favors.”) and three items that capture Communitarian/Individualist philosophies (e.g., “How much of the time do you think you can trust the federal government in Washington DC to do what is right?”). (In a pre-test, these EGSS subscales correlated strongly with the Kahan et al. (2011) subscales.) We averaged responses on the two subscales among respondents in each state, and then ran two regressions. In the first, we regressed the lowest income tax rate in each state on average Egalitarian/Hierarchical responses within the state, average Communitarian/Individualist responses within the state, and their interaction. The second regression utilized the highest income tax rate in each state as the dependent measure. As predicted, each regression revealed a significant interaction between egalitarianism and communitarianism: State income taxes were highest in states that were highest in both egalitarianism and communitarianism, and clearly lower elsewhere.

Taken together, the results suggest that income tax may generally reduce productivity, unless the population enduring the tax has a large proportion of Egalitarian-Communitarians. Such populations may support high income tax and work harder when income taxes are high.

Conspicuous Consumption Reflects How Redistribution Influences Perceived Social Justice

EXTENDED ABSTRACT

The market-based economies in the United States and Western Europe face what has been called a crisis of legitimacy. At the heart of this crisis lie questions about the extent to which unequal rewards and the resulting inequality of incomes in society are justified and deserved. The wealth gap between the top one percent of U.S. earners and the rest of society has more than doubled in the last 20 years (*The Economist* 2011), while growth rates of Western economies have slowed. Among calls for increasing taxes on higher earners to reduce income inequality and fiscal debt, policy makers have to stimulate consumer spending. To inform this debate, we examine whether perceptions of, and preferences for, status consumption as a reliable signal depend on redistribution preferences and their mutual association with just-world beliefs (BJW; Lerner 1980), specifically beliefs about how deserved variations in people’s income are.

Status consumption, also conspicuous consumption (Veblen 1899), is a meaningful signal of status only when it involves exerting effort or incurring other costs to obtain the signalled status (Grafen 1990; Miller 2009; Spence 2002). For example, Nelissen and Meijers (2011) found that the social benefits of wearing conspicuous clothing disappear when participants are aware that the clothes are not the beneficiary’s own, that is, when the beneficiary did not pay for the clothes. Status—and conspicuous consumption as a signal of status—is not meaningful when it is undeserved, that is, when it does not reflect exerted effort (Drèze and Nunes 2009).

The degree to which effort is a source of success reflects Lerner’s (1980) theory of the Belief in a Just World (BJW; Alesina and Angeletos 2005; Bénabou and Tirole 2006). BJW refers to the belief that individuals are responsible for their own fate and therefore generally receive what they deserve. Although it is highly functional to believe that individual outcomes are the predictable consequences of

people's behaviors (Lerner 1980), everyday life as well as statistical data often belie that belief. For example, Hochschild (1982) finds no difference in the effort invested by the top and bottom percentiles of earners, suggesting that hard work is not (highly) correlated with high income (Alesina and Glaeser 2004; Lerner 1980).

Alesina and Angeletos (2005) and Bénabou and Tirole (2006) model how beliefs about the role of effort as a determinant of individuals' success yield societal preferences for fiscal redistribution to reduce income inequality. A dominant social belief that individual economic success is highly correlated with personal agency and thus deserved (high BJW) yields regimes with relatively low redistribution, whereas a dominant belief that success is not (always) deserved (low BJW) yields regimes with relatively high redistribution. In turn, the resulting redistribution regimes also shape consumers' BJW and perceptions of deservedness (Alesina and Angeletos 2005; Bénabou and Tirole 2006).

We build on these reciprocal effects between just-world beliefs and redistribution to investigate how redistribution-driven perceptions of deservedness manifest in status consumption. If people in favor of lower redistribution tend to have a stronger BJW and thus a stronger belief that people's income is deserved, they should place more value on conspicuous consumption as a meaningful signal of deserved status. Alternately, if people in favor of more redistribution tend to have a weaker BJW and thus a weaker belief that people's income is deserved, they should value conspicuous consumption less as a meaningful signal of deserved status. We thus hypothesize that a preference for lower (higher) redistribution leads to a higher (lower) value of status consumption, and that this effect is driven by BJW. Data from two experiments and a national consumer survey support this hypothesis.

In Study 1, we directly tested whether manipulated redistribution attitudes affect the perceived deservedness of conspicuous consumption. The results indicate that people with a preference for lower (higher) redistribution are more likely to interpret conspicuous consumption as signal of deserved status. In Study 2, we then explored the mediating mechanism with a national panel survey that measured consumers' attitudes toward taxation, their BJW, and their value of possessions as a signal of success. It is shown that consumers' attitudes toward taxation affect their value of possessions as a signal of success and that this effect is driven by BJW. The correlational results of Study 2 are replicated in Study 3 in which manipulated attitudes toward redistribution via taxation are proven to affect preferences for conspicuous yet not for inconspicuous consumption (Griskevicius et al. 2007), again driven by BJW.

Our work adds to recent research that has begun to examine consumption behavior in its political and macroeconomic context (Cutright et al. 2011). Our contribution is threefold. First, we offer a theory of conspicuous consumption that extends beyond mere status signaling by linking it with recent economic theories of redistribution and beliefs about social justice (Alesina and Angeletos 2005; Bénabou and Tirole 2006). Thus, we show that beliefs about the causes of (in)equality, not just actual inequality (Christen and Morgan 2005) or equality (Ordabayeva and Chandon 2011), influence consumer spending. Second, by shedding light on the effects of redistribution on specific types of consumption, our theory adds a new facet to research on the complex and often contradictory effects of taxation on consumer spending and on the economy (Feldstein and Elmendorf 1990; Romer and Romer 2010). Third, we present initial experimental evidence that redistribution can undermine consumers' fundamental social beliefs, such as whether hard work results in deserved material wealth, a notion of major motivational importance in society and a key aspect of the American Dream.

SESSION OVERVIEW

Building on existing literature, the proposed session will contribute to a better understanding of how consumers engage with service firms. Research papers to be presented investigate this topic from multiple theoretical and substantive perspectives, offering a broader view of consumers' perceptions of positive and negative service relationships. Given the growing importance of service relationships for both service and product firms, a better understanding of how consumers react to and benefit from and are negatively impacted by good (vs. bad) service experiences is likely to have a significant effect on future research on consumer services. The proposed session will contribute to the understanding of several content areas that are of great interest to ACR conference attendees, including social closeness, consumer revenge, consumer vulnerability, and customer satisfaction.

Broadly, the four papers in the session explore consumers' response to service experiences. First, Anderson et al. examine the issue of consumer complaining through the lens of consumer vulnerability. They introduce a new the construct of *consumer vulnerability* and define it as a state that arises when individuals face potential high levels of perceived risk coupled with low levels of perceived control. The authors present a research model that shows a positive correlation between complaint rates and customer satisfaction levels which the authors theorize is driven by the differential vulnerability of the individual.

Building on this research, both Umashankar and Ward as well as Rohani et al. examine how consumers respond to service failures and how self-expression can sometimes mitigate the residual negative feelings the consumer harbors toward the provider. First, Umashankar and Ward observe how the social closeness between the service provider and the consumer impacts the way in which complaining affects consumers' perceptions of the firm after a service failure. They show that customers in close (vs. distant) relationships are less likely

to complain after a service failure, and that when consumers do so, close consumers feel more positive about the provider as a result, while distant consumers subsequently feel more negative about the provider. In related work, Rohani et al. look specifically, at consumers' desire to take revenge on the firm. They show that revenge can be mitigated with time and surveys. Specifically, the authors show that time reduces the desire for revenge when combined with answering multiple surveys as consumers experience some catharsis from giving feedback. However, the passage of time without the presence of surveys surprisingly has an amplification effect on desire for revenge.

Lastly, Fombelle et al. examine customer service experiences from the opposite perspective and investigate the effects of acknowledging very *satisfied* customers. The authors demonstrate the benefits of acknowledging positive feedback from consumers following a successful service experience. This research demonstrates that better management of the post-purchase process for the most satisfied consumers can provide substantial gains for firms in the form of increased patronage and loyalty.

The discussion will aim at facilitating a broader understanding of consumers' engagement (positive and negative) with service firms. Across the four papers, the way in which firms enable and respond to consumer feedback after a service experience will be considered with an eye on investigating the key questions of: How should and when should firms encourage consumer interaction after a service? How does the mode of expression affect consumers' subsequent perceptions and actions toward the firm?

Suffering in Silence: Close Customers' Reluctance to Complain Damages Service Relationships

EXTENDED ABSTRACT

Firms strive to create strong relationships between their service providers and customers (Yim, Tse, and Chan 2008). Indeed, strong customer relationships drive favorable word of mouth (Verhoef, Franses, and Hoekstra 2002), justify price premiums (Bolton 1998), and lower staff turnover (Sheth and Parvatiyar 1995), all of which leads to higher firm profits. Such relationships can be cultivated through close customer-service employee interactions, which help strengthen customer-firm linkages (Yim, Tse, and Chan 2008). Furthermore, the extant literature on customer service relationships touts the benefits of close customer-service employee relationships insofar as when something goes wrong, consumers are more forgiving if the service relationship is built on friendship rather than on an exchange relationship (Goodwin 1996). However, more recent research suggests that close relationships with customers may not always benefit the firm. In fact, when consumers have a 'friendship' with the firm, in some instances they have stronger negative reactions to a service failure (Wan, Hui, and Wyer 2011). Yet, the few papers that exist in this area largely focus on customers' perceptions of a service failure as the outcome of interest rather than the consequences of these perceptions, for the firm. Wan, Hui, and Wyer (2011) aptly note that future research should consider, "Other reactions, such as complaining and switching service providers."

In this research, we build on prior findings and consider how providing feedback may impact consumers' subsequent behavioral responses to the provider (i.e. perceptions of the provider, consumer loyalty) after a service failure or a delightful customer experience.

The act of self-expression (in the form of complaining or complimenting) can be beneficial for consumers as complaining is cathartic and enables them to air their grievances and express their disappointment while complimenting may intensify the positive experience (Bearden and Oliver 1985; Alicke et al. 1992; Dunn and Dahl 2012; Pennebaker and Beall 1986). However expressing one's opinion can also make the issue more salient to the individual. We identify the moderating variable of social closeness in differentially predicting whether self-expression is beneficial or detrimental to consumers' loyalty to the firm after a service failure. Research on social closeness indicates that although individuals in close relationships are more likely to self-disclose, they are also motivated to limit direct, negative feedback or express negative emotions in order to keep the relationship intact (Bell 1978; Locke and Horowitz 1990; Sommers 1984).

Given the extant research on self-disclosure to close others, we predict that customers in close (vs. distant) relationships will be less likely to provide feedback (complain) after a service failure, whereas they will be more likely to complement the provider following service delight. Furthermore, we predict that when consumers do complain, close consumers will feel more positive about the provider as a result, while distant consumers will subsequently feel more negative about the provider. Three studies support these predictions.

Study 1

In our first study we asked participants to recall and describe a very poor (vs. delightful) service experience with a close (vs. distant) service provider. Participants were then asked whether they gave feedback to the service provider. The data reveal a main effect such that participants were more likely to give feedback to the provider after receiving a delightful experience. However, as predicted the main effect was qualified by a marginal interaction with social closeness such that after a poor experience, individuals were more likely to give feedback to a distant (vs. close) service provider ($F(1, 134) = 3.65, p < .06$).

Study 2

Based on the open-ended responses to Study 1, we created a scenario that drew from common experiences reported by our participant pool. In our second study, participants read a scenario which manipulated both the service experience and the social distance between the participant and the service provider. In a 2 (service experience: poor vs. delightful) \times 2 (social closeness: close vs. distant) experiment, participants read about receiving an excellent (vs. terrible) haircut from a hairdresser with whom they had a very close (distant) relationship. Again, the data reveal a main effect such that participants were more likely to give friendly feedback after receiving a delightful (vs. complaining after a bad) experience ($F(1, 152) = 19.24, p < .0001$). However, a marginal social closeness by experience interaction ($F(1, 152) = 3.75, p < .05$) was also replicated, indicating that when consumers who receive a disappointing (vs. pleasing) service from a close (vs. distant) provider, they are less likely to voice their dissatisfaction.

Study 3

Finally, we more closely examine the process of giving feedback after a bad experience, and how giving feedback effects consumers' subsequent desire to return to the service provider. In a 2 (social closeness: close vs. distant) \times 2 (subsequent complaint: complain vs. no complain) experiment, participants read only the poor service scenario. After reading the scenario, participants had (vs. did not have) an opportunity to complain about the poor service they

received. We find a marginally significant interaction ($F(1, 224) = 2.61, p < .10$) such that close customers who complain (vs. do not complain) are more likely to return to the hairdresser, whereas distant customers are less likely to return to the hairdresser after complaining (vs. not complaining). The results indicate that while complaining enables close customers to express their discontent thereby mitigating their bad experience, it may increase distant customer's focus on the service failure and lead them to abandon the provider.

Pour Oil on Troubled Water: The Effects of Mere-Measurement and Time on Customer Desire for Revenge

EXTENDED ABSTRACT

Since revenge significantly affects both victim and offender, research on revenge has received increasing attention in the psychology (McCullough, Fincham, and Tsang 2003; McCullough, Kurzban, and Tabak 2010) and marketing literatures (Grégoire, Tripp, and Legoux 2009). One of the most robust findings is that revenge substantially and quickly decreases over time. It has been convincingly argued that revenge is associated with intense emotions (e.g., anger) and cognitions (e.g., betrayal) that are difficult and unhealthy to sustain over time.

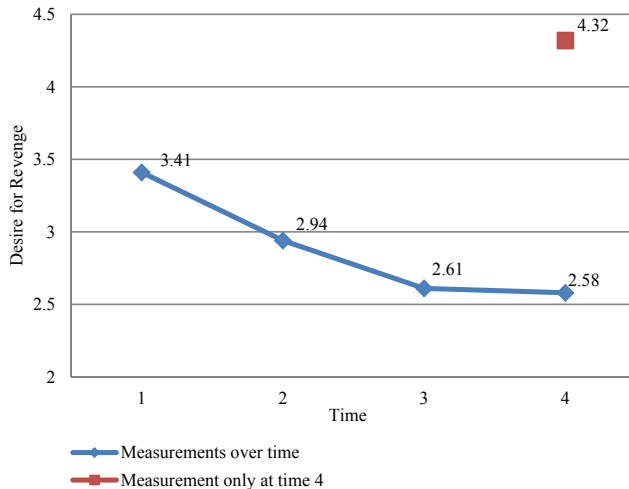

The current research further explores the effects of time on customer desire for revenge, which is defined as the motivation of bringing the firm down to get justice after a service failure (Bechwati and Morrin 2003). The research addresses a key weakness of most longitudinal designs which refers to the confounding effect of the variable "time" with "answering a survey". We argue that very fact of answering a questionnaire can influence a desire for revenge. This effect is known as the mere-measurement (Fitzsimons and Morwitz 1996). In other words, this research wonders whether the observed reduction in revenge over time is caused by a mere-measurement effect, the effect of time, or the combination of both factors.

Two rival explanations exist for the mere-measurement effect in this context. The "catharsis effect" paradigm argues that answering a survey about service failures allows customers to vent their negative emotions and actively process the situation (Barclay and Skarlicki, 2009); this effect would reduce a desire for revenge over time. On the other hand, the "amplification effect" paradigm suggests that answering questions about an unfair experience may lead customers to mentally re-experience the service failure (Chandon et al. 2011; Fitzsimons and Morwitz 1996), which would reinforce a negative mood and enhance rumination (Bono, McCullough, and Root 2008; McCullough et al. 2001). This alternate process would sustain customer desire for revenge over time.

To address this issue, we performed a longitudinal experiment with an online third party organization, ConsumerAffair.com, over 60-days. The study involved two conditions. The first condition involved four series of questionnaires that were administered every two weeks over two months. The second condition involved a survey that was sent only at the end of two months. Participants were randomly assigned to one of the two conditions. In the first condition, 111 customers completed the four surveys over time. In the second condition, 56 participants completed the only survey received after the two month period. The "desire for revenge" is measured with an established five item scale ($\alpha=.96; M=3.41; SD=2.11$) (Grégoire, Tripp and Laufer 2009).

For the first condition, we analyze the evolution of the means with a within-subject ANOVA with the four levels of revenge desire that correspond to the four waves. Overall, the coefficients for the linear term ($F[1, 111]= 22.11; p < .000$) and the quadratic term ($F[1, 111]= 4.97; p < .028$) are both significant. This result implies that the

Figure 1: The Effects of Mere-measurement on Desire for Revenge over Time

desire for revenge decreases following a quadratic pattern over time. Moreover, the desire for revenge of the participants who answered only one survey at the end of two months is significantly higher compared with those who received a survey at wave 1 ($M=4.32>M=3.41$; $t[50]=2.82$; $p<.01$) in the other condition. Another t-test reveals that the desire for revenge of the customers who answered multiple surveys over the two months is significantly lower than those who answered one survey at the end of the two-month period ($M=4.32>M=2.58$; $t[162]=4.87$; $p<.000$).

Overall, our findings offer a better understanding of the effects of time on desire for revenge. On the one hand, time reduces the desire for revenge when combined with answering multiple surveys. In this first case, we found a catharsis effect of answering multiple surveys over time, which is consistent with the result of previous studies. On the other hand, time without the presence of measurement bias surprisingly has amplification effect on desire for revenge. Customers who did not answer a survey about a service failure in the two-month period have the highest revenge desire. This result may be explained as follows: customers did not have the opportunity to retrieve and re-process their negative experience by answering multiple surveys. This important result contradicts most evidence reported in the revenge literatures, and questions the appropriateness of many longitudinal designs.

The Effects of Consumer Vulnerability on Service Evaluations and Wellbeing Outcomes

EXTENDED ABSTRACT

Working with a large health service provider, we explore the effects of consumer vulnerability on post-service failure evaluations, outcomes, and behaviors. First, we introduce an individual-level, multidimensional construct of consumer vulnerability (potential harm, perceived level of risk, perceived level of control). Then, we develop a framework of post-service failure evaluations, outcomes, and behavior as a function of consumer vulnerability. Consumer vulnerability in the health care domain is of utmost importance, as patients may experience physical pain, psychological pain, illness, fear of the unknown, and a perceived lack of control during the service interaction (Berry and Bendapudi 2007). Not only can service failures in health care lead to objective harm to patients/consumers, the resulting drops in service quality and customer satisfaction scores can lead to decreases in federal funding for the health care

institution and decreases in pay-for-performance for providers. Our key research question is: how does consumer vulnerability influence evaluations of the service experience, complaint behavior, and ultimately the health and well-being of the consumer? In examining department-level patient satisfaction and complaint data, we identified a positive correlation between complaint rates and customer satisfaction levels in some departments; these departments received high patient satisfaction scores but also high rates of complaints. We believe that the different levels of consumer vulnerability within each department may be driving this relationship, perhaps due to the differences in customer expectations for the service encounter and differences in the criticality of care.

The construct of consumer vulnerability is becoming increasingly important due to changing economic conditions, evolving health complexities and disparities, immigration patterns, and the widening educational divide. In this research, we define *consumer vulnerability* as a state that arises when individuals facing potential economic, physical, or psychological harm experience high levels of perceived risk coupled with low levels of perceived control. Our conceptualization allows potential harm to be present, (e.g., membership to a vulnerable population, such as a cancer patient), but if that individual feels in control of their health, then individual-level vulnerability can still be relatively low. Vulnerable populations or groups have been covered quite extensively in the macro-marketing sense (see *Journal of Macromarketing* December 2005); researchers typically discuss vulnerability as a grouping variable, with vulnerable populations characterized by their degree of physical sensitivity/competency, mental competency, and sophistication level (Morgan et al. 1995). In the consumer literature, individual-level consumer vulnerability has been discussed in Luce and Kahn (1999) and the Health Belief Model (Becker 1974, Rosenstock 1974), where vulnerability is operationalized as one's perceived susceptibility to contracting a disease in the future.

Here, we re-conceptualize consumer vulnerability as a multidimensional, higher-order construct with three dimensions: potential harm, perceived level of risk, and perceived level of control. The first dimension, *potential harm* is the presence of chronic or situational factors that pose objective threats to an individual, such as individual characteristics (e.g., physical issues), individual states (e.g., grief), and external conditions (e.g., discrimination) (Baker, Gentry, and Rittenburg 2005). The second dimension, one's *perceived level of risk*, is a subjective perception of susceptibility to harm caused by a potential threat (Luce and Kahn 1999; Rosenstock 1974). And the third dimension, *perceived level of control* is a belief about one's influence over outcomes and events (Klein and Helweg-Larsen 2002; Wallston et al. 1987). A new diagnosis or false-positive test results can lead to a loss in one's sense of control and order (Luce and Kahn 1999; Pavia and Mason 2004). Loss of control over the service outcome can cause customers to experience stress, anxiety, and feelings of low self-efficacy (Berry and Bendapudi 2007).

We then explore how the construct of consumer vulnerability operates within a service evaluation and outcome model. We posit that vulnerable consumers are more likely to be physically or psychologically harmed during a service failure, especially within a health care context. We also build upon the classic expectation/disconfirmation models of perceived service quality (Parasuraman et al. 1985) and customer satisfaction (Oliver 1980; 1993), to suggest that consumer vulnerability influences service evaluations and outcomes by impacting one's expectations for the service experience. We hypothesize that higher levels of vulnerability may lead to greater expectations for the service interaction, as the consumer has a greater need for critical care, objectively and subjectively. To test

our hypothesis, we conducted a pilot study using department-level survey data for 32 departments. In the survey, we asked three independent coders to evaluate some of our key variables by department. The coders were selected for their wide base of knowledge about the health care institution and all of its departments, but were completely blind to our research hypotheses and purpose of the study. The coders rated patient-provider relationship strength and length, health severity and complexity (objective harm), patient expectations for care, and subjective wellbeing. We found a positive correlation between health severity and service expectations ($r = .36, p < .05$) and a positive correlation between health complexity and service expectations ($r = .37, p < .05$). These results provide some initial department-level support for our hypothesis that a patient's vulnerability may influence expectations for the service interaction. We are now analyzing patient-level satisfaction data to test our full model.

Overall, we introduce a new conceptualization of individual-level customer vulnerability and present a transformative consumer research model of how vulnerability may influence post-failure evaluations, outcomes and behaviors. Our research provides new insights to researchers interested in individual-level vulnerability, as well as to service firms for understanding the role of consumer vulnerability in shaping service quality and satisfaction ratings. We hope to start the discussion of how we can deliver services in a manner that decreases consumer vulnerability by potentially increasing perceptions of control or reducing perceptions of risk. While we look at these relationships in the context of health care, we expect similar issues to be present in encounters with critical services, such as in the areas of financial services and education.

Acknowledging Consumer Gratitude: Leveraging the Voice of the Consumer to Increase Loyalty

EXTENDED ABSTRACT

When consumers' purchase experiences end in dissatisfaction, complaints are often triggered and most customer-oriented firms invest heavily in recovery with hopes of addressing their complaints and restoring loyalty. While addressing complaints is certainly a critical customer service strategy, it is imperative that these efforts don't detract from investments in maintaining relationships with the most satisfied customers. In fact, evidence from companies like Starbucks suggests that the revenue differential between highly satisfied and satisfied customers dwarfs that of the difference between unsatisfied and satisfied customers (see Figure 1). More specifically, highly satisfied customers spend 3.4 times more over their lifetime than satisfied customers (Moon and Quelch 2006).

Data like these suggest that the savvy manager would dedicate more effort to managing relationships with their most satisfied consumers. Traditionally, most efforts focused on managing these relationships have centered on moments of truth during the core service experience. While these efforts help build baseline satisfaction lev-

els with a focus on the service delivery stage of the purchase journey, they ignore post-purchase stages of the journey, which offer a great opportunity to build the relationship outside of the service facility. By leveraging ongoing consumer research efforts, firms can create new moments of truth focused on dialogue with their best customers. More specifically, when these most satisfied customers reply positively to customer satisfaction assessments, these words of praise traditionally are documented and then quickly forgotten. We contend that these words of praise represent an opportunity for service firms to create a new moment of truth focused on acknowledging the feedback and extending the dialogue with their best customers. Ultimately, these relational investments will increase bonds with their best customers and result in increased patronage.

Although research on acknowledgement of positive feedback is sparse in the marketing literature, several other streams of research are particularly applicable. At a fundamental level, research on reciprocity finds that people respond to each other in kind—positive actions on behalf of one entity elicit positive actions from another, and vice versa (Gouldner 1960). Relatedly, extensive research exists on the mechanism governing the process of expressing gratitude to a customer, as well as the resulting changes in behavior of that customer. The current research focuses on the organization's expression of gratitude. We are suggesting that a simple expression of gratitude can result in relationship-building outcomes. Past research also suggests contingencies to this relationship. Drawing on literature from marketing, social psychology, information systems, and online commerce, the authors have identified acknowledgement type, acknowledgement speed, and reward provision as potential moderators to the relationship between acknowledgment and positive relational outcomes (see Figure 2 for Conceptual Model). First, the type of acknowledgement indicates the level of customization the company response includes in the expression of gratitude. The key question here is whether or not a customized response is necessary or if a generic expression of gratitude can suffice. Secondly, the timing of the acknowledgment may prove critical. While an immediate response may feel automated and disingenuous, a long delay may cause the consumer to feel like the company really didn't care. We seek to identify the proper delay in company response. Lastly, a small token of appreciation or reward may play a key role. The nature of this reward may also be relevant, as monetary and social rewards may trigger different consumers from consumers (Heyman and Ariely 2002).

The current research seeks to understand the effect of extending the dialogue with very satisfied customers who offer positive feedback. Specifically, we investigate the effects of acknowledging very satisfied customers with an expression of gratitude via a brief email. Along with an initial pilot study, Study 1 utilizes an online, scenario-based survey to provide initial support for the benefits of acknowledging positive feedback from consumers following a successful service experience. In an effort to extend these findings, we partner with a large, full-service restaurant chain to conduct a follow-up lon-

Figure 1: Comparison of Customer Spending Across Satisfaction Levels

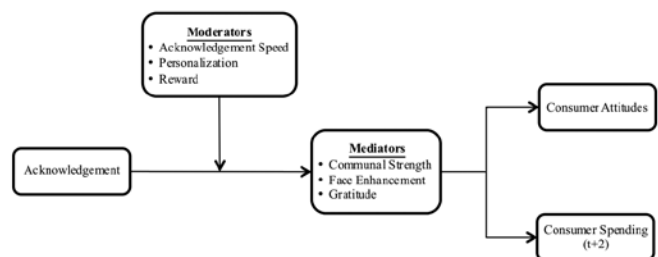

Figure 2: Conceptual Model

itudinal field experiment for Study 2. Additionally, we consider the moderating effects of acknowledgement speed, personalization, and incentive provision. This research demonstrates that better management of the post-purchase process for the most satisfied consumers can provide substantial gains for firms in the form of increased patronage and loyalty.

In Study 1, online panel participants read a scenario in which they had a great dining experience, completed a satisfaction survey regarding the experience, and then received or did not receive an acknowledgment from the restaurant. Results support the relationship between acknowledgment and positive relationship outcomes, as both satisfaction and willingness to recommend were significantly higher when consumers received an acknowledgment after providing positive feedback. Although level of personalization did not produce significant effects, acknowledgment speed and reward incentive significantly moderated the relationship between acknowledgment and positive relationship outcomes.

The sample for Study 2 consists of customers of a large, full-service restaurant chain who indicated high levels of satisfaction on a guest satisfaction survey following a dining experience. Half of the sample received an acknowledgment email from the restaurant. Initial results are consistent with those found in Study 1, such that consumer attitudes and repatronage intentions are significantly higher when an acknowledgment is received compared to when no acknowledgment is received. Interestingly, there appear to be significant gender differences, as well; acknowledgment positively impacts women's attitudes and intentions significantly more so than men. Also, face enhancement and communal strength appear to fully mediate this relationship.

While the first phase of Study 2 data collection assesses the attitudinal changes associated with firm acknowledgment of positive feedback, the second phase will assess behavioral changes. Over a six-month time period, behavioral measures such as time until next visit, number of visits, and total spend per visit, will be tracked. Thus, we hope to provide support for the attitudinal and behavioral changes of acknowledging positive consumer feedback

Paper #4: Is Variety the Spice of Love?

Jordan Etkin, Duke University, USA

SESSION OVERVIEW

Maintaining close relationships is an integral part of life, and people spend a good deal of time interacting with close others (Kahneman et al. 2004; Leary et al. 1994). We go on dates with our spouse, cook with our family, and shop with our friends. As these examples suggest, many of the ways we interact with close others involve consumption. Dating may require the purchase of flowers, movie tickets, dinner, or drinks. Cooking typically means a trip to the grocery store. And shopping outings may lead to any number of purchases, from clothes to jewelry and sporting equipment to electronics. How do our close relationships shape the way we behave as consumers?

Our session sheds light on this question. Each paper adopts a unique perspective on how close relationships shape consumer behavior, drawing on diverse methodology and theory. Paper 1 (Ramanathan and Vohs) begins by discussing how relationships change inferences drawn from feelings synchrony. When consumers share an experience (e.g., watching a film) with a close friend, the more evaluations of the experience align, the more connected one feels to the friend (i.e., synchrony is attributed to closeness of friendship). If consumers instead share an experience with a stranger, greater alignment in evaluations improves ratings of the experience overall (i.e., synchrony is attributed to a higher quality experience).

Paper 2 (Anik and Norton) move from considering friendships to early stages of dating. They demonstrate that consumers derive positive utility from playing "matchmaker". Connecting others (i.e., making matches) is intrinsically rewarding, increasing the matchmaker's happiness by closing gaps in their social network. Next, Paper 3 (Brick, Fitzsimons, Fitzsimons, and Chartrand) examines brand preferences among married couples. Brick et al. consider how the extent that two romantic partners share similar brand preferences (i.e., brand compatibility) impacts life and relationship satisfaction. Results of a longitudinal couples study suggest that the impact of brand compatibility on satisfaction depends on one's power status within the relationship; high-power partners are more satisfied when brand compatibility is high, but the opposite is true of low-power partners.

Finally, Paper 4 (Etkin) explores how the variety of joint-activities couples do together influences pro-relationship motivation. When partners perceive their relationship to be in early stages, doing varied (vs. similar) joint-activities increases pro-relationship motiva-

tion (e.g., willingness to spend on dinner). When partners perceive their relationship to be in later stages, in contrast, doing similar (vs. varied) joint-activities increases pro-relationship motivation. Etkin demonstrates similar effects on a range of relationship-related consumption behaviors.

Despite the fact that consumers often evaluate, purchase, and consume in the presence of others, relatively little is known about how close relationships influence such behaviors. Our session begins to address this gap. Across papers we consider a several types of close relationships, including friends, dating partners, and married couples, and a diverse set of consumer behaviors, ranging from evaluation of shared experiences and brand preferences, to matchmaking and partners' willingness to spend on joint-activities. Together, these papers further understanding of how close relationships shape consumer behavior.

How do Friends and Strangers Interpret Shared Experiences? Synchrony as Relationship-Bolstering or Experience-Heightening

EXTENDED ABSTRACT

People spend the vast majority of their waking time interacting with others, whether casual acquaintances or intimate partners (Kahneman et al. 2004; Leary et al. 1994). We intentionally spend time with friends, family, coworkers, and acquaintances by engaging in joint-activities such as watching TV or shopping (American Time Use Survey; Bureau of Labor Statistics, U.S. Government, 2003). Yet close others are not the only ones with who people share experiences. People meet and connect with strangers in social settings such as shopping malls, museums, art galleries, movie theaters, concerts, or train and plane rides. These interactions are not meaningless, either: they influence the way that people perceive those events.

In the current research, we argue that shared experiences create synchrony among interaction partners, provided they can observe each other during the interaction. As people share an experience, their evaluations of that experience become entwined and co-vary with each other. This synchrony emerges due to evaluations being colored by shared emotions (Neumann and Strack 2000; Ramanathan and McGill 2007). We posit that when moment-to-moment ratings of a shared experience become highly synchronous, synchrony will have spillover effects that vary as a function of whether participants have a basis for attributing the synchrony to the relationship or some contextual feature.

For people in an existing relationship, the experience of similar emotions at similar times enhances relationship satisfaction (Gonzaga, Campos, & Bradbury, 2007; Murray et al., 2002) and bolsters the strength of the relationship. Hence, friends may consider a highly synchronous experience as validation of the relationship. We therefore predicted that friends experiencing synchrony will show greater interpersonal closeness after the shared experience than would friends who experienced low synchrony or as compared to strangers. We predicted that high synchrony among friends would not, however, influence evaluations of the experience itself because friends look to the relationship as being the source of the synchrony. We did not expect strangers to use the experience of synchrony as affirmation of their (nascent) relationship. To the extent that they do experience synchrony, strangers might focus on the situation more than the relationship in determining what the feeling of synchrony

means. We therefore predicted that strangers experiencing high levels of synchrony with each other would evaluate the experience more positively compared to those not experiencing synchrony but would not differ in interpersonal closeness.

In two experiments, we tested whether friends and strangers consume and interpret shared experiences differently. In Experiment 1, we did or did not allow dyads of friends (22 pairs) or strangers (18 pairs) to see each other while they sat side-by-side to watch a funny film. Three key dependent variables were assessed. One was moment-to-moment film ratings, from which were derived our measure of synchrony. Participants moved a joystick to indicate their liking of the film at each second. The extent to which participants' ratings could predict their partners' ratings at different frequencies indicated the degree of synchrony the dyad exhibited. Further, two video cameras recorded participants' facial expressions continuously while the video clip was played. A second outcome was retrospective film evaluations, which were summary judgments of the film after its completion. A third outcome was seating distance in a waiting room, which we took to indicate momentary relationship closeness. These outcomes were related to each other in specific ways, and they were predicted by relationship type and whether participants could observe one another during the film. Partners who could see one another exhibited higher synchrony than partners who could not, and this was especially strong for friend dyads. The greater synchrony for friends in the low partition condition was due to their glancing at each other and sharing emotions of the same valence, while strangers in the same condition seemed most influenced by unreciprocated glances.

The extent to which partners' ratings exhibited a high degree of synchrony predicted more positive retrospective film ratings, but this occurred for strangers and not friends. Friends, in contrast, sat closer together to extent that their real-time film ratings exhibited a high degree of synchrony. Therefore, we hypothesized that strangers looked to the situation as the source of their feelings of synchrony, whereas friends looked to their relationship.

Experiment 2 used a similar design to directly test the attribution hypothesis. We allowed all participants to see each other, which meant that friends would likely show more synchrony than strangers. (They did.) Germane to the attributional story, we tested whether telling half of the participants that the aim of the study was to test the effects of the quality of seating in the room on shared experiences would diminish not only the overall levels of synchrony (which it did) but also erode the link between synchrony and retrospective film ratings for strangers and seating distance for friends. In both cases, having an alternate idea of what might be causing the feelings mitigated the effects we had seen in Experiment 1. This attribution effect suggests that friends' and strangers' interpreted the feelings that arise during a shared experience as being signals of the quality of the relationship or the experience itself, respectively.

The Rewarding Nature of Matchmaking

EXTENDED ABSTRACT

At some point, most people have made matches between others, from grabbing and introducing two strangers at a party to brokering romantic connections; even if not matchmakers themselves, many people can think of a friend or acquaintance who is notorious for their efforts to make such introductions – even if sometimes awkwardly unsuccessful. We investigate this proclivity to match others, demonstrating that such matchmaking – creating ties between others – has a causal impact on their happiness.

Certainly, a great deal of evidence suggests that people enjoy connecting themselves to others and that having such social connections is strongly and consistently associated with higher well-being. Indeed, humans spend some 80% of their waking hours in the company of others (Emler 1994; Kahneman et al. 2004). Social interactions and social support impact both subjective and objective well-being, with social relationships both serving as a buffer against and hastens recovery from negative events ranging from depression to physical illness (e.g., Berkman and Syme 1979; Cohen and Janicki-Deverts 2009; Seeman 1996; Uchino 2004).

We explore the emotional impact of making matches not between oneself and others, but between two other people. In one view, such matchmaking should have no impact on happiness, because matchmakers are by definition introducing people they already know and are thus not growing their own circle of social support. In another view, matchmaking could negatively impact happiness; research in social networks has noted that “brokers” – people who stand between two other actors in a social network – derive power from those two people *not* knowing each other (Burt 1998; Simmel 1955); thus, such an introduction might *decrease* one's social capital. We propose a third view: closing gaps in one's social network is rewarding because it facilitates people's general and fundamental need for closure (Kruglanski 1989). We suggest that people high in need for closure are more likely to not just assume (Flynn, Reagans, and Guillory 2010) but actually *create* connections between others and that meeting this “need for network closure” is associated with increased happiness for the matchmaker.

Four studies examine the psychology underlying people's proclivity to play “matchmaker”. Study 1 first explores the relationship between chronic matchmaking and happiness. In an online survey, participants rated their propensity to make matches between others, reported their total number of acquaintances and friends, and completed a well-being scale (Diener, Emmons, Larsen, & Griffin, 1985). We found that chronic matchmakers are happier with their lives overall even when controlling for the size of their social networks, offering correlational evidence that real world matchmaking is rewarding.

Study 2 documents the causal impact of matchmaking on happiness in a lab setting. We assigned people ($N = 128$) to match individuals to each other and measured their happiness pre- and post-matching. We also investigated whether the type of match matters by randomly assigning people to one of three tasks: making matches on the basis of who would get along well (*match*), who would get along poorly (*mismatch*), and who had the most similar social security numbers (*random*). We found that matching people with the goal of creating connections (*match*) resulted in significant increase in pre- to post-matching happiness compared to making matches on any other dimension (*mismatch* or *random*).

Study 3 assesses the benefits of matchmaking using a different methodology: rather than measuring happiness directly, we measured the intrinsic reward of matchmaking by examining people's persistence on a matching task. Participants ($N = 168$) came to the lab and were informed that they would be completing fifty trials of computer tasks and could choose how to split these trials between two tasks: a matching task and a boring unrelated task. We instructed participants either to match a target individual based on who they would best get along with (*match*) or who they looked most similar to (*appearance*). We measured the number of matchmaking trials completed before switching to the boring task and also varied whether participants completed each trial of the task for free, for 1¢, or for 2¢, a design that allowed us to document the intrinsic reward of matchmaking.

As expected, participants in the free conditions completed more than twice as many *match* task trials than the *appearance* task, suggesting that connecting others based on liking (vs. physical similarity) is intrinsically more rewarding. Interestingly, incentives increased the number of trials participants completed of the *appearance* task, in a significant linear trend from free to 1¢ to 2¢, but not of the *match* task; here, incentives significantly *decreased* willingness to complete trials both for participants in the 1¢ and 2¢ conditions compared to those in the free condition. These results suggest that while payment increased motivation for the less intrinsically appealing *appearance* task, incentives crowded out motivation for the more intrinsically appealing *match* task.

Study 4 examines the moderating effects of NFC on the relationship between condition and the number of trials completed. Participants ($N = 179$) were given the same task as in Experiment 2. They then completed the 47-item NFC scale (Webster and Kruglanski 1994; $\alpha = .85$). We found that people high in “need for network closure” are most likely to find connecting others to each other rewarding, with that reward being particularly pronounced when making matches with the goal of social connection (*match*).

Taken together, these experiments provide evidence for a causal relationship between matchmaking and happiness. Inducing people to make matches between strangers increased happiness in the moment, and people found creating meaningful matches to be more intrinsically rewarding than other types of matching. We document that having a “need for network closure” enhances the intrinsic reward of matchmaking. Our investigation offers a model for how matches at the micro level can translate into social capital at the macro level. We suggest that people who make matches do not necessarily suffer from losing their broker status, but in fact can reap rewards from matchmaking and that this reward value increases social capital at the group level.

Power and Brand Compatibility in Close Relationships: A Dyadic Investigation

EXTENDED ABSTRACT

Although consumers often evaluate, purchase, and consume brands in the presence of others, relatively little is known about the role that brand preferences play in close relationships. To fill this gap, we introduce the term *Brand Compatibility*, which refers to the extent to which two people in a romantic relationship have similar brand preferences. In this first investigation of brand compatibility, we propose that its effect on relationship and life satisfaction depends on one’s personal sense of power within the relationship. Being low in power leads one to take on close others’ emotions (Anderson et al. 2003), and to be more likely to incorporate close others’ intentions into their own intentions (VanderDrift et al. 2012). Given this, we suggest that brand compatibility reflects two different states for those high and low in relationship power: For those high in power, brand compatibility may indicate that their partner is accommodating their interests. For those low in power, brand compatibility may indicate that they are accommodating their partner’s interests. If so, brand compatibility may produce different effects on relationship and life outcomes for those who are high versus low in relationship power. It may lead those high in power to feel happier, and those low in power to feel less happy, with the relationship and their lives more broadly. In this paper, we examine these ideas dyadically, by measuring brand preferences from both members of a romantic relationship.

A diverse set of dating and married couples – 136 heterosexual couples (56.5% Caucasian, 33.5% Asian, 10% mixed or other; $M_{age} =$

20.80; $SD_{age} = 2.16$) with a mean relationship duration of 34.42 ($SD = 29.10$) months completed the study.

Participants came into the laboratory as couples and completed a battery of personality and relationship measures, including two standard scales assessing power, modified for close relationships (Anderson, John, and Keltner 2012; Ronfeldt, Kimerling, and Arias 1998). The two scales individually had acceptable reliabilities (α s = .86 and .69), but were highly correlated ($r = .53$). As such, we combined the items to produce one mean power scale ($\alpha = .84$). Participants also completed a standard life satisfaction scale (Diener, Emmons, Larson, and Griffin 1985) and a standard relationship assessment (Rusbult, Martz, and Agnew 2005) that measured both self-reported satisfaction and evaluations of the attractiveness of alternatives to the relationship.

One month later, participants completed an online follow-up questionnaire, which measured brand compatibility. Rather than asking couples to rate the compatibility of their brand preferences, a potentially biased measure, we asked partners about their brand preferences individually and then created a brand compatibility score from those responses. Participants provided the names of their own and their partner’s favorite brands for several common product categories (e.g., beer, chocolate). Four research assistants, blind to hypotheses and familiar with brand choices in the Canadian market, coded these responses. Responses were rated on a 1 (completely incompatible) to 5 (completely compatible) scale. The following guidelines were used: 5 for the same exact brand (e.g., Diet Coke and Diet Coke), 4 for almost the exact same (e.g., Diet Coke and Coke), 3 for the same brand family (e.g., Coke and Sprite), 2 for brands that are related brand families, but would not be included in a brand price promotion (e.g., Schwepps and Dr. Pepper), and 1 for different, competing brand families (e.g., Coke and Pepsi).

Analyses employed multilevel modeling procedures (Kenny, Kashy, and Cook 2006), which account for violations of statistical independence. As predicted, relationship power interacted with brand compatibility to predict life satisfaction, $F(1, 207.17) = 6.38$, $p < .01$. High power participants (+1SD) reported higher levels of life satisfaction when they and their romantic partner shared compatible brand preferences than when they reported incompatible preferences, $t = -2.2$, $p = .03$. In contrast, low power participants (-1SD) reported lower levels of life satisfaction when their brand preferences were compatible than when they were incompatible, $t = 2.3$, $p = .02$. Power and brand compatibility also interacted to predict relationship evaluations as measured by attraction to alternatives, $F(1, 225.05) = 4.14$, $p = .04$, but not as measured by self-reported satisfaction, $F < 1$, ns. High power participants reported more attraction to alternatives when their brand compatibility was low than when it was high, $t = 1.9$, $p = .06$, while low power participants reported more attraction to alternatives when their brand compatibility was high than when it was low, $t = 1.95$, $p = .04$.

We found that for people high in power, having high brand compatibility with their partner leads to better evaluations of the relationship and their life. But for those low in power, high brand compatibility leads to worse evaluations of their partner and life. We speculate this is because high brand compatibility results from low power partners accommodating the preferences of higher power partners, although this mechanism remains to be tested. In sum, we have introduced the construct of brand compatibility and shown that it, in conjunction with power, influences relationship and life satisfaction. The results suggest that brand compatibility may be a useful tool for looking at relationship processes, and highlight the potential relevance of consumer behavior for the understanding of close relationships.

Is Variety the Spice of Love?

EXTENDED ABSTRACT

Relationship partners do many things together. They eat dinner, watch television, discuss their days, and potentially even take art classes or travel. Different couples, however, vary in the variety of joint-activities they engage in. Some couples tend to do relatively similar activities; watching different TV shows on consecutive nights or eating slightly different dinners. Other couples tend to do relatively dissimilar or varied activities; watching TV one night, going out to dinner the following night, and playing tennis the next. Spending time together is positively correlated with relationship quality (Kilbourne, Howell, & England, 1990; Kingston & Nock, 1987; Orden & Bradburn, 1968; Orthner, 1975), but might the *variety* of activities couples do together matter, and if so, how?

We suggest that the impact of activity-variety on relationship quality depends critically on where partners see themselves in the course of their relationship. Socio-emotional selectivity theory (Carstensen, Isaacowitz, & Charles, 1999; Carstensen, Gross, & Fun, 1997) suggests that how much time people see ahead of them (i.e., future time abundance) varies over the life course. Perceptions of future time abundance, in turn, impact what people value. When people see lots of time ahead of them, for instance, they value feeling excited, whereas when they see little time ahead, they value feeling calm (Mogilner, Aaker, & Kamvar, 2012; Mogilner, Kamvar, & Aaker, 2011).

Perceptions of future time abundance should also vary in romantic relationships. Couples who think they are in early stages of a committed relationship should see much time ahead, whereas people who think they are in later stages should see less time ahead (relative to time passed). We suggest that these differences will affect what people value. When partners perceive their relationship as relatively short to-date, they should value excitement in the relationship, but partners who perceive their relationship as relatively long to-date should value stability in the relationship.

These differences in valuation, in turn, should shape how similar versus varied joint-activities impact motivation and satisfaction with the relationship. Variety, by definition, is associated with stimulation and change (Berlyne, 1970; Khan, 1995; Raju, 1980). Consequently, we predict that varied joint-activities should make a relationship feel more exciting. Similar joint-activities, in contrast, should increase feelings of stability. Thus, engaging in varied activities should benefit the relationship when partners perceive the relationship to be in its early stages, whereas similar joint-activities should be more beneficial when a relationship seems to be in its later stages.

Five experiments support these predictions. Across studies we assess the impact of joint-activity variety on pro-relationship motivation (i.e., willingness to behave in relationship-enhancing ways). In study 1, we ask participants their perceptions of how long they've been in their current relationship to-date (1-7) and to list three similar or three different activities done with their partner in the past week. We then asked participants to describe their current relationship in as much detail as they wished; time spent writing served as our measure of pro-relationship motivation. Results suggest that among participants who perceived their relationship as shorter, listing *different* joint-activities increased time spent writing about the relationship ($M_{diff} = 139.7$, $M_{sim} = 100.2$; $t(132) = 2.36$, $p < .05$). Among participants who perceived their relationship as longer, however, listing *similar* joint-activities increased time spent writing about the relationship ($M_{sim} = 119.9$; $M_{diff} = 80.4$; $t(132) = -2.35$, $p < .05$).

Studies 2 and 3 replicate this basic interaction, extending the design of study 1 in several ways. Instead of measuring perceived

relationship duration, we manipulate it by varying the frequency of response scales provided to participants for questions regarding their relationship's duration (see Etkin and Ratner 2012). We also used different measures of pro-relationship motivation: willingness to spend on a special occasion dinner for one's partner (study 2) and avoidance of an attractive member of the opposite sex (study 3). Results of both studies support our predictions that varied (similar) joint-activities benefit one's relationship at perceived early (later) stages.

Study 4 tests the proposed process driving these effects. We found joint-activity variety increased pro-relationship motivation by increasing feelings of excitement when relationships seemed short (95% CI: .08 to .98), but not long (95% CI: -.92 to .14). In contrast, joint-activity variety decreased pro-relationship motivation by decreasing feelings of stability when relationships seemed long (95% CI: -.50 to -.04), but not short (95% CI: -.05 to .35). These results support our suggestion that when relationships feel short (long), engaging in more varied (similar) joint-activities enhances pro-relationship motivation by increasing feelings of excitement (stability).

Our final experiment tested whether these findings extend to the field. Particularly for men, giving flowers to one's partner is a standard way of showing caring and devotion. We stopped men walking in a large downtown metropolitan area and gave them a survey that manipulated relationship duration and joint-activity similarity. Then, as thanks, we gave them the opportunity to pick up a free rose (from a flower shop a few blocks away) to give to their significant other. We tracked whether participants redeemed the rose. Results support our predictions. In the short duration condition, more men picked up the rose after listing different joint-activities ($M_{diff} = 14.3\%$, $M_{sim} = 2.9\%$; $\chi^2 = 2.67$, $p = .10$). In contrast, in the long duration condition, more men picked up the rose after listing similar joint-activities ($M_{sim} = 17.6\%$, $M_{diff} = 8.1\%$; $\chi^2 = 3.98$, $p < .05$).

Maintaining good romantic relationships is an important part of life. Indeed, satisfying relationships are crucial for both physical and psychological health (Baumeister and Leary, 1995). While popular wisdom suggests that people should incorporate more variety into their relationships, our findings indicate that this may not always be the best approach. Doing varied joint-activities seems to be particularly, if not uniquely beneficial early on in relationships. Later in relationships, or in cases where people see their relationship as long, doing similar joint-activities should be more beneficial.

Dan Ariely, Duke University, USA

SESSION OVERVIEW

Time is perhaps our most precious resource: the number of hours and days we are granted is decidedly finite. How can we spend the finite time we are allotted to most benefit ourselves and others? The four papers in this session examine time from different angles to highlight its central role in consumer well-being and virtue. Together, they demonstrate how our conceptualization of time, as well as its actual passage, is imperative to understanding the effects of our decisions on our own well-being and the well-being of others.

In particular, the first two papers examine the effects of time on happiness from people's own experiences. The first paper shows that exposure to fast-food brands affects subjective time perception, making people impatient and less able to enjoy happiness from pleasurable experiences. The second paper demonstrates how perceptions of the time people have left in life impact the relative happiness they gain from ordinary and extraordinary experiences. The final two papers investigate how time influences immoral behaviors that could affect others' well-being. The third paper finds that activating the concept of time encourages self-reflection and reduces immoral behaviors. The last paper examines how self-deception and immoral behaviors attenuate with the passage of time.

These four papers echo this year's theme, "Making a Difference," as all of them illuminate specific behaviors and choices that can make a difference in how well people live, in terms of both experienced well-being and honest behaviors. Each paper contributes to the study of consumer well-being or morality by highlighting the integral role of time. Given the fundamental importance of these constructs, we expect our proposed symposium to generate significant interest among a broad audience at ACR, including researchers with interests in well-being, time, aging, social connection, prosocial behavior, morality, and decision making. All four papers are either completed manuscripts or manuscripts in preparation.

The goal of the session is to incite questions and future research on the determinants of consumer well-being and virtue and the psychological influence of temporal factors. Each presenter will have fifteen minutes to present their paper, leaving about fifteen minutes for questions from the audience, integrative discussion, and ideas for future research.

While all of these papers relate to consumer well-being and time, each paper provides a unique perspective and proposes different answers to the fundamental question, "What can we do to live well?" By integrating different dimensions of time, measures of well-being and virtuous behavior, environmental triggers, and psychological factors, we hope to provoke a fruitful discussion at ACR that bears on both important theoretical and substantive issues.

Too Impatient to Smell the Roses: Exposure to Fast Food Brands Impedes Happiness

EXTENDED ABSTRACT

There is more to life than increasing its speed.
—Mahatma Gandhi

Innovative products and services offering convenience, speed, and temporal efficiency have brought remarkable changes to the use of time in our society. While we used to wait for weeks or months for letters to arrive, simultaneous global communication between individuals and groups for negligible cost is now only a few key strokes away. The processing of information is on a similar asymptotic trajectory approaching instantaneity: Sifting through piles of papers and books in libraries has largely been replaced by online search engines that deliver almost instant hits. This societal shift towards the instantaneous and the acceleration of activities with the explicit intention of saving time is infused into our very sustenance. Frozen prepared meals save us from having to spend time preparing food and the microwave saves us from having to wait for an oven to cook it. Better yet, fast food restaurants offer hot meals that can be picked up at drive-thru windows and are ready to be consumed on the go.

We tested whether exposure to the ultimate symbols of an impatience culture—fast-food brands—undermined people's ability to experience happiness from pleasurable visual and auditory stimuli. The essence of fast food is not what you eat (e.g., tacos, fried chicken, burgers, or pizza), but how you eat it. This is meaningfully conveyed by the manner in which fast food is served. Fast-food packaging facilitates temporal efficiency because there are no dishes to wash, no waiter to wait for, and portable containers make meals easier to eat while multitasking (i.e. in the car or at your desk). To demonstrate that the implicit effects of fast food occurs independent of the type of food, we examined whether the same food served in different packaging would interfere with people's enjoyment of pleasant stimuli. Participants in the fast-food condition viewed pictures of food in ready-to-go branded packaging; whereas, participants in the control condition view the same food displayed on ceramic tableware).

To determine whether fast food impedes happiness directly or by interfering with enjoyment of pleasant experiences, Experiment 1 randomly assigned participants to rate their state of happiness after seeing 10 beautiful nature photos or not. We hypothesize that when participants view the beautiful nature photos, those primed with fast food would be less happy than those primed with control stimuli, but that when there are no photos, the priming stimuli would not cause any differences in people's state of happiness. Therefore, Experiment 1 enabled us to assess whether fast food makes people less likely to "smell the roses."

Two hundred fifty-seven participants were randomly assigned to a 2 (fast food vs. control) × 2 (pictures vs. no pictures) facto-

rial design. Among participants who did not have the opportunity to view the nature pictures, those in the fast-food condition exhibited a non-significant trend to be slightly happier ($M=4.64$, $SD=1.51$) than those in the control condition ($M=4.25$, $SD=1.62$), $t(107)=-1.28$, $p=.20$. Among those participants who had a chance to view the nature pictures, however, those in the fast-food condition reported a significantly lower state of happiness ($M=4.86$, $SD=1.34$) than those in the control condition ($M=5.45$, $SD=1.18$), $t(146)=2.83$, $p=.005$. This revealed that fast food does not have a direct negative effect on happiness, but rather impairs individuals' positive emotional response to pleasant stimuli. Importantly, this suggests that impatience only manifests its deleterious emotional influence by interfering with the experience of pleasurable stimuli that have the potential to be relished.

In Experiment 2, one hundred and twenty-two participants were randomly assigned to the same fast-food vs control condition as in the first experiment but in this case all participants subsequently listened to the first 86 seconds of 'The Flower Duet' from the opera *Lakmé*. Participants in the fast-food condition rated themselves as less happy after listening to the music, subjectively perceived of time passage of the music as longer (i.e., "how long do you feel you spent listening to the song you just heard"), and report greater impatience experienced while listening to the music (e.g. "I was impatient for the music to end so I could finish the survey") (all $ps < .05$). Follow-up tests indicated both the subjective experience of time and reported impatience while listening to the music mediated the effect of condition on participants' experience of happiness. These findings suggest exposure to symbols of the culture of impatience can impair people's ability to derive happiness from encounters with pleasurable things in life because they become too impatient to "smell the roses."

Advertising the experience of happiness is a mainstay of most fast-food marketing. Consider the advertising of McDonald's, the most prevalent and recognizable fast food company in the world. In 1979, McDonald's launched the "Happy Meal" targeted at children. In 2003, McDonald's officially named its clown mascot, Ronald McDonald, the "Chief Happiness Officer" of the company. Many of McDonald's specific advertising campaigns depict customer's enjoyment and pleasure emanating from the consumption of their food (e.g., "I'm lovin' it" campaign). Ironically, the haste and impatience promoted by fast food appears poised to undermine people's ability to smell the roses—experiencing happiness from enjoyable events.

Contrary to the associations with happiness typically proffered by fast-food advertisers in the appetitive domain, we find that the impatience induced by symbols of fast food can distract us from appreciating beauty emanating from other sensory domains where one might otherwise obtain happiness from smelling the proverbial roses. While fast food may promote instant gratification, it can also blind us to opportunities of greater happiness even when they are right in front of us. These findings lead us to pause and ponder an otherwise largely unquestioned aspect of speed and impatience: As we have become more hasty and efficient, what have we lost?

Happiness from Ordinary and Extraordinary Experiences

EXTENDED ABSTRACT

How should we invest our finite resources to maximize our happiness? One influential stream of literature finds that experiential purchases bring greater happiness than material purchases (e.g., Van Boven and Gilovich 2003). But *which* experiences lead to greater happiness? Prior work has not yet begun to categorize and compare experiences to see which ones most resonate and increase well-being.

While some researchers have suggested a special role for special, once-in-a-lifetime experiences in consumer well-being (Zauberman, Ratner and Kim 2009), others have highlighted the importance of savoring mundane, everyday experiences (DeVoe and House 2012). Hence, the current research investigates this important distinction and attempts to resolve these inconsistencies. While ordinary experiences are common, frequent, and within the realm of everyday life, extraordinary experiences are uncommon, infrequent, and go beyond this realm (Sussman and Alter 2012). Will consumers enjoy greater happiness from a lovely dinner with a close friend at a favorite neighborhood restaurant, or from a once-in-a-lifetime, gastronomically inventive feast at elBulli?

Because the very definition of happiness varies over time (Mogilner, Kamvar and Aaker 2011), we predicted that the answer to this question would depend on one's perspective on time. Indeed, five studies suggest that extraordinary experiences lead to greater happiness among those with an extensive future. Meanwhile, when time is seen as limited, ordinary experiences are increasingly linked to happiness.

An initial study, mirroring Van Boven and Gilovich's (2003) approach, asked participants to recall and describe a happy experience that was either ordinary or extraordinary, and to report their resulting level of happiness. Content analysis suggests that engagement in social relationships and indulgence in comforts accounts for most happy ordinary experiences. Conversely, life milestones or cultural travel are most representative of happy extraordinary experiences. To serve as a proxy for future time perspective, we examined experiential happiness by participant age. Among younger participants (whose future is more extensive), extraordinary experiences resulted in greater happiness than ordinary experiences ($M = 7.86$ vs. 6.69 , $F(1,217) = 13.20$, $p < .001$); however, among older participants (whose future is more limited), no difference in reported happiness emerged ($M = 7.84$ vs. 7.59 , $F < 1$). In other words, while happiness from extraordinary experiences did not vary with age ($F < 1$), ordinary experiences led to greater happiness for older (vs. younger) participants ($F(1, 217) = 7.72$, $p = .006$).

To further investigate whether these categories of experience naturally resonate, we asked a separate group of participants to rate 20 randomly selected experiences generated in the first study. This group was able to reliably distinguish between others' described experiences, rating extraordinary experiences as significantly more extraordinary than the ordinary experiences ($M = 6.61$ vs. 3.62 , $t(120) = 19.60$, $p < .001$). Importantly, their predictions of happiness followed the same pattern: younger participants reported that extraordinary (vs. ordinary) experiences would lead to greater happiness ($M = 6.96$ vs. 6.24 , $F(1, 119) = 27.34$, $p < .001$), whereas older participants' reports of happiness did not differ by experience type ($M = 7.01$ vs. 6.83 , $F(1, 119) = 1.57$, $p > .10$).

Next, we examined a natural data source to see if the same pattern holds. A sample of Facebook users reported their last five status updates that reflected personal experiences and completed a measure of future time perspective (Lang and Carstensen 2002). They then rated and categorized these experiences as ordinary or extraordinary. Results indicated that future time perspective predicted both ratings ($\beta = .16$, $t = 2.11$, $p = .04$) and categorizations ($\chi^2(1) = 4.81$, $p = .03$) of reported experiences: even in this organic setting, those who saw time as extensive made more extraordinary updates, and those who saw time as limited made updates reflecting more ordinary experiences.

Given that our findings hinge on future time perspective, a fourth study tested for potential differences between past and future (planned) experiences. Participants described past happy experi-

ences or future experiences they expected to be happy, then rated these experiences on how ordinary or extraordinary they were. Finally, they reported their future time perspective. Regression results were consistent: regardless of past or future status ($t < 1$), those with a more extensive perspective reported more extraordinary experiences, while those with a limited perspective reported more ordinary experiences ($\beta = -.28, t = -2.90, p = .005$).

Our final study sought convergent evidence by manipulating time perspective: participants were led to view their lifespan as either extensive or limited. A second goal of the study was to examine how associating a brand with consumer experiences would affect brand attitudes. Participants viewed an advertisement for a Flip video camera that urged them to “Capture life’s everyday [extraordinary] moments.” Results revealed a significant interaction of experience \times time perspective on brand attitudes ($F(1, 210) = 5.74, p = .02$). In particular, those with an extensive time perspective viewed the brand more positively when it highlighted extraordinary (vs. ordinary) moments ($M = 5.60$ vs. $5.12, F(1, 210) = 5.79, p = .02$). However, brand attitudes did not vary by experience among those with a limited time perspective ($M = 5.46$ vs. $5.66, F < 1$). That is, while highlighting extraordinary experiences led the brand to be perceived similarly regardless of time perspective ($F < 1$), highlighting ordinary experiences was seen more positively among those who viewed their future as limited rather than extensive ($F(1, 210) = 7.29, p = .007$). Results for purchase likelihood were fully consistent.

Together, our findings highlight a previously unexamined dimension of experience, distinguishing ordinary from extraordinary experiences. Results show that this distinction is meaningful, resonates with people, and matters for brand attitudes as well as subsequent happiness. Follow-up analyses from our first study suggest that self-definition may drive these effects ($\beta = .01, t = 2.56, p = .01$): the experiences that define us vary with our perspective on time, and what defines us may bring us greater happiness.

Time, Money, and Morality

EXTENDED ABSTRACT

It seems a day doesn’t go by without some unethical behavior by a politician, movie star, professional athlete, or high-ranking executive splashing the cover of newspapers. Although less sensational, revelations of cheating have also crept into the sciences, and continue to show up in classrooms, businesses, and marriages. Sadly, such actions have ruinous consequences, hurting individuals, families, corporations, and entire academic fields. Given that decades of psychology research have shown that people strive to maintain a positive self-concept (Adler, 1930; Rogers, 1959) and that morality is central to people’s self-image (Aquino & Reed, 2002; Chaiken, Giner-Sorolla, & Chen, 1996), the prevalence of unethical behavior and the fact that even good people are prone to lose track of their moral compass is surprising (Ayal & Gino, 2011; Mazar, Amir, & Ariely, 2008; Shalvi, Eldar, & Bereby-Meyer, 2012). Are there simple ways to encourage self-reflection, thus decreasing individuals’ tendencies to behave immorally? Here, we focus on two triggers that are ubiquitous enough in the environment to have a chance at instigating a widespread effect on unethical behavior: money and time.

Prior research has shown that when people focus on money they behave in self-interested (but not self-reflective) ways. For instance, merely thinking about money leads people to be less helpful and fair in their dealings with others, less sensitive to social rejection, and to work harder towards personal goals (Vohs, Mead, & Goode, 2006, 2008; Yang, Wu, Zhou, Mead, Vohs, & Baumeister, 2012; Zhou, Vohs, & Baumeister, 2009). However, when focused on time, peo-

ple become more generous in their charitable giving (Liu & Aaker, 2008) and are more motivated to connect with loved ones (Mogilner, 2010)—a behavior that is particularly treasured when reflecting on one’s life (Frederickson & Carstensen, 1990; Loewenstein, 1999). We thus predict that priming people to think about time, rather than money, will lead to more ethical behavior by encouraging people to reflect on who they are, making them more conscious of how they conduct themselves so as to maintain a positive self-image.

Study 1 tested this by priming either time or money and then measuring cheating. Participants were first presented with a sentence unscramble task which surreptitiously exposed them to time-related, money-related, or only neutral words (Mogilner, 2010). Next, participants played a “Numbers Game” in which they had the opportunity to cheat and receive additional money. The results show that participants were more likely to cheat in the money condition (87.5%, 28/32) than in either the control condition (66.7%, 22/33; $\chi^2(1, N=65)=3.97, p<.05$) or the time condition (42.4%, 14/33; $\chi^2(1, N=65)=14.44, p<.001$). Participants were also less likely to cheat in the time condition than in the control condition ($\chi^2(1, N=66)=3.91, p<.05$). In other words, money primes encouraged unethical behavior while time primes discouraged it.

Study 2 replicates these results while also providing initial insight into why time discourages unethical behavior. Participants were primed with time or money through searching for songs that had lyrics exemplifying how people feel about either time or money. Next, participants completed the same Numbers Game, but here it was framed as either an intelligence test or a personality test indicative of the person they are. The results showed a significant interaction ($F(1,138)=3.99, p<.05$): Only when the game was framed as an intelligence test did thinking about money lead to greater cheating than thinking about time ($F(1,138)=6.69, p=.01$); however, when the game was framed as a personality test, there was no difference in cheating between the money and time conditions, $F<1$.

Study 3 again tests for the role of self-reflection. Participants were primed with money or time by either counting a stack of 30 \$1 bills or days in a paper calendar (1 page per day). Half of the participants completed this task facing a mirror while half did not. Participants then completed the same Numbers Game from Study 1. Results showed a significant interaction ($F(1,116)=4.30, p=.04$): Only when participants did not complete their tasks in front of a mirror did thinking about money lead to greater cheating than thinking about time ($F(1,116)=9.11, p=.003$). When a mirror was present, however, there was no difference in cheating between those in the money and time conditions, $F<1$.

Study 4 measured self-reflection directly through self-report measures. Participants were primed with time or money using the same sentence unscramble task from Study 1, and then asked to rate their amount of self-reflection. Next, they completed a word unscramble task which provided an opportunity to cheat for extra money. The results show that those in the money condition reported lower levels of self-reflection compared to both the control ($p=.001$) and the time condition ($p=.001$), and participants reported greater self-reflection in the time condition than in the control condition ($p=.024$). The same pattern of results was found for cheating: Those in the money condition were more likely to cheat than those in either the control ($\chi^2(1, N=143)=4.04, p=.044$) or time condition ($\chi^2(1, N=145)=16.44, p<.001$), and were less likely to cheat in the time condition than in the control condition ($\chi^2(1, N=138)=4.16, p=.041$). Finally, a mediation analysis revealed that self-reflection drove the effect of the prime on cheating behavior.

Taken together, these findings suggest that although priming money increases cheating, priming time reduces cheating because it

encourages self-reflection. This suggests that finding ways to nudge people to reflect on the self at the time of temptation, rather than on the potential rewards they can accrue by cheating, may be an effective way to curb dishonesty.

Temporal Decay, Reinstatement, and Debiasing of Self-Deception

EXTENDED ABSTRACT

Research on the individual psychology of ethical decision making tends to take a “one-shot” approach by examining the effect of one or more specific variables on one subsequent unethical act, or a global approach assessing general beliefs such the tendency to view oneself in a positive light (e.g., Alicke, 1985; Chambers & Windschitl, 2004; Moore & Kim, 2003; Taylor & Brown, 1988). Along these lines, Chance et al. (2011) documented how a single act of cheating can lead to self-deception in the short term. The current investigation explores ethics over a longer time course, examining how an initial unethical behavior changes people’s beliefs in the longer term – and how those beliefs are impacted by both receiving more information about one’s abilities over time (Study 1) and being provided with subsequent opportunities to engage in further unethical behavior (Study 2).

People misbehave: They lie, they cheat, they steal, they betray. Yet most view themselves as good and moral individuals (Aquino & Reed, 2002). One means of resolving this apparent inconsistency between bad behavior and a positive self-image is through self-deception (Tenbrunsel & Messick, 2004): distorting negative behavior to reflect positively on the self– for example, by cheating on tests and attributing improved performance to ability. Given the costs of self-deception to both individuals and organizations, we explore two means by which self-deception can be decreased: natural decay and an attentional intervention. We show that self-deception diminishes over time when self-deceivers are repeatedly confronted with evidence of their true ability (Study 1); importantly, however, this “learning” fails to make them less susceptible to future self-deception (Study 2). Given the ease with which self-deception recurs, we test a mechanism for debiasing self-deception: asking participants to reflect on the fact that they may have cheated, thereby drawing their attention to the true cause of their high performance (Study 3). Taken together, these studies offer insight into when and how self-deception can be attenuated.

Cheating and self-deception paradigm

Participants are assigned to a control or an answer condition. Both groups complete a series of tests of general knowledge trivia such as “What is the only mammal that truly flies?” (from Moore & Healy, 2008). At the beginning of the study, they learn that for each test, they will earn an additional \$0.25 for each correct answer. Participants in the answers condition have the answers to all ten questions printed in an answer key at the bottom of the page. Their instructions read, “It’s okay to check your answers as you go, but please do your own work.” (A pilot study showed that using the answers to achieve a higher score was perceived as cheating and unethical.) The control group has the same test questions, but no answer key. Everyone completes Test 1, and then receives a score sheet with an answer key on which they record their score. Thus, before continuing to Test 2, participants in both conditions have seen the answer key to Test 1 and know their Test 1 score. They then look over Test 2 before writing down their predicted score. After predicting their score, they complete the test, which does not have answers at the bottom. Cheating is measured by significant differences in per-

formance between the control and answers groups on Test 1. Self-deception is measured by significant differences between predictions and scores on subsequent tests for participants in the experimental conditions but not the control condition.

In Study 1, we observed the natural decay of self-deception over time, finding that when faced with repeated exposure to counterevidence – in this case, scoring lower on three tests they could not cheat on – self-deceivers eventually come to terms with reality. In everyday life, however, people face repeated temptations to engage in questionable behavior, and thus repeated opportunities for self-deception. Therefore, Study 2 tested whether a second chance to cheat would reinstate self-deception, overwhelming the effect of learning from corrective feedback. It did. Self-deception is therefore sticky, therefore reducing it may require an intervention after cheating has occurred, but prior to making predictions of future performance. In Study 3, we tested whether drawing attention to the answer key before the prediction task would reduce self-deception. We added a new “answers/attention” condition in which we interrupted test takers before they predicted their scores on Test 2 to ask them to reflect on the effect that the answer key might have had on their performance on Test 1. Participants in the answers/attention condition predicted lower scores on the second test than those in the answers condition, despite both groups having cheated to a similar degree on the first test.

In our experiments, participants have the opportunity to cheat on a test, and then to self-deceive about their own ability. We explored two means by which self-deception may be decreased: by repeated counterevidence, and drawing attention to the root cause. Our studies demonstrate that time and repetition of unbiased feedback can reduce self-deception and eventually eliminate it (Study 1); however, the tendency can reemerge when the opportunity for cheating presents itself again (Study 2). Attentional interventions early in the process, however, may debias self-deception (Study 3). While we examined the impact of self-deception on people’s beliefs about their future performance, self-deception in contexts like these may also impact people’s subsequent behavior. For example, it may lead them to spend less time preparing for future challenges, thus reducing learning in addition to hampering the possibility of good future performance. Future research could examine this type of behavioral consequence, both in the context of academic cheating as well as in other contexts where people may inflate their performance by cheating and then deceive themselves.

SESSION OVERVIEW

Common adages like, “you get what you work for” and “there are no shortcuts” emphasize the importance of putting in significant “hard work” or effort to obtain the outcomes you desire. In the current session, we apply the notion of “hard work” to consumption. While prior research has shown that shopping difficulty leads to greater product liking (Cardozo 1965) and people value products more that they make themselves (Norton Mochon and Ariely 2012), limited research has explored what drives the desire to expend higher effort, the consequences of increased effort beyond valuation, or the contexts in which higher effort does not yield greater valuation. What makes us want to work hard? How might this desire shape our product preferences? How does hard work change our expectations or beliefs? And finally, do we always want what we work for? In the current session, we answer these questions, exploring what causes people to desire higher-effort products and the consequences of increased effort across product and service contexts.

The papers in this session flow from antecedents to consequences. First, Cutright and Samper establish low personal control as a causal factor that drives a desire to expend greater effort and seek out products that require higher effort (e.g., exercise equipment that emphasizes harder vs. easier effort to see results). They find that low-control consumers view these higher effort products as a vehicle to restore control. Next, Naylor, Haws and Summers look at the consequences of higher consumer effort in a loyalty context, establishing that the increased effort put forth by active loyalty program members leads to increased feelings of control over randomly-determined outcomes. Buechel and Janiszewski also look at the consequences of higher vs. lower effort in contexts where consumers have control over product design and composition (e.g., Build-a-Bear). They find that when choices and assembly are integrated (i.e., you create as you build), increased effort drives increased value of the components, yet this effect reverses when choices and assembly are segregated (you make a plan first, then build). Finally, Mathur, Block and Yucel-Aybat examine how higher effort tasks can be shaped to improve

performance and satisfaction for different types of consumers (entity vs. incremental theorists) depending on the presence of common goal progress cues.

These papers, all at advanced stages of completion, should appeal to anyone with an interest in consumer effort, identity, personal control, product design, customization, loyalty programs and goals. More broadly, this session should resonate with anyone interested in how hard work is shaped by and shapes the consumption process. Consumers are becoming more involved in choosing and designing the products, services and activities they enjoy, thus expending a higher level of effort. By examining this effort, we provide an avenue to make a difference in consumer welfare; we can empower consumers to use hard work to restore control over their lives, be cognizant of their biases in light of their hard work, target their work toward activities that will yield greater value, and help develop products that can more aptly benefit different types of consumers in high-effort contexts.

Doing it Hard Way: Low Personal Control Drives Preference for High-Effort Products

EXTENDED ABSTRACT

Get stronger, healthier, skinnier, smarter, and cleaner with less work. Such messaging is hard to escape in today’s marketplace. At every turn, a product promises to help us improve in a variety of areas with exceptional ease. Consistent with such communication, research suggests that people often seek experiences that require the least effort (e.g., Child 1946, Russell and Mehrabian 1975). However, people also often appreciate more effortful experiences (Aronson and Mills 1959, Gibbs and Drolet 2003, Kivetz and Simonson 2003). Thus, we ask the question—when it comes to improving the self (and its extensions, such as the home), do consumers seek high or low effort products?

We predict that feelings of control will be a critical determinant of whether consumers choose high or low effort products. Specifically, we posit that when feelings of control are low, individuals will want to re-establish control (e.g., Fiske, Morling and Stevens 1996). Consequently, they will prefer products that emphasize and demonstrate how their personal effort is required to generate results. We test this hypothesis across 5 studies.

In study 1, our goal was to simply establish that low control leads people to favor the idea of high effort over that of low effort. Participants first completed a common control manipulation (“write about a time when you had low (high) control”) (e.g., Kay, et al. 2008) and were presented with 9 different inspirational ads, 3 emphasizing high effort (e.g., “You get what you work for”) and 3 emphasizing low effort (e.g., “Relax.”). For each ad, participants were asked, “How much do you agree with this quote?” Analyses revealed a significant interaction of control manipulation by ad type ($F(1, 54) = 7.42, p = .01$). Individuals in the low control condition preferred the high effort ad ($M = 5.95$) over the low effort ad ($M = 4.99$). The difference was not significant in the high control condition (in this study or in the remaining studies).

In study 2, we established that the desire for high effort products when control is low manifests itself in product attitudes. We manipulated control as in study 1 and then presented participants with two current Swiffer™ commercials. In the low effort condition, the

Swiffer ad stressed how easy it is to clean with Swiffer. In the neutral condition, the Swiffer ad highlighted the technical features of Swiffer. Analyses revealed a significant interaction of control and effort condition on liking for Swiffer ($F(1, 92) = 4.67, p = .03$). Individuals in the low control condition preferred Swiffer more when it was associated with the neutral ad ($M = 6.04$) than when it was associated with the low effort ad ($M = 5.33$).

In study 3, we sought to better understand the drivers of our effect. We manipulated control with an established essay manipulation similar to studies 1 and 2 and then presented participants with a Nike sneaker that emphasized that it would either take less effort to get in shape with the shoe (“You don’t have to work as hard to get fit fast”) or more effort (“If you work hard, you get fit even faster.”). Results revealed a 2-way interaction, ($F(1, 151) = 3.90, p = .05$) such that when control was low, individuals preferred the high effort ad ($M = 4.75$) to the low effort ad ($M = 3.91$). This result was fully mediated by the degree to which people felt empowered and restored feelings of control when thinking about the sneakers (95% CI, $B = -.66; -1.34, -.06$).

In study 4, our goal was to build on the prior studies and understand not only purchasing attitudes, but also behavior. We manipulated feelings of control and then presented individuals with an ad about golf clubs that either emphasized that very little effort (“Improves performance with limited practice or effort”) or a great deal of effort is required to improve performance (“Improves performance when accompanied by diligent practice and effort”) outcomes with the club. Participants were then given an opportunity to practice putting, followed by questions regarding purchase intent. Results indicated that when control was low, participants practiced longer ($F(1, 160) = 5.34, p = .02$) irrespective of effort condition, indicating a desire for greater control over their performance. Importantly, participants were more likely to purchase the clubs that were advertised with the high effort message ($M = 3.78$) than the low effort message ($M = 2.91$), suggesting preference for a product that was congruent with their desire to expend greater effort.

In study 5, we ran a field experiment to test our hypotheses. We recruited intramural basketball players directly after a game and presented them with a Nike shoe print ad. The ad suggested that either less effort (“Work Less, Jump Higher”) or more effort (“Work Harder, Jump Higher”) was required to improve their performance. Results revealed a 2-way interaction ($F(1, 82) = 3.91, p = .05$) whereby when feelings of control were low (i.e., when individuals lost), individuals were more interested in purchasing the shoe when presented with the high effort ad ($M = 3.76$) versus the low effort ad ($M = 2.75$).

In conclusion, we find that when feelings of control are low, people prefer products that require hard work over those that require little work to achieve the same outcome. We posit that this seemingly irrational preference is due to a desire to reassert control through high effort.

Earning Luckiness: The Effect of Active Loyalty Program Membership on Consumer Predictions of Randomly-Determined Marketing Outcomes

EXTENDED ABSTRACT

Prior research on loyalty programs has examined how structural and motivational features affect consumer behavior within program confines (Bagchi and Li 2011; Dr ze and Nunes 2009; Kivetz 2005; Kivetz and Simonson 2002, 2003; Kivetz, Urminsky, and Zheng 2006; Lewis 2004). We add to this work by showing that loyalty program membership has psychological effects extending beyond the context of the program itself. Our series of studies demonstrates

that consumers display a “lucky loyalty” effect, such that active loyalty program members feel they have a greater subjective likelihood of experiencing positive randomly-determined outcomes offered by the firm administering the loyalty program, even when these outcomes are unconnected to the loyalty program. We propose that status earned in a loyalty program through past purchases can lead to a relative illusion of control compared to non-members of the program or program members who lack elite status. This illusion of control, in turn, leads consumers to believe that randomly-determined positive firm-related outcomes are more likely to happen to them than to other customers of the firm. Why should this be the case?

Thompson et al. (1998) introduce the “control heuristic” to argue that judgments about control are based on two conditions: In order for an individual to perceive that he or she has control over an outcome, he or she must (1) find the outcome desirable and (2) perceive a link between his or her actions and the outcome. We propose that both of these conditions are present for elite members of loyalty programs considering randomly determined, positive outcomes like winning a sweepstakes or other promotional contest. These consumers will naturally find the outcome desirable and, if they have put in enough effort to earn elite status with the company through past patronage, they will feel that they have earned special treatment. We posit that these two conditions (desirable outcome and perceived link between actions and outcome) lead to the perception that active members of loyalty programs who have earned elite status are more likely to receive randomly-determined firm-related positive outcomes compared to others who have not earned the same elite status in the loyalty program.

We test our hypotheses across five studies that explore different types of loyalty programs and different types of randomly-determined outcomes. The primary purpose of study 1a was to test whether hotel loyalty program members with elite status feel they are more likely to win a random drawing for a gift basket during a hotel stay than non-members of the loyalty program. Note that the drawing was open to all hotel guests and was not contingent on loyalty program membership or status. We conducted a 2 (loyalty program elite status: yes vs. non-member of loyalty program) between-subjects ANOVA with predicted likelihood of winning the random drawing as the dependent variable. The results revealed that elite loyalty program members thought they were more likely than other guests to win the drawing (2.91 vs. 2.39; $F(1, 196) = 7.27, p < 0.01$), supporting our prediction of a relative illusion of control for elite loyalty program members versus non-members. We also found that the perception that one has earned special treatment from the firm mediated the effect of loyalty program status (vs. non-membership) on predicted likelihood of winning the gift basket using procedures recommended by Preacher and Hayes (2008) and Zhao, Lynch, and Chen (2010); the mean indirect effect was positive and significant ($a \times b = .0522$), with a 95% confidence interval excluding zero (.0069 to .1172). Study 1a thus provides evidence that elite loyalty program members think they are more likely to receive positive randomly-determined outcomes than non-loyalty program members and that this “lucky loyalty” effect is mediated by a sense of having earned special treatment from the firm. Study 1b compares retail credit card holders who have earned versus not earned “Valuable Customer” status with the retailer. The results replicate the lucky loyalty effect and mediation by special treatment using a different positive firm-related outcome ($M_{\text{elite status}} = 2.88, M_{\text{no status}} = 2.44; F(1, 286) = 5.67, p < 0.05$).

Study 2 again uses a retailer discount context and provides additional evidence for the causal role of effort in the lucky loyalty effect by manipulating whether the consumer had to exert effort (by making purchases with the firm) in order to obtain elite status within

a loyalty program. As expected, the lucky loyalty effect obtains only when status is earned and not endowed ($M_{\text{earned status}} = 3.16$, $M_{\text{unearned status}} = 2.59$, $M_{\text{no status}} = 2.38$; $F(1, 198) = 6.61$, $p < .01$).

In studies 3 and 4, we demonstrate important boundary conditions to the lucky loyalty effect that provide further support for the control heuristic as the causal mechanism. Specifically, in study 3 we show that the lucky loyalty effect does not extend to randomly-determined desirable outcomes not related to the firm administering the loyalty program, including outcomes related to other firms (i.e., winning a prize under a soda cap, winning a restaurant raffle, getting an airline upgrade) or organizations (i.e., winning money in the lottery), and outcomes not related to any firm or organization (i.e., hitting green lights vs. getting stopped at red lights) (all p 's $> .15$). Finally, study 4 provides additional evidence in support of the control-related mechanism by demonstrating that the lucky loyalty effect does not obtain when the random firm-related outcome is undesirable (i.e., a sprinkler going off in the customer's hotel room during their stay).

Theoretically, our work contributes to the literature on illusory control (Langer 1975; 1977; Thompson et al. 1998), as our research shows that individuals appear to believe that they can "earn" control over positive randomly-determined outcomes through effort. It also has significant implications for firms deciding how to use loyalty programs and promotional contests.

Customized Assembly: How Does Effort Influence the Value of To-be-assembled Products?

EXTENDED ABSTRACT

Consumers often invest effort by participating in the production of products. Customized product assembly, for example, involves making a series of product composition choices while investing physical effort in assembling a product (e.g. Build-a-Bear).

Consumer participation in the production of products has been shown to lead to a greater valuation of the finished product (Dahl and Moreau 2007; Deng et al. 2010; Norton et al. 2012). This increased valuation has been attributed to an increased fit between the final product and consumer preferences (Delleart and Stremersch 2005; Franke and Piller 2004), feelings of competence (Dahl and Moreau 2007; Norton et al. 2012), and feelings of pride/accomplishment (Dahl and Moreau 2007; Deng and Hutchinson 2011). The increase in valuation contrasts principles of economic theory, which suggest that effort expended during the design and assembly process should be subtracted from the value of the co-produced product (Bendapudi and Leone 2003; Dellaert and Stremersch 2005; Etgar 2008; Meuter and Bitner 1998).

We propose that positive or negative utility can be derived from the product assembly experience itself. To understand the utility from customization and assembly efforts that is independent from the end product (product fit, pride and accomplishment) we assess how customized assembly influences the perceived value of the components of the to-be-assembled product. This approach assumes consumers will assign more value to the components (e.g., the parts at Build-a-Bear) that provide a better customized assembly experience.

We hypothesize that assembly effort increases the perceived value of the components of the to-be-assembled product when the assembly experience is positively engaging (i.e. creative), whereas assembly effort decreases the perceived value of the to-be-assembled product when the assembly experience negatively engaging (i.e., irritating). A customized assembly experience is more positively engaging when customization and assembly are integrated (i.e., the experience is creative) as opposed to segregated (i.e., the experience is irritating).

We tested our predictions in four experiments using simple craft activity kits. Participants in our experiments were asked to create holiday themed figures by (1) choosing adornments from different adornment options (e.g. two different ears, mittens, shoes), (2) cutting out the adornment pieces and (3) assembling the figures by pasting these pieces onto a line-drawing of the figures. In all our experiments effort expended to create the figure was manipulated by the number of adornments participants selected (3 vs. 8). Our dependent variable was their valuation of the craft activity kit (i.e. the to-be-assembled-product).

Study 1 manipulated whether customization decisions and assembly actions were integrated or separated. In an integrated "assemble-as-you-go" condition, participants were asked to pick the first adornment (e.g. ears) from two options, cut them out and paste them on the figure. Then they were asked to pick the second adornment (e.g. mittens), cut them out and paste them on the figure, and so forth. In a separated "assemble-at-the-end condition" participants chose their adornments and cut them out but did not paste them on the elf (i.e. assemble) until all choices were made and all pieces were cut out. In the "create-as-you-go" condition more effort (i.e. more choices and more pasting) led to a higher valuation of the components of the to-be-assembled product ($F(1, 152) = 6.75$, $p < .05$). Mediation analysis revealed that this higher valuation was a consequence of participants being positively engaged in the assembly task (i.e., finding the task creative; 95% CI = .56, 9.22). In the "assemble-at-the-end condition, more effort led to a lower valuation of the components of the to-be-assembled product ($F(1, 152) = 4.81$, $p < .05$). This lower valuation was a consequence of participants being negatively engaged in the assembly task (i.e., finding the task irritating; 95% CI = -7.6, -.06).

Study 2 used the "create-as-you-go" condition from study 1. To separate the customization decision from the assembly process, half of the participants in this study created a plan of their choices before creating the figure "as they were going". As in study 1, in the "no-plan-create-as-you-go" condition more effort led to a higher valuation of the components of the to-be-assembled product ($F(1, 162) = 8.38$, $p < .05$). In the "plan-create-as-you-go", more effort led to a lower valuation of the components of the to-be-assembled product ($F(1, 162) = 7.76$, $p < .05$).

Study 3 used the "assemble-at-the-end" condition from study 1. To make this negatively engaging assembly process more positively engaging, half of the participants' mindset was manipulated by having these participants think about what it was like to be young, create art at school and bring it home to share it with the family during the assembly process. As in study 1, in the "no-mindset-assemble-at-the-end" condition, more effort led to a lower valuation of the components of the to-be-assembled product ($F(1, 174) = 3.49$, $p = .06$). In the "positively-engaging mindset assemble-at-the-end" condition, more effort led to a higher valuation of the components of the to-be-assembled product ($F(1, 174) = 11.22$, $p < .05$).

In summary, we show that the effort associated with customized assembly can add or detract from the perceived value of the components of the to-be-assembled product. By focusing on the value of the craft kit (or the-to-be-assembled-product) we show an influence of the customized assembly experience that is independent of the consequences of the customized assembly (i.e., the finished product).

The Effect of Goal Progress Salience Cues in Effortful Consumer Domains: An Implicit Theory Perspective

EXTENDED ABSTRACT

Consumers are faced with a plethora of products and services that provide cues to mark progress (called goal progress salience or GPS cues). Several firms endeavor to provide indications of progress (e.g., e-book readers that provide information about the percentage of the e-book completed; video games that provide information about the skill a player has learned at different levels) with the assumption that consumers appreciate this information. The literature on goal progress has generally shown that providing progress cues tends to bolster performance and goal achievement (Cheema & Bagchi, 2011). However, contrasting research (e.g., Amir and Ariely 2008) has shown that progress cues could hinder goal pursuit and task performance. In this research, we suggest that the effects of GPS cues may not be uniform for all individuals and for all kinds of consumption domains. Specifically, we suggest and find that the consumption domains that are deemed demanding and require consumer effort are differentially impacted by the presence and type of such progress cues, contingent on whether consumers endorse an incremental-theory and focus on learning goals or endorse an entity-theory and focus on the outcome.

Research has identified two types of implicit theories: entity and incremental. Entity-theorists tend to view people, events, and objects in relatively fixed, unchanging terms; whereas incremental-theorists possess a more dynamic and flexible view (Plaks, Grant, & Dweck, 2005). People often rely on their implicit theories to guide judgment and behavior when they encounter task domains that require effort and are deemed difficult. In the current research, we propose that when encountering demanding domains, entity-theorists, who are outcome-focused, will prefer opportunities that demonstrate favorable outcomes and provide evidence of their ability/achievement. Hence, cues that will inform entity-theorists about their achievement (e.g. cues that highlight percentage completed) will help them meet their performance goals. Thus, they will be less likely to persevere on a task and their performance will be negatively impacted. However, due to the positive outcome they infer from these cues, entity-theorists' task-evaluations will be favorable. In contrast, incremental-theorists, who are process-focused and are driven by learning goals, will not be impacted by GPS cues that highlight completion. Since incremental-theorists focus on building mastery skills in order to achieve end goals, they will only be impacted by GPS cues that highlight learning, such that they will more favorably evaluate tasks that include learning-GPS cues, but their performance will be unaffected. In three studies, we support these expectations with both behavioral and self-reported measures using scenarios in which consumers must expend effort (proofreading a difficult article) and find converging evidence in different consumption domains (maze books and language learning products).

In study 1, set as a proofreading task, respondents proofread a dense chemistry article (demanding task) or a gossip article (less demanding task) that had been separated into five sections. After each section, half the respondents saw completion-GPS cues indicating the extent of completion, while the rest of the respondents did not see any completion-GPS cues. Implicit theory was manipulated by having respondents read and internalize proverbs associated with either an entity or incremental-theory (Poon & Koehler, 2006). Results supported our expectations, such that in the demanding task condition, when the completion-GPS cue was present, entity (vs. incremental) theorists evaluated the task more favorably ($M_{ET-Cue} = 2.82$, $M_{IT-Cue} = 2.25$; $p = .06$), but their performance (measured as the ac-

curacy of proofreading) was worse ($p < .05$). When the completion-GPS cue was *not* present, entity (vs. incremental) theorists evaluated the task *less* favorably ($M_{ET-no-Cue} = 1.97$, $M_{IT-no-Cue} = 2.82$, $p < .05$). In the less demanding task condition, both theorists' task evaluations and performance were unaffected regardless of the absence/presence of GPS cues.

In study 2, we extended this finding by examining the effects of GPS cues that highlight learning, expecting incremental-theorists to more favorably evaluate tasks that included such cues. Implicit theory was manipulated as done in study 1. In a high-effort consumer domain, in which a Morse-code training package was presented as four modules, participants saw progress bars which informed them either about the percentage of the task completed (completion-GPS cue condition), or the skill they had learned (learning-GPS cue condition) at the end of the each module. As expected, entity (vs. incremental) theorists evaluated the Morse code training program more favorably when completion-GPS cues were present ($M_{ET-Completion} = 5.26$, $M_{IT-Completion} = 4.88$) and were more likely to buy the training module when they saw the completion (vs. learning GPS cues) ($M_{ET-Completion} = 3.77$, $M_{ET-Learning} = 3.02$; $p < .05$). Incremental-theorists, in contrast, evaluated the Morse code training product more favorably when they saw the learning (vs. completion) GPS cues ($M_{IT-Completion} = 4.90$, $M_{IT-Learning} = 5.62$; $p = .06$). We also observed that entity (vs. incremental) theorists felt better about themselves ($M_{ET-Completion} = 5.34$, $M_{IT-Completion} = 4.59$; $p < .05$) and thought that they were good at Morse code when they saw the completion (vs. learning) GPS cues ($M_{ET-Completion} = 4.40$, $M_{ET-Learning} = 3.83$).

In study 3, we replicated these results using another consumer product category that requires consumer effort, a puzzle book of mazes. Participants completed four different mazes and saw either completion-GPS cues or learning-GPS cues. Results show that in the presence of completion (vs. learning) GPS cues, entity-theorists evaluated the mazes more favorably ($M_{ET-Completion} = 4.85$, $M_{ET-Learning} = 4.11$) and felt that they improved their ability ($M_{ET-Completion} = 4.19$, $M_{ET-Learning} = 3.48$). However, incremental-theorists evaluated the mazes more favorably ($M_{IT-Completion} = 4.10$, $M_{IT-Learning} = 4.99$) and felt that they improved their ability ($M_{IT-Completion} = 3.25$, $M_{IT-Learning} = 4.20$) in the presence of learning (vs. completion) GPS cues.

Thus, in three studies, we show that an individual's implicit theory of change and whether the consumption domain is associated with expending effort, serve as important determinants of how such cues that highlight progress or learning impact task pursuit, achievement, and consumer satisfaction.

Paper #4: Digital Shopping: What You Need to Consider

Nikhil Sharma, V.P. of Shopper Insights, The Nielsen Company, USA

SESSION OVERVIEW

Digital technologies are becoming a pervasive component of consumers' purchase experience. For example, U.S. e-commerce sales accounted for 5.4% of total sales in 2012 (Thomas, Davie, and Weidenhamer 2012) while mobile technologies influenced 5.1% of all U.S. retail sales in 2012 (Brinker et al. 2012). As we progress into the digital age, marketers have the opportunity to use advanced technologies, such as computers, smartphones and location-based services, to gather consumer insights, influence consumer decisions at the point-of-purchase, and engage consumers in a truly unique manner. However, in order to tap into the wealth of opportunity offered by digital advancements, marketers must first understand how consumers utilize, interact, and react to these technologies. Therefore, the four papers in this session explore how new technologies impact consumers decisions and behaviors.

In the first paper, Sciandra and Inman investigate consumers' lay beliefs associated with in-store mobile technology use and assess how mobile technologies alter purchases. In particular, the authors explore the influence of shopping-related and shopping-unrelated mobile device use on consumer outcomes. Depending on use, Sciandra and Inman find that, counterintuitively, mobile technologies can lead to more unplanned purchases, more forgotten items, longer time spent shopping, and additional shopping trips. The second paper by Sheehan and Van Ittersum examines the influence of temporal distance on consumers' mobile promotion redemption. They demonstrate that the perceived temporal distance between a promotional offer and the promoted product influences redemption and evaluation of the promoted product. While smartphones and smart carts provide flexibility in interacting with consumers, the results suggest that the timing of mobile marketing interventions during a shopping trip significantly impacts consumer decisions. In the third paper, Jia, Dai, and Jia explore the impact of mobile technologies on pro-social behaviors such as donation activities, recycling habits, and aiding strangers. The authors find that consumers' wireless social network characteristics predict behavior in pro-social contexts. In particular Jia et al. show that greater social status (as measured by iPhone usage

and connectivity asymmetry) negatively impacts voluntary behaviors intended to help others. Finally, Sharma assesses the impact of digital technology on the consumer package goods (CPG) industry and outlines key principles for marketing success. The author identifies two barriers and accelerants to success of CPG in digital channels and finds that consumers' preference for digital outlets depends upon the characteristics of the shopper and product category.

This proposed session brings together a combination of leading scholars and practitioners to examine consumers' use of and response to digital technologies in general and mobile in particular. As a cohesive unit, the four papers illuminate the role of technology in the consumption environment and provide guidance for managers as they interact with the new "digital consumer." These papers address a broad range of digital issues; further, each paper focuses on real-world problems facing marketers and consumers and maintains a cogent session theme. Importantly, because these papers also make conceptual contributions to multiple streams of literature (e.g., construal-level theory, social influence, in-store decision making), this session should appeal to a broad audience.

Smart Phones, Bad Decisions? The Impact of In-store Mobile Technology Use on Consumer Decisions

EXTENDED ABSTRACT

A critical topic of interest to marketers, in-store decision making is common for many consumers (Inman and Winer 1998). One understudied factor impacting consumer decisions are mobile technologies such as cellphones and smartphones. As mobile devices continue to grow in popularity, it is critical that marketers understand how these devices are used in retail environments.

Recently, mobile technologies have been praised for helping consumers make better decisions (Shapiro 2012). However, research acknowledges unintended visual and cognitive impairments associated with these devices (e.g., Strayer, Drews, and Johnston 2003; Strayer and Johnston 2001). Consequently, the use of mobile technologies in shopping environments may act as a double-edged sword with both positive and negative implications for shoppers.

We argue that the nature of mobile use (shopping-related vs. shopping-unrelated) will differentially impact consumer outcomes. When used in an unrelated manner (e.g., talking, texting, surfing the web), we predict that multi-tasking exhausts attentional resources and results in negative outcomes such as purchasing more unwanted products or more time spent shopping. When used in a related manner (e.g., checking prices, using shopping applications), we predict that mobile technologies may have both positive and negative outcomes. For example, consumers should be better equipped to track spending and be more likely to purchase forgotten needs items. However, we also argue that relevant technology use may still prove distracting and result in more impulse purchases and longer shopping times.

To gain a richer understanding of consumer in-store mobile use we completed two exploratory studies. In Study 1a, 30 consumers were asked to describe a time they used their mobile device in a retail setting. Seventy percent of respondents indicated they used their phones to perform at least one shopping related and one shopping unrelated function during the trip. Despite using phones in both related and unrelated manners, 80% of respondents indicated that their

phone enhanced their decision making while only 13% of respondents indicated that their phone acted as a significant distraction.

In Study 1b consumers again described a time they used their mobile device in a retail setting. However, half of the participants were prompted to discuss a time they used their phone in a related manner, while the remaining half were prompted to discuss a time they used their phone in an unrelated manner. The purpose of this study was to reveal lay beliefs of in-store mobile technology use. As anticipated, participants in the related condition believed their phone use helped with shopping ($p < .001$) and enhanced decision making ($p < .001$) more than participants in the unrelated condition.

In addition, we asked participants to evaluate shopping outcomes in direct comparison to situations in which they were not using their phone. In comparison to not using a mobile device, participants in both groups disagreed that they had bought more; disagreed that they forgot to purchase more products that they intended to purchase; and disagreed that they spent more money (all p 's $< .001$). This implies that consumers do not believe mobile technology use to greatly impact the nature, number, or cost of products purchased.

Study 2 used data from the 2012 POPAI Shopper Engagement Study to investigate the influence of in-store phone use on consumer purchases. In the study, shoppers across the U.S. were interviewed before and after grocery shopping. We included a survey question asking about mobile technology use during the trip. This information allowed us to partition consumers into four mobile usage categories: 1) no phone use, 2) related use (Related), 3) unrelated use (Unrelated), and 4) related *and* unrelated use (Both).

We find that in-store mobile technology significantly altered consumers' behaviors. First, looking at unplanned purchases, we find that consumers in the Unrelated usage condition made more unplanned purchases when compared to consumers not using phones ($\beta = .12, p < .01$). However, shoppers in the Related or Both conditions did not show any difference in unplanned purchases compared to shoppers not using phones. Therefore, under certain conditions in-store mobile phone use stimulates additional consumer purchases.

Second, looking at number of items planned but not purchased, we found that participants in the Unrelated condition missed more planned items than consumers not using mobile technologies ($\beta = .26, p < .05$). Further, consumers in the Related condition missed marginally more planned items than individuals not using mobile technology ($\beta = .19, p < .10$). This result is consistent with our contention that mobile technology use distracts consumers from the shopping task.

Third, assessing trip length, we found that Unrelated phone use enhances the positive effect of number of items purchased on shopping time ($\beta = .01, p < .05$). Therefore, it appears that Unrelated phone use can substantially increase the amount of time spent in-store for shoppers planning to purchase many items.

Finally, we found an interesting relationship between phone use and deviations from expected spending. Overall, shoppers in the Unrelated condition spent less than they expected compared to shoppers not using a phone ($p < .05$). However, Unrelated technology use strengthened the positive impact of number of items purchased on deviations from expected spending ($\beta = .02, p < .01$). Essentially, as consumers in the Unrelated condition made more purchases they exceed expected spending more rapidly. Further, Unrelated use strengthens the negative relationship between planned items not purchased and deviations from expected spending ($\beta = -.05, p < .05$). This result is consistent with our prior finding that consumers using phones in an Unrelated manner miss more planned items and suggests that these consumers may need to make additional shopping trips to purchase forgotten items.

In summary, we find that mobile phone use can exert a distracting influence on shoppers and interfere with shopping goals. Further, it appears that consumers do not anticipate these effects. While consumers understand the positive implications of in-store mobile technology use, it appears they are unaware of the negative impact these devices can have, especially when used in a distracting manner. Depending on use, mobile technology may lead to more unplanned purchases, more planned but not purchased items, longer shopping times, and additional shopping trips.

So Close, Yet So Far Away: The Influence of Temporal Distance on Mobile Promotion Redemption during a Shopping Experience

EXTENDED ABSTRACT

Consumers have traditionally been exposed to price promotions either before entering a store or at the moment of choice (Blattberg, Briesch, and Fox 1995). Yet, with the proliferation of consumer facing technology, such as smartphones or smart shopping carts, retailers and manufacturers have a greater level of flexibility as to when to present shoppers with promotions during a shopping experience. This research contributes by examining the role of the temporal distance between the promotional offer and the promoted product and its influence on redemption likelihood, product perceptions, and spending behavior.

Priming literature states that promotional offers should be transient, which suggests that shoppers are more likely to redeem a promotion when it is encountered closer to the purchase decision for the promoted product (Crowder 1976). However, temporal construal theory suggests that the temporal distance between the promotion and the promoted product positively influences consumer perceptions about the product (Liberman, Sagristano, and Trope 2002). Specifically, when decisions are perceived to be temporally distant, individuals construe these decisions in terms of abstract, high-level terms, while more temporally proximal decisions are based in concrete, low-level considerations (Liberman and Trope 1998). Temporal distance increases the influence of the value of high-level construals, while reducing the value of low-level construals, in consumer purchase decisions and evaluations.

An important distinction between high- and low-level construals of goal-directed behavior is the focus on desirability versus feasibility considerations (Liberman, Trope, and Wakslak 2007; Vallacher and Wegner 1987). Desirability considerations refer to the value of the decision outcome (the "why" of the behavior), whereas feasibility considerations refer to the ease or difficulty of reaching the decision outcome (the "how" of the behavior; Trope, Liberman, and Wakslak 2007). This implies that when the temporal distance between the promotional offer and the promoted product is close (e.g., the promotion is offered immediately prior to the purchase decision), shoppers would be relatively more influenced by feasibility considerations, such as the costs and uncertainties associated with acquiring the promoted product (Castaño et al. 2008). When the temporal distance between the promotional offer and the promoted product is longer (e.g., the promotion is offered in advance of the purchase decision), shoppers are relatively more influenced by desirability considerations, such as the brand or taste (Alexander, Lynch, and Wang 2008).

In order to examine the influence of temporal distance between the promotional offer and the promoted product on redemption likelihood and spending behavior, we conducted a number of simulated shopping tasks. In Study 1, participants were presented with a shopping list consisting of 8 different product categories and told that

their decisions would occur in the order of the shopping list. After every purchase, the shopping list indicated what purchases have been made with a strikethrough (ex: ~~bread~~) to draw attention to the temporally sequence of purchase decisions (Hornik 1984). Participants were randomly assigned to one of three conditions: a temporally distant promotional offer (received prior to the 2nd purchase decision), a temporally proximal promotional offer (received prior to the 5th purchase decision that was for the promoted product), or a control condition with no promotions. The promotional offer was “\$2 off Starbucks ground coffee.” The results indicate the promotions were effective: participants in both promotion conditions were more likely than the control condition to purchase Starbucks (21% vs. 6%; $\chi^2=9.129$, $p<0.01$). More importantly, and consistent with temporal construal level theory, participants were more likely to redeem temporally distant promotions than proximal promotions (34% vs. 17%; $\chi^2=4.78$, $p<0.05$).

Study 2 replicated Study 1 with the three exceptions. First, to mitigate concerns of primacy, participants shopped for 12 items with the promoted product as the 11th purchase decision. The temporally distant promotion occurred before the 5th purchase decisions, while the proximal promotion occurs before the 11th purchase decision. Second, the promotional offer was reduced from \$2 to \$1. Third, perceptions of the promoted product were collected to examine the salience of desirability considerations. As in Study 1, the promotions were effective (37% vs. 8%; $\chi^2=7.05$, $p<0.01$), and participants were more likely to redeem temporally distant promotions than proximal promotions (50% vs. 26%; $\chi^2=2.84$, $p<0.1$). Furthermore, participants who received the temporally distant promotional offer evaluated the taste and quality of the coffee more favorably than those who received the temporally proximal promotion ($F(1,87)=5.57$, $p<0.05$). This suggests a temporally distance promotion may actually enhance a shopper’s evaluation the desirability characteristics of the promoted product.

In order to examine the robustness of the effect of promotional temporal distance and the proposed mechanism in more detail, Study 3 promoted a product in a different category: \$1 off for Freschetta frozen pizza. Furthermore, additional perceptual measures were collected to examine the effect of the temporal distance on both desirability and feasibility considerations. The results again show that the promotional temporal distance increases the likelihood that participants redeem the promotion and purchase the promoted product (50.0% vs. 39.5%; $\chi^2=1.85$, $p<0.10$). Furthermore, the promotional temporal distance is shown to positively relate to a consumer’s perceptions of the promoted product’s taste (5.66 vs. 5.18, $F(1,96)=4.15$, $p<0.05$). An examination of the purchases of those participants that did not purchase the promoted product revealed some interesting results. The temporally proximal promotion leads to a lower spending on pizza (\$6.39 vs. \$6.19; $t(1,94)=1.63$; $p=0.10$), resulting in higher share for the least expensive brand (39% vs. 20%; $\chi^2=4.14$, $p<0.05$). Thus, temporally distant promotions appear to enhance the desirability considerations (e.g., taste) of the promoted product, while the temporally proximal promotion enhances the influence of feasibility considerations (e.g., price).

This research makes two important contributions. First, we are among the first to examine how consumer make distinct inferences about products by increasing the temporal distance between the promotion and product within a single shopping trip. Second, we significantly extend the literature on Construal Level Theory (Thomas, Chandran, and Trope 2006) by demonstrating how the level of a construal about a promoted product changes within a shopping trip as a function of only a few purchases.

The Wireless Good Samaritan: Pro-social Behavior in Mobile Networks

EXTENDED ABSTRACT

A growing body of research on individual and group behavior in digital social networks (Borgatti et al. 2009; Eagle, Pentland, and Lazer 2009; Kossinets and Watts 2006; Lazer et al. 2009; Onnela et al. 2007) suggests that network and telecommunications patterns can predict social relationships and other behavioral constructs (Eagle et al. 2009; Onnela et al. 2007). Population-scale telecommunications databases of prior behavioral histories thus open new avenues for investigating pro-sociality, especially given how the ubiquity of mobile telecommunications in modern life has irrevocably altered the basic parameters of social interactions. In a world where most human beings are constantly interconnected through wireless networks, mobile telecommunications (e.g. voice call, text message, internet) have not only expanded the boundaries of traditional social interactions, but have also began to substitute for face-to-face interactions (Eagle et al. 2009; Onnela et al. 2007). How pro-social behaviors function within humanity’s unprecedented state of networked interconnectivity remains an open question, especially given the known basis of pro-sociality in face-to-face environments.

Pro-social norms are evolutionarily adaptive social characteristics displayed not only by humans (Axelrod and Hamilton 1981; Danielson 2002; Fehr and Fischbacher 2003; Fehr and Gächter 2000; Nowak and Sigmund 2005; Trivers 1971) but also by species ranging from chimpanzees to rats (de Waal 2008; de Waal, Leimgruber, and Greenberg 2008; Rutte and Taborsky 2007). For many species, including our *homininae* relatives, pro-social acts are strongly biased in favor of kin and reciprocating partners, and are never extended to strangers (Rutte and Taborsky 2007). Even amongst humans, adherence to pro-social norms is often determined by un-altruistic factors such as personal identification, relatedness, immediacy, peer pressure, and potential future interactions (Axelrod and Hamilton 1981; Danielson 2002; Fehr and Fischbacher 2003; Fehr and Gächter 2000; Nowak and Sigmund 2005; Trivers 1971). However, these conventional theoretical preconditions for pro-social behavior are much weaker, if not completely non-existent, during interactions between strangers in non-traditional wireless network contexts. Vastly different from our evolutionary environments (Axelrod and Hamilton 1981; Danielson 2002; Fehr and Fischbacher 2003; Fehr and Gächter 2000; Nowak and Sigmund 2005; Trivers 1971), wireless or virtual social contexts are often anonymous, distant, one-to-one, and single-shot. Exploring pro-social behavior within such contexts not only allows us to explore how social network characteristics can predict pro-sociality in the modern social landscape, but also tests the durability of the social norm in a ‘vacuum’ environment.

In a large-scale exploratory phone survey and two randomized field experiments, we successfully use people’s social network characteristics to predict the strength of objective and verifiable pro-social behavior in a large wireless network. Besides demonstrating what specific network characteristics predict actual pro-social behavior in multiple domains (Studies 1 and 2), we also test the causality of our predictors in between-condition field experiments within the network (Study 3).

Across three studies that involved 10,000 mobile phone users (who were connected to 330,000 other users on a mobile network), we used field experiments that combine measures of verifiable behavior, population-scale databases of network behavior, and between-condition manipulations to study the basis of pro-social behavior. We found that individuals’ social status (e.g., iPhone ownership) and network structure (e.g. network centrality) could predict

Digital Shopping: What You Need to Consider

EXTENDED ABSTRACT

Success in the digital shopping environment requires a deep understanding of shopper needs and the ability to effectively deliver products to consumers. The digital revolution has transformed industries like music, books and travel almost entirely because e-commerce solutions delivered shopper needs in ways that traditional channels couldn't match. Are consumer packaged goods (CPG) next in line? Further, is technology a friend or a foe to retailing in CPG? This paper provides a thorough assessment of the impact of digital on the CPG industry, and outlines key principles for marketing success in a world where digital is the new normal. While we acknowledge that both shopper understanding and economic considerations dictate success in the digital world, this paper focuses primarily on the former: the shopper, their category needs, and the digital touchpoints that influence their behavior.

Digital technology is widely pervasive today and will only continue to grow at a rapid pace into the future. For example, over 117 million people own smartphones, and approximately 80 percent of them use these devices for shopping activities like finding stores, making lists, checking prices, researching products, sharing content, and purchasing (Nielsen Mobile Shopping Report, Q1 2012; Nielsen Mobile Panel, 2012). Amidst these activities, people seek to satisfy three fundamental needs when they shop: convenience, choice, and value. We believe that product category characteristics will interact with these fundamental needs and influence digital sales of CPG products.

To examine this contention, we conducted extensive research across 36,000 shoppers of CPG products spanning 18 categories, including both food and non-food items. Based on our research and analysis of online purchase data, we identified two barriers and two enablers that collectively determine how successful a CPG category can be in e-commerce. The two category characteristics identified as barriers to digital success are urgency and inspection. The urgency barrier refers to shoppers' desires to buy and use immediately, without waiting to have the product delivered. The second barrier is the inspection barrier or the need to inspect certain products. Concerns about spoilage can discourage online purchasing because they negatively affect the product value proposition if items get discarded. Moreover, since consumers are more likely to buy other products that they need while examining spoilable goods, the inspection barrier has a secondary effect on the entire basket.

In addition, our research uncovered two category characteristics which enable the success of CPG in e-commerce: the stock-up enabler and the price enabler. Storable goods, such as products with predictable consumption rates and a long shelf life (e.g., diapers and dog food) lend themselves to online purchasing. As for price factors, online retailers enjoy several cost advantages over traditional operations, particularly related to overhead. Lower costs of doing business online often translate directly to lower consumer prices or steeper discounts for digital shoppers. This allows marketers to retain price sensitive shoppers in a more profitable way.

Along with CPG product categories, our research also investigates consumer usage of digital touchpoints (e.g., websites, social media sites, blogs, and coupon sites) and how these touchpoints influence shoppers' purchase decisions for various CPG categories. Based upon our analysis, three key findings emerged. First, preference for digital touchpoints varies across shoppers. In particular, consumer demographics influence the type of digital media consulted. For example, African-American shoppers use store websites more than other consumers while Hispanic shoppers tend to rely more

their pro-social behavioral intentions (Study 1) and actual pro-social behavior in a range of contexts (Study 2). Specifically, in Study 2, we sent text messages, ostensibly messages from a stranger, to 5,000 randomly selected mobile phone numbers (directly connected with 137,710 other subscribers) that requested a response, e.g. "I'm feeling depressed with the holidays, can you send me some cheerful message?" Higher status predicted less altruistic helping behavior, more response latencies, less detailed responses, etc.

Critically, we are able to causally test this relationship with between-condition experimental manipulations. In Study 3, research assistants called 2,000 randomly selected numbers (with 76,783 other direct connections) and masqueraded as a visitor who just arrived in a city, who ostensibly misdialed while trying to call a friend, and attempted to ask for directions "since you're already on the line". Number of questions answered and time spent were used as dependent variables. We manipulated the accent of the caller as a novel proxy for social status, and found that individuals with higher status within their wireless network discriminated against lower-class accents in terms of amount of help rendered. That an interaction between social status network-variables and an exogenous manipulation of social status moderated previous effects showed that the network variables in Studies 1 and 2 did not reflect some factor unrelated to social status, such as dispositional curiosity or information overload

Whereas previous network research has often been limited by correlational results and lack of hypothesis testing, our research strategy bridges the gap between network research and traditional scientific research by allying the predictive power of network data with classic experimental design and hypothesis testing. Our methodology is the first to combine measurements of verifiable behavior, exogenous between-condition experimental manipulations, and large-scale network data analysis, and uses a previously untapped wealth of individual behavioral histories from wireless devices to identify and confirm the drivers of pro-social behavior.

We advance the understanding of theoretical constructs of social network connections by linking them to real behavior. We show that it was not the number and strength of connections between people in a network, but the relative structure of those connections that best predicted actual behavior. In particular, we identified connectivity asymmetry as a network variable that proxies for social status and can predict a wide range of behaviors. We show that greater social status predicted less pro-social behavior in several domains, contrary to traditional notions of social responsibility and social welfare.

Furthermore, we introduce several new measurement techniques to capture real and verifiable pro-social behavior; our use of binary response rate and strength of response (measured both explicitly by task completion, and implicitly by time spent) represents an ecologically valid measurement that can be used in numerous communication contexts for any research question that looks at response strength (e.g. advertising response, falling for phishing).

Most importantly, our results showcase the possibilities of using large network based field experiments in experimental social sciences, which has recently come under criticism for small sample sizes, biased selection and self-reported information, and other methodology flaws. A network based approach can potentially facilitate experiments with sample sizes in the millions and capture real behaviors that were previously inaccessible before detailed and objective histories of individual behavior from large consumer-technology databases became widely available.

on blogs. Second, shoppers prefer different digital touchpoints for different CPG categories. For example, consumers use coupon sites most often when purchasing diapers; brand emails most often when purchasing baby food or diet aids; and store websites most often when purchasing small appliances. Finally, an integrated approach, leveraging traditional and digital touchpoints, is most effective. Focusing solely on a social or mobile strategy is not prudent. Marketers must recognize which digital touchpoints are effective and use them judiciously in concert with traditional marketing efforts.

For the CPG industry, digital shopping represents an evolutionary development bringing manufacturers and retailers closer to the consumer. Effective digital shopper marketing requires that marketers identify the decisions shoppers make along the path to purchase, when they intend to buy specific products, and then determine the right mix of digital touchpoints to influence those decisions. In conclusion, our research investigates how category characteristics of CPG alter digital sales and identifies how consumers' preferences for digital outlets vary across categories. We contend that by leveraging digital and its distinct characteristics, retailers can complement brick-and-mortar operations rather than replace them, building sales on both fronts. For manufacturers, we conclude that digital is no longer optional. It is paramount that manufacturers engage shoppers using digital touchpoints, particularly mobile, to influence relevant decisions on their path to purchase.

SESSION OVERVIEW

Understanding how people make decisions about consumption, particularly indulgences, is important from the perspective of not only marketing but also public health and policy. Much of the existing research examines decisions in which a more virtuous/healthy option is contrasted with a more indulgent/unhealthy one. Furthermore, the experimental target is often to understand how related goals or particular attributes of the choice targets might bias the outcome. However, in everyday life, consumption decisions can arise in a manner that is intertwined with other considerations. A choice to go to a party might add social elements or framing to a decision to accept an alcoholic drink, or to absent-mindedly dip in to a bowl of chips. Thus this session examines how seemingly separate events can influence individuals to pursue more or less indulgent consumption paths. The events studied range from personal choices or experiences to entirely exogenous occurrences. However, across findings, their impact on consumption appears to be related to how important a person feels the event is to their own self and/or goals.

To better approach the complexity of these effects, the work in this session represents both laboratory experiments, and empirical analyses of “real world” data. The first paper, by Karmarkar and Bollinger, shows that taking an environmentally virtuous action caused grocery shoppers to reward themselves by increasing purchases of indulgent foods in addition to purchasing more “green” items. But it also shows that this result was sensitive to common competing motivations. In the second paper by Wadhwa and Kim, losing a chance based game subsequently led to an increased desire for unrelated rewarding items. Notably, this effect was dependent on how strongly the loss was felt – that is, on the game’s outcome being “near-win.”

The work by Cornil and Chandon extends beyond losing a game oneself, to watching others lose. Using archival and experimental data, they find that a loss in a sporting event can increase consumption of unhealthy food by fans who identify with the losing team. This effect was tied to degree to which the loss was felt as a personal one. Balancing these data on increased indulgences, work by Dai, Milkman and Riis, provides evidence that externally defined events can also promote more “industrious” choices when they are seen as opportunities or signals for the individual to make a fresh start.

Again, the power of these events arose from how meaningful they were to the individual.

As implied, these papers raise the general question of how important self-identification with an event is as a mechanism (or moderator) for these effects. Related discussion questions are 1) whether it is also important that the acts of consumption are strongly affective and/or associated with the self and 2) whether the impact of separate events is related to being an unconscious influence, or a conscious motivation. By combining experimental results with field (or empirical) data, these findings may provide practical suggestions for “making a difference,” in addition to appealing to researchers who study consumption, health-related behavior and goals/motivation.

BYOB: Bringing Your Own Shopping Bags Leads to Indulging Yourself and the Environment

EXTENDED ABSTRACT

As concerns about climate change and resource availability become more central in the public discourse, the use of reusable grocery bags has been strongly promoted as an environmentally and socially conscious virtue. Thus it is useful to ask whether adoption of this behavior could subconsciously influence consumers’ in-store choices (e.g. Dijksterhuis et al. 2005). As a physical reminder of a virtuous act, reusable bags might be assumed to prime shoppers’ attention or motivation towards environmentally responsible products. Similarly, bringing one’s own bags could be self-signaling, suggesting to the consumer that they themselves are “green” or “good”, leading to a higher spend on organic or healthy foods and possibly avoiding indulgent ones, for the sake of consistency.

However, we propose that as an indicator of a virtuous self, bringing a bag gives shoppers permission to make *less* virtuous choices. Such a result is consistent with licensing effects, in which a virtuous action in one domain allows individuals to select indulgences in subsequent choices (Fishbach and Dhar, 2005, Khan and Dhar 2006). Here we demonstrate support for both priming and licensing effects of bringing one’s own grocery bags via a combination of experimental studies and empirical analysis of real world shopping data.

In our first study, participants (N = 74) were asked to examine a schematic of a grocery store layout, and to imagine going to shop at this store. We asked participants to list ten food items they would be likely to purchase during this trip. People who imagined they had brought reusable bags with them listed significantly more indulgent items, such as desserts or snack chips, than those who had received no information about bags ($F(1,72) = 4.39, p < .05$).

A second experimental study investigated whether this increased consideration of indulgent purchases was accompanied by an increase in their perceived value. Participants (N=377) again were instructed to imagine shopping for groceries, and were (were not) told that they had brought their own bags with them. They then indicated their willingness to pay (WTP) for groceries from “green”, “hedonic” and “baseline” (e.g. canned soup) categories. In an additional manipulation, participants either did, or did not, see prices associated with each item. For the group who received no price information, those who imagined shopping with reusable bags showed a relatively higher WTP for *both* green ($F(1,337)=8.52; p < .005$) and hedonic ($F(1,373)=13.97; p < .001$) foods as compared to the baseline.

However, when price information was present, no effects of bringing a bag were found for either category.

Together, these experimental results suggest that the use of reusable shopping bags might have a significant influence on grocery purchasing behavior in stores. However, the findings here are sensitive to other information, such as the salience of reference prices. Thus it was important to examine whether these results existed “in the field”, where consumers are exposed to many different competing influences. In addition, using real data meant that the decisions reflected true incentive compatibility, in comparison to the hypothetical experimental situations.

Thus as a third study, we performed an empirical analysis of cardholder transaction data from one location of a large U.S. grocery store chain. The data include over 2 million transactions by approximately 60,000 households, although we restrict the sample to frequent shoppers. Transactions in which the consumers had their own shopping bags were identified by a small monetary bag credit. Using a rich set of controls, we found that having one’s own bags increased consumers’ probability of purchasing both hedonic items (e.g. chips and high sugar foods like desserts or candy) as well as organic versions of products. These data also show how the effects of bringing one’s own bag are sensitive to common competing motivations. In studies 1 and 2, the data was restricted to individuals who did not have dependents under the age of 18, as the presence of children in a household has distinct influences on grocery basket composition, particularly in the realm of health conscious choices (Mangleburg, 1990; Prasad et al, 2008;). For study 3, we designed one set of controls to identify shoppers with young dependents in their household. Our analysis confirmed that the effects of bringing one’s own bag on indulgent purchasing only held for those consumers who *did not* show other purchases related to having very young children.

We demonstrate that remembering to bring one’s own grocery bags may license consumers to treat themselves while also priming them to treat the environment. This suggests that consumers would be particularly sensitive to the impulse indulgences often found at checkout registers, as the presence of the bags becomes highly salient at this point. It also predicts that environmentally related products could benefit from this stage of the shopping experience, since their consideration should be increased as well. In addition, seating our effect within the licensing literature suggests that its occurrence is dependent on consumers’ having some agency in choosing to bring their bags (Khan and Dhar 2006). Thus as several communities, cities and countries consider laws banning disposable bags (New York Times, 2012), the strength of these effects are likely to depend more on individual consumer’s attributions for whether they (or the government) are the reason they are bringing their own bags.

The Nearly Winning Effect

EXTENDED ABSTRACT

Prior research on goal gradient theory has shown that one’s motivational drive associated with a reward intensifies with increasing advancement toward the reward (Hull 1983). These findings raise an interesting question—what would happen to this intensified motivational drive when one nearly wins a reward? To answer this question, we turn to an emerging body of research on motivation, which suggests that the motivational drive is more general in nature, such that once induced through an incidental cue, it could lead to a broad array of reward seeking behaviors (Van den Bergh, Dewitte and Warlop 2008; Wadhwa, Shiv and Nowlis 2008). Drawing upon these findings, we propose that the intensified but unsatiated motivational drive induced as a result of nearly winning a reward could enhance

the desire to seek subsequent unrelated rewards. We term this effect, the “nearly winning” effect. We examine our nearly winning effect hypothesis in four studies, including a field study, and also rule out alternative accounts related to mood and arousal.

In Study 1, we tested our basic research hypothesis related to the nearly winning effect. The winning factor was manipulated by having participants play an eight trial game, similar to the computer game—minesweeper—where they saw a box of 16 tiles, half of which contained a rock, while other half contained a diamond. If they managed to find eight diamonds, they could win a pen. The game was rigged such that in the clearly-losing condition, participants only managed to find one out of the eight diamonds. In order to examine our argument related to increasing advancement toward the reward, we included two nearly-winning conditions in this study. In both the nearly-winning conditions, participants managed to find seven of the eight diamonds. However, in one of the conditions, participants missed a diamond on the eighth trial (nearly-winning-advancement) whereas in the other condition, participants missed a diamond on the second trial itself (nearly-winning-no advancement). Therefore, in the nearly winning-no advancement condition, while participants still nearly won the reward, they were aware of losing the reward from the second trial and thus the feeling of advancement toward the reward was attenuated early on. Subsequently, participants were informed that they could return their survey and collect a small gift (a chocolate bar) from another experimenter at the end of the corridor. The speed with which they walked to get the chocolate bar became the main dependent variable in this study. Consistent with the nearly winning hypothesis, our results show that those who missed a diamond on the eighth trial in the computer game (nearly-winning-advancement condition) showed a greater desire for chocolate bar, as manifested in the walking speed toward the chocolate bar, than those in the nearly-winning-no advancement or clearly-losing conditions. Furthermore, there was no difference in walking speed between the nearly-winning-no advancement and the clearly-losing conditions. Given there was no difference in these two conditions, in the subsequent studies, we dropped the nearly winning-no advancement condition.

In the second study, we sought to provide stronger support for our underlying conceptualization by examining the role of reward value in moderating the nearly-winning effect. Further, in this study, we used level of salivation toward a reward as a way to measure one’s desire for a reward (Gal 2012). We argue that if the nearly winning effect is driven by a general increase in desire for a reward, then those in the nearly-winning condition versus clearly-losing condition should salivate more when presented with an unrelated high reward value item, but not a low reward value item. The winning factor was manipulated using the same game used in the first study and the reward value was manipulated by having participants view a picture of either a high reward value (100 dollar bills) or a low reward value (five cents) item. Our findings provide support for our hypothesis—nearly winning versus clearly losing in the game subsequently led to a higher salivation level toward an unrelated high reward value item, but not toward a low reward value item. No such difference was found in the level of salivation for participants in the clearly-losing condition. Moreover, there were no differences found in the mood or arousal levels across conditions in this or in subsequent studies.

In the third study, we provide further support for our conceptualization related to the activated motivation drive by showing that the nearly-winning effect gets attenuated when the motivational drive is dampened in an intervening task. Participants played the same game used in the previous two studies. In this study, we also included a winning condition (wherein participants did manage to find all the

eight diamonds). Subsequently, we manipulated the motivational drive dampening by having participants sample either an unpleasant odor or a neutral odor (adopted from Wadhwa et al., 2008). Participants then engaged in a purportedly unrelated card arranging reward responsivity objective test (CARROT; Powell et al. 1996), which measures how much effort an individual exerts to earn a reward. Consistent with our predictions, those in the nearly-winning condition, versus clearly-losing condition and clearly-winning conditions, exerted significantly more effort to earn an unrelated reward (as measured by CARROT). Further, this nearly winning effect was attenuated when the motivational drive was dampened in an unrelated intervening task.

In the last study, we test the generalizability of the nearly winning effect by conducting a field study at a fashion-accessory store. Consumers participated in a short survey in an exchange for a chance to win \$20 gift certificate by playing an instant scratch-off lottery. Consumers were randomly assigned to one of the three winning conditions where they won (clearly-winning) the lottery, or lost the lottery by one digit, which was the last digit (nearly-winning) or by the last five digits (clearly-losing). The amount they spent in the store became the main dependent variable in this study. Consistent with our predictions, our findings show that those who nearly won the reward spent significantly more than those who clearly won or lost the reward.

In sum, findings from this research show that nearly winning a reward as compared to clearly losing or winning a reward can activate a general motivational drive leading to a broad array of reward seeking behaviors.

From Fan to Fat?: Vicarious Losing Increases Unhealthy Eating, but Self-Affirmation Is an Effective Remedy

EXTENDED ABSTRACT

Sport watching is more popular than ever: 108 million Americans watched the 2013 NFL Super Bowl and 2.2 billion people watched the 2010 FIFA soccer World Cup. Using archival and experimental data, we explore whether the vicarious defeats and victories that supporters experience influence their ability to regulate their food intake.

Supporters tend to perceive their team's successes and failures as theirs (Hirt et al. 1992), which has a measurable effect on their self-regulation abilities. Football and soccer defeats, especially when they are narrow or unexpected, increase alcohol-related criminality (Rees and Schnepel 2009), traffic fatalities (Wood, McInnes, and Norton 2011), and domestic violence (Card and Dahl 2011).

Consistent with studies showing that ego threats increase preferences for indulgent food (Baumeister, Heatherton, and Tice 1993), we expected that people would eat less healthily after the defeat of a football team that they support. Second, as vicarious sports victories improve the perceived self-worth of supporters (Hirt et al. 1992), we hypothesized that vicarious football victories would lead to healthier eating. Third, we expected that allowing supporters to self-affirm after experiencing a vicarious defeat would eliminate its impact on unhealthy eating, as self-affirmation reduces the impact of vicarious sports defeats on self-serving biases (Sherman et al. 2007) and, more generally, improves people's self-regulation abilities (Schmeichel and Vohs 2009).

The first study is a quasi-experiment in which we examined the self-reported daily food consumption of a representative panel of 730 US consumers and 3150 consumption days, during two NFL seasons. We assumed that most people in the panel watch football games and support the team of the city where they live, based on sur-

veys showing that about 60% of Americans declare being NFL fans (Gallup 2012). We examined the effects of 450 Sunday games on consumption on the day of the game and on the following Monday and Tuesday. We measured unhealthy eating by calculating saturated fat consumption and calorie intake from the food consumption data provided by the panelists.

Compared to their average consumption, people consumed 16% more saturated fat and 10% more calories on Monday if their team had lost the day before but consumed 9% less saturated fat and 5% less calories if their team had won. In contrast, consumption was at its usual level on the same Monday among people assigned to control groups: those living in cities without an NFL team and those living in cities whose NFL team did not play on that Sunday. Second, we found that the outcome of the game had no effect on food consumption on the Sunday of the game and on the following Tuesday. This shows that the Monday effects were not compensated on the subsequent day or anticipated on the previous day. Third, we found that these effects were particularly strong when the outcome of the game was uncertain, as measured by a low point spread in the bookmakers' predictions. This suggests that surprise and disappointment are important drivers of the effect. Fourth, we found that saturated fat consumption was especially low when the victory was crushing and particularly high when the defeat was tight, which is consistent with the literature on close-call counterfactual thinking (Medvec and Savitsky 1997). Finally, we found that the effects were stronger in cities where people identify the most to their NFL team (based on survey data): a 28% increase in saturated fat consumption following a defeat, and a 16% decrease following a victory. Gender did not moderate these results, which is consistent with extant studies on the impact of game outcomes on cardiac accidents (Carroll et al. 2002; Kloner et al. 2011).

We replicated these results in a controlled laboratory experiment in France. Participants were asked to describe either a victory or a defeat by their favorite sport team. After this, they were given the opportunity to eat different foods. We found that people asked to think about a defeat ate more unhealthy food and less healthy food than people asked to think about a victory. Three coders also measured the extent to which the participants engaged in spontaneous self-affirmation when describing the sporting event. As expected, we found that spontaneous self-affirmation helped vicarious losers limit their consumption of unhealthy food.

In a third study, we asked a representative panel of French participants to watch a 7-minute video of a soccer game and manipulated self-affirmation. Participants were randomly assigned to a 3 (defeat, victory, control) x 2 (self-affirmation, control) between-subject design. The games of the victory and defeat conditions were important finals that the French national soccer team had either won (Euro 2000) or lost (World Cup 2006) against its archrival, the Italian national team. The control game opposed two Belgian soccer teams, irrelevant to participants' identity. In the self-affirmation condition, participants were asked after watching the videos to rank their core values and to elaborate on their top-ranked value (McQueen and Klein 2006). Participants in the control condition were asked to list the important features of chairs. Then, we measured participants' desire for various foods. Compared to the control condition, watching the defeat video increased preferences for less healthy food whereas watching the victory video increased preferences for healthier food. As expected, the effect in the defeat condition was attenuated when participants could affirm their core values.

These results contribute to the literature on self-control by showing how an important contextual factor of everyday life (sporting events) can promote or hinder healthy eating. We also show how

the interplay between sport watching and eating relates to identity issues. A simple self-affirmation intervention can eliminate the unhealthy consequences of the vicarious defeat. Ultimately, this research has important managerial and political implications: we show what kinds of games are susceptible to raise health issues, providing precious information to regulators -and socially responsible advertisers- concerned with the obesity epidemic.

The Fresh Start Effect: Temporal Landmarks Motivate Aspirational Behavior

EXTENDED ABSTRACT

The notion that renewal is possible and offers individuals an opportunity to improve themselves has long been endorsed by our culture. For example, many religious groups engage in ritual purification ceremonies, Christians can be “born again,” and the metaphorical phoenix rising from the ashes ubiquitously represents rebirth. This suggests a widely shared belief that we have opportunities throughout our lives to start fresh with a clean slate, with the well-known “New Year’s effect” representing just one example of a far broader phenomenon. The current research explores naturally-arising points in time when an individual is particularly motivated to engage in aspirational behaviors (or activities that help people achieve their wishes and personal goals).

Past research suggests that temporal landmarks, including personally-relevant life events (e.g., anniversaries, birthdays) and reference points on the calendar (e.g., holidays, the start of a new week/month/year/semester) demarcate the passage of time and create discontinuities in our memories, experiences, and time perceptions (Robinson, 1986; Shum, 1998). Further, temporal landmarks may increase the subjective distance between a person’s current self and past self (Libby & Eibach, 2002; Peetz & Wilson, 2013; Wilson & Ross, 2003). The theory of temporal self-appraisal posits that the more disconnected people feel from their past selves, the more likely they are to disparage their past selves (Wilson & Ross, 2001). By doing so, they are able to maintain a positive perception of themselves in spite of past failures (Wilson & Ross, 2001). Consequently, we conjecture that temporal landmarks separate people from their imperfect past selves, which makes them feel superior and thus capable of pursuing their aspirations. We hypothesize that this process of wiping the slate clean generates fresh start feelings and motivates people to tackle their goals.

Across three studies, we document evidence of the proposed “fresh start effect” in the field. Study 1 examines public interest in a widespread goal – dieting – by using ordinary least squares (OLS) regression to predict daily Google search volume for the term “diet” ($N_{\text{days}}=3,104$). We find that relative to baseline, interest in dieting increases at the start of new weeks (by 14.4%), months (by 3.7%), and calendar years (by 82.1%), and following Federal holidays (by 10.2%; particularly following holidays that survey respondents report “feel more like a fresh start”) (all p ’s < 0.001).

Study 2 moves from measuring intentions to actions by examining the actual frequency of engagement in another aspirational behavior – exercise – using university gym attendance records ($N_{\text{members}}=11,912$, $N_{\text{days}}=442$). Again, OLS regressions show that relative to baseline, the probability of visiting the gym increases at the beginning of the week (by 33.4%), month (by 14.4%), year (by 11.6%), and semester (by 47.1%), as well as following school breaks (by 24.3%) (all p ’s < 0.05). Also, birthdays (with the exception of 21st birthdays) increase gym attendance by 7.5% ($p < 0.001$), indicating that personal temporal landmarks, like calendar landmarks, can produce a “fresh start effect”.

Study 3 uses data from the goal-setting website StickK.com to examine a wider range of goals (including job, educational and financial pursuits). OLS regressions ($N_{\text{goals}}=66,062$, $N_{\text{days}}=866$) show that people are more likely to create goal contracts at the beginning of a week (by 62.9%), month (by 23.6%), year (by 145.3%), and following Federal holidays (by 55.1%; again particularly following holidays that feel like fresh starts), as well as following their birthdays (by 2.6%) (all p ’s < 0.05 except birthdays: $p=0.07$). Importantly, we find that temporal landmarks motivate people to tackle a broad set of health-irrelevant goals (e.g., “study harder for GMATs”), suggesting that the fresh start effect is not merely the result of efforts to rebalance one’s health after over-indulging.

Three additional laboratory studies provide support for our hypothesized mechanism. In Study 4, we manipulated the psychological meaning associated with a temporal landmark. Participants ($N=303$) read about a middle-aged female, Jane, who was not satisfied with her weight and would soon start a new position at work. In this three-condition, between-subject experiment, participants were told either that Jane (a) viewed the new job as a meaningful life change, but it would not affect her daily routines; (b) did not view the job change as meaningful, but it would shift her daily routines; or (c) did not consider the job change to be meaningful, and it would not shift her daily routines. Participants then rated how motivated Jane would be to add healthier habits to her life following the change. As expected, a meaningful job change was perceived to be more likely to motivate health improvements than a job change described in either of the other two conditions ($ps < .001$). Furthermore, participants’ rating of the extent to which the new job would feel like a fresh start to Jane fully mediated the effect of the meaningful job change on Jane’s motivation to improve her health.

Studies 5a ($N=199$) and 5b ($N=203$) present scenarios examining the effects of two different temporal landmarks: moving to a new city (5a) and celebrating a birthday (5b). We replicate our Study 4 finding that more meaningful temporal landmarks generate stronger fresh start feelings and thus are perceived as more likely to motivate aspirational behaviors (in this case, quitting smoking) than less meaningful but objectively equivalent temporal landmarks. We also measured the extent to which participants believed each scenario’s protagonist would feel (1) disconnected from his/her past self, and (2) close to his/her ideal self. Supporting our proposal mechanism, mediation analysis shows that fresh start feelings following temporal landmarks originate from a psychological dissociation from one’s past self and a perceived increase in closeness to one’s ideal self.

Together, this research investigates how and why temporal landmarks can affect individuals’ motivation to engage in aspirational behaviors. Organizations and individuals may be able to capitalize on various temporal landmarks to facilitate goal pursuit. Also, marketers of products designed to help people attain desirable objectives (e.g., gym memberships, healthy restaurants, online education programs) may be best able to appeal to consumers’ desires for self-improvement by advertising to consumers at fresh start moments.

Paper #4: The Influence of Time-Interval Descriptions on Goal-Pursuit Decisions

Nira Munichor, Hebrew University of Jerusalem, Israel

Robyn A. LeBoeuf, University of Florida, USA

SESSION OVERVIEW

Many important consumption decisions, such as making a purchase now (vs. saving), paying more for faster delivery (vs. being patient) or choosing to pursue long-term goals (vs. giving into temptation), have intertemporal components. Extensive research studying preferences over time has demonstrated that consumers often deviate from normative theories (Frederick, Loewenstein, and O'Donoghue 2002), effectively acting against their long-term interest. Despite the calls to utilize decision research to increase consumer welfare (Ratner et al., 2008), little research has examined ways to help consumers make decisions that are in line with their long-term goals. Four papers in this sessions address this gap by pointing out important ways in which consumers can be nudged to make decisions that are in line with their long-term interests.

The first paper by Bartels, Urminsky, and Frederick demonstrates that consumers' patience in financial decision-making depends on: (1) consumers' awareness of the inherent intertemporal tradeoff and (2) their caring about the future self. They show that connectedness to one's future-self influences financial decision making primarily when tradeoffs are apparent. Their research shows that getting consumers to make far-sighted financial decisions, in line with their long-term goals, require a combination of both valuing future outcomes and recognizing opportunity costs.

The second paper by Kim and Iyengar informs us that impatience, observed mainly with monetary outcomes, might underestimate consumers' impatience when it comes to durable purchases. They show that consumers are significantly more impatient when considering durable goods than monetary outcomes and that this impatience is rooted in the shrinking estimates of their usage duration for such products. Their results show that interventions that would help decrease shrinkage in time perceptions (Zauberman, Kim, Malkoc and Bettman 2009) can increase patience for both durable (and monetary) goods.

The third paper by Lee, Malkoc, and Rucker shows that consumer impatience can be remedied by giving them contextualized or generalized control. Their studies demonstrate that consumer impa-

tience can be, at least in part, attributed to consumers feeling *not* in control of their decisions. They show that endowing consumers with control either locally (by giving them explicit options) or globally (by making them feel powerful) decreases their impatience. Their results point out simple interventions that can nudge consumers to make long-term oriented decisions.

The final paper by Munichor and LeBoeuf demonstrates that describing the future intervals as extents (e.g., in 3 months) as opposed to dates (e.g., by July 1st) increases consumers' likelihood of pursuing long-term goals. Their results indicate that when time is presented as *extents* consumers' attention to long-term goals and their benefits is increased, while date descriptions draw attention to day-by-day passage of time. Their results highlight how simple framing changes can be powerful tools in increasing consumers' long-term orientation.

Taken together, papers in this session propose ways to nudge consumers to make long-term oriented decisions. The session is aligned with the conference theme, as it attempts to "make a difference" in consumers' well-being. We expect this session to draw an interdisciplinary audience from intertemporal choice and consumer welfare literatures.

To Know and To Care: How Awareness and Valuation of the Future Jointly Shape Consumer Savings and Spending

EXTENDED ABSTRACT

Consumers are often advised to cut back on everyday small spending and invest the money instead, which can make a substantial difference in the long run. Adopting and maintaining such a strategy requires the consumer to both (i) consider the tradeoff inherent in the purchase; i.e. purchasing now requires foregoing an opportunity to use the money to further one's long-term interests, and (ii) care enough about the future self who would benefit from their forbearance to warrant restraint in the present. We argue that consumer financial decision-making hinges on a specific interaction between both components that has not been demonstrated in prior research. Across six studies, we show that the psychological relationship with one's future self (operationalized as the degree of *connectedness* to one's future self; Parfit 1984) influences financial decision making primarily in those contexts where tradeoffs are apparent (Frederick et al., 2009). Thus, far-sighted choices require the combination of both valuing future outcomes—as affected by connectedness and reflected in the discount rate—and the recognition of opportunity costs.

In Studies 1a (N=88) and 1b (N=233), we show that manipulating participants' awareness of opportunity costs interacts with measured factors relating to their valuation of the future (connectedness in Study 1a and estimates of temporal discounting in Study 1b) to impact a typical purchase decision. As in Frederick et al. (2009), participants were asked whether or not they would purchase an entertaining DVD for \$14.99, and in the opportunity cost condition the reminder "keeping the \$14.99 for other purchases" was added to the not-purchase option. Participants were also asked to rate their perceived connectedness to the future self in Study 1a and were asked to complete a short temporal discounting task (choosing between \$900 available in a year and various smaller amounts available immediately) in Study 1b. In both studies, we find a significant interac-

tion between the opportunity cost reminder and factors relating to people's valuation of the future. In Study 1a, participants' ratings of connectedness influenced purchase decisions when participants were reminded of opportunity costs ($r = -.41$, $p < .01$), but not in the no-reminder control condition ($r = .04$). Similarly, in Study 1b, purchase decisions are related to our measure of temporal discounting when participants were reminded of opportunity costs ($r = -.20$, $p < .05$), but not in the no-reminder control condition ($r = .09$, $p > .10$).

In Study 2 ($N=199$), we replicate Study 1a (manipulating the salience of tradeoffs and measuring connectedness), and also measure the propensity to plan. We find a significant three-way interaction between connectedness, opportunity cost salience and planning, such that connectedness reduces spending when participants *either* see an explicit opportunity cost reminder *or* have a high propensity to plan (and therefore spontaneously consider opportunity costs).

In Study 3 ($N=146$), using a 2×2 between-subjects design, we crossed a manipulation of connectedness with an opportunity cost manipulation, measured people's purchase intentions, and then measured temporal discounting. We manipulated connectedness by having participants read a short description of "recent research" suggesting that young adulthood is either characterized by stability in identity (inducing high connectedness) or is characterized by instability in identity (inducing low connectedness). Participants then chose between purchasing one of two iPads (64 Gb for \$829 or 32 Gb for \$599) or buying neither product. The price difference was highlighted for the lower cost iPad in the "opportunity cost" conditions ("leaving you \$230 for other purposes"), but not in the control condition. We found that making people feel less connected to the future self increased temporal discounting ($\delta_s = .51$ vs. $.58$ for low vs. high connectedness, $p < .05$), replicating Bartels and Urminsky (2011). When people were reminded of opportunity costs, manipulating connectedness reduced purchases of the expensive iPad (9% vs. 0%, low vs. high connectedness, $p < .07$), but the manipulation had no effect when people were not prompted to consider opportunity costs (8% vs. 7%). We found a significant interaction of manipulated connectedness and manipulated opportunity cost on the average spend ($p < .05$). The difference in intended spend was mediated by the connectedness-manipulation-induced changes in discounting when opportunity costs were highlighted, but not when they weren't.

In Study 4 ($N=130$), we generalize to a more naturalistic manipulation of tradeoff salience. We asked participants to rank the desirability of six product categories (pocket video cameras, blenders, bed sheets, pocket watches, laser printers, and nonstick frying pans), and choose between one more expensive and one less expensive product from each of these categories. The order of the last two blocks (ranking and choosing) was varied and served as our manipulation of tradeoff salience. Ranking before choosing induces recognition of tradeoffs—that the satisfaction of one purchase goal is likely to entail the subordination of other purchase goals—and it also causes participants to think of at least five other uses of their money before their first decision to splurge or save. Our primary dependent variable was the number of expensive items purchased, which was reduced by manipulated connectedness when tradeoffs were highlighted (2.19 vs. 1.45, low vs. high connectedness) but not when tradeoffs were not highlighted (i.e., when participants chose before ranking the product categories: 2.03 vs. 2.36; interaction $p < .05$). In particular, the increase in fiscal restraint that we observe occurs almost exclusively for decisions involving those product categories that each participant ranked as less personally desirable. As a result, higher-connectedness respondents' tastes for spending are both reduced and more focused on higher-valued goods when considering opportunity costs (i.e., after completing the ranking task).

Lastly, Study 5 ($N=304$) measured adult bank account holders' savings and spending behaviors and attitudes. We find a correlation between connectedness and savings (even controlling for income and demographics) among participants who reported that they enjoyed managing their finances and looked forward to it. In contrast, we find no such correlation among participants who report that they dislike managing their finances and dread having to do so, presumably because their lack of engagement suppresses consideration of financial tradeoffs.

Making Decisions For the Future: Value of Delayed Durables and Shrinkage in Usage Duration

EXTENDED ABSTRACT

Durable goods provide not only immediate benefits but also an extended stream of benefits over their usage duration. Consumers often face situations where they have to make purchase decisions for durables available only after a delay. Delayed purchase of durables are challenging both to consumers and retailers. For consumers, they should appropriately compare a future alternative to any available immediately and decide whether it is worth delaying their purchases. Such decisions are essentially intertemporal tradeoffs. For retailers, selling goods not in stock is challenging as they have to consider appropriate financial incentives for inducing consumers to delay their purchase (e.g., price discounts for back-orders). How consumers change their valuation for alternatives depending on temporal availability will clearly impact the level of monetary compensation.

Past work on intertemporal decision making has repeatedly shown that delayed alternatives look less attractive than immediately available ones. This may be due to individuals preferring immediate over delayed consumption, uncertainty associated with future preferences, or subjective perception of delays. Note that these factors are likely to influence the discounting of all types of goods like monetary outcomes or consumables as well as durables.

Durables, however, are different from other types of goods because they provide a stream of utility over a usage duration. For instance, a television purchased today provides benefits starting from the purchase time till the time of discard. Does using a product over a duration have implications for how their benefits are discounted? Past work provides little direction. In fact, some past research has tested factors impacting time discounting using durables but reports no systematic difference in preference for durables and for monetary outcomes.

In the current article, we seek to investigate how durables are discounted and, in particular, what role does usage duration play in this process. We posit and find evidence that consumers subjectively shrink the expected usage duration associated with durables that are expected to be purchased in the future. That is, they expect to use the same durable for a shorter period of time when it is purchased in the future than immediately. This shrinkage in usage duration serves as a factor of time discounting *in addition to* other factors such as time preference or uncertainty in future preference (which are unrelated with usage). As a result, a future durable looks even less attractive than an immediate one even after accounting for all factors known to influence time discounting.

Supporting our premise on the shrinkage in usage duration, we found evidence for the shrinkage effect in usage duration in two types of judgment: estimation of unknown usage duration and subjective perception of a known duration. In study 1, we show that estimated usage duration shrink when a durable (e.g., a smartphone) is planned to be purchased in the future as compared to the present.

In study 2 and 3, we demonstrate the shrinkage effect in subjective scaling of a given duration that is objectively given to participants.

Demonstrating the implication of the shrinkage effect, in study 4 we show that individuals' tendency to shrink future usage durations (relative to usage durations starting from the present) is an important determinant of their impatience for durables. That is, those who shrink future usage duration more would expect to use the same durable purchased in the future for a shorter period of time as compared to those who shrink it less. As a result, the former consumers would discount the value of delayed durables more and would become more impatient for immediately available durables than the latter consumers.

In study 5 we further demonstrate that the shrinkage effect in usage duration would result in more impatience for durables than for monetary outcomes, if all other conditions are equal. Note that various factors known to influence time discounting for monetary outcomes such as pure time preference, uncertainty, subjective perception of delays, and various individual and situation factors would influence time discounting for durables as well. But the shrinkage effect in perceived usage duration is a unique factor that influences only the time discounting of durables. Therefore, if all other conditions are equal, consumers would be more impatient for durables than they would be for money.

Taken together, our results demonstrate the important role of usage duration and its judgment in determining consumers' intertemporal preference for durables. We also discuss the implications for retailers in determining the optimal level of monetary compensation for delayed durables.

Loosing vs. Gaining Control: Enhancing Feelings of Control Reduces Present Bias

EXTENDED ABSTRACT

Consumers regularly make decisions about the timing of their consumption. For instance, they decide how fast to ship an online purchase, when to take vacations, or when to make a large purchase. Extant research on such decisions has shown a variety of consumer phenomena, most notably present bias (a.k.a. hyperbolic discounting). Preferences are considered present-biased when a consumer is willing to pay higher premiums to avoid a 3-day delay in shipment (e.g., \$5, or \$1.8 per day) than a 10-day delay (e.g., \$10, or \$1 per day; Malkoc and Zauberman 2006).

A substantial amount of research has investigated the underlying mechanisms for present-bias. The last decade has seen a surge in research that theorized, and empirically tested, a host of cognitive explanations, based on changes in mindsets (Malkoc, Zauberman and Bettman 2010), representation of the outcomes (Malkoc and Zauberman 2006), resources (Zauberman and Lynch 2005) or time itself (Zauberman et al. 2009).

In this research, we propose a more affective mechanism to account for present-biased preferences. Prior research has theorized that forgoing a current outcome is painful and leads to a feeling of deprivation (Hoch and Lowenstein 1991), resulting in impulsiveness and impatience; however, this account has not been empirically tested. More importantly, the theory is not precise as to why the act of deferral is so painful. Based on this notion, we propose that the mere act of consumption deferral leads consumers to feel that they have less control of their consumption. In a typical present bias elicitation task, participants are asked to imagine having an outcome in the present (e.g., a DVD available today) and then asked to delay this outcome for monetary gain. Such a proposition elicits a feeling of lack of control over the consumption decision. Therefore,

we propose that when asked to forgo a presently available outcome, consumers feel they have less control over their consumption. As a result, consumers, now wanting to regain control, represent the subsequent intertemporal choice as an opportunity to gain control, requiring higher premiums in their immediate responses and resulting in present bias. We investigate this proposition in four studies. Experiment 1 shows that giving people control over their consumption timing decreases present bias. Experiments 2 and 3 demonstrate that a more generalized sense of power and control leads to similar reductions in present bias. Finally, experiment 4 shows that decreasing the level of control can increase present bias.

In experiment 1, using a typical present bias paradigm, we asked participants to imagine having ordered a DVD online where their default delivery was scheduled for the same day. They then imagined delaying their delivery by 3 days and 10 days (within-subjects) and asked to indicate the premium they required to delay. Participants in the "choice control" condition were first asked *whether* they would like to delay the delivery *before* they indicated their delay premium. We expected that merely having a chance to express their willingness to delay to make participants feel more in control of their consumption decision, decreasing present bias. Results supported this prediction, with significantly lower level of present bias in the choice control condition ($M_{3\text{days-}10\text{days}} = .45$), compared to the standard present bias paradigm ($M_{3\text{days-}10\text{days}} = .66$; $t(147) = 2.04, p < .05$).

In experiment 2, we examined whether a generalized and previously evoked sense of control could influence the extent of present bias in subsequent tasks. To evoke control, we induced participants with power, which has been found to directly affect one's sense of control (Fast et al. 2009). Since high power individuals feel they have more control over their outcomes, we predicted that high power would diminish present bias. To test this idea, half of the participants recalled an incident where they had power over others, a task that has been successfully used to induce power (Galinsky, Gruenfeld, and Magee 2003). The other half simply recalled events of the previous days. Next, all participants imagined having a cash refund (\$45) that was available that day and asked to delay it by 4 and 10 weeks. As predicted, participants who were induced with power showed less present bias ($M_{4\text{weeks-}10\text{weeks}} = 1.29$), compared to the control condition ($M_{4\text{weeks-}10\text{weeks}} = 2.62$; $t(97) = 1.78, p = .07$). In experiment 3 we replicated these findings using an alternative method to induce power (via an employee/employer task, Dubois, Rucker, and Galinsky 2010).

In the final experiment we examined whether taking control away from participants would have the opposite effect and increase present bias. To that end, some participants completed a deferral task where they imagined ordering a DVD online, scheduled to arrive within 24 hours. They were then asked to indicate their premium to delay it by 3 days and 10 days. The remaining participants (low control) were instructed to imagine that they chose to pick up their DVD from a local store. However, when they arrived at the store, their DVD was not available, but the clerk offered to have it delivered to their home within 24 hours. They were then asked to indicate their delay premium to defer the receipt of this DVD by 3 days and 10 days. We predicted and found that having already lost control over their consumption, these low control participants showed greater present bias ($M_{3\text{days-}10\text{days}} = .66$), compared to those in the baseline condition ($M_{3\text{days-}10\text{days}} = .38$; $t(171) = 2.26, p < .05$). Moreover, we found that feelings of control over consumption mediated the observed effect.

In sum, our studies show that the feeling of control in related (experiments 1 and 4) and unrelated (experiments 2 and 3) contexts influences the extent of present bias. Further, we consistently find that decreasing (increasing) feelings of control increases (decreases)

present bias. Taken together, this research suggests that the feeling of control plays an important role in present bias, and demonstrate a more affective explanation for present bias.

The Influence of Time-Interval Descriptions on Goal-Pursuit Decisions

EXTENDED ABSTRACT

A diet ad proclaims, “Sign up today and lose 25 pounds in 2 weeks!” What would influence a consumer’s decision to pursue this diet? Although many factors might play a role (Aarts, Gollwitzer, and Hassin 2004; Freitas et al. 2002; Zhang, Fishbach, and Dhar 2007), this paper focuses on one unexplored factor in particular: the description of the *time interval* allowed for goal completion. We suggest that whether the interval is described by extents (“2 weeks from today”) or dates (“between today and May 6”) influences goal-pursuit decisions.

Although how a time interval is described may seem unimportant, it can affect how people plan for the future (LeBoeuf and Shafir 2009) and evaluate future transactions (LeBoeuf 2006; Read et al. 2005). We suggest that time-interval descriptions also affect whether people initiate goal pursuit, with people being more likely to pursue goals with completion intervals described by extents than by dates. We suggest that changes in time focus (i.e., focus on the near vs. distant future; Lee, Lee, and Kern 2011) underlie such effects. Whereas extent descriptions refer to “chunks” of time (e.g., weeks, months) and may lead to a focus on the interval as a whole, date descriptions direct attention to specific time points (LeBoeuf 2006; Malkoc et al. 2010; Read et al. 2005) and may prompt a focus on the day-by-day passage of time, conjuring considerations such as what one will do each day. Thus, an interval described as “three months from today” may focus people more on the distant future than does an interval described as “between today and July 23.” This leads us to predict that, when people are contemplating pursuing a goal during a time interval, extent descriptions of that interval may direct people’s attention more to the goal’s long-term benefits, which may increase the goal’s perceived importance, and less to the other mundane tasks that will occupy the interval. This may result in greater willingness to pursue desirable goals.

Study 1a tested the effect of interval description on people’s willingness to diet. Participants indicated whether they would be willing to lose 1.5 pounds in two weeks, with time interval described either by extents or dates. Participants also reported how long the target interval seemed. More participants were willing to diet when the interval was described by extents than dates (65% vs. 44%, respectively, $\chi^2(1)=4.06, p=.04$), but interval description did not affect perceived interval length. Study 1b replicated these results using a savings goal. Thus, people are more likely to pursue a goal when the allocated time interval is described by extents, rather than dates, and this effect seems not to be driven by a change in the interval’s perceived length.

In study 2, participants indicated whether they would be willing to read three books in one month (described by extent or date) and indicated how many books they would commit to reading within that interval. Study 2 also examined the possible mechanism by collecting ratings of the goal’s importance. When the interval was described by extents, versus dates, participants pursued reading at a higher rate (35% vs. 10%, respectively, $\chi^2(1)=4.74, p=.03$), were willing to read more books ($M_{\text{extents}}=1.84$ vs. $M_{\text{dates}}=0.93, t(53)=2.62, p=.01$), and found the goal more important ($M_{\text{extents}}=4.31$ vs. $M_{\text{dates}}=3.26, t(53)=2.19, p=.03$). Goal importance mediated the relationship between interval description and goal pursuit (95% CI: .040, 1.51).

These results hint at one possible underlying mechanism: extent descriptors lead to greater perceived goal importance and to greater goal pursuit, perhaps because extent descriptions trigger a focus on a longer time horizon and long-term consequences.

If extent descriptors lead people to focus more on the distant future than do date descriptors, they should only increase willingness to pursue goals with *positive* long-term consequences, such as studying, and not goals with *negative* long-term (but positive short-term) consequences, such as watching television. To test this hypothesis, participants in Study 3 considered pursuing one of two goals—watching more television or studying more—for one month. The effect of time-interval descriptor depended on the type of goal ($\chi^2(1)=5.38, p=.02$). Participants were more likely to pursue the television goal when time was described by dates versus extents (45% vs. 26%, respectively, $\chi^2(1)=4.38, p=.04$). For studying, however, dates yielded less goal pursuit than extents (4% vs. 14%, respectively, $\chi^2(1)=3.17, p=.075$). Thus, people are more likely to pursue goals with positive long-term consequences when time is described by extents, but they are more likely to pursue goals with positive short-term consequences when time is described by dates. These findings suggest that extents lead to a greater focus on the distant future than do dates.

Study 4 explored another boundary condition: interval length. When goal completion stretches out over a very long interval, people may naturally focus on the distant future and therefore on long-term consequences. In this case, people may be less sensitive to relatively small focus adjustments caused by description nuances (see also Goodman and Malkoc 2012), and therefore descriptions may have a lessened impact on people’s general time focus and subsequent decisions. To test this hypothesis, participants read an article about adverse effects of dairy consumption and indicated their likelihood of reducing their dairy consumption within either one month or three years. The effect of interval descriptor depended on interval length ($F(1,131)=4.80, p=.03$). Participants were more likely to reduce consumption within one month when the interval was described by extents than dates ($M_{\text{extents}}=3.03$ vs. $M_{\text{dates}}=2.23, t(64)=2.29, p=.03$). For three years, however, there was no such difference ($M_{\text{extents}}=3.00$ vs. $M_{\text{dates}}=3.52, t(67)=1.06, p>.2$).

In summary, even small nuances in how a goal and the time interval allocated to its pursuit are described can alter the decision to pursue that goal. An interval described by amounts of time may focus people more on the distant future than an interval described by dates. This increases people’s willingness to initiate goal pursuit during that interval, as long as goal pursuit has positive long-term consequences and a relatively short duration.

SESSION OVERVIEW

Even though the world has seen great economic growth in past decades, the gap between rich and poor continues to widen in most nations (Gurría 2011). While some consumers' resources are increasing, a large number of consumers are increasingly facing more difficult financial situations. As this disparity between the wealthy and the poor grows, understanding how consumers arrive at different points along this spectrum and how they behave is more important than ever. Along these lines, a recent JCR curation highlighted the importance of studying the financial climate of the consumer and understanding how it affects consumers (Peracchio, McGill and Luce 2012).

The goal of this session is shed further light on this increasingly important topic, and to gain a better understanding of the antecedents of, beliefs about and implications for consumers' financial constraints. In doing so, this session looks at financial constraints from a number of angles, and addresses implications for consumer policy and well-being. While the first two papers explore antecedents of actual and perceived future financial constraints, the last two papers examine outcomes of financial constraints on consumer behavior.

The first paper by Olivola and De Neve looks at a potential antecedent of financial constraints and explores evidence from a unique 15-year longitudinal dataset suggesting that intuitive decision makers are more likely to have lower financial well-being. The second paper by Berman et al. demonstrates an important bias in consumer predictions of their own future financial constraints. In seven studies, they provide evidence that consumers under-weight the impact of future changes in expenses compared to future changes in income on estimations of future available monetary slack. Tully, Hershfield and Meyvis next present four studies examining the effects of financial constraints on consumers' decision criteria and choices in discretionary spending. The authors suggest that financially constrained consumers are more apt to prefer material versus experiential purchases when spending discretionary money due to an increased focus on how long their purchase will last. Finally, Fernbach, Lynch, and Kan investigate the relationship between resource constraints and

consumer planning. They differentiate two psychologically distinct types of planning ("efficiency planning" and "priority planning") and show how consumers' level of constraint affects the type of planning a consumer employs.

The papers included in this session offer findings that are of interest both theoretically and practically. The papers offer new insights regarding the causes of real and perceived future financial constraints and the shifts in consumer behavior that result from such constraints. On a pragmatic level, the included papers further our understanding of when financial constraints can lead to potentially sub-optimal behaviors. Finally, by looking at financial constraints with a multi-method approach, this group of papers suggests many new avenues for future research focused on financial constraints.

From Intuition to Insolvency: Intuitive Decision Makers End up More Financially Constrained

EXTENDED ABSTRACT

People shape their lives through the decisions that they make. Whether these choices produce beneficial or detrimental outcomes for the decision maker largely depends on the decision process itself. Therefore, *how* people approach decisions, and not just *what* they choose, has important consequences. Broadly speaking, people can approach decisions in two ways (e.g., Kahneman, 2003; 2011; Slovic, 1996): through careful deliberation (using logic, reason, and rational considerations) and/or by relying on their intuitions (going with their "gut feelings"). Poets, philosophers, and scholars have long debated the relative merits of human deliberation vs. intuitions. This debate has raged on in the social sciences, particularly among decision researchers, with some arguing that intuitions alone generally lead to suboptimal choices (Baron, 1998; Gilovich, Griffin, & Kahneman, 2002; Kmett, Arkes, & Jones, 1999), while others have defended the merits of intuitions and questioned the value of deliberation (Dijksterhuis, Bos, Nordgren, & van Baaren, 2006; Dijksterhuis & Nordgren, 2006; Wilson et al., 1993; Wilson & Schooler, 1991). Far from abating, this ongoing debate about intuitions has received renewed attention from researchers and spilled out of academic circles and onto the public sphere (e.g., Gigerenzer, 2007; Gilovich, 1991; Gladwell, 2005; Gropman, 2007; Kahneman, 2011; Myers, 2002).

Yet most studies examining the success or failure of intuitive choices have been carried out in controlled settings with limited real-world validity. More importantly, in nearly all of these studies, the impact of relying on intuitions has been evaluated over very short time periods. In contrast, there have been few longitudinal studies relating individual decision making tendencies (whether someone tends to rely on intuitions when making decisions) to important life outcomes. Clearly, understanding the long-term impact of an intuitive decision making style would inform the debate concerning the merits of intuitions.

Here, we use a unique longitudinal dataset to measure the predictive impact of an intuitive decision making style on financial wellbeing. Specifically, we examine how the tendency to rely on intuitions (even in adolescence) predicts financial outcomes up to 12-15 years later. These data were drawn from a multi-wave, panel study that surveyed a nationally representative U.S. sample of approximately 15,000 respondents over four time periods (Waves 1-4), starting in adolescence, and going up to adulthood. In all four waves,

respondents reported whether they tended to rely on their “gut feelings” when making decisions, using a five-category scale. In the most recent wave (Wave 4), they reported various aspects of their financial circumstances, including their income, financial assets, debts, gambling problems, etc. The richness and longitudinal nature of these data allow us to measure the impact of intuitive decision making styles on later (and current) financial well-being while controlling for a host of variables related to respondents’ characteristics and early environments (e.g., ethnicity, gender, socio-economics, parents’ education, respondents’ academic performance, etc.).

We find that intuitive decision making is a negative predictor of financial wellbeing: the more respondents reported relying on their gut feelings to make decisions, the worse their financial situation was in the final wave of the survey. Specifically, a greater reliance on gut feelings to make decisions was associated with lower positive indicators of financial wellbeing (personal yearly earnings, neighborhood safety, likelihood of having health insurance, and likelihood of owning their home) and higher negative indicators of financial wellbeing (debt problems and difficulty paying bills, the need for government financial assistance, job loss, and gambling problems). Furthermore, for many of these indicators, this relationship holds whether decision making style is measured early on (in Waves 1 and 2) or when respondents are older (Waves 3 and 4). We also find that this relationship holds when we control for indicators of cognitive ability (e.g., GPA and other measures of school performance) and for conscientiousness (one of the ‘Big Five’ personality traits).

Finally, we test (and ultimately reject) a rational self-selection account of our results, according to which intuitive people are less well off financially because they have intentionally chosen to pursue careers that pay less (e.g., the arts), and not because they are more prone to errors in financial decision making. Specifically, three pieces of evidence refute this account. First, the tendency to rely on gut feelings also predicts an increased risk of having gambling problems, which is presumably not caused by one’s career choice. Second, intuitive decision making styles measured in Waves 3 or 4 (i.e., after most respondents have already selected their career paths) negatively predict financial wellbeing even when we control for intuitive decision making styles measured in Waves 1 and 2 (i.e., before and/or while most respondents select their career paths). In other words, even after controlling for an early tendency to rely on gut feelings when making decisions (which may be correlated with a person’s career preferences), we find that *additional* increases (vs. decreases) in this tendency later in life are associated with more negative (vs. positive) financial outcomes. Finally, we find that the tendency to rely on gut feelings when making decisions is negatively related to self-reported life satisfaction, which runs counter to the notion that intuitive decision makers are deliberately (and happily) choosing to pursue low-paying professions.

Our findings suggest that relying on gut feelings to make decisions leads to negative life outcomes, at least in the financial domain. The recent financial crisis and the events that followed have highlighted the dangers of hasty financial decisions and their impact on individual, national, and global financial wellbeing. Based on our results, we strongly caution against teaching children and/or adults to rely on their gut feelings when making financial choices.

Expense Neglect in Forecasting Personal Finances

EXTENDED ABSTRACT

In economics, “life cycle” consumption models postulate that consumers borrow and save across time periods in order to account expectations about changes in income and expenses over time. But

it is a nontrivial problem to predict future income and expenses, and therefore whether it makes sense to consume now, to save or to borrow. Any mistake in the forecasting of one’s finances can cause serious negative consequences, such as derailing a future retirement plan or driving someone into long term-debt. How, then do people form their expectations about how much money will be available in the future? Zauberman and Lynch (2005) demonstrated the role of perceptions of spare money (i.e., money slack) in influencing people’s intertemporal preferences. But we know little about what inputs drive these perceptions of spare money, and in particular, whether people are sensitive to changes in income and expenses as they form these judgments.

Across seven studies, we demonstrate that even though people generally think their expenses will rise in the future, they neglect or under-weigh expenses compared to income when forecasting their future spare money. In other words we find that while people expect that both their income and expenses to increase in the future, they naturally are much more sensitive to changes in income rather than changes in expenses when predicting their future financial situation.

In Studies 1a-c (N = 580), we sampled a wide range of participants with varying financial conditions. Our sample included fully employed and part-time employed adults, unemployed adults, and adults not currently in the labor force (Study 1a); university students (Study 1b); and business executives (Study 1c). Participants were asked to tell us how much spare money they currently have this week and how much spare money they expect to have over a fixed time in 3 months and 12 months from now (1 = “Very little spare money” to 11 = “Lots of spare money”). In addition, participants estimated how much they expected their income and expenses to change in 3 months and 12 months from now (-5 = “I expect my income[expenses] to greatly decrease” to +5 = “I expect my income[expenses] to greatly increase”).

For each sample, we ran a regression that included expected income change and expected expense change as independent variables, and expected change in spare money as a dependent variable. The results show that the growth in spare money is fueled by the expectation that income will be higher at more distant points in the future than it is today. Interestingly, people do not factor in their expense growth when estimating their future finances, and consequently, their expectations about spare money are determined primarily by their expected change in income rather than their expected change in expenses. See table 1 for a summary of the results.

In Study 2 (N = 244), we examine whether the previous results are due to the possibility that participants evaluate income and expenses on different scales. To test this, half the participants were asked to evaluate their expected income and expense growth on a standard likert scale, as before, whereas the other half of the participants were asked to evaluate their expected income and expense growth using a modulus that normalizes judgments on a single scale (e.g., if your income today is 100 chips, what will be your income in 12 months). We find that regardless of scale, participants consistently neglected to incorporate expenses when judging future slack.

Study 3 (N = 301) rules out the possibility that participants under-weigh future expenses because they believe that future expenses are more uncertain than future income. Participants were first asked to make judgments of their future income and expense growth and were then asked to state how confident they were in their estimate. Surprisingly, we find that participants felt more confident about their future expense growth (M = 8.09), than their future income growth (M = 7.83, paired-t = 2.27, p = .024). Furthermore, we replicate our main finding, suggesting that even though participants are highly confident about the extent to which their expenses will grow in the

Table 1: Summary of Main Results

Note: A ratio of greater than 1 indicates that participants are over-weighting income relative to expenses, whereas a ratio of less than 1 indicates that participants are over-weighting expenses relative to income.

For studies using a modulus scale, we report median income and expense change in percentages.

* $p < .05$, ** $p < .01$, *** $p < .001$

future, they still do not sufficiently account for expenses compared to income when estimating future slack.

Studies 4a (N = 302) and 4b (N = 74) rules out the possibility that these results are due to a bias caused by the manner in which we ask participants to estimate their available spare money. In particular, asking participants about how much slack they have may be priming them to think about the driver of spare money (i.e., income). If so, then asking participants to think about how financially constraint they are may cause participants to think about the driver of financial constraint (i.e., expenses). In Study 4a, half the participants are asked to estimate how much slack they have now and in the future, whereas the other half is asked to estimate how financially constraint they are now and in the future. We find that a focus on constraint does not diminish or eliminate expense neglect. In Study 4b, we replicate our findings using a three-item measure of resource availability that includes (1) a subjective assessment of spare money, (2) a subject assessment of financial constraint, and (3) an assessment of whether or not participants think they are likely to be able to pay an unexpected bill of \$1,500.

Finally, we make a series of attempts to debias participants by focusing their attention on the various sources of expenses that may change in the future (Study 5, N = 243), how their expenses have changed in the past (Study 6, N = 159), and the role that exceptional expenses may play on current and future slack (Study 7, N = 184). However, we are unable to find any consistent factor that leads participants to increase the weight that expenses play in determining future available money slack. This speaks to the robustness of ex-

pense neglect as a bias that impacts the way individuals forecast their future available spare money.

Financial Constraint Induces a Shift Toward Material Versus Experiential Purchases Through Long Term Focus

EXTENDED ABSTRACT

As people try to spend their money in ways that maximize their happiness, they need to trade off investments in experiential versus material purchases. Past research has shown that money allocated to experiential purchases may result in greater long-term happiness (e.g., Carter and Gilovich 2010; Nicolao, Irwin, & Goodman 2009; Van Boven & Gilovich 2003), suggesting that consumers should spend more money on experiential purchases (Dunn et al. 2011). The current research examines what happens when people feel financially constrained and this trade-off is more pressing than usual. Are financially constrained consumers more likely to spend their limited resources on experiences, thus allocating their scarce resources to get a bigger happiness bang for their buck? We propose that, rather than increasing the hedonic efficiency of their investments by focusing on experiential purchases, financially constrained consumers instead allocate more of their scarce income to material goods. Specifically, we propose that financial constraint increases concerns about durability, which in turn shifts preferences towards material goods.

Given that financial constraints tend to highlight opportunity costs (Spiller 2011), we propose that, financially constrained con-

sumers will recognize that a purchase today may inhibit a purchase tomorrow, thus focusing them on future consequences of the purchase and the longevity of their purchase. Whereas material goods tend to physically persist over time, experiences are characterized by a shorter objective life expectancy. Thus, although experiences have been shown to provide longer lasting happiness, material purchases may appear more enduring. Because physical duration is likely more salient than the longevity of memories at the time of purchase, we suggest that consumers under financial constraint are partial to material rather than experiential options.

In three studies, we provide evidence that consumers thinking about real or hypothetical financial constraints are more likely to choose material versus experiential choices across a variety of shopping scenarios. In study 1, we manipulate financial constraints by asking consumers to imagine and write an essay about life on or not on a budget. Next, they are asked to imagine that they have decided to spend their money on something nice for themselves as a treat and then are provided with six pairs of options that were pre-tested to equate on expected happiness, desirability, and perceived value of the item at the stated price. We observe that participants imagining life on a budget are more likely to prefer the material options than participants imagining life not on a budget, $F(1,71) = 12.02, p < .001$. Importantly, they are also more likely to mention duration as a factor in their choice than participants in the no-budgeting condition, $F(1,71) = 4.30, p < .05$.

In Study 2, we replicate the findings of Study 1 using another manipulation of financial constraint. Further, we rule out an alternative explanation that the increased focus on duration in study 1 was due to the fact that budgeting artificially increases a consumer's focus on the future.

The study uses a 2(income change: increase, decrease) by 2(response type: planning, feeling) between-subjects design. To manipulate financial constraint, participants are asked to imagine that their income has either increased or decreased by thirty percent. In the planning conditions, participants are asked to devise a plan or budget for how they would live on their new monthly income, whereas in the feeling conditions, participants are asked to write what kind of emotional response they would have to the new monthly income. Participants then complete a shopping task similar to the one used in Study 1. We present participants with possible reasons for each of their choices and ask them to indicate which ones they considered. As predicted, participants who imagine an income decrease are more likely to prefer the material option than participants who imagine an income increase, $F(1,252) = 21.01, p < .001$. Neither response type nor the interaction of response type with income change has any effect on choice (all F s < 1). We show that this shift in choice is mediated by participants' increased focus on duration while making their choice (95% CI = .2521, .6349; 10,000 re-samples) (Preacher and Hayes 2008).

Study 3 aims to show the relationship between financial constraints and preference for material options by highlighting participants' actual financial constraints. Instead of manipulating participants' perceived financial situation, we manipulate the extent to which participants consider their own financial constraints while making their choices. To do so, half of the participants are asked to consider their current financial situation before completing the shopping task. As in Study 2, we present participants with possible reasons for each of their choices and ask them to indicate which ones they considered. As predicted, participants who are asked to consider their financial constraints are more likely to prefer the material options than participants in the control condition, $F(1,160) = 3.89, p = .05$. Replicating Study 2, an increased focus on duration mediates

the effect of the manipulation on preference for the material options (95% CI = .2398, .9392; $N = 160$; 10,000 re-samples) (Preacher and Hayes 2008). Thinking about one's financial situation shifts participants' focus towards duration, which in turn leads to an increased preference for the material options.

Finally, using data from The Bureau of Economic Analysis (BEA), we show that in quarters of higher unemployment, when financial constraints are greater, consumers spend disproportionately more on material items (goods) than experiences (services), $\beta = .06, t(210) = 5.25, p < .001$. This analysis provides real world support for the hypothesis that during times of greater financial constraints, consumers shift their expenses toward material goods.

The present research indicates that consumers facing financial constraints are more likely to choose material purchases over experiential purchases when making discretionary expenditures. Ironically, it appears this shift is driven by a belief that material goods will provide longer lasting benefits – even though prior research suggests that long-term happiness is better served by investing in experiences.

Squeezed: Effects of Constraint on Consumer Planning

EXTENDED ABSTRACT

This research investigates the relationship between different types of consumer planning and resource constraint. The connection between resource constraint and planning has been acknowledged in previous research (Lynch et al. 2010; Spiller 2011) but has not been explored or analyzed in detail. Furthermore, in contrast to the notion that planning is a unidimensional phenomenon (Lynch et al. 2010), we differentiate between two psychologically distinct types of planning: “efficiency planning” and “priority planning.”

Efficiency planning is intended to yield resource savings by accomplishing a goal as efficiently as possible, with the aim to avoid opportunity costs entirely. For instance, consumers ‘trip-chain’ to accomplish several shopping goals without wasting travel time (Brooks, Kaufmann, and Lichtenstein 2004).

In contrast, priority planning requires deciding what to forego given current constraints and necessitates direct consideration of opportunity costs. Whereas efficiency planning concerns local considerations relevant to the current goal, priority planning weighs countervailing goals against one another. For instance, given only an hour to accomplish numerous shopping goals, a consumer might decide that not everything can get done and forego visiting the shoe store.

These two kinds of planning are connected in that both are responses to resource constraint (or lack of resource slack; Zauberaman and Lynch 2005). The difference is that efficiency planning is relevant when savings in the resource are precious, but there is no consideration of competing goals. Prioritization comes when one realizes that the resource is so constrained that tradeoffs have to be made.

Because efficiency planning does not involve incurring opportunity costs but priority planning does, consumers should begin with efficiency planning, switching only when increasing resource constraint requires that they do. Thus we predict that the type of planning consumers tend to do should vary with resource constraint.

Moreover, if efficiency and priority planning are indeed discriminable constructs, there is reason to believe that engaging in one type will inhibit the other type. Local concerns associated with efficiently accomplishing a single goal may crowd out global concerns related to competing goals (as in the planning fallacy; Kahneman and Tversky 1979; Buehler, Griffin, and Peetz 2010). More generally, generating a plan of one-type may lead to output interference for other types (Alba and Chattopadhyay 1985). From a motivational

perspective, developing an efficiency plan may feel like progress, making it harder for people to release the goal (Kivetz, Urminsky, and Zheng 2006). Relatedly, consumers are averse to wasted utility (Bolton and Alba 2012), suggesting that abandoning an efficiency plan to prioritize a different goal may feel like a loss.

In study 1, 153 mTurk participants answered a series of questions about holiday gift shopping and reported their financial constraint level. We show by confirmatory factor analysis that efficiency and priority planning are distinguishable constructs, and find that the share of priority plans made to efficiency plans increases with constraint.

In Study 2 we manipulated constraint level rather than measuring it; We asked 102 mTurk participants to list what they planned to buy each of five people over the holidays, then asked them to report how they would change their holiday gift shopping plans in reaction to a small, moderate or large financial shock in the form of an unexpected bill. Blind coders categorized responses into 'priority' (e.g., "give up on the gift", "buy something different") and 'efficiency' (e.g., "shop sales", "use coupons"). Corroborating study 1, the proportion of priority plans relative to efficiency plans increased with constraint. Moreover, participants were significantly more likely and faster to generate a plan of the same type as their previous plan as compared to a plan of the other type, supporting the idea that engaging in one type of planning interferes with the other.

A weakness of studies 1 and 2 is they cannot shed light on the dynamics of planning as it unfolds in real time. Therefore, in studies 3 and 4 we utilized a virtual environment that simulates a shopping trip in a mall. Undergraduate participants completed a shopping list by visiting stores and purchasing items from their list. Maps positioned in the mall indicated the location of different store types throughout the mall and the items available in each store, allowing participants to save time by viewing the map and engaging in efficiency planning. This paradigm allowed us to manipulate time constraint and the presence of a priority structure, so that we could observe planning in a setting that resembles how behavior unfolds in real time.

In study 3, we varied the time allowed to complete a series of shopping trips, providing a separate time budget for each trip. The key result was that participants ($N=41$) engaged in more efficiency planning (i.e., map viewing) under constraint.

In study 4, rather than giving a separate time budget for each shopping trip, participants were given a single time budget to cover trips to three malls shopped in sequence. As in Study 3, participants ($N=62$) were paid for each item they located and purchased off an 8-item shopping list for that mall, with an additional payment if they purchased all 8 items at the mall. A priority structure was induced by doubling the payments at the third mall. Thus, if all three shopping lists could not be completed, participants would earn more by being sure to purchase all eight items at the third and final mall, abandoning shopping at the first two malls if that was required under conditions of higher constraint. We found that with increasing constraint, more time spent efficiency planning in the earlier malls reduced prioritization, causing efficient planners to fail to allocate enough time to maximize payoffs in the last mall.

The four experiments provide converging evidence about how different types of planning are influenced by resource constraint. Ironically, the attempt to save a resource by being efficient can sometime lead people to get caught up in local considerations, neglecting a course of action that may be preferable when considered in the context of other, more important goals.

Paper #4: Factionalized Fatshionistas: Dynamics within Collectives of Stigmatized Consumers Engaged in Marketplace Change Efforts

Eileen Fischer, York University, Canada

Daiane Scaraboto, Pontificia Universidad Católica de Chile, Chile

SESSION OVERVIEW

Goffman (1963) describes stigma as the possession of an attribute that has a negative connotation, and that deviates from what is considered normal in a specific category of people. Prior work in consumer research has looked at stigma in relation to low-literate consumers (Adkins and Ozanne, 2005), coupon redemption (Argo and Main, 2008), senior citizen discounts (Tepper, 1994) and subcultures (Henry and Caldwell 2006). However, the focus of this research has primarily been on stigma management, and the strategies that consumers use to deal with the negative effects of stigma, while the dynamics of stigmatization remain largely unexplored. In addition, bearing in mind the extent to which technology impacts consumers' lives, it is surprising to note that little effort has been made to examine the relationships between stigma and the media (see Kozinets, 2001 for an exception). Specifically, what roles do the media and media consumption practices play in the dynamics of stigmatization, including the perpetuation of existing stigmas and creation of new stigmas? What consequences are associated with the end of a stigma, either when the stigmatized practice ends, or when it gains greater legitimacy in the marketplace?

Overall, in line with the conference theme 'Making a difference', the proposed aim of this special session is to make a difference by going beyond stigma management and exploring the complex dynamics at the nexus of stigma, consumption, and the media.

The session will begin with a focus on the role of television in the context of the stigmatization of African American women. Elizabeth Crosby will present her work on the impact of sexual stigmatization on African American women. The findings suggest that the media play an active role in perpetuating sexual stereotypes, sometimes resulting in their internalization into women's sense of self. The focus of the session will then shift to stigmatized media consumption practices, and particularly the consequences of the cessation of a stigmatized media practice. Cristel Russell and Hope Schau draw on a longitudinal research program addressing consumers' experience of four discontinued television programs to develop a model of consumer loss accommodation and find evidence that stigma associated with some TV series impairs consumer loss accommodation. Stephanie Feiereisen, Dina Rasolofarison, Kristine de Valck and

Julien Schmitt also examine the consequences for consumers of the end of a stigma, but in a different context: the legitimization of the stigmatized media practice (watching TV series). The authors investigate the tensions in consumer narratives arising from traditionally negatively-laden television consumption and the positive evaluations of current television series viewing, gained from increasing legitimization processes of TV series such as *Mad Men*. In line with this research, Eileen Fischer will present her work with Daiane Scaraboto which also looks at the dynamics of stigmatization and legitimization in the marketplace. Fischer and Scaraboto draw on longitudinal online archival research in the network of *Fashionistas* to examine the consequences for a collective of stigmatized consumers, of engagement in efforts to gain greater legitimacy in mainstream markets.

Jezebels, Gold Diggers, and Hoes: African-American Women's Experiences with Sexual Script Development

EXTENDED ABSTRACT

African-American women continually face sexual stigmatization. Scholars observe that African-American women are often viewed as promiscuous (Collins, 2000). This research unpacks the relationship between sexual stereotypes and consumption. Specifically, I examine how consumption can perpetuate sexual stereotypes and create sexual scripts. Additionally, I investigate how sexual stigmatization affects African-American women and how they manage the stereotypes. As part of a larger study exploring African-American women's experiences with stigma, I conducted 23 interviews. Informants also constructed collages. All informants live in a small city in the Midwest. They come from a variety of social classes and are between the ages of 19 and 56. All interviews were audiotaped and transcribed, yielding more than 650 pages of text. In analyzing both the collages and the written text from the depth interviews, I searched for emergent themes while also engaging in dialectical tacking (Strauss and Corbin, 1990). Although I did not initially intend to focus on sexual stigmatization, the prevalence of it in the narratives prompted me to further explore the stereotypes. Sexuality is an important component to an individual's identity. People are often defined in part by their sexuality (Foucault, 1978). Simon and Gagnon (1984) argue that sexual identity frameworks can be viewed as sexual scripts. They help build people's attitudes and beliefs about their own and others' sexuality. These scripts are developed through exposure to sexual stereotypes. African-American women's sexual stereotypes have evolved into very particular sexual scripts, such as the promiscuous Jezebel or "hoe", gold digger, and welfare mother. These scripts are often reinforced through consumption. Informants argue that their sexuality is criticized more than women of other races, especially in the media. Sonya argues that African-American women are portrayed as promiscuous or as gold diggers in sharp contrast to other races. Another informant, Shenelle, says "It's always in the media that we are gold diggers." Informants also note that music-related products can increase these stereotypes through lyrics and videos that frequently portray African-American women as sexual objects. Because of the stereotypes, society expects African-American women to make certain consumption decisions. For example, informants argue that they are expected to dress in provocative clothing. These fashion expectations are reinforced through the media. African-American women also face the welfare mother stereotype. While the primary characteristics of this stereotype are

Stigma and Accommodation to Consumption Loss

EXTENDED ABSTRACT

associated with economics, there is a sexual component, in that the welfare mother is portrayed as promiscuous and willing to have children with multiple men to increase her standard of living. Informants discuss how the welfare mother is often a negative caricature in the media. The sexual stereotypes denigrate African-American women, reinforcing negative perceptions. With these sexual scripts being constantly reinforced, some African-American women accept the stereotypes and incorporate it into their identity, in a process known as stereotype threat (Steele and Aronson, 1995). The existence of the ascribed sexual scripts actually results in its internalization into the women's sense self. This outcome is something that my informants admit battling. On informant, Sherry, discusses how the prevalence of the gold digger stereotype in the media, makes it hard to resist. Other informants note that they know African-American women who fall victim to stereotype threat. The reinforcement of these sexual scripts is especially influential to adolescents, significantly affecting how they view their own sexuality and what is acceptable sexual behavior. This can lead to significant negative health consequences for African-American women as these sexual scripts may encourage them to engage in unsafe sexual practices. For example, African-American women run a higher risk of adolescent pregnancy and sexually transmitted diseases than women of other races (Centers for Disease Control, 2013).

However, some African-American women fight against the stereotype and refuse to internalize it. There are several ways that informants combat sexual stereotypes. Many informants stress the importance of education in reducing stereotypes. Paige designs programs to educate people about African-Americans so society learns that they are not reducible to a set of stereotypes. Mentoring other African-American women is also important. Sonya describes the advice that she gives young African-American women: "I tell young women when you go on a date don't feel like you have to have sex with someone... don't dress in a way that is inappropriate. You can feel elegant and glamorous without feeling like you have to lower yourself by putting on hot pants." Other informants refuse to buy products that promote stereotypes. Marissa says "I think [rap music] perpetrates a sexual stereotype ... I don't like my kids to listen to it." Similarly, Sonya purchases music that portrays African-American women in a more positive light and encourages others to do the same.

Informants feel that they need to constantly fight against society's preconceived expectations. Elise says, "You need to be on guard to make sure that you don't give the image that you are going to be in any way allowing yourself to be open to any funny business." The constant battle to transcend the stereotypes can be arduous. Many informants say that it is "exhausting" and feel as though people are constantly watching them. These women need to constantly exhibit front-stage behavior (Goffman, 1959), which is tiring and makes them smother part of their identity. This can lead to feelings of unfairness. Adele notes: "Women may feel they have to suppress part of themselves... [My grandmother] would say that people think black girls are fast or promiscuous so you have to be extra, extra careful to make sure you never give the impression that you are in anyway doing that. You need to be... an extra, extra, extra good girl in order to make sure no one thinks anything is going to happen."

Sexual scripts can distort African-American women's attitudes and beliefs about their own sexuality identity and how it should be expressed. Unfortunately, consumption plays a significant role in reproducing sexual stereotypes of African-American women. The sexual scripts that emerge in this research yield consumer welfare implications that demand serious consideration.

Stigma is a known impediment to identity expression and identity work (Goffman, 1963; Snow and Anderson, 1987). By examining four discontinued television (TV) series varying in cultural stigma attached to the series, we show how accommodation processes unfold and are affected by the countervailing effects of consumption sociality and stigma. Triangulating across data sources and methods (extended participant observation, long interview and online forum analysis), we find compelling evidence that consumers experience loss on multiple levels (personal, social and cultural) and that sociality affects practices available in the interconnected processes of intrapsychic transformation, psychosocial status transition, as well as the continuation of communal and symbolic connections. TV series were selected because consumers' experience of TV series often spans several years and usually occurs in domestic space fostering intimacy through intense parasocial attachments, which form and evolve like interpersonal relationships (Russell et al., 2004). TV series are also often consumed socially, allowing assessment of the impact of brand withdrawal on social interactions and networks surrounding brand consumption like families experiencing the loss of a ritual-infused retail space (Otnes et al., 2008) and fellow brand enthusiasts (Kozinets, 2001; Schau et al., 2009). Finally, TV series are intricately connected to the broader cultural environment which impacts consumers' responses to withdrawals. For example, *Star Trek* fans experience social derogation stemming from mainstream North American attitudes about their brand devotion being "geekish" (Kozinets, 2001), which impacts their experience of brand loss. Loss accommodation is theorized to be anchored in culture, or the manner in which the broader community views the relationship with the lost person or object and sanctions ways to deal with the loss. When the general community provides sympathy and support for one's loss, it acknowledges its legitimacy and facilitates the accommodation process (Kamerman, 1993). When loss is felt throughout a community, as in a natural disaster (Delorme et al., 2004), the sociocultural dynamics surrounding loss are essential to the meaning-making process and identity reconstruction that ensues (Bonsu and Belk, 2003). Conversely, if the broad culture does not recognize the validity of the loss, disenfranchisement can ensue. When the loss is a "socially undervalued relationship," people may feel stigmatized and this stigma "contravenes or cancels out the meaning of the loss" (Fowlkes, 1990) impairing the accommodation processes. Stigma leads to disenfranchised grief because their affection for the product is not widely accepted and their grief is invalidated. Echoing previous research (Henry and Caldwell, 2006; Goffman, 1963; Snow and Anderson, 1987), we find different ways in which fans deal with the powerlessness resulting from this stigma: some withdraw into an enclave, mainly a virtual one, through the fan forums that offer a safe social space for expressing and sharing their grief; others instead, attempt to conceal their grief symptoms altogether and deny themselves the right to express it, even though this maladaptive strategy usually led to chronic grief; yet others distance themselves from the stigmatized groups and attempt to return to the mainstream (Snow and Anderson, 1987). In contrast, the Auckland Museum, an institution of high culture, celebrated the TV series *OF* and placed the brand at the center of New Zealand culture. The mainstream media contributed to the creation of a collective memory (Connerton, 1989), for viewers and non-viewers. The museum acted as a public forum where personal experiences of the brand became interlinked with collective experiences (Rowe and Wertsch, 2002). These highly publicized events served not only transformation and transition roles

for the viewers but a connection role as well. The exhibit's opening event was a commemorative one that allowed participants to celebrate the life of the series. But this connective role was missed by those *OF* fans who were unable to attend because they live overseas. Unable to prepare for, attend, and then reflect on the event, they feel disenfranchised. We identify the countervailing roles of consumption sociality and consumption stigma in allowing or preempting access to transitive and connective resources, thus altering the ways in which loss accommodation unfolds. Consumption sociality is significant in consumers' loss accommodation because kin collectives (immediate and extended families), proximal social networks (corporeal friends), and the broad cultural context offer access to practices of transition and connection that supplement the intrapsychic transformation process that has been the primary focus of previous research on loss. We find that consumers who hide their emotional connection to a cancelled series from the wider community are hindered in their loss accommodation. Their grief is never validated by the community and becomes a shameful affliction (Doka, 2002). Social media enable cultural bereavement by sustaining or creating communities of fans who feel safer from outsiders' view and can grieve and mourn together (Sanderson and Cheong, 2010). Our findings that online communities grew upon the discontinuation of soap operas echo an early study by Fischer, Bristor and Gainer (1996): we find unambiguous evidence that consumers seek out support in online environments when it is difficult to find proximal people dealing with the same issue (in their study it was families with Down's Syndrome children). We find consumers seeking support for their loss in part because of perceived stigma from their proximal friends, who do not understand the loss. In contrast, online community forums offer the opportunity for reciprocal self-disclosure (Moon, 2000). As Sanderson and Cheong documented in the case of Michael Jackson's death (2010), accessing sociality via social media enables consumers to create tributes and share them with receptive and sympathetic others. The sharing is therapeutic in that it allows for meaning reconstruction following the loss (Neimeyer et al., 2010). Thus, even when a consumption loss is stigmatized by the mainstream, consumers can access or even build sociality resources unavailable in their proximal social networks by turning to social media.

The End of Stigma? Understanding the Dynamics of Legitimization in the Context of TV Series Consumption

EXTENDED ABSTRACT

This research focuses on the consumption practices and meanings associated with television series. Specifically, we investigate the tensions in consumer narratives arising from traditionally negatively-laden television consumption and the positive evaluations of current television series viewing, gained from increasing legitimization and normalisation processes. We show that these tensions generate complex dynamics through which legitimization is accompanied by the reproduction of existing stigmas and the creation of new stigmas. TV watchers have been stigmatized for a long time. Collins (1993) reports that television has traditionally been regarded by scholars as the least legitimate form of popular culture, judged as a "bad object" despite increasingly sophisticated textual analyses and equally sophisticated audience research. Lodziak's assertion (1986) that heavy TV consumers cannot afford to do anything else is illustrative of this stigma. These early findings are echoed in Mitu (2011)'s recent work which shows that television is still regarded as a low-quality medium nowadays. However, while television remains stigmatized, TV series are widely popular. In 2011, fiction was rated the top genre worldwide (41% of the best performing programmes), and among fiction,

TV series were the best performing format, accounting for 69% of the fiction entries (Cassi, 2012). Some TV series like *Madmen* have even acquired the status of cultural object in highly educated spheres (Glevarec, 2012). This suggests that perceptions towards TV watchers, or at least towards individuals who watch certain TV programs, are gradually shifting. Goffman (1963) argues that a stigma "refers to an attribute that is deeply discrediting". According to Crocker, Major, and Steele (1998), stigmatization affects how individuals perceive themselves, but also how they feel others perceive them. Despite its relevance, consumer research on stigma remains limited and focuses mainly on stigma management (e.g., Adkins and Ozanne, 2005; Tepper, 1994; Viswanathan, Rosa, and Harris, 2005; see Sandikci and Ger, 2010 for an exception). Particularly noteworthy is that stigmatization does not affect all TV series watchers in the same manner, as certain series are stigmatized while others are highly respected. For instance, to define "quality television" Thompson (1996) referred to *Hill Street Blues* or *Moonlighting*, while *Knight Ryder* and *McGyver* were classified as "regular television". We interviewed 16 demographically diverse TV series watchers. The authors asked a mix of grand tour questions and floating prompts (McCracken, 1988). Following a general discussion, participants were asked to discuss the meanings they associate with series, their watching practices and whether they believe watching TV series is associated with social stigma. Interviews lasted from 25 minutes to 1h05 minutes, were audio recorded and transcribed. An initial identification of themes was developed, and theoretical categories were elaborated on during open and axial coding procedures. We then began a process of dialectical tacking, moving back and forward between our findings and the relevant literature to deepen our understanding of the practices and meanings associated with TV series consumption. Five key narratives were identified. First, the role of new practices in the legitimization process of TV series consumption emerged: Consumers watch TV series less on television than using streaming, downloads or DVD box sets. These practices allow watchers to engage in TV series consumption while distancing themselves from the negative connotations associated with television as a medium. Thus, consumer narratives replicate the cultural stigmatization discourses around television conveyed by the media and scholars, but at the same time, watching TV series is part of an on-going normalisation process. Second, this process is facilitated by a shift from consumers' bond to TV channels' schedule and agenda, to consumers' perceived control of their viewing time, accessing series online or using DVD boxed sets. Third, a process of 'reverse stigmatization' was identified: Whereas TV series viewers used to be stigmatized, those who do not watch any TV series would now be stigmatized as outside the norm. Fourth, the normalisation process does not apply to all TV series and is contingent on the low social status of the perceived audience. A recurring example of genre that remains stigmatized is soap operas. Non-soap-viewers distance themselves from soap-viewers, while soap-viewers' narratives echo confession-like acknowledgment of their viewing practice, and engage in a strategy of concealment (Miller and Kaiser, 2001). Fifth, new stigmas are appearing as new practices develop. A key example of such practices is binge-watching i.e. watching several episodes of the same TV series in a row. Binge-watchers are stigmatized by non-binge-watchers, the latter considering the former as antisocial. Interestingly, stigmatization occurs among binge-watchers themselves. Tensions are particularly evident between those binge-watching socially versus individually. The social ones use an 'us' versus 'them' discourse to legitimize their own behaviour. They present their binge-watching as a group activity, shared with friends or with their partner, which is considered as normalised whereas binge-watching alone is regarded

as asocial and deviant. We contribute to prior work on stigmatization (Kozinets, 2001; Sandikci and Ger, 2011) by looking at the dynamics of stigmatization and normalisation as social processes in the context of TV series. TV series seem to undergo a legitimization process followed by other popular genres in the past e.g., jazz; graphic novels; thrillers (Glevarc, 2012). This evolution is facilitated by the Internet which has profoundly reshaped the patterns of TV series consumption. However, we show that far from operating in a linear manner, the dynamics of legitimization are complex and accompanied by the reproduction of existing stigmas, i.e. soap operas, and by the creation of new stigmas, i.e. reverse stigmatization and binge-watching practices. Our informants' narratives evince a degree of cognitive reflexivity that underscores their awareness of the complexities associated with the legitimization process. Consider Stefan's comment: "For TV series it's different because TV in a way is sort of stigmatized right now [...]. I think for TV series it's much more of a cultural thing. The fact that you don't watch strictly on TV but you watch on a laptop, it's different from watching on TV. And you find a lot of friends who feel cool when they watch TV series, but they don't feel cool when they watch TV. That's my thought".

Factionalized Fatshionistas: Dynamics within Collectives of Stigmatized Consumers Engaged in Marketplace Change Efforts

EXTENDED ABSTRACT

Consumer researchers have typically studied stigmatized consumers as individuals facing powerlessness, constrained product choices, discrimination in customer service, and higher risk in market interactions (Adkins and Ozanne, 2005; Henry and Caldwell, 2006). The focus of this work has tended to be on understanding experiences of marginalization and the tactics individual consumers use to cope with stigma. Researchers have noted, for instance, that instead of withdrawing into an enclave, stigmatized consumers may challenge the stigma by making attempts to participate in mainstream markets (Henry and Caldwell, 2006). Recently, some attention has been directed toward understanding the factors that may lead stigmatized consumers who face marginalization in a particular marketplace to mobilize collectively and to engage in efforts to gain access to the goods and services they desire (Scaraboto and Fischer, 2013). Thus far, however, we lack an understanding of what happens to the collective of stigmatized consumers when they engage in market change efforts. In this study, we address this gap. We ask: What are the consequences, for the collective of consumers who consider themselves to suffer from the stigma, of engagement by stigmatized consumers in efforts to participate in mainstream markets? To address this research question, we have engaged in ongoing online archival research in the network of Fatshionista bloggers and followers that we studied in our earlier work. Fatshionistas are plus-sized consumers who want more options from mainstream fashion marketers (Scaraboto and Fischer, 2013). They are stigmatized within mainstream society in general, and the fashion industry in particular, because their body size exceeds that regarded as attractive and socially acceptable (Bordo, 1993; LeBesco, 2005). In earlier work, we monitored 10 blogs that discuss plus-size fashion regularly, from their first post through to December 2010. Since then, we have monitored blogs and responses for two additional years, and have collected media articles that discuss Fatshionistas' engagement in the fashion market. Our analysis of this data was guided by our research question, and informed by concepts from relevant theories. From institutional theory, we consider the notions of legitimacy (the degree of which can vary across categories of actors within a market or field);

institutional boundaries (distinctions perceived between categories of actors in a market or field [Zietsma and Lawrence, 2010]); and institutional work (actions aimed at creating, maintaining and/or disrupting institutions [Lawrence and Suddaby, 2006]). We also drew on concepts from actor-network theory, including its central premise that the success of any network relies on the ability of focal actors in the network to tie together the interests of multiple actors through processes of "translation." Translation processes are those in which disparate actors are recruited to engage in alliances that help stabilize the network in a way that suits the focal actor's interests. Our findings highlight three consequences for the collective of engagement by stigmatized consumers in efforts to ameliorate their marginalization in a marketplace: 1) Some members of the consumer collective – but not all of them – gain recognition for taking on institutional work that is supportive of the institutional norms and logics. In the case of Fatshionistas, this institutional work is the creation of fashionable "looks" with available plus-size outfits, and of fashion commentaries that are disseminated online through blog postings. This activity is in essence the same kind of institutional work undertaken by fashion photographers and fashion editors, and contributes to reinforcing the logic of art that is central to the field of fashion (Scaraboto and Fischer, 2013). However, while a few Fatshionistas gain recognition from others and attract an online following, most actors in the Fatshionista collective are not active in these kinds of institutional work. 2) Institutional boundaries emerge between members of the stigmatized collective. Those who have been most fully enrolled in the fashion industry are singled out from those who have been largely ignored by focal actors in that network. In the case of Fatshionistas, a boundary emerges that differentiates those who fit "the formula for mainstream media: white, cis(gendered), good looking, middle class, young and able-bodied," (Perkins, 2013). These Fatshionistas tend to be at the lower end of the plus size range. This contributes to the formation of a boundary between the younger, smaller plus-sized consumers and those who are older and/or in the larger end of the plus-size range. The emergence of this division is in part due to the fact that mainstream marketers, when faced with pressure from Fatshionistas, cater to those in the smaller size ranges so as to concede conditional, or "phantom acceptance" (Goffman, 1963) to plus-size consumers. 3) Stigmatized consumers who are members of the more favored sub-group and who gain recognition for their institutional work may abandon – or may be perceived as having abandoned – the goal of promoting social transformation. This is especially likely if the stigmatized consumer can, and does, reduce the pervasiveness of her stigma. In the case of Fatshionistas, this can happen through weight loss and/or through the formation of a close alliance (e.g. paid employment) with a mainstream marketer. Fatshionistas who have neither lost weight nor allied closely with mainstream marketers may then publicly call into question the actions of those who have done so, labeling them as "sell-outs" who have been co-opted and have "let down" others who nominally share the same stigmatized status. Stigmatized consumers who continue to be neglected by mainstream marketers may further polarize schisms within the collective by reinforcing, in their fashion blogs, other issues of ongoing concern to the stigmatized group, such as medical negligence and employment discrimination. These bloggers consider gaining access to the mainstream fashion field as insufficient to fight the stigma of fat and "fear that the joining of oppressed and oppressor in brand relationships is not furthering fat activism" (Perkins, 2013). Our analysis suggests that these consequences can significantly destabilize an actor network anchored on a shared stigmatized identity. Whether this destabilization will impede stigmatized consumers from accessing mainstream markets should be the subject of future research.

SESSION OVERVIEW

Consumers and practitioners are often mistaken about the most effective ways to get motivated or to enhance perceived value. In part, their mistakes may be due to not recognizing the counterintuitive forces that operate on consumer value and motivation. This session will highlight the variety of counterintuitive ways that people come to see things as particularly valuable, and get motivated to act.

In the first talk, Maglio describes how consumers who rely on careful, rational reasoning end up making poor decisions. Remarkably, those who rely on their intuition feel more satisfied with their chosen options, leading them to pursue these options with larger investments of both money and effort. Next, Akhtar, Paunesku, and Tormala outline how using weak rather than strong arguments can motivate political advocacy. Weak arguments bolster supporters' appraisals of their abilities to advocate effectively, making these arguments, surprisingly, more useful than strong arguments for rousing supporters. Third, Kappes and Balcetis find that focusing on the actions people have done makes them feel less entitled to rewards—although they apply the opposite criteria when judging others' entitlement. Finally, Hershfield, Galinsky, and Roese show that, ironically, thinking about how a company almost didn't make it (rather than how it was destined for success) makes its products seem more valuable. Counterfactual reflection on the company's origin imbues it with meaning, which in turn heightens willingness to pay for its products.

While surprising at first, these interesting effects are, in fact, far from counterintuitive and instead derive from predictable psychological precursors to valuation and action. The papers included here show that the manner in which basic facts are framed steers the course for how they are processed and acted upon: feelings of satisfaction predicting donations (Maglio), feelings of efficacy predicting behavioral intentions (Akhtar et al.), feelings of self-worth predicting consumer demands (Kappes & Balcetis), and feelings of meaning predicting willingness to pay (Hershfield et al.). By focusing on the processes underlying valuation and motivation, these four papers provide a way forward for consumers and practitioners hoping to better understand surprising judgments of value and investment of resources.

Taken together, these papers ask: What are the larger themes that account for counterintuitive, and even ironic, consumer be-

havior? These studies highlight the fact that value and motivation depend not only on qualities of the product and of the person, but also on the way that the consumer approaches a decision. Since these decision processes are more malleable than product attributes or personality characteristics, they offer new insights into the precursors of purchase decisions, and into understanding counterintuitive consumer behavior.

Implementing Intuitive Decisions

EXTENDED ABSTRACT

Deliberative decision strategies have historically been considered the surest path to sound decisions, but recent evidence suggests that intuitive strategies may be equally effective. By relying upon an *affect heuristic*, people use their feelings as a guide to decisions about choice options rather than weighing the individual pros and cons (Slovic et al. 2002). Such feeling-based choice has been shown to improve decision quality, leading people to more accurately choose among hypothetical cars and vacations (Mikels et al. 2011) and to more accurately predict real-world outcomes like stock prices and the weather (Pham, Lee, and Stephen 2012). However, an open question remains as to how feeling-based decisions are translated into action. Because intuition boosts choice satisfaction (Mikels et al. 2011), which in turn enhances effortful action (Locke and Latham 1990), we predicted that people would work harder toward decisions reached using gut feelings versus deliberation.

Study 1 assessed commitment to choice options as a function of decision strategy. Participants were presented with information about four different (ostensibly real) restaurants. Beforehand, they were randomly assigned to process the information based on either a “deliberative, rational analysis”, their “intuitive, gut feeling”, or with no explicit instruction. The information was presented in a grid format in which participants saw the 12 pieces of information defining the first restaurant for 10 seconds, then the 12 pieces of information defining the next restaurant for 10 seconds, and so on. We constructed the choice options such that one restaurant was the “best” option in that it had more positive attributes (75%) than the others (50%, 50%, and 25%). After learning about the restaurants, they received 12 entries into a lottery in which they could win a \$50 gift certificate. Participants indicated, for each of the entries, one of the four restaurants about which they had learned. They were free to allocate the tickets however they wished among the four restaurants. They were told that we would select a random entry (i.e., one participant + restaurant choice) to win \$50 to the restaurant indicated on that specific ticket. Our dependent variable of interest was the number of lottery entries participants allocated toward the best restaurant. Consistent with our hypothesis, participants in the gut feeling condition allocated more tickets to the best restaurant than those in the rational or control conditions; the later two conditions did not differ from each other.

Study 2 used a similar paradigm to consider the relationship between intuition and effortful action. It also tested the moderating role of when decisions are implemented, as past research has suggested that a break between learning and choosing can compromise the benefits of intuition (Mikels et al. 2011). Participants were presented with information about four different restaurants (one at a time and for 10 seconds each), but they then choose the one they preferred. They were told that each participant would, by default, receive 5

entries into a lottery for a \$50 gift certificate toward the restaurant they chose. Additionally, they would have the opportunity to earn additional entries into the lottery by performing a word search task after making their choice, and all bonus entries would go toward their chosen restaurant. Participants were randomly assigned to process the information deliberately or intuitively, and the information about the restaurants was presented in the same manner as Study 1. Here, however, the options were constructed such that no one restaurant dominated the others; instead, each was defined by 50% positive attributes and 50% negative attributes. After the information presentation, participants chose the restaurant they preferred.

Next, participants had the chance to find up to twenty words in the word search task. For each correctly identified word, we would provide them with one additional entry in the lottery. For half of the participants, they performed the word search task uninterrupted. For the other half, a pop-up ad appeared very early during the word search (before any words were identified) that participants had to close in order to proceed. We recorded how long participants spent on the word search task and also scored how many words they had correctly identified.

Neither the main effect of decision style nor the main effect of distraction was significant, but we did obtain the predicted interaction between the two factors. When not presented with a pop-up ad, participants in the gut feeling condition spent more time working on the word search task than those in the rational condition. However, when the pop-up ad was presented, participants in the gut feeling condition spent less time working on the word search task than those in the rational condition. We observed an identical pattern of results for the number of words found. This suggests that intuitive decisions are most effectively translated into action immediately. Adding a break – even briefly – between choice and implementation negated the benefit for intuition.

Study 3 examined choices in a different domain and targeted actual spending behavior. Participants were presented with information about four different children's charities (one at a time and for 10 seconds each). They were randomly assigned to process the information deliberately or intuitively. All of the options were defined by 50% positive attributes and 50% negative attributes. After the information, they chose the charity they preferred. Additionally, they were given the opportunity to donate to their chosen charity from the \$2 they had received for participation. As predicted, participants who chose their charity based on intuition felt more satisfied with their choice and donated more money to that charity.

In sum, this research identifies important downstream consequences for how people approach decisions in the first place. Consistently, people focused on feelings worked harder and longer toward their choices, suggesting that affect facilitates the immediate implementation of decision-relevant action.

Weak > Strong: The Ironic Effect of Argument Strength on Supportive Advocacy

EXTENDED ABSTRACT

A great deal of research has tested the effect of argument quality—or message strength—on persuasion (for reviews see Petty & Wegener, 1998; Petty, Rucker, Bizer, & Cacioppo, 2004). This vast literature consistently shows that, when argument quality does exert an impact on persuasion (e.g., under conditions of high message processing), strong arguments produce more persuasion than do weak arguments. The present research suggests that under some conditions the opposite strategy may be superior—in particular, presenting weak rather than strong arguments might motivate greater advocacy

and action. Across three studies, we show that when individuals already agree with a cause (i.e., it is pro-attitudinal), receiving weak arguments in its favor can prompt them into advocating more on its behalf. Perceived argumentation efficacy mediates this effect such that people exposed to weak arguments are more likely to feel they have something valuable to contribute. Moreover, consistent with the notion that it is driven by subjective feelings of *increased* efficacy, the effect is more likely to emerge when initial argumentation efficacy and attitude certainty are moderate or low. Individuals with high argumentation efficacy and high certainty generally advocate regardless of the strength of arguments received.

Study 1. Prior to the 2012 presidential election, participants were told that the researchers conducting the study were part of a new national initiative entitled *Voter's Voice*. The initiative was ostensibly designed to inform Americans about why other citizens are motivated to support or oppose particular political candidates. All participants were told that the researchers were investigating the ways in which voters view and make sense of their fellow citizens' reasons for supporting and opposing those candidates. All participants were also led to believe that the information they provided could be used in get-out-the-vote campaigns and political advertisements. Following this introduction, participants reported their attitudes towards Obama's reelection. Then, participants were assigned to read arguments made by other citizens in support of Obama's reelection campaign. They read either weak or strong arguments for Obama, and then they answered questions about their willingness to advocate (i.e., trying to persuade others, making phone calls for Obama, donating money to Obama's campaign) and their subjective feelings of efficacy (i.e., knowledge compared to others, perceived argumentation effectiveness).

Results indicated that when participants received pro-attitudinal (i.e., pro-Obama) arguments, they ironically showed greater intention to advocate for Obama when those arguments were weak rather than strong. Perceived argumentation efficacy mediated this effect. In essence, when participants came to feel more efficacious at arguing for a cause than their like-minded peers, they displayed greater willingness to promote, endorse, and advocate for it. This subjective feeling of efficacy was derived from weak arguments. As expected, this pattern did not hold for counter-attitudinal participants, who had similar levels of advocacy regardless of whether they saw weak or strong arguments. Finally, the argument quality manipulation (even among pro-attitudinal participants) did not change participants' attitudes or affect their voting preference.

Study 2. The primary objectives of Study 2 were to replicate the weak > strong effect among pro-attitudinal participants and to explore the moderating role of perceived argumentation efficacy. Pro-attitudinal participants went through the same paradigm as in Study 1, except that before seeing the weak or strong arguments, they completed an ostensibly unrelated task in which their argumentation skills were analyzed. Participants were given false feedback that their argumentation skills were either in the 91st percentile (high argumentation efficacy) or in the 53rd percentile (moderate argumentation efficacy). Results indicated that weak arguments led to greater advocacy for those who were told that they were moderately effective at arguing. Participants in the high argumentation efficacy condition had higher levels of advocacy regardless of the type of arguments they saw. As in Study 1, perceived efficacy mediated this effect. Thus, participants were more motivated to advocate for a cause more when they felt that they would be effective at doing so, whether that feeling came from our efficacy manipulation or the fact that their peers had made weak arguments.

Study 3. Our goals in the third study were to replicate the weak > strong effect in a completely different paradigm and to determine its relationship with a well-established, conceptually related moderator—attitude certainty. Participants were asked to imagine that their town recently proposed a policy that would make all school cafeterias vegetarian by law. After reporting their attitudes and attitude certainty towards the policy, participants were told that the town government was going to hold a town hall meeting before they made their decision. In this town hall meeting scenario, participants were exposed to either weak or strong arguments from other citizens against the policy (i.e., pro-attitudinal arguments as participants also were largely against this policy). After reading these arguments, participants answered questions about their willingness to advocate for their views (i.e., trying to persuade others, sharing their views with friends). Results indicated that pro-attitudinal (i.e., anti-vegetarian policy) participants who were low in attitude certainty showed the weak > strong effect, expressing greater intent to advocate when they saw others' weak rather than strong arguments. By contrast, participants who were high in attitude certainty expressed high advocacy intentions irrespective of the quality of arguments others made.

Discussion. Taken together, these findings reveal that weak arguments can play an important role in motivating advocacy. They suggest, counterintuitively, that it might sometimes behoove advocacy groups to expose their supporters to weak arguments from others—especially if those supporters initially feel uncertain about their attitudes or about their ability to make the case for them. Weak arguments appear to be capable of bolstering such supporters' subjective appraisals of their own abilities to advocate effectively, and perhaps also of the need to advocate in the first place. Ironically, then, motivating supporters to advocate on behalf of a cause might be facilitated by the strategic use of weak arguments. New questions for research exploring the intersection of attitudes, persuasion, feelings, and motivation will be raised, and implications for understanding self-efficacy and attitude certainty will be discussed.

Feeling Entitled Because of Who You Are

EXTENDED ABSTRACT

Consumer behavior is driven in part by feelings of entitlement. Particularly when selecting goods and services that are not necessities, consumers may reward themselves with particularly desirable selections to the extent that they feel deserving. Although entitlement beliefs may therefore play an important role in consumption behavior, these beliefs are also associated with negative outcomes like acting selfishly in ways that take a toll on others (e.g., Campbell, Bonacci, Shelton, Exline, & Bushman, 2004; Fisk, 2010; Harvey & Martinko, 2009; Moeller, Crocker, & Bushman, 2009). The goal of the current research was to aid in understanding the source of entitlement beliefs.

Lerner (1991) defined entitlement as “the judgment, often tacit, that someone, or some category of people, is entitled to a particular set of outcomes *by virtue of who they are or what they have done*” (italics added; p. 13). Who people are, or their attributes, include personal characteristics like being smart, a hard worker, and experienced in a given area; what people have done, or their actions, are behaviors like having earned a degree from a prestigious university and working a 60-hour week. A pre-study supported our supposition that people see others as entitled to desirable outcomes to the extent that those others emphasize their actions rather than their attributes. We predicted, however, that this would not apply when people thought about their own entitlement. Instead, people should

feel more entitled to desirable outcomes when they think about who they are than when they think about what they have done.

We tested this idea in four experiments by manipulating whether people focused on their attributes or their actions and then measuring entitlement. As dependent variables, we measured both general entitlement, using an established instrument, the Psychological Entitlement Scale (PES; Campbell, et al., 2004), and also beliefs about specific outcomes that were deserved (e.g., salary).

In Experiment 1, participants were instructed to think about either “the kind of person that you are” (attribute focus condition) or “the kinds of things you do” (action focus condition) as they responded to a resource dilemma. Those in the attribute focus condition subsequently scored higher on the PES than those in the action focus condition. Control measures indicated that construal level (abstract versus concrete thinking) did not explain the effect.

In Experiment 2, law students read that many lawyers earn a high salary “because of who they are” (attribute focus condition) or “because of what they do” (action focus condition). Controlling for gender and the type of law participants were interested in practicing, those in the attribute focus condition had higher PES scores and also gave a higher number as the starting salary to which they believed they were entitled.

We next investigated mechanisms underlying entitlement beliefs. As the first mechanism tested, we asked whether *perceived consistency* of favorable inputs increases entitlement. Attributes describe more enduring behavior than actions (Semin & Fiedler, 1988). Perhaps the attribute focus manipulations made participants think about their favorable inputs as being especially enduring or characteristic, and they rewarded themselves accordingly. Apart from this *consistency* mechanism, we tested a second mechanism. We asked if *self-worth* increases entitlement. Most people think of themselves as good and worthy people (Baumeister, Tice, & Hutton, 1989), so the more that they base their judgments of entitlement on these global evaluations of the self, the more entitled they should feel. In this case, even information about an ancillary negative input might boost entitlement, if it leads people to focus on their attributes.

In Experiment 3, we tested both the effects of perceived consistency and self-worth on entitlement. Students completed a tattoo-drawing task and received positive or negative feedback that focused on their attributes or actions. Participants indicated how much (hypothetical) pay they deserved for their drawing. Both attribute-framed feedback and positive feedback increased entitlement to pay, and the effects of one factor did not depend on feedback valence. If consistency were the only underlying mechanism, then attribute-framed feedback would have increased entitlement when positive and decreased entitlement when negative, but there was no such interaction effect. Moreover, participants who received negative attribute-framed feedback also reported the highest PES scores of any condition. Thus, these findings provide support for the self-worth mechanism.

Further support came from Experiment 4, where participants were randomly assigned to complete a task that would induce temporarily low or high feelings of self-worth (Brown, Dutton, & Cook, 2001), before they wrote personal ads focusing on the “kind of person you are” (attribute focus condition) or on the “kinds of things you do” (action focus condition). PES scores as well as entitlement to a desirable romantic partner were highest in participants with high feelings of self-worth who focused on their attributes.

In sum, these four experiments shed light on the sources of high entitlement beliefs, which in turn have consequences for consumer behavior.

Wanting What Almost Wasn't: Counterfactual Reflection Heightens Valuation of Branded Products

EXTENDED ABSTRACT

Apple and Google were started in garages. FedEx took off with \$27,000 in winnings at a Vegas blackjack table. Southwest was conceived on a cocktail napkin. The story behind a brand has always been important to its consumers; indeed when the above companies come up for discussion, references to their interesting starting points are often not far behind. These examples also suggest that some origin stories contain a particular twist, a fork in the road or a close-call with disaster, that make the current stature of the brand seem more valuable. If not for the improbable blackjack win that saved the company from bankruptcy, there would be no FedEx today, and this story may make the company seem, as a result, more valuable. The present research explores the impact of these "what might have been" reflections on brand perceptions and consumption experiences. We further explore whether a particular mechanism – the elevation of product's sense of meaningfulness to the individual – underlies the counterfactual reflection effect on brand experience.

In Study 1, we tested the idea that counterfactual reflections are associated with greater preference for given brands at a very general level. If counterfactual reflection enhances brand attitude, then all else being equal, the salience of counterfactuals regarding brand origin might be associated with brand preference. To this end, we asked participants to list either their favorite or least favorite brand. We predicted that participants would be more likely to indicate that their favorite brand had a turning point or "fork-in-the-road" moment (i.e., a salient counterfactual embedded in the brand origin story) compared to their least favorite brand. In line with our hypothesis, a greater proportion of participants noted a fork-in-the-road moment (i.e., counterfactual connected with brand) for their favorite versus least favorite brand (32.3% vs. 22.1%), $c^2(1, N = 324) = 4.27, p = .039$.

The goal of Study 2 was to test the causal impact of counterfactual reflection on brand valuation. We manipulated counterfactual reflection by creating two framings of the origin story behind a well-known brand (Gatorade), one inviting the participants to reflect on "what might have been" and the other sticking solely to factual events. We predicted that participants in the counterfactual condition would be willing to pay a greater amount for a correspondingly branded product than those in the factual condition. Indeed, participants in the counterfactual-reflection condition expressed a higher willingness-to-pay ($M = \$2.14, SD = \1.18) than did participants in the factual-reflection condition ($M = \$1.72, SD = \0.89), $t(132) = 2.33, p = .021, d = .40$. In short, highlighting the counterfactual origins of Gatorade led to a higher willingness to pay for a 20-ounce bottle of Gatorade.

Whereas Study 2 documented the impact of counterfactual reflection on product evaluation, Study 3 pushed further to examine consumption experiences. Specifically, in Study 3 we examined whether counterfactual reflection influences how much participants enjoyed consuming a product. If the counterfactual reflection makes evaluations of the brand more positive, this evaluative effect might spill over to consumption experience. To this end, participants in the counterfactual-origins condition read a description of a fictional chocolate company that highlighted the ways in which events could have turned out differently. Participants in the factual-origin condition read a description that simply discussed the origins of the company. All participants were then given a chocolate wrapped in silver foil ostensibly from Droese Chocolates to sample and rated the taste and flavor of the chocolate on 7-point scales, from which we created a composite taste-flavor score ($\alpha = .93$). We predicted that reflect-

ing on the counterfactual origins of a chocolate company would improve the very taste of its chocolates. An omnibus ANOVA revealed significant differences among the three conditions in ratings of the chocolate, $F(2, 38) = 4.35, p = .02, h_p^2 = .19$. As predicted, a contrast test revealed that participants in the counterfactual-origins condition rated the chocolate as having better taste and flavor ($M = 4.90, SD = .71$) than did participants in the factual-origins condition ($M = 4.00, SD = .90$) and the control condition ($M = 4.33, SD = .89$), $t(38) = 2.72, p < .01$.

Past research has found that people find meaning in mutability (Galinsky et al. 2005; Kray et al. 2010, Ersner-Hershfield et al. 2010). That is, counterfactual reflection increases the meaningfulness of an event or relationship. Study 4 tests whether perceptions of meaningfulness underlie the effect of counterfactual reflection on branded product valuation. We hypothesized that counterfactual reflection would lead to a heightened sense of meaningfulness, which would in turn heighten willingness-to-pay. To do so, participants read about a man who had nearly missed his flight (counterfactual condition) or missed his flight by a large margin (non-counterfactual condition), and then went on to having a meeting with a friend at the airport that led to the formation of a chocolate company. An outlier from the near-miss condition who was more than 2.5 SDs above the mean WTP price was excluded from the analyses that follow. In line with our hypothesis, participants in the near-miss condition were willing to pay significantly more for the box of chocolates ($M = \$9.20, SD = \5.02) than were participants in the far-miss condition ($M = \$6.87, SD = \3.98), $t(70) = 2.19, p = .032, d = .51$. Moreover, participants in the near-miss condition also saw *Droese Chocolates* as more meaningful ($M = 3.99, SD = .95$) than did participants in the far-miss condition did ($M = 3.31, SD = 1.04$), $t(70) = 2.90, p < .01, d = .68$. To examine the mediating role of meaningfulness, we regressed willingness to pay scores on condition and perceptions of meaningfulness. As hypothesized, when taking into account meaningfulness, condition was no longer a significant predictor of willingness to pay, $b = .15, t = 1.26, p = .212$, whereas meaningfulness was a significant predictor, $b = .32, t = 2.76, p = .007$.

SESSION OVERVIEW

This session is focused on the current ACR theme of “Make a Difference” by exploring how individuals can make a difference in their own lives, enhancing their abilities to pursue desired self-regulation goals, understanding the obstacles to self-regulation, and improving goal engagement and goal outcomes. Decades of research in both psychology and consumer behavior have attempted to identify behaviors that support and moderate self-regulation. A multitude of products and therapies have all targeted self-regulation goals, attempting to help consumers save money, exercise more, quit smoking, lose weight, and address dozens of other self-regulation goals. We address this critical domain by asking: when do consumers remain engaged with self-regulation goals, and when do they disengage? In particular, we explore this question from the perspective of the self through a focus on various moderators such as individual traits, self-perception, and self-affirmation.

In the first paper, Touré-Tillery and Fishbach focus on self-perception as driver of goal engagement. The authors show that when individuals perform actions that have a strong visual impact (e.g., writing a donation amount with brightly colored ink versus subdued ink) this leads them to perceive the behavior as more diagnostic of the self, thus increasing goal engagement as individuals seek to maintain a positive image of the self.

In the second paper, Zemack-Rugar, Corus, and Brinberg show that imagined or anticipated goal failure can sometimes impact goal engagement in the same way as actual, past goal failure, and at other times – differ from past failure. The authors explore moderators of goal engagement preceding or following goal failure including individual characteristics (one's score on the “Response to Failure” scale) and the reason for failure (internal vs. external attribution).

In the third paper, Koo, Labroo, and Lee look at the role of self in self-regulation by examining how a potent individual difference – regulatory focus – affects goal engagement. The authors explore why a prevention (vs. promotion) focus is more effective at increasing goal engagement, and show that prevention oriented individuals succeed at self-regulation by focusing on goal-engagement, and not by focusing on avoiding goal-inconsistent behaviors.

In the fourth paper, Vohs, Park, and Schmeichel uncover unexpected effects of self-affirmation on goal engagements. The authors show that affirming the self can aid in goal-engagement when the goal is easy (consistent with prior research), however, self-affirmation can be detrimental to goal pursuit when the goal is challenging and individuals experience failure.

In summary, all papers address the role of self in self-regulation, presenting counter-intuitive findings, unexpected effects, new process theories, and new moderators. These papers (all in advanced stages of completion) further the field's understanding of self-regulation and should be of interest to a variety of researchers focusing on goal behavior, sequential choice, individual differences, and self-regulation. This session provides great insight for consumers, marketers, and researchers alike as to how we can all “Make a Difference” and promote successful self-regulation goal pursuit.

Making an Impact on the Self: How Sounds and Colors Increase Goal Engagement

EXTENDED ABSTRACT

Imagine completing a form to indicate how much money you want to donate to charity. Now imagine that, for some reason, you receive a bright orange pen to complete this form. Would this visually impactful ink color influence your donation? Would it influence how you see yourself?

People will make goal-consistent choices when they believe these choices matter for the goal outcome, or for their own self-concept (i.e., self-signaling; Bodner and Prelec 1996; Prelec and Bodner 2003). Thus, a person will donate money to charity because it will save lives, or because it will make her feel more generous—or both. Many factors can make a choice seem consequential for the self-concept. For example, explicitly linking a choice to an identity (e.g., be a voter; Bryan, Walton, Rogers, and Dweck 2011), or positioning a choice at the beginning or end of a sequence (Touré-Tillery and Fishbach 2012) promote adherence to goals by making choices seem more representative of the self, or self-diagnostic. These patterns of behavior occur because individuals are motivated to maintain a positive self-concept (Gao, Wheeler, and Shiv 2009; Schlenker 1985) and will “do the right thing” when it seems most telling of the self.

Research shows individuals for whom outcomes are typically experienced as dependent upon their own actions tend to develop an internal locus of control, and become more likely to exert themselves when engaged in important tasks (Rotter 1966). We propose the immediate perceptual effect of an action, although irrelevant for goal pursuit, will operate as a type of contingent outcome. Producing a visual contrast when writing with a bright color on a form printed in black, or producing sound while clicking through webpages will increase people's sense of control and responsibility for that action. Thus, we hypothesize that actions with such visual or auditory impact will seem more self-diagnostic, and hence will increase adherence to valued goals, because individuals wish to maintain a positive self-concept. Three experiments confirmed our hypotheses for pro-social and voting goals.

In Experiment 1, we started with participants who generally value charity goals involving monetary donations (MBA students). Participants indicated their likelihood to donate to UNICEF on a survey printed in black ink. The study employed a 2 (visual impact:

high vs. low) between subjects design. Participants in the low-impact condition received a black pen to fill out the survey, whereas those in the high-impact condition received a bright-color pen (orange, light blue, or purple) which contrasted more sharply with the survey print. We found participants were more likely to donate when using color (vs. black) pens. We argue visual impact made the decision appear more diagnostic for self-inferences about generosity, and thus promoted adherence to prosocial goals.

Experiment 2 used the same design and visual-impact manipulation to explore our hypotheses in the domain of civic goals and test the mediating role of self-diagnosticity. Participant (US citizens) wrote a short essay about their political views in color or black, and we assessed the perceived self-diagnosticity of this action by measuring perceptions of (1) political identity and (2) representativeness of expressed views. Participants also indicated their voting intentions for the presidential elections—a measure of goal adherence. We found writing in the visually impactful color (vs. black) pen seemed more self-diagnostic, and increased voting intentions. Finally, perceived self-diagnosticity mediated the effect of visual impact on voting intentions.

In Experiment 3, we extended these findings to real giving behavior and auditory impact, and tested the moderating role of the “need to self-signal.” The 2-part experiment employed a 2 (need to self-signal: high vs. low) x 2 (auditory impact: high vs. low). First, participants indicated how frequently they engage in various charitable acts. The scales provided to answer these questions constituted our manipulation of need to self-signal. In the high need to self-signal condition, participants used a high-frequency scale designed to make them feel selfish; but the low need to self-signal condition featured a low-frequency scale meant to make them feel generous. In a presumably separate study, a computerized dictator game, participants allocated money between themselves and an anonymous other. In the high-impact condition, participants heard computer sounds when clicking to move to the next screen, whereas the computer volume was off in the low-impact condition. We found participants with a low need to self-signal were unaffected by auditory impact. By contrast, participants with a high need to self-signal shared more in the sound (vs. mute) condition, suggesting the auditory impact made their decision seem more diagnostic for inferences about their own generosity, and thus promoted adherence to prosocial goals.

Taken together, these studies show actions producing a minor visual or auditory impact are deemed more diagnostic for self-inferences, and therefore promote adherence to prosocial and voting goals. These findings suggest marketers and public policy makers can promote adherence to important goals by incorporating subtle perceptual effects into consumers’ decision making processes. For example, having consumers fill out retirement planning paperwork in ways that produce visual contrasts or sounds might improve saving decisions.

What I Haven’t Done Can’t Hurt Me: The Effects of Imagined Future Failure on Goal Disengagement

EXTENDED ABSTRACT

Prior research has identified a phenomenon called the “What-the-Hell Effect” in which consumers who experience initial goal failure respond with goal disengagement, and enact further counter-goal behaviors (Cochran and Tesser 1996). Recent research has qualified these findings, by demonstrating that the tendency to enact this disengagement response is based on an individual difference, and that a scale (the Response-to-Failure scale) can be used to predict who will respond to failure with goal disengagement and who will re-

spond with resumed goal efforts (Zemack-Rugar, Corus, and Brinberg 2012).

In the present research we extend these findings by looking not at the response to real, past failure, but rather the response to imagined, future failure. Whereas previous research has explored the effects of imagined future virtues on current behavior (Khan and Dhar 2007) and the effects of other self-regulation plans or intentions (Baumeister, Masicampo, and Vohs 2011), no research has explored the effects of imagined future vices on current behavior.

Yet, anticipating failure is quite common in consumer lives. For example, if a consumer is expecting to attend a conference during which they are unlikely to be able to adhere to their health/fitness goals, they face a decision in the days leading up to the conference – should they engage with the goal and try to lose a few extra pounds to allow for the upcoming, inevitable weight gain? Or should they disengage from the goal, give up, and indulge in the days leading up to the conference? We explore the similarities between anticipated future failure and past failure (studies 1 and 2), and the differences between the two (study 3).

In studies 1 (food domain) and 2 (budget domain) we show that anticipated future failure can lead to the same behavioral patterns as past failure, thus, response to future failure can be predicted by the Response to Failure scale. We conduct a one factor (future failure/no future failure) between subjects design, with a second measured factor of Response-to-Failure scale. Prior research shows that individuals high (low) on this scale tend to respond to past failure with more (less) goal disengagement. We predict that the same pattern will occur in response to anticipated, future failure.

In both studies, participants were presented with a scenario that either had an anticipated future failure described or had no future failure, followed by a self-regulation choice in the present (i.e., at a time preceding the future failure). After indicating their choice, participants completed the Response-to-Failure scale. As predicted, we found a two way interaction of the scale by future failure condition in both studies ($ps < .05$). When no future failure was expected, the scale did not predict choice; when future failure was expected, individuals with high (low) scores indulged more (less), enacting more (less) of the “What the Hell” effect (i.e., disengaging from the goal) even when failure had not actually occurred (i.e., was in the future). These findings indicate that imagined future failure and actual past failure can give rise to similar emotions and cognitions, and that these emotions and cognitions have similar predictive power relative to sequential behavior.

Study 3 explores whether and when past and anticipated failure may differ. We argue that the key difference between anticipated failure and past failure is the perception of changeability (Gilbert and Ebert 2002). When failure is in the past, it cannot be changed. Thus, the cause of failure is not important; only the fact of having failed matters. We thus predict that when past failure has occurred (regardless of cause) individuals high (low) on the Response-to-Failure scale to enact more (less) goal disengagement. In contrast, when failure is in the future it can be perceived as changeable. Thus, individuals will focus on the causes of failure, perceiving that if *they* are the cause of failure (i.e., internal attribution) they could somehow change things and perhaps avoid or mitigate failure. Given that individuals might perceive they could avoid failure, we expect they would not enact the “What the Hell” regardless of their Response-to-Failure scale score, and will remain engaged with the goal.

In contrast, if individuals perceive that *someone else* is the cause of failure (i.e., external attribution) they would feel failure is less changeable or avoidable; thus, they will respond to future failure in the same way they would respond to past failure, with those

higher (lower) on the Response-to-Failure scale enacting more (less) of the “What the Hell” effect, i.e., showing more (less) goal disengagement.

To test these predictions we conducted a 2 (timing of failure: future/past) by 2 (failure reason: internal [me]/external [others] attribution) between subjects design, with measured Response-to-Failure scale as a third factor. Participants were presented with a scenario in the academic domain, in which they either expected future failure or had incurred past failure related to a school assignment. We separately manipulated whether the reason for failure was either internal (they chose not to study) or external (circumstance outside their control prevented them from studying). Participants were then asked to indicate the likelihood that they would continue to study (i.e., engage in goal) versus go out with friends that night (i.e., disengage from goal). Participants were also asked to indicate the degree to which they perceived the events described in the scenarios as changeable, as both a manipulation check and potential mediator measure.

As predicted, we found a significant three way interaction of time of failure by cause of failure by individual score ($p < .05$). Patterns of means indicate that when failure was in the past, participants high (low) on Response-to-Failure-score disengaged from the goal more (less) regardless of the failure’s cause. However, when the failure was in the future, only participants whose cause of failure was outside of their control (i.e., external) disengaged from the goal, while participants whose cause of failure was internal did not respond with goal disengagement even if they were high on the Response-to-Failure scale.

The Role of Goal Engagement in Self-Regulation

EXTENDED ABSTRACT

One of the ways to frame goal engagement is through a simple but elegant two category model, distinguishing between promotion and prevention self-regulatory orientations. Prior research has shown that a prevention orientation is associated with better self-regulation relative to a promotion orientation (Chen et al. 2005; Freitas et al. 2002; Sengupta and Zhou 2007; Shah et al. 2002). The present research looks at why this occurs.

Prior work would suggest that prevention-oriented people would prioritize resisting temptations as the strategy for goal attainment. However, there are reasons to believe that a prevention orientation may not necessarily entail active avoidance of temptation. Instead, we propose that a prevention orientation heightens the engagement with the goal overall, thus leading to self-regulation success. In particular, given prevention-focused individuals’ sensitivity to negative outcomes, the possibility of goal failure looms large for them. When faced with self-control dilemmas, their vigilance is heightened, and their attention focuses on what is most important—to engage with or approach the goal — rather than necessarily on avoiding temptations that may thwart successful goal pursuit. In contrast, promotion-oriented individuals focus on preventing errors of omission; this leads to a multifocal strategy of engaging in goal pursuit by both approaching the goal and countering temptation simultaneously. Despite the fact that multipronged approaches would, on the surface, seem to predict more successful outcomes, this approach may ironically undermine self-regulation.

As a result we predict that prevention-oriented individuals will be more engaged with the goal, and more focused on approaching goal-related stimuli. We predict that they will make self-regulation choices based on a preference for/approach towards goal-congruent behaviors, will have more goal-approach thoughts, and less thoughts/strategies related to avoidance of goal-incongruent behaviors. As a

result of this goal-engagement strategy, prevention-oriented individuals will be more successful at self-regulation than promotion oriented individuals.

We tested these hypotheses in four studies. In Study 1, we focus on the role of self by looking at regulatory focus as an individual difference (Lockwood, Jordan, and Kunda 2002). Participants were asked to indicate which self-regulation strategies they would use to resolve a self-regulation dilemma of studying versus spending time with friends. We found that the more prevention-oriented participants were more likely to adopt a goal-centric strategy that moves towards the goal and were more likely to succeed at self-regulation (i.e., to stay home and study).

In Study 2, we sought more direct evidence for the different self-regulation strategies by assessing participants’ reasoning of self-regulation choices. Participants tasted and evaluated two sample products: a granola bar (health goal-compatible) and a chocolate bar (temptation). After the test, participants chose one of the sample snacks as a token of appreciation, and indicated the strategy they used to choose their snack by selecting one of the following: 1) “going for the sample that is healthy” (goal-engagement strategy); 2) “not choosing the sample that is unhealthy” (temptation-avoidance strategy); 3) “going for the sample that is tasty” (goal-disengagement strategy) and 4) “not choosing the sample that is not tasty” (goal-avoidance strategy). Finally, we measured participants’ regulatory orientation. We found that the more (less) prevention-oriented participants were, the more (less) likely they were to deploy the strategy of “going for the healthy option,” which led to a higher likelihood of choosing the granola bar.

In Study 3, we primed participants with different regulatory orientations, and presented them with the same self-regulation dilemma as in Study 1. Then, we asked participants to list all the factors they considered when making their decision. We found that participants in the prevention (promotion) condition generated more (less) thoughts that focused on academic success, which in turn led to a higher likelihood of their deciding to stay home to study, reflecting better self-control.

In Study 4, we instructed individuals to adopt a goal-engagement strategy or a temptation-avoidance strategy, and explored the effects on promotion- versus prevention- oriented individuals; a control (no thought) condition was also included. As predicted, among promotion-oriented participants, those who followed the goal-engagement strategy were more likely to choose the healthy salad, demonstrating better self-control, relative to those in temptation-avoidance or control conditions. Among prevention-oriented participants, those who followed the temptation-avoidance strategy were less likely to choose the healthy salad than those in the goal-engagement or control conditions.

These findings provide convergent evidence regarding the role of self in self-regulation and the importance of goal-engagement. The findings show that individuals who are higher on prevention orientation are more successful at self-regulation, consistent with previous findings. What is more, the data further show that the reason for this is not avoidance of temptation or counter-goal behavior, but rather goal-engagement and approach towards goal-congruent behaviors. Our research counters what is currently thought about what it means to be promotion- and prevention-oriented, which opens up new avenues for insights and exploration.

Self-Affirmation Can Enable Goal Disengagement

EXTENDED ABSTRACT

Research indicates that affirming core values helps to bolster the legitimacy of the self and promotes reacting with equanimity to threats to self-regard. Self-affirmed people accept information about their personal flaws as credible and view those flaws as plausible causes of future problems. They have been shown to react to these humbling realizations by intending to bring the self in line with more virtuous standards (Sherman & Cohen, 2006). Thus, an open acknowledgment of one's personal characteristics (perhaps especially one's flaws) is central to how self-affirmation helps regulate goal-directed behavior.

In contrast, we propose that engaging in self-affirmation can sometimes dampen performance and motivation. We predicted that compared to non-affirmed individuals, self-affirmed individuals will react to initial task failure with goal disengagement. In particular, because self-affirmation can increase openness to negative information about the self, we reasoned that being self-affirmed before failing at a task could lead individuals to take the negative feedback of failure more to heart, thus lowering their perceptions of self-efficacy. In turn, self-affirmed individuals who failed at an initial task might exert diminished effort and show reduced motivation on a subsequent task related to the same goal.

Experiment 1 was a 2 (self-affirmed/not) by 2 (failure/no failure) between subjects design. After a self-affirmation (or no self-affirmation) manipulation, participants were instructed to move individual pieces of rice with chopsticks. In the failure condition participants were instructed to perform quickly and well, a goal likely to result in failure due to the difficulty and unfamiliarity of the task. In the no-failure condition participants were expected simply to give the chopsticks task a try, without performance expectations. After an initial attempt at the task we measured three outcomes: performance expectations and actual performance on subsequent attempts, and interest in attempting another rice-moving task.

We found that when failure had occurred, affirming core values led to reduced performance expectations and actual performance and less desire to engage in a subsequent chopstick task ($M_{Expectation} = 4.04$, $M_{Performance} = 5.66$, $M_{Interest\ in\ another\ attempt} = 4.34$) relative to the no-affirmation condition ($M_{Expectation} = 5.34$, $M_{Performance} = 9.80$, $M_{Interest\ in\ another\ attempt} = 5.37$). In contrast, when no failure had occurred, participants who self-affirmed showed improved performance expectations and actual performance and a greater desire to engage in a subsequent chopstick task ($M_{Expectation} = 6.21$, $M_{Performance} = 12.03$, $M_{Interest\ in\ another\ attempt} = 5.77$) relative to non-affirmed individuals ($M_{Expectation} = 4.53$, $M_{Performance} = 6.47$, $M_{Interest\ in\ another\ attempt} = 5.00$). This latter finding is consistent with prior work on the benefits of self-affirmation (Epton & Harris, 2008). These effects suggest that initial failure caused self-affirmed individuals to disengage from a goal.

Experiment 2 utilized a 2 (affirmed/not) by 2 (attainable/not) between subjects design. Once again, participants self-affirmed (or not), and then completed two tasks: (1) the chopsticks and (2) the RAT task (RAT; Mednick, 1968); the tasks were said to measure "thinking on one's feet". In the attainable (unattainable) condition, participants were given the impression that achievement of the tasks was likely (unlikely). As predicted, in the unattainable goal condition having affirmed cherished values reduced effort expended on the chopstick task, intended effort on another attempt at the chopsticks tasks, and performance on the RAT task (self-affirmation condition: $MEffort = 4.97$, $MIntended\ effort\ on\ another\ attempt = 5.00$, $MRAT$

$performance = 8.30$, non-self-affirmation condition: $MEffort = 5.65$, $MIntended\ effort\ on\ another\ attempt = 5.81$, $MRAT\ performance = 10.06$). In the attainable condition, being self-affirmed (vs. not affirmed) led to enhanced effort and performance (self-affirmation condition: $MEffort = 6.2$, $MIntended\ effort\ on\ another\ attempt = 6.64$, $MRAT\ performance = 10.92$, non-self-affirmation condition: $MEffort = 5.50$, $MIntended\ effort\ on\ another\ attempt = 5.40$, $MRAT\ performance = 9.10$).

Experiment 3 further explored the process underlying the effects of self-affirmation. We posited that people who are self-affirmed and fail at a goal would downgrade their ability to reach the goal and therefore adopt a more negative attitude toward the self. We predicted that this drop in perceived self-efficacy would statistically account for ensuing poor performance. We test this hypothesis by conducting a 2 (failure/not) by 2 (affirmation/not) between subjects study in which participants were asked to rate their competence, responsibility, capability, and work ethic. Participants first affirmed/not, and then were given either easy (no failure) or difficult (failure) versions of RAT. Participants were then asked to rate their self-efficacy (using the measures above) with respect to a subsequent (moderately difficult) RAT task; performance on this task was also measured.

Participants who self-affirmed and did not experience failure (easy RAT) rated their self-efficacy as being higher and performed better on a subsequent version of the task relative to those who did not self-affirm. In contrast, participants who self-affirmed and experienced failure (difficult RAT) evaluated themselves unfavorably relative to those that did not self-affirm. These individuals also performed worse on a second version of the task, an effect that was statistically accounted for by changes in self-efficacy.

These results suggest that what self-affirmation does to affect goal-directed behavior, it does through changes to the working self-concept. Affirming the self can lead people to internalize the implications of failure, which in turn leads to disengagement from unattainable goals. This research helps move the field toward a fuller understanding of the nature of self-regulation by exploring how self-affirmation works in dynamic choice. The effects of self-affirmation are shown here to differ depending on whether prior task experience was positive or negative.

SESSION OVERVIEW

Although we would like to believe that dishonest behavior is limited to a small group of unscrupulous individuals, the fact is that most of us engage in these behaviors (Ariely 2012). This session explores three overarching and important questions about dishonesty: (1) What are the interpersonal dynamics that influence dishonest behavior? (2) What are the psychological processes that govern unethical behavior? (3) What are the consequences of dishonest behavior? Existing research, published in marketing and psychology, has not explored this combination of themes. Further, we examine these questions in consumer situations, such as using counterfeit products, failing to disclose information on surveys, and being unfaithful to a favorite brand.

The first two papers examine interpersonal dynamics and consequences. Both papers examine how people respond to situations where being honest might elicit negative judgments from others. *John and Norton* show that individuals prefer to withhold information (e.g., recreational drug use) that could cause others to judge them in a negative way. But, paradoxically, individuals who chose to withhold information (and not tell the truth) are judged more negatively than individuals who chose to reveal the information. *Wang and John* examine the use of counterfeit luxury goods, and explore how consumers respond when others either compliment (“That looks nice on you”) or question (“Is that real?”) the counterfeit user. Compliments encourage more dishonest behavior (hiding the fact it’s a counterfeit; interest in buying more counterfeits), whereas a simple question deters subsequent dishonest behavior.

The last two papers examine psychological processes and consequences. *Amaral and Meyers-Levy* study how construal level influences expectations of unethical behavior. When judging an unknown person, individuals adopt a high construal level, leading them to anticipate this person will engage in more unethical behavior. However, when individuals consider their own behavior, which encourages an extremely low construal level, they anticipate much less unethical

behavior. *Consiglio, Kuper, Norton, and Gino* explore a new type of dishonest behavior—being unfaithful to one’s favorite brand by flirting with a competing brand. They find that flirting with a competing brand raises arousal levels, and arousal is misattributed to their favorite brand, which results in an even greater desire for the brand. Interestingly, being “unfaithful” to the favorite brand has a positive impact on one’s relationship with the brand.

Taken together, this set of papers opens up several new avenues of research on dishonesty. Each paper includes a completed set of experiments. Given the variety of settings and questions, this session is likely to appeal to a broad set of conference attendees interested in morality and ethics, self-presentation, social signaling, and branding. Further, this session fits well with the theme of the 2013 ACR conference, “Making a Difference.” Dishonest behaviors are pervasive among consumers, yet there is a need for further understanding of how these behaviors emerge, and how they negatively impact individuals.

What Hiding Reveals: Ironic Effects of Withholding Information

EXTENDED ABSTRACT

Imagine being asked about your recreational drug habits by your employer, and realizing that in order to be completely truthful you’ll have to admit that you have occasionally indulged. In four experiments, we show that people believe that the best way to deal with such situations is to opt out of answering at all – but that this strategy is costly, because observers often infer the very worst when consumers choose not to answer such questions: “If he refuses to even answer this question, he must have a serious drug problem.” The internet has created a fundamental shift toward openness, and with this shift, consumers are increasingly facing choices of whether to share or withhold information. Previous research shows that consumers tend to ‘infer the worst’ about products when marketers fail to provide information on the products’ key attributes (e.g., Kivetz & Simonsohn 2000; Huber & McCann, 1982; Simmons & Lynch 1991). In contrast however, we focus on consumers’ decisions of whether to share or withhold their personal data – and the wisdom or error of such decisions.

In Study 1, participants were asked which of two individuals they would prefer to date. They were shown, side-by-side, each “prospective date’s” response to multiple choice questions about their frequency of engagement in six taboo or illegal behaviors (such as failing to inform a partner about a sexually transmitted disease): the response options were “never,” “once,” “sometimes,” “frequently,” and “choose not to answer.” One of the prospective dates answered all six questions; the other prospective date answered four questions but selected “choose not to answer” for the remaining two. We also varied the prospective dates’ responses to the questions: in the “never” condition, for example, one of the prospective dates endorsed “never” for all six questions, while the other prospective date endorsed “never” for four questions and “choose not to answer” for the other two. We included similar conditions using “once,” “sometimes,” and “frequently.” In all conditions, participants expressed greater interest in the prospective date who had answered all six questions – even in the “frequently” condition. In other words, relative to a prospective

date who had left two questions blank, participants were more interested in dating someone who had admitted to frequently neglecting to tell a partner about a sexually transmitted disease and to frequently stealing goods worth more than \$100.

Study 1 shows that omitting information can lead to more negative judgments; Studies 2A and 2B begin to address whether consumers understand this process, or erroneously believe that leaving questions blank is an effective impression management strategy. In Study 2A, participants were asked to indicate how frequently, if at all, they engage in two behaviors – one desirable (donating to charity), the other undesirable (fantasizing about doing terrible things (e.g., torturing) others). They were told that their response to only one of the questions would be shown to a rater, who would rate their attractiveness as a date. The other question would simply be displayed without the participant's response. Participants were asked which of the two responses they would like to display. The majority of participants (62%) chose to display their answer to the desirable question, leaving the undesirable question blank.

Study 2B tests whether this choice is a mistake. Both questions from Study 2A were displayed and participants were shown how a prospective date had answered one of them (the modal response from Study 2A was used); the other question was purportedly left blank by the prospective date. We manipulated whether the desirable or undesirable question was unanswered. In contrast to choices in Study 2A, participants in Study 2B expressed greater interest in the prospective date when s/he had answered the *undesirable* question, relative to when s/he had answered the desirable question (and left the undesirable question blank). Moreover, when we asked participants to guess the prospective date's answers to a series of new questions, results were consistent with the dating interest ratings, suggesting that non-disclosure may have enduring effects on person perception. Taken together, Studies 2A and B show that ironically, participants choose to opt out of answering questions about undesirable behaviors even though doing so makes them less attractive in the eyes of others.

Finally, Study 3 tests a moderator for observers' negative judgments of non-disclosers. We predicted that people who have recently withheld information – and therefore are more likely to understand that nondisclosure may not be driven only by desires to hide horrible information – are less likely to subsequently judge non-disclosers harshly. Participants were first asked to answer sensitive questions about themselves; for each question, they had the option of selecting “choose not to answer.” We manipulated participants' propensity to select “choose not to answer” by varying the other available response options (i.e., sometimes / frequently / always VS. never / once / sometimes); participants were more likely to select “choose not to answer” for the former response scale than the latter. Next, participants were shown a prospective date's answers to the same questions and rated their interest in dating the person. We again manipulated whether the prospective date had chosen not to answer some of the questions. As predicted, the negative judgments of prospective dates who had left questions blank were buffered when the raters themselves had been induced to leave questions blank.

Taken together, these results suggest consumers can be prone to withholding information when they would be better off sharing it, and point to situations in which this tendency may be exacerbated (e.g. when those who are judging them have not, themselves, recently withheld information). Moreover, the internet's fundamental shift toward openness may exacerbate these issues, as withholding information becomes more anomalous, and hence, more conspicuous.

Faking It with Luxury Counterfeit Products: How Social Feedback Can Make Us More or Less Dishonest

EXTENDED ABSTRACT

Purchase of counterfeit luxury goods is a worldwide phenomenon. Past research in marketing has mostly focused on why consumers purchase counterfeit luxury goods (e.g., Han, Nunes, and Dreze 2010; Wilcox, Kim and Sen 2009). However, little attention has been directed toward understanding how consumers feel, think, and respond to wearing luxury counterfeits. A notable exception is research by Gino, Norton and Ariely (2010), who found that wearing luxury counterfeits made users feel less authentic and resulted in more subsequent episodes of cheating.

We examine the social context of wearing luxury counterfeit goods. We propose that consumers feel and respond differently to the experience of wearing luxury counterfeit goods when it takes place in a social context. The first two experiments (Study 1A & 1B) show the social context of purchasing luxury counterfeits influences the way people feel about wearing counterfeits. We find a reversal of Gino, et al.'s results when consumers purchase counterfeits in a social setting. The next two experiments (Study 2 & 3) show that social feedback from others regarding luxury counterfeits influences whether users will engage in further dishonest behavior. We find that consumers engage in further dishonest behaviors—lying about the luxury good being real and being interested in buying more counterfeits—only when others compliment them on their fake luxury product. When others ask a simple question (“Is it real?”), we show a reversal of Gino, et al.'s results. Subsequent dishonest behavior is diminished.

Study 1A & 1B

In study 1A, female participants were randomly assigned to wear (1) an authentic Tiffany's bracelet (2) an authentic Tiffany's bracelet labeled as counterfeit or (3) control unbranded bracelet. Participants wore the bracelet for 15 minutes while filling out a survey of filler questions. After 15 minutes, participants rated themselves on different personality traits, including “honest” and “genuine” (focal measure), on a scale from 1 (not at all) to 9 (extremely). Results replicate previous research (Gino, Norton and Ariely, 2010), showing participants in the counterfeit condition felt less honest and less genuine than participants in the authentic condition ($M = 6.41$ vs. 6.12 , $p < .05$).

In study 1B, we followed the same procedure, except participants were told to imagine the bracelet was purchased while overseas in a study abroad program (social setting). We expected the social setting would provide a way for users to rationalize their purchase of a counterfeit, which would eliminate negative feelings about themselves. As predicted, we found no differences in feelings of “honest” and “genuine” between participants who wore the counterfeit versus authentic Tiffany's bracelet ($p > .90$). Interestingly, participants in the counterfeit bracelet condition reported themselves to be significantly *more* honest and genuine than participants wearing the control bracelet ($M = 6.05$ vs. 5.50 , $p = .01$). Thus, the results from Study 1A and 1B suggest that wearing counterfeits without a social context elicits negative self feelings, but wearing counterfeits purchased in a social setting eliminates these negative feelings.

Study 2

In this study, we examine how social feedback while wearing counterfeits influences subsequent dishonest behavior. Participants were randomly assigned to one of the following experimental conditions: 2 (bracelet: counterfeit vs. control) x 2 (social feedback: com-

pliment vs. question). The bracelet conditions and basic procedures were the same as Study 1B. However, after wearing the bracelets for a period of 20 minutes, all participants were asked to imagine themselves wearing a counterfeit Tiffany's bracelet to a shopping mall, where they are approached by a salesperson who comments on the bracelet in a complimentary way (e.g., "I really like your Tiffany bracelet. It looks so cute on you!") or a questioning way (e.g., "I really like your Tiffany bracelet. Is it real?"). Participants were then asked to write down how they would respond to the salesperson, and these responses were coded in terms of honesty on a 5-point scale (1=confess it's a counterfeit; 3=intentional ambiguous response; 5=lies and hide the fact that it's counterfeit). Results showed that social feedback mattered. For participants in the counterfeit bracelet condition, those receiving a question (vs. complement) were more likely to be honest and confess the bracelet is not real ($M = 3.26$ vs. 1.55 , $p < .001$). Moreover, these participants were also more likely to confess than participants in the control condition who received a question from the salesperson ($M = 3.26$ vs. 2.47 , $p = .04$). Thus, receiving a compliment while wearing a luxury counterfeit product encouraged users to engage in more dishonest behavior.

Study 4

We continued to examine how social feedback influences subsequent dishonest behavior. Participants were randomly assigned to one of three conditions: compliment, question, or no feedback (control). Each participant was brought to a private interviewing room and was asked to wear a Burberry scarf (which was labeled as a counterfeit) and complete filler tasks. After 15 minutes, a female confederate entered the room pretending to look for a lost cell phone. She made a quick comment about the Burberry scarf in the compliment and question conditions consistent with Study 3, or made no comment at all (control). After this brief interruption, participants completed a survey, including an assessment of attitudes toward counterfeit products (4 items, e.g., "It is okay to buy a counterfeit product as long as I buy the real authentic product someday"). Finally, participants were taken to another private room which had different "counterfeit" luxury products displayed. Participants evaluated them in private and indicated their interest in purchasing these products in the future (1-9 scale). Results showed that participants who received a compliment when wearing a fake luxury scarf were more likely to engage in subsequent dishonest behavior involving counterfeits. Compared to participants in the question condition, participants receiving a compliment exhibited more positive attitudes towards counterfeit products ($M = 4.22$ vs. 3.27 , $p = .02$), as well as more interest in purchasing counterfeit products in the future ($M = 7.19$ vs. 4.09 , $p < .001$). Counterfeit purchase intention was also higher for participants receiving a compliment versus those in the control condition ($M = 7.19$ vs. 5.89 , $p = .07$).

The Effect of Construal Level on Consumers' Anticipations Involving Ethical Behavior

EXTENDED ABSTRACT

Despite the many lapses in ethical behavior that have attracted widespread attention in recent years, little is known about the cognitive processes that shape people's (un)ethical behavior and expectations of when it will occur. This lack of understanding exists despite substantial research on this topic within marketing. One factor that has contributed to this state of affairs is that most of the research has focused simply on the practical implications and applications of ethics in marketing. Limited attention has focused on theory-driven inquiry.

This research offers an initial attempt to fill this void by drawing on a corpus of work concerning both psychological distance and construal level theory (Lieberman and Trope 2008). Psychological distance refers to the gap that often exists in time, space, or likelihood that separates an event or object from the personally experienced reality of the here and now. Moreover, variations in psychological distance have been found to affect people's construal level, which refers to the level of abstraction at which people think about and mentally represent an event in memory (Trope, Liberman, and Wakslak, 2007). Increases in an event's psychological distance (e.g., an event will happen in the more distant future or to a person other than oneself) prompts individuals to think about an event in a more abstract, less detailed manner, while decreases in psychological distance elicit thoughts about the event in a more concrete or specific manner. Social distance would seem to be of importance in ethical situations for at least two reasons. First, ethical issues generally emerge in social contexts, making it likely that variation in social distance could be germane in ethical situations. Second, and more critically, because psychological distance regards the self, here and now as its lowest endpoint or anchor, assessing one's own behavior should stimulate exceptionally concrete representations of the situation.

Importantly, prior research has demonstrated that adoption of a high construal level prompts people to place greater priority on the desirability of pertinent end-states or goals. In contrast, adoption of a low construal level leads people to place higher priority on the feasibility and means used to achieve the end-state or goal. We found these observations particularly pertinent to ethical contexts because in such contexts people aspire to achieve a desirable end-state or higher level goal by employing a means that is unethical. The theory that underlies our hypotheses integrates the preceding two notions, namely, (a) a high (low) construal level increases the relative importance assigned to desirability (feasibility) aspects of ethics-related situations, and (b) a focus on desirability encourages unethical behavior by fostering a desire to attain end-states/goals irrespective of ethical considerations, yet a focus on feasibility/means promotes more ethical behavior by heightening the salience of unethical actions. Combining the aforementioned premises we derived the following hypotheses. When individuals consider the behavior of an unknown (distal) person and thereby adopt a relatively high construal level, they should anticipate that this person will engage in more unethical behavior when the event's psychological distance is greater. But when individuals consider the behavior of the self -- an individual that fosters adoption of an extremely low construal level -- they anticipate that the self will eschew unethical behavior, irrespective of other less potent factors that alter construal level.

The first two experiments found support for this hypothesis in nine different ethical scenarios that varied construal level in a number of ways. In both experiments, construal level was manipulated by altering the focal actor (i.e., social distance: the self or an unknown other). In experiment 1, it was also manipulated through the temporal distance (i.e., close vs. far distance) of the event; in experiment 2, changes in temporal distance were replaced by a fluency manipulation that varied a novel dimension of psychological distance (see Alter and Oppenheimer 2008). In both experiments a significant two-way interaction revealed that for an unknown other, a higher construal level (i.e. more temporal distance or reduced reading fluency) increased the expectation of unethical behavior, but expectations that the self would behave unethically were low regardless of variation in the event's temporal distance or fluency.

Experiment 3 sought to extend our research from the cognitive to the behavioral domain. This was accomplished by providing participants with an opportunity to behave dishonestly (Gino and Ariely,

2010). In this experiment, participants were primed to process information at a higher or lower level through a series of categorization tasks (Fujita, et al., 2006). The results indicated that participants who were exposed to the high (low) construal-level prime cheated more (less).

Finally, study 4 sought evidence of the mechanisms that underlie the preceding effects. Consistent with our theorizing, by relying on a design very similar to that used in experiment 1, we found that participants generated more desirability-related thoughts when the expected behavior concerned an unknown other and a temporal distance manipulation prompted participants to further process the scenarios at a higher construal level. But, participants produced more feasibility-related thoughts (i.e. thoughts about the unethical means) when the event concerned one's own anticipated behavior (i.e., which prompted use of a very low construal level), and this occurred regardless of variation in the temporal distance factor. Further, analyses of mediated moderation and mediation found that the number of participants' desirability and feasibility related thoughts accounted for the effects of the social and temporal distance factors on participants' expectations of unethical behavior.

Brand (In)fidelity: When Flirting with the Competition Strengthens Brand Relationships

EXTENDED ABSTRACT

The consequences of infidelity are detrimental to the continuity of romantic relationships. In order to shield themselves against temptations, individuals who are committed to a relationship devalue the attractiveness of alternatives or pay less attention to them (Johnson and Rusbult 1989; Lydon, Fitzsimons, and Naidoo 2003). Such defensive tactics are more difficult to implement in the context of marketing relationships. In the marketing world, numerous brands are available and actively try to lure consumers away from their competitors by means of commercials, promotions, free samples, and other attempts to win consumers' preferences. Even the most loyal consumers are exposed to positive information about attractive alternatives, and may even find themselves appreciating other products and brands that compete with their favored brands. What happens when loyal consumers are tempted by other brands? In five studies, we demonstrate that a temporary interest spurred by a competitor positively impacts committed brand relationships. We propose that flirting with a competing brand induces arousal, and this arousal increases consumers' commitment with their favorite brands through a misattribution process: consumers who flirt with a competitive brand feel more aroused than participants who do not flirt, and they misattribute this arousal to their favorite brand.

We test the positive effect of being unfaithful to brands in a series of studies using a diverse array of paradigms. In study 1, we show that appreciating a competitive brand's favorable characteristics induces loyal participants to consume greater amounts of their favorite brand in the near future. We presented participants with four favorable features of a soft drink and asked them to evaluate each of them. As predicted, participants loyal to Coca-Cola (Pepsi) who rated favorable features of Pepsi (Coca-Cola) intended to consume more of their favorite soft drink in the upcoming week, compared to loyal participants who rated the same favorable features of Coca-Cola (Pepsi).

In study 2, we provide initial evidence in support of the misattribution hypothesis by examining if the effect of flirting depends on the similarity between one's favorite brand and a competing brand. The reason for this prediction is that flirting with a similar brand may facilitate the misattribution of flirting-induced arousal from the

similar brand to the favorite brand. Participants listed their favorite beer as well as other five beers, and then ranked these five other beers from the most similar to the most dissimilar to their favorite beer. Subsequently, they were asked to imagine that their favorite beer, a beer that was similar or dissimilar to their favorite beer, or red wine (control) was chosen by experts as the best beverage to complement a plate of smoked meats in a food tasting event. Analysis revealed that loyal participants who read a positive scenario about a similar beer expressed even greater love for their favorite beer compared to participants who read the same scenario involving their favorite beer, a dissimilar beer, or wine.

In study 3a and 3b, we investigated the role of perceived agency in flirting, and examined whether the brand flirting effect could influence real behavior. In both studies 3a and 3b, participants in a control condition were instructed to watch a 30-second advertisement for their non-preferred brand. Participants in the experimental condition were given a choice between watching either a 10-minute advertisement for a favorite brand or a 30-second advertisement for a competing brand in the same product category. We predicted that the vast majority of participants in the experimental condition would choose to watch the shorter advertisement – in other words, we predicted the majority of participants would choose to flirt with a brand competing with the brand to which they were loyal. The 30-second advertisements presented in the experimental condition and control condition were identical. Specifically, participants in study 3a watched a 30-second advertisement for their non-preferred soft drink (either Coca-Cola or Pepsi). As additional compensation for their participation in the survey, participants were then instructed that they would be entered into a lottery to win a 2-Liter bottle of a soft drink. Participants indicated whether they would like to receive a bottle of Coca-Cola or Pepsi if they won the lottery. In study 3b, participants watched a 30-second advertisement of Starbucks or Dunkin' Donuts and were told that they would be asked to watch another advertisement later in the survey, and that they could choose which one of two 30-second advertisements they preferred to watch. Participants were further instructed that one of the advertisements was for Dunkin' Donuts, and that the other advertisement was for Starbucks. In both studies, participants expressed a greater preference for their favorite brand when they chose to watch an ad for a competitive product, compared to when they were forced to do so, indicating that perceived initiation of flirting is an important antecedent of its effect.

Our last study shows that excitement mediates the effect of flirting on the desire to consume one's favorite brand. In this study, participants were asked to imagine consuming their favorite potato chips, or a similar brand of potato chips. Participants next indicated how exciting it would be to eat those chips and the extent to which they intended to consume their favorite brand of chips in the near future. Consistent with the proposed misattribution process, mediation analysis indicated that flirting with a similar brand elicits excitement, and this excitement, in turn, leads to higher desire to consume a favorite brand in loyal consumers.

In short, this research offers important new insight into the consequences of flirting with a non-favored brand on consumers' subsequent attitudes and behavior. Taken together, our findings suggest that being unfaithful does not damage committed brand relationships - on the contrary, it can even strengthen the bond between loyal consumers and their favorite brands. We conclude by discussing the implications of this research for competition dynamics and customer retention.

SESSION OVERVIEW

Consumers try to make optimal decisions and companies want those decisions to be optimally profitable. In pursuit of that optimization, companies carefully calibrate how to present information to consumers. Although rational economic theory suggests that it should not matter how the information is structured, work in social psychology and economics have found dramatic effects on consumer behavior. This session features research on key aspects and novel applications of choice architecture, bringing to light new means to substantially affect consumer decision making. Together, they seek to answer the question of how each part of the decision can be most effectively structured to maximize welfare for all parties.

One well-documented means of influencing choice is posting reference prices. In the first talk (Perfecto, Jung, Nelson, Gneezy, & Gneezy), Perfecto will discuss four large field data sets ($N = 124,193$) and two large-scale field experiments ($N = 4,119$) from online companies, which examine the efficacy of defaults and anchors in a pay-what-you-want setting. In this context of maximal consumer flexibility, Perfecto finds that reference prices do influence behavior, but not always as previous lab research would suggest.

Not only are certain choices (e.g., defaults) important in decisions, but their order of presentation is important as well. In the second talk (Lee & Feinberg), Lee will propose a model of attraction effects, applied to appeals scales in a donation context (e.g., several suggested donations and an “other” option). Lee’s 3.5-year quasi-experiment suggests that scale points do exert significant attraction effects, and that these effects vary across different donors. Lee’s model also has consequences for “laddering,” in which charities alter their requests depending on individuals’ donation histories.

Regardless of the order of choices, the information that accompanies them is critical in decision making. The third talk (Goswami & Urminsky) will show how posting the exercise equivalent (e.g., the number of minutes biking needed to burn the calories in the item) is more effective and helpful metric to consumers looking to eat healthily. One field study and two lab studies reveal that, compared to no information, including the exercise equivalent significantly reduces caloric consumption, whereas including calorie information yields only a negligible reduction.

Finally, the previous talks have examined situations in which there are many options. Mochon will begin the session by discussing the opposite problem: choice sets of one. With five studies, Mochon demonstrates people’s strong aversion to having only one option, aside from deferral. He shows that this effect is not due to the additional information a larger choice set provides, and that it disappears when the deferral option does not include further searching.

In summary, this session addresses some of the gaps and shortcomings in the choice architecture literature. The issues examined in this session have important implications for policy and societal well-being, as well as basic scientific understandings of how people make decisions. As a result, this session will appeal to researchers interested in the prosocial behavior, health psychology, judgment and decision making, as well as those interested in policy or charitable giving. This session speaks to the theme of making a difference in a number of ways: all four talks challenge the status quo in their respective literatures. Some, such as Perfecto and Lee do so methodologically, with novel methods testing the robustness of longstanding findings. Others, such as Mochon and Goswami, do so theoretically, by probing the boundaries of their respective fields.

Default Effects Under Pay-What-You-Want: Evidence from the Field

EXTENDED ABSTRACT

Pay-what-you-want pricing is a flexible pricing system which allows consumers to pay any price they want, typically including very small amounts or even \$0. A classically selfish consumer might be expected to pay the lowest price possible, exploiting the opportunity to acquire goods or services for free. However, real-world examples of online companies adopting pay-what-you-want indicate that people frequently choose to pay more than the minimum. In fact, we observe that customers are heavily influenced by suggestions offered (implicitly or explicitly) by the company. In this research, we investigate the power of these suggestions in the forms of reference prices and defaults under pay-what-you-want with a new level of precision.

Reference prices can be powerful in the context of pay-what-you-want. Some references can be implicit, such as when a company donates some of their profits to charity (Gneezy, Gneezy, Brown, & Nelson, 2010). Other references can be explicit prices: for example, when customers learn about the average price paid by others, that information eliminates the otherwise significant influence of anonymity (Gneezy, Gneezy, Reiner, & Nelson 2012). Such a reference price may contain information about what is “fair”, “appropriate”, or simply “common”. A plausible consumer approach might be to find such a reasonable cue and adjust (down) to a preferred amount. The weakest type of reference price is in the provision of a simple default. Research on default effects in various contexts suggests that a majority of people follow the default choices set by companies (Madrian & Shea, 2001; Thaler & Bernartzi, 2004; Johnson et al., 1993). By studying reference prices in the maximally flexible environment of pay-what-you-want, and by doing so through collaborating with three online companies, we can investigate the influence of reference price with precision.

To achieve this, we analyzed the sales data from three online companies: a board game company, a video game retailer, and an

ebook retailer. In Study 1, we analyzed data from the board game company's promotion of a small expansion set of cards under pay-what-you-want pricing (N=74,592). Customers saw an unexplained default price of \$5.00 on a sliding scale and told customers that it costs them \$3.00 to make and ship the cards. Both of these prices proved to have substantial effects on consumer behavior: 56.1% paid the default price of \$5, and 7.7% paid \$3, the cost to the company per product. 21.1% paid nothing, but the promotion was still quite profitable, earning over \$70,000.

Although the board game company allowed its customers to pay \$0, their product was physical and therefore difficult to pirate illegally, unlike other online goods (e.g., digital music). Perhaps the pull of piracy would overwhelm this success if the product were purely electronic or sold at a nonzero price. In Study 2, we looked at an ebook retailer that employs pay-what-you-want pricing and has both of these factors at play. The company sets a default price and each bundle features one to two additional, bonus books, which are unlocked by paying more than a set price. We find a similar pattern of payments across their four promotions (N=10,615): roughly 30% paid the default, 33% paid a lower reference price (the minimum price for bonus books), and 15% paid the minimum price (\$1).

These findings indicate that a substantial proportion of customers choose to pay a default price. Perhaps people think that the default or reference price are somewhat fair. How does a high default price perform when there are other competing reference prices? Also, what price do customers settle in the end if they are adjusting from a reference price? To answer these questions, in Study 3 we collaborated with an online video game store that sells a single computer game. Our field data set (N=44,042) includes the company's 35 pay-what-you-want promotions. The default price was \$5.00. The company also features two additional reference prices: \$1.00 and the current average price. If a customer pays \$1, they will have an access to a virtual video library to download games. When customers beat the moving average, they receive small bonus features such as game music and screensavers. Across 35 promotions, less than 3% paid the default price, 26.6% paid \$1, and 18.43% beat the average by paying \$0.01 more than the average. These results suggest that a high default price was overridden by the two other competing incentive-ridden reference prices. One of these, the moving average exposed a different peculiarity in human responses to the choice architecture: a strong magnetism towards round numbers.

We conducted two randomized field experiments in which we manipulated the default settings on the ebook retailer's site. In our first experiment (Study 4), we tested how the salience of charity as well as the default charity option influenced payments and purchase rates. We also manipulated the default price. In a 2x2x2 between-subjects design (N=3,214), we manipulated whether an option to donate to charity was put before or after the payment question, whether donating was opt-in or out, and whether the default price was \$12 or \$15. We found a large increase in donation rates when donating was opt-out (77.4% vs. 38.7%, $t(3212)=24.2$). However, much more surprising was the absence of an effect of default price on amount paid ($M=\$8.24$ vs. $M=\$8.31$, $t(3212)=0.49$). This wasn't because the defaults weren't influential, as customers were 12 times more likely to pay \$12 in the \$12 condition ($X^2=273.03$), and 5 times more likely to pay \$15 in the \$15 condition ($X^2=139.42$). The price defaults were very influential, but a higher default did not lead to a higher overall payment amount.

In our second field experiment with the ebook retailer (Study 5), we further investigated the consequences of a high reference price and the corresponding high default price. To test this, we ran a 2 (reference price: normal vs. high) x 2 (retail price: absent vs. salient)

between subjects design (N=906). The retail price (\$28.88) was about twice the other default price (\$14) and acted as the high reference price. Customers pay more when they see a higher default price ($M=\$11.63$ vs. $\$10.75$, $t(905)=-2.5$). They paid less ($M=\$10.78$), however, when they knew the retail value than when they did not ($M=\$11.60$, $t(905)=2.0$). Intuitively, the retail value should help them justify the default price and adjust down less from it. Yet, our results suggest that the retail price as a reference price helps customers to justify adjusting their price further down from it.

In summary, reference prices and defaults heavily influence consumer decisions under pay-what-you-want. People like paying in round numbers. More people choose to give and they pay more when the charity is opt-out. Depending on the other available reference prices, the high default price can produce higher payments.

Modeling Scale Attraction Effects: An Application to Charitable Donations and Optimal Laddering

EXTENDED ABSTRACT

The charity industry is substantial (\$300B annually), expanding rapidly, and presently accounts for over 2% of US GDP. Intriguingly, individual, non-corporate giving comprises the lion's share of this total, nearly three-quarters in 2012. To obtain these individual-level donations, charities nearly universally present an "appeals scale" when contacting potential donors. In the charity sector, the appeals scale refers to a list of "scale points" (specific suggested amounts) and an "other" category, allowing the respondent to donate any amount not on the scale. Orthodox economic theory might therefore suggest that the points used on the scale "should be" irrelevant, since one can ignore them without penalty or effort. But it remains an empirical question whether, behaviorally, respondents are indeed influenced by these sorts of commonly-used scales and, if so, in what ways.

Choosing scale points well is an important decision for charities: overly high scale points can be ignored as being "outside my comfort zone", or even potentially alienate donors who feel they are being pressed for much more than they're prepared to give. Worse for the charity, overly low scale points may actually pull donations downward. Despite their widespread use, such scales seem to be designed in a one-off manner by individual charities, and to date there have been no formal models in marketing to help guide them, based on data they already possess. To that end, we develop a comprehensive model of scale attraction effects that describes in detail how each scale point 'pulls' a donor away from the latent, intended dona-

tion amount; and moreover, how the pulls of each of the points on the scale accumulate to influence the final, observed donation.

Our model is grounded in a variety of behavioral theories, mainly from the traditions of pro-social influence (Cialdini and Goldstein 2004), specific manipulations in charitable contexts (Weyant and Smith 1987, Shang and Croson 2009), the use of both internal and external referents (Mayhew and Winer 1992), assimilation-contrast (Schwarz and Bless 1992), as well as prior modeling work in charitable giving specifically (e.g., Diepen et al. 2009). This is accomplished in several stages. First, each potential donor is presumed to have some personal propensity to comply with a donation request that is either higher or lower than what they might have otherwise given; the “compliance degree” is 100% when the asked amount is the same as the intended amount (if one is asked for what one intended anyway, compliance should be perfect), and decreases with the distance between these. Second, the “pulling amount” captures how much influence is exerted by a scale point. The model intrinsically captures a “Goldilocks Effect” where asking for a bit more is likely to be successful, and asking for much more is unlikely to be, but the best course of action is somewhere in between; and we can then estimate this “optimal” ask point for each individual. Lastly, an “accumulated pulling amount” provides a number of possible mechanisms for the multiple scale points’ pulls to work together.

Using panel data from a unique 3.5 year quasi-experiment, we provide a joint account for both whether a donation is made (incidence) and, if so, its size (amount). This allows us to resolve, on a household basis, a conundrum present in all donation drives, as well as prior research: how are the act of asking for donations and the amount received statistically intertwined? The model incorporates heterogeneity across donors in scale attraction effects, and this is critical: otherwise, we would presume that every household is equally susceptible to scale attraction effects. Estimating a variety of models allows us to empirically choose, for the first time in a donation context, among previously-posed operationalizations of both internal and external reference effects.

Results suggest that scale points do exert substantial attraction effects, and moreover that these vary markedly across donors. In addition, there is a strong asymmetry in the size of pulling effects: donors are more easily persuaded to give less than more, roughly three times as much. Seasonal donation patterns are pronounced, and these too differ across the donor pool. A significantly negative error correlation (-0.387) between (latent) donation propensity and (observed) donation amount highlights the importance of accounting for unobserved correlation in these quantities, and that merely modeling donation amount alone would provide an insufficiently rich basis for charities to optimize their appeals. Regarding reference point theory, for these specific data, the “internal” referents were best captured by the average of all prior observed donation amounts; “external referents”, by including all five scale points, as opposed to a particular subset on which respondents might anchor.

One advantage of our method is the ability to conduct a “counterfactual” analysis, whereby possible appeals scale policies can be compared. We examine three of especial interest: finding an optimal request for each household, finding one for each donation “group” provided by the charity, and simply allowing people to continue at their habitual donation levels. Results suggest that, compared to “no appeal”, the “group appeal” is 24.4% better, and “individualized appeal” 27.1%, in terms of yearly expected donation amount. This in turn provides some preliminary guidance on “laddering”: how much charities should increase amounts subsequently requested of individual donors, based on their donation histories.

Working out Consumption: Designing a Robust Information Intervention for Healthful Eating

EXTENDED ABSTRACT

Providing consumers with calorie information has received a great deal of attention, as municipalities such as New York City have mandated greater disclosure and retailers (including Panera and McDonalds) now provide calorie information on their menu boards nationwide. However, tests of providing decision makers with information on the calorie content of food has yielded very mixed results (Bollinger, Leslie, & Sorensen, 2010; Elbel, Gyamfi, & Kersh, 2011; Loewenstein, 2011). Using the idea of channel factors (Leventhal, Singer, & Jones, 1965), we develop a low cost and robust mapping intervention (Thaler & Sunstein, 2008) which makes the welfare consequences of choices more easily evident to the decision maker.

In a field study conducted at the end of December and beginning of January, museum visitors (n=1127) were offered a choice of candy bars before completing an unrelated survey as a compensation for their time. The survey was about gift card preferences, and a few demographic questions were asked at the end. Visitors chose between four different candy bars whose calorie content ranged from 70 to 280 calories in increments of 70 calories (Snickers, 280; Hersheys, 210; Chips Ahoy, 140; M&Ms 70). Notably, the candy bars all disclose calories on their packaging. The museum patrons chose a candy bar from one of four boxes which either showed in large font (a) just the names of the candy bars, (b) the names and calorie information, (c) names with calories and “exercise equivalents” (e.g., number of minutes of running or biking required to burn the calories). Ordinal regression revealed that, compared to the no information disclosure condition, visitors consumed significantly fewer calories, on average, in the conditions where exercise equivalents were additionally made available (mean = 177 calories vs. 199 calories; Wald=9.4, p<.01). However, the reduction in calorie consumption was only marginally significant when calorie information alone was disclosed. The effect of exercise equivalents was robust across age, income, and gender.

The two waves of data collection in our field study provided an opportunity to contrast the effects of informational interventions with a natural experiment on goal-setting. Prior research has re-

ported that making New Year's resolutions facilitates success in goal pursuit (Norcross, Mrykalo and Blagys 2002). We find that nearly a third of our January sample made a New Year's resolution, and 80% of the resolutions were health and fitness related. In a separate initial question about general goals asked in both waves, we also find a higher rate of health goals in January than in December (73% vs. 65%, $p < .01$). However, despite the effect of New Year's on setting health goals, we find no main or interaction effect of December vs. January on the calories of the option chosen. Likewise, collapsing the December and January data, we find no direct or moderating effect of having a self-reported health goal. Participants with and without either health goals or New Year's resolutions were equally likely to take a high-calorie candy bar in the control condition, and were not differentially affected by the informational interventions.

In two additional hypothetical-choice studies we replicate the effect of the exercise equivalent information (although mere calorie information had similar effects in these studies) and find no effect of health goals or New Year's resolutions. We do find that the exercise equivalents intervention is more effective for those higher in food guilt (Cepeda-Benito, Gleaves, Williams, & Erath, 2001) or who score higher on restrained eating (Polivy, Herman, & Howard, 1988). To put it another way, higher guilt and restrained eating significantly predict lower calorie consumption when exercise equivalent information is present, but not otherwise.

Our studies provide strong evidence that providing exercise equivalents along with calorie disclosure is a robust and effective way to reduce calories in unplanned consumption opportunities. Our results highlight the need for informational interventions to be salient and interpretable, and demonstrate a surprising advantage in effectiveness of well-communicated informational interventions over spontaneous goal-setting.

Single Option Aversion

EXENDED ABSTRACT

This work documents an effect labeled 'Single Option Aversion' where the choice share of an option increases (relative to deferral) when a competing attractive option is added to the choice set, contrary to the predictions of rational utility based models of search (Weitzman 1979), and recent work in consumer behavior on choice conflict and choice deferral (Dhar 1997; Iyengar and Lepper 2000; Tversky and Shafir 1992). A series of studies demonstrate this effect, and establish some of its boundary conditions.

Experiment 1A demonstrates the existence of single option aversion. In this study, participants were presented with a decision scenario where they were asked to imagine that they were looking to buy a DVD player. Participants in the *Sony* condition were shown a Sony DVD player, and were asked whether they would buy that option, or continue searching. Participants in the *Philips* condition saw a similar setup, except with a Philips player. Participants in the *Both* condition were presented with both options and the option to continue searching. Participants were reluctant to choose a DVD player when only one option was presented, as 9% chose to make the purchase in the Sony condition and 10% in the Philips condition. However, when both options were presented together, the choice shares of each of the alternatives significantly increased (32% chose the Sony and 34% chose the Philips; p 's $< .05$). Experiment 1B replicates this effect using the same design, but with real choices involving candy bars.

Experiment 2 demonstrates that single option aversion is not driven by the additional information available in the two option condition (e.g. Hsee et al. 1999; Moorthy et al. 1997). Rather, there is something psychologically unique about being presented with the choice between a single option and deferral. In this study, participants were asked to imagine that they were looking to purchase a camera. Three of the conditions replicated the conditions in Experiment 1. Participants were presented with either a Sony, a Canon or both of these cameras, and were asked whether they would pick one of the options available or continue searching. In the fourth condition, participants were presented with both cameras, and were asked to pick the one they preferred. Following this forced choice, they were presented with the camera they chose and were asked whether they would purchase that model, or continue searching. Thus participants in this 'single option plus comparison' condition had all of the information available in the 'both' condition, but ultimately had to make a choice from a choice set containing only one option. Replicating the prior studies, participants chose both the Canon and Sony cameras less often when presented alone than when presented together (p 's $< .01$). Importantly, participants were also less likely to pick these options in the 'single option plus comparison' condition (p 's $< .01$) than in the both condition. Thus, even holding the information constant, participants were reluctant to pick an option when the final choice set involved a single option. Interestingly, these results suggest that single option aversion doesn't just depend on the total number of options available, but also how these are partitioned. Temporarily isolating one of them can dramatically increase deferral.

Experiment 3 examines whether single option aversion occurs only when the deferral option involves further search, or whether consumers avoid single options regardless of what the deferral option is. In this study participants were asked to imagine that they

were looking to buy a new dishwasher. They were then randomly assigned to one of four conditions based on a 2X2 between subjects design. Half of the participants were presented with one option, while the other half were presented with two options. For half of the participants, the deferral option involved further search (as in the prior studies) while for the other half the deferral option involved not choosing any of the options presented. While single option aversion was replicated in the 'search' conditions, this effect was eliminated in the conditions where the deferral option did not involve search. Therefore single option aversion is moderated by the framing of the deferral option.

Experiment 4 tests whether single option aversion has any lasting effects on choice. It examines what choices participants who choose to defer in the single option condition make, once more options are added to the choice set. In this study, participants got to decide which charity received a \$1 donation. Participants in the single option condition were initially presented with the choice between donating their dollar to the American Red Cross or deferring to see what other charities were available. If they deferred, the Wounded Warrior Project was added to the choice set, and they had to decide whether to pick one of the two charities available or to continue searching. If they deferred again, a third charity was added to the choice set and they were forced to pick one of the three options. Participants in the two option condition were initially presented with both the American Red Cross and the Wounded Warrior Project, and if they chose to defer, the third option was added and they were forced to pick one of the three options. Replicating the prior studies, participants were less likely to donate their dollar to the American Red Cross when this was the only option presented than when it was presented with a competing option ($p < .05$). Importantly, participants in the single option

condition continued to be reluctant to pick an option even after the second charity had been added to the choice set. Indeed, participants in this condition were significantly less likely to donate their money (relative to those in the two options condition) to both the American Red Cross and the Wounded Warrior Project (p 's $< .05$), once this second option had been added to the choice set. Thus single option aversion can have lasting effects on choice. Once participants have been exposed to a single option and begin to search, they continue search even after more options are added.

SESSION OVERVIEW

The familiar maxim about gift-giving, “it’s the thought that counts” assumes that simply demonstrating a desire to give is enough – the gift itself does not matter. This session presents research challenging the assumption that giving is always altruistically-motivated and provides evidence that the gift presented communicates more about the giver than just his/her desire to give (Belk 1979; Caplow 1982; Sherry 1983; Ward and Broniarczyk 2011). The gift giver may hope to achieve many goals with his/her gift, ranging from the altruistic desire to provide joy to more egoistically-motivated reasons that benefit the giver. These motivations often interact with the goals of the recipient to determine the effectiveness of the gift and its impact on the relationship. Extant consumer research on gift giving has primarily focused on the exchange of dyadic gifts from the giver to the recipient for purposes of interpersonal relationship maintenance and as a means of symbolic communication in relationships (Belk 1979; Caplow 1982; Sherry 1983; Belk and Coon 1993). In this session, we focus on instances in which the purpose of giving is to affect change on the relationship (Anthony, Cowley, and Duhachek) influence relationship closeness (Broniarczyk and Ward; Schlosser and Beck) or to avoid guilt by spending appropriately (Rucker and Denton). Across the four papers, some important aspects of the gift purchase process are considered, investigating the key questions of: How much to spend and what should the giver spend it on? What will be the impact of the gift on the relationship now and over time?

First, Anthony, Cowley, and Duhachek investigate the selection of an appropriate gift to facilitate forgiveness for a previous transgression from the perspective of the giver. In related work, Broniarczyk and Ward examine the impact of gifting as a function of the social distance between giver and recipient. The authors demonstrate that givers may ignore a recipient’s gift requests in favor of a gift that demonstrates how well the giver knows the recipient. Schlosser and Beck corroborate this notion and demonstrate that the selection of a gift is based on what it says about the giver. Specifically, they show that a sweet gift is given in the hope of leaving a positive impression, or at least avoiding a negative impression of the personality of the giver. Finally, Rucker and Denton provide evidence that the purchas-

ing process can partially be driven by the desire to avoid feelings of guilt on the part of the giver. In each of these cases it is the thought that counts, but the thoughts may not be what the recipient, nor the giver, might have expected.

The four papers in this session offer interesting synergies that should be of broad appeal not only to researchers in the area of gift-giving, but also researchers working on social distance and network effects, motivation, regulatory focus, emotions and anticipatory emotions, mental accounting and relationship marketing.

Forgive by Remembering or Forgive by Forgetting: The Temporal Match Between Victim Motivation and Apology Gift Preferences

EXTENDED ABSTRACT

Gift giving involving a reparative motivation has received limited attention in the consumer behavior literature. However, using gifts to encourage forgiveness is so common there are websites dedicated to apology gifts, apology cards, and forgive-me gifts. There is even an apology gift buying guide in Shopwiki.com with suggestions for consumers based on the severity of the transgression: itty-bitty mistakes, big mistakes and absolutely massive mistakes. Their premise is that the severity of the transgression should determine gift selection. The other tip offered is that the more luxurious or decadent the gift the better. We agree that choosing the right gift may be a worthwhile investment as research has found that simple apologies are not always effective (e.g. Fehr and Gelfand 2010). However, we argue that the most effective type of apology gift is one that matches the temporal focus that is activated by the victim’s motivation following an interpersonal transgression. In other words, luxurious and decadent may not always be the answer.

Consumer researchers have made a distinction between hedonic goods that induce pleasure and alternatives that are more functional/utilitarian in nature and instrumental to achieving another goal (e.g. Dhar and Wertenbroch 2000; Kivetz and Simonson 2002; Strahilevitz and Myers 1998). Whereas hedonic alternatives are associated with the attainment of immediate pleasure, utilitarian goods provide delayed benefits and thus are conducive with a longer-term focus (Loewenstein, Read and Baumeister 2003; Wertenbroch 1998). Gifts offered as a form of apology following an interpersonal transgression, may also vary along this dimension such as offering the victim a voucher for an aromatherapy massage known to be a relaxing experience (hedonic gift) or a deep tissue massage known to relieve back ache and pain (utilitarian gift).

We propose that the victim’s preference for either a hedonic versus utilitarian apology gift, will vary given the victim’s motivation for forgiveness, and in turn, the temporal focus activated by their motivational goal. Specifically, we argue that if the victim is motivated to forgive the transgressor by avoiding thoughts about the problem (i.e. an avoidance motivation) - a ‘*forgive by forgetting*’ mentality- we propose that a hedonic gift should be preferred as it will help to maintain the short-term focus necessary to distract the individual from thinking about the transgression incident thereby facilitating temporary mood regulation. Consequently, the resulting positive mood should signal that *all is well*, and that no changes to the relationship need to occur (Schwarz and Clore 1983), which may encourage relationship repairation. Alternatively, rather than forgetting about the incident, the victim may be motivated to forgive the

transgressor by thinking about the incident (i.e. an approach motivation) via engaging in a more problem-focused style of coping (Carver 1989). In this case, the victim's motivation to 'forgive by remembering' will require a long-term focus to remember the past and consider the future, such that the transgression incident can be integrated into the bigger picture of the relationship. This in turn, should lead to a preference for a utilitarian apology gift, which is consistent with a longer-term focus and will encourage the victim to maintain the broad focus necessary to understand how the transgression is an isolated event.

Study 1: The Reparation Gift Preference Effect

Eighty-one university students participated in a study comprising a 2 (victim motivation: avoidance, approach) × 2 (apology gift: hedonic, utilitarian) mixed-design with the last factor as a repeated measure. Participants were first instructed to imagine that a close friend had revealed a secret of theirs to a large group of people. Participants were then given an explicit motivation to avoid or think about the incident. Next they were told that the friend wanted to offer them an apology gift. As hypothesized, a repeated-measures ANOVA revealed a significant interaction ($F(1,79) = 10.50, p < .005$). Participants with an avoidance (approach) motivation preferred hedonic (utilitarian) gifts to a significantly greater extent.

Study 2a and 2b: Measuring Temporal Focus

The purpose of study 2a and 2b was to provide evidence that victim motivation activates a differential temporal focus, which in turn, affects gift preference. In study 2a, 80 university students were randomly assigned to a 2 (victim motivation: approach, avoid) × 2 (gift type: utilitarian, hedonic) between-subjects design. Victim motivation was manipulated using an implicit priming word-puzzle and temporal focus was measured using a reaction time task (with average time to respond on neutral words as a covariate). The results revealed a significant interaction for the primed factor ($F(1, 77) = 3.97, p < .05$). Participants primed with an avoidance (approach) motivation responded more quickly to words associated with a short-term (long-term) focus, and tended to prefer hedonic (utilitarian) apology gifts ($F(1, 76) = 4.08, p < .05$).

In Study 2b we replicated the effects using the Construction of Narratives Questionnaire (Lieberman, Trope, Macrea and Sherman (2007) as a measure of temporal orientation. We also provide evidence that when an avoidance (approach) motivation is activated, participants reported they would spend less (more) time thinking about the transgression ($t(1, 39) = -2.44, p < .05$). Hence, supporting our 'forgive by forgetting and forgive by remembering' claim.

Study 3: Manipulating Temporal Focus

In Study 3, to provide direct causal evidence for our claims temporal focus was manipulated with 175 university students randomly assigned to a 2 (victim motivation: avoid, approach) × 2 (temporal focus: near, far) between-subjects design. When the primed temporal focus was consistent with the temporal focus that naturally occurs with victim motivation (avoid – short-term focus, approach – long-term focus), the pattern was consistent ($F(1, 171) = 2.91, p = .09$).

Discussion

Choosing the right apology gift is important as it may serve to encourage forgiveness if made appropriately, and may be detrimental to relationship reparation if made inappropriately. We show that a match between the temporal focus of the victim's motivation and the consumption benefit of the gift is an important determinant of forgiveness and relationship repair. Buyer beware, gift selection is not

simply a matter of matching the purchase price to the severity of the transgression, nor will a hedonic gift always get you out of jail free.

Sweet Protection: Using Sweets to Manage Relationships

EXTENDED ABSTRACT

Gift-giving is a common consumer behavior. For instance, when going to a Superbowl party, an individual may bring a bag of chips or cookies. Likewise, one may choose a gift box of assorted nuts or chocolates, or a gift basket of coffee or cocoa. In all of these instances the gift involves an indulgent food. Yet we propose that the taste of the food will influence its likelihood of being given as a gift, especially when the giver's motivations are to avoid negative evaluation.

Individuals manage relationships to balance self-other connections and to self-protect. Because foods with sweet (vs. other) tastes carry prosocial associations (Meier et al. 2012), individuals may give sweet gifts in order to communicate that they are metaphorically sweet (agreeable) or to buffer against potential negative evaluation—sweeten the recipient. Thus, our goals are twofold: to examine (1) whether sweet foods are given more often as gifts, and if so, (2) whether this is motivated by self-presentation or self-protection.

Our first goal motivated study 1, in which we randomly assigned 160 undergraduates to either a sweet or salty condition. Those in the sweet (salty) condition were asked to think of foods such as chocolates and cookies (chips and pretzels). Next, participants rated their agreement with the following statements: "I give these foods as gifts," "I often celebrate with others by having these foods," "I give these foods as a 'thank-you'." As expected, there was an overall effect of taste on associations with gift-giving ($F(1,158) = 108.89, p < .01$). Those in the sweet condition rated foods as more strongly associated with gift-giving ($M=4.86$), celebrations ($M=5.42$), and thank-you gifts ($M=4.78$) compared with those in the salty condition ($M= 2.28, 3.87$ and 2.52 , respectively). Thus, evidence supported our prediction that sweets are used more during gift/social exchange than a different (salty) taste.

If sweet foods are given to manage relationships, then giving foods with sweet (vs. other) tastes should vary depending on (1) whether the gift-giver is primed to think of oneself as agreeable (i.e., as a caring person), and (2) how close the giver is to the recipient. Our second study thus builds on the first by examining this as well as why sweets are given as gifts. In particular, we assess whether the underlying mechanism is to (a) convey one's own sweetness (a self-presentation motive) or (b) buffer against negative evaluation (a self-protective motive). We expect that the closer givers feel to recipients, the greater their fear of negative evaluation, especially when they perceive themselves to be agreeable (i.e., concerned about others). We expect that fear of negative evaluation will result in giving the sweetest option as a self-protective strategy to make others kinder (i.e., to sweeten others).

In study 2, 203 undergraduates were randomly assigned to a condition in a 2 (agreeableness: high vs. low) × 2 (social distance: far vs. close) design. To manipulate agreeable self-perceptions, participants in the high (low) agreeableness condition were asked to recall and describe one time (15 times) in the past week when they did something nice for someone. Logic suggests that increasing the number of recalled occasions should increase the difficulty of completing this task, and this recall difficulty should reduce perceptions one is agreeable (Schwarz et al. 1991). Next, participants rated how caring, nice, and supportive ($\alpha=.92$) they perceived themselves to be. Then in a purportedly unrelated study, participants

in the close (far) social distance condition were asked to imagine they were attending a birthday party for a close friend (former roommate) with whom they had a good (strained) relationship. They were told this person enjoys gourmet chocolate and asked to choose one from among four bars to give as a gift. The bars differed in taste: sweet berry, sour berry, sea-salt, and bitter espresso. Prior research (Beck and Schlosser 2013) shows that although all options are sweet, the sweetest option (sweet berry) had the strongest prosocial association.

Next, participants rated the extent to which they wanted to be perceived as prosocial (helpful, friendly, dependable, and kind; $\alpha = .74$) in addition to other decoy positive items such as intelligent, strong, assertive, logical, attractive, and dominant (Leary and Allen 2011). Following this, participants rated their agreement with three items from a fear of negative evaluation scale ($\alpha = .89$) that included "I am afraid that others will not approve of me" (Leary 1983). After this, as a manipulation check, because the IOS (inclusion-of-other-in-self) scale reflects social distance (Ijzerman and Semin 2009), participants were asked to rate how close the fictitious person is to themselves using the IOS scale (Aron, Aron, and Smollan 1992). The results supported the effectiveness of both our agreeableness and social distance manipulations.

As expected, we found a significant interaction between level of agreeableness and social distance on sweet gift choice (Wald's $\chi^2 = 4.04, p < .05$). As predicted, in the close condition, those feeling more agreeable were significantly more likely to give sweeter gifts (77%) than those feeling less agreeable (50%; Wald's $\chi^2 = 7.49, p < .01$). There were no differences between levels of agreeableness in the far social distance condition (61% vs. 61%; Wald's $\chi^2 < 1$). This interaction is suggestive that individuals give sweets to mitigate the fear of negative evaluation. To test this more directly, we modeled both direct and indirect interactions on both the mediator and dependent variable. Importantly, using the bootstrap analysis (Preacher and Hayes 2008), we found support that the indirect effects of agreeableness on choice through fear of negative evaluation occur when social distance is close (95% CI: .11, .75) but not when social distance is far (95% CI: -.05, .36). We did not find evidence for a mediating role of self-presentation (95% CIs included zero across levels of moderator).

This research makes at least three contributions by (1) identifying how metaphors serve a symbolic function in gift exchange (Belk and Coon 1993), (2) demonstrating how relational context (McGraw et al. 2003) influences the selection of gifts with certain tastes, and (3) isolating the mechanism—fear of negative evaluation—influencing sweet gift choice.

Ask and You Shall (Not) Receive: Close Friends Prioritize Relational Signalling Over Recipient Preferences in Their Gift Choices

EXTENDED ABSTRACT

Imagine your birthday is approaching and a friend asks you what you want as a birthday gift. You consider for a moment, then tell your friend exactly what you want. When your birthday arrives, does your friend present you with the gift you suggested or an alternative item that s/he has chosen especially for you? This familiar scenario brings to light the persistent tension in communal relationships between the opposing forces of behaving altruistically (doing things that benefit the other without concern for oneself) versus egoistically (responding to others' needs to ensure one's own relationship needs) (Clark and Mills 1993; Batson 1987; Sherry 1983). In the context of gift giving, givers may select gifts altruistically, resulting in the choice of an item that matches the recipient's expressed prefer-

ences, or egoistically, resulting in the choice of an item that allows the giver to demonstrate his/her knowledge of the recipient, thereby signaling the relationship.

In the context of a gift registry we consider the difference between how close versus distant friends manage these conflicting goals as prior research has identified social closeness to account for many of the differences in gifting behavior (Belk 1976; Gino and Flynn 2010; Ward and Broniarczyk 2011). One might expect a close friend, who is particularly concerned with the needs of the recipient, to choose altruistically an item that satisfies the recipient's explicitly expressed preferences. However, we show that close (vs. distant) givers are also more sensitive to the social and interpersonal expectations that underlie gift exchanges and are likely to choose egoistically instead.

In three studies, we demonstrate that close (vs. distant) givers are more likely to experience a conflict between their competing goals. A pilot study confirmed that givers endorse their two main goals to be to choose 1) an item that matches the recipient's preferences and 2) expresses the relationship between them. Ultimately, givers resolve this conflict by distorting their perceptions of the gift options, enabling them to favor the egoistic (over the altruistic) gifting goal, and relationally signal (Balcutis and Dunning 2006; Kunda 1990). In contrast, distant friends ironically are more likely to choose altruistically.

Study 1

In our first study we examine givers' two opposing goals of choosing a gift that matches the recipient's expressed preferences versus making a free choice that allows the giver to relationally signal. In a single factor design, using giver-recipient dyads composed of actual close or distant friends, we simulate a realistic registry choice in which half of the participants are designated recipients and the other half, givers. The recipients create their own individual registries from a set of lamps, which reveal their true preferences to the giver. Subsequently, givers choose a gift from among the lamp options. The results reveal a main effect of social closeness on givers' likelihood to choose one of the non-registry lamps ($\chi^2 = 5.9, p < .01$) such that 61% of close friends versus 23% of the distant friends chose a non-registry gift.

Study 2

Next, we examine how close friends justify diverging from the registry to a potentially less liked gift. Specifically we look at how close friends' perceptions of the degree to which three gifts fulfill their gifting goals change depending on whether the giver assesses or chooses the item. We predict that when close givers are simply assessing the gift (without any intention of making a choice), they are objective about its match with recipients' preferences. However, when close givers have to make a choice, they are encumbered with their concerns about how the gift will behave as a signal to the recipient about the relationship. By interpreting the relational signaling gift as most liked by the recipient, the close giver may resolve the goal conflict and choose this gift without sacrificing his/her important goal to choose altruistically.

We manipulate whether participants chose or did not choose a gift. The gift choice set was specifically designed such that choice of a particular lamp gift was indicative of a specific gifting motivation to 1) match recipient's preference (the Registry gift) or 2) relationally signal. Thus the study design pits the relationally signaling gift against the Registry gift. As predicted, those in the Non-choice condition were significantly more likely to think the Registry gift would be liked by the recipient ($M = 5.08$) while those in the Choice condi-

tions indicate that the relationally signaling gift will be preferred by recipients ($M = 4.18$, ($F(1, 107) = 13.40$, $p < .01$).

Study 3

Lastly, we investigated close (vs. distant) givers' propensity to persist in gift search to resolve their goal conflict and whether having an additional registry item diminishes or exacerbates givers' likelihood of choosing a relationally signaling gift. Givers were presented with the same gift lamps described in Study 2. After looking at the lamps close (vs. distant) participants were asked if they wanted to choose one of the lamps as a gift for the recipient or continue looking at an additional product category which included another item that the recipient had put on his/her registry and two other non-registry products. We expected close (vs. distant) friends to feel more conflicted and persist in looking at additional gift options that could satisfy both objectives. We find the predicted interaction between givers' choice strategies and the social closeness to be significant, $\chi^2(5, N = 156) = 44.37$, $p > .0001$ indicating that social closeness influences givers' choice strategies. Yet, ultimately, close givers were even more likely to choose the relationally signaling classic gifts (60%) than registry gifts (22.5%) ($1, N = 156$, $t = -4.11$, $p > .0001$). Conversely, in the distant friend condition, givers were far more likely to choose registry items (68.4%) than make a relationally signaling classic choice (11.84%) ($1, N = 156$, $t = 7.69$, $p > .0001$) across both choice sets.

These studies demonstrate that close (vs. distant) givers are more likely to experience a conflict between their competing goals resulting in the choice of egoistically motivated gifts rather than altruistic gifts.

Mental Stealing Effects on Purchase Decisions for Others

EXTENDED ABSTRACT

Past research on mental accounting has focused on how consumers create budgets for themselves to control the flow of resources (Thaler 1980; 1999; Thaler and Johnson 1990). This research examines how consumers' creation of a mental account, or budget, for another person affects the consumers purchase decisions for that other. Although some prior research suggests might focus on finding a good gift, we predict that the formation of a mental account for another can sometimes lead to consumers avoid optimizing on the best gift. Instead, consumers will spend in a manner to avoid feeling as if they have stolen from another person's account, an experience we term *mental stealing*.

Mental stealing is defined as a sense of guilt due to an individual feeling that they are stealing from another individual by spending less money than they had cognitively committed to the person in their mind. The creation of a mental account may lead consumers to be averse to spending significantly below the budget due to the feeling that they are stealing resources that have already been given to the other person. In experiment 1, we predict that aversion to mental stealing can lead to decreased purchase intentions towards gifts that meet gift criteria but which are priced significantly below the budget. In experiment 2 we examine whether a mental account must be created for mental stealing to occur, as well as the mediating effect of self-reported guilt. Finally, experiment 3 examines a moderator of the mental stealing effect based on a consumer's ability to make future reparations.

Experiment 1: Does Mental Stealing Occur?

Undergraduates were randomly assigned to a 3 Gift Price (\$10, \$25, \$50) x 2 Recipient (self, other) between groups design. Par-

ticipants were asked to imagine they were shopping for a gift for themselves or for a friend. The creation of a mental account was manipulated by instructing all participants that they had not decided how much money they wanted to spend, so they have budgeted and set aside \$50 dollars in available funds for this gift. Subsequently, all subjects were asked how likely they would be to buy a \$10, \$25, or \$50 gift. Gifts were described as well-made and of good quality, and participants were told that the gift recipient was sure to like the gift and would not know the amount paid. A significant interaction emerged ($p < .01$). Participants shopping for a friend were significantly less likely to buy the \$10 gift compared to the \$25 gift and \$50 gift ($p < .05$). In contrast, participants shopping for the self were significantly more likely to buy the gift in the \$10 condition compared to the \$25 gift condition and \$50 gift condition ($p < .05$). These findings are consistent with concerns for mental stealing as the discrepancy between the \$50 mental budget and \$10 gift was sufficient to elicit concerns for keeping too much money from another person's account for oneself. These effects did not emerge when consumers are buying for the self, working against an anchoring interpretation and consistent with the idea it is harder to steal money from the self than from others.

Experiment 2: Does the Creation of a Mental Budget Matter?
