Preface

It was our great pleasure to co-chair the 2014 North American conference of the Association for Consumer Research, which was held in Baltimore, MD, from Oct. 23-26. This volume reports the presentations made in special sessions, competitive paper sessions, working paper session, roundtables and the film festival.

This year's conference theme was "**Back to Fun**." While all of us see our scholarship (both our research and our pedagogical endeavors) as an important and serious undertaking, it's hard to deny that our job is one of the most fun in academia. Our topic is inherently interesting and impactful, we have tremendous agency, and our ACR community is filled with colleagues who are as nice, generous, and multifaceted as they are intelligent. Life is indeed good! But, the stress of publication and promotion can take its toll. Thus, we sought to talk more at this conference about the joy that helps motivate us through the challenges of rigorous research. When we truly enjoy what we do, our work is deeper, more careful, more relevant, and more interconnected. Fun is serious stuff, after all.

The 2014 ACR conference attracted 1278 participants, 73 special session proposals (59% accepted), 541 competitive paper submissions (41% accepted), 374 working paper submissions (78% accepted), 8 roundtable proposals (87% accepted) and 17 film festival submissions (76% accepted).

This year we introduced or modified a few innovations:

- **The Forum Program** provided specially curated sessions, available at every session of ACR for maximum accessibility. The Forum Program included three types of sessions**:** *Roundtables*, *Perspectives,* and *Workshop* sessions,
- **The Presidential Address,** a separate event that allowed interested parties (and drawing a standing room only crowd) to come and hear Linda Price's remarks in a dedicated and celebratory space,
- **Friday Social Lunch**, speech-free, because we knew that many people were seeing friends for the first time and were excited to connect,
- **Dedicated "together" spaces: The Coauthor Room and The Wellness Room**, to congregate more easily for both work and relaxation.

We thank our generous donors, especially our schools, the Ivey Business School, Western University, Canada, and the Poole College of Management, North Carolina State University. Thank you so much. Also providing major support was the American Marketing Association Consumer Behavior SIG, the *Journal of Marketing Research*, the *Journal of Consumer Research*, the Marketing Science Institute, the Society for Consumer Psychology, the University of Maryland, the University of Arizona, and the Schulich School of Business at York University.

Running this conference is a major undertaking, and would be overwhelming were it not for the incredible advice and assistance freely given, with a smile, by many volunteers. In particular, it would be well-nigh impossible without the following wonderful people: ACR Executive Director Rajiv Vaidyanathan, Conference Manager Paula Rigling, and website manager Aleksey Cherfas. We also gratefully acknowledge Membership Executive Manager Praveen Aggarwal, Communication Executive Manager Ekant Veer, ACR's Executive Assistants Aaron Christen and Jessica Mendez Jeffers and the wonderful assistance of administrative coordinator Anna Potrawiak. Thanks also to the enthusiastic assistance from PhD student volunteers: Jeff Rotman, Jennifer Jeffrey, Juan Wang, Mansur Khamitov, Scott Connors, Sean Hingston, Justin McManus, Lidan Xu, Beth Du Fault, and Ainsle Schultz.

Each year the ACR Conference Co-Chairs must rely on the expertise and hard work from other co-chairs, and we would like to thank Film Festival Co-Chairs Marylouise Caldwell and Paul Henry, Working Paper/Poster Co-Chairs Tiffany Barnett White and Hope Schau, the Forum Program Co-Chairs Kent Grayson and Deborah Small, Mid-Career Mentorship Co-Chairs (Pre-tenure) Cait Poynor Lamberton and Kelly Hawes, and (Post-tenure) Americus Reed and Gavan Fitzsimons and Doctoral Symposium Co-Chairs Eileen Fischer and Peter Darke. *Whew!* That is a lot of people. No one ever has to say yes when asked to help, and we want to thank you very much for saying yes to us, and then delivering such an outstanding program!

Thanks also to our Program Committee, as well as to the hundreds of Competitive and Working Paper reviewers who sent in on-time and high quality feedback for submitting authors – the resulting conference was a fantastic reflection of your hard work! And a final thank you to ACR 2014 President Linda Price, who believed in us enough to give us the chance to put on the big show!

June Cotte, Ivey Business School, Western University
Stacy Wood, Poole College of Management, North Carolina State University
ACR 2014 Conference Co-Chairs

Conference Committees & Reviewers

PRESIDENT

Linda L. Price, University of Arizona, USA

CONFERENCE CHAIRS

June Cotte, Ivey Business School, Western University, Canada
Stacy Wood, Poole College of Management, North Carolina State University, USA

PROGRAM COMMITTEE

Jennifer Argo, University of Alberta, Canada
Zeynep Arsel, Concordia University, Canada
Stacey Menzel Baker, University of Wyoming
Jim Bettman, Duke University, USA
C. Miguel Brendl, Northwestern University, USA
Katherine Burson, University of Michigan, USA
Margaret Campbell, University of Colorado, USA
Elizabeth Cowley, University of Sydney, Australia
Amy N. Dalton, Hong Kong University of Science and Technology, Hong Kong, China
Kristin Diehl, University of Southern California, USA
Amber Epp, University of Wisconsin - Madison, USA
David Gal, University of Illinois - Chicago, USA
Miranda Goode, Ivey Business School, Western University, Canada
Steve Hoeffler, Vanderbilt University

JoAndrea Hoegg, University of British Columbia, Canada
Margaret Hogg, Lancaster University, UK
Jiewen Hong, Hong Kong University of Science and Technology, Hong Kong, China
Jeff Inman, University of Pittsburgh, USA
Barbara E. Kahn, University of Pennsylvania, USA
Shanker Krishnan, Indiana University, USA
Selin A. Malkoc, Washington University in St. Louis, USA
Antonia Mantonakis, Brock University, Canada
Michael Norton, Harvard Business School, USA
Theodore Noseworthy, University of Guelph, Canada
Steve Nowlis, Washington University in St. Louis, USA
Cele Otnes, University of Illinois at Urbana-Champaign, USA

Andrew W. Perkins, Washington State University, USA
Anastasiya Pocheptsova, University of Maryland, USA
Aric Rindfleisch, University of Illinois at Urbana-Champaign, USA
Stefanie Robinson, North Carolina State University, USA
Manoj Thomas, Cornell University, USA
Matthew Thomson, Ivey Business School, Western University
Christian Wheeler, Stanford University, USA
Katherine White, University of British Columbia, Canada
Tiffany White, University of Illinois at Urbana-Champaign, USA
Alison Jing Xu, University of Minnesota, USA

FORUMS (PERSPECTIVES, ROUNDTABLES, & WORKSHOPS) CHAIRS

Kent Grayson, Northwestern University

Deborah Small, University of Pennsylvania

FILM FESTIVAL CHAIRS

Marylouise Caldwell, University of Sydney, Australia

Paul Henry, University of Sydney, Australia

WORKING PAPER CHAIRS

Tiffany Barnett White, University of Illinois, USA

Hope Schau, University of Arizona, USA

DOCTORAL SYMPOSIUM CHAIRS

Eileen Fischer, York University

Peter Darke, York University

MID-CAREER MENTORSHIP PROGRAM CHAIRS

Pre-tenure
Cait Poynor Lamberton, University of Pittsburgh
Kelly Hawes, Vanderbilt University

Post-tenure
Americus Reed, University of Pennsylvania
Gavan Fitzsimons, Duke University

BALTIMORE SOCIAL COMMITTEE

Meng Zhu, Johns Hopkins University, USA
Rebecca Trump, Loyola University Maryland, USA

Marie Yeh, Loyola University Maryland, USA
Rebecca Hamilton, Georgetown University, USA

SPECIAL THANKS TO

Rajiv Vaidyanathan, University of Minnesota Duluth, USA
Paula Rigling, Conference Planner, Texas, USA
Anna Potrawiak, Ivey Business School, Western University, Canada

2014 ACR Presidential Address

Obliquity, Wonderment and The Grand Adventure of Doing Consumer Research

Linda L. Price, University of Arizona, USA

Oh, how I envy you not everyone has the chance to face the
unspeakable terrors of the great unknown
Hoo, hoo
Today's the day
In only a matter of moments
You'll all be on your way
What lurks around the corner
Not a soul can say
But I can guess
More or less
Hidden dangers
Great duress
Ah, the moment of glory
Is close at hand
Hoo, hoo
It's gonna be grand

OWL, in Pooh's Grand Adventure:
The Search for Christopher Robin

Leading up to today a lot of people have asked me how the Presidential address was coming along and I have to say that although I kinda, sorta knew what I wanted to talk about over a year ago, there's a big difference between kinda, sorta knowing and actually having something to say. It wasn't until the "best used by" date on the milk carton was well past the ACR conference that I started to panic about what I was **actually** going to say. I ended up with the title you see before you, which itself has about it a ***character of misadventure***.

However, before I attempt to coax you along that winding path, I'd like to thank Angela Lee for the lovely introduction. Over the course of this year I have truly come to think of Angela as a goddess who is enormously caring and thoughtful about all things small and large.

Also, I want to thank those of you who are here today for choosing to be here!! At ACR there's a lot of competition for your time, and I'm grateful for a few minutes of your attention. I especially want to thank June Cotte and Stacy Wood for putting together a wonderful, creative, fun conference and also for allowing people to **opt out** of this event, so that I don't have to compete with your best friend over lunch. In addition, I want to thank the Marketing Department at Eller College of Management, University of Arizona for providing a little additional incentive to **opt in.** Celebrating life on a Friday afternoon with family, friends and a glass of champagne is always a good way to spend time.

Finally, I want to thank the membership of ACR for giving me a chance to serve as President. From the time I first joined ACR in 1981 I felt it was my home and extended family. I carried the little blue book of ACR members around with me everywhere, believing that if I were ever somewhere in need, the ACR community would be there for me. In this role, I've had a chance to test that proposition. Working with Angela Lee, Jeff Inman, Sharon Shavitt, Amna Kirmani, Rajiv Vaidyanathan, the ACR Board and many, many others in the ACR community has reaffirmed for me why this is such a special organization.

About the time I was originally trying to figure out what I wanted to talk about Michel Pham did a wonderful Presidential Address at SCP on *The Seven Sins of Consumer Research*—that also went viral in our community, and at that point, and a few times since then, I seriously considered outsourcing my talk to him (2013). You might also be surprised to learn that I briefly flirted with playing the piano, it was suggested I could dance, and a few well-meaning colleagues, who are probably not here today, told me to just cancel it.

In Michel Pham's address he echoed the call of many others, including many past ACR Presidents, for more relevant research (2013; Andreasen, 1993; Mick, 2006; Keller 2008; Inman, 2012). A focus on relevance, very broadly defined, was also the topic of the inaugural editorial by the new *Journal Of Consumer Research* editorial team, and a major organizing theme for the new *Journal of the Association for Consumer Research* that Jeff Inman talked about in his Presidential Address, and we'll hear more about this at tomorrow's luncheon (Inman, 2012). The concern over the lack of relevance applies not just to consumer research, but also to the marketing discipline more generally. A recent paper in *Journal of Academy of Marketing Science* documents how little of our research ever gets cited in business disciplines outside of marketing (Clark, Key, Hodis and Rajaratnam 2014), and a preconference event at AMA Winter 2015 will also focus on how we can be more relevant.

Michel went on to talk in detail about some of the things that we do that make us largely irrelevant to ourselves and everyone else. He concluded like others by suggesting that we need changes in how we train doctoral students and in the reward structure. Although not the topic of Michel's talk, we have also seen increased concern about research integrity and how to police it with a general understanding that these problems are also driven by our training and reward structures. His last sentence carries a familiar, and discouraging tone:

"As long as researchers are rewarded mostly for maximizing the number of articles that they publish in A-level journals rather than for the lasting impact of their articles, regardless of the journals where they are published, then narrow scope, narrow lenses, narrow epistemology, disregard for content, overgeneralization, research by convenience, and "theories of studies," will remain prevalent in our field," and the relevance of consumer research will remain a struggle (2013, p. 422).

I think he's right about the things we are doing wrong, and I'm all for us trying to change these things every day in our organizations, and in our relations with students and colleagues, but I think there's something more important at stake here, it's the very essence of why and how we do what we do. And that's what I'd like to talk about today.

Randomly selected like many of the books that inspire me, a couple years ago I picked up a little book titled *Obliquity: Why Our Goals are best Achieved Indirectly*, by John Kay (2011). He wanted to persuade people that the path to success and happiness does not run through the bottom line. He dedicated the book to Sir James Black a Nobel Prize-winning pharmacologist, but also a scientist who accidentally created a lot of shareholder wealth through his discoveries. Sir James Black called it "the Principle of Obliquity:

Goals are often best achieved without intending them." John Stuart Mill in his autobiography eloquently writes:

I never, indeed, wavered in the conviction that happiness is the test of all rules of conduct, and the end of life. But I now thought that this end was only to be attained by not making it the direct end. Those only are happy (I thought) who have their minds fixed on some object other than their own happiness; on the happiness of others, on the improvement of mankind, even on some art or pursuit, followed not as a means, but as itself an ideal end. Aiming thus at something else, they find happiness by the way (1893; p. 117).

Perhaps all of us have thought about the obliquity principle with regard to our students, our best students are typically not the ones that ask "how do I get an A in this class." Similarly, I would posit that the most successful academics typically do not have publishing or tenure as their goals. Perhaps, even the quest for relevance is a double-edge sword if sought out the same way that PhD students now quest for "hot topics." Who would have thought that a cross-country, summer road trip to learn about consumers and their possessions would end up a consumer odyssey that transformed the field of consumer research, and my own research, in profound ways, (Belk, Wallendorf and Sherry, 1989)?

Speaking personally, because that's the misadventures I'm most familiar with, a lot of my most exciting, fun and surprising research was deemed by leaders in the field as irrelevant, no longer interesting, or a project that could never be published in a leading marketing journal—something not to waste my time on. When as a brand new assistant professor I worked with an incoming PhD student Debbie MacInnis on a theoretical paper on Imagery Processing we were assured it would be impossible to publish—one of the reviewers to the very end wrote it off as "highly speculative," which it was (MacInnis and Price, 1987). Many people told Larry Feick and me not to waste time on the Market Maven project because word-of–mouth is just not interesting to managers (Feick and Price, 1987). Numerous wise scholars told me that my project with Eric Arnould done in the context of white water river rafting (but that tried to solve niggling puzzles about satisfaction and communitas) would never see the light of day in a marketing journal (Arnould and Price, 1993). When I worked with PhD students Carolyn Curasi then at University of South Florida (Curasi, Price and Arnould, 2004), and later Amber Epp then at University of Nebraska to explore Family Identity in all it's myriad complexity (Epp and Price, 2008), we were assured family decision-making was dead. Obviously, my own vexing questions, questions that kept me awake at night were not widely recognized as "relevant." I'm sure many of you in the audience have had this same experience—difficult, troublesome quests that others found irrelevant. So perhaps even relevance is best approached using the Principle of Obliquity.

Lately I've been wondering if we do a better job of teaching doctoral students how to publish articles and get tenure than we do of giving our students "the deep principles of science and the love of it, what's behind it and why it's worth doing," (Feynman 1988; p. 14). Richard P. Feynman, a reluctant Nobel Prize-winning physicist, notes this is exactly what his father gave him, and he reflects:

"I've been caught, so to speak—like someone who was given something wonderful when he was a child, and he's always looking for it again. I'm always looking, like a child, for the wonders I know I'm going to find—maybe not every time, but every once in a while," (1988, p. 14).

Another one of my favorite books, I picked up many years ago on a sale shelf. The book is by Martin Gardner, who has written extensively in math, science and philosophy, but also literary criticism and fiction. The title is *The Whys of a Philosophical Scrivener*, and it's filled with essays self-described as "What I believe and Why," (1983). My favorite essay is "Surprise: Why I Cannot Take the World for Granted," in which Martin Gardner describes the magnificent gift of wonderment. Albert Einstein observes, "The finest thing we can experience is the mysterious. It is the fundamental emotion which stands at the cradle of true art and true science. He who does not know it and can no longer wonder, no longer feel amazement, is as good as dead, a snuffed-out candle." The incredible, inexhaustible mystery of everyday life with all its rhythms and lines of flight to unexpected places is a constant inspiration (Deleuze and Guattari 1987). And as consumer researchers we are immersed in it—the mystery is all around us, all the time.

If you are watching the new PBS series or have read the book "How We Got to Now," then you know that a practical discovery or invention can have wide-reaching consequences—can literally change our world (Johnson, 2014). A printing press that enables people to read books is also the source of demand for eyeglasses, which in turn generates microscopes and telescopes and a revolution in what we see in biology, astronomy, medicine and physics. Everything changes because of this small thing. At the center of health, sustainability, financial wellbeing and happiness, consumer behavior is right up there with brain surgery and rocket science in complexity, scope and potential impact—we can change the world.

Lewis Thomas, another of my favorite scientists, argued that to create scientists we should have courses that teach "informed bewilderment"—he writes "every important scientific advance that has come in looking like an answer has turned, sooner or later—usually sooner—into a question. And the game is just beginning," (Thomas, 1983). I believe we should engage our students and ourselves with "deep play." Diane Ackerman writes, "Make-believe is at the heart of play, and also at the heart of much of what passes for work. Let's make-believe we can shoot a rocket to the moon,"(1999, p. 7). She elaborates, "The spirit of deep play is central to the life of each person and also to society inspiring …arts, exploration and discovery." "Swept up by the deepest states of play, one feels balanced, creative, focused." "Deep play thrives on a romance with life." It is "a love affair with the world," (Ackerman 1999, p. 19).

Science that follows the questions as they tumble out across an unanticipated line of flight can't be rigidly locked into some formulaic template for how to publish consumer research. By focusing less on publishing templates and more on how to follow a question through cracks and crevices and over walls and up mountains, letting the question itself bounce against our theories and assumptions and with us tell a story—we can instead share findings with all the qualities of a good, trustworthy, prospective and useful story (Weick 1995, cited about 15,000 times). This then would be consumer research as a grand adventure filled with mystery and import rather than a publishing game.

My perspective on research as a grand life adventure is certainly not unique to me. Many people here today are embracing and living this grand life adventure. My dear colleague Sidney Levy is a case in point. At 93, he comes into the office five days a week unless he's speaking somewhere around the globe. He also tucks in going to the Opera, piano lessons, and is teaching himself Chinese. I remember him sharing with me his thrill at his first experience with M-Turk, bursting with enthusiasm at this new way to reach out to people and understand their lives. He publishes articles all the time, including a recent JCR, but more as a byproduct of his "love affair with the

world." He's certainly an anomaly, but he exemplifies research as adventure, delight, persistence; research as community, creation, and self-completion. I may not last as long as Sidney, but if I die collecting data it's okay with me.

When I am able to pursue research as a grand adventure—a peak experience of ecstasy, rapture, bliss; and awe, mystery, humility and surrender it is a mindset that leaves me thoroughly delighted with all the research I did and didn't publish, and all the mysteries that await my gaze tomorrow. However, for all of us, including me and everyone in this room, it requires resisting four temptations that are built into things we hear daily about how to be a successful academic researcher.

We all succumb to these temptations some of the time. We succumb because it is the spooky forest we live in—as owl tells pooh and companions "the eye of the skull itself." It's easy to lose sight of its illusions, mere shadows and assumptions. We fear for our students, our families, our colleagues and ourselves.

TEMPTATION #1

If you want a grand adventure, resist the temptation to "View Publication as a Significant Part of Your Job." Instead view each research project as a new road to wander along, driven by the question not the answer. If you look at publishing as a job, then you try to maximize output and minimize input. This frames research in a particular way: research is what you do to get published. A colleague explained to me how this works. He admonished me to pick a substantive topic (preferably one that not many people have published in) and then pick a theory (again, it's better if there's not much out there that you have to read). Finally, add a good, robust methodology and crank out publications. The goal is to minimize additional reading and learning in order to generate your next article.

Given that I grew up in a forest of books and questions, wishing nothing more than to stay there forever, to treat reading, learning and data collection as costs seems strange. Blind alleys are not a waste of time, they are intriguing, unique adventures with friends, and occasionally I find my way out of them. To be honest, as any one of my co-authors will confirm, I personally have zero sense of direction. I would still be somewhere on the outskirts of Eastern Hungary without Robin Coulter and her maps. But still, for me, new research projects are adventures filled with wonder risk, ordeal and thrill. Would I have published more using my colleague's wise adage? Possibly, but I doubt I would have had nearly as much fun.

In fact, with honesty as a guide, when Robin Coulter, Larry Feick and I adventured in Central and Eastern Europe right after the fall of the Berlin Wall to learn more about the Origins of Product Involvement and Brand Commitment even we weren't sure anything we were doing would ever be more than our own field notes and amazing memories. Even we were surprised when it was finally published as a lead article in JCR—thank you David Mick (Coulter, Price and Feick, 2003)! We literally muddled for a decade publishing a little here and a little there, but mostly just trying to figure it out for ourselves. Nevertheless, I'll never regret all the amazing experiences and frustrations that were part of that.

Last week, instead of working on this address I spent my Friday with Ainslie Schultz, a PhD student at University of Arizona, doing an experiment where students decorated pumpkin cookies with four colors of icing and four different decorating tips (lots of lovely noise). Ainslie and I, already fans of Page Moreau and Darren Dahl, developed a whole new respect as we tried to clean icing tips between sessions (Dahl and Moreau, 2007). And we used already baked cookies! I think the most important take-away for me from watching all these students do this, is not something that will ever

be published! The expression of a young woman in the first session created a song of difference and repetition that continued all day, with many students again and again, and it touched me (Deleuze, 1994). I've told the story already a dozen times. She decorated her cookie, and not just that, she decorated the plate it was on. And as she set it on the table so we could take a picture, she crossed her arms across her chest, sighed deeply and said, "My mother would love this cookie." I venture to say she was engaged in deep, creative and meaningful play. I hope that I can help more people have that feeling more often.

TEMPTATION #2

Resist the temptation to "Pursue a Clear and Consistent Research Program." Again, let obliquity be your guide. I remember at my consortium when Peter Wright talked about his research program and he revealed that while it looked clear and consistent, that was an unintended consequence of his own burning questions. I never forgot that lesson. Ph.D. students are too often led to believe that the fruit of each research project is another research project that over time composes a clear research program. This is a useful strategy. It minimizes additional inputs, and makes it easy for administrators and tenure review committees to discern a researcher's identity.

Very early in my career I remember going to an ACR session where Beth Hirschman, then a young mother, was investigating childcare choices, later in her ACR Presidential address she talked about challenges of compulsion and addiction in consumers' lives (Hirschman 1992). In between, she invited us to explore consumption as a process filled with fantasy, feelings and fun (Holbrook and Hirschman 1982). It seems to me that Beth, like many of my favorite researchers, always let her own vexing questions be her research guide. Although, I have followed up on an earlier research project with another one, for me too, my research projects reflect my environment, my alliances, life-stage, and current concerns. I'm always hoping that the answers that come out of my research will be useful for me in my own life.

Even more so, now that I'm old, I believe in holding dear the option to reinvent myself as a researcher. With this perspective, the world is a constant explosion of research questions, and finding answers seems useful to daily life. Some recent research that I'm doing with Ainslie Schultz and Robin Coulter suggests that believing that *you* can change, that *you* can reinvent yourself, that *you* can actively pursue and make a *fresh start* is an important adaptive life strategy that leads us to be more creative, happier, more willing to try new things, more resilient in the face of failure (Schultz, Price and Coulter 2014). Other research by Dweck and her colleagues shows that adolescents that believe that *people* can change, perform better in high school. Moreover, teaching adolescents that *people* can change can help alleviate or prevent depression (Miu and Yeager 2014; Yeager, Johnson, Spitzer, Trzesniewski, Powers, and Dweck 2014).

TEMPTATION #3

The temptation to "Choose Co-authors Strategically, to Advance One's Career" is a third temptation. The motley crew that is Winnie the Pooh's grand adventure would never have been brought together as the most expert team to find Christopher Robin, but they were the team that wanted to find him the most. Again, let obliquity be your guide. Petty and Cacioppo were accidentally a great team who substantially changed our perspectives on how consumers process information with their Elaboration Likelihood Model (1986). They loved arguing so much that they moved in together and put blackboards up so they could battle effectively. Kohli and Jaworski were accidentally a great team. Two recently minted PhD students

who generally took opposite sides of an argument in my marketing theory seminar and often went to the board and took over the class to make their respective points, they created lasting change in our mindset with their paper on market orientation, a paper that has been cited almost 7000 times (Jaworski and Kohli 1990). Barney Glaser who collaborated with Anselm Strauss for 27 years, talked about how Anselm generated in him a " 'high' for doing sociology that has never left me," (1991, 103). Another of his co-authors, David Mains wrote, "If you become a working colleague of Anselm's chances are high you will become a personal friend. Conversations with him tend to be adventures… His curiosity is contagious..." (1991, p. 7)

At first glance it seems like choosing co-authors strategically will insure that you have the skills that are required and you know what each person will bring to the project, but if you want research to be a grand adventure choose co-authors because they are fun, entertaining, passionate, surprising and willing to take risks. Working with my co-authors, side by side, key to key is incredible "deep play." I have had so much fun with them. We have explored foreign lands and wild places, cuddled up over computers and campfires, cried in our beer and occasionally shared champagne—in fact some of us are doing that right now, here today. We have muddled more and published less than you can imagine, but we have filled hallowed academic halls all over the world with our laughter, speculations, and debates.

We sometimes forget that science is very much collectively produced—it's potential for morphogenesis, transformation, and change is created by an assemblage of actors, problems, perspectives and, at least in my case, a kitchen table, and an appropriate amount of lovely coffee and later wine. Each research project is a unique combination of differences, craziness, accidents, synergies, and life events. My love and affection for my co-authors has sustained me through births, deaths, divorces, childrearing, and an almost not quite empty nest. Journal rejections are hardly a test for these relationships.

TEMPTATION #4

If on our grand adventure, there is a scary eye of the skull that we must vanquish, it is the temptation to "Chart a Publication Path toward Tenure." This is truly the worst temptation of all. There's a charming experiment on embodied creativity that shows, perhaps not too surprisingly, that when people are put in boxes, literally put in boxes, they are not as creative as when they are not (Leung, Kim, Polman, Ong, Qiu, Goncalo, and Sanchez-Burks, 2012). Tenure was intended to promote academic freedom and risk-taking but it has become a horrible, entrapping box. If the goal is to publish in order to get tenure then you minimize time spent in the library, time spent in the field, time spent collecting data. You don't take on anything too big or too risky or too long term. In short you engage in all of the sins of consumer research that Michel Pham articulated in his SCP presidential address.

Applying the principle of obliquity, if you resist this temptation I think there's a good chance you will publish lots of amazing and impactful research and you will also get tenure. There are many examples in this room of people who did. I have heard Punam Keller, Jerry Zaltman, Leigh McAlister and many others talk about exactly this on many occasions—the fears loom larger than the realities.

Far, far more importantly, if you resist this temptation, then you can choose to do research that permeates your life, and changes how you think about the world. Whether it's published or not, whether it appears in a leading journal or not, it will become an intimate and lasting part of your personal history—a period of transformation and growth—something worth having done. To do research that matters begins first and foremost with doing research that matters to you—

that addresses your own mysteries and burning questions! That you would do forever and for free because the people you are working with, the places it takes you and the answers you find are as rewarding and pleasurable as the wonderful party that Stacy Wood and June Cotte have planned for us on Saturday night is also sure to be. See you there!!

Thank you very much!!

Special Session Summaries

Beyond Vulnerability: Building Resilient Consumers and Communities

Chairs: Marlys Mason, Oklahoma State University, USA
Stacey Menzel Baker, University of Wyoming, USA

Paper #1: Narratives of Cultural Trauma (and Resilience): Collective Negotiation of Material Well-being in Disaster Recovery

Stacey Menzel Baker, University of Wyoming, USA
Courtney Nations Baker, University of Wyoming, USA

Paper #2: Community Resiliency in the Aftermath of the New Zealand Earthquakes

Julie Ozanne, Virginia Tech, USA; University of Melbourne, AU
Lucie Ozanne, University of Canterbury, New Zealand

Paper #3: Consumption Under Restriction: Vulnerability and Resilience in a Maximum Security Prison

Ronald Hill, Villanova University, USA
Justine Rapp, University of San Diego, USA

Paper #4: Health and Consumer Vulnerability: Identity Dissolution and Resiliency Behaviors

Marlys Mason, Oklahoma State University, USA
Teresa Pavia, University of Utah, USA

SESSION OVERVIEW

Consumers' lives are characterized by a variety of pressures related to self, family, community, and the macroenvironment (Baker & Mason 2012). Over time these pressures may build until a person is pushed to feel that he/she can no longer cope. At other times, a sudden trigger event may thrust consumers into experiencing overwhelming adversity. In such cases, consumers may turn to the market and consumption for some form of resolution.

Consumer research widely acknowledges the positive role that the consumption of goods and interactions with markets play in consumer lives and identities. What is not as commonly recognized is the personal or social instability, and potential vulnerability, related to the lack of access and acceptance within markets (Baker, Gentry & Rittenburg 2005; Baker & Mason 2012). Markets and consumption are sources of meaning, connection, and freedom, but at times can also be sources of exclusion, inequality, and social conflict. When faced with such adversity in addition to everyday pressures or trigger events, consumer vulnerability may occur.

Vulnerability is a state of human existence characterized by powerlessness and lack of control (Baker & Mason 2012). Vulnerability can be profoundly overwhelming; vulnerability can drive people to seek some resolution. Resiliency is argued to be a process that reduces consumer vulnerability, promotes current well-being, and ideally connects consumers with access and engagement to the needed social or market resources that strengthen self and environment from future susceptibility. Further research is needed in the ways in which consumers who experience vulnerability attempt to build resiliency through consumption and market forces.

In this session, four papers explore the resiliency of human beings and their capacities to create individual and social change through consumption and market forces. Drawing from different theoretical and contextual lens, the authors examine how resiliency might be constructed. The first paper by Baker and Baker highlights

how cultural trauma and resilience narratives sustain collective community recovery efforts following a devastating disaster. The second paper by Ozanne and Ozanne examine the evolving community response, capacities, and ultimately resiliency across a four year span following a series of earthquakes. Moving from community to an individual perspective, in the third paper, Hill and Rapp investigate resiliency in a maximum security prison, an environment which is characterized by restricted choice, depersonalization, and commoditization. The fourth paper by Mason and Pavia investigate serious health threats to consumer identity and market presence, which spark efforts to reconstitute identity, restore market engagement, and build personal resiliency. Together the studies reveal rich insights into what is resiliency and how persons overcome devastating conditions to build it. Our informants do not passively accept vulnerability or powerlessness. The consumers and communities actively and constructively resist constraints to adopt resilience behaviors.

Narratives of Cultural Trauma (and Resilience): Collective Negotiation of Material Well-being in Disaster Recovery

EXTENDED ABSTRACT

Cultural trauma occurs "when members of a collectivity feel they have been subjected to a horrendous event that leaves indelible marks upon their group consciousness, marking their memories forever and changing their future identity in fundamental and irrevocable ways" (Alexander 2004, p.1). Importantly, cultural trauma is not caused by catastrophic events in and of themselves; but, instead, is socially constructed and located in meaningful relationships between discourse, practice, structure, and events (Alexander 2004; Breese 2011; Oliver-Smith 1999; Smelser 2004).

Routines, social bonds, and material and ecological worlds are irrevocably changed in times of cultural trauma. Imagine a community devastated by mass unemployment, war, terrorist attack, criminal activity, technological malfunction, or a natural hazard event and notions of *how* inhabitants garner resources, rebuild infrastructure/homes, and seek other forms of recovery may come to mind. Discourse centers on the destructive event, followed by demand for symbolic and institutional reparation. Who or what is to blame? Who are the victims? What kind of material help is needed? Community history, the suffering of its members, actions taken to alleviate suffering, and the relationship between the impacted community and the rest of the world narrate the trauma. Such narratives stimulate and inform practices to restore community functioning.

By blending theory from cultural sociology with data derived from a documentary TV series on community recovery after a tornado devastated Greensburg, Kansas,, our work explores how collective memories about trauma *and* resilience morph and change over the course of disaster recovery. Using cultural trauma theory as our basis, we theorize why there is demand for trauma *and* resilience narratives, how such demand is created and sustained, and of what the structure and content of the narratives are composed. We also discuss the effects of such narratives on anticipated and realized consump-

tion post-disaster, and theorize why communities have different experiences in garnering outside support for their recoveries.

Theoretical Framing. Collective memory theory explains how members of a social group retain, alter, or re-appropriate public knowledge of events from the past (Halbwachs 1950, 1980; Schwartz 1982). Though there is no *single* memory, collective memories are shared and are allowed to change and develop as group needs for the memories change (Schwartz 1991). Collective memory is a social construction; social groups reinterpret the past to be consistent with present concerns and social groups remember what they want and need to remember (Schwartz 1991). The public discourse over collective events determines whether an event or set of events constitutes cultural trauma (Alexander 2004). And, how such events are interpreted greatly impacts future consumption practice and discourse in community. In other words, cultural trauma theory employs collective memory theory as its basis for understanding narratives about particular events.

Our work analyzes the narratives of loss *and* recovery in a 29-episode television series, <u>*Greensburg: A Story of Community Rebuilding*</u>, produced by Leonardo DiCaprio and aired on the Planet Green television channel via Discovery Networks. The series' cover description illustrates the interplay between collective narratives on trauma *and* resilience in a disaster.

> *On May 4, 2007, a deadly tornado struck Greensburg, Kansas, ripping the town to shreds. Ninety-five percent of the town was destroyed, 11 lives were tragically lost, and survivors were left without homes, businesses, schools and basic city services. Greensburg was gone, and it seemed that all was lost for its residents. Out of the rubble came resilience and courage...the spirit of the Greensburg citizens is what makes the journey most inspirational, as ordinary people of great character choose to create a better life for themselves and their children.*

Narrative analysis concentrates on community members' interpretations, as revealed during the television program (Heider 2001). This analytic method does not sit squarely within any theoretical tradition, but the approach "gives prominence to human agency and imagination, [and] it is well suited to studies of subjectivity and identity" (Riessman 1993, p.3). The interpretation of the episodes is complete. Each episode is analyzed as multiple blocks of text/narratives. As suggested by Riessman (1993) and Thompson (1997), analysis moved from the specific toward higher levels of abstraction. First, data from each narrative set was analyzed independently of one another. We created spreadsheets in which we listed aspects of different core narratives related to loss and recovery. We looked at how stories about particular experiences were told and asked why they were told that way (Riessman 1993). Time references to specific passages were listed. Next, we compared narratives across episodes (and time) and looked for changes and commonalities along the story lines. In the last phase emergent themes are stated in light of combined literatures on collective memory, cultural trauma, and consumer vulnerability.

In contrast to previous consumer behavior explorations of disaster where the impacts of disaster on consumption and self-identity are explored (Sayre 1994) or trade-offs between self-identity and collective identity are illuminated (Baker and Hill 2013), this research sits squarely in the cultural tradition, and explores broader macro-cultural narratives, as well as the marketing and public policy implications that flow from them. We highlight collective memories in times of cultural trauma to explain the demand for and interplay between trauma and resilience narratives. Our discussion highlights

human perspectives of trauma and resilience, and then provides a theoretical perspective on cultural trauma and the processes that sustain it. We indicate how narratives relate to anticipated and realized consumption post-disaster, as well as provide implications for consumer well-being and disaster response.

Community Resiliency in the Aftermath of the New Zealand Earthquakes

EXTENDED ABSTRACT

Within the social sciences, community capacity is widely examined as the characteristics of a community that impact its ability to mobilize and address social problems (Goodman et al. 1998). More recently, researchers are moving from an interest in community capacity to community resiliency--or the ability of a community to bounce back following a disaster (Baker 2009; Longstaff 2005). Whereas community capacity is the potential to mobilize resources, resiliency is the effective deployment of resources to address a crisis. This new emphasis on resiliency means that researchers are no longer examining single-event disturbances but are adopting a longer-term perspective to understand how communities respond in the face of ongoing disturbances, such as the continuing challenges facing the U.S. Gulf Coast region (Baker and Hill 2013).

We examine how a community responded to a series of earthquakes based on four years of ethnographic field work. Prior to the earthquake, our research was focused on examining a local exchange system where services were traded to get needs met and build skills. This meant that we had first-hand knowledge of the town and established relationships in the community before the disaster hit. Following a series of earthquakes, our research expanded to examine the community-wide response to the disaster. We build upon the conceptual framework developed by Norris et al. (2008) to present resiliency as a set of adaptive and networked capacities that town members activated to solve immediate practical problems and enhance individual and collective efficacy.

Over a six year period, the local trading system had developed and evolved significant capacities. The trading organization established extensive communication and social capacities that were regularly practiced through the thousands of hours of services that were exchanged. At first, these capacities were activated to encourage trading services to meet individual needs but, over time, larger projects were organized to meet broader community needs. Across years of exchanging services, a culture of caring emerged where town members worked to meet local needs. Notably, the community was practicing skills that were preparing them to work together to solve unanticipated problems by engaging in team work to respond to practical challenges, tap into relevant expertise within the team, and collaborate to get the job done.

Following the crises, the local exchange network was able to activate its communication capacity to send and receive critical information through its social network allowing crucial resources to flow. Moreover, the flat organization demonstrated that is was nimble, creative, and flexible at problem solving by leveraging the distributed knowledge and resources of its social network. It was particularly sensitive to local vulnerabilities, identifying and responding to individuals (e.g., families in crisis) and groups with special needs. For example, the Medical Center was provided with volunteers to assist by calling 156 elderly residents to check on physical and emotional needs. Volunteers also organized material and emotional support for families in crises with damaged homes and organizational members who required assistance with damaged facilities.

Relying on in-depth and nuanced knowledge of the local community, the local exchange organization was far more responsive to local vulnerabilities than were external emergency personnel and organizations, which often take a top-down authoritative approach and leave before the difficult work of reconstruction begins (Guion, Scammon, and Borders 2007; Klein and Huang 2007). Moreover, the local exchange system encouraged old and new rituals and narratives of resiliency as the larger community prepared itself for the long and extensive work of reconstruction. For instance, members organized frequent community celebrations to bring residents together in fellowship as well as enhance the weak and strong social ties that had been created and have been shown to be critical to community recovery (Aldrich 2011, 2012). As more community members practiced collective problem solving, the community developed greater redundancy in terms of the people who could be activated during the continuing crises. For example, much of the built environment in the local town was damaged and many recreational and gathering areas were destroyed. Community members organized people across several work days where a lot was cleared, a Petanque court was built, a garden was planted, and tables, benches, and a performance stage were built. This area is now an important gathering site that is regularly used and maintained by the town.

Consumption Under Restriction: Vulnerability and Resilience in a Maximum Security Prison

EXTENDED ABSTRACT

Choice is one of the most studied phenomena in the consumer behavior literature, allowing scholars to discern emotional and psychological drivers and reactions to interactions within the marketplace (Luce, Bettman, and Payne 2001). While the majority of our literature evaluates consumer choice architectures and decision-making in situations of abundant choice (Chernev and Hamilton 2009), we seek to expand comprehension of the much less understood context of consumption under *severe restriction* of choice (Botti et al. 2008). Markus and Schwartz (2010, p. 344) aptly define choice as "what enables each person to pursue precisely those objects and activities that best satisfy his or her own preferences within the limits of his or her resources," but they also recognize that "there is bound to be someone, somewhere, who is deprived of the opportunity to pursue something of personal value." Accordingly, we seek to learn more about how consumers react to situations of extreme choice restriction induced by a total control institution that negates the kinds of freedom implicit in most of the current research models in consumer behavior.

The most extensive forms of restriction may occur in what Goffman (1963) calls total-control institutions, exemplified by prisons, psychiatric hospitals, concentration camps, and other intensive forms of person-over-person control. For instance, individuals who are incarcerated in certain lock-down facilities face elimination of nearly all human rights as punishment for crimes committed. Early views of such treatment are often rooted in the belief that incarcerated persons are "outlaws," and are not protected by the same legal rights as law-abiding citizens (Vogelman 1968). Accordingly, inmates typically live in cells with one or more persons, are told what and when to eat, how and when to bathe, work, and recreate, and face strict regulation of personal possessions and random searches, leading to heightened levels of psychological distress and subsequent behavioral reactions.

Our goal is to advance the understanding of consumer behavior processes and their impact on consumption in the face of such extreme restrictions through first-hand accounts of life in a maximum security prison. Designed to house about 3,300 men, it typically operates beyond capacity by several hundred prisoners. The 60+ acre walled complex lies in the middle of the grounds and contains several cellblocks, along with a variety of service units for food, spiritual needs, medical care, education, and work. The average age of the men is 37 years old, with a racial balance of 50% black, 38% white, 11% Hispanic, and 1% listed as other. The dominant licit occupation before arrival is unskilled laborer, the mean reading level is below 8th grade, and over 40% did not graduate from high school or have a diploma equivalent. Men arrive shackled in the back of police vans after stays of up to one year or more in a local jail while awaiting sentencing. The intake process follows a strict routine and consists of psychological testing, removal of possessions including clothing, a cavity check for contraband, assignment of a number that is used to refer to them instead of their names, and provision of prison garb and toiletries of state issue. The men are also asked where they want their bodies delivered at their deaths, emphasizing the unlikelihood of parole.

The process of discovery passed through three phases that were co-created by one of the researchers and the men. Tenets of ethnography where researchers occupy a locally appropriate role (Hill 1991), as well as principles of participatory action research (PAR) where community members are invited into research on their terms for the purposes of consciousness-raising and institutional change (Ozanne and Saatcioglu 2008), guided this project. The sensitive nature of the men's subordinate position in the prison system required an initial period of trust building (phase 1), while phase 2 involved a shift in the power relationship away from the traditional researcher role to that of facilitator and active participant in the process. The final phase (3) required a reversal of leadership, whereby the men used these data and interpretations to press for collective agendas in formal settings and initiate novel methods of advocacy.

This investigation provides a rare glimpse into a total control institution that seeks to depersonalize and commoditize men under its charge, in part, through restricted choices and consumption. Our study yielded themes and subthemes based on perspectives of incarcerated men. The first theme involves depersonalization, capturing dehumanizing and commoditizing processes that the men were subject to by the prison system. The second theme deals directly with consumption consequences that provide relief from prison life and its assault on humanness. Our findings show negative short-term outcomes of masking current realities and the return to previous ways of exchange relationships that mirror pre-incarceration consumption experiences. The final theme examines psychological responses to depersonalization and commodification, focusing on coping reactions by the men. Resulting coping behaviors of blaming the self or others for their predicaments and lack of choice, isolating themselves or bonding with others who face the same circumstances, and desire to seek higher ground by looking to advance oneself through new consumption avenues lead to several alternative ways of achieving need satisfaction and revealing various levels of resilience.

Health Challenges and Consumer Vulnerability: Identity Dissolution and Resiliency Behaviors

EXTENDED ABSTRACT

When conceptualizing vulnerability, it is common to think of someone as vulnerable because they are limited in their ability to engage effectively in the marketplace (Baker, Gentry and Rittenberg 2005; Shultz and Holbrook 2009). Such vulnerability can arise from a variety of individual and external factors, but one's health and body may be a catalyst central to experiencing vulnerability (Mason and

Pavia 2006; Pavia and Mason 2014, 2004). It is through our bodies, whether healthy or challenged, that we consume and construct identities. This consumption and construction occur within a dynamic market environment structured on resources, social norms and processes which can heighten one's vulnerability (Baker and Mason 2012). In this paper, we highlight the ways that health can evoke vulnerability through consumption challenges and identity dissolution. We then examine consumer attempts to reconstitute lost facets of identity and build lasting resiliency through altered consumption and market engagement.

Staggering numbers of consumers live with health limitations due to illness, aging, and disability. In the U.S., nearly 27 million persons live with heart disease, 20 million with cancer, 16 million with diabetes, 25 million with asthma, and 52 million with arthritis (CDC 2014). Furthermore, with aging populations, health limitations are rising. In the U.S. the majority of persons over 65 years have at least one chronic condition and 62% report having a physical limitation which restricts basic living activities (CDC 2014). What these numbers don't reveal are the difficulties and ongoing uncertainties that millions of consumers with health challenges face in their daily living and consumption (Charmaz 1991; Frank 1995).

Previous consumer research has explored consumption during transitions embedded with health crisis and limitations including illness diagnosis, disability, advanced age, or loss of a loved one (Baker 2006; Barnhart and Penaloza 2013; Gentry et al. 1995; Mason and Pavia 2006; Pavia and Mason 2004; 2014). The research has found that significant adjustments in consumer attitudes and behaviors occur during these transitional periods. Such adjustments occur because health challenges limit one's ability to access or successfully navigate the marketplace. For example, physical barriers to the market and an inability to consume in past fashion may exacerbate recognition of bodily limitations (Barnhart and Penaloza 2013; Mason and Pavia 2006). Uncomfortable encounters and critical gazes in the marketplace may further stigmatize and negatively impact self-perceptions (Baker 2006; Pavia and Mason 2012). Through times of adversity, consumer vulnerability is heightened. Furthermore, during a health crisis, the act of consuming and participating in the market takes on deep, reflexive meanings (Pavia and Mason 2004), and the inability to do so is likely to evoke a vulnerability that involves the dissolution of core parts of the self. However, consumer studies also reveal that individuals are not destined to these stereotypical or stigmatized consumer identities (Barnhart and Penaloza 2013; Pavia and Mason 2012). Further research is needed regarding the vulnerability and resiliency that emerges when core facets of the self are threatened and consumption paradoxically involves both triggers and resolutions.

This research explores the vulnerability, identity concerns, and resilient behaviors that consumers experience or undertake in light of daunting health circumstances. More specifically, we examine identity dissolution and reconstitution through acts of consumption and market engagement. Moving beyond notions of consumer vulnerability as an adverse market interaction, and drawing from the illness literature (Charmaz 1991; Frank1995), we first identify deeply valued facets of one's identity which are threatened when confronted with severe health challenges. Based on these underpinnings of vulnerability and identity dissolution, we then examine the ways in which consumption and market engagement may help reconstitute identity and build resiliency. Adopting a grounded theory approach (Charmaz 2006), more than sixty depth interviews were conducted with individuals facing acute diagnosis, chronic illness, disability, and end-of-life issues.

Emerging themes reveal that beyond market exclusion, deep trajectory concerns related to role stability and productive value, social/relational stability and separateness or stigmatization, emotional stability and dependency, temporal stability and liminality, and financial stability and lost market status erode important facets of identity. Faced with ongoing identity dissolution and vulnerability, consumers enact, mobilize, and challenge those norms which have threatened their identity. They attempt to construct a more resilient identity, which contests the loss and focuses on redefining and reconstituting valued aspects of self. However, continuing metaphors of opposition (e.g., self vs. body, struggle vs. surrender, idealized body vs. real/experienced body, freedom of bodily movement vs. physical constraint and dependency) reveal ongoing challenges in overcoming adversity. Despite setbacks, consumers persist in crafting consumption practices aimed at reconstituting identity, restoring market engagement, and building lasting resiliency.

SESSION OVERVIEW

Incentives can be extremely useful tools for encouraging desirable behaviors. Hence, incentives are often linked to prosocial behavior in two different ways: 1) Because people often lack the motivation to do good deeds on their own, incentives are employed to encourage prosocial behavior, including blood donations, volunteering, and pro-environmental acts (Gneezy, Meier, and Rey-Biel 2011). 2) Good deeds *themselves* can be employed as incentives to encourage other desirable behaviors (e.g., someone donates to charity for each pound that you lose; Imas 2014). Such "prosocial incentives" may be effective because people care deeply about a social cause or like to signal their virtue to themselves and others.

These connections point to the possibility of a virtuous cycle: incentives encourage good deeds, which in turn become the incentives themselves. The four papers in this session present a full picture of this relationship, illustrating boundary conditions and guidelines for implementation, both when incentives promote good behavior and when good behavior is the incentive. Across various contexts that cover a range of desirable behaviors, the presentations use a mixture of field studies and controlled laboratory experiments to demonstrate both consequential effects and their underlying mechanisms.

The first two papers identify characteristics of incentives that influence their effectiveness in encouraging good deeds. **Barasch and Small** investigate the relative effectiveness of carrot versus stick incentives in the prosocial domain. Although sticks are more successful for non-prosocial acts, carrots outperform sticks in motivating prosocial behavior due to their greater potential to serve as self-signals of generosity. **Anik, Norton, and Ariely** examine the use of contingent match incentives for non-profits (e.g., "if X% of others give, we will match all donations") on donation behavior. A large-scale field study and two lab studies demonstrate the success of contingent percentages at middle values (around 75%) where both social proof and plausibility, the countervailing forces that influence donation behavior, are at work.

The second two papers focus on how good deeds can be used *as incentives* to motivate other behaviors. **Keenan, Imas, and Gneezy** examine whether "prosocial incentives" improve effort beyond standard incentives. Their field studies show that prosocial incentives

increase participation and effort both in a recycling program and a labor market, and work better in public than in private. Finally, **Müller, Mazar, and Fries** examine how companies can incentivize consumer purchase by offering donations to offset the negative externalities caused by their products. Companies benefit most from providing donations in product-unrelated domains, unless the product-related damage is personalized.

Because implementing incentives can be challenging, it is important to understand what features of incentives make them effective. Together, these papers highlight various novel intersections between incentives and prosocial behavior, helping point the way to a virtuous cycle of greater personal enjoyment and social good. Given the widespread applicability of the issues discussed, the session should attract researchers interested not only in prosocial behavior and incentives, but also crowding out, nudges, and field studies. We hope that the theoretical and practical implications of each presentation will generate a fruitful discussion.

The Motivating Force of Carrot versus Stick Incentives on Prosocial Behavior

EXTENDED ABSTRACT

Since 2010, dozens of major cities have started imposing a surcharge on disposable paper and plastic bags commonly used at grocery and retail stores. However, in the face of this tax, some retailers have turned the "stick" incentive into a "carrot" by giving shoppers a discount for each reusable bag they bring in. But which will be more effective at changing behavior, both at the point of purchase and subsequently in other environmental contexts? More generally, what is the relative effectiveness of carrot versus stick incentives on prosocial behavior?

While much is known about the effects of extrinsic rewards on individuals' performance and actions (Deci, Koestner, and Ryan 1999), little work has directly compared *reward* incentives (carrots) to incentives that *penalize* people for poor behavior (sticks). Prior work has shown that due to loss aversion, stick incentives to avoid losses outperform carrot incentives to achieve gains (Goldsmith and Dhar 2013; Imas 2014). We hypothesize the opposite pattern when incentives are designed to motivate prosocial behavior.

People often look to their own prosocial behavior to signal to themselves that they are good people, and tend to act accordingly in the future (Gneezy et al. 2012). In the context of motivating consumers to perform good deeds, we predict that carrots will outperform sticks due to their greater potential to enable people to signal to themselves that they are indeed good. Negative framing has been shown to reduce the warm glow that individuals derive from engaging in prosocial behavior (Andreoni 1995). As such, we suggest that the controlling nature of sticks may impede people's ability to make positive inferences about themselves. Thus, people acting to avoid a punishment may be less likely to infer they are doing good because they are truly charitable. We test these hypotheses in seven studies.

First, the results of two scenario studies testing people's behavioral intentions provide initial evidence that carrots outperform sticks in real consumption situations. In these studies, participants were given a short description of a situation in which they would receive a carrot incentive for performing a prosocial act or a stick incentive for failing to perform a prosocial act. Then, they reported how likely they would be to engage in that act. In **Study 1**, people were

more likely to report that they would bring their own reusable bags to a grocery store if the store offered them a refund for every bag they brought than if the store charged them for every disposable bag they had to use (t=2.92; p=.010). In **Study 2**, people reported greater compliance when an energy company offered financial rewards for efficient energy use than when a company charged its consumers for excessive energy use (t=3.54; p<.01).

Next, five laboratory studies examining real behavior lend further support, finding that carrot incentives are more effective than stick incentives in actually motivating prosocial actions. In all these studies, participants performed real tasks for charity and were randomly assigned to receive either a monetary reward for each completed task, incur a monetary penalty for each unfinished task, or receive no incentive. We controlled for compensation amount by equating the minimum and maximum amount participants could receive in each incentive condition.

In **Study 3**, we found that relative to stick incentives, carrot incentives led individuals to commit to performing more charitable tasks in advance of the actual behavior (t=3.66; p<.001). In **Study 4**, carrot incentives induced individuals to perform more charitable tasks, even without pre-commitment (t=2.58; p=.01). In **Study 5**, when working for a carrot rather than a stick, participants performed more charitable tasks even after these incentives were removed (t=3.12; p<.01). In all three studies, the control condition was similar to the stick incentive condition. In addition, our results supported a self-signaling mechanism: relative to sticks, participants working for carrots rated themselves as more generous (Study 4; t=2.74; p<.01) and reported greater willingness to perform a separate task for charity in the future (Study 3; χ^2=6.98; p=.03).

Two final studies provided additional support for a self-signaling process by directly comparing carrot and stick incentives between prosocial and non-prosocial domains. In a 2x2 between-subjects design, participants were randomly assigned to write words either for a charity's or a company's annual report, and to receive either a monetary reward for each word they wrote (carrot) or a monetary punishment for each word they did not write (stick).

Study 6 found a significant interaction, such that the effect of incentive type depended on whether the behavior affected prosocial inferences (F=9.06; p=.003). For those working for a company, stick incentives were more effective than carrots (F=4.99; p=.02), replicating work showing that loss aversion operates in non-prosocial domains. However, for those working for a charity (i.e., completing prosocial tasks), carrots outperformed sticks (F=4.09; p=.04), replicating our earlier findings that people work more for rewards than punishments when doing so better enables self-signals of virtue.

Study 7 replicated this interaction (F=8.61; p=.004), as well as the simple effects in the company domain (F=3.73; p=.05) and charity domain (F=4.97; p=.03). In addition, individuals in the charity-carrot condition predicted that they would have done more tasks in the absence of the incentive than individuals in the charity-stick condition (F=4.45; p=.04), reflecting greater perceptions of their own generosity. In the company condition with no prosocial implications, there were no differences between carrot and stick incentives on self-reported generosity predictions (F=.13; p=.72), and predictions of task completion were lower overall than in either charity condition, confirming the crucial role of charitable self-perceptions in altering how incentives affect behavior.

Across seven studies, we demonstrate that carrot incentives are more effective than stick incentives in prosocial domains. While loss aversion makes stick incentives more successful in non-prosocial domains, carrots have greater potential to allow consumer self-signals of generosity through the completion of prosocial actions. These results underscore the importance of understanding which types of incentives are effective in different contexts.

Contingent Match Incentives Increase One-Time and Recurring Donations

EXTENDED ABSTRACT

Imagine that you are making an online donation; as you check out, you are given the option to upgrade to a recurring donation. If you are like many donors, you'd be unlikely to make such a commitment. Now imagine that you see a message, informing you that the charity will match all donations made that day, if – and only if – X% of donors agree to upgrade to a recurring donation. Would this type of matching incentive – what we term a contingent match – change your likelihood of upgrading? And if you were in this situation, what percentage would motivate you most? If the match were set to "kick in" if 25% of people upgraded, you might feel that while the match is likely to occur, the percentage being set so low indicates that very few people are expected to upgrade. In contrast, if the match were set at 100% of donors – sending a strong signal that many people are expected to upgrade – you might feel that it is unlikely that everyone will agree, such that the likelihood of the match occurring is low. Therefore, we suggest that upgrading to recurring donations will be highest for a middle value which signals both that many other people are likely to upgrade (offering social proof) and that hitting the match target remains plausible.

Decades of research suggest that people's behavior is shaped by the behavior of others (Asch 1956; Cialdini 1993; Griskevicius et al. 2006; Sherif 1936). Social proof has been shown to guide a diverse set of actions such as helping in emergencies, littering, and recycling (e.g., Buunk and Bakker 1995; Latané and Darley 1968). Previous research suggests that consumers are sensitive to social proof when deciding to make one-shot donations (e.g., Shearman and Yoo 2007); as a result, we expected that donors would also be sensitive to social proof when considering recurring donations.

Note, however, a critical difference between typical instantiations of social proof ("X% of people have engaged in the behavior") and contingent matches ("*If* X% of people engage in the behavior"); both suggest that many people have or are expected to engage in a behavior, but the latter has an element of uncertainty. As a result, we predicted an important role for another construct: plausibility. Certainly, individual motivation is strongly influenced by plausibility that goals can be reached (Bandura and Schunk 1981; Fishbach and Dhar 2005; Koo and Fishbach 2008; Zhang, Fishbach and Dhar 2007). Therefore, we expected donors' decisions to upgrade to recurring donations to be influenced not only by social proof (where a higher percentage is generally better) but also by plausibility (where a percentage that is too high may seem unreachable).

In three experiments, we assessed the impact of contingent match incentives. In Experiment 1, we partnered with Global Giving, a non-profit organization that connects donors with grassroots projects. After browsing the projects available on GlobalGiving.org, on the check-out page, donors ($N = 12{,}769$) viewed the project, the amount of donation they selected, and the frequency of the donation. It was optional to switch the frequency from one-time (the default) to a monthly recurring donation. Our dependent variable was the percent of people who converted from one-time to recurring donations. Donors were randomly assigned to one of seven conditions. Donors in the *control* condition had the opportunity to spontaneously upgrade one-time donations to monthly recurring donations. Those in the *prompt* condition were provided with a prompt that encouraged them to "help make a sustained impact by upgrading to a monthly

recurring donation." Those in the *standard match* condition were told: "A generous anonymous donor has agreed to match 100% of new monthly donations today." Finally, donors in one of the four *contingent match* conditions were told: "A generous anonymous donor has agreed to match 100% of new monthly donations today, but only if 25/50/75/100% of donors start a recurring donation today."

We found that informing potential donors that their donations would be matched if and only if 75% of other donors agreed to upgrade led to the highest percent of upgrades. Most interestingly, two years after the completion of the field experiment, the follow-through rates on the seven different pledges revealed that donors in the *75% contingent match* condition not only kept giving for the most number of months, but they also donated the highest total amount, suggesting that the *75% contingent match* creates significantly higher value for the charities over the long term.

Next, we conducted a controlled experiment to assess social proof and plausibility as potential mechanisms. Participants (*N*=275) were asked to imagine taking part in Experiment 1 and indicate whether they would upgrade to recurring donations. We also measured *social proof* by asking participants "what percent of people who see this message would upgrade to a monthly recurring donation?" and *plausibility* by asking them "how likely do you think that the project would reach its goal?" Replicating our results from the field experiment, participants in the *75% contingent match* condition indicated the highest willingness to upgrade to recurring donations. We also showed that *social proof* and *plausibility* mediated the effectiveness of contingent matches.

Finally, in Experiment 3, we examined whether the impact of contingent matches is specific to recurring donations, or extends to a simpler decision: one-time donations. In an online experiment, participants were randomly assigned to one of four conditions – *standard match*, *50% contingent match*, *75% contingent match*, or a *control* condition – and chose whether to keep a $.50 payment or donate it to a charitable cause. Once again compliance peaked at 75%, and we found that the effect of contingent matches also hold for one-time donations as they do for recurring donations.

Across three experiments, we suggest and provide evidence that contingent match incentives are an effective and underutilized means of inducing people to become recurring donors. We are happy to share that Global Giving has integrated these incentives into their business model as the contingent matches allowed them to double the amount of money raised through recurring donations.

Prosocial Incentives in the Field

EXTENDED ABSTRACT

Designing incentive schemes to motivate performance is critical for organizations and individuals. Recent work demonstrates that prosocial incentives (i.e., connecting effort directly to charitable contributions) may be more effective than standard, self-benefiting incentives (Imas, 2014). Specifically, individuals exert more effort under a prosocial incentive compared to a self-benefiting scheme, though only at low incentive levels. When incentives are high, the two incentive schemes become equally effective. Individuals increase effort in the self-benefiting condition under high incentives compared to low, while those in the prosocial condition show insensitivity to incentive size—their effort does not increase with higher incentives.

While these results suggest prosocial incentives may at times provide stronger motivation than the commonly used self-benefiting ones, several open questions remain. First, although individuals often choose to behave prosocially when in a situation that requires them to decide whether to do so, they may intentionally *avoid* such situations if possible (Andreoni, Rao & Trachtman, 2012; DellaVigna, List & Malmendier, 2012). Since prior work on prosocial incentives has only studied behavior after subjects were assigned an incentive scheme, it is important to examine whether individuals are more likely to opt-out of projects with prosocial incentives when given the opportunity.

Second, signaling models of prosocial behavior suggest giving is motivated by the desire to appear prosocial to both oneself and others (Bénabou & Tirole, 2006). In these models, individuals derive utility from a positive self and social image, and prosocial behavior acts as a signal that further bolsters that image. Consistent with signaling models, prosocial effort is greater in public than in private (Ariely, Bracha, & Meier, 2009). Since effort under prosocial incentive schemes is tied to charitable contributions, these results imply that making effort public could increase performance under prosocial incentives to a greater extent when compared to standard incentives.

Finally, the relevance of prosocial incentive schemes for organizational and policy applications critically depends on their effectiveness in the field. It is therefore important to demonstrate the usefulness of prosocial incentives outside of the lab in naturalistic contexts. In two field studies, we show that in addition to increasing effort, prosocial incentives encourage participation and are more effective in public versus private settings.

Study 1 was run in the context of recycling. We made announcements for an upcoming recycling drive in a total of 12 classrooms, and asked students (N=846) to indicate on a slip of paper their intention to participate. Those who indicated that they would like to participate also provided their email address and specified how many recyclables they planned to bring. All were told that individuals who opted-in to participate would receive a reminder email prior to the drive, including the number of recyclables they planned to bring.

Students saw one of two incentive schemes for bringing in recyclables (For Self or For Others), crossed with one of two levels of visibility (Private or Public). In the For Self condition, individuals expected to receive a direct payment of 0.05 cents per recyclable brought to the drive. In the For Others condition, 0.05 cents would be donated to the Make-A-Wish foundation per recyclable brought. In the Private condition, individuals opted-in to participate privately by marking a sheet of paper and slipping it into an envelope that was passed to the front of the class. In the Public condition, after marking the paper, individuals who opted-in were asked to raise their hands and bring the sheet to the front of the room. Students were told the procedure prior to making their decisions.

Results showed individuals were significantly more likely to participate in the recycling drive when money from recyclables went to charity rather than themselves. The prosocial incentive scheme had a significant main effect on participation, with 19.1% of students agreeing to participate in the For Others treatments compared to 7.4% in the For Self treatments (*p*<.01). Pairwise comparisons showed significantly more sign-ups in both the public and private For Others treatments (23.9% and 15.1%, respectively), compared to sign-ups in the public and private For Self treatments (6.79% and 8.09%, respectively), though the difference between private For Others and private For Self was marginally significant (*p*=.06). Making participation public had a significant effect on sign-ups, but only in the prosocial treatment: 23.9% signed up in the For Others public treatment compared to 15.1% in the private treatment (*p*<.05). In contrast, making the act public had no significant effect on participation in the For Self treatments (6.79% vs. 8.09%, n.s.).

In Study 2, we aimed to replicate the results of Study 1 in a different domain—an online labor spot-market. We used Amazon Mechanical Turk's spot-market to advertise a task requiring workers to populate an image database with pictures in a particular domain (e.g., wildlife). The advertisement featured the basic details of how these images should be collected, as well as the flat fee for completing the task, which entailed collecting ten links to images from the web. It also included a link to learn more information and to sign up. Once workers (N=872) clicked on the link, they were randomized into one of four conditions, which varied the incentive (Low/$0.01 per 10 images vs. High/$0.05 per 10 images) and the beneficiary (For Self vs. For Others, where the Others is one of six charities). The flat participation fee was the same in each of the four treatments. This design allowed us to test how many workers opted-in to working under the incentive scheme, as measured by the ratio of those who finished the task to those who clicked on the link, as well as effort of workers conditional on opting-in.

Results revealed that when incentives were Low, workers were more likely to opt-in to the prosocial incentive scheme (62% For Others) than in the standard incentive scheme (53% For Self, *p*=.04). As incentives increased, however, workers were just as likely to complete the task under the prosocial incentive scheme (64% For Others) as under the standard one (61% For Self, *p*=.45).

How Conventional Products Can Use Cause-Related Marketing Campaigns To Make Up for Not Being Organic

EXTENDED ABSTRACT

The production and consumption of products can cause various damages to the environment (e.g., air pollution) and society (e.g., unfair trade). As consumers are becoming increasingly attentive to social and ethical considerations – in part due to the offering of fair trade or organic products – and thus, more aware of products' negative externalities, the purchase and consumption of conventional products may become increasingly associated with guilt (Dahl, Honea, & Manchanda, 2003). To alleviate potential guilt so that consumers continue buying conventional products, some companies use cause-related marketing (CM) campaigns in which they promise a donation to a cause every time a consumer purchases their product. The idea behind this approach is related to moral regulation (Mazar & Zhong, 2010): if customers' moral self-concept is threatened by the purchase or consumption of a product that is associated with negative externalities, a morally good act such as a donation can "save" it.

The challenge when designing such CM campaigns is that companies can offer a donation to fight a problem caused by their products (*same domain-donation*) – for example, a donation to offset water pollution when buying coffee – or they can offer a donation to fight a problem unrelated to their products (*other domain-donation*) – such as a donation to fight illiteracy. However, little is known about which type of donation would be more beneficial for companies and why.

Research on moral regulation simply suggests that licensing and compensation-mechanisms can be successful regardless of whether the two counterbalancing behaviors are in the same domain (Monin & Miller, 2001) or in differing domains (Mazar & Zhong, 2010), but does not compare the effectiveness of both types to each other. Intuition suggests that a *same domain-donation* has the advantage of directly reducing a product's specific negative externalities, potentially making the product and thus the consumption appear less harmful – which should translate into less guilt and increased

demand for the conventional product. Yet, a same domain-donation might increase the saliency of the damage supported by one's consumption and thus make oneself feel hypocritical. Consequently, the consumer's guilt might be promoted rather than reduced, such that the consumer might choose a less harmful product instead. An *other domain-donation* avoids emphasizing the product's negative externalities and subsequent feelings of hypocrisy and thus could provide a better guilt-reduction mechanism or simply a good feeling.

In one field and one laboratory study, both with incentive compatible, consequential purchases, we show that consumers are more likely to buy a conventional product (rather than an organic product) when coupled with an *other domain* CM campaign than when coupled with a *same domain* CM campaign – unless the *same domain* CM campaign is personalized.

In our first experiment, we operated a coffee stand during a music festival on a European university campus, where we sold conventional and organic coffee at Euro 1.20 each and varied between subjects (N = 290) the sign accompanying the conventional coffee. A pre-test within the same population revealed that water pollution was an environmental damage that was highly associated with the production of conventional coffee. Another pre-test revealed that fighting illiteracy was viewed as equally important as fighting water pollution, and both causes were viewed to fit equally well with the product category coffee. Thus, in one condition (*same domain*) the sign read that for each purchase of a cup of conventional coffee, 10 cents would be donated toward offsetting water pollution caused by the production of coffee. In another condition (*same domain-personalized*), the sign read that for each purchase of a cup of conventional coffee, 10 cents would be donated toward offsetting water pollution caused by the production of the consumer's ("your") coffee. In a third condition (*other domain*), the sign read that for each purchase of a cup of conventional coffee, 10 cents would be donated toward offsetting the educational disadvantages caused by illiteracy. We added two control conditions without any donation: one in which both coffees were offered at the same price (Euro 1.20; *control + equal price*) and one in which the conventional coffee cost 10 cents less (i.e. Euro 1.10) than the organic coffee (*control*).

We found that when both coffees where offered without a donation and at the same price (control + equal price), only 17.9% purchased the conventional coffee. Not surprisingly, this market share increased (up to 28.1%) when the price of conventional coffee was decreased by 10 cents (control condition). More importantly, demand for conventional coffee significantly increased when instead of lowering the price, the product was coupled with a donation in an other domain (28.1% vs. 58.3%; *p* < .001), while a same domain-donation failed to significantly increase purchases (28.13% vs. 36.8%; *p* = .31). Interestingly, however, the same domain-donation did significantly boost the purchase of conventional coffee when it was personalized (28.1% vs. 66.4%; *p* < .001).

We replicated our findings in an incentive-compatible laboratory experiment, in which we offered participants the possibility to purchase coffee before taking part in an unrelated study. In contrast to the field experiment, this setting also allowed us to observe decisions to abandon the purchase of coffee (no matter if conventional or organic) altogether. Further, it allowed us to examine the underlying process. The results of this laboratory experiment revealed that the positive effects of a personalized same domain-donation as well as of an other domain-donation on the purchase of conventional coffee were fully mediated by the relative guilt associated with the purchase of conventional versus organic coffee.

Our findings are particularly interesting for companies intending to use CM for conventional products that have less harmful com-

petitors. We show that offering the right type of donation can allow such products to increase their market share without giving up profit – the customers are willing to pick up the tab.

SESSION PROPOSAL

Despite the lasting financial crisis that put a strain on consumers' resources, the business of luxury and premium goods has grown tremendously across product categories and geographical areas in recent years (Bain 2013). This trend sparked renewed interest in understanding when and why consumers purchase status products and services as luxury items (e.g., Bellezza et al. 2014; Dubois et al. 2012; Han et al. 2010; Ordabayeva and Chandon 2011; Rucker and Galinsky 2008). The session brings together state of the art research in this area by bridging two important questions: first, how do products, services, people or even behaviors become associated with high or low status? Second, how might such associations affect the way people acquire and consume products and services or interact with high vs. low status people?

The first two papers shed light on conditions under which behaviors or types of products can become associated with status. First Bellezza, Keinan, and Paharia investigate conspicuous consumption related to spending time. In contrast to the theory of the leisure class (Veblen, 1899/1994) suggesting that individuals who conduct idle lives, and spend their time on leisure are perceived to be higher in status, the authors demonstrate across four studies that "being busy" can become a status symbol. Second, Dubois and Ruvio explore the theme of status creation by examining the conditions under which luxury experiences (e.g., a fancy vacation) are preferred over luxury goods (e.g., an expensive car). The authors demonstrate that power (powerlessness) trigger preference for experiential (material) luxury offerings over material luxury offerings and the moderating role of the stability of consumers' power position.

The next two papers focus on the implication of acquiring status through preferences for status products. Specifically, Paharia and Thompson show that brands having a large amount of resources with which to compete in the marketplace can become perceived as "top dog" brands, and are preferred by consumers who have a higher need for status or in a consumer context where status is salient (e.g., a brand that is used publicly rather than privately). Finally, Ordabayeva and Fernandes conclude the session by investigating the relationship between status preferences and political ideology. Throughout five studies conducted inside and outside the lab with inherent measures of ideology as well as ideology primes, the authors show that conservatives and liberals seek status in fundamentally different ways: while conservatives seek status through conspicuous consumption, liberals seek status through sustainable consumption. This happens because liberals and conservatives seek to communicate fundamentally different moral values that they uphold to others.

This session is of interest to a broad swath of consumer researchers and of special interest to those interested in status, conspicuous consumption, power, and political ideology. By providing a series of thought-provoking findings of when status associations are created in the marketplace and their implications for when and why luxury brands might be favored by consumers, this session offers novel insights on status processes and paves the road for future research.

Conspicuous Consumption of Time: When Busyness and Lack of Leisure Time Become a Status Symbol

EXTENDED ABSTRACT

The lavish expenditure of scarce and valuable resources, such as money and time, can act as a signal of status and wealth. While past research has primarily focused on how the expenditure of *money* has been a vehicle to signal social status, in this research we focus on how the conspicuous expenditure of *time* can lead to the same end. Veblen (1899/1994) suggests that the wealthy consume time unproductively as demonstrated by their ability to live idle lives. Specifically, leisure is defined as the non-productive consumption of time. Thus we would expect that those who have the ability to waste time, and are not busy, would be perceived to have higher levels of social status. However in modern Western society, hard work, ambition, and busyness are respected admirable traits and appear to be associated with success and wealth. Anecdotal evidence suggests that being busy can evoke pride, and is often made public to others through the process of complaining or bragging (Kreider, 2012). We investigate whether a busy or non-busy lifestyle will indicate higher levels of social status and portray a high aspirational image.

We propose that working hard and busy lifestyles lead to greater inferences of social status in comparison to working less hard and non-busy lifestyles. The underlying paradigm shift for status attribution based on time expenditure may be linked to the development of a highly structured human resources market in advanced economies. In contrast to people who do not work, or work for limited hours, busy individuals might be perceived as highly sought after and desired in the job market. Busyness might speak to the intrinsic qualities and capabilities of the individual who, as a scarce and precious resource herself, is like a rare gemstone and thus perceived to have higher status. Accordingly, we predict that the positive inferences in response to busyness and lack of leisure time are mediated and driven by the perception that a busy person is a scarce resource in high demand. We then consider boundary conditions related to agency, whether working long hours is perceived as a deliberate choice, and find that the positive status attributions associated with busyness at work are muted when an individual is perceived to have no agency in her choice to be busy. We further demonstrate the moderating role of observers' time affluence (Kasser and Sheldon 2009), an individual difference measuring whether one feels pressed for time, and find a

stronger effect of busyness for observers who feel their own time is very limited.

A series of experiments test our conceptual model and explore how busyness conveys status in the eyes of others. We uncover the mediating (perceived scarcity) and moderating processes related to the effect (agency over the decision to be busy and time affluence). We employ various methods to manipulate busyness and products related to busyness with participants representing different countries and cultures.

As a preliminary investigation, we first explore Twitter data categorized as "humblebrags," which consist of self-deprecating boasts (Alford 2012), and find that a significant number of them relate to busyness. Inspired by these findings, study 1 uses hypothetical Facebook posts to either communicate a busy lifestyle or a non-busy lifestyle, in addition to considering the role of agency. In studies 2A and 2B, in addition to generalizing the effects from study 1, we also consider the mediating role of scarcity – the degree to which a person is perceived to be scarce and in demand. In study 3, we explore the moderating factor of observers' time affluence, an individual difference (Kasser & Sheldon 2009). In this study we also explore perceived ambition as another potential mechanism driving the positive effect of busyness. In studies 4A and 4B, we consider specific marketing implications for brands and products associated with busyness. Specifically in study 4A, we considered two brands: Whole Foods, pretested to be associated with an expensive lifestyle, and Peapod, a service associated with a busy lifestyle. In study 4B, we conducted a similar study but instead of grocery stores, participants considered a person who either wore a Bluetooth ear device (associated with a busy lifestyle) or a pair of gold earrings (associated with an expensive lifestyle). In both studies, we further examine individual level differences in time affluence in the observers. Finally, in study 5 we consider how busyness can be portrayed in advertisements. In a follow-up study, we also explore cross cultural responses to busyness at work and we demonstrate a reversal of the effect, whereby busyness leads to lower rather than higher inferences of status.

Recent research suggests that high-status individuals tend to avoid blatant and conspicuous displays of wealth or status, and instead seek alternative ways to differentiate themselves from lower-status individuals (Bellezza et al., 2014; Berger and Ward, 2010; Han et al. 2010). For example, sophisticated luxury consumers elect to use less known and less conspicuous luxury brands. We contribute to this literature by investigating the conditions under which busyness can serve as an alternative, nonconventional signaling mechanism and lead to positive inferences of status in the eyes of others. We demonstrate a nuanced kind of conspicuous consumption that operates by shifting the focus from the preciousness and scarcity of goods, to the preciousness and scarcity of individuals. While owning expensive products signals status through the value of these material goods, displaying one's busyness and lack of leisure signals status through the value of the person.

When Do Consumers Prefer to Look Like a King vs. Feel Like a King? Power-Induced Preferences for Experiential vs. Material Luxury

EXTENDED ABSTRACT

The repeated two-digit growth in the luxury industry (Bain, 2013) has sparked significant efforts to explain such sustained success (Rucker and Galinsky, 2008; Han, Nunes and Drèze, 2010). However, research mostly focused on luxury products in the form of material objects (e.g., handbags) despite luxury's success largely stemming from experiential offerings—from art performances to unique travel adventures. This type of luxury, in contrast to material objects, offers unique intrinsic (e.g., sensorial) benefits associated with the experience (e.g., an opera). Interestingly, marketers can offer the same item – e.g., a car – as a material object (e.g., by emphasizing the uniqueness of the car's features) or as an experience (e.g., by emphasizing the uniqueness of the driving experience).

Yet, little theory speaks to when and why luxury managers should frame luxury as an experience or as a material possession. On the one hand, past research proposes that experiences can be more psychologically rewarding than possessions (Van Boven and Gilovich, 2003), suggesting that consumers might prefer experiential luxury to material luxury. In support, work on materialism suggests experiences are more personal and self-defining than material possessions (Carter and Gilovich, 2012). On the other hand, conspicuous and compensatory consumption research argues material luxury might provide a means to alleviate the discomfort associated with a low-ranked position (e.g., Charles et al., 2009). We integrate these findings by offering two novel propositions on how a fundamental feature of society, power (i.e., asymmetric control over valued resources in relationships (Rucker, Galinsky and Dubois, 2012), affects consumers' aspirations to purchase experiential vs. material luxury goods.

First, building on work showing that power increases the salience of one's inner feelings and needs (Guinote, 2009) but powerlessness increases the salience of one's social surroundings (Van Kleef et al., 2008), we theorize that a state of high power might heighten one's intrinsic aspirations whereas a state of low power might heighten one's extrinsic aspirations. Intrinsic vs. extrinsic aspiration refers to the extent to which people consider own needs irrespective of social externalities (Kasser and Ryan, 2011). Given that experiences tend to be self-defining (Carter and Gilovich, 2012) but material items increase consumers' visibility (Han, Nunes and Drèze, 2010), we propose that power might induce people to focus and weight different aspects of a product; leading the powerful to prefer experiential over material luxury, but the powerless to prefer material over experiential luxury. In short, the powerless might prefer luxury that can make them "look like a king," but the powerful preferring luxuries that make them "feel like a king."

Second, we theorize the stability of one's power can moderate preferences for experiential vs. material luxury. Power stability refers to the sustaining character of a powerful or powerless position (Tajfel, 1984). In consumer settings, power instability might stem from personal and contextual variables, such as variability in one's role (e.g., variability of one's job security) or in valuation of one's own resources (e.g., variability of stock exchange). Because instability might reinforce a power holder's motivation to signal one's authority, we propose that in an unstable situation (Scheepers and Ellemers, 2008), powerful consumers might prefer material luxury over experiential luxury. In contrast, because instability might alleviate a powerless' need to engage in compensatory signaling by opening the possibility that s/he might move up the hierarchy, we propose that in an unstable situation, low-power consumers' preference for material luxury over experiential luxury will reduce. We conducted two experiments to test these hypotheses and analyzed the data using ANOVAs, regressions and/or t-tests. Across experiments, manipulation checks confirmed all manipulations were successful.

Experiment 1: Power-Induced Preference for Experiential vs. Material Luxury One hundred and twenty one participants were randomly assigned to a 3 (power: high, control, low) × 2 (offering type: experiential, material) between-subjects design. First, participants recalled a time they had or lacked power (Galinsky et al., 2003).

Baseline participants did not complete any task. During the second task, participants either evaluated an evening at the opera and an exclusive massage (experiential condition) or a pair of luxury glasses and an exclusive pen (material condition). Participants indicated their willingness-to-pay (WTP) in % of the retail price (Rucker and Galinsky, 2008). Results revealed a main effect of power such that low-power participants' WTP was higher than both that of baseline and high-power participants, replicating classic findings (Rucker and Galinsky, 2008). There was also a main effect of framing reflecting higher WTP for experiential luxury than material luxury (Van Boven and Gilovich, 2003). Most importantly, there was a significant power × offering type interaction, such that low-power participants preferred material luxury to experiential luxury, compared to other conditions. In contrast, high-power participants preferred experiential luxury to material luxury, compared to other conditions.

Experiment 2: Framing Luxury as Experience or Material. One hundred and sixty participants were randomly assigned to a 2 (power: low, high) × 2 (stability: low, high) × 2 (framing: material, experiential) between-subjects design. Participants were assigned to a role of boss or employee (De Dreu and Van Kleef, 2004). Importantly, participants were told that power positions would either remain unchanged (stable condition) or that they might be switched later (unstable condition; Sligte et al., 2011). Next, participants evaluated an ad for a pen either the pen's experiential benefits or its material benefits. In the stable condition, we replicated experiment 1's results. In the unstable condition, results revealed a significant power × framing interaction: high-power participants reported a higher WTP for the material luxury than for the experiential luxury, reversing the pattern in the stable condition; in addition, there were no marked preference for either the experiential luxury or the material luxury among low-power participants.

Overall, our results successfully replicated and integrated classic findings from both the power (Rucker and Galinsky 2008; 2009) and materialism (Carter and Gilovich, 2010; Van Boven and Gilovich, 2003) literatures. In addition, we shed light on an important moderator how power informs luxury tendencies – the stability of consumers' power position. Implications for power and luxury marketing practices will be discussed.

When Underdog Narratives Backfire: The Effect of Perceived Market Advantage on Brand Status

EXTENDED ABSTRACT

As Under Armour – a relatively new athletics apparel company – considers how to expand into new markets across the world, the brand must consider a fundamental question: How should they position themselves relative to their competitors? Being a relatively weaker brand compared to rivals such as Nike and Adidas, Under Armour could capitalize on an "underdog effect," and position themselves as disadvantaged in the market place, but with the determination to battle the competition. Underdog narratives have been found to enhance consumers' brand evaluations because people identify with the underdog's struggles (Paharia, Keinan, Avery & Schor, 2011). Accordingly, consumers may root for the weaker Under Armour as they fight against powerful companies such as Nike.

However, exposing oneself as an underdog also exposes a fundamental weakness, the fact that the brand has fewer resources than their competitors. In interpersonal domains, previous work has shown that one's ability to attain resources is positively associated with a higher level of social status (Magee and Galinsky, 2008; Marmot, 2004). Similarly, in consumption domains, the ability to signal status is an important driver of consumers' preferences (Rucker and

Galinsky, 2008; Eastman, Goldsmith, and Flynn, 1999). Accordingly, if Under Armour positioned itself as an underdog brand, could they unknowingly alienate consumers who care about status?

In this research we investigate a novel condition under which we find a "top dog effect," when consumers prefer brands that have more (vs. less) resources to compete in the marketplace. While luxury brands intentionally use scarcity to signal status, we find that having a large amount of resources to compete in the marketplace as a top dog is also associated with status. Controlling for price and quality, we find that for consumers who care more about status (i.e., consistently worry about status when selecting products and services) or purchase contexts that increase the importance of status (e.g., public vs. private consumption experiences), top dog brands are favored. Importantly, we show that preference for top dog brands in high-status contexts: 1) can be observed even when the top dog brand is less unique and less scarce than underdog brands, 2) is not driven by the fact that top dog brands are more well-known, and 3) is mediated by consumers' perceptions of brand's power which lead to feelings of higher individual status.

Four experiments tested our hypotheses that top dog brands can signal status, and are therefore preferred in contexts where status is important and by those who have a higher need for status as an individual difference. In study 1, we show that top dog brands are perceived to have more status than underdog brands, and that preference for them is moderated by an individual difference, the importance of status. Experiment 2 was conducted between three distinct groups: undergraduate liberal arts students, Mechanical Turk participants, and undergraduate business school students. Each group significantly varied on their stated importance of status from one another. For the undergraduate business school students, a group who cares about status more, we found a preference for the top dog brand. However for undergraduate liberal arts students and the Mechanical Turk participants, groups who care about status less, we found an underdog effect. Again, these effects were moderated by the importance of status. In experiment 3 rather than consider the individual or the group, we varied the situational context and manipulated whether status was more relevant or less relevant. We found that participants favored the top dog brand more in the high status relevant context, when considered for public use, than in the low status relevant context, when considered for private use. Again, this effect was moderated by an individual difference, the importance of status. Finally in experiment 4, we test the mediating role of being able to signal status. We find that for people who cared about status, the ability to signal status through a top dog brand mediated their preference for the top dog brand, however for the people who care about status less, the ability to communicate status was not relevant. Furthermore, we find that the brand's power, versus the fact that it may be more well-known, is driving the effect. Finally, we explore demographic segments and find African Americans, who care about status more than Caucasians, like top dog brands more because they better enable them to signal their status.

Taken together, our studies qualify previous research documenting a positive effect of underdog narratives. More specifically, we make four contributions to the literature: 1) we provide evidence of a top dog effect in contexts where status considerations are important, 2) we show that a positive top dog effect can occur despite the fact that consumers tend to more readily identify with underdog brands, 3) we demonstrate that top dog preference is based on the brand's ability to confer status, controlling for alternative mechanisms related to brand awareness, price, perceived risk, and finally, 4) we find that a position of resource abundance can trump perceptions of uniqueness and scarcity as a signal of status in the marketplace.

Politics and Status: How Political Ideology Shapes Status Concerns and Preferences

EXTENDED ABSTRACT

As political opinions become more polarized, consumers increasingly find themselves at the opposite ends of the political debate (Abramowitz and Saunders 2008). While the majority of adult consumers (upwards of 65%) identify themselves as conservative or liberal (Gallup 2012), little is known about how political ideology influences behaviors that are not ideological in nature. Recent data uncovers interesting differences in the consumer behaviors of conservatives and liberals. Specifically, it seems that conservatives and liberals prefer different brands, restaurants, and entertainment (Duhigg 2012); show different patterns in energy consumption (The Economist 2007); and display different products at home (Carney et al. 2008). However, it is unclear whether these differences are stable, why they arise, and whether they are causally linked to ideology.

In this research, we examine the effect of political ideology on status consumption. Drawing on the moral foundations theory (Haidt 2012; Haidt and Graham 2007; Haidt and Joseph 2004) which suggests that conservatives and liberals prioritize different sets of moral values (Graham et al. 2009; Graham et al. 2011), we hypothesize that conservatives and liberals seek status in systematically different ways because they wish to signal different moral values through their purchases. We predict that conservatives will seek status through conspicuous consumption which signals power and fulfills conservatives' esteem for authority and in-group loyalty. On the other hand, liberals will seek status through sustainable consumption which signals concern for social welfare and fulfills liberals' desire to promote fairness and prevent harm. We thereby propose that there is a direct causal link between political ideology and status consumption, that moral values may serve as signals of status, and that political ideology can explain when and why individuals use altruism or power cues to signal status. We test our predictions in five studies conducted inside and outside the lab using well-established scales of ideology as well as a novel prime.

Study 1 examined the effect of inherent political ideology on status-seeking through conspicuous and sustainable consumption. To manipulate the status-seeking motivation, half of participants read a scenario about starting a new job at a very competitive workplace (status prime condition), and the other half read a scenario about losing house keys or concert tickets (control condition, Griskevicius, Tybur and Van Den Bergh 2010). Afterwards, participants indicated their preference between sustainable and conspicuous products in four categories (dishwasher, household cleaner, batteries, car) using three items (product preference and attractiveness on 9-point scales, 1 = definitely conspicuous product, 9 = definitely sustainable product; product choice on a dichotomous scale), followed by a 7-item ideology scale (Nail et al. 2009). To test the role of moral values, we administered a 5-item moral identity internalization scale (Aquino and Reed 2002; Winterich, Zhang and Mittal 2012). Consistent with our predictions, preferences for sustainable (vs. conspicuous) products significantly strengthened with the degree of participants' liberalism (vs. conservatism), but only when the internalization of moral identity was high and the status motivation was active.

Study 2 tested our theory using the same sustainable and conspicuous descriptions of the dishwasher and cleaner as in Study 1, but with a manipulation of the type of setting (public vs. private) in which the product purchase was taking place (instead of the status prime used in Study 1). Participants in the public (vs. private) condition read that they were purchasing the products in a busy physical (vs. an online) store (Griskevicius et al. 2010). We then measured participants' political ideology and moral identity internalization. The results revealed that preferences for sustainable (vs. conspicuous) products strengthened with the degree of liberalism (vs. conservatism), but only in public and when the internalization of moral identity was high.

Study 3 tested the mediating role of moral values. All participants were first exposed to the status prime used in Study 1 and then indicated their preferences for dishwasher, cleaner and batteries. Next, they answered 18 questions about the relative importance of binding authority / group loyalty dimensions ("factor 1") compared to individualizing fairness / harm prevention dimensions ("factor 2") in moral decisions using 7-point scales, 1 = "factor 1 is definitely more important" to 7 = "factor 2 is definitely more important." Finally, participants completed a single-item ideology scale, 1 = "extremely liberal" to 9 = "extremely conservative" (Jost et al. 2003). The mediation was significant: there was only a significant indirect effect of ideology on preferences for sustainable (vs. conspicuous) products through the relative strength of individualizing (vs. binding) moral values.

Study 4 tested the causal effect of ideology by priming ideological ideals and the role of inherent status-seeking motivations by measuring individuals' self-monitoring tendencies. Participants descrambled sentences that communicated conservative or liberal ideals, after which they filled out the product preference items as in Study 1, followed by a 13-item self-monitoring scale (Lennox and Wolfe 1984). As predicted, liberal (vs. conservative) primes strengthened preferences for sustainable (vs. conspicuous) products, but only when individual self-monitoring was high.

Study 5 relied on novel secondary data to test whether the conservatism of US states would influence web search for conspicuous products. We examined the volume of searches for forty conspicuous terms (conspicuous brands, product categories and concepts) on Google in each of fifty US states between 2004 and 2012. We linked the search data to state conservatism (the proportion of individuals from a representative sample of the state population who identified themselves as conservative in the 2012 Gallup state of the state metrics and the number of times the state voted for a republican presidential candidate in 2000, 2004, 2008, and 2012). As predicted, controlling for state GDP and population density, interest in conspicuous products online was stronger in conservative states than in liberal states.

Our findings contribute to research on political ideology, consumer behavior, and moral foundations by uncovering a systematic relationship that links ideology, moral values, and consumer decisions that are devoid of politics. More generally, our findings add to an emerging stream of research which underlines the importance of accounting for consumers' ideological beliefs as a powerful predictor of consumer behaviors (e.g., Fernandes and Mandel 2013; Kidwell, Farmer, and Hardesty 2013). The results have useful implications for marketers.

SESSION OVERVIEW

Individuals spend a lot of money on gifts each year. According to the National Retail Federation (NRF 2013), holiday retail sales were over US$602 billion in 2013 – 40% more than Belgium's gross domestic product – and much of that spending was on gifts for others. Similarly, in November 2013, the average household planned to spend about $801 on holiday gifts alone, and that was just on "planned" purchases (American Research Group 2013). Despite the fact that consumers spend much of their income on gifts for others, relatively little is understood about how consumers select such gifts and whether such gifts actually bring happiness to the recipient. Stated more formally, what gifts are selected for others, and how much happiness is derived from the exchange? It is these questions that our session intends to address.

The first paper by Cheng, Meloy and Polman begins with a common challenge of gift-giving: Shopping for picky people. The authors delineate what it means to be a picky person (from the perspective of the giver), and how shopping for someone who is thought to be picky is different from shopping for someone who is thought to be difficult. This paper identifies some of the gifts consumers prefer to buy for picky people, and how people negotiate the burden of shopping for picky people.

The next two papers continue to examine gift-giving, and both extend this research by identifying different asymmetries between givers and receivers. In one paper, Chan, Mogilner, and Van Boven demonstrate that when the gift giver is motivated by feelings of gratitude versus guilt, the strategies and choices are different. Their research shows that givers feel more connected to their receivers when the givers' motivation is guilt, but receivers feel more connected to their givers when the motivation for the gift is based on feelings of gratitude. In the other paper, Goodman investigates the relationship between giving and receiving experiential gifts. He finds that givers prefer to give material gifts, rather than experiential gifts, because material gifts are more conventional and easier to give. However, receivers prefer to receive experiential gifts, evidencing a gap between what givers prefer to give and what receivers prefer to receive.

Finally, in the last paper, Helion and Gilovich examine how the recipient chooses to spend a gift that they have received in the form of a gift card and compare the effects of spending gift cards versus cash on others. They find that people are more generous when using gift cards, such that people are more likely to buy dinner and books for others when they are using a gift card rather than when they are using cash.

Taken together, these papers provide insight into the gift-giving process. In theoretical terms, people have considerable experience acting as both givers and receivers, yet despite the extensive experience that people have as both givers and receivers, it seems people struggle to transfer information from one role (giver) and apply it to another role (receiver). In practical terms, people spend substantial amounts of money on gifts. By better understanding the context and constraints of the gift-giving process, we hope to improve overall well-being for both givers and recipients.

Choosing Gifts for Picky People: Where is the Fun in That?

EXTENDED ABSTRACT

In this paper, we discuss the challenges of choosing gifts for picky people. Such choices are common – in a recent survey concerning Black Friday, consumers reported that 39% of their purchases were for people they considered "picky" (NPD Group 2014). Despite the ubiquity of buying gifts for picky people, little research has formally examined how such gift purchases are made. In this vein, we explore how consumers cope with choosing gifts for picky people. First, we show how buying a gift for someone picky is uniquely different from other forms of difficulty that may accompany a gift choice. For example, we argue that "pickiness" is a unique construct because it focuses solely on the perceived preferences of the recipient. In contrast, a gift choice may be "difficult" should it stem from environmental and contextual constraints (e.g., choosing a gift for a recipient who lives far away); relationship closeness (e.g., choosing a gift for a co-worker or boss); and personal constraints (e.g., insufficient funds). Then, we examine whether consumers' choices (such as what gift consumers decide to buy) and their respective shopping tendencies (such as consumers' willingness to pay) systematically differ when a gift recipient is picky vs. difficult. Study 1 begins by defining "picky" in a gift-giving context. Study 2 examines gift choices people make for picky versus difficult recipients. Study 3 examines the effort and money consumers are willing to spend on picky recipients (relative to difficult recipients). Finally, study 4 examines the specific strategies that are employed in selecting a gift for a picky recipient.

Study 1. Participants (n=205) imagined selecting a gift for a "picky" or "difficult" person in a between-subjects design. They rated how well each of 18 short phrases described their gift recipient on a 1(*not at all*) to 11 (*extremely*) scale. Half of the phrases were drawn from descriptions of difficult gift recipients; for example, choosing for someone distant (Otnes et al. 1992, 1993). The other half of phrases were drawn from the literature on picky eating; for example, phrases that describe people who display narrow preferences and avoid consuming specific foods (Carruthers et al. 2004). In addition we added phrases we created, such as *snobby* and *decisive*. Five factors emerged (VE=61.88%). Picky gift recipients were seen as having narrower preferences (M_{Picky}=7.47, M_{Diff}=6.76, p=.012) and stronger opinions (M_{Picky}=7.02, M_{Diff}=5.93, p<.001). Difficult gift recipients were perceived as more likely to have different tastes than the giver (M_{Picky}=6.29, M_{Diff}=6.93, p=.031), be someone in a relation-

ship-conflict with the giver (M_{Picky}=5.13, M_{Diff}=5.82, p=.012), or be someone of a different age/income group than the giver (M_{Picky}=5.67, M_{Diff}=6.59, p=.003). Overall, the results reveal that picky recipients are differentiated from difficult gift recipients through their narrow preferences and stronger opinions. An open question, however, is whether these beliefs affect consumers' gift choices and the strategies they decide to implement. We addressed this issue next in study 2.

Study 2. Participants (n=206) were randomly assigned to one of two conditions (picky/difficult) and asked to imagine participating in a Secret Santa exchange. After describing their gift choices in an open-ended response, participants rated how much effort they would exert in obtaining a gift for their gift recipient (from 1 to 11), estimated their WTP for the gift, and reported whether they believed the gift recipient would return or re-gift their gift (from 1 to 11). We analyzed the open-ended responses and found that participants provided less specific identifying details (e.g., brand names) when describing a gift choice for a picky recipient (20% mentioned a brand name) versus a difficult recipient (38.2%), χ^2=8.12, p=.004. Furthermore, givers reported expending less effort selecting a gift for a picky recipient (M_{Picky}=6.18, M_{Diff}=7.16, p=.021). And participants indicated they would spend less money for a picky recipient (M_{Picky}=\$31.04, M_{Diff}=\$35.40, p=.009). Finally, although there were no differences in perceptions that the gift would be returned, participants did believe that a picky recipient was more likely to re-gift the item in the future (M_{Picky}=3.30, M_{Diff}=2.71, p=.046). These results indicate that givers spend less money on a gift for a picky recipient – we investigated this further in study 3.

Study 3. Participants (n=162) were assigned to a 2 (social distance: acquaintance, friend) x 2 (recipient: picky, difficult) between-subjects design. Givers' WTP for the recipient's gift was assessed. While difficult friends received a more expensive gift than difficult acquaintances ($M_{DFriend}$=\$43.00, M_{DAcq}=\$27.73), social distance did not moderate the amount of money givers intended to spend on picky gift recipients ($M_{PFriend}$=\$32.73, M_{PAcq}=\$31.53, p=.008).

Study 4. Study 4 was a 3 (recipient: picky, difficult, control) x 2 (social distance: acquaintance, friend) between-subjects design. Participants (n=277) considered seven popular gift-giving strategies (Otnes et al. 1993) and were asked to select the strategy they preferred, according to recipient condition. Two popular strategies include the *ask strategy* (where participants ask the recipient what they want) and the *fun strategy* (where participants give the recipient something delightful). The *ask strategy* was preferred over the *fun strategy* when the recipient was picky, but we did not observe this difference in the difficult or control conditions (Ask_{Picky}=77.2%, Ask_{Diff}=37.0%, Ask_{Cont}=31.2%, and Fun_{Picky}=5.4%, Fun_{Diff}=32.6%, Fun_{Cont}=31.2%; χ^2=49.41, p=.000). This suggests that people do not use the same gift-giving strategies for picky recipients relative to difficult/neutral recipients.

Discussion. Our studies show that gift givers do not approach the gifting process for picky recipients in the same way they would approach choosing gifts for other types of recipients (notably, difficult recipients). Givers recognize that picky recipients are more decisive and have narrower preferences. This results in a greater probability that they will put in less effort, spend less money on picky friends, and may ask the picky recipients directly for gift ideas instead of trying to delight them. This leaves a number of open questions for future research, including whether there are asymmetries in giver/picky recipient perceptions of what the ideal gift is, the attractiveness of material versus experiential gifts for picky recipients, and whether gift choices for picky recipients vary based on givers' motivation for the gift (gratitude versus guilt).

Gratitude, Guilt, and Gift Giving

EXTENDED ABSTRACT

Gratitude and guilt are both socially-adaptive emotions that help cultivate interpersonal relationships. This research shows that the same situation of social inequity can elicit feelings of gratitude or guilt, and that both emotions motivate people to give gifts to restore the relationship. For example, if one spouse performs the lion's share of the housework, the idle spouse may feel grateful (for the other's benevolence) or guilty (for inadequately contributing), and give their spouse a gift. We further explore the downstream social consequences of gifts that say "thanks" versus "sorry" and find that a gift can help restore social equity, but with differential effects for the giver and recipient. Gift givers report greater improvements in relationship closeness from giving out of guilt, whereas recipients tend to report greater relationship improvements from receiving a gift given out of gratitude.

Experiment 1 tested the hypothesis that gratitude and guilt can arise in the same situation of social inequity, but are differentially associated with the actions of others and the self. Participants read and imagined themselves in four randomly-ordered scenarios in which another person had helped them when they were in need (e.g., they left the kitchen a mess and their roommate cleaned up for them). Immediately after reading each scenario, participants rated how grateful and guilty they would feel in that scenario (1-7), as well as to what extent the other person went above and beyond what was required of him/her and to what extent they themselves fell short of what was expected of them (1-7).

The results of Experiment 1 showed that gratitude was more closely associated with ratings of the other person's actions than guilt: both emotions were positively associated with perceptions of benevolence, however the effect of gratitude ($\beta = 0.76$, t=17.30, p<.001) was four times that of guilt ($\beta = 0.19$, t=7.42, p<.001). In contrast, guilt was more closely associated with ratings of one's own actions than gratitude: both emotions were positively associated with perceptions of personal shortcomings, however the effect of guilt ($\beta = 0.64$, t=15.24, p<.001) was four times that of gratitude ($\beta = 0.16$, t=2.24, p<.03). These results suggest that although these emotions arise from the same situations, gratitude is more focused on the extent to which the other person has gone above and beyond whereas guilt is more focused on the extent to which they had fallen short.

Experiment 2 examined the extent to which gratitude and guilt motivate gift giving. Participants imagined that they had asked a friend to help them move to a new apartment and that s/he spent the weekend helping with the move. Participants were randomly assigned to one of three conditions and asked to write about why they would feel grateful or guilty in the situation, or to write about the situation in an objective, unemotional way. Participants then indicated how likely they would be to give a gift to their friend (1-7). Those who wrote about feeling grateful and guilty reported they were more likely give a gift to their friend compared to those who wrote unemotionally (ps<.05); the likelihood of giving a gift did not significantly differ between participants in the grateful and guilty conditions (p>.66). These results highlight that both gratitude and guilt are emotions that motivate gift giving.

Experiments 3A and 3B examined how giving and receiving gifts that express gratitude or guilt affect relationship closeness. In Experiment 3A, participants imagined they had left the kitchen a mess and that their roommate had cleaned up after them. Participants then wrote about the extent to which their roommate had gone above and beyond (gratitude condition), about the extent to which they had fallen short (guilt condition), or no essay (control condition).

They next rated the how close and connected they would feel to their roommate in the situation (1-9). Participants were asked to imagine they decided to give a gift of a drink to their roommate. Finally, participants rated how close and connected they would feel to their roommate after giving the gift (1-9). Results showed the guilty participants experienced a greater improvement (change) in how close they felt to their recipient as a result of giving the gift, compared to grateful participants (F=7.30, p<.008).

In Experiment 3B, participants read a scenario similar to in Experiment 3A, however they imagined they were the roommate who had cleaned up the kitchen for their messy roommate. Participants rated how close and connected they would feel to their roommate in this situation (1-9). Participants were next shown an image of a drink with a note attached that said either "thanks" or "sorry," and asked to imagine their roommate had given them this gift. Participants rated how close and connected they would feel to their roommate after receiving the gift (1-9). Results showed that participants who received a "thanks" gift experienced a greater improvement (change) in how close they felt to their roommate as a result of receiving the gift (t=2.37, p<.02).

Experiments 4A and 4B replicated the results of Experiments 3A and 3B using a more natural expression of gratitude and guilt. Instead of imagining a drink, gift givers in Experiment 4A (i.e., the messy roommates) created a card for their roommate using cardstock and markers. These cards were then randomly distributed to recipients in Experiment 4B (i.e., the roommates who cleaned up). The results again showed that guilty gift givers experienced greater improvements in relationship closeness as a result of giving a card than grateful gift givers (F=19.18, p<.001); in contrast, recipients of cards made by grateful gift givers experienced greater improvements in relationship closeness than those who received cards made by guilty gift givers (F=6.00, p<.02).

Together, these studies reveal the social benefits derived from gifts given out of gratitude and guilt to be asymmetrical. Whereas giving a gift out of guilt proves more connecting, receiving a gift given out of gratitude proves more connecting. This poses a challenge for gift givers seeking to build closer relationships and highlights the important role of emotions in gift giving.

Giving Happiness: Do Experiential Gifts Lead to More Happiness?

EXTENDED ABSTRACT

Gift giving increases consumer happiness (Dunn, Aknin, and Norton 2008) and is a frequent social and consumer behavior in both time and money ($800+ billion). It has received enormous attention—not only from consumer researchers (e.g., Belk and Coon 1993; Otnes and Beltramini 1996), but also from sociologists, anthropologists, economists, and psychologists (e.g., Camerer 1988; Komter 1996; Robben and Verhallen 1994; Schwartz 1967). Much of this research is qualitative or game theoretic, and has provided a wealth of insight. However, there is little empirical evidence as to what type of gifts—material or experiential—consumers tend to give, which ones lead to the most recipient happiness, and whether gift-giving consumers accurately estimate these differences. After all, the main goal of gift giving is not to increase the giver's happiness, but to increase the happiness of the person receiving the gift.

To further examine what type of gifts consumers believe will lead to the most happiness, I asked 100 Mechanical Turk (MTurk) workers to list gifts that they recently received, and then rate each gift as more material or more experiential. I found that a vast majority of gifts (81% of holiday gifts and 66% of birthday gifts) were viewed as more material than experiential. Thus, consumers not only prefer to give material gifts, but it also seems that they do not believe that giving experiential gifts will lead to more happiness than giving material ones.

Though gift givers might prefer to give material gifts, recent research on consumer happiness suggests that experiential gifts may lead to more happiness. When spending money on oneself, research shows that experiences lead to more happiness than material goods, assuming they turn out positively (Nicolao et al. 2009; Van Boven and Gilovich 2003). The process leading to this "experiential advantage" is due to several factors associated with experiences: greater identity relevance (Carter and Gilovich 2012), more comparability (Carter and Gilovich 2010), less regret and interchangeability (Rosenzweig and Gilovich 2012), slower adaptation (Nicolao et al. 2009), and greater social associations (Caprariello and Reis 2013). On the one hand, these theories suggest that a gift should be different because the choosing is done for the recipient, and thus it will not be susceptible to choice comparability, decision regret, or identity relevance, suggesting that an experiential gift is unlikely to be more central to the recipient's self-concept. On the other hand, the adaptation and the social association theories predict that the experiential advantage should hold for gifts. I conducted several studies to examine whether consumers accurately predict the best gifts and why they prefer to give material gifts.

In the first study, I addressed what makes material gifts different to examine why consumers prefer material gifts. For instance, it is possible that material gifts are more traditional and are thus given due to social norms—the proper gift should fit into a box and to be easily exchanged. Similarly, it could be that material gifts are viewed as more memorable, less risky, more appreciated, are easier to choose, require more effort to buy, or require more effort from the recipient. To test these explanations, I asked 375 MTurkers to list three gifts that they were thinking about giving and rate them on the following dimensions: enjoyable/happiness, giver effort, receiver effort, decision difficulty, traditional, memorable, negative outcome, appreciation, and material/experiential. Three conclusions emerged. First, experiences were perceived as being less traditional ($M_{Experience}$=3.56) than material gifts ($M_{Material}$=3.92, t(403)=2.21, p<.05), supporting the notion that experiences can violate gift giving norms. Second, givers perceived experiences as requiring more receiver effort ($M_{Experience}$=2.89) than material gifts ($M_{Material}$=2.06, t(401)=5.58, p<.001), suggesting that the extra planning required for an experience can place an extra burden on the recipient. Finally, givers did not believe that experiential gifts ($M_{Experience}$=5.63) would be more enjoyable by recipients than material gifts ($M_{Material}$=5.58, t(401)<1).

In the second study, a 2(give vs. receive) x 2(material vs. experiential) between subject design, I asked participants to recall an experiential/material gift that they received/gifted for the holidays. Participants then indicated how much this gift contributed to their own/recipient's happiness across three happiness measures (adapted from Nicolao et al. 2009). A significant interaction (t(132)=2.00, p<.05) supported the experiential advantage for gift recipients ($M_{Experience}$=5.61 vs. $M_{Material}$=4.74, t(132)=3.41, p<.01), while gift-givers did not believe in an advantage for experiences ($M_{Experience}$=4.97 vs. $M_{Material}$=4.81, t<1). Thus, it seems that consumers are biased towards material goods when in fact experiences would lead to more recipient happiness.

Study 3 used a different methodology whereby participants recalled three gifts that they either received or gave around the holidays. As in study 2, participants rated how much each gift contributed to their own or recipient's happiness, and rated each gift as more material or more experiential. Using a hierarchical analysis

regressing happiness on to each participant's material/experiential ratings, the results again showed a significant difference between givers and receivers. Givers did not believe that their experiential gifts led to more happiness (b=.034, t(233)=1.10, *p*=.27), while receivers showed that experiential gifts led to more happiness (b=.157, t(233)=3.30, *p*<.01).

In sum, the research shows that though giving experiences leads to more receiver happiness than giving material goods, givers believe otherwise. Consumers tend to give more material gifts because they are more traditional—and thus more likely to conform to the social norms of gift giving—and because givers view them as demanding less effort from the part of the receiver. For receivers, though, the extra effort and nontraditional nature of experiences is outweighed by the additional happiness. Therefore, it seems that consumers would be better off giving more experiences than material gifts. Yet, this may be a hard pill to swallow for many gift givers, because they mispredict their recipient's happiness pre-consumption. And even if givers overcome their mispredictions about experiences, the extra happiness associated with experiential gifts comes at a cost—they are perceived as less traditional and requiring more effort from the recipient.

Mental Accounting and Gift Card Spending

EXTENDED ABSTRACT

How people spend money can be strongly influenced by what, exactly, is being spent. Although individuals enjoy receiving and (sometimes) spending money in any form, how money in the form of a gift card is spent remains unclear. Gift cards were the most requested holiday item in 2009, and had held the top position for the previous three years (NRF 2009). With gift card spending increasing, it is important to know how gift cards are spent as compared to other tender types. The principle of fungibility entails that money not be endowed with specific meaning that might constrain its use. This is an implausible assumption in the case of gift cards, which are typically attached to a specific retailer. In our research, we show that gift cards reduce guilt associated with hedonic spending, thereby increasing indulgent purchasing and generosity towards others.

Study 1. Participants (n=200) were asked to imagine that they had either a gift card or cash, and had to choose between buying a hedonic item (a novel) or a utilitarian item (a book on doing one's taxes at home). Following the purchase decision, participants reported how guilty they would feel buying each item. A higher proportion of participants in the gift card condition (76%) indicated that they would purchase the hedonic item as compared to individuals in the cash condition (57%), X^2(1, N=200)=8.69, p<.01. To test our prediction that guilt mediates the relationship between condition (gift card or cash) and hedonic purchasing, we conducted a mediational analysis (Hayes 2013). Although condition predicted both hedonic purchasing (*b*=-.90, p<.01) and guilt (*b*=-.72, p<.01), the relationship between condition and hedonic purchasing dropped to nonsignificance when adjusting for differences in guilt. A bias-corrected bootstrap 95% CI indicated that the indirect effect through guilt was significant, $a \times b$ = -.72, 95% CI: [-1.24, -.22].

Study 2. Participants (n=40) were given the opportunity to earn money ($5) by completing a trivia task. Half of the participants received their money as a gift card; the other half received their payment in cash. All participants were required to spend their earnings in a laboratory store stocked with items that had been pretested as hedonic or utilitarian. Individuals in the gift card condition spent a significantly higher proportion of their money on luxury items (*M*=.76,

SD=.29) than individuals in the cash condition (*M*=.47, *SD*=.38), t(36)=2.53, p<.05.

Study 3. Six years of transactional data were collected from a bookstore. The dataset included all individuals who had used a gift card during this period and a randomly selected subset of those who had made credit card purchases. Individuals (n=13,883) were separated into three types: those who exclusively used a credit card, those who exclusively used a gift card, and those who used both a credit card and gift card. Our primary analysis focused on individuals who had used both tender types. We calculated, for each of these participants, the proportion of their total gift card expenditures that: 1) were made in hedonic departments (e.g. college memorabilia); and (2) were made in utilitarian departments (e.g. textbooks). A significantly higher proportion of the total amount spent with gift cards were in hedonic departments (*M*=.52, *SD*=.43) compared with credit cards (*M*=.21, *SD*=.17), t(331)=12.597, p<.0001. Additionally, individuals who had exclusively used a gift card spent a significantly higher proportion of their total amount in hedonic departments (*M*= .54, *SD*= .44), compared with individuals who had exclusively used a credit card (*M*= .30, *SD*= .28), t(12,840) = 33.361, p<.0001.

Study 4a. The previous studies focused on how individuals use gift cards to treat themselves; in the following studies, we examined how gift cards might promote generosity towards others. Participants (n=78) were asked to imagine that they were out to dinner with a friend and were planning on paying with a restaurant gift card or with cash. Participants were told that they had enough money on the gift card (or cash in their wallet) to pay for both meals, and were asked if they would buy both their and their friend's meal. A higher proportion of individuals in the gift card condition indicated that they would purchase their friend's meal (85.7%) as compared to individuals in the cash condition (60.5%), X^2(1, N=78)=6.075, p<.01.

Study 4b. Participants (n=92) were asked to imagine that they were at a bookstore with a friend and were planning to pay with a gift card or with cash. Participants were told that they had enough money on the gift card (or cash in their wallet) to pay for both their and their friend's book, and were asked if they would buy both. A higher proportion of individuals in the gift card condition indicated that they would purchase their friend's book (74%) as compared to individuals in the cash condition (42.9%), X^2(1, N=92)=9.208, p<.01.

Study 5. This study examined the differences between gift cards and cash received as a gift when it comes to experiential and material purchases. Participants (n=120) were assigned to one condition of a 2 (tender type: gift card or cash gift) x 2 (purchase type: experiential or material) full factorial design. A binary logistic regression model was used with tender type (-1 = cash gift and 1 = gift card) and purchase type (-1 = material and 1 = experiential) as predictor variables, and with treating a friend (1 = Yes and 0 = No) as the dependent variable. We found two main effects: 1) individuals were more likely to buy their friend an item when using a gift card than when using a cash gift (*B*= .96, *SE* = .23, p <.0005), and 2) were more likely to treat a friend to an experiential rather than a material purchase (*B* = .829, *SE* = .23, p <.0005).

These studies indicate that gift card spending is unlike that made with other tender types. Gift cards increase hedonic spending compared to cash and credit cards, due in part to decreased guilt about hedonic purchasing. Additionally, gift cards may increase generosity towards others.

Paper #4: Sense and Mental Imagery: The Persuasive Implications of Visualizing Proximal and Distant Senses

Ann E. Schlosser, University of Washington

SESSION OVERVIEW

Mental imagery is a familiar aspect of most people's everyday life (Marks 1999). Defining and measuring it, however, is difficult (Kosslyn, Thompson, and Ganis 2006).

Paivio (1969) was among the first to demonstrate the fundamental importance of imagery in memory and information processing, and to show that this construct can be experimentally manipulated. Since then, imagery has been studied extensively within consumer behavior literature. However, the vast majority of research has focused either on static visual imagery (the mental representation of static and fixed objects; e.g., Petrova and Cialdini 2005), or on how to facilitate and induce visual imagery of an attribute (e.g., McGill and Anand 1989).

The goal of this special session is to group together research on less studied, but not less important, aspects of mental imagery. Each of four papers contributes uniquely to our understanding of mental imagery and raises several important questions. Collectively, we ask what unexplored elements of mental imagery can be relevant in consumer research. Consequentially, can a subtle variation in these imageries automatically and subconsciously affect consumer perceptions, preferences, and behaviors? As these papers show, imagery is relevant in numerous research domains within consumer behavior, and the special session is uniquely positioned to attract a broad audience at ACR.

The first paper in the session, by Cian, Krishna, and Elder, focuses on dynamic imagery, an aspect of imagery that has received almost no attention in consumer research. Across four studies incorporating multiple methodologies and technologies, the authors show that icons able to evoke dynamic imagery affect consumer behavior (in their propensity to act).

With an analogous reasoning, in the second paper, Hagtvedt proposes that colors are able to change how consumers imagine product attributes. Previous studies in consumer research that have examined colors have left the relation between colors and mental imagery largely unexplored. In this work, seven studies address this issue showing how judgments related to density, heaviness, durability, and convenience change systematically based on the color of the stimuli.

The third and the fourth papers in the session focus on multi-sensory experiential imagery beyond visual imagery. Specifically, the third paper, by Elder, Poor, and Xu, shows across four studies how images evoked using different sensory modalities (e.g., imagining a barbecue through smell versus vision) affect perceptions of distance from the product advertised, ultimately affecting behavioral intentions and attitudes.

The fourth paper, by Schlosser, continues the theme of how multi-sensory imageries can vary in psychological distance, changing the perspective. Indeed, the three studies described in this paper use different manipulations of social distance and show how imagery vividness mediates the effect.

Each paper contributes to our overall theoretical understanding of the less explored aspects of mental imagery and their effect in a consumer context. Ultimately, we hope this session, in accordance with the ACR theme of this year, will spur further discussion of and *inspire passion* in the exploration of these new topics.

A Sign of Things to Come: Increasing Desired Behavior through Dynamic Iconography

EXTENDED ABSTRACT

We propose that perceived movement (or dynamic imagery) from static visuals prepares the observer for action and impacts behavior. The ability of static images and icons to convey movement presents one of the more intriguing, yet underexplored characteristics of visual stimuli. Unlike static visual imagery, dynamic imagery allows for images within the mind to continue in motion, resulting in a moving trajectory or perceived movement of a static image (Clark and Paivio 1991).

We operationalize our research within the context of traffic icons. The number of people injured or killed in traffic accidents each year is staggering, and traffic signs are placed in areas of potential danger to evoke desirable driving behaviors and reduce accidents. Can a subtle difference in traffic icons affect human behavioral response?

In this research, we focus on one dimension of the traffic icon – the perceived movement (or dynamic imagery) that the icon elicits. We hypothesize that dynamic imagery will affect human behavior. Specifically, perceived movement will lead to a propensity for the observer to act, influencing his/her behavior, reaction times, and attention. We test these hypotheses across four studies.

Exploring the implications of subtle changes in traffic signs on consumer behavior, we also contribute to a recent call for research on consumer and societal well-being (Mari 2008; Mick 2008; Mick et al. 2011).

In study 1a, we created four different stimuli, with each stimulus containing a road with a road sign of children crossing as seen from above. Two of the signs were visual icons of children (with lower and higher dynamism visuals). The other two signs were control conditions (higher and lower dynamism verbal depictions of the visual sign, namely, "running children" and "children ahead"). These verbal depictions allow us to test whether differences in behavior are due to differences in inferred conceptual meaning of perceived movement, or whether there is something unique about dynamic visual imagery. Participants were randomly assigned to view one of the four maps and were instructed to imagine themselves driving

on the road depicted in the picture. They were further instructed to click on the location of the road where they would start to slow down their vehicle in response to the traffic sign. We programmed the survey to place a small car where the participant clicked. The final position of the car (click), as measured in pixel coordinates, represented our main dependent variable of interest. We found support for our hypothesized effect: participants indicated earlier positions to begin slowing down when shown a higher dynamism versus lower dynamism visual sign. Similarly, the higher dynamism visual sign differed from both verbal signs. Together, this suggests that the perceived movement in the higher dynamism visual sign affects behavior and not simply the activation of the concept of the sign.

Study 1b tests if the results of study 1a carry over to a consumer setting, and within a less familiar context with less known signs. We created an aerial view of a mall parking lot with a road sign. The road sign portrayed a higher or lower dynamism icon of a shopper with a shopping cart. Instructions and the procedure were similar to study 1a. As in the prior study, participants indicated earlier positions to begin slowing down when shown a higher dynamism versus lower dynamism visual sign.

In study 2, we extend the findings of studies 1a and 1b in a video driving simulation. We created a driving video that showed a drive along a country road as seen from the driver's point of view. During the video, two types of traffic signs appeared randomly on the screen (warning signs or informative signs). The warning signs were traffic signs with either lower or higher dynamism. We use informative signs as control condition. Participants were asked to press the "i" key if the sign was informative and "w" if the sign was a warning. Our dependent measure in study 2 is reaction time to the signs presented. Supporting our hypothesis, results revealed that participants reacted significantly faster to warning signs with higher dynamism than to warning signs with lower dynamism, or to informative signs. There was no difference between warning signs with lower dynamism and informative (control) signs.

In study 3, we examine how perceived movement affects attention. Specifically, we created eight pictures depicting a first-person driving view, with four lower dynamism and four higher dynamism signs. We used four different driving scenes and backdrops. Participants were randomly assigned either to a condition with only lower dynamism signs or to a condition with only higher dynamism signs. We used eye-tracking technology to measure the time to first fixation, which is the time in milliseconds from when a scene is shown to a person until the person's eyes fixate the traffic sign. The eye-tracker results in study 3 support our hypotheses that static pictures with higher perceived movement are able to draw attention more quickly, resulting in an earlier fixation (vs. less dynamic signs).

Our findings show the behavioral consequences of perceived movement from static visuals. In four studies, using multiple methodologies and technologies, a higher dynamism (vs. lower dynamism) icon results in an earlier (studies 1a and 1b) or faster (studies 2 and 3) propensity to act.

Theoretically, our exposition of the effects of perceived movement on behavior provides a foundational framework for future research within consumer psychology and behavior. Finally, our studies show dynamic imagery to be an important and underexplored construct within both cognitive psychology and consumer behavior.

Dark is Durable, Light is Convenient: Color Value Influences Perceived Product Attributes

EXTENDED ABSTRACT

This research demonstrates that consumer perceptions of product attributes such as durability and convenience are malleable; they can be influenced by something as simple as the shade of color applied to the product's surface. Darker shades enhance the perception of durability, but lighter shades enhance the perception of convenience. Both effects arise because consumers associate darkness with weight (Alexander and Shansky 1976; Walker, Francis, and Walker 2010). We expect that when consumers imagine using heavy products (relying on their mental imagery), they tend to view them as more robust and durable, but less convenient or easy to handle, than lighter products. The current findings contribute to the literature on sensory and imagery phenomena in general (Krishna 2012) and color in specific (Bagchi and Cheema 2013; Gorn et al. 2004; Labrecque, Patrick, and Milne 2013), as well as durability and convenience (Berry, Seiders, and Grewal 2002; Bruce, Desai, and Staelin 2005).

The empirical investigation comprises seven experiments. First, three pilot studies are designed to replicate and add nuance to existing findings pertaining to the influence of color value (i.e., the degree of darkness or lightness in a given color, with black on the low-value end and white on the high-value end) on perceived weight. Next, four main studies shed light on the influence of color value on perceived convenience and durability.

Pilot Study A served as a preliminary investigation of the proposed variable underlying the influence of color value on perceived weight, namely, perceived density. Participants viewed a comparatively light (100% value) or dark (80% value) grayscale image of the same forest, and results revealed that the participants viewing the darker image perceived the forest to be denser. Pilot Study B extended this finding to the context of consumer products. It was designed to investigate the mediating role of perceived density in the influence of color value on perceived weight, while also ruling out an alternative explanation for the findings, namely, that the results might stem from a perception of contrast between target stimuli and background. Participants were randomly assigned to one of six conditions. On a computer screen, they viewed either a light (100% value) or dark (50% value) blue suitcase, placed next to an intermediate (75% value) blue suitcase. The intermediate suitcase served as a benchmark. Contrast was manipulated by displaying the background in one of the three identical shades used for the suitcases. The study was a 2 (color: light vs. dark) x 3 (background: light vs. dark vs. intermediate) between-subjects experiment. Results revealed that the suitcase with the darker (vs. lighter) color was perceived to be heavier, while there were no effects stemming from contrast. Similarly, the darker suitcase was perceived to be denser, and this perception of density mediated the influence of color value on perceived weight. Pilot Study C replicated this pattern of results, including the mediating role of density, but the experiment relied on colored blocks that the participants physically lifted before estimating their weight.

In Study 1A, participants viewed images of two red laptops that were identical in shape and color, except that the color of one was comparatively light (100% value) while the color of the other was comparatively dark (50% value). When given a goal of durability, a significantly larger proportion of participants chose the darker laptop, while also identifying it as the heavier one. In Study 1B, participants viewed the same two laptops but were given a goal of convenience. A significantly larger proportion of participants chose

the lighter-colored laptop, while identifying the darker-colored laptop as heavier.

In Study 2A, participants viewed either a light (100% value) or dark (50% value) blue suitcase, depending on randomly assigned condition, and they reported perceived durability and perceived weight of the suitcase. Results revealed that the darker-colored suitcase was perceived to be more durable as well as heavier than the lighter-colored suitcase. Further, perceived weight mediated the influence of color value on perceived durability. In Study 2B, participants viewed one of the same two suitcases from the previous study, and they reported perceived convenience and perceived weight of the suitcase. Results revealed that the darker-colored suitcase was perceived to be less convenient but heavier than the lighter-colored suitcase. Further, perceived weight mediated the influence of color value on perceived convenience.

In these seven studies, judgments related to density, heaviness, convenience, and durability changed systematically based on the color of the stimuli, showcasing the prominent role of visual imagery in altering the perceived qualities of an object. This research goes beyond prior literature in showing that the perception of usage-relevant attributes depends on product color, suggesting a more elaborate process than would be needed for the perception of basic physical properties such as weight. In each of the main studies, participants only viewed images and hence must base their perception of product attributes such as convenience on the imagined rather than actual use of the products. However, follow-up studies could be conducted to investigate whether these perceptions change when physically interacting with the products.

So Close I Can Almost Sense it: The Impact of Differences in Sensory Imagery Distance on Consumer Attitudes and Intentions

EXTENDED ABSTRACT

Sensory experiences, including sensory images (e.g., visual and haptic imagery), are difficult to compare to one another as they share few common dimensions. However, one underlying dimension that sensory experiences share and uniquely differ on is the distance from the stimulus required for perception (Rodaway 1994). Thus, for a stimulus to be perceived by the sense of touch it must be close to the individual, whereas for the same stimulus to be perceived visually, it may be further away. We propose and show that sensory imagery follows a similar pattern to actual perception on this distance dimension. Across four studies, we specifically highlight how images evoked using different sensory modalities affect both the perceived physical and psychological distances between the consumer and the stimulus, ultimately affecting attitudes and intentions. In general, more proximal (closer) sensory images lead to higher attitudes for physically or psychologically close experiences, whereas more distal (farther away) sensory images lead to higher attitudes for physically or psychologically distant experiences.

Pilot Study. With the pilot study we test whether the five senses differ in their imagined distance from a given stimulus. Forty participants were told to imagine a steak skillet using each of the five senses in randomized order (we chose food as it can be experienced with all of the senses). They then rated how far the skillet was away from themselves in their image (0-10 feet).

As hypothesized, taste was rated as the closest sensory image, followed by touch, smell, vision, and sound. The imagined distance for hearing did not differ from that of vision or smell. However, hearing, smell, and vision each significantly differed in distance from both touch and taste. Touch and taste did not differ from one another.

Thus, the results from the pilot study suggest that hearing, vision, and smell may be classified as more distal sensory experiences, with touch and taste classified as more proximal sensory experiences. We use this classification of sensory experiences in the subsequent studies.

Study 1A. In study 1a, we randomly assigned participants to use their sense of taste (proximal) or sense of vision (distal) to imagine all of the experiences they would have while visiting a restaurant. Our dependent variable measured how far the imagined restaurant was perceived to be from where participants lived (0-200 miles). We found that when participants were told to imagine a proximal sensory experience, they reported the distance of the restaurant to be significantly closer than those told to imagine a distal sensory experience ($M_{proximal}$=13.67, M_{distal}=29.96: p<.05).

Study 1B. In study 1b, participants read a restaurant review that contained either proximal (taste and touch) or distal (vision and sound) sensory experiences. Participants were shown a six-month calendar and were asked to indicate when they would like to make a reservation for the restaurant. This measure served as our dependent variable. We also measured attitudes toward the restaurant to ensure that any differences in temporal distance weren't attributable to differences in attitudes. There was no difference in attitudes resulting from the reviews (p>.5). However, there was a difference in the reservation date. When participants read the proximal review they made reservations significantly closer in the future than when they read the distal review ($M_{proximal}$=5.62 weeks, M_{distal}=9.50 weeks; p<.05).

Study 2. In study 2 we establish conditions of congruence and incongruence between sensory imagery and physical distance, and then explore the impact of the level of congruity on attitudes. We hypothesize that congruence between sensory imagery and physical distance will lead to higher attitudes than incongruence.

One hundred and seventy-five participants were told that they would be imagining a restaurant experience. Participants were randomly assigned to one of two physical distance conditions (city in which they live or different state). Next, they were randomly assigned to imagine all of the taste or visual experiences they would have at the restaurant. We captured attitudes toward the restaurant as our dependent variable.

As hypothesized, the interaction between sensory imagery and physical distance was significant (p=.02). Planned follow-up contrasts reveal that within the same-city condition, proximal imagery led to higher attitudes than distal imagery ($M_{proximal}$=8.06, M_{distal}=7.64; p=.09). Within the different-state condition, distal imagery led to higher attitudes than proximal imagery ($M_{proximal}$=7.32, M_{distal}=7.78; p=.07).

Study 3. One of the natural consumer contexts in which differences in sensory imagery proximity may be consequential is when comparing online versus in-person purchase decisions. In study 3, we explore this context. We propose that for an in-person (online) presentation proximal (distal) sensory imagery will lead to higher attitudes.

One hundred and fifty-seven undergraduates were told that they would be providing product evaluations for a toy football. Participants were randomly assigned to read one of two advertisements: a proximal advertisement focused on the touch experience of the football, or a distal advertisement focused on the sound the football made when squeezed. Next, participants were randomly assigned to either view the football in person, by opening a box to the side of the computer (but not to touch or move the football inside), or to view a picture of the football online. We captured their attitudes toward the football as our dependent variable.

The hypothesized interaction was significant ($p < .005$). Follow-up contrasts revealed that when the football was presented in-person, the proximal advertisement led to higher attitudes than the distal advertisement ($p<.01$). However, when the football was presented online, the distal advertisement led to higher attitudes than the proximal advertisement ($p=.13$).

Our findings across a pilot study and four additional studies suggest that the specific sensation consumers use to form their images can have important consequences on attitudes and intentions.

Sense and Mental Imagery: The Persuasive Implications of Visualizing Proximal and Distant Senses

EXTENDED ABSTRACT

Mental imagery is often treated as synonymous with visual imagery. Yet, as reflected in the mental-imagery scale developed by Betts (1909), mental imagery encompasses all of the senses: sight, sound, smell, touch and taste. Although it has been recognized that mental imagery can involve all five senses, the majority of research on mental imagery has concentrated upon visual imagery (Elder 2008; MacInnis and Price 1987). Consequently, it is unclear whether there are differences in imager evoked across these different senses, and if so, when one is more effective than the other. This research aims to address these questions.

Based on construal level theory, I derive predictions about referring to different senses is most persuasive and why. Psychological distance is egocentric, with the reference point being the individual in the present moment, and can vary depending on the degree of temporal, spatial, and social distance (Trope and Liberman 2010). Similarly, senses can be characterized in terms of distance from the individual. For instance, based on whether an item needs to be within an individual's reach in order to be sensed, smell and touch have been characterized as intimate senses, whereas hearing and sight have been characterized as distant senses (Rodaway 1994). Likewise, others have proposed that taste is most proximal because an object needs to be inside one's mouth in order to be tasted, followed by touch, smell, hearing and sight (Skurnik and George 1964; Trope and Liberman 2010). If senses vary in psychological distance, then referring to a sense should be more persuasive when it matches other dimensions of psychological distance (e.g., both sense distance and social distance are proximal). Furthermore, the underlying mechanism is proposed to be ability to vividly imagine the product. I predict that individuals will be better able to formulate a vivid mental image when sense distance matches the psychological distance of a different dimension (e.g., taste and present tense). I test these hypotheses in four experiments.

Study 1 examines 31,889 Yelp.com restaurant reviews posted in 2012. Consistent with prior research on online reviews, the key dependent variable was the number of "useful" votes a review received from readers (Chen and Lurie 2013). Furthermore, consistent with other research on online reviews (Ludwig et al. 2013), the text of the reviews were automatically coded using the linguistic inquiry and word count (LIWC) program (Pennebaker et al. 2007). The key independent variables extracted from the LIWC were mentions of present tense and mentions of sight and touch. As predicted, regression analyses yielded both a significant present x sight effect (b=-.02, p<.05), and present x touch effect (b=.02, p<.05), such that more mentions of sight (touch) led to more useful votes when there were also more (less) use of the present tense.

Study 2 extends these results with a lab study comparing a different pair of senses (sight and sound), and using a different dimension of psychological distance. 107 participants were randomly assigned to a condition in a 2 (social distance: pictures present vs. absent) x 2 (sense: sight and sound) experimental design. Because study 1 compared the most proximal sense (touch) to the most distant sense (sight), sound was chosen to provide the most conservative test of the hypothesis. All participants read an extremely favorable (5-star) review of a stereo written by a male who lived in the same city as where they attended school (to hold constant spatial distant). To manipulate social distance, consistent with past research indicating that pictures of reviewers can reduce social distance (Schlosser 2009), in the low (high) distance condition, a picture of the reviewer was present (absent). Sense was manipulated in the review itself. Using content from actual peer reviews of stereos posted on websites, two reviews were constructed that either discussed the favorable features of how the stereo looked or sounded. After reading the review, participants reported their attitudes toward the stereo as well as their perceptions of the reviewer. At the very end of the study, participants reported their demographic information. Participants' gender and whether they are a native English speaker were included as covariates in the analyses to control for any variation in social distance due to being of a different gender or nationality than the reviewer. As expected, the sense x social distance interaction was significant ($F(1,99)=4.85$, p<.05; $F(1,103)=4.24$, p<.05 without covariates). Attitudes were higher when sound was mentioned and social distance was low than high (Ms=5.64 vs. 5.11), whereas attitudes were higher when sight was mentioned and social distance was high than low (Ms=5.41 vs.5.20).

Study 3 further tests the hypothesis by comparing sight with touch, using a different manipulation of social distance as well as tests for mediation. 100 participants were randomly assigned to a condition in a 2 (social distance: own vs. different university) x 2 (sense: sight vs. touch) experimental design. Participants saw a screen capture of a website for a university sweatshirt that they were considering buying for a friend who either attended the participant's university (low social distance) or a different university (high social distance). General information about the sweatshirt was identical with the exception of being described in terms of touch ("See the difference") or sight ("Feel the difference"). In addition to product attitudes, participants also reported their intentions to buy the product and their attitudes toward the website. Finally, to test for mediation, participants completed a measure of how vivid their image of the product was. Replicating and extending the results of the prior studies, the sense x social distance interactions were significant for product attitudes, site attitudes and purchase intentions ($Fs(1,93)>4.98$, p<.05) with the cell means being in the predicted direction. Furthermore, sense x social distance significantly affected imagery vividness ($F(1,93)=4.27$, p<.05). Finally, bootstrapping methods suggest that imagery vividness is a significant mediator of the sense x social distance effect on attitudes and intentions (95% confidence intervals excluded zero).

Taken together, the results of three studies are suggestive that human senses can vary in psychological distance, thereby influencing how persuasive a message is.

SESSION OVERVIEW

Millions of consumers around the world have high-interest credit card debt. In the US alone, credit card use grew 50% in the last decade (US Census Bureau, 2010), with an average household credit card debt of $10,678 (a 29% increase from 2000; see Chu & Acohido, 2008). This growth in indebtedness has not only had a devastating effect on individuals' personal finances, but has also been associated with increased negative affect (Silvera et al., 2008), lower life satisfaction (Norvilitis et al., 2006), greater instances of domestic violence (Fox et al., 2002) and even suicide (Yip et al., 2007). Despite the ubiquity of indebtedness, many essential questions about credit card use and debt repayment are just coming under the lens of consumer research. This symposium will present cutting-edge research on the psychological underpinnings on using credit, and new insights toward repayment motivation and behavior, with an emphasis on how to reduce consumer indebtedness.

First, Cryder will explore why using credit is so alluring. Cryder's research reveals that the term 'credit' prompts consumers to mentally code credit as a gain, changing the psychophysical representations of spending. A 'credit' (relative to a 'loan') mindset prompted consumers to respond quicker to gain-oriented words, view credit as a larger windfall gain, increased consumer happiness and resulted in additional interest in spending. These findings highlight how credit card terminology may introduce ambiguity to psychological processes of spending, encouraging consumers to feel as if they are spending a windfall gain, rather than incurring a loss, which may contribute to overspending and buildup of debt. Second, Kettle will examine how consumer motivation to repay existing credit card debt is affected by their repayment strategy. Using credit card data and online experiments, Kettle's research shows that the most effective strategy is for consumers to focus their debt payments on a single debt (rather than simultaneously repaying many debts). This focused pursuit leads consumers to perceive greater progress and increases motivation to repay. Third, Donnelly demonstrates that consumers pay more toward their credit card debt if they are given the option of paying off specific purchases, rather than making a payment on

the aggregated balance. When given the option consumers prioritize payment of more 'painful' purchases- splurges and interest charges.

Building on these findings, our symposium next examines real relationships between a credit card company and its customers. Mazar will present findings from a large-scale field experiment with over 500,000 delinquency instances, in which she manipulated the interactive voice recording message that reminds customers of their past dues. Mazar shows that creating a sense of urgency, targeting debt literacy, and helping customers to form implementation intentions substantially decreased delinquency and the time to repay one's past dues.

Spending too much on credit, making insufficient payment and missing the payment due date can prove costly to consumers, potentially resulting in long-term consequences. Together, the talks in this symposium will shed light on the benefits produced by small interventions grounded in judgment and decision-making that may significantly help consumers combat their debt.

Spending Credit Like a Windfall Gain

EXTENDED ABSTRACT

Credit card debt plays a significant role in total consumer debt, totaling $4,530 of average debt per credit card holder in 2011 (Federal Reserve Bank, 2010; 2011). Credit cards pose multiple challenges to consumers. First, credit cards have high interest rates: once consumers have accrued credit card debt it is expensive to pay off. Another challenge posed by credit cards is that, at least in some cases, credit cards encourage consumers to spend more in the first place, imposing a "credit card premium" (Feinberg 1986; Raghubir and Srivistava 2008; Prelec and Simester, 2001; Soman 2003).

The "credit card premium" describes the tendency for consumers to spend more, up to 100% more, with credit cards compared to other spending currency such as cash (e.g., Feinberg 1986; Prelec and Simester 2001). Lower liquidity constraints, deferral of payment (Laibson 1997; Soman 2001), and decreased transparency of the payment amount (Soman 2003) combine to partially explain the credit card premium. However, we propose that there is an additional contributing factor that remains to be understood. Specifically, we hypothesize that using the term "credit" changes psychophysical representations of spending. Whereas typical spending is coded as a loss, we hypothesize that the term "credit" prompts consumers to mentally code credit as a gain. Therefore, spending credit is psychologically represented as the reduction of a gain, a hedonically less painful prospect than incurring an equivalently sized loss (Kahneman and Tversky, 1979). We test this idea in five experiments.

Experiment 1 used a Lexical Decision task to compare the term "credit" with a financial term that implies a similar arrangement, "loan". Structural differences between these two financial instruments should, if anything, encourage consumers to be more likely to view a loan as a windfall because loan money tends to be in-hand whereas credit money is merely accessible. Nevertheless, we predicted that consumers primed with credit would be more likely to exhibit associations with gains.

Participants first read financially relevant sentences that included the word "credit", the word "loan", or were control sentences. They then judged whether flashed configurations of letters were words or non-words. Participants were marginally significantly

more likely to accurately identify gain-related words when they were primed with "credit" as opposed to "loan" or with control sentences. Additionally, participants primed with "credit" were significantly more likely to accurately identify gain-related words compared to loss-related words or filler words. This pattern did not exist in the "loan" nor control conditions.

Experiment 2A tested whether consumers offered a line of credit represent that account as a gain more frequently than do consumers who are offered an equivalently structured loan. In Experiment 2A, participants were either asked to imagine that they had received a $500 "line of credit" or a $500 "loan." They then were asked to imagine what their account would look like as represented by a bar graph. Next, participants were shown two bar graphs, one with a bar representing $500 shown as a gain, and the other with the bar representing $500 shown as a loss. Participants were asked to choose which graph was the closest to their mental representation of their account. Participants in the "credit" condition were significantly more likely to choose the graph with the bar representing a gain than were participants in the "loan" condition.

Experiment 2B tested the same idea, but used a tightly controlled comparison between a $500 "credit account" versus a $500 "account" described in equivalent terms. Participants in the "credit account" condition were significantly more likely to choose the graph with the bar representing a gain than were participants in the "account" condition.

Experiment 3 investigated the idea that the term "credit" prompts consumers

consider themselves more favorably in terms of subjective gains or well-being. Participants indicated to what extent their happiness would change after receiving a $500 line of credit versus a $500 loan. Participants who imagined receiving a line of credit reported a significant increase in happiness whereas participants in the loan condition reported no change; this difference was significant between conditions.

Finally, experiment 4 examined anticipated spending. Participants who imagined that they had received a $500 line of credit versus a $500 loan predicted that they would be more likely to purchase a $50 DVD set and a $250 plane ticket.

Using a credit card incurs a financial loss. Yet, credit card terminology introduces ambiguity to the psychological process of spending that encourages consumers to feel as if they are spending down a windfall gain rather than incurring a loss. Such ambiguity may contribute to overspending and over time, to the excessive buildup of consumer debt.

Debt Repayment Strategy and Consumer Motivation to Get Out of Debt

EXTENDED ABSTRACT

Consumers with problematic levels of debt tend to have multiple sources of debt, and must regularly decide how to allocate repayments across their debt accounts. We examine how the allocation of a consumer's debt repayments influences their subsequent motivation to get out of debt. We theorize that paying down debt accounts sequentially (focusing repayments on one account at a time) rather than simultaneously (spreading repayments out across accounts) causes consumers to perceive greater progress which, in turn, increases their motivation to repay their debt. Evidence from a large consumer debt data set and two experiments provides strong support for the proposed process.

We obtained a dataset (from HelloWallet.com) with a total of 68,858 rows, each representing a separate month for each credit card account (with a revolving balance) for a total of 2,522 clients. In every month, we measure how their repayments varied from entirely simultaneous (all repayments equal across all accounts) to entirely sequential (only one repayment is made across the indebted accounts). Our measure is based on the Index of Dispersion (Cox and Lewis 1966) and, once normalized, is a continuous score bounded between 0 and 1, where 0 indicates a completely simultaneous strategy and 1 indicates a completely sequential strategy.

We analyzed the effect of debt repayment strategy in month t on the total amount of repayments in the subsequent month ($t + 1$), while including fixed effects for a consumer's total debt, number of credit cards, credit card spending, and total debt repayment. In support of our theoretical account, the use of a more sequentially oriented repayment strategy has a positive influence on one's debt repayment in the subsequent month. This effect is robust to varying levels of indebtedness, credit card spending, and repayment amounts.

To test the proposed psychological process, we conducted two experiments that examined the effect of different debt repayment strategies on consumers' perceptions of progress and motivation to repay debt. We presented participants with a hypothetical debt repayment scenario, and independently manipulated the total amount of debt repaid and how that amount was allocated across their debt accounts. In support of our theoretical account, participants who had been randomly assigned to more sequential debt repayment strategy perceived greater progress toward the goal of getting out of debt and indicated greater motivation to repay their debt, and perceived progress mediated the effect of debt repayment strategy on motivation.

This is the first research to examine the psychological mechanisms underlying the relationship between debt repayment strategy and motivation to repay debt, and is the first to consider the motivational effects of paying down accounts gradually, as opposed to the discrete events of paying such accounts off altogether. This latter distinction is very important because while closing out a revolving debt account is a very rare event, indebted consumers do regularly make repayments towards their debt accounts, and it is thus important to understand how the ongoing repayment of debt accounts influences the motivation of indebted consumers.

Balance Reframing: Paying by the Purchase Promoted Higher Payments

EXTENDED ABSTRACT

Consumers treat credit differently than other forms of payment. People spend more when using credit cards compared to cash or checks (e.g., Rick, Cryder & Loewenstein, 2008). Possibly, the reason credit cards increase spending is because they allow the consumer to separate the pleasure of buying from the "pain of paying" (i.e., the discomfort of spending money; see Prelec & Loewenstein, 1998), and make the true cost of each purchase more difficult to evaluate by compiling all consumption in a monthly bill (Raghubir & Srivastava, 2008). This strategy relies on insights from prospect theory and the value curve proposed by Kahneman and Tversky (1979). The value curve proposes that humans are sensitive to changes or differences in wealth rather than absolute magnitudes, and that losses loom larger than gains. Considering that credit card companies pool many small losses into one larger loss, they are able to reduce the total loss felt by a consumer (Thaler, 1985).

While this strategy has likely contributed to the accumulation of debt, recent research concerning debt repayment has suggested that aggregated debt balances are overwhelming and difficult to repay. For instance, when consumers are confronted with multiple debts they often prioritize the debt with the smallest balance first (even

when this is not the most financially optimal strategy; see Amar et al., 2011). This tendency is aligned with the literature on sub-goals, suggesting that a short, proximal task will help fuel commitment toward subsequent larger tasks. In fact, a consumer who prioritizes repaying the smallest balance is 14% more likely to become debt free than a consumer who consistently targets the largest balance debt (Gal & McShane, 2012). Further, research has suggested that information presented to consumers at the time of repayment influences repayment decisions. For instance, repayers anchor on the minimum payment requirement (Navarro-Martinez et al., 2011).

Given these conditions, the current study proposes that segregating losses, by allowing consumers to make payments toward each individual purchase on a credit card bill could increase feelings of loss, resulting in increased repayment. The saliency of each cost may (a) increase the pain of parting with money and increase the motivation to repay the purchase, and (b) change perceptions of the manageability of the debt because this process breaks down the charge into smaller pieces.

We presented consumers with a hypothetical purchasing scenario where they made purchases in certain categories (i.e., vacation, clothing). Participants were told that all of these purchases were made on a credit card and were saddled with the same amount of debt. Consumers were presented with either an aggregated debt balance, or an aggregated debt balance with line items that composed the debt (segregating the losses of the debt). Consumers who saw line items were able to allocate money towards certain purchases, while those who saw the aggregated balance were only able to allocate toward the total balance. Consumers who were able to repay toward specific purchases allocated more money toward debt repayment (M = \$561.64), than those who paid toward the aggregated balance (M = \$473.50), p < .001 (a near 19% increase in repayment).

In another scenario, consumers were presented with the same hypothetical purchasing task but were told that half of the purchases were made on a credit card that allowed purchasing toward the individual purchases, while half were made on a credit card that allowed purchasing on the total balance. Consumers paid significantly more toward the card that allowed repayment toward specific purchases (M = \$333.01), relative to the card that allowed repayment toward the total balance (M = \$131.75), p < .001 (a near 153% increase in allocation). Consumers perceived the card that allowed payments on the whole balance as bigger than the card that allowed payments toward specific purchases t (179) = 2.36, p = .019.

Consumers who were given the option to repay toward specific purchases prioritized payments toward interest charges and vacations. Previous research has suggested that consumers prefer to pay off vacations prior to the trip because paying for purchases after the benefits have been received is averse (Hirst et al., 1997). Our findings suggest that when given the option, consumers will make payments toward items they find aversive, or where losses loom larger. Nearly 40% of consumers expressed interest in switching to a credit card that allowed for repayment by the purchase, and this effect was even larger (50%) for consumers who maintain a credit card balance from month-to-month, suggesting that this method might have increased benefits to individuals who struggle with repaying their debts.

Applying Behavioral Science in the Field: Nudging Customers to Pay Their Credit Card Dues

EXTENDED ABSTRACT

Consumer loans, in principle, serve an important function in society benefiting both consumers and lenders (Shapiro, 2011; Skiba, 2012). In particular, using credit cards can help consumers to manage cash flow and expand their financial capabilities. At the same time, credit card loans can also be costly to both consumers and lenders. For consumers who do not pay off their balance in full each month debt can quickly spiral out of control due to accumulating daily interest charges on their outstanding debt. In addition, consumers, who do not make their monthly minimum payment (also referred to on monthly statements as "total due"), become delinquent, which usually results in late fees and potentially downgraded credit scores. The lenders on their side face the risk of not being able to recuperate their loans in case of consumer defaults. In this project we focus on testing interventions that might be helpful in diverting such potential lose-lose situations of delinquency for both lenders and borrowers.

In an effort to avoid such damaging and expensive actions, once a card holder has missed one monthly minimum payment and therefore becomes delinquent, credit card companies often make use of interactive voice recording messages (IVR) to make borrowers aware of their total due amount and prompt them to pay it such that their accounts are no longer delinquent (i.e. their accounts move from being "past due" to become "current"). To the extent that IVRs are effective, they can be an economical way to intervene early on in the delinquency process, and potentially eliminate some of its negative consequence.

Standard IVR messages typically tend to assume that the account holder has full information, experience, and knowledge and, therefore, if anything, all they need is to be reminded of their lapse (i.e. that they have a total due amount). While this reminder-approach has merit, it ignores the possibility that the individuals facing delinquency have low levels of financial and debt literacy (Soman and Mazar, 2012). For example, according to a 2009 National Financial Capability Study (FINRA Investor Education Foundation, 2012), people low on financial literacy are significantly more likely to engage in negative (i.e. costly) credit card behaviors. Yet, only about two-thirds of Americans are estimated not to comprehend the workings of credit cards (Lusardi and Tufon, 2009). Thus, one of the main goals of the current research is to test the potential benefits of a script that is focused on better explaining the situation and the actions needed to resolve it.

In addition to the potential limiting effect of debt literacy, there are other possible barriers that could prevent delinquent customer from repaying their debt. For one, it is possible that while repaying their debt is generally desirable, that this intention is not sufficient to create a repayment action. In this regard, it has been shown that helping people to make plans (i.e. forming implementation intentions; Gollwitzer, 1999; Gollwitzer, Bayer, and McCulloch, 2005; Gollwitzer and Sheeran, 2006; Milkman et al., 2011; Nickerson and Rogers, 2010) and making them actively commit to their intentions (Cialdini and Goldstein, 2004; Shu et al., 2012) can increase their likelihood of following through on these plans. These findings have powerful implications for interventions directed toward increasing socially important behaviors that individuals intend to, but often fail to, perform. Thus, in addition to providing delinquent customers with an explanation of their situation and the actions needed to resolve it (debt literacy), we also tested the effect of creating implementation-intentions for their debt repayment (implementation intentions), and the effect of prompting a promise to repay (active commitment).

Together with a North American credit card company that has a substantial share of higher risk subprime customers (i.e. customers of lower credit quality) we tested the effects of five variations of the traditional IVR message (control condition) on customers' likelihood and speed to make payments on their account such that they were no longer delinquent.

The results from our large-scale field experiment conducted over 9 months with over 500,000 call observations suggest that small and fairly cheap changes to an automated IVR message can significantly alter behavior: they can increase the likelihood and speed to pay current a delinquent credit card account. Specifically, our results show that creating a sense of urgency, coupled with a focus on debt literacy and the formation of implementation intentions reduced delinquency by 3.3% (in absolute percentage points) and increased the average speed by which delinquent account holders set their accounts in order by almost a full day (0.9 days).

While it is possible that the improvement in repayment to the focal credit card accounts was done at the expense of other debts, the results suggest that delinquency is not simply an outcome of either forgetting or sheer inability to make a payment. Instead, delinquency might also be due to a lack of understanding or awareness of its meaning as well as non-specific plans to follow through on one's payment intentions.

SESSION OVERVIEW

Planning has been argued to be beneficial for improving consumer welfare, ensuring people are more motivated to pursue their goals such as exercising more and saving more money (Lusardi and Mitchell 2007; Sniehotta et al. 2005). Prior research has investigated how goal characteristics and planning interact to influences motivation and goal pursuit (Bagozzi and Dholakia 1999). For instance, Earley and Perry (1987) found that people given specific challenging goals do more task planning than those without such goals. Townsend and Liu (2012) showed that planning can backfire and lessen self-control when consumers are far away from achieving their goals.

The proposed session brings together four papers that provide new insights into the interplay effects of goals and planning on consumer welfare. The opening paper by David and Haws investigates how the "inclusion" plans focusing on goal-consistent behavior (e.g., eating healthy food) differ from the exclusion plans focusing on goal-inconsistent behavior (e.g., avoiding unhealthy foods) in influencing healthy eating. They find that high-control consumers are more likely to develop and benefit from inclusion plans. Although low-control consumers tend to develop exclusion plans, they select more healthy food when they have inclusion plans.

Second, Bayuk and Laran examine how planning interacts with goal difficulty to influence consumer motivation to live healthier. They show that planning makes the pursuit of easy goals even easier, which decreases motivation to pursue the goal. When a goal is moderately difficult to reach, planning facilitates goal pursuit by making people believe the goal is important and requires effort to achieve.

Third, Huettl, Kovacheva, and Inman focus on failed purchases in a large-scale field study and identify trip, shopper, and product category characteristics that predict why some purchases were planned but not fulfilled. They also find that customer satisfaction with the retailer decreases when shoppers fail to achieve these planned shopping goals.

Finally, Huang, Dholakia, and Tam investigate how planning in the first domain influences consumers' motivation to plan in a second domain. They find that when people form an abstract plan and answer questions regarding why their goal is important, they are more motivated to plan for a second irrelevant domain (e.g., living a healthy life style) compared with when they form a concrete plan where they specify all the event details.

Overall, these papers highlight several new insights into how goals interact with planning to impact consumer welfare using a wide range of research methodologies (longitudinal surveys, field and lab experiments). Giving the relevance of these topics to consumers, marketers, and public policy makers, we believe this session will appeal to a broad ACR audience who are interested in consumer planning, goals, self-control, self-regulation, consumer welfare, in-store decision making, learning, and anyone who is fascinated by the factors that affect their goal achievement.

Saying "No" to Cake or "Yes" to Kale: Plans to Exclude or Include Foods to Reach Health Goals

EXTENDED ABSTRACT

Research in self-control demonstrates the importance of specific goals and plans for achieving these goals. Although many strategies for goal pursuit have been examined (Hoch and Loewenstein 1991), a fundamental distinction that deserves further attention is whether the pursuit plans focus on acceptable (a positive focus) or unacceptable (a negative focus) behaviors. As such, we examine the adoption and use of "inclusion" versus "exclusion" plans with respect to eating behaviors. Fundamentally, focusing on what one should do versus should not do is quite different psychologically, and likely leads to differential effectiveness, yet advice abounds regarding "the best foods for your health" or "foods you should never eat." To better understand the effectiveness of these systematically different types of plans, we focus on differences based upon individuals' propensities for self-control (Hofmann et al. 2012).

We advance novel contributions by integrating important considerations for inclusion or exclusion-focused self-control strategies based on individual differences in self-control (measured by the Tangney et al. 2004 GSC scale in all three studies). First, we predict and find that high self-control individuals tend to establish plans that encourage goal-consistent behavior (inclusion strategies), focusing on what they *should* do; whereas, low self-control individuals more naturally use plans that attempt to discourage goal-inconsistent behavior (exclusion strategies), instead focusing on what they *should not* do, likely making it even harder to resist. Second, for high self-control individuals, inclusion plans foster goal commitment. Third, although low self-control individuals report higher commitment to exclusion plans, these individuals make more healthy choices when they have inclusion plans. Overall, the findings suggest inclusion-based plans are more effective, and yet these are uncommon for those who struggle the most to maintain control.

In study 1, participants were prompted to list specific rules they use to guide their food consumption. Participants then evaluated 23 specific strategies created by the authors from online sources providing healthy-eating guidelines. Participants indicated how often they used each strategy. The open-ended rules were coded for inclusion versus exclusion plans. We found that lower self-control individuals were more likely to use exclusion plans than were those high in self-control, who instead showed a propensity to use inclusion plans. Responses to the list of provided strategies revealed that the use of ex-

clusion plans was strongly associated with lower self-control, while the use of inclusion plans was more strongly associated with higher self-control. As such, study 1 establishes important fundamental differences in the inclusion versus exclusion nature of plans developed by those higher or lower in self-control.

Study 2 was a longitudinal study designed to assess commitment to goals following development of inclusion versus exclusion plans. Participants were exposed to one of three experimental conditions: inclusion plans (i.e., focusing on foods that should be eaten), exclusion plans (i.e., focusing on foods that should not be eaten), and a control condition (no plan). After three weeks, participants indicated how committed they were to meeting their goal. The results reveal that, low (high) self-control individuals with exclusion plans were more (less) committed than those with inclusion plans. In addition, in the inclusion condition, high self-control individuals were more committed than those low in self-control; whereas, in the exclusion condition, commitment did not differ as a function of individual-level self-control. We also found that, among low self-control individuals, inclusion plans may have the same effect as having no strategy; whereas, among high self-control individuals, exclusion plans operate in a manner similar to having no specific strategy. We next examine the impact on plan development, liking of foods planned to be included or excluded, and subsequent food choices.

Study 3 asked participants to imagine that they were pursuing a health related goal. We manipulated pursuit strategies using the same procedure as in study 2. To ascertain how effective participants' were in developing lists that would be motivating, participants were later presented with the specific items that they had listed and were asked to indicate how much they liked each item. After several unrelated tasks, participants were presented with a list of 16 hypothetical snack choices (8 healthy and 8 unhealthy; Laran 2009) that they could receive for their participation and were asked to indicate their top five choices. The results reveal that low self-control individuals listed more food items in the exclusion condition, whereas high self-control individuals listed more items in the inclusion condition. Interestingly, high self-control individuals who were in the inclusion condition liked their listed items more than those who were in the exclusion condition, showing a tendency to focus on favored items to approach. In addition, in the exclusion condition, low self-control individuals report higher liking of their listed items than high self-control individuals, showing that they were focusing on items that were very attractive to them, likely increasing the difficulty of resisting them. We also found that low self-control individuals selected a higher number of healthy items in the inclusion condition than in the control condition. Thus, although low self-control individuals tended to focus on foods they really liked but that should not be eaten, these individuals could enhance their progress by focusing instead on foods that they should eat.

Our research advances new insights into the application of self-control strategies, specifically those involving inclusion or exclusion plans. We demonstrate that individuals higher in self-control utilize more positive (inclusion-related) plans. In addition, we provide evidence suggesting that, through the use of inclusion-related plans, individuals lower in self-control may be able to enhance their goal-related performance.

It's Just Too Easy: How Planning Affects Perceived Effort, Goal Value, and Motivation

EXTENDED ABSTRACT

Most existing research that examines at the impact of forming plans on goal pursuit suggests that plans are helpful (e.g., Gollwitzer and Sheeran 2006). Yet, recent research examining goals such as losing weight and saving money suggests that plans are not universally beneficial. For instance, Townsend and Liu (2012) find that those in poor standing actually exhibit less self-control when they form plans versus when they do not. Buehler and Griffin (2003) and Spiller and Lynch (2010) examine holiday shopping behavior and find that both (1) increased propensity to plan for the future and (2) forming detailed time plans are associated with greater planning fallacy. Bayuk et al. (2010) show that planners are less likely to consider alternative means to attain the same goal versus non-planners. These findings suggest that plans benefit consumers in their goal pursuits in some situations but not in others.

We propose that the difficulty of the goal moderates the beneficial effects of planning. Forming a plan increases the salience of the actions that need to be taken to achieve the goal. Since people tend to value things that require effort, to a certain point (Brehm and Wright 1989; Labroo and Kim 2009), we suggest that planning influences perceptions of effort and motivation differently depending on the level of goal difficulty. We show that when planning makes the necessary behaviors seem less effortful, motivation to pursue the goal decreases. When planning makes the necessary behaviors seem more effortful, motivation to pursue the goal increases.

Specifically, we propose that when the goal is relatively easy, planning should lead people to feel that the necessary actions require minimal effort. Thus, planners (vs. non-planners) should be less motivated to pursue the goal or engage in goal-consistent behaviors. When the goal is of moderate difficulty, planning should lead people to feel that the necessary actions are effortful. Based on our conceptualization, planners (vs. non-planners) should be more motivated to pursue the goal. Lastly, when the goal is of extreme difficulty, planning should lead people to feel that the necessary actions are tremendously effortful, but that this feeling is also present for people who think about the goal but don't form a plan. Therefore, both planners and non-planners should be, overall, less motivated to pursue the goal and less likely to engage in a goal-consistent behavior. We test our hypotheses in several studies looking at goals such as being physically fit and being healthy, where we both measure and manipulate goal difficulty.

Study 1 (N = 163) examined a common student goal – to be physically fit. Participants were told that a governmental agency is promoting a challenge across universities to see whether people can manage to lose weight and be physically fit, where the challenge will involve losing 8 pounds. Next, participants either wrote a plan about how they would accomplish such a goal or, in the control condition, wrote about everything that comes to mind for the same period of time. As the key dependent variable, participants were asked if they would participate in such a challenge should it come to their university. Lastly, participants selected whether this goal would be relatively easy, moderately difficult or extremely difficult to achieve. When participants felt the goal would be relatively easy, planners (22.6%) were less likely to participate in the challenge than non-planners (39.3%; *p* = .04). When the goal seemed moderately difficult, planners (70.6%) were more likely to participate in the challenge than non-planners (53.9%; *p* = .03). When the goal seemed extremely difficult, both planners (23.5%) and non-planners were equally unlikely to participate in the challenge (19.0%; *p* = .52).

Study 2 (N = 219) examined the goal of being healthy. First, participants wrote about the importance of being healthy, eating healthy and cutting calories to increase the salience of the goal. Next, they were told that reducing the number of calories they consume is a crucial step to eating healthier. They were assigned to decrease their calorie intake by 300, 700, or 900 calories, which were

pre-determined to be the number of calories other participants felt would be relatively easy, moderately difficult, or extremely difficult to eliminate from their diet. Some participants formed a detailed plan of how they will pursue this goal, whereas others spent an equivalent amount of time writing about how they spent their prior day. Following an unrelated fifteen-minute filler task, participants were told to exit through a side door where a student was doing school work and had a visible bowl of miniature candy bars on her desk. Each participant was offered to take as many as he or she wants under the pretense that these are department holiday candy, while the number of candies taken was secretly recorded and was the key dependent variable. When the goal was easy (improving diet by 300 calories), planners (1.46) took significantly more candy bars than non-planners (.61; $p < .01$). When the goal was of moderate difficulty (improving diet by 700 calories), planners (.48) took significantly fewer candy bars than non-planners (1; $p = .01$). Lastly, when the goal was extremely difficult (improving diet by 900 calories), there was no significant difference among planners (1.19) and non-planners in the number of candy bars they picked up (1.44; $p = .26$).

This work contributes to prior research on the impact of planning on goal pursuit. We demonstrate that forming a plan can increase or decrease peoples' likelihood to engage in goal consistent actions and their motivation to pursue the goal, and show that the relationship between planning and goal pursuit often depends on the difficulty of the goal.

Planned but Not Purchased? A Field Study of Drivers and Consequences of Failed Purchases

EXTENDED ABSTRACT

When investigating shopping behaviors that show deviations from shoppers' plans, research has focused on unplanned purchases (e.g., Inman et al. 2009; Kollat and Willett 1967). However, little is known about the purchases consumers plan but do not complete (Park et al. 1989). These "failed" purchases have important implications, as they suggest a lost opportunity for purchase conversion and revenue. To the best of our knowledge, our research is the first that comprehensively examines the drivers and consequences of failed purchases in a field study.

We define failed purchases as products that were planned at the beginning of the shopping trip (i.e. explicitly identified as planned by the shopper, see Inman et al. 2009) but were neither substituted nor bought by the end of the trip. In this analysis we focus on three groups of factors – shopper characteristics (shopping enjoyment, price sensitivity, and propensity to plan), trip aspects (duration, number of aisles, and availability of a written list), and category characteristics (fresh, refrigerated, frozen, and hedonic categories).

Research has shown that consumers who extract hedonic value from shopping are more impulsive (e.g., Beatty and Ferrell 1998) and more receptive to in-store stimuli. The more product and display information shoppers take in, the more likely they are to deliberately change their plans or to become distracted and forget about them. Thus, we expect that shopping enjoyment will lead to more failed purchases (H1). Furthermore, we hypothesize that price-sensitive consumers will prioritize the goal of paying low prices over the goal of acquiring products. Therefore, we predict that higher price sensitivity will lead to a greater number of failed purchases (H2). Since research on the "intention-behavior gap" has shown that detailed action planning mediates intentions and behavior (Sniehotta et al. 2005), we argue that individuals' chronic tendency to plan positively impacts plan fulfillment (H3).

The influence of shopping trip duration on unplanned purchases is well established in the literature (e.g., Inman et al. 2009). The longer consumers shop, the more they are exposed to in-store stimuli which may ultimately diminish their self-regulatory resources (Muraven and Baumeister 2000). Consequently, longer trips are associated with a greater number of failed purchases as the consumer is less likely to stick to her plan (H4). Similarly, the more aisles shopped, the greater the number of stimuli the shopper is exposed to and therefore, the higher the likelihood of unpurchased items (H5). Finally, we predict that a written list will help the shopper to follow through (H6), since research indicated that the explicit form of a plan fosters its attainment (Sniehotta et al. 2005). Moreover, having a written list suggests that shopping goals are concrete which makes it harder to influence shopping behavior (Lee and Ariely 2006).

While failed purchases directly impact retailers' revenues, we investigate a less obvious consequence – shopper's satisfaction with the store. Research has shown that when individuals experience goal failure, dissatisfaction with the task results (Locke and Latham 1990). Furthermore, consumers are likely to direct their disappointment from product failure or stockouts towards the manufacturer or retailer (Folkes 1984; Fitzsimons 2000). Thus, we expect that the greater the number of failed purchases, the lower the satisfaction with the store (H7). Furthermore, we argue that the detrimental effect on satisfaction is even stronger when a written list is used (H8). Since the written list represents the shopper's commitment to her plan, it explicitly documents the discrepancy between intention and result, thus increasing the shopper's disappointment.

To test our hypotheses, we use data from 2401 shoppers from the 2012 shopper intercept study conducted by the Point of Purchase Advertising Institute (POPAI). Before entering the store, shoppers indicated their planned purchases. Once shoppers completed their trips, interviewers copied the receipts and collected information about personality traits, trip characteristics, and overall store satisfaction. We find that 18% of planned purchases do not make it to the shopper's cart. To test our predictions regarding the drivers of failed purchases, we estimated a hierarchical model since the data represent a multilevel structure (i.e., purchases nested within shoppers). The dependent variable is type of purchase (planned, failed, unplanned, or substitute) and, for the results presented here, it represents the probability of a failed vs. a planned purchase. To analyze the effects of failed purchases on satisfaction, we used regression analyses.

Our results show that shopping enjoyment, price sensitivity, adjusted trip duration, and number of aisles shopped increase the probability of failed purchases. Conversely, general propensity to plan and the use of a written shopping list decrease this probability. Interestingly, we find that shoppers who are price sensitive but also enjoy shopping are more likely to fulfill their plans. At the category level, we find that failed purchases are less likely to be fresh or refrigerated but more likely to be frozen products. Additionally, our analysis on satisfaction supports our prediction that failed purchases lead to lower satisfaction with the retailer. As expected, we find that having a written list accentuates the detrimental effect of failed purchases.

Taken together, our results demonstrate that a number of shopper, trip and category factors influence the incidence of failed purchases. More importantly, failure to follow through with one's shopping plan is associated with lower satisfaction with the store. Thus, failed purchases cause a "double whammy" for retailers. Not only is there a loss of profits due to the unpurchased items, but a potentially even greater loss due to dissatisfied shoppers who may migrate or spread negative word-of-mouth. Interestingly, we find that having a shopping list is a double-edged sword: it helps shoppers to complete

their plans but it also makes plan failures more salient. In conclusion, our research is the first to provide a comprehensive view on a scarcely researched but important component of in-store decision making.

A Metacognitive Perspective on the Motivational Benefits of Planning Across Domains

EXTENDED ABSTRACT

Consumers often make plans sequentially in different, unrelated domains. For instance, they may plan a vacation, then decide on their grocery shopping for the week. What effects does planning in one domain have on subsequent planning in a different domain? In this research, we examine how different types of plans made in the first domain influence motivation to plan in the second domain. Prior literature has demonstrated the positive role of planning in achieving goals such as exercising more (Sniehotta et al. 2005) and following beneficial medical routine (Gollwitzer and Oettingen 2007). Planning helps people develop and implement behavioral intentions (Gollwitzer 1999). However, whether benefits of planning can be "transferred" from the first domain to the second one is an open question. We are particularly interested in the role of two types of plans, concrete versus abstract.

Learning or skill transfer is an important component of many consumer behaviors (e.g., Hutchinson and Eisenstein 2008). Prior literature on learning and problem solving suggests that transfer often does not occur between conceptually similar but perceptually different problems because people cannot make connections between situations that have different surface structures (Barnett and Ceci 2002). Ways of facilitating transfer across domains focus on getting participants to work with training materials at a deep or strategic level (Gick and Holyoak 1980). More generally, learning metacognitive strategies such as analytical thinking, self-explanation, and self-regulation often leads to successful transfer (Halpern 1998).

We hypothesize that when compared with concrete planning where people specify all event details, abstract planning where people answer questions regarding why their goal is important to them will be more effective in enhancing motivation to plan in a second unrelated domain. The reasons for this proposition are three-fold. First, answering the "why" question encourages people to focus on causal relationships that connect actions to outcomes. This metacognitive justification process has been shown to improve consumers' performance beyond that of simply verbalization or specifying a plan (Huang and Hutchinson 2013). Furthermore, thinking about why the desired goal is important might prime "importance" and make people regard the second domain as important (Chartrand and Bargh 1996). Second, thinking in an abstract way makes people forward-looking and focus more on the future (Fujita et al. 2006). Third, asking people to specify their plans may encourage them to put too much emphasis on specifics of the original plan, which might increase their perceived difference between the two irrelevant domains as they pay much attention on the surface features (Barnett and Ceci 2002).

We tested these hypotheses in three studies. In Study 1 (N=155), we randomly assigned participants to three conditions: concrete planning, abstract planning, and control. In both planning conditions, participants created a detailed plan for a forthcoming event. In concrete planning condition, participants provided details such as when, where, with whom, and specific activities they would engage in. In abstract planning condition, participants answered why the event was important to them, the overall goal and specific objectives they wanted to achieve, and why these goals were important to them. The control group participants did nothing at this stage. All

participants were then asked to indicate their motivation to plan to live a healthy life style next month by answering questions including effort they would put into developing a plan, the importance of developing an effective plan, motivation to engage in activities to live a healthy life, and effort to fit living a healthy life style into their daily schedule. Consistent with our hypothesis, people forming an abstract plan (including "why") in the first domain demonstrated the greatest motivation to plan living a healthy life style when compared with both concrete and control conditions ($ps <. 05$); there was no difference between the latter two conditions.

In Study 2 (N=257), we added one abstract-without-why condition where people answered similar questions as in the original abstract planning condition without the questions of why the event and the goals they would achieve were important. It was found that forming an abstract plan without answering the "why" question was not as effective as the original abstract condition and did not differ from either the concrete or control conditions in increasing people's motivation to plan for a second domain.

We hypothesized that the abstract-without-why planning condition might make individuals look forward and focus on the whole picture; however, it does not share the same benefits resulting from the metacognitive processing and the heightened importance of the second domain as in the abstract-with-why planning condition. Thus, once the second domain is important to people, it is possible that performance of the abstract-without-why condition may improve. To test this proposition, in Study 3 (N=356) we manipulated goal importance. Specifically, after participants finished their planning in the first domain, we asked them to rank order seven domains (e.g., living a healthy life style, saving/investing money for the future, etc.) based on how important each domain was to them. They were then randomly assigned to answer planning motivation questions for either their most or least important domain. Both a main effect of domain importance and an interaction effect between domain importance and planning type emerged. Specifically, when the second domain was the participant's least important domain, there was no difference across planning conditions. However, when the second domain was participants' most important domain, both abstract planning conditions (with and without why questions) led to greater planning motivation than both the concrete and the control conditions. Results from three studies suggest the beneficial effect of planning at a metacognitive level on increasing motivation to plan in a second irrelevant domain. We discuss the implications for both consumers and public policy makers.

SESSION OVERVIEW

Hardly a waking hour goes by without communication. Millions of tweets and Facebook messages are shared each day, and people share all sorts of their and others' stories and news with friends and colleagues. This interpersonal communication is not only frequent, it is also important. The content of what people share affects everything from the products people buy (Chevalier and Mayzlin 2006) to the drugs doctors prescribe (Iyengar et al. 2011).

But, what role does the emotional charge of the content play in sharing? Emotional experiences happen all the time. People see upbeat movies, dread an upcoming exam, or sit through an embarrassing date. But while some work has begun to examine when people share positive versus negative word of mouth (Angelis et al. 2012; East, Hammond, and Wright 2007) and other work has demonstrated the more emotional things are more likely to be shared (Berger 2011; Berger and Milkman 2012; Rime 2009), we still know extremely little about the role of emotion in interpersonal communication. For example, how does sharing emotion impact the person who shares it? How do aspects of the audience (e.g., whether they are close or distant others), impact whether people share positive or negative word of mouth? How does emotion impact whether people talk about the future or the past? Is the expression of one emotion online related to future expression of other emotions? With what frequency are specific emotions, and not just valences, conveyed?

This session addresses these, and related questions, as it integrates various research perspectives to deepen our understanding of the relationship between emotion and word of mouth. **Stephen and Verocchi Coleman** analyze over 100,000 social media posts to ascertain the prevalence, stability, and evolution of specific emotions, finding firstly that some emotions (guilt, shame) are more stable and predictable than others (happiness, anger), and secondly that some emotions develop and evolve into others while neutral words do not. **Dubois, Bonezzi, and De Angelis** study when people share positive or negative word of mouth, demonstrating that close others activate an interdependent construal which leads people to share more nega-

tive things. **Weingarten and Berger** examine how emotionality impacts when people talk about, finding that people are more likely to talk about the same event if it is happening in the future because it evokes greater emotion. Finally, **Weber, Moore, MacDonnell, and Argo** study how emotional sharing affects the sender, illustrating that audience size (small versus large) moderates whether people feel more or less intense after emotional expression.

Taken together, these talks examine the multiplex ways in which emotion shapes, and is shaped by, word of mouth. We not only explore how audience factors such as tie-strength may influence word of mouth valence, but how emotionality can influence when people talk about, and how emotional sharing affects the sender.

Given the importance of interpersonal communication, this session should appeal to a wide range of audiences, including researchers who study word of mouth, emotion, social influence, self-regulation, attitude change, social connectedness, and social networks.

Collective Feelings: The Predictable and Systematic Nature of Human Emotion Expression Over Time

EXTENDED ABSTRACT

A fundamental characteristic of human communication is expressing emotion, which facilitates interpersonal communication and fosters collective understanding. Expressed emotions thus play a key role in organizing social systems. Emotions are so important to social interaction that emotionally deficient individuals have been shown to face social isolation, stunted relationships, and reduced well-being (Thoits 1985). However, despite the importance of emotions to people's relationships and interactions, researchers have been unsuccessful in reliably predicting individuals' emotional states over time, largely because emotions individuals experience and express are often caused by unforeseen situations. Thus, emotions are thought to be inherently unpredictable and predicting the patterns of specific emotions as they unfold over time is very difficult, if not completely impossible (for both biological and psychological reasons; Larsen & Kasimatis 1990). However, being able to predict emotions—or at least observe systematic patterns over time—could be beneficial. For example, predicting the collective emotional state of a population could be useful in diverse fields, such as public health monitoring, political campaigns, advertising, and marketing.

This research shows that it is possible to identify stable intertemporal patterns of emotional experience when individuals' emotions are examined in the aggregate. Our findings suggest that emotions may have properties similar to other phenomena that appear to be random at the micro level but are more systematic when examined at the macro level or in the aggregate. These phenomena, often termed "superorganisms," are manifestations of collective behavior whereby knowledge and behavior is shifted from the individual to the collective (Hölldobler & Wilson 2009). For example, this phenomenon has been found in the popular "wisdom of crowds" concept and economic prediction markets for events as diverse as elections and sporting events (Arrow et al. 2008).

We find a similar property exists when individuals' expressions of emotions in social media are examined over time in the aggregate. Although individuals' emotions might fluctuate randomly when examined by themselves, when they are looked at collectively they appear to have some stable and predictable patterns. We use data cover-

ing emotion expressions in social media posts over a 330-day period from January 1 to November 25, 2012. Social media is an ideal environment for studying emotions over time because users appear to express a range of emotions on a daily basis through what they write. Since emotions play a pivotal role in both communication and social relations, and social media is a pervasive and frequently used form of communication, examining emotions in the context of social media helps develop better understandings of both human communication and collective emotions.

Our data is comprised of daily samples of English-language social media posts that were collected by a research agency that randomly drew posts from all publicly available social media posts. The sampled posts were passed through a natural language processing algorithm that identified expressions of each of eight common emotions: anger, disgust, embarrassment, fear, guilt, happiness, sadness, and shame. For each day we know the number of posts in the sample that were identified as expressing each of these emotions. Our dataset contains 6,947,808 posts in which these emotions were expressed. We first examined the relative prevalence of these emotions in posts and how they varied over time. Fear, happiness, and guilt were the three most expressed emotions, and embarrassment was the least expressed emotion. On any given day, fear, guilt, and happiness were likely to be the most-expressed emotions, although there was some between-day variation in which of these emotions was the most prevalent. For example, the daily share of posts with expressions of fear—the generally most prevalent emotion—ranged from 4.20% to 43.94% (mean = 22.68%). There was also substantial between-day fluctuation in numbers of posts expressing each emotion.

We then considered whether these observed fluctuations over time were stable, systematic, and therefore at least potentially predictable, which would be evidence supporting our hypothesis that, when examined collectively, emotions do exhibit systematic intertemporal patterns. One way to test for the predictability of a time series is to examine its stochastic properties to see whether it is "stationary" or "non-stationary." A "stationary" time series has constant mean and finite variance over time, thus making the series predictable in the sense that it will revert to the mean. A "non-stationary" time series has a mean and variance that change randomly (e.g., a random walk), which makes the series completely unpredictable because it will never revert to a stable mean level. We found that all of the eight emotions' time series were stationary, either directly (five out of eight) or after accounting for time-trend components. Finally, we tested how accurately each emotion could be predicted into the future by fitting forecasting models to data. The fits of these models varied across emotions, indicating that not all emotions are as collectively systematic and predictable as others. For example, the model for happiness had excellent predictive fit but the model for disgust did not. However, the worst-fitting model still managed to account for 26% of the variance in the emotion, and averaging across emotions, the mean forecasting fit was high (mean r^2 = .52, std. dev. = .20).

While each emotion's intertemporal variation indeed has an unpredictable random component, these results indicate that there is a nontrivial, relatively sizeable systematic component and, critically, that these time series are all stationary and expected to be stable in the long run. Prior to this current investigation, anticipating what the general emotional state of a population will be, based on current emotion states, would have been considered an exercise in futility—however, the present findings demonstrate that that type of aggregate-level prediction is, in fact, possible.

Positive with Strangers, Negative with Friends: How Interpersonal Closeness Affect Word-of-Mouth Valence through Self-Construal

EXTENDED ABSTRACT

A great deal of research in word-of-mouth (WOM) has aimed to understand whether consumers are more likely to share positive or negative information (Brown & Reingen 1987; Herr, Kardes, & Kim 1991). While some scholars have shown negative can trump positive WOM (e.g., Kamins, Folkes, & Pernes 1997), others have found positive WOM to prevail (e.g., East, Hammond, &Wright 2007). Yet, little is known about *when* consumers are more likely to share positive versus negative WOM.

This research explores the role of interpersonal closeness as one factor that can influence consumers' tendency to share positive versus negative information. By interpersonal closeness, we refer to the perceived psychological proximity between a sender and a recipient (Gunia, Sivanathan, & Galinsky 2009). Perceived proximity can stem from social similarity (Latanè et al. 1995), tie strength (Marsden and Campbell 1984), or even the type of language used (Brown and Gilman 1960). To illustrate, the more two people have strong ties, occupy similar roles in society or share particular physical or physiological traits, the higher their interpersonal closeness.

Our theorizing builds off the premise that the act of communicating, because it is embedded within social interactions, might activate different social identities in senders' mind (Brewer 1991). That is, addressing a close other should bring in mind social identities in which the self is closely associated with others (e.g., a friend); in contrast, addressing a distant other should bring in mind social identities in which the self is remotely associated with others (e.g., a distant acquaintance). Thus, communicating to a close other might highlight assimilation motives and activate an interdependent self-construal but communicating to a distant other might highlight contrasting motives and activate an independent self-construal. Self-construal refers to the extent to which the self is defined independently of others or interdependently (Markus and Kitayama 1991; Gardner et al. 1999). In turn, we propose that differences in self-construal might affect the valence of information a WOM sender might share by shifting the salience of positive vs. negative information. In support for this proposition, ample research has shown that changes in self-construal affect regulatory goals (Aaker and Lee 2001) and subsequently direct people's attention to positive vs. negative information (Idson, Liberman, & Higgins, 2000; Cunningham et al. 2005).

Thus, we hypothesize that low interpersonal closeness activates an independent self-construal, prompting senders to share more positive relative to negative information, whereas high interpersonal closeness activates an interdependent self-construal, prompting senders to share more positive relative to negative information. Two experiments test this hypothesis.

Experiment 1 tested our basic hypothesis that senders of a WOM message tend to share more negative information, relative to positive information, the closer they feel to the message recipient. French participants read a review of a camera containing four positive and four negative attribute and wrote a WOM message to an hypothetical recipient either using the T pronoun (*tu*, typically used with close others) or the V pronoun (*vous*, typically used with distant others; Brown and Gilman 1960). Importantly, a separate pre-test revealed that merely using T-form (V-form) when answering the Singelis scale (1994) activated an interdependent (independent) self-construal. We counted the number of positive and negative attributes in the messages generated. Results revealed that participants included more negative attributes in their message when using the

T-form than when using the V-form ($p < .01$), suggesting that people shared more negative (positive) WOM when addressing a close (distant) other.

Experiment 2 aimed to further investigate the role of self-construal. That is, if the effect stems from differences in self-construal, activating an interdependent mindset should increase the relative proportion of cons in senders' message, even when senders feel distant from recipients; in contrast, activating an independent mindset should increase the relative proportion of pros in senders' message, even senders feel close from recipients. (Sedikides et al. 1993).

To examine this possibility, we manipulated interpersonal closeness between senders and recipients and their self-construal before participants wrote a WOM message using a 3 (self-construal: interdependent vs. independent vs. baseline) × 2 (relationship: close vs. distant) between-subjects design. First, participants interacted in pairs with another participant to increase feelings of closeness by asking a series of questions to one another (Sedikides et al. 1993). At the end of the interaction, half of the participants stayed with their assigned partner for the following information-sharing task (close condition; initial pair preserved); the other half of the participants switch partner (distant condition; new pair formed). Next, we assigned one of the pair member to be a WOM sender and the other pair member to be a WOM recipient. We asked senders to write about their last experience at a restaurant and share this information with the recipient. However, before engaging in this information-sharing task, senders completed a self-construal priming task (Gardner et al. 1999) in the interdependent condition and in the independent condition. Senders assigned to the baseline condition did not complete any task.

We computed a valence index (number of positive thoughts minus negative thoughts divided by total number of thoughts). In the baseline condition, participants wrote more negative messages when addressing a close recipient than addressing a distant recipient ($p < .05$), replicating Experiment 1. When primed to be independent, participants' messages were positive ($p < .05$) and similar to messages generated in the baseline distant condition (ns). In contrast, when primed to be interdependent, participants' messages were negative ($p < .05$) and similar to messages in the baseline close condition (ns). Put simply, making senders more interdependent led them share more negative messages, even when addressing distant others. In contrast, making senders more independent led them share more positive messages, even when addressing close others.

Overall, this research provides new insights on WOM diffusion by investigating how a central feature of WOM communication – interpersonal closeness between senders and recipients –influence the sharing of positive vs. negative information. We show that consumers tend to share more positive information with distant compared to close others, and that this effect stems from the activation of different self-construal. Implications for WOM and self-construal are discussed.

If the Future Feels Fine: When Are People Likelier to Share the Past or the Future?

EXTENDED ABSTRACT

People talk frequently about emotional experiences they face in everyday life. They may discuss embarrassment due to running into an old girlfriend a day earlier, a recent frustrating sports game, or excitement about the upcoming weekend. But, how might the temporal position of an event, its placement in the past or future, change whether people talk about the event? Will people be likelier to discuss the same concert a week before or a week after it happens?

We propose that whether people are likelier to discuss events in the future or past depends on two factors: emotionality and self-presentation. Past word of mouth research has emphasized that people are likelier to share more emotional events (Berger 2011; Berger and Milkman 2012), and other work suggests the future is more emotionally evocative than the past (Van Boven and Ashworth 2007). Therefore, an event coming up in the future will be likelier to be shared than the same event in the past due to the former's heightened emotionality.

However, this pattern should be moderated by whether the event reflects well or badly on the sharer. Self-presentation has a major impact on what people share: people are likelier to share things that reflect favorably rather than unfavorably on them (De Angelis et al. 2012; Wojnicki and Godes 2008). We therefore propose that the future's increased emotionality will decrease sharing when the content reflects negatively on the sharer, but will increase sharing otherwise.

We test these hypotheses in 6,000 social media posts and two laboratory studies.

Study 1: Field Data

We first examined the distribution of past and future across social media posts and whether the future tended to have fewer negative posts, which may have content that reflects badly on people. We collected 3,000 tweets and 3,000 statuses and coded them based on when the posters were discussing (e.g., yesterday, an hour from now, a month from now). These tweets and statuses were also coded on valence (e.g., positive or negative). We found that for posts over a day from now, people were likelier to discuss future events versus past events (χ^2 (1, N = 346) = 44.439, $p < .001$). Consistent with our theory, these future posts had more positive (68.94%) events relative to neutral (8.95%) and negative (22.13%) events compared to past positive (49.55%) versus neutral (5.40%) and negative events (45.05%; χ^2 (2, N = 346) = 19.15, $p < .001$). This pattern may suggest that at temporal distances over a day away during which there is more future shared, there is less content that potentially reflects negatively on the sharer.

Two laboratory studies further test our hypotheses.

Study 2: Vacation

Study 2 tests how time frame and temporal distance influence sharing. Participants were asked to imagine that they were either going on week-long vacation at a friend's vacation a week from now (future condition) or had come back a week ago (past condition). We also manipulated if the vacation was a week from then or a month to test the generalizability of the effect. We asked participants to indicate how likely they would be to talk about the vacation with others and how emotional (happy) thinking about the vacation home made them.

First, as expected, a 2 (Past vs. Future) x 2 (Week vs. Month) ANOVA showed a main effect of time frame ($F(1, 214) = 20.57$, $p < .001$). Participants were likelier to share using the vacation home in the future ($M = 5.94$) as opposed to the past ($M = 5.12$). Second, the same ANOVA on emotionality revealed a main effect of time frame: participants felt happier thinking about the vacation if it was in the future ($M = 5.94$) as opposed to the past ($M = 5.60$); $F(1, 214) = 8.22$, $p = .005$). Third, felt emotion mediated the impact of time frame on sharing (95% CI [.073, .396]). Taken together, Study 2 demonstrates that people are likelier to talk about the same event in the future (compared to the past) due to the heightened emotionality of the future.

Study 3: Court.

Study 3 explores whether the increased likelihood of discussing future events is moderated by if the event reflects negatively on the sharer.

Participants read about having a court date one week from now (future condition) or ago (past condition). We also manipulated whether the event reflected badly on them (they were in court for stealing from a local shop) or not (they were in court for jury duty). We measured participants' willingness to talk about this event with others and their felt emotionality.

As predicted, there was a Future x Reflection on Self interaction ($F(1, 599) = 8.20$, $p = .004$). When the event did not reflect negatively on them (i.e., they were in court for jury duty), participants were more likely to talk about it if it was happening in the future ($M = 5.13$) than if it happened in the past ($M = 4.51$; $F(1, 599) = 10.75$, $p = .001$). When the event did reflect negatively on them (i.e., they were in court for stealing), the pattern reversed, albeit nonsignificantly: people were slightly likelier to talk about the event if it was in the past than in the future ($M = 2.35$ vs. $M = 2.18$; $F(1, 599) = .73$, ns).

Moreover, a moderated mediation analysis shows that mood mediates these effects (95% CI [-.55, -.14]). As expected, feeling worse increased sharing when the event did not reflect negatively on the sharer (i.e., jury duty, 95% CI [.05, .24]) but decreased sharing when it did (i.e., stealing, 95% CI [-.35, -.05]).

Taken together, these results provide evidence for our hypotheses that (1) emotionality can drive people to talk about future (versus past) things and (2) that these effects are moderated by whether the event reflects negatively on the speaker.

In conclusion, these field data and laboratory studies enhance our understanding of the psychological processes underlying "when" people talk about, and can inform how processes such as emotionality and self-presentation interact.

The Public Heart: The Impact of Sharing Emotions on Social Media

EXTENDED ABSTRACT

Social media is a rapidly growing venue where consumers and firms can converse with larger audiences than ever before. For instance, Facebook has over one billion users and 15 million brands in their network (Koetsier 2013), and Facebook users have an average of 190 friends (Backstrom 2011). Across these platforms, sharing emotional content is common (e.g., minutes after Michael Jackson's death, the number of status updates on Facebook more than doubled; Facebook Data Science 2009). However, prior research has primarily focused on one-on-one emotional sharing (i.e., narrowcasting; Rimé et al. 1991). Our work investigates how broadly sharing positive brand-related emotions via social media impacts the sharer. We posit that when individuals share emotions, the intensity of these emotions changes depending on the size of the audience with whom they share (broad vs. narrow), and on their public self-consciousness (PSC; Fenigstein, Scheier and Buss 1975).

When they have an audience, individuals focus on themselves as an object of attention increases (Carver and Scheier 1978), and when they have broad social-media audiences, individuals focus even more on how their audience perceives them (e.g., Berger and Milkman 2012; Karakayali and Kilic 2013; Vitak 2012). Thus, we predict that sharing broadly (i.e., to a large audience) forces attention away from the emotion that is being shared and instead onto the sharer and their audience's perceptions, inhibiting individuals' ability to relive the emotion, and dampening it instead.

This should be particularly true of individuals low in PSC (LPSC), who do not normally focus on their audiences; thus, we expect LPSCs will feel more (less) intense after narrowcasting (broadcasting). However, focusing on the audience should be natural for individuals high in PSC (HPSC), who are habituated to considering their audience (Kassin 1984); thus, they should be able to relive emotions shared broadly. Further, because HPSCs care about how they are perceived by others (Bushman 1993) they should consider the social benefits they gain by sharing *positive* emotions, which will reflect well on them (cf. Berger and Milkman 2012). As such, broadcasting (narrowcasting) positive emotions should make HPSCs' emotions more (less) intense.

Finally, we expect that feelings of closeness with their sharing audience will mediate our results for HPSCs. This group focuses on their audience naturally and should thus feel more in tune and closer to them, especially when they share their positive emotions and experiences with them. LPSCs are less used to considering their audiences (Fenigstein 1984) and may not feel as close with them when they share. In general, we predict that sharing with an audience with whom one is (not) close will (dampen) increase emotional intensity.

Study 1 used a within-subjects design to determine whether broadly sharing a positive brand-related emotion via Facebook could dampen its intensity. Undergraduates (N=57) described a recent brand experience and reported how positive and intense the emotional experience was (4 items, pre-sharing). They then posted an "I love [brand]!" status update on their Facebook account, and completed the same measures about the emotional experience (post-sharing; αs>0.87). Consistent with our predictions, participants' emotions were significantly less intense post-sharing ($M_{post} = 4.46$, $M_{pre} = 5.03$; $t(56) = 4.64$, $p < .01$). Further, a measure of how close individuals felt with the "majority of [their] Facebook friends" significantly predicted this decrease in emotional intensity, providing early evidence for our mediator.

Study 2 used a 2 (PSC: high vs. low) by 2 (Facebook sharing: broad vs. narrow) between-subjects design. Undergraduates (N=81) recalled a recent positive experience they had at a restaurant and then reported the name of the restaurant and the positive emotion they experienced. They then logged into their Facebook accounts and either posted a status update (broad) that said "I love [restaurant]!" or sent the same message to a single friend of their choosing (narrow). Following this, participants competed emotional intensity measures (α=0.78) about the experience and a single-item measure of audience closeness. PSC was measured at the start of the semester via mass testing.

The two-way interaction between sharing and PSC was significant ($F(3, 69) = 9.408$, $p = .003$). Using bootstrapping and Hayes' (2013) simple moderation model, we decomposed the interaction between our broad (post) vs. narrow (message) conditions. At the mean level of PSC, there was no difference for sharing (p > .8). However, LPSCs (-1 SD) had lower emotional intensity, while HPSCs (+1 SD) had higher emotional intensity, after sharing broadly compared to narrowly. Moderated mediation analysis showed that audience closeness significantly mediated ($p < .05$) the impact of sharing on emotional intensity for those at the mean and high levels of PSC, but not for those low in PSC.

Study 3 will hold audience size constant (broad) and use a 3 (Facebook sharing: own vs. brand vs. neutral) by measured PSC between-subjects design. We will manipulate whether participants post a positive status update about a brand to their own Facebook page, the brand's page, or a neutral page setup by the experimenters. This will assess the impact of audience *type*, where posting on one's own page is broadcasting to friends—whose perceptions can be anticipat-

ed by HPSCs, and from whom positive benefits can be gained—but posting on a brand or neutral page is broadcasting to an unknown audience, whose reactions will be unknown and from whom positive benefits are not be as important. To the extent that HPSCs gain emotional intensity by anticipating that sharing reflects well on them in the eyes of their friends, we should replicate our Study 2 findings in the "own" page condition. In the "brand" and "neutral" page conditions, we expect no intensity boost for HPSCs, but rather mitigated emotional intensity, as with LPSCs. We will also measure the extent to which individuals focus on themselves, their audience, and their emotions, to elucidate the underlying process.

The current investigation finds that individuals high (low) in PSC feel more (less) intense after sharing positive emotions broadly. Closeness with one's audience mediates the findings for HPSCs.

SESSION OVERVIEW

Consumers regularly evaluate choices and make decisions on behalf of and with others. Yet, relatively little is known about how consumers make these types of decisions. This session seeks to advance knowledge in this domain by examining choices and decisions made *for* and *with* others. What are some of the consequences of choosing for and with others? Are interpersonal dynamics important to consider when studying this topic? These are some of the questions this session aims to address.

The first paper by Dzhogleva Nikolova, Lamberton, and Coleman begins with a negative consequence of choosing with others: Specifically, they compare whether people behave more unethically when they make decisions in a dyad versus alone. Results reveal that people intuit that joint "crimes" (unethical decisions made with others) lead to social bonding. Therefore, dyads behave more unethically than individuals only in situations when social bonding is needed. Interestingly, results show that collaborative wrongdoing generates social bonding only for some individuals but has perverse effects for others. This paper demonstrates that joint decision-making can have negative consequences and highlights the importance of studying interpersonal dynamics in this domain.

The second paper by Etkin continues to examine the role of interpersonal dynamics, and demonstrates a neutral consequence, variety-seeking, in this domain. Specifically, she finds that perceptions of relationship length affect whether individuals prefer variety or similarity in their choices for others. When the length of the relationship seems short, individuals choose more variety and prefer more varied products and experiences to give to others. Etkin also examines willingness to pay for more or less varied products when choosing for others (e.g., bouquet of flowers), which demonstrates how aspects of the relationship affect choices made for others.

The next two papers demonstrate positive consequences of choosing for and with others in terms of ego-depletion and relationship dynamics. In the third paper, Polman and Vohs find that choosing for others is less depleting (and more fun) than choosing for the self. The authors also find that self-construal moderates the effect of choosing for others on depletion depending upon whether the decision maker is self or other-oriented. These findings highlight that self-other decision making can be explained within the theory of self-construal, and again demonstrate the importance of studying interpersonal dynamics in this domain.

In the last paper, Brick, Chartrand and Fitzsimons compare the effects of choosing with others to those of choosing for others on power and satisfaction in romantic relationships. Previous research would suggest that the person who gets to make all of the choices for their partner should have the most power in the relationship, in other words choosing for others should be associated with greater power. However, the authors find that choosing *with* one's partner (i.e., shared decision making) is associated with greater power and also greater relationship satisfaction, highlighting an important, positive consequence of choosing with, as opposed to for, others.

Taken together these papers provide some initial insight into the consequences of choosing for and with others. They also demonstrate how interpersonal dynamics are necessary to consider when studying this topic. These papers will appeal to a broad audience as they highlight different theoretical frameworks and topics, e.g., morality, close relationships, self-regulation, variety-seeking, that can be studied in this domain, and, they suggest various avenues for future research.

The 'Partners-in-Crime' and the 'Lone Wolf': Comparing the Unethical Behaviors of Dyads and Individuals

EXTENDED ABSTRACT

Recognizing the widespread occurrence of fraudulent behaviors and their costs to businesses, individuals, and society, researchers have examined individual and situational factors underlying individuals' unethical behavior (e.g., Mead et al. 2009; Gino et al. 2013). However, people often solve ethical dilemmas along with others. For example, Enron's notorious fraud was committed jointly by CEO Jeffrey Skilling and founder Kenneth Lay. Furthermore, people on sports teams, in the workplace, or in academic settings often have to make joint ethical decisions.

Despite the prevalence of such decisions, little research has examined whether people are more unethical when they make decisions jointly in a dyad versus alone. The present research takes a first step toward addressing this gap in the literature, comparing the ethical decisions of dyads and individuals.

Interestingly, the existing literature makes opposing predictions. On one hand, according to the accountability literature, which suggests that "the need to justify one's views to others" encourages more careful and accurate decisions (Tetlock and colleagues 1983, 1987), it could be argued that decision-making in dyads will be more ethical than solo decision-making. However, research on diffusion of responsibility shows that individuals feel less personal responsibility for group actions (Leary and Forsyth 1987), thus predicting that dyadic decision-making will be more unethical than will that of the 'lone wolf.' Further, shared risk-taking and guilt-sharing can provide bonding experiences (Lowe and Haws 2014). Thus it is possible that if individuals wish to form a social bond with others, the opportunity to make joint unethical decisions could provide an avenue. In such cases, the 'partners-in-crime' should display more unethical decision-making than should the 'lone wolf.'

To test these possibilities, our first study presented participants (n=62) with two versions of a cheating scenario adapted from Shu et al. (2011). In Scenario A participants imagined that a student was given the opportunity to make up for a missed exam. The student had the option to cheat by taking a graded copy of the exam from his classmates. In Scenario B participants had to imagine that the same

ethical decision had to be made jointly by a pair of students. After reading both scenarios, participants indicated who they believed was more likely to cheat using a 7-point scale where "1=the student in Scenario A" and "7=the two students in Scenario B." Furthermore, participants imagined that the two students in Scenario B had decided to cheat together. They then responded to questions regarding the social consequences of such collaborative wrongdoing. Results revealed that people intuit that the pair of students will be more likely to cheat than the individual student (M = 4.69 vs. 4 (scale midpoint), $t(61)$ = 2.52, p = .01). Moreover, people anticipate that two cheating students will feel more connected, less distant, and like each other more (all p's < .02) after "partnering-in-crime."

Based on these findings, we anticipate that individuals may use joint unethical behavior opportunities to create social bonding. We designed two studies to test this prediction: one using individuals who already know one another and thus, have a less salient need to socially bond through their decisions, and the other using unfamiliar students, who may use joint decisions as a social bonding tool. In Study 2, participants (n=111) were MBA students. In addition to sharing a cohort and having worked together on projects in prior semesters, they completed this experiment at approximately the midpoint in a 14-week semester. As such, they were already part of a fairly tight-knit group and would not need to use unethical behaviors to bond socially. In this context, we anticipated that the dyads would be more ethical than individuals. Participants were presented with an ethical decision making scenario based on Charles Ponzi's scheme (Wiltermuth 2011). They had to decide – either alone or jointly with a partner - how likely they would be to take on additional investors in their business although the potential for profit was limited (1="Not Likely At All;" 7="Very Likely"). Results showed that the dyads (M = 2.21) were less likely to behave unethically than the individuals (M = 3.22; $F(1, 67)$ = 5.33, p = .02).

In Study 3, we recruited undergraduate students from the university community. Here, we anticipated a small likelihood that the dyad members would know each other. Participants (n=253) first completed the Trait Self-Control Scale (Tangney et al. 2004) online as we expected that low and high self-control people might view vicious behaviors such as joint "crimes" differently and thus experience different social bonding consequences. When participants came to the lab (1-2 weeks later), they were randomly assigned to either individual or dyadic conditions and given the same ethical decision as in Study 1. Then participants in the dyads answered questions designed to measure social bonding (how much they liked their partner, how willing they were to work with their partner again) and indicated the extent to which they knew each other (all on a 7-point scale where 1="Not At All" and 7="Very Much"). Manipulation check results confirmed that dyad members did not know each other well (M = 1.32 vs. 4, p < .0001). In this context, results showed that dyads (M = 5.14) were more likely to cheat than individuals (M = 4.47, $F(1, 133)$ = 5.48, p = .02). Finally, results highlighted that the likelihood of cheating had a weak positive impact on social bonding - but only for low self-control individuals (b = .11, p = .07). Higher likelihood of cheating in fact had a negative effect for high self-control individuals (b = -.20, p = .02).

Our next study will explore our prediction that social bonding needs underlie these effects by manipulating the activation of such needs. We will also seek to replicate our findings about the possibly perverse effects of unethical joint decisions on higher self-control individuals, who appear to distance themselves from their 'partners-in-crime' rather than effectively creating social bonding through their actions.

Choosing Variety for Shared Consumption

EXTENDED ABSTRACT

Consumption experiences are often shared with others. Consumers eat out with their friends, watch movies with their families, and vacation with their significant others. Indeed, more consumption experiences may be shared than not (Raghunathan and Corfman 2006; Ramanathan and McGill 2007). Despite this fact, little research has examined how people make choices for shared consumption. Consider a couple who shares multiple experiences each week. These individuals could choose to incorporate more variety into their shared experiences, or less variety into them. On Friday, Saturday, and Sunday night, for example, the couple could go out to eat, see a movie, and attend a concert, or they could eat at three different restaurants. What might affect how much variety they choose to share?

I propose that the length of consumers' relationship plays a critical role by changing the emotions that they value. Research on the psychology of aging and longevity demonstrates that people's preferences change over time (Carstensen 2006; Carstensen et al. 1999). Whereas younger individuals tend to value feeling excited, older people tend to value feeling calm (Bhattacharjee and Mogilner 2013; Mogilner et al. 2012). Building on this idea, I suggest that relationship length should also affect what emotions consumers value. Just as age (i.e., the length of one's life) changes whether feeling excited or calm is desirable, relationship length should have similar effects. Relationships can be (or seem) short and new, or they can be (or seem) longer and more established. When relationships seem short (like feeling young), consumers should value excitement in their relationship. When relationships seem long (like feeling old), in contrast, consumers should value feeling calm. Evidence from a pilot study supports this reasoning, demonstrating a negative correlation between relationship length and the importance of excitement in relationships (r = -.39, p = .001), and a positive correlation between relationship length and the importance of calmness (r = .26, p = .04).

Importantly, the variety consumers choose to share with their partner should affect how exciting or calm that relationship feels. A great deal of work shows that choosing more variety increases stimulation and excitement (Berylne 1970; Kahn and Ratner 2005; Raju 1980), whereas choosing less variety reinforces a sense of stability and routine (Khare and Inman 2006; Menon and Kahn 1995; Wood et al. 2002). Thus, sharing more (less) varied experiences should make relationships feel more exciting (calm). Consequently, when relationships are (or seem) short, consumers should prefer sharing more varied experiences with their partner compared to when relationships are (or seem) long.

Four studies test this prediction. In study 1, I manipulated perceived relationship length using a response-frequency scale manipulation adapted from prior research (Etkin and Ratner 2012; Schwarz et al. 1998). Then, I invited participants to choose four consumption experiences to share with their partner over the coming week. The choice set included three options – going out to eat, watching a movie, and listening to live music – and I recorded how many distinct options participants chose. Results demonstrate more variety-seeking among shared experiences (i.e., participants chose a greater number of distinct options) when made to feel their relationship was short (M = 2.48) versus long (M = 2.15; $F(1, 51)$ = 4.50, p < .04).

Building on these findings, studies 2a and 2b explore how relationship length affects consumers' willingness to pay for variety. Following the same relationship length manipulation from study 1, male participants were asked their willingness to pay for two bouquets of roses (order randomized): one with varied colors (high va-

riety option) and one with a single color (low variety option). A 2 (relationship length) X 2 (variety) X 2 (order) repeated-measures ANOVA on log-transformed willingness to pay only revealed the predicted interaction (F(1, 129) = 6.57, p < .02). Participants were willing to pay more for the low variety bouquet when led to perceive their relationship as long (M = .05) versus short (M = -.05). Participants were willing to pay more for the high variety bouquet, in contrast, when led to perceive their relationship as short (M = .07) versus long (M = -.07).

Study 2b manipulated perceived relationship length in a different way, and then measured willingness to pay for a more versus less varied shared experience. Specifically, participants reported the length of their relationship in years and months, and then described how that was a short (long) amount of time. Next, they read a description of a cruise vacation package and were asked how much they were willing to pay for it. In the low (high) variety condition this cruise package was described as offering many similar (different) experiences. A 2 (relationship length) X 2 (variety) ANOVA only revealed the predicted interaction. When led to perceive their relationship as short, participants were willing to pay more for the high (M = $1420.81) versus low variety package (M = $748.34). When led to perceive their relationship as long, in contrast, participants were willing to pay more for the low (M = $1343.42) versus high variety package (M = $918.13).

Finally, study 3 demonstrates an important boundary condition of this effect. While perceived relationship length affects the variety chosen to share with one's partner, it does not change variety-seeking behavior for experiences consumed alone. Relationship length thus has a unique effect on variety chosen for shared consumption. Together, these studies demonstrate that consumers' romantic relationships exert a significant impact on the choices that they make. Consumers choose more variety, and prefer more varied products and experiences, when their relationships seem short versus long.

When choosing for others is more fun (and less depleting) than choosing for the self

EXTENDED ABSTRACT

Decades of research show that people prefer activities that provide them with opportunities to make choices. However, empirical research shows that people describe their choices as difficult, paralyzing, and exhausting. This inconsistency is called the *paradox of choice*, whereby people have opportunities to make more choices than ever before, yet do not seem to benefit from them, psychologically (Schwartz 2004). Still, people insist on maximizing their choice opportunities, even when these opportunities lead them to perform worse and feel worse (Botti and Hsee 2010).

Prior work has shown that an implication of making choices is in the energy that people have to put toward acts of self-control. Research has found that making choices requires self-regulatory resources that deplete with use (Vohs et al. 2008). We studied people who make choices for other people, about whom little is known in terms of their self-regulatory capacity. We were drawn to this issue because decision making is rarely solitary and often involves including and thinking about others: Parents make decisions on behalf of their children, managers make decisions that affect their employees, graduate students delegate important decisions to their professors, and those with little experience in a domain delegate choices in that domain to those with more experience.

Research has shown that people think more "happy thoughts" when they choose for others. For example, people who decide for a friend to go on a blind date tend to fantasize about the possible positive outcomes, like how exciting the date could be. In contrast, people who decide whether to go on a blind date themselves tend to imagine a pessimistic fate, like having an awful time with a boring partner (Beisswanger et al. 2003). Research has found that people's choices for others are more idealistic and pleasure seeking than choices people make for themselves (Laran 2010; Lu et al. 2012). Along these lines people make more creative and more assertive choices for others than they do for themselves (Kennedy and Ames 2013; Polman and Emich 2011). These lines of work suggest that people display less inhibited behavior when deciding for others, precisely the kinds of behavior that people find enjoyable and fulfilling (Apfelbaum and Sommers 2009; Grant and Gino 2010).

We report three experiments that test whether choices for others are less depleting than choices for the self. We also investigate a moderator, self-construal, and test whether choosing for others is less depleting for self-oriented, as compared to other-oriented, decision makers. In study 1, 450 participants responded to ten scenarios each describing a situation in which a choice has to be made. In the first nine scenarios, we asked participants to choose for themselves or for someone else indicated in the scenarios. We also included two no-choice, neutral conditions in which we asked participants to think about how hard it would be to make the choice as if it was for the self or someone else, respectively. The tenth scenario differed from the previous scenarios in that it described a choice where participants could recommend choosing the status-quo–an indicator of depletion that has been used successfully in past research (Danziger et al. 2011).

Our results showed that there was no difference between the two neutral conditions, so we collapsed these conditions into one neutral condition, where the proportion recommending the status-quo was .35. The proportions recommending the status-quo in the conditions where participants chose for themselves and for others were .52 and .38, respectively. A chi-square test revealed a significant difference among the three conditions, $\chi^2(2, N = 450) = 10.45$, $p = .005$. Planned comparisons revealed that there was significantly more preference for the status-quo when participants chose for themselves than when participants chose for others (which did not differ significantly from the neutral condition).

In study 2, 195 participants responded to ten scenarios in which participants made choices for a same-sex friend or for the self, and reported their enjoyment. Next, participants were asked to drink a relatively unpleasant mixture of water, vinegar, and drink mix. We carried out a bootstrapping procedure to determine whether enjoyment mediates the relation between choice and depletion (ounces of unpleasant drink mixture consumed). Results indicated that the indirect effect was estimated to lie between -1.23 and -0.35, confirming that enjoyment did act as a mediator. The overall chain thus supports the prediction that choosing for others is an enjoyable pursuit, which in turn buffers against depletion.

In study 3, 312 participants completed the Self-Construal Scale (Singelis 1994) that measures participants' self-orientation and other-orientation. Then, participants responded to nine scenarios in which participants selected a choice for a friend or for the self, and reported their enjoyment. Next, participants were asked to solve 5 unsolvable anagrams. The amount of time participants spend on the anagrams is indicative of ego depletion. We conducted a moderated mediation analysis to assess the indirect effect of choice on depletion through enjoyment at the different orientations of self-construal. The 95% confidence interval for the indirect effect of choice among other-oriented participants ranged from 23.72 to 100.25. In addition, the 95% confidence interval for the indirect effect of choice among self-oriented participants ranged from -73.06 to -5.99. Since neither

of these confidence intervals contain zero, we conclude that the indirect effects are statistically significant.

A broad range of behaviors has been identified to result from depletion. Depleted people behave more unethically, spend more money, and make riskier decisions – and since these findings have relied on depletion to obtain their results, an investigation that combines research on self-other decision with research on depletion is potentially fruitful. Given that people enjoy choosing for others, they are buffered against depletion, and hence they may make decisions that are, in keeping with the examples above, more ethical, tightwad, or risk-free. This possibility is encouraging for future research and our set of studies can set in motion a foundation for future work on self-other choice.

Shared Decision Making and Power in Relationships

EXTENDED ABSTRACT

Imagine three different team scenarios. In the first, you are on a team and you get to make all of the choices for the team. In the second, you are on a team and someone else makes all of the choices. And in the third, you are on a team and everyone shares in the decision making. Which scenario do you think you would feel the most power? In the present research, we find that individuals who relinquish some control and make a decision together, ironically, perceive greater power in their relationship than if they had made the decision entirely themselves. These findings suggest that shared decisions, even those as small as which soap to buy, can increase perceptions of power in the relationship.

Power can be defined as control over valued resources and the capacity to influence the behavior of others (Anderson and Galinsky 2006; Emerson 1962; French and Raven 1959; Keltner et al. 2003; Steil 1997), while resisting the influence of others over oneself (Cromwell and Olson 1975). Power in romantic relationships can similarly be thought of as the capacity to influence others, in this case partners (Huston 1985). As it stands, the existing literature makes competing predictions about whether making all of the decisions in the relationship should lead to more or less power in the relationship. Making all of the choices in the relationship should lead to greater influence over that relationship, and thereby greater power. However, making all of the choices necessarily implies that one is involved in the relationship, and Waller's (1937) principle of least interest suggests that the person who is less involved in the relationship has more power. By not making any of the decisions one is able to remain less involved in the relationship, and maintain greater power in the relationship.

On the one hand, by making all of the choices one has influence over their partner, which is associated with greater power; yet, on the other hand, by not making any choices one is less involved in the relationship which is also associated with greater power. The best option, then, would be for an individual to perceive oneself as having influence and for the partner to show interest. This is the case in shared decision making. Therefore, our theory posits that perceiving decisions as shared, which combines an individual's influence plus partner's interest, should lead to the greatest perception of power in the relationship. We test and find evidence for our theory across four studies.

In our first study we investigate whether greater shared decision making is associated with greater power in the relationship. 288 individuals from an online U.S. subject pool participated in the study. Participants completed the Personal Sense of Power scale (Anderson et al. 2012; α=0.85), a filler task, and then answered the Decision Making Measure, a series of 10 items capturing different types of decisions made in the relationship. Participants were given three response options: I mainly decide, my partner mainly decides, or we decide together. We summed the number of shared responses to create a Shared Decision Score. In line with our prediction that greater overall shared decision making is associated with the most power in the relationship, a regression analysis revealed that as the number of shared responses increased, so too did perceptions of power in the relationship.

In our second study we manipulated shared decision making through a shopping recall paradigm. We hypothesized that individuals in the shared decision making condition would report the greatest perceptions of power. 290 individuals (80 men) from an online U.S. subject pool participated in the study. Participants were randomized to recall a time when either they, their partner, or they and their partner made a decision and purchased an item for they and their partner to use. Participants completed the same power measure as used before (Anderson et al. 2012; α=0.88). They were also asked to indicate how happy they currently were with their relationship on a 1 (extremely unhappy) to 10 (extremely happy) scale. In line with our hypothesis, planned contrasts revealed that individuals in the shared condition reported significantly greater power in the relationship, and also greater relationship satisfaction.

To extend the previous results, we conducted two field studies where both members of the couple participated. In the first field study, 59 couples participated in a procedure similar to study 1. We included a measure of overall relationship satisfaction (Rusbult et al. 1998). Using a multi-level modeling approach, we found a significant effect for shared decision making on power in the relationship. Specifically, as partners reported greater shared decision making, they also reported greater power in the relationship. Furthermore, we found that as shared decision making increased so too did relationship satisfaction. These results suggest that increasing power and relationship satisfaction as a result of shared decision making is not a zero-sum game as both partners could report increased power as a function of greater shared decision making.

In our second field study, 44 couples were each randomized to one of the three shopping recall conditions used in study 2. We tested our process theory that sharing decisions combines self influence plus partner interest, which in turn, leads to greater perceptions of power using a six-item measure. We included a measure of relationship satisfaction as our outcome variable. We predicted that self influence and partner interest mediate the relationship between shared decision making and satisfaction. In line with our hypothesis, a multiple mediation analysis demonstrated that shared decision making was associated with greater levels of self influence and partner interest, and these two constructs mediated the relationship between shared decision making and relationship satisfaction. Altogether these findings demonstrate how important making decisions and choices with others can be. Additionally, they highlight how important the role of consumer choices, even small ones such as recent purchases, can be for relational welfare.

Sherry X. Yu, Washington University in St. Louis, USA

SESSION OVERVIEW

Being happy is perhaps the most common and important goal consumers have. Over the past decade happiness has received increasing attention from psychologists, economists, sociologists, and consumer researchers alike – indeed, ACR has devoted their annual conference to the theme of getting "Back to Fun." Findings from these literatures provide much insight into how to measure happiness and why happiness is important (Diener et al. 1995; Diener and Seligman 2002; Dunn et al. 2008; Kahneman et al. 2004; Lyubomirsky et al. 2005; Mogilner 2010; Mogilner et al. 2012; Van Boven and Gilovich 2003). Yet, several questions have received less attention: What makes people happy? Can consumers actively manage their happiness? And how does (un)happiness shape decision-making?

Our session sheds light on these questions. The first two papers focus on the antecedents of happiness, drawing on diverse methodology and theory. Paper 1 (Etkin and Mogilner) begins by discussing how the degree of variety among consumers' activities affects happiness. Three experiments demonstrate that while doing more varied things increases happiness over moderate to long time intervals (an hour, a day, a week, etc.), doing less varied things increases happiness over short time intervals (10 minutes, 30 minutes). Paper 2 (Quiodbach, Gruber, and Norton) builds on these findings by discussing how the emotional diversity consumers experience affects their happiness. Two cross-sectional studies show that over and above emotional valence, greater "emodiversity" corresponds to improved wellbeing.

Moving past antecedents, Papers 3 and 4 focus on how happiness relates to decision-making. Paper 3 (Dalton, Goodman, and Malkoc) challenge the notion that experiential consumption leads to greater happiness than material consumption. Three studies show that when people recalled a happy event (e.g., getting married), commemorating that event with a material purchase (vs. celebrating it with an experience) improved long-term memory of it, and increased how happy people felt when they thought about it. Finally, Paper 4 considers how (un)happiness affects decision-making in jury contexts. Eight studies utilizing diverse methods demonstrate that consumers underweight emotional losses, which affects how they compensate injured parties.

Together, these papers shed led on what makes people happy (activity variety, emotional diversity) as well as how happiness shapes consumers' decisions (experimental vs. material consumption, jury decision-making). Further, they suggest multiple ways to manage fun and happiness in our lives: changing the variety of activities one does, the emotions one experiences, or the way one marks happy occasions. Whereas limited research to-date has explored such antecedents and consequences of happiness, the work presented in this special session begins to address this gap. Given the increasing interest in happiness and having fun in various consumer disciplines, the session is likely to attract a wide audience. Attendees can expect to have fun and the speakers not to take themselves too seriously.

Does Variety Make People Happy?

EXTENDED ABSTRACT

Does variety increase happiness? Would an hour spent juggling emails, meetings, and data analysis or a workday focused only on data analysis lead to greater happiness? Would a Saturday spent bouncing from running errands, to cooking an elaborate dinner, to playing with one's kids or a Saturday dedicated solely to playing with the kids lead to greater happiness? This research experimentally tackles this fundamental question of how best to spend one's time—on more or less varied activities.

Prior research suggests that people generally value variety. People are stimulated by variety among thoughts (Pronin and Jacobs 2008), shapes (Berylne 1970), and food (Rolls et al. 1981), and they are drawn to highly varied product assortments (Kahn 1995; McAlister and Pessemier 1982; Simonson 1990). Furthermore, incorporating variety into positive experiences and relationships has been proposed as an effective means of countering hedonic adaptation (Bao and Lyubomirsky 2013; Lyubomirsky et al. 2005; Sheldon et al. 2012). It may thus be that integrating greater variety into people's behavior more broadly will make them happier.

But, should variety always increase happiness? Although variety offers many benefits, it also imposes some costs. Variety is inherently complicated and complex (Berylne 1970). In fact, the very reason that variety may reduce hedonic adaptation is that it requires people to actively process dynamically changing information (Lyubomirsky et al. 2005; Sheldon and Lyubomirsky 2012). This complexity can be aversive. People are less satisfied with their choices, for example, when product assortments include too many varied options (Iyengar and Lepper 2000). Ultimately, varied sets demand more attention than similar sets, which can disrupt people's ability to focus (Etkin and Ratner 2012; Folkes and Matta 2004; Redden and Hoch 2009). There may thus be times when infusing one's schedule with variety feels too demanding to allow for happiness.

When, then, would incorporating more variety into one's activities increase happiness, and when might it decrease happiness? The answer is likely tied to associated feelings of productivity. Doing more varied activities should generally make people feel as though more has been accomplished during that time period (Ahn et al. 2009; Zauberman et al. 2010). A day filled with varied activities, for example, should seem fuller than the same day filled with similar activities. When their time seems full, people feel more productive (Mogilner et al. 2012), and feeling productive is critical to happiness (Diener et al. 2009; Hsee et al. 2010; Seligman 2011).

This may backfire, however, when considering time intervals that are too short to accommodate high amounts of activity. Filling 30 minutes, for example, with highly varied activities may make people feel less productive, because there is too much to do to feel that anything has actually been accomplished. Consequently, although incorporating more variety into one's activities may increase happiness over most time periods (e.g., an hour, a day, a week, a month), it may instead decrease happiness over particularly short time periods (e.g., 30 minutes). We therefore suggest that whether variety makes people happier depends on the time interval over which people do more or less varied activities.

Three experiments test whether and when variety increases happiness. Experiment 1 examined how variety affects happiness over multiple periods of time. We varied whether MTurk participants recalled doing more or less varied activities during their past 10 minutes, 30 minutes, hour, day, week, month, and year, and then measured how happy they were over that time. A 2 (variety) X 2 (time interval) ANOVA revealed the predicted interaction ($F(1, 595)$ = 5.14, $p < .001$). As expected, recalling more (vs. less) varied activities did make people feel happier over an hour (M_{high} = 4.93 vs. M_{low} = 4.30), a day (M_{high} = 5.30 vs. M_{low} = 4.45), a week (M_{high} = 5.30 vs. M_{low} = 4.73), and a month (M_{high} = 5.07 vs. M_{low} = 4.58). This effect reversed, however, over the short time periods of 10 and 30 minutes. In these conditions, recalling less varied activities increased happiness (10 minutes: M_{low} = 4.90 vs. M_{high} = 4.52; 30 minutes: M_{low} = 5.01 vs. M_{high} = 4.54). These results held controlling for gender, age, and chronic need-for-stimulation.

The next two studies delve further into these findings by examining effects of actual (rather than perceived) variety among activities, and by manipulating whether a given time frame seems shorter or longer. Experiment 2 was a two-part study. Participants were recruited in the morning, assigned to do more or less varied activities over the course of the day, and then surveyed again at the end of that day, allowing us to test whether doing more or less varied things influenced change in happiness. To explore the underlying process, we also manipulated how long that day seemed (short vs. long), and measured productivity perceptions. Supporting our theorizing, doing more (vs. less) varied activities increased happiness when the day seemed long (M_{high} = .95 vs. M_{low} = .04), mediated by seeing time as more productive (ab = .11; 95% CI: .03 to .24). This effect was attenuated, however, when the day was made to seem short (M_{high} = .46 vs. M_{low} = -.05).

Experiment 3 manipulated the variety of activities participants engaged in over a short amount of time (10 minutes), again varying whether that time seemed short or long. Contrary to the results for a long time interval, doing less (vs. more) varied activities increased happiness over 10 minutes (M_{low} = 4.76 vs. M_{high} = 4.06), mediated by increased productivity (ab = -.14; 95% CI: -.40 to -.01), but this effect was attenuated when 10 minutes was made to seem short (M_{low} = 4.93 vs. M_{high} = 4.73).

In sum, this work provides the first empirical link between the variety of people's activities and their happiness, showing that doing more varied activities often makes people happier, but not always. For variety to increase happiness, a sufficiently long time period is required. Over particularly short time periods – namely, less than 30 minutes – doing a variety of different activities decreases feelings of productivity, resulting in less happiness.

Emodiversity and the Emotional Ecosystem

EXTENDED ABSTRACT

Compare three individuals: Person A experiences three moments of joy in a given day, Person B experiences two moments of joy and one moment of contentment, and Person C experiences two moments of joy and one moment of anxiety. If we sum the number of positive emotions (joy and contentment) and subtract the number of negative emotions (anxiety), A and B would be equally happy, and happier than C. Indeed, research suggests that high levels of positive emotion and low levels of negative emotion are an essential component of subjective well-being (Diener et al. 1999; Fredrickson 2001). Is subjective well-being simply the result of such simple arithmetic subtractions? We investigate whether not just the mean levels but also the *diversity* of emotions that people experience may have hidden benefits for their well-being. We show that the "emodiversity" of A, B, and C's emotions—the variety and relative abundance of the emotions they experience—is an independent and integral component of the human emotional ecosystem, one that predicts both mental and physical health.

We drew our prediction from research in the natural sciences on the benefits of biodiversity (i.e., the variety and abundance of different types of organisms within an ecosystem). Across habitats ranging from deep-sea to grassland through tropical forest, biodiversity has been repeatedly shown to foster adaptive functioning (e.g., Danovaro et al. 2008). Biodiversity promotes ecosystem resilience (Elmqvist et al. 2003) and fosters resistance to extreme and undesirable events such as diseases, pathogens, and invasive species (e.g., Knops et al. 1999).

Might diversity play a similarly critical role for the human internal emotional ecosystem? Certainly, the human mind is a natural system that shares important features with other natural systems (Johnston et al. 1998). In addition, biodiversity plays a key role in environmental health by enhancing adaptive flexibility (Heller and Zavaleta 2009; Rammel and Van den Bergh 2003); likewise, flexibility in human biological and psychological processes is associated with adaptive mental functioning and enhanced resistance to disease (Kashdan and Rottenberg 2010; Mikolajczak et al. 2010). As a result, we adapted the Shannon biodiversity index, which quantifies the number of species and the evenness of species in a biological ecosystem (Magurran 2004; Shannon 1948), to quantify emodiversity, or the richness (how many specific emotions are experienced) and evenness (the extent to which specific emotions are experienced in the same proportion) in the human emotional ecosystem.

In Study 1, 35,844 respondents reported their propensity to experience 9 specific positive and 9 specific negative emotional states, and completed a measure of mental health which assessed depression (MADR-S; Meites et al. 2008). We computed Shannon's biodiversity index for positive emotions, negative emotions, and all emotions and entered these emodiversity scores into a series of regressions predicting depression. Greater emodiversity, whether computed for positive emotions, negative emotions, or all emotions, was consistently linked to lower depression, independently of mean levels of positive and negative emotions. These associations were best characterized as linear and our findings remained robust after controlling for gender, age, and the five primary dimensions of personality.

In Study 2, we explored whether emodiversity also predicted physical health. We recruited a representative sample of adults through a large mailing conducted by a governmental health insurance service in Belgium (N = 1,310). Respondents were asked to report their propensity to experience 10 specific positive and 10 specific negative emotional states, as well as a number of health-related

behaviors. In addition to these self-reported data, we obtained objective health measures from the health insurance service for each respondent over the last 11 years: number of visits to family doctors, number of days spent in hospitals, and the Defined Daily Dose (DDD), a typical indicator of medication consumption based on the average maintenance dose per day. Finally, we also obtained the total costs to the Belgian government for each of these expenses.

As before, mean positive emotion, mean negative emotion, and emodiversity scores were calculated for each respondent and entered into regressions predicting each health outcome. All measures of emodiversity were positively related to physical health, over and above mean positive emotion and mean negative emotion. The sizes of these effects were nontrivial: emodiversity was a stronger predictor of physical health than eating healthily, not smoking, and exercising frequently. These benefits were evident in decreased costs to the Belgian government as well: an increase of one standard deviation in overall emodiversity was equal to annual savings of 993.22 euros per person, per year, for the Belgian government.

Although the cross-sectional nature of this design precludes causal inferences, our findings dovetail with an emerging literature showing that a complete understanding of the impact of emotions on well-being requires more than an understanding of mere overall levels. For example, fluctuation around one's average level of emotion has been shown to be related to psychological-health above and beyond mean levels of emotions, while too much variability can be maladaptive (e.g., Gruber et al. 2013).

Why could emodiversity be beneficial for mental and physical health? As with research suggesting that biodiversity increases resilience to negative events because a single predator can't wipe out the entire biological ecosystem, it is possible that emodiversity prevents specific emotions—in particular detrimental ones such as acute stress, anger or sadness—from dominating one's emotional ecosystem (e.g., Mcewen 2004). For instance, the experience of prolonged sadness might lead to depression but the joint experience of sadness and anger – although unpleasant – might prevent individuals from completely withdrawing from their environment. The same biodiversity analogy could be applied to positive emotion. Humans are notoriously quick to adapt to repeated exposure to a given positive emotional experience (Frederick and Loewenstein 1999); positive experiences that are diverse may be more resistant to such extinction.

While future research is needed to document the precise pathway by which emodiversity improves outcomes, our results taken together support the notion that emodiversity is a significant and previously unidentified metric for assessing the health of the human emotional ecosystem.

Celebrate or Commemorate? When Material Purchases Lead to Stronger Memories and More Happiness

EXTENDED ABSTRACT

Imagine that you have just received a much-desired promotion and want to mark this milestone to make it more memorable for years to come. Should you celebrate the promotion with an experience (e.g., party or vacation) or commemorate it with a material purchase (e.g., watch or ring)? Recent research established an "experiential advantage," demonstrating that when recalling past purchases, experiences lead to more happiness than materials (Nicolao, Irwin, and Goodman 2009; Van Boven and Gilovich 2003). These findings would lead to celebration (vs. commemoration) recommendation.

However, when honoring special life events, the purchase itself is not the main driver of happiness; instead, the purchase is made to help facilitate the memory of the event and to create positive affect

and happiness over time. One way to move an event into long-term memory is rehearsal, which reduces the natural decline in memory over time (Elster and Loewenstein 1992; Tulving and Thompson 1973; Thompson 1982). We argue that material items (vs. experiences) can enable this rehearsal better by serving as a reminder of the memory. That is material items might enhance a positive memory and allow for the consumer to extract more utility over time.

In this research, we propose when marking a special occasion, commemorating through material purchases (vs. celebrating with experiences) allows for rehearsal and thus lead to better memory for the event over time. Furthermore, rehearsal of an event not only increases vividness of ones' memory, but it also reduces the rate at which positive affect fades (Skowronski and Walker 2004). Accordingly, we predict that purchasing a material item to commemorate (versus an experience to celebrate) will lead to more vivid memory and stronger positive affect associated with a special event or achievement over a long period of time. However, since the rehearsal only influences long-term memory, we do not expect material advantage to emerge for short time intervals. Finally, since the advantage of commemoration appears over longer periods of time, we do not expect consumers to able to predict the long-term advantage of commemorative purchases. Four studies provide support for these predictions.

In study 1 (n = 221), we examined whether participants would predict a long-term memory advantage for commemorative (vs. celebratory) purchases in a 2 (purchase: celebrate vs. commemorate) x 2 (time horizon: 1 year vs. 2 year) between subjects design. We asked participants to imagine they are about to graduate and decide to spend $300 to celebrate [commemorate] because they want to remember the day. We then asked how well and how vividly they expect to remember their graduation day in 1 [20] years, after making this purchase. Participants were accurate in predicting memory decay over time (i.e., they believed that their memory would fade over time, (β = .18, $t(147)$ = 2.14, p < .05). However, they did not expect a memory advantage to commemorating over celebrating (*ns*), suggesting that consumers expect memory to decay similarly for both celebrations and commemorative purchases.

In study 2 (n = 151), we examined if people predict that they will be happier with a commemorative (vs. celebratory) purchase to honor a special achievement. Participants imagined that they reached the end of their college career and received a $1000 gift card to a jewelry store (commemorative) [to Travelocity (celebratory)]. They then indicated how happy they thought the purchase would make them and how much it would contribute to their life happiness. Contrary to the commemorative purchase advantage we show in the next two study, participants predict being happier with the gift card for a celebration than for a commemorative item ($F(1, 148)$ = 61.84, p < .001). This shows that people are not aware of the higher level of happiness that commemorative purchases bring them (vs. celebratory purchases).

In study 3, we examined the memory for a special event when participants were primed either a celebration or commemoration. To control for the purchase type, we asked married participants (n = 151) to describe either their wedding reception (a celebratory experience) or their wedding ring (a commemorative material good). Participants rated their memory of this special occasion, how well their purchase reminds them of this occasion, and how long they had been married. As expected, we found a significant type of purchase (celebration/commemoration) by time since marriage interaction for both the memory measures (β = .23, $t(147)$ = 2.74, p = .007). Immediately after the wedding, individuals had a more vivid memory when they thought about their celebration compared to their commemorative

item (*p's* < .01). However, as time passed, people who thought about their commemorative purchase had a better memory of their wedding) than those who thought about their celebratory purchase (*p's* < .05). This study shows that over time, material items can enhance memory compared to an experience.

In study 4 (*n* = 148), we extended our findings to positive affect, by examining whether participants have (1) a better memory and (2) greater positive affect associated with their graduation day based on how they marked this special event (celebration vs. commemoration) We asked all participants to think back to their most important graduation, and then asked them to either recall how they commemorated or celebrated. Participants then responded to four measures: memory (how vividly they remember the day), purchase reminder (indicated how well the purchase reminds them of graduation), happiness (positive affect when recalling the day), and years since graduation. We found the same significant time by celebrate/commemorate interaction on memory of the day (β = -.61, *t*(144) = -2.06, *p* = .04). Bootstrapping analysis showed a significant indirect effect through the purchase reminder mediator on memory (95% CI = -.26, -.002). Further, bootstrapping analysis also revealed a significant indirect effect of memory on happiness (95% CI = -.12, -.003), suggesting that a commemorative purchase can increase the positive affect associated with an event over time by serving as a better reminder of the event.

In sum, these results not only provide a key exception to the experiential advantage, but they also demonstrate an important role of material goods in consumer happiness. The results suggest that consumers should commemorate instead of celebrate special occasions, if they want to increase happiness and protect special memories of events and achievements.

Neglect of Emotional Losses in Compensation Decisions

EXTENDED ABSTRACT

Of the losses people suffer, many are emotional losses such as fear, grief and anxiety, and many emotional losses are inflicted by others. Emotional losses entail grim consequences, as they lower the subjective wellbeing of the affected persons. The current research studies how laypersons serving as mediators and jurors make compensation decisions for emotional losses. The research finds a general tendency in them to overlook emotional losses, especially when there are economic losses present.

Our theory builds on three propositions. First, most people believe that emotional losses should be compensated for. Second, people prefer to base their decisions on "hard" (objective, tangible, material and substantial) factors rather than on "soft" (subjective, intangible, immaterial, and unsubstantial) factors. Third, people perceive emotional losses to be soft relative they perceive economic losses. Thus, we propose that people will base their compensation judgments on emotional losses when the emotional losses are the only losses and will ignore emotional losses and base their compensation judgments on economic losses instead if there are both emotional and economic losses. Based on this analysis, we predict a counter-normative effect in compensation decisions: Holding the emotional loss constant, people will award less compensation to the victim of an emotional loss if the victim also incurs a small economic loss than if the victim incurs only the emotional loss. We refer to this anomalistic effect as the less-for-more effect. According to our theory, the reason for the less-for-more effect is that emotional losses appear soft relative to economic losses. Therefore, we also predict that the less-for-more effect will disappear if the emotional loss is removed or replaced by an economic loss, or if the emotional loss is "hardened" (e.g., monetized) before making a compensation judgment. In summary, we have the following hypotheses:

Hypothesis 1   *Holding the emotional loss a person incurs constant, people will award less compensation to the person if the person also incurs a small economic loss than if the person incurs no economic loss.*

Hypothesis 2   *The less-for-more effect hypothesized in H1 will disappear if the emotional loss is replaced by an economic loss.*

Hypothesis 3   *The less-for-more effect hypothesized in H1 will disappear if the emotional loss is monetized prior to making a compensation decision.*

We tested these hypotheses in a set of seven experiments. Experiment 1 tested H1 and demonstrated the basic less-for-more effect using a car-accident scenario, in which a reckless driver hit an old woman and inflicted grave psychological distress on her. We found that participants awarded lower compensation to the victim if she also incurred a small economic loss than if she did not, regardless of whether the value of the economic loss was specified or not. The finding suggested that if there was no economic loss people based their compensation decision on the emotional loss, but there was a small economic loss people based their compensation decision on the small economic loss instead.

Experiment 2 and Experiment 3 replicated the less-for-more effect when compensation was service time (Experiment 2) or course credits (Experiment 3) rather than monetary payment. These results were important, because they ruled out stimulus-response compatibility as an alternative explanation for the less-for-more effect.

Experiment 4 tested H2 by manipulating the presence or absence of an economic loss. It found that that the less-for-more effect occurred only if there was an emotional loss and disappeared if the emotional loss was removed. Experiment 5 further tested H2 by showing that the less-for-more effect disappeared when the emotional loss was replaced by an economic loss.

Experiment 6 and 7 tested H3 by exploring another moderator – monetization of the emotional loss. The results showed that monetizing the emotional loss before making a compensation decision removed the less-for-more effect and boosted compensations for the emotional loss.

This research makes multiple contributions. Empirically, it demonstrates a robust and counter-normative less-for-more effect and reveals the tendency to neglect emotional losses in the presence of economic losses. Theoretically, it corroborates existing research by showing a dualism in decision makers: they acknowledge the role of soft factors in well-being yet are unwilling to base decisions on such factors. This has implications not only for judgments involving emotional versus economic factors but also for judgments involving soft and hard factors in general. Prescriptively, this research suggests two strategies for emotional-loss victims to claim compensations: do not mention economic losses unless they are large, and nudge mediators to monetize the emotional losses before making their compensation decisions.

Like economic losses, emotional losses hurt the wellbeing of the injured person. The current research draws public attention to such losses, and suggests ways to make compensations for emotional losses fairer.

SESSION OVERVIEW

Political ideology refers to "the set of attitudes that explains how society should work in order to achieve social justice and social order (Jost 2006)." Political ideology not only influences individuals' behavior in politically related contexts (e.g., voting) but also influences our everyday preferences and consumption behavior. For example, recent research shows that conservative consumers shop at Walmart more often while liberal consumers go to Starbucks more often (Gelman 2008). Despite the fact that political ideologies are one of the important drivers determining our daily life consumption behaviors, it is surprising that a few researchers in the consumer literature have recently begun to empirically examine how political ideology influences consumer behavior in daily life (e.g., Fernandes and Mandel 2013, Khan et al. 2013, Kidwell et al. 2013). To address this gap, the papers comprising this session proposal are designed to answer the following question: "How does political ideology affect a wide variety of consumers' reaction and behaviors (i.e., choices, persuasion, unhealthy behavior, and donation)?"

The first paper by Farmer and his colleagues examines how differences in political ideology impact consumer choices. They found that liberals preferred hedonic, novel, and desirable options while conservatives preferred utilitarian, status quo and feasible options. They also showed the mediating role of deliberation. The second paper by Duhachek and colleagues investigates how political ideology affects persuasion depending on ad framing. They demonstrated that conservatives (liberals) showed greater preferences toward products when they were shown the ad highlighting "stability (change)." They also showed the mediating role of a stability (vs. change) mindset. The third paper by Murdock and colleague examines how political ideology influences consumer reactions to warning labels initiated by government agencies. They found that when the FDA is associated with the warning label, conservatives (vs. liberals) showed greater tendencies to engage in unhealthy behavior (e.g., decrease their intention to quit smoking, increase their intention to purchase unhealthy food and order unhealthy side dishes). The last paper by Kaikati and colleagues discusses the impact of political ideology in donation contexts. Specifically, they examine how conservatives (vs. liberals)' donation intention will vary depending on the salience of the unifying social identity. They found that when salient social identities increase the motivation for social approval, conservatives increase their donation.

Taken together, the papers presented in this session will make theoretical contributions because all four papers are closely related and well grounded in theory, consequently enhancing our broad and in depth understanding of the relationship between political ideology and a wide range of consumer behavior. Furthermore, each one reports several experiments and presents novel findings to consumer researchers as well as provides important insight for practitioners and public policy makers who are interested in marketing products or developing persuasive messages under the influence of political ideology.

Political Ideology and Consumer Decision Making

EXTENDED ABSTRACT

Recent research in psychology, genetics, and neurology have identified fundamental differences in the way people think and behave relative to their political ideology (Alford, Funk, and Hibbing 2005; Kanai et al. 2011). Given these fundamental differences, it is likely that liberals and conservatives vary in the way they make decisions (Kidwell, Farmer, and Hardesty 2012). Yet, surprisingly little attention has focused on understanding how political ideology influences the choices that consumers make.

Political ideology is defined as the set of attitudes that explains how society should function in order to achieve social justice and social order, and is best conceptualized as a unidimensional construct with liberals on the left and conservatives the right (Jost, Federico, and Napier 2009). In order to assess the effects of political ideology, this research focuses on choice preferences. Specifically, the choice preferences between hedonic and utilitarian options, novel and status quo options, and feasible and desirable options are examined.

Conservatives may have a stronger inclination for a status quo option as they are more likely to defend and justify existing systems (Jost et al. 2003). Conversely, liberals are more open to experience which leads them to exploring their environment for what is unique, such as a novel option (Carney et al. 2008).

Some choices require consumers to consider both the process (feasibility) and the outcome (desirability) of the choice. Feasibility follows a low-level construal and is perceived as more concrete, while desirability follows a high-level construal, and is perceived as more abstract (Trope and Liberman 2010). Liberals are more likely to appreciate and prefer the abstract, leading them toward a preference for desirable options, whereas conservatives' dogmatic thinking leads them to focus on more specific, concrete characteristics (Shook and Fazio 2009).

Finally, consumers' choices are often composed of deciding between hedonic and utilitarian options. Utilitarian attributes are more objective and easily justified (Shafir, Simonson, and Tversky 1993). This is appealing to conservatives as they seek an ease of justification (Jost et al. 2003). The experiential nature of hedonic options, instead, is better appreciated and more preferred by liberals, as they are more open to experience (Carney et al. 2008).

Deliberation. The one explanation that can synthesize the differences between liberals and conservatives is how much they deliberate when making decisions, where liberals are predicted to delib-

erate more than conservatives. This is supported by the difference in their brain structure, where liberals are more likely to override habitual processing and are more open to experience (Carney et al. 2008), while conservatives are more likely to rely on rules and structure when making decisions and to think in more black and white terms (Jost et al. 2003).

The selection of a status quo option relies more on familiarity and past experience, while deliberation is positively linked to trying something new (Eidelman and Crandall 2009). When comparing feasible and desirable attributes, the evaluation of feasible attributes is often consistent, where the weight assigned to desirable attributes often guides decisions, such that feasible options are chosen when the desirable options are not deemed to be as important (Todorov, Goren, and Trope 2007). Finally, by deliberating less, conservatives are more likely to focus on the objective nature of utilitarian options, where greater amounts of deliberation help liberals justify a hedonic indulgence (Kivetz and Simonson 2002).

Studies Summary. Five studies are conducted to examine political ideology's impact on consumer choice. In study 1 we investigate the reported and actual behaviors of adult consumers relative to their political ideology while controlling for the age and household income of participants. Conservatives were more likely to provide utilitarian reasons for purchasing a vehicle while liberals were more likely to provide hedonic reasons ($\beta = .21$, $p < .05$). In a restaurant task, conservatives were more likely than liberals to go to nationally recognized restaurants (B = .32, $p < .05$), and were less likely than liberals to try new things at these restaurants (B = -.26, $p < .05$). Conservatives were also more likely to have Microsoft Windows installed as their operating system instead of more novel Linux or Apple operating systems (B = .44, $p < .05$). Finally, conservatives were more likely to prefer feasible vacations which are closer to home and cost less, while liberals would rather go on more desirable vacations which involve traveling farther from home ($\beta = -.22$, $p < .05$) and spending more money ($\beta = .21$, $p < .01$).

Studies 2 and 3 provide a more scientific and robust examination of these differences by employing multiple measures of political ideology and choice sets. The results from these studies present evidence that liberals and conservatives make systematically different choices. In studies 2a and 2b conservatives were more likely to prefer utilitarian foods, status quo restaurants, and short but dull (feasible) books while liberals were more likely to prefer hedonic foods, novel restaurants, and long but interesting (desirable) books. In studies 3a and 3b conservatives were more likely to prefer a utilitarian apartment, a status quo mutual fund investment, and a feasible concert gift while liberals were more likely to prefer a hedonic apartment, novel mutual fund investment, and a desirable concert gift.

Study 4 then tests the process mechanism of deliberation underlying the influence of political ideology on decision making using the same choice set from studies 2a and 2b. Deliberation was found to underlie these differences in decision making where liberals deliberated more than conservatives. Deliberation, or the amount of thinking, was solely responsible for these effects and was shown to work apart from the type of thinking and other potential alternative explanations.

Finally, study 5 uses the same choice set from studies 3a and 3b while experimentally manipulating levels of deliberation. Participants in the high deliberation condition exhibited liberal decision making tendencies for all three tasks while those in the low deliberation condition exhibited conservative decision making tendencies regardless of their political ideology. These results provide further support for deliberation as the underlying mechanism.

Stability vs. Change: The Effect of Political Ideology on Product Preference

EXTENDED ABSTRACT

Political ideology influences individuals' behavior in the politically related contexts as well as influences individuals' everyday preferences and consumption behavior. In this context, prior research has shown the effect of political ideology on consumer behavior that has political implications (e.g., Crockett and Wallendorf 2004). Moreover, a few researchers have recently begun to examine how political ideology shapes consumer attitude toward products that are devoid of political content (Fernandes and Mandel 2013; Khan et al. 2013). However, little is still known how political ideology influences consumer attitude toward non-political products and how practitioners can apply these findings to their advertising campaigns to attract more consumers.

To fill these gaps, the present research identifies a new mechanism and a new boundary condition of the effect of political ideology on product preference. First, although Fernandes and Mandel (2013) showed that political ideology affects consumer choice for non-political products, they exclusively examined variety seeking. Hence, the current research extends the existing literature by testing a different dependent variable (i.e., product preference). Second, although Khan et al. (2013) showed that conservative consumers prefer national brands, they only looked at a correlation between two variables. From their findings, the causal relationship between two is inconclusive and it is hard to understand "*why*" political ideology affects consumer preference for non-political products. Therefore, the current research articulates and empirically tests a new mechanism through which political ideology impacts consumer preference for products described in the ads. Finally, scant research has examined how marketing firms can incorporate these findings to their communication campaigns to attract more consumers who have different political ideologies. To address these gaps, this research proposes a new moderator (i.e., ad frame) and tests how conservatives vs. liberals show different preferences for the products when they are shown different types of product ads (i.e., either highlight stability or change).

First, we propose that conservatives will be more likely to maintain their current choices while liberals will be more likely to switch their current choices because previous research has demonstrated that conservatives prefer what is familiar and stable because change produces greater unpredictability and chaos while liberals are more open to experience new environments and pursue the novelty (Jost et al. 2003; Thorisdottir et al. 2007). Second, we posit that conservatives will show greater preferences toward the product when the ad includes the words related to stability (e.g., maintain, keep) than when the ad contains the words related to change (e.g., change, move) while the pattern reverses for liberals because previous research found that conservatives showed implicit and explicit preferences toward words such as "stable," and "tradition" whereas liberals showed implicit and explicit preferences toward words such as "flexible," and "progress" (Jost et al. 2008; Jost et al. 2009). Finally, regarding the mechanism through which political ideology affects consumer preference for products, we propose that political ideology activates different psychological mindsets that might carry over to a variety of subsequent tasks, which drive the effect of political ideology on product preference. Specifically, we propose that conservatives will activate stability mindsets whereas liberals will provoke change mindsets because previous research has demonstrated that conservatives prefer what is stable whereas liberals are more open to what is new (Jost et al. 2003; Thorisdottir et al. 2007). These activated mindsets will subsequently influence consumer preference for products.

Study 1 examined the effect of political ideology on product preferences in the context of the diet program. Participants were asked to imagine that they were on a diet and worked out at the fitness club for last two months but they found that their weight hasn't been changed a lot although they followed the diet program strictly. They were then asked to rate the likelihood that they would renew the membership and that they would switch to the new diet program (1=not at all likely, 9=very likely). The political ideology was measured on a scale adopted from Jost et al. (2007). The result revealed that conservatives were more (less) likely to renew the membership (switch to the new diet program) as compared to liberals.

Study 2 investigated the effect of the match between political ideology and message frames (i.e., change vs. stability) on persuasion. Specifically, participants were presented the ad message regarding the car emphasizing either change or stability (Change condition: We've been changing for 100 years. We're the symbol of moving forward! Change your outlook! [Stability condition: We've been here for 100 years. We're the symbol of consistency! Keep your life great!]). Next, we measured their attitude toward the product and political ideology. We found that a stability (vs. change) appeal was more persuasive for conservatives whereas a change (vs. stability) appeal was more persuasive for liberals.

Study 3 examined the underlying process. If the change or stability mindsets constitute the underlying process, by manipulating this process directly, we should be able to wipe out the effects of political ideology and have only the effects of the ad message frame and the mindset. Thus, in this study, we strived to manipulate the change (vs. stability) mindset directly by adopting the method used by Wood (2010) to examine the role of the change (vs. stability) mindset in the proposed effects. In addition, in this study, we manipulated political ideology through a procedure used by Fernandes and Mandel (2013). The same procedure and instruction to manipulate the message frame (i.e., change vs. stability) were used as study 2. After viewing the ad regarding the car, participants rated their attitudes toward the car. The results indicated that when the change mindset was made accessible, participants preferred the product when the message frame emphasized change while the pattern reversed when the stability mindset was made accessible.

Overall, our findings contribute to the consumer literature by examining the effects of political ideology on consumer attitudes in the politically unrelated contexts and uncovering why conservatives and liberals show different preferences for the products depending on the ad messages. Furthermore, the results have implications for practitioners by showing how they develop better advertising campaigns to attract more customers.

The Effect of Political Ideology on Reactions to Warning Labels and Consumption Regulations

EXTENDED ABSTRACT

The escalating health problems stemming from unhealthy consumer behaviors (e.g., overeating, smoking) prompt government officials to use a variety of public policy tools. For instance, in order to deter smoking, the Food and Drug Administration (FDA) is attempting to require graphic health warnings on all packages of cigarettes (Mears 2012). However, such labels can have unintended effects (Wansink and Chandon 2006), inducing psychological reactance (Brehm 1966), a motivational state focused on restoring a restricted freedom, which can often have a boomerang effect where the restricted activities become more attractive (Fitzsimons and Lehmann 2004).

Research on reactance has shown that warning labels lead to high reactance especially when the label source is deemed as authoritative (Bushman and Stack 1996). For example, college students were less likely to agree with a message advocating teaching machines when the message came from a prominent professor versus a high school student (Brehm 1966). While recent research on reactance has demonstrated how government regulations result in psychological reactance (Laurin, Kay and Fitzsimons 2012), an important factor—individuals' political ideology—has not received much attention from research on reactance. Since political ideology is at the heart of how people react to governments (Jost et al. 2003), it is especially relevant to investigate its role in the context of public policy initiatives and government regulations. We draw on research on political ideology (Jost 2006; Kidwell et al. 2013) and reactance (Brehm 1989; Fitzsimons and Lehman 2004) to suggest that reactions to warning labels and regulations may be influenced by consumers' political ideology. Further, we investigate how the source of these initiatives (e.g., government agency vs. businesses) interact with consumers' political ideology (i.e., conservative vs. liberal) to impact consumer reactions to warning labels and regulations.

Across three studies we demonstrate that 1) conservatives (vs. liberals) are more likely to act counter to the warning label when it is associated with a governmental source (Study 1), 2) this reaction only occurs among conservatives that are high in trait reactance (but not in high-reactance liberals) (Study 2), and 3) the underlying process of this effect is that high-reactance conservatives draw implications from government regulations that possible additional restrictions are on their way (Study 3).

In Study 1, 525 smokers viewed a series of graphic health warnings. The source of the graphic warning label (FDA vs. no-source control) was varied between subjects. In the control (FDA) condition the health warning stated: "(FDA) Warning: Cigarettes are addictive." Political ideology was measured by using a modified version of the political attitudes scale (Nail et al. 2009). The results showed a significant two-way interaction between label condition and political ideology ($p < .05$) such that in the FDA (vs. control) condition conservatives were significantly less likely to quit smoking ($p < .05$) whereas the label source did not have an effect on liberals' quitting intentions ($p > .70$).

In Study 2, 106 participants imagined themselves purchasing a pizza in a grocery store. Label (FDA vs. no-source control) was varied between subjects. The pizza had a front-of-package nutritional label that indicated an unhealthy amount of fat, saturated fat, and salt. In addition to political ideology, we measured participants' trait reactance (Hong and Faedda 1996). Replicating study 1, the results showed a significant two-way interaction between label condition and political ideology ($p < .05$). Further, in line with our theorizing, a significant three-way interaction between political ideology, reactance, and label condition ($p < .05$) showed that the effect was driven by conservatives who are high in reactance.

In Study 3, 156 participants imagined that they are at a local drive-through fast food restaurant, where due to high obesity rates large beverages had been removed from the menu by either the FDA (government condition) or the restaurant chain (business condition). Participants further imagined that they ordered Combo #1, which includes a cheeseburger and a small soda (no alternative size). Then they were asked which side dish they would prefer with their meal. The results showed that high-reactance conservatives were more likely ($p < .05$) to order an unhealthy side dish when the source of the regulation was the FDA (vs. business), while this effect was not significant for liberals regardless of their trait reactance level. Further, this effect appeared to be mediated by high-reactance conserva-

tives' concerns about potential future government restrictions in the domain of the regulation.

This research adds to the reactance literature by examining the process through which authoritative sources lead to negative reactions to warning labels. Specifically, we show that, at least in the context of warning labels and regulations, political ideology of the consumer is an important factor in reactance. As such, the present research is the first to investigate how differences in the way various consumer groups view the influencing agent leads to reactance and, hence, limits the success of public policy initiatives. Further, our findings add to the political ideology literature by highlighting how threat to freedom can, under certain conditions, trump respect for authority for those with conservative political orientation. From a public policy perspective, these results are important as the FDA may ironically lessen the impact of its own initiatives if consumers know that it is the FDA that is behind the warning labels.

Conforming Conservatives: How Norms of Salient Social Identities Overcome 'Heartless Conservative' Tendencies

EXTENDED ABSTRACT

Perceptions of bleeding heart liberals and heartless conservatives abound (e.g., Farwell and Weiner 2000), though some research has demonstrated that these perceptions are not always represented in actual behavior (Brooks 2006) and individuals of either political ideology are equally likely to donate, as long as the cause aligns with their values or moral foundations (Winterich, Zhang, and Mittal 2012). The current research moves beyond political ideology to consider how the multiple identities that consumers hold impact the extent to which political identity, and corresponding perceptions of giving, actually impact donation decisions.

While conservatives may have more individualistic and competitive orientations than liberals, who tend to have more prosocial orientations (Van Lange et al. 2012), research has also demonstrated that conservatives are more likely to conform to group norms (Cavazza and Mucchi-Faina 2008). Moreover, Jugert and Duckitt (2009, p. 698) argue that "the personality dimension of social conformity should increase group identification, since persons with a dispositional tendency to conform to their group's norms should be inclined to identify more strongly with their groups." This research suggests that conservatives will be more likely to conform to the donation tendencies of their group than liberals, but, notably, conformity is not limited to the political group with which one identifies.

Consumers hold multiple identities (Winterich et al. 2012), which may differ in salience at any given moment (Reed 2004). For instance, although students from the same university can define themselves in terms of liberal—conservative social identities, situational constraints can lead the same individuals to ignore these identities and to focus instead on the shared college identity for self-definition. Contextual activation of this common in-group identity heightens the need to maintain in-group cohesiveness and harmonious relations with other group members. Here, we expect that conservatives will be particularly motivated to comply with the norms and stereotypes of the salient in-group, even when this in-group consists of 'bleeding heart liberals.' In this context, conservatives faced with charitable decisions that would be discussed with *fellow college students* holding liberal views should be motivated to seek approval from the audience (Torelli 2006), and hence factor into their decisions the more generous expectation of their fellow students. In turn, this will boost their own generosity to fit with a liberal audience's norms for charitable giving. When a common social identity (e.g., fellow college students) is not salient, though, the effect of a liberal

audience on increasing conservatives' generosity will be attenuated. This conformity to group norms by conservatives is consistent with the personality trait of politeness, a sub-dimension of agreeableness, that is reflective of conservative beliefs (Hirsch et al. 2010). Moreover, the desire to conform to manage one's impressions among group members reflects a greater value on binding or group-focused moral foundations, which include group loyalty and duty, by conservatives (Graham, Haidt, and Nosek 2009). Notably, while liberals also hold multiple identities that may differ in salience, liberals do not value conformity to the same extent as conservatives.

The current research focuses on donation decisions in the case of needy people judged to be responsible for their plight (Reyna et al. 2005) for which behavior consistent with heartless conservatives has been previously demonstrated. Two studies show that conservatives who anticipate accountability to individuals who hold the opposing political ideology exhibit greater generosity in their charitable decisions, compared with those who anticipate interacting with individuals holding the same political ideology or those making charitable decisions in private, and that this effect is mediated by the desire to seek approval from the audience. This effect emerges only when a shared identity (i.e., college student identity) is salient and is only observed for conservatives rather than liberals. The effect disappears when the charitable cause involves a politically polarizing issue inconsistent with conservatives' moral foundations.

In study 1, students from a Midwestern university were divided in three groups and were asked about the amount of money they would donate to an individual in need. They were further told that they would later discuss their decision with *fellow college students* described as liberals (conservatives), or made a private decision. Half of the participants in each group were presented with a non-polarizing cause ("a person with medical problems due to obesity caused by poor diet and lack of exercise," Farwell and Weiner 2000), whereas the other half were presented with a polarizing cause ("a person with AIDS due to promiscuous homosexual relations—from pre-test). Results showed that conservatives (liberals) exhibited greater generosity (no change) toward the needy person in the non-polarizing condition when accountable to liberals versus when accountable to other conservatives or making decisions in private. Furthermore, this effect was mediated by the desire to seek audience approval (White and Peloza 2009). The effect was absent for the polarizing cause that was inconsistent with conservatives' moral foundations.

In study 2, we provided further evidence of mediation and, importantly, also showed that the effects dissipate when a common identity is not salient. Half of the college student participants were presented with the non-polarizing cause in Study 1 and made their donation decision under the expectation of discussing it with *fellow college students* (*salient social identity* condition) described as either liberals or conservatives, whereas the other half made a decision to be discussed with *others* described as liberals or conservatives (*non-salient social identity* condition). Results from this study replicated the findings in Study 1 in the salient social identity condition, but showed that the effects dissipated in the non-salient condition.

Drawing from the rich literature on conformity among conservatives, we show that while conservatives may be rigid in their beliefs (i.e., the rigid attitudes of the right, Jost et al. 2003), they may actually be more malleable in their behavior. Specifically, in order to manage impressions, conservatives motivated to comply with the norms and stereotypes of the salient in-group will alter their behavior, resulting in increased donations that conflict with perceptions of heartless conservatives. Future research should consider the extent to which such conformity in behavior can alter attitudes through self-perception.

SESSION OVERVIEW

Perceived control refers to a belief that one can determine one's own internal state and bring about desired outcomes (Nelson & Cohen 1983; Wallston et al. 1987). While people are generally highly motivated to attain and maintain a sense of control (deCharms 1968; Brehm 1966; Langer 1975), perceived control can be quite paradoxical in nature, with surprising antecedents and consequences (Botti et al. 2009). Accordingly, the role of the perceived control construct has not been fully explored in consumer research. This gap in our knowledge raises two important questions: 1) How might perceived control play a role within consequential consumer domains? and 2) What contextual factors influence the downstream effects of perceived control?

The proposed session addresses these questions by combining four papers that uncover important antecedents and consequences of perceived control within consequential consumer domains: healthcare, charitable giving, food consumption, and corporate social responsibility. In the first paper, Friedman and colleagues shed light on an unexpected paradox of perceived control. They find that even though people desire information about undesirable future events (e.g. the development of an incurable genetic illness) and predict such information will increase their sense of control, acquiring such knowledge ultimately diminishes their feelings of control and satisfaction. In the second paper, Cutright and colleagues document the impact of perceived control on charitable giving. Specifically, the authors demonstrate that when people are low in control, they rely on their salient emotions in an effort to restore perceived control via more narrowly-defined and structured charitable behavior. In the third paper, Hadi and Block examine perceived control from a different angle, by documenting a means of artificially manufacturing feelings of control. They find that active food acquisition generates

a false impression of choice, leading to increased food consumption for individuals high in dispositional need-for-control. While these first three first papers explore perceptions of personal control, the last paper explores judgments of another's degree of control. Hildebrand and colleagues find that for disasters perceived to be controllable by its victims, monetary contributions produce higher company evaluations than in-kind contributions of equivalent monetary value. However, the reverse is true for disasters perceived to be uncontrollable.

Collectively, this session highlights the interesting and often unexpected ways perceived control can be enhanced and mitigated, and how it can play a role in societally relevant domains. Importantly, the collection of papers show that the impact of perceived control on downstream behavior depends on distinct contextual factors: information desirability (Friedman et al.) emotions (Cutright et al.), dispositional need-for-control (Hadi & Block), and donation type (Hildebrand et al.). Given the interesting juxtaposition of these papers and the consequential nature of the dependent variables examined, we expect this session to stimulate much discussion and appeal to a large group of conference attendees.

"Control and Happiness: Knowing About the Future Hurts the Present"

EXTENDED ABSTRACT

The sense of being in control, of perceiving experiences as caused by deliberate actions and not by external forces, is a basic individual need (deCharms 1968). Consumers who feel in control are usually happier, and when control is threatened they seek to reinstate it (Brehm 1966; Langer 1975). Recent research has investigated two different sources of perceived personal control, freedom of choice and power (Inesi et al. 2011), but classic literature cites information as yet another source (Averill 1973). For example, Schulz (1976) showed that freedom of choice is correlated with predictability, and that access to information about a future event leads to the same psychological benefit of control even in the absence of choice.

Research has however demonstrated that, although people strive to feel in control, the actual experience of control does not necessarily increase subjective well-being. For example, in conditions involving undesirable options, consumers prefer having freedom of choice but their affective reactions and outcome satisfaction suffer as a result (Botti, Orfali, and Iyengar 2009). In this paper, we predict a similar effect in the context of undesirable information. Specifically, we hypothesize that consumers prefer having information about an undesirable future event because they believe that they would feel more in control. However, the availability of this information will not improve their life satisfaction either before or after the occurrence of the event. We focus our investigation on future, undesirable events that are unavoidable, such as the development of some genetic diseases.

In the first study, participants imagined contacting their doctor after being told that some relatives had lost their sight. Participants also imagined the doctor explaining that some genetic diseases cause blindness and cannot be prevented, and that a genetic test could be conducted to ascertain the presence of the gene mutation. Participants were then asked whether or not they would undergo the genetic testing and why. Ninety percent of participants answered that they

would undergo the genetic test. Forty percent of the reasons provided were related to knowledge for the sake of it: these participants wanted to know because they attributed an intrinsic value to this information. Another 40% of the reasons revolved around the concept that knowing would allow for better preparation and coping. Only 8% of the reasons mentioned that knowing would be a motivation to enjoy life before the ensuing of the illness (12% were a mix of other reasons). Thus, about 80% of the justification for the willingness to know about an undesirable future was explained with the belief that this knowledge would improve control, either as a need in itself or as a way to better deal with the disease.

To investigate the psychological consequences of knowing about an undesirable future, we conducted a second study that meant to simulate in the lab a situation that was similar, although less consequential, to that illustrated in study 1. Participants were informed that they would take part in two unrelated studies and that the first study involved watching a video, which was pretested for being relatively neutral. Half of the participants was also informed about the subsequent study, which involved tasting a disgusting yoghurt flavour. The other half of the participants was told that the description of the second study would be provided only after they had concluded the first study. Thus, all participants went through the same two experiences, a neutral one and an unpleasant one, with the main difference that some knew about the pending unpleasant future and some did not. Results show that participants who knew about the undesirable future yoghurt liked the video less than those who did not know. Knowledge did not have a positive effect even after the undesirable event happened, as participants who knew about the undesirable future yoghurt liked it marginally less than those who did not know.

Study 3 employed a scenario that was more similar in content to that of study 1. After imagining a doctor recommending them to take the test, participants were randomly divided into two groups: the first group imagined that the test was positive and they would develop the illness; the second group imagined that the test was negative. We compared these two groups with a control group including participants who did not read any scenario. In the second part of the study, participants who took the test imagined that they either developed, or not, the illness while those in the control condition were told that they either developed the illness or that their life continued pretty much unchanged. After each study parts, participants were asked to estimate their general feelings and level of perceived control within the next year. Results showed that participants who knew that they would develop the illness because they took the test predicted more negative affect and less control than both participants who knew they would not develop the illness and those in the control group. After developing the illness, participants who knew in advance about the illness predicted more negative affect and less control than those who did not know.

Study 4 tested our hypotheses with patients who are legally blind. These patients were asked whether they knew that they would lose their sight before they experienced any symptoms and assigned to two groups on the basis of their answer to this question. We then asked them to assess their level of affect and sense of control during the first year following their vision loss using the same questions employed in study 3. About half of the data has been collected so far, so results are only preliminary but directionally confirm the findings of study 3.

This set of studies suggest that although consumers want to know about an undesirable future event because they believe this would increase control over their lives, this knowledge not only does not make them feel more in control but it also reduce present happiness, both before and after the occurrence of the event.

"Boundaries of the Heart: The Interplay of Personal Control and Emotion on Donation Decisions"

EXTENDED ABSTRACT

How do consumers respond when their sense of personal control over outcomes in life is threatened? More specifically, how does it change what they are willing to give to others? Building on prior research suggesting that low feelings of control lead individuals to seek greater structure in their lives, or the sense that 'there's a place for everything and everything is in its place' (e.g., Kay et al. 2008, Cutright 2012), we expect that individuals will find it particularly important to keep their emotions 'in place' when control is low. In other words, they should be more likely to confine the traditional carry-over effects of emotions (e.g., Lerner et al. 2004) to specific, relevant areas. We expect this to be particularly important in the area of charitable giving, where emotions are often considered to be critical in determining outcomes (e.g., Small & Verrochi 2009). Specifically, we predict that when control is low, people will use their salient emotions to increase (or decrease) donations only for organizations that are highly relevant to the source of their emotions. For example, if individuals are sad after thinking about abandoned pets, those with low feelings of control should be the most likely to use this sad feeling—and the empathy and desire for connection that often stems from sadness (Mouilso et al. 2007; Small & Lerner 2008)—to concentrate their donations on pets. Conversely, high control individuals will be more likely to use their sad feelings to spread donations across a broad range of charities.

In our first study designed to test this idea, we assigned participants to one of two control conditions. Participants were asked to write about a (positive) time when they had low or high control over an outcome (e.g., Kay et al. 2008). They were then introduced to a standard emotion manipulation (Small & Lerner 2008). Specifically, they were asked to write about how one of two tragic events made them sad: either the Boston marathon bombing or the movie theater shooting in Aurora, Colorado. Participants were then asked to allocate $200 across charities related to the victims in Aurora, Boston, or an unrelated topic. As expected, we found that when control was low, individuals preferred to direct their donations to organizations that were relevant to their current emotions. The low control individuals who wrote about the Boston tragedy donated more to Boston victims than those who wrote about Aurora (M_{Boston} = $95.95 vs. M_{Aurora} = $75.42; p = .03). Similarly, the low control participants who wrote about the Aurora tragedy donated more to Aurora victims than those who wrote about Boston (M_{Aurora} = $75.63 vs. M_{Boston} = $57.51; p =.03). Importantly, such differences did not exist in the high control conditions (ps > .37).

In a second study, we sought to demonstrate that even fairly incidental experiences of sadness (e.g., sad situations that are not linked to the charities) will evoke similar patterns of behavior, such that low control participants will be the most interested in donating to organizations that are as relevant to the source of their sadness as possible. To test this idea, participants were first assigned to a low or high control condition as in Study 1. They were then asked to watch a sad movie clip. Individuals either felt sad about the death of a loyal dog (*I am Legend*) or because of the emotional pain of a young boy (*The Champ*). Participants were then asked to allocate $200 to a series of charities related to dogs, children or unrelated topics. Results revealed that the low control participants who saw the sad dog clip were more likely to donate to dogs than those who saw the child clip (M_{dog} = $45.66 vs. M_{child} = $26.20, p = .01). Similarly, the low control participants who saw the sad child clip were more likely to donate to children than those who saw the dog video (M_{child} = $32.54 vs. M_{dog}

= $19.87, *p* = .04). These comparisons were not significant when control was high (*ps* > .32).

In a third study, we sought to demonstrate that our hypotheses extend beyond sadness. We therefore aimed to conceptually replicate our results with an emotion that should lead to very different reactions than sadness. Specifically, we hypothesized that when consumers experience feelings of disgust and consequently have little desire to donate (given that they are motivated to move away from and expel things and ideas in their environment; Lerner et al. 2004), those with low control should reduce their donations only within relevant areas. To test this idea, participants were assigned to a low or high control condition. They were then asked to watch a very disgusting video, which either showed a dog eating feces or a child doing the same. Participants were then asked to allocate $200 to child or dog-related charities (as in Study 2). As expected, the low control participants who viewed the disgusting dog donated less to dogs than those who viewed the child video (M_{dog} = $23.21 vs. M_{child} = $46.25, *p* = .02). Similarly, the low control participants who viewed the disgusting child donated less to children than those who viewed the dog video (M_{child} = $30.00 vs. M_{dog} = $46.31, *p* = .06). These differences did not hold in the high control conditions (*ps* > .28). Thus, individuals in the low control condition were more likely to use the action-tendencies associated with disgust (the need to expel and move away) and apply it to the charity that was most relevant to the source of the disgust.

Together, these studies suggest that when control is low, individuals erect mental boundaries that dictate which charities are relevant to their current emotions and which ones are not. This allows them to allocate their money in a way that feels ordered and structured, and reject the notion that outcomes are randomly or chaotically determined, which is particularly comforting when feelings of control are low.

"I Take Therefore I Choose? The Impact of Active vs. Passive Acquisition on Food Consumption"

EXTENDED ABSTRACT

In general, we tend to take things that we have chosen. We reach out and take our desired snack from a refrigerator, favorite book off a bookshelf, and preferred brand from a store shelf. On the other hand, we are often given things we do not choose. A loved one might hand us a gift they picked for us; a child might find unsolicited vegetables piled onto her plate. Perhaps then, this distinction between taking and receiving has built a blueprint in our minds: we take what we choose, but are given what we do not choose. If this is the case, might the mere gesture of reaching for and taking something make us feel as though we chose it?

This research investigates the consequences of physically taking (actively acquiring) vs. receiving (passively acquiring) equivalent food items. Specifically, we show that even when there is no true choice available, the act of physically taking food items can generate a false impression of choice, an effect we term "embodied illusion of choice," which has meaningful consequences on consumers' food evaluation and consumption.

A growing body of research has documented the ability of incidental cues to impact eating behaviors, both in terms of food evaluation and consumption volume. For example, packaging (Xiaoyan, & Srinivasan 2013) and portion sizes (Rolls, Morris, & Roe 2002) have been shown to unknowingly impact the amount of food people consume. In this research, we borrow from embodiment literature to propose a new extraneous factor that influences food consumption: active vs. passive acquisition. Embodiment research reminds us that

bodily situations can nonconsciously impact how we think and feel (Varela et al. 1991, Barsalou 2008). In this research, target objects are acquired under both conditions (both entail arm flexion), but the difference stems from the agent of initiation: in the active condition, individuals themselves initiate the acquisition; while in the passive condition, an outside agent acts as the initiator. We argue that it this distinction, between initiated (active) acquisition and un-initiated (passive) acquisition, that drives differences in perceived choice, even when no actual choice available. If such physical gestures can indeed induce perceptions of choice, how would this illusion impact an individual's evaluation and consumption of food items?

The ability to choose is valuable to most individuals, and thus providing choice generally leads to improved attitudinal outcomes (Ryan & Deci 2000, 2006; Leotti et al. 2010). Among other domains, this "pro-choice" effect has been documented the area of food and beverage evaluation and intake (Botti & Iyengar 2004; Weber, King, & Meiselman 2004; Zeinstra et al. 2010). In fact, early research has demonstrated that people perceive aversive foods (e.g. grasshoppers) to be less disagreeable if they feel they have chosen to eat them (Zimbardo et al. 1965). In this research, we explore how the mere act of actively (vs. passively) acquiring food items may lead individuals to evaluate these items more highly and consume more, just like an offering of real choice might.

However, extant literature also suggests that the impact of providing choice may vary for different types of people, implying that not everybody has an equal desire to choose. For example, individuals who place low value on autonomy and the need to control seem to value choice less than those who place high value on such factors (Snibbe & Markus 2005), and measurable differences emerge in individuals' need-for-control (Burger & Cooper 1979). Thus, we additionally suggest that the impact of acquisition on consumption is moderated by an individuals' need-for-control, such that the difference between passive and active acquisition conditions is attenuated for individuals low (vs. high) in need-for-control.

Study 1 provides initial evidence of an embodied illusion of choice via a two-factor (acquisition: passive vs. active) between-subjects design. Respondents (N=96) were told they would taste and evaluate candy. Participants in the passive condition were handed a piece of wrapped candy from a bowl by the experimenter, while participants in the active condition reached out and took a piece from the experimenter's bowl (all candies were identical). Participants were offered to take another piece of candy upon exiting. Results produced significant effects of acquisition on product evaluation and on whether or not subjects took another candy: participants evaluated the candy better and were more likely to take another when they had actively taken the initial piece of candy than when it was handed to them.

Study 2 examined the impact of embodied choice on consumption of a chocolate bar, explored the mediational role of "feelings of choice," and investigated the role of individuals' need-for-control. The manipulation procedure was identical to study 1. After acquiring the chocolate, respondents (N=127) completed a need-for-control scale, and were instructed to eat as much of the chocolate as they wished. Afterwards, they indicated their feelings of having chosen to consume the chocolate (e.g. "I felt as though I had a choice of whether or not to try this chocolate"). The remaining chocolate was weighed in order to calculate how much each participant consumed. Analysis results indicated a significant acquisition x need-for-control interaction on consumption. Participants at high levels of need-for-control ate more chocolate when they actively took it than when they passively received it. However, individuals low in need-for-control demonstrated no significant difference in consumption between ac-

quisition conditions. A bootstrapping moderated mediation analysis confirmed that for those high in need-for-control, feelings of choice mediated the effect of acquisition on consumption.

We contribute to extant literature by documenting uncovering an illusion of choice phenomenon, suggesting that mere physical gestures can foster feelings of choice in an individual via active (vs. passive) acquisition of food items. Thus, we contribute not only by documenting a new antecedent of food behavior, but also by addressing a recent call (Wansink 2004) to explore the psychological mechanisms that drive such effects. Our research offers public health implications accordingly. Given the childhood obesity epidemic, it may be beneficial to encourage children to self-serve themselves healthy foods (e.g. via a salad bar) at school cafeterias, but discourage self-service of unhealthy foods.

"Consumer Evaluations of Corporate Relief Efforts to Disaster Victims: When Controllability Matters"

EXTENDED ABSTRACT

From forest fires to tsunamis, from Katrina to Sandy, companies have devoted billions of dollars, both in cash and in-kind, to disaster relief in just the last decade (U.S. Chamber of Commerce 2011). Yet, insights into how consumers react to corporate contributions to disaster relief remain scant. We draw on prior research about control attributions (Meyer and Mulherin 1980; Weiner 1980) to argue and demonstrate that consumers' reactions hinge not on the nature of the contribution per se but rather on their assessment of its fit with the perceived controllability of the disaster.

Extant research (Meyer and Mulherin 1980; Weiner 1985) points to the attributions observers make about the controllability of an event as powerful drivers of the extent to which they react emotionally to it and those affected by it. Based on this, we contend that consumers tend to react more emotionally [rationally] to disasters they perceive to be less [more] controllable by victims. More importantly, we predict that a consumer's reactions to a company's disaster relief efforts will be based on the fit between the emotional level elicited by a given disaster and the nature of the corporate contribution.

Because controllable disaster elicits less emotional (and more rational) responses, the more rational monetary contributions will be perceived to be higher in contribution-controllability fit and thus will receive more positive evaluations than the emotional laden non-monetary contributions. In contrast, since an uncontrollable disaster elicits strong emotional reactions, the more caring and loving in-kind contributions will be perceived to be higher in contribution-controllability fit and receive more positive evaluations than monetary contributions. Moreover, because the perceived controllability of a disaster is central to our theorizing about consumer evaluations of monetary versus in-kind corporate relief efforts, different levels in controllability of a disaster should influence consumers responses only when consumers actually desire, and are therefore cognizant of control related issues, i.e., when controllability is situationally or chronically salient. We tested our basic hypotheses in 3 studies.

In study 1 we used a 2 (Contribution Type: Monetary vs. in-kind) x 2 (Disaster Controllability: High vs. low) between-subjects design. Participants first read a fictitious news account of a large-scale avalanche, and a logistics company's subsequent disaster relief efforts. In the high [low] controllability condition, the article explicitly stated that the avalanche and consequent aftermath could [could not] have been prevented by the affected community. The article also reported that a logistics service company had contributed either a million dollars that would be used for logistics support [monetary] or logistics services worth a million dollars [in-kind] towards relief ef-

forts. After reading the article, participants provided their evaluation of the company and perceived controllability-cause fit. An ANOVA on Company Evaluation produced a significant two-way interaction; in the high [low] controllability condition, the firm's monetary [in-kind] contribution produced higher evaluations than in-kind [monetary] contribution. The ANOVA on Fit presented a similar pattern. More importantly, mediated moderation analysis (Hayes 2013) demonstrated that Fit mediated the interactive effect of Contribution Type and Disaster Controllability on Company Evaluation.

Studies 2 and 3 were designed to demonstrate that controllability over a disaster influences consumers' emotional reactions to it (study 2) and that consumers' emotionality level underlies their perceptions of fit and evaluations of corporate contributions (study 3). In addition to demonstrating the first step of the proposed process, study 2 was also designed to provide support for the role of controllability salience by measuring participants' Desirability of Control (Burger and Cooper 1979) and using it as a moderator. Thus, we examined the effect of disaster controllability on emotionality level with a 2 (Disaster Controllability: high vs. low) x 2 (Controllability Salience: continuous) between- subjects design. We assessed participants' level of emotionality/rationality by measuring their reaction time to four focal words, two with strong emotional content (i.e., emotional, feeling) and two with strong rational content (i.e., rational, strategic). We created an Emotionality index by subtracting the natural log transformation of the reaction time for the two emotional words from that for the two rational words. As predicted, we found a significant interaction effect: Participants high in Controllability Salience presented higher Emotionality index scores in the uncontrollable (versus controllable) disaster condition. Participants low in Controllability Salience were no different in their Emotionality index scores across disaster controllability levels.

Study 3 examined the second step of the proposed process, i.e., people that are more [less] emotional perceive a stronger fit and evaluate more positively in-kind [monetary] types of help. This study employed a two-factor – Emotionality (high vs. low) and Contribution Type (monetary vs. in-kind) – between-subjects design. We first manipulated participants' level of emotionality using a method developed by Hsee and Rottenstreich (2004). After performing the priming task, participants read a fictitious news report about an avalanche in California, along with information about a company's contribution to disaster relief. Type of help was manipulated similarly to study 1. As expected, the ANOVA on Company Evaluation revealed a significant 2-way interaction. Specifically, participants in the low [high] emotionality condition evaluated the company more positively when the donation was monetary [in-kind]. As well, the ANOVA with Fit as the dependent variable revealed a similar pattern. More importantly, Fit mediated the interactive effect of Contribution Type and Level of Emotionality on Company Evaluation.

The findings reported make three important contributions. First, it advances our understanding of consumer responses to a company's corporate social responsibility activities in the important domain of disaster relief (Ellen et al. 2000; Nestlé Waters 2013). Second, it provides evidence for the underlying psychological process, implicating consumers' level of emotionality in their responses to firm actions in this domain. Third, it broadens our extant understanding of fit, a notion central to the CSR literature (Pracejus and Olsen 2004), by introducing a new type of fit (i.e., that between the perceived controllability of a disaster and the type of contribution) that is particularly germane to consumer judgments of companies' contributions to disaster relief, and possibly even a broader range of social and environmental issues, wherein controllability perceptions loom large.

Erin Percival Carter, University of Colorado Boulder, USA
Lawrence E. Williams, University of Colorado Boulder, USA

SESSION OVERVIEW

The pursuit of pleasure shapes consumers' attempts to socially bond and fulfill their desires, as well as their responses to marketing activities. Indeed, hedonic pursuits guide choice (Dhar and Wertenbroch 2000), self-regulation (Fishbach and Labroo 2007), and brand preference (Hagtvedt and Patrick 2009). Recently, there has been renewed interest in understanding the mechanics of pleasure, and the role that hedonic pursuits play in consumers' lives (Alba and Williams 2012; Haws and Poyner 2008). Although it has been long assumed that the pursuit of pleasure is the hallmark for rational human behavior (Bentham 1789), such pursuits often feature a dark side, involving failures of impulse control (Loewenstein 1996) and their corresponding negative emotions (e.g., guilt; Giner-Sorolla 2001). As we prepare to turn our focus "back to fun," the papers presented in this session explore the complexity of hedonic pursuits and their consequences.

Goldsmith and Hershfield demonstrate that judgments of others' indulgent behaviors, such as overeating, overspending, and gambling, are sensitive to the context in which the behavior occurs. Judges are less harsh when the indulgent behavior occurs in an atypical (vs. familiar) context. Han and colleagues ask what are the consequences of guilt and shame, two negative feelings that often arise following hedonic pursuits. They find that these discrete negative emotions shift the way people construe their mental worlds. Warren and McGraw extend their examination of the nature of humor, demonstrating that humorous consumption and humorous marketing tactics involve both safety and pain. Finally, Carter and Williams distinguish between hedonic (fun) and eudaemonic (meaningful) consumption experiences, showing that consumers seek variety when exposed to the former, but prefer prolonged exposure to the latter.

Collectively, these papers seek to add to the literature on understanding the impact of the pursuit of pleasure, and its unintended (sometimes negative) consequences. The session should appeal to consumer researchers interested in indulgent consumption, mixed emotional experiences, the interplay between affect and cognition,

and consumer choice. We hope this session will stimulate future theory development on the complexities of hedonic experiences.

Crime…and Punishment: The Effects of Context on Signal Strength and the Consequences for Condemnation

EXTENDED ABSTRACT

It has been widely recognized that consumers attempt to justify their behavior, especially when the behavior is self-indulgent (Dhar and Wertenbroch 2000; Kivetz and Keinan 2006; Kivetz and Zheng 2006) and/or violates a personal goal (Goldsmith and Dhar 2013). However, far less is known about if and how consumers might pro-actively utilize elements of the behavioral context in an effort to justify their indiscretions *a priori*. For example, imagine an individual, Rob, who enjoys gambling; however, he and his wife have a goal to save money. One of his former gambling buddies comes to visit. What might Rob do in order to preemptively justify a gambling indiscretion? The current research takes the perspective of the consumer as a manipulative agent, and argues that consumers who seek to "sin" will pursue a-typical contexts in which to do so, because a-typical contexts deflect the behavioral attribution away from the self. Hence, the same indiscretion will lead to less harsh judgments from others when the behavioral context is a-typical (vs. typical), due to a shift in the extent to which the behavior is seen as reflective of the self.

This prediction raises the important question of what constitutes an a-typical (vs. typical) context. For example, if Rob and his friend were to gamble in Las Vegas this context might be a-typical (provided Rob does not reside in Las Vegas); however, it also has unique behavioral norms regarding gambling, which should logically affect gambling behavior. However, we argue that consumers' judgment of others can vary even as a function of largely irrelevant contextual factors. Specifically, we examine how condemnation is affected by where the indiscretion took place (a-typical: neutral location far from home vs. typical: neutral location near to home), the person's familiarity with the context (a-typical: neutral unfamiliar context vs. typical: neutral familiar context), and the person's mental state at the time of the indiscretion (a-typical: intoxicated vs. typical: sober). Across these studies, we find that observers judge others less harshly for their indiscretions when the behavioral context is a-typical (vs. typical), and that this shift in judgment is mediated by the extent to which the behavior is seen as reflective of the self. Further, we show that the a-typicality of the behavioral context also affects how individuals make choices for themselves, with a-typical contexts (e.g., a "special day") sanctioning more self-indulgent behavior. This supports our contention that consumers may pro-actively pursue a-typical contexts in order to engage in self-indulgence (comparatively) free from judgment.

We test these predictions in a series of nine lab and field studies. Study 1 tests if people perceive the behaviors of others to be less reflective of the self in a-typical behavioral contexts by having them evaluate a vignette describing an actor who engaged in an indiscretion (e.g. over-eating) on one occasion and a neutral behavior (e.g., maintaining a diet) on another occasion. The behavioral context in which the indiscretion transpired (a-typical: neutral location far from home vs. typical: neutral location near to home) was varied between participants. Participants were asked to indicate how similar they

thought the actor's authentic self was to the self who indulged using a measure derived from Aron et al.'s (1992) Inclusion-of-the-other-in-the-self scale. Results revealed that when the behavioral context was a-typical, because the actor was away from home, participants indicated there was less overlap between the "self who indulged" and the "authentic self," as compared to when the indiscretion took place near home (p = .016).

Study 2 builds on these results by examining how an actor's familiarity with the behavioral context (a-typical: neutral unfamiliar context vs. typical: neutral familiar context) affected other's judgment of their indiscretion (over-spending) and found that when the behavioral context was a-typical, because the actor was in a local shopping mall she had not been to previously, the over-spending was judged less harshly than when the local mall was familiar (p = .032). Further, in line with our theoretical mechanism, the over-spending was seen as less reflective of the actor's self when the context was a-typical as compared to when it was typical (p = .034) and the shift in signal strength mediated the relationship between context typicality and judgment (95% CI=-.278, -.024).

Study 3 provides a conceptual replication for Study 2 by manipulating if the behavioral context was a-typical (vs. typical) by manipulating the description of the actor's mental state (intoxicated vs. sober). Again, we observed that when the behavioral context was a-typical, here because the actor was drunk, observers condemned the actor's indiscretion (gambling) less harshly as compared to when he was described as sober (p < .001). Further, results show that the actor's behavior when intoxicated was seen as less reflective of the actor's self (p < .001) and this shift in signal strength mediated the relationship between context typicality and judgment (95% CI=-.3901, -.1185).

Study 4 provides a direct replication for Study 3 in addition to demonstrating an important boundary condition. Even though observers may, by default, assume certain behavioral contexts (e.g., intoxication) are a-typical, they should correct these assumptions if the actor is described as having extensive familiarity with the context (e.g., a history of alcohol consumption). Study 4 demonstrates this is the case by revealing that prior exposure to the behavioral context moderates the effect of context typicality on judgment, in addition to ruling out other alternate accounts for the observed results. Study 5 builds on these results by demonstrating that when the observers' attention is occupied (e.g., due to cognitive load), context typicality has less of an effect on how others are judged. Study 6 uses data from real-world criminal sentencing trials and provides convergence with the observed results by revealing that judges allocated significantly shorter criminal sentences for crimes committed in a-typical (vs. typical) behavioral contexts. The remaining studies (7 – 9) suggest that context typicality has implications for the choices actors make as well, with a-typical (vs. typical) behavioral contexts facilitating more self-indulgent choices.

We conclude by discussing the theoretical and practical implications of these findings.

Emotions Shape Construal Levels: The Case of Guilt and Shame

EXTENDED ABSTRACT

Recent research has begun to demonstrate that discrete negative emotions affect consumer attitudes and decision-making. Consumers often experience feelings of guilt and shame in daily life and yet little is known about how guilt and shame affect decision-making. For example, consumers may feel guilty when they engage in overeating or they may feel ashamed after a night of binge drinking. Given their prevalence in consumer experience and marketing communications, it is critical to understand how these discrete emotions affect how consumers process information and make subsequent decisions. However, scant research has explored how feelings of shame and guilt influence subsequent decisions unrelated to guilt or shame. The current research aims to advance extant consumer research by shedding light on how guilt and shame influence information processing, judgments and decisions.

Our research employs construal level theory (Trope and Liberman 2003, 2010) to illuminate one such psychological process triggered by the experience of these two emotional states. It has been speculated that emotional experiences may change how individuals construe information in a subsequent task. We build on this general assertion and propose that guilt and shame may influence judgments and decisions by systematically altering the level at which information is construed. Specifically, we posit that guilt leads consumers to construe subsequent situations at lower levels whereas shame leads them to adopt higher levels of construal. Guilt (shame) will systematically influence subsequent decisions by prompting a preference for lower- (higher-) level construal features. We also examine the psychological processes underlying these changes in construal level.

Both shame and guilt are negative self-conscious emotions that lead individuals to see themselves as the agent of socially undesirable outcomes. Recent research has begun to tease apart how these two emotions impact subsequent judgments and behaviors (Dearing et al. 2005; Duhachek et al. 2012). Previous research disambiguates discrete emotions of guilt and shame according to the unique appraisals that give rise to each (Lewis 1971; Tangney and Dearing 2002; Tracy and Robins 2004). In particular, guilt is experienced when individuals appraise negative outcomes to a specific action. In contrast, shame is experienced when individuals attribute the negative outcomes to the entire self. Guilt-laden individuals are likely to focus on the specific behavior or situation, resulting in behavior-specific appraisals whereas shame-laden individuals are likely to focus on the global self, leading to global-self appraisals when negative events occur.

Furthermore, building on the Appraisal-Tendency Framework (ATF; Lerner and Keltner 2001; Lerner et al. 2007), we posit that since guilt is caused by behavior-specific appraisals, individuals experiencing guilt may view subsequent events in a consistent way with their appraisals, activating local appraisal tendencies that lead individuals to give greater weight to specific aspects of subsequent situations. In contrast, individuals experiencing shame may view the subsequent tasks in line with their global-self appraisals, activating global appraisal tendencies that give greater weight to global aspects of events.

Next, we posit that these appraisal tendency-based differences between the two emotions may systematically alter the way individuals construe subsequent information. According to CLT, when considering the specific behaviors and situations, individuals tend to adopt lower levels of construal. In contrast, when considering personalities and dispositions, individuals tend to adopt a higher level construal (Nussbaum et al. 2003). Bringing the CLT framework into the emotions literature, we argue that individuals experiencing guilt may construe information at a lower level since individuals experiencing guilt are more likely to consider the context in which a specific behavior occurred than the global aspects of a subsequent task. Conversely, because individuals experiencing shame may consider global or dispositional aspects in a subsequent task to a greater degree, we propose that individuals experiencing shame may adopt higher level construals.

Based on our proposition, we predict a carry-over effect of guilt on subsequent judgments such that options with lower construal level features (i.e., high feasibility) are preferred to options with higher construal level features (i.e., high desirability). We predict that shame leads to the opposite pattern in subsequent decisions. Further, we posit that these effects operate through unique appraisal tendencies resulting from the emotion.

We tested the proposed effects and the underlying processes in three studies. In study 1, we manipulated emotions by having participants to recall an incident where they felt guilt or shame or what they did yesterday (i.e., control condition) and then measured construal level using the BIF scale (Vallacher and Wegner 1989), which measured the level at which individuals construe certain activities (i.e., lower score implies an activation of low construal mindsets). Results shows that that participants in the guilt (vs. control) condition activated lower construal levels (BIF$_{score\_guilt}$=12.29 vs. BIF$_{score\_control}$= 14.97; $p < .05$) while those in the shame (vs. control) condition activated higher construal levels (BIF$_{score\_shame}$=18.25 vs. BIF$_{score\_control}$= 14.97; $p < .02$). In studies 2 and 3, we extend our theorizing in the judgment context by presenting options varying in their feasibility and desirability (Study 2: choice of a concert varying in interest versus price; Study 3: choice of auction websites varying on product selection vs. user-friendly interface) and testing how emotions influence preference toward these options. Study 2 found that guilt increases preference for options with high feasibility whereas shame increases preference for options with high desirability. Study 3 replicated the findings of study 2 and illuminated the processes underlying these effects by finding mediation showing that guilt (shame) activates lower- (higher-) level construals via activation of local (global) appraisal tendencies (Please see Table for the results in studies 1-3).

Overall, our findings contribute to the literature on emotions and construal level by showing that discrete negative emotions of guilt and shame provoke distinct construal mindsets as well as by articulating theory and demonstrating empirical evidence to identify specific appraisal mechanisms through which emotions produce distinct mindsets.

Beyond Funny Ads: Empirical and Theoretical Insights into Humorous Consumption and Marketing

EXTENDED ABSTRACT

Humor is a fun, hedonic experience enjoyed by consumers across the globe (Gulas and Weinberger 2006; Martin 2007). The marketing literature discusses humor in the context of advertising (Eisend 2009; Gulas and Weinberger 2006), yet consumers experience humor in a wide variety of other consumption-related activities. Consumers spend billions of dollars and countless hours seeking humor in films, television, websites, books, magazines, and even greeting cards. People share laughs with friends, lovers, acquaintances, and strangers on a daily basis (Martin 2007; Provine 2001). Humor helps improve relationships, increases enjoyment, boosts creativity, facilitates coping, and mitigates the perceived intensity of negative life events (Galloway and Cropley 2009; Isen et al. 1987; Keltner and Bonnano 1997; Martin 2002). Humor can also improve social interaction, learning, and development by increasing tolerance for social differences and by facilitating approach towards novel, mildly stressful stimulation (Frederickson 1998; Gervais and Wilson 2005; Martin 2007).

A key reason for marketing's focus on humorous advertising is its reliance on incongruity-resolution theory, which argues that humor occurs when a person makes sense of (i.e., resolves) an unexpected or abnormal stimulus (Alden et al. 2000; Suls 1972). Although incongruity-resolution theory predicts humor in situations in which there is a set-up followed by a punch line, as is often the case in advertisements, incongruity-resolution theory has a more difficult time predicting humor in other marketing and consumption contexts (see Martin 2007).

Recent research outside of marketing suggests an alternative perspective: humor occurs when a person simultaneously appraises something as both a violation (i.e., anything that threatens a person's wellbeing, identity, or normative belief structure) and benign (i.e., okay, acceptable, normative; McGraw and Warren 2010; McGraw et al. 2012; Veatch 1998). For example, play fighting, which frequently elicits laughter in both children and non-human primates, involves a physical attack (i.e., violation) that doesn't hurt (i.e., benign). Puns and wordplay, a source of humor for literate humans, similarly involve a benign violation, typically some a linguistic error that is correct according to another language rule. Our research draws on the benign violation theory (BVT) in order to gain new insight into the antecedents and consequences of humor across a broader range of marketing mix variables and consumption experiences.

Study 1 investigated when consumers experience humor. To see if the BVT offers an improvement over an incongruity-resolutions account, we asked participants (N = 126) to find three YouTube videos: one humorous video, one inspiring video, and one frightening video. A good theory of humor should adequately discriminate between humorous and non-humorous consumption experiences. Therefore, we measured whether or not participants perceived a benign violation or whether or not they perceived a resolved incongruity in each of the videos. Participants received detailed definitions of benign and violation or incongruity and resolution, depending on between-subjects condition, before completing the measures. Incongruity-resolution did not differentiate humorous videos from non-humorous videos– participants were as likely to perceive a resolved incongruity in the inspiring (44%) and frightening (30%) videos as they were in the humorous videos (32%). In contrast, participants were more likely to perceive a benign violation in the humorous videos (47%) than in either the inspiring (17%) or frightening (17%) videos. Thus, BVT better distinguished humorous from non-humorous consumption experiences than the leading humor theory.

The BVT also makes new predictions about the consequences of being funny. One prediction is that consumers are more likely to share content that seems threatening, painful, insulting, taboo, illogical, uncomfortable, or just plain wrong (i.e., content containing a violation) compared to strictly benign content. If viewed from a benign perspective, a violation may counter-intuitively create a positive hedonic experience: humor. Humorous violations may be shared more than content that lacks a violation both because negative information attracts more attention than positive information (Baumeister et al. 2001) and because consumers are more likely to share content that elicits positive rather than negative emotions (Berger and Milkman 2012). We explored whether videos containing violations are more likely to be funny and be shared by consumers by having research assistants code a sample of 76 YouTube videos for violation severity and humor. Consistent with the BVT, violation severity was positively related to views (b = .46), and this effect was mediated by the extent to which the videos were humorous (indirect effect = .31).

Although humor captures the attention of consumers (Madden and Weinberger 1982) and motivates content sharing (study 2), the BVT identifies humor's dark side. Specifically, because a violation is necessary for humor, humorous marketing can have a negative effect on brand attitudes by arousing negative feelings in addition

to perceived humor. We tested this idea by contrasting product, distribution, pricing, and promotion tactics depicting benign violations with similar tactics not depicting violations. For example, we compared reactions to a pricing policy that discriminates against wealthier, monolingual English speakers (i.e., a sign reads: Orange Juice $5; Jugo de Naranja $4) with reactions to a store that charges all customers the same price (the sign reads: Orange Juice $5; Jugo de Naranja $5). Most consumers consider blatant price discrimination unfair (i.e., a violation). However, the discrimination may simultaneously seem benign both because it can be justified by an alternative norm (the English speakers can probably afford to pay the extra dollar) and because the discrimination is psychologically distant (it's geographically distant and victimizes other people). Participants (N = 114) rated perceived humor, negative affective reactions, and brand attitude in response to one of four marketing tactics (product, distribution, price, promotion). Consistent with the BVT, participants were more likely to perceive humor in the tactics containing benign violations than in the purely benign tactics (67% vs. 12%). However, the humorous benign violations were also more likely to offend participants (4% vs. 56%) and, consequently, led to less favorable attitudes towards the marketer compared to purely benign tactics (M = 2.8 vs. 4.4; seven-point scale). Thus, although benign violations evoke humor and can help capture attention and prompt sharing, marketers need to be careful because benign violations can elicit negative responses in addition to humor.

Prolonging the Search for Meaning: How Hedonic Versus Eudaemonic Consumption Experiences Shape Preference for Variety

EXTENDED ABSTRACT

Although the quest for pleasure guides many consumer decisions, consumers also obtain utility from non-hedonic sources. Indeed, people are able to derive positive affect from negative emotional experiences, exemplified by the consumption of entertainment that centers around tragic, horrific, or otherwise aversive content (Andrade and Cohen 2007). In the present research, we explore the extent to which consumers' preferences are differentially affected by exposure to fun versus meaningful consumption experiences.

Guided by re-emergent theorizing emphasizing the philosophical distinction between hedonia (the pursuit of pleasure) and eudaemonia (the pursuit of meaning; Oliver and Raney 2011; Baumeister et al. 2013), we find that people seek variety when consuming hedonic (but not necessarily meaningful) experiences, but prefer stability when consuming eudaemonic (but not necessarily fun) experiences. This pattern suggests that consumers experience a tradeoff between experiencing pleasure in the present, and collecting meaningful experiences over time (cf. Keinan and Kivetz 2011). While eudaemonic consumption experiences might not be as pleasurable in the moment, consumers nevertheless prefer to stick with these meaningful experiences for longer periods of time compared to hedonic experiences, because they believe that the benefits of meaningful experiences will take longer to develop and last longer into the future.

In an initial test (study 1; N = 90), we assessed consumers' lay intuitions regarding the difference between hedonic and eudaemonic entertainment experiences. We examined people's beliefs regarding the minimal amount of time they would need to derive a benefit from consuming fun versus meaningful films. We pretested movie genres and identified three hedonic genres (comedies, action, horror) and three corresponding eudaemonic genres (documentaries, drama, art house). Participants were instructed to imagine that they were presented with a two-hour movie from each genre and asked to indicate how many minutes of each movie they would need to watch before they would feel satisfied with the experience. Participants indicated that they would need to watch the meaningful films for a longer period of time to feel satisfied (M = 75.5 minutes), compared to the fun films (M = 62.3 minutes; F(1, 89) = 14.03, p < .001). These results provided initial evidence that consumers seek to prolong their exposure to eudaemonic experiences.

We next examined in study 2 (N = 138) whether people would prefer stay the course or switch to something new when their hedonic versus eudaemonic consumption experiences were interrupted. Participants recruited from Amazon's Mechanical Turk were randomly assigned to view either a fun or meaningful 10-minute film (selected on the basis of a pre-test). Four minutes into the film, participants were interrupted and told that the study included other films. As the primary DV, participants were asked to indicate whether they would prefer to (1) continue watching the film they had been initially assigned to, (2) switch to a different but similar film from the same genre, or (3) switch to a different and dissimilar film from a different genre. To examine our hypothesis that participants watching the meaningful film would be less likely to switch to a different film than subjects watching the fun film, we conducted a logistic regression. Subjects in the eudaemonic condition were significantly less likely to choose to switch to a different film than subjects in the hedonic condition (31% vs. 55%; Wald = 7.68, p < .01).

In study 3 (N = 184), we aimed to replicate and extend study 2 by examining the process by which exposure to hedonic versus eudaemonic experiences shapes consumers' variety-seeking preferences. Hedonic experiences should be more impactful in the present, whereas eudaemonic experiences (emphasizing a search for meaning and self-growth) should have a lasting impact into the future. Indeed, the utility of watching meaningful (but not necessarily pleasurable) films such as *Hotel Rwanda* and *Schindler's List* is often not felt immediately, but instead at a later point (e.g., after one reflects upon the movie watching experience). Such considerations led us to hypothesize that people would be less likely to seek variety when exposed to meaningful (vs. hedonic) experiences because they expect the benefit of meaningful experiences to persist into the future. Accordingly, we again find that those exposed to part of a meaningful (versus hedonic) film were less likely to switch to a different film (33% vs. 48%; Wald = 3.99, p < .05). Importantly, we also find that this effect on stay-versus-switch decisions was mediated by participants' expectations that exposure to the meaningful (versus hedonic) film would have a lasting impact, changing who they are, how they think, and their outlook on life (b = -.16, 95% CI: -.27 to -.07).

Our final study (study 4; N = 94) examines an important boundary condition for consumers' ability to derive deeper meaning from a consumption experience. The ability to find meaning should depend on consumers' level of expertise with the experience (LaTour and LaTour 2010). To illustrate, classically trained musicians should be in a better position to derive eudaemonic meaning from concertos, compared to musical novices. Hence, we predict that experts would find it easier to find meaning in a consumption experience, which in turn will reduce their desire for varied experiences. To test this prediction, we presented participants with a short video featuring a musical performance. Participants were instructed to try to derive either pleasure from the video (by focusing on what is most enjoyable and fun) or meaning from the video (by focusing on what is most purposeful and valuable). A moderated mediation analysis revealed that for experts, looking for meaning (versus pleasure) in

the video led them to request to view a similar (versus different) follow-up video, an effect mediated by experts' expectations that the watching the video would have a lasting impact (b = .62, 95% CI: .01 to 1.25). For novices, no such effect emerged. Thus it appears that expertise with consumption experiences permits the search for meaning, a search that consumers are then motivated to prolong.

We discuss the implications of these findings for understanding how and why consumers derive pleasure from unpleasant experiences, and for aiding consumers' search for different types of happiness (cf. Mogilner, Aaker, and Kamvar 2012).

SESSION OVERVIEW

Consumers face purchase decisions with large sets of possible options on a daily basis. To select an acceptable or desirable product amidst the overwhelming variety, consumers may employ sets of decision heuristics to simplify the decision (Bettman et al. 1998). These heuristics can determine whether consumers are satisfied with their purchase, or if the consumer even purchases anything at all.

But, what can the retailer do to structure consumers' choices to influence consumer decision strategies and bolster purchase likelihood? An enormous line of research has explored how changing the choice architecture or default option can drastically affect individual behavior (Johnson and Goldstein 2003), while other work has shown that various decision aids can affect search processes and choice (Dellaert and Haubl 2012; Haubl and Trifts 2000). Yet, there are still many modern innovations in retailing, in addition to the consideration of expanding assortment issues (Iyengar and Lepper 2000; Scheibehenne, Greifenender, and Todd 2010) that may have implications for consumer behavior. How may these innovations affect consumers' decisions, and can they inform the theory of consumer behavior? How might the size of the assortment otherwise influence how consumers consider what to buy? Can providing consumers with wish-lists on which to place desired goods increase the likelihood they'll ultimately return to purchase those items? Does allowing consumers the opportunity to try on a smaller set of options at home improve purchase likelihood? How may in-store layouts affect purchase abandonments?

This session addresses how various modifications in assortment structure and choice architecture can influence consumers' decisions in both in-store and online settings. **Goodman** and **Naylor** investigate how large assortment sizes cause consumers to use inclusion-based (vs. exclusion-based) selection strategies as a method of minimizing choice difficulty. **Gartmeier, Mau,** and **Reinartz** explore how perceived product distance in the store can reduce purchase abandonments by increasing target-orientation in the decision-making process. However, this perceived product distance may also cut unplanned purchases unless purchase impulse is simultaneously increased. **Hamilton** and **Popovich** study the use of wish-lists in online retail settings. Contrary to theories that might predict these wish-lists would increase purchase likelihood, they instead find that the wish-lists segment purchase choices into multiple stages and ultimately depressed purchase intentions. **Weingarten** and **Kahn** study how imposing a delay between the assortment viewing stage and the consideration set stage can affect purchase likelihoods. Counter to lay intuitions that the delay or waiting hurts satisfaction, they find an improvement in purchase satisfaction and likelihood after a delay between the decision stages. These projects examine how both assortment structure and decision aids across both in-store and online settings may affect consumers' purchase decisions, and have substantial implications for retailers in terms of how to structure their choice architecture.

Given the range of topics in this session, it should appeal to researchers who are interested in choice overload, consumer choice behavior, choice architecture, time preference, variety, and heuristic decision-making more broadly.

When Consumers Prefer to Include: Consideration Set Construction Strategies from Large Product Assortments

EXTENDED ABSTRACT

When visiting both online and brick-and-mortar retailers, consumers are bombarded with an overabundance of choice, and research has documented the costs associated with choosing from large assortments (e.g., Iyengar and Lepper 2000; Kuksov and Villas-Boas 2010; Scheibehenne, Griefenender, and Todd 2010). Yet, little attention has been given to how consumers manage choice from retailers offering large assortments. Many consumer choices are made in a hierarchical fashion (Kahn and Lehmann 1991), and consumers often narrow down the choice set to a more manageable consideration set (Chakravarti, Janiszewski, and Ülkümen 2006). But how do consumers narrow large assortments to smaller sets? And what factors affect the strategy consumers use to form a narrower set?

There are two strategies consumers use to narrow down a set—include and exclude. From a normative perspective, an include strategy should lead to the same outcome as an exclude strategy; however, research shows that strategy selection can bias the decision process (e.g., Chakravarti et al. 2006; Heller et al. 2002; Irwin and Naylor 2009). In this research we investigate how the choice context affects the strategy consumers use to narrow the choices offered by a retailer. We provide evidence that consumers are more likely use an include (vs. exclude) strategy when faced with larger assortments and when they are in a maximizing mindset, and this strategy can bias choice.

In study 1a we presented participants with a planogram of either a small (6) or large (30) assortment of chocolates and asked them to narrow down their options by either circling the options they like or crossing out options they do not like. Participants were more likely to use an include (vs. exclude) consideration set strategy in the large (M=56%) compared to the small assortments (M=31%, $\chi^2(1,N=72)$=4.48, $p < .05$). Further, this strategy affected consideration set size: Participants had considerably smaller consideration sets after using an include (M=5.61) compared to an exclude strategy (M=8.14, $F(1,68)$=55.04, $p < .001$), and this was especially the case when faced with a large assortment ($F(1,68)$=50.06, $p < .001$).

Study 1b replicated these findings using a different procedure and product category. Participants viewed a display of pens via com-

puter and narrowed down a set of 32 (6) by dragging-and-dropping pens that they want to either include or exclude for/from further consideration. Again, participants were more likely to use an include strategy in the large (*M*=77%) compared to small assortment (*M*=62%, χ^2(1,N=153)= 4.48, *p* < .05).

These results suggest that consumers shift to an include strategy when faced with a large assortment because large assortment change the decision process. In addition to creating more difficulty, large assortments also raise expectations (Diehl and Poynor 2010) and lead decision makers to focus on positive reasons to justify their choices (Sela, Berger, and Liu 2009). Thus, we expected maximizers to be especially likely to use an include strategy because maximizers will be more likely to raise their expectations and feel the need to justify their choice.

Study 3a used the same pen paradigm as study 1b, but participants in the lab were asked to sort pens into a bag that they would either consider (include) or not consider (exclude) for purchase later in the study. After narrowing down the set, they made a final choice, received their pen, and responded to the the 13-item maximize/satisficer scale (Nenkov et al. 2008). Again, participants were more likely to use an include strategy in the large assortment condition (*M*=.50) compared to the small (*M*=.36, Wald χ^2(1,N=208)= 4.02, *p* < .05). There was also a marginal assortment by maximize/satisficer interaction (Wald χ^2(1,N=208)= 3.14, *p* = .077), whereby maximizers were more likely to use an include strategy in large assortments (*M*=.59) compared to small (*M*=.33, Wald χ^2(1,N=208)= 6.81, *p* < .01). Study 3b was the same design using pens and chocolates with the procedure in study 1a, and found the same results: Participants were more likely to use an include strategy in the large assortment condition (*p* < .05), and there was the same assortment by maximize/satisficer interaction (*p* < .05).

Study 4 manipulated maximizer/satisficer mindset (Ma and Roese 2014) and assortment size. We asked MTurk participants to narrow down vacations that they were considering from either a large (30) or small (6) set. Participants dragged-and-dropped potential vacation destinations into a box labeled as either include or exclude. Again, those in the large assortment were more likely to include (*M*=.86) than those in the small (*M*=.72, Wald χ^2(1,N=287)=4.21, *p* < .05). There was also a marginal interaction with maximize/satisficer, consistent with study 3 (Wald χ^2(1,N=287)=3.16, *p* = .075), whereby maximizers were more likely to use an include strategy in large assortments (*M*=.92) compared to small (*M*=.79, Wald χ^2(1,N=208)=9.90, *p* < .01).

Study 5 examined the downstream consequences of an include strategy on the decision process. To establish causality, we manipulated the type of strategy (include vs. exclude). Analyzing written thought protocols, we found that participants using an exclude strategy expressed fewer positive thoughts (*F*(1,127)= 16.97, *p* < .001) and more negative thoughts (*F*(1,127)=15.70, *p* < .001), and they deliberated more on alternatives that were not in the consideration set ($M_{Include}$=.31 vs. $M_{Exclude}$=.45, *F*(1,127)=15.45, *p* < .001). In addition, these participants focused more on negative attributes (*F*(1,126)=4.67, *p* < .05) compared to those using an include strategy.

In sum, this research shows how decision context systematically effects consideration set construction strategies used by consumers, biasing the decision process towards an include strategy. Consumers are more likely to use an include strategy when faced with larger assortments, and when consumers are in a maximizing mindset. Thus, consumers in a maximizing mindset and facing large assortments will process the choice differently—they will focus more on positive attributes and thoughts, and elaborate less on alternatives outside of the consideration set.

More Than a Mental Barrier? The Effect of Perceived Product Distance on Consumers' In-Store Purchase Decision Processes

EXTENDED ABSTRACT

Retailing managers regularly face decisions regarding distances, such as temporal distances in the context of when to launch a new product or spatial distances in terms of how to present a product in the physical store environment. For example, in a grocery retailing context, retailers increasingly use refrigerator units equipped with glass doors in order to achieve energy and cost savings. Moreover, in a series of pre-studies that we have conducted in cooperation with two leading German grocery retailers, we find that having customers choose from refrigerators with glass doors increases their perceived distance to a particular product because the consumer is not able to immediately and directly experience the product. This example shows that consumers make increasingly purchase decisions involving physical and psychological distance in the store. As consumers' physical and psychological distance from a product strongly influences consumers' preferences and decisions, the impact of distance looms large at the point-of-sale (POS).

Interestingly, despite the fact that there is growing interest among practitioners and researchers alike to understand the antecedents and consequences of psychological distance in a retail setting, there is virtually no insight how consumers' in-store decision behavior, such as unplanned buying, changes depending on the actual and psychological distance at the POS. Instead, most research analyzing psychological distance in retailing mainly focuses on the relationship between psychological distance and price perceptions, assortment size preferences, and product preferences. Specifically, Bornemann and Homburg (2011) show that with increasing psychological distance, people are more likely to construe price according to its high-level and desirability implications for quality and less likely to focus on its role as monetary sacrifice. Goodman and Malkoc (2012) find that while consumers prefer large assortments when choices take place in a psychologically proximal situation, they are more likely to prefer small assortments when choices pertain to psychologically distant situations. But this effect reverses when consumers consider desirability/feasibility trade-off information inherent in the assortment size decision. Mogilner, Aaker, and Pennington (2008) show that consumers prefer prevention- (vs. promotion-) framed products in psychologically close situations whereas promotion- (vs. prevention-) framed products become more appealing in a psychologically distant situation. Although these empirical studies have made important contributions to the topic, they do suffer from the following limitations: First, the studies focus on well-established antecedents of psychological distance, such as temporal, social, and geographical distance. However, this focus does not capture the diversity of psychological distances occurring in a retail setting. Second, the studies do not cover the link between psychological distance at the POS and in-store decision-making—although construal level theory (CLT) almost predicates that psychological distance will influence purchase decisions at the POS. Third, the studies address consumers' preferences and behavior solely in fictitious purchase scenarios in which participants have to imagine the purchase situation. Participants are fully aware of this situation and make their decisions consciously—a circumstance that might not be representative for in-store purchase decisions.

Therefore, in contrast to existing research on psychological distance, our study examines how the perceived product distance influences consumers' purchase decision processes at the POS. In particular, our contributions to the literature are as following: First, we identify a new antecedent of psychological distance, i.e., physical

barrier—an instrument that is commonly used in retailing. Second, we examine the well-established phenomenon of psychological distance in a new context, i.e., in-store decision-making. Specifically, we investigate the effect of psychological distance on purchase decisions at the POS, such as unplanned buying and purchase abandonments, and hence, examine new consequences of psychological distance that are of monetary importance to retailers. Third, we explain the underlying process of this effect by including process measures that we obtain from observations at the POS. Fourth, we show a mechanism that plays a major role in daily purchase decisions and hence, influences the effect of perceived product distance on in-store purchase behavior, namely purchase impulse. Fifth, in contrast to existing research that mainly uses laboratory experiments, we additionally conduct a field study which allows us to examine natural purchase decisions that are made unconsciously in the complexity of reality—an important extension when investigating psychological factors in daily purchase decisions, especially in the context of unplanned buying. Nevertheless, a laboratory experiment serves to validate and generalize our main findings.

Based on CLT, we propose that the decision-making process is more focused and goal-oriented under conditions of a high level of perceived product distance. Our dependent variables are amount of purchase abandonments, i.e., whether a product, once considered, is rather purchased than returned to the shelf, and amount of unplanned purchases, i.e., whether products are being purchased that were not part of the original shopping list. Using a quasi-experimental between-subjects design that involves one factor with two levels—low vs. high level of perceived product distance—our field study (N = 1172) shows that a consumer's perceived product distance influences his or her decision behavior at the POS: Consumers in the high distance condition, i.e., choosing from refrigerators with glass doors, have significantly less visual and physical product contacts compared to those in the low distance condition, such as choosing from refrigerators without glass doors. Further, the amount of purchase abandonments significantly decreases in the high distance situation meaning that consumers are indeed more goal-oriented and focused. Moreover, the increased target-orientation of consumers leads to a significantly decreased number of unplanned purchases in the high distance condition compared to the low distance condition; an effect that can have negative monetary consequences for retailers. These findings point to important outcomes of psychological distance in a real store environment. Further, the laboratory experiment shows that the negative effect of psychological distance on unplanned purchases can be reduced by increasing a consumer's purchase impulse, a variable that could easily be incorporated by retailers using, for example, in-store coupons or product tastings.

The Desire to Acquire Wish List Items: The Ironic Effect of Choosing to Delay Aspirational Purchases

EXTENDED ABSTRACT

Consumers have always had the ability to defer certain purchases, but doing so has gotten easier over time. Most major retailers including Amazon, Target, and Barnes and Noble have a wish list option integrated into their websites which gives consumers the ability to save products for future consideration. This research focuses on the increasingly popular use of wish lists to keep track of the consumer's own potential future purchases.

By encouraging reconsideration of attractive options, wish lists facilitate a type of choice deferral that has not been thoroughly investigated in previous research on deferral. Previous work has primarily examined the factors that increase the likelihood of postponing a choice, including incomplete information (Greenleaf and Lehmann 1995; Gunasti and Ross 2009), the lack of a clearly dominant option (Chernev 2006; Dhar and Simonson 2003; Iyengar, Huberman, and Jiang 2004), and search difficulty (Putsis and Srinivasan 1994). In contrast, wish list usage often entails the selection of a most preferred alternative—it is only the purchase itself that is deferred.

Previous research points to two possible ways that wish list usage could impact consumer decision making. One possible effect of wish lists is to serve as an interruption of the goal to acquire a desired item. According to this view, placing an item on a wish list is likely to increase the likelihood that it will eventually be purchased. This goal-directed choice account predicts that this shift in preference is caused by an increase in the importance of desirability attributes, relative to feasibility attributes, after the wish-list interruption.

In contrast, we propose that wish lists serve as choice partitions, segmenting a unitary purchase decision into a two-stage decision: First, whether to place an item on a wish list, and second, whether to subsequently purchase the wish listed item. We predict that, contrary to conventional wisdom and the predictions of some goal-directed choice theories, the use of wish lists can decrease likelihood of purchase, relative to a decision making process without the use of a wish list for desired offerings. We predict that desirability attributes (e.g., why consumers want a product) are relatively more important in the first stage, in which consumers are considering whether to put an item on a wish list. Conversely, in the second stage when consumers decide whether to purchase a wish-listed item, feasibility attributes (e.g., how the product will be acquired and used) should be relatively more important.

Five experiments tested these predictions. The first study demonstrates decreased purchase intent for items placed on a wish list relative to a scenario in which they are given an equivalent choice without a wish list. A product placed on a wish list was less likely to be purchased than an item in an otherwise similar purchase decision context without a wish list ($F(1, 100) = 5.58$, $p < .05$). In a related study, willingness to pay was also significantly lower in the wish list condition than in the purchase condition ($F(1, 88) = 4.17$, $p < .05$).

The second study revealed that using a Wish List, Shopping Cart, or Saved for Later list to defer a purchase for later consideration will each similarly induce a two-stage decision-making process, regardless of the specific label of the delay device. The mean purchase likelihood in the purchase (without delay) condition was significantly higher than each of three delay mechanisms (e.g., purchase vs. wish list $t(78) = 2.42$, $p < .05$). Thus, decreased purchase likelihood seems to be driven by delay rather than by the aspirational nature of labeling the delay mechanism a "Wish List" vs. another often-used label (e.g., Shopping Cart, Saved for Later list).

The third and fourth studies examine the underlying process, demonstrating a primacy of desirability over feasibility in initial wish list product evaluations. In experiment 3, desirability attributes were more important relative to feasibility attributes for the decision to put the item on the wish list, as compared to the decision to purchase the item after it had been on a wish list ($F(1, 51) = 46.95$, $p < .001$). In experiment 4, a repeated measures MANOVA revealed that there was a significant interaction between the two factors of desirability/feasibility and decision stage (pre- vs. post-wish list; $F(2, 127) = 5.40$, $p < .01$). The importance of desirability attributes was significantly higher and the importance of feasibility attributes was significantly lower for the pre-wish list decision than the importance of feasibility attributes for the post-wish list decision.

The fifth study shows the effect of wish list usage on choice, revealing a within subjects preference reversal, with different options selected for a wish list and chosen for purchase. Participants

were relatively more likely to place a more desirable item on a wish list, and relatively more likely to choose a more feasible item from a wish list to purchase ($\chi^2(1) = 19.49$, $p < .05$). In addition, many of the participants who initially chose the more desirable option switched their preference to the more feasible option ($z = 3.75$, $p < .0001$).

These five experiments demonstrate that, contrary to conventional managerial wisdom, placing items on a wish list can lead to decreased purchase likelihood. We propose that a wish list effectively partitions a one-stage purchase decision into a two-stage decision: first placing the item on the wish list and later reevaluating the item for possible purchase. We proposed and provide evidence for a greater focus on desirability attributes in the first stage of the decision and a greater focus on feasibility in the second stage as the process driving the observed decrease in purchase likelihood. Our results suggest that deferring a purchase by using a wish list can function as a means of consumer self-restraint when shopping, whereas retailers may face a potential danger in providing a wish list, particularly for highly desirable products. Wish lists are an important aspect of adding ease and convenience to the online purchase experience. However, retailers may ultimately need to work on reestablishing consumers' desire for their wish listed items.

Deciding Now and Later: The Benefit of Delay in Staged Decision-Making

EXTENDED ABSTRACT

One advantage of online assortments is that without the physical constraints, the assortments can be quite large. Although these large assortments can increase variety perceptions (Broniarczyk, Hoyer, and McAlister 1998; Kahn and Wansink 2004) and hence attract consumers, too much variety can potentially damage satisfaction and purchase (Iyengar and Lepper 2000; Scheibehenne, Greifeneder, and Todd 2010). Further, for some categories it is difficult to determine preferences without examining the physical product. To solve these problems, many retailers have offered consumers the opportunity to "try on" products that might consider buying at home. We investigate how the structure and timing of such consideration sets, or "home try-on sets," can have on ultimate purchase likelihoods and satisfaction from large online assortments.

With "home try on programs," customers can select a consideration set of products from a virtual assortment to try on at home free of charge. However, under this set up there is a delivery delay that separates when the customers views the assortment from when they consider the smaller choice set. The delivery can potentially take up to a few days, which may either have a positive or negative effect on ultimate purchase likelihoods. Past research has offered evidence that the delay can affect decision making positively because of anticipation effects (Loewenstein 1987) or unconscious thought operations (Dijksterhuis 2004), or negatively due to the stress of waiting (Buell and Norton 2011), or indeterminately because of changing preferences over time (Frederick, Loewenstein, and O'Donoghue 2002).

We hypothesize that the delay between a home try-on set and the initial viewing of a large assortment will increase satisfaction and purchase intentions for two reasons. First, the delay may influence consumers' decision strategies in constructing their consideration sets. Knowing about the delay may shift the set of strategies used in screening during the assortment step that may have downstream consequences on satisfaction during the try-on step post-delay (Beach 1993; Bettman, Luce, and Payne 1998; Chakravarti and Janiszewski 2003). Second, the delay may decontextualize the choice to minimize regret (Kahneman and Miller 1986; Ritov and Baron 1995) for

unselected options (that would otherwise depress satisfaction and purchase intentions) from a previous stage because those options will be less accessible after the passage of time.

We first demonstrate that most consumers' intuitions lie counter to our hypotheses. Participants responded to a scenario regarding buying either shoes or glasses with a new company that enables customers to try the product at home before purchase. This service was described to have a few-day delay in delivery. This new company was also said to be considering introducing a service with immediate delivery (within an hour); some participants also learned this company would charge a small fee for this service. Participants were asked to indicate if they would prefer the few-day delivery or the immediate delivery (or indifference), and how likely they would be to buy with three or five pairs and with or without a delay. Finally, participants selected from a list of decision strategies that would best describe what they would do with three pairs, with five pairs, and with a few-day delivery or with immediate delivery. No differences in patterns were seen between shoes vs. glasses, so we collapsed their results.

Participants indicated a preference for immediate delivery over a few-day delivery (and indifference) when there was no fee (69.23%, 8.33%, and 22.44%, respectively; (2) = 95.12, $p < .001$), but were fine with a few-day deliver over immediate delivery or indifference when there was a fee (46.50%, 33.76%, and 19.74%, respectively; (2) = 16.87, $p < .001$). Participants also thought they would be likelier to buy with immediate delivery ($F(1, 312) = 88.12$, $p < .001$) and with five pairs to try ($F(1, 312) = 58.43$, $p < .001$). Participants also believed they would use different choice strategies depending on if they had three or five pairs to try ((1) = 8.97, $p = .003$) and if they had an immediate vs. a few-day delivery ((1) = 5.91, $p = .015$). This initial study suggests that contrary to our hypotheses, consumers would prefer immediate delivery (no delays) and to have more options to try. However, consumers indicated they would employ different decision strategies based on a delay and try-on set size, which may have implications for their actual satisfaction.

We also conduct two lab studies that suggest, contrary to consumer beliefs, the benefit of a delay between assortment and try-on. In study one, participants simulated selecting pairs of glasses from an online assortment in the lab. Participants first picked either three or five pairs from a large virtual assortment of glasses that they were instructed they would try on in the lab. Some participants then received the pairs they selected and could try them on before indicating their satisfaction with their chosen set and likelihood of purchase. Other participants, upon selecting pairs for their consideration set, experienced a brief delay and completed an unrelated filler task before receiving their consideration set. Participants who experienced the delay were more satisfied with their consideration set ($F(1, 114) = 9.03$, $p = .003$), and indicated higher purchase intentions ($F(1, 114) = 5.46$, $p = .021$). This study provides initial evidence, with a simulated delay in the lab, that a delay in decision-making can improve satisfaction and purchase intentions.

In study two, the delay was lengthened such that participants either selected a consideration set of three or five pairs of glasses a few days in advance or in the lab before receiving their consideration set in person. When controlling for category involvement (Zaichowski 1994), we found an interaction: delay improved consideration set satisfaction for those who picked five pairs, but not for those who picked three pairs ($F(1, 219) = 4.14$, $p = .043$). These participants who had a delay also more positively anticipated their try-on when they selected five rather than three pairs ($F(1, 79) = 7.74$, $p = .007$). We thus find confirmatory evidence with a real delay that under some conditions, a delay can improve product satisfaction.

SESSION DESCRIPTION

Our goal in this session is to extend research on the influence of time perception on consumers' decisions, and conversely the influence of consumers' decisions on time perception. In this session, we focus on two variations of time perception. One way to alter time perception is by shifting people's sense of where they stand in the timeline of their lives (Montepare, 2009). Another way to alter time perception is by varying the context and framing of the time period (e.g peak-end effect; Fredrickson & Kahneman, 1993). Extending the research on time perception, this session examines two important questions.

First, we explore how feeling younger or older than our actual age (time-perception with respect to oneself) influences the decisions we make. Hershfield and Alter present work on end-of-decade effects (i.e. being of an age that ends in 9). They show that as people get close to markers (end of a decade) associated with the passage of life, they feel subjectively older and have a greater need to search for meaning. These feelings increase consumers' likelihood to make extreme decisions such as pursuing extramarital relations and taking part in marathons. Rozenkrants and Huang extend the idea of the disassociation between one's felt-age and actual age. They show that people who are made to feel older versus younger are more likely to focus on the needs of others, and thus are more likely to partake in pro-social behaviors, such as donating and saving the environment. Understanding how time perception influences subjective experiences and, subsequently, influences decision making is key in overcoming decision making barriers such as the desire for immediate reward and temporal discounting.

Next, we explore how the decisions consumers make regarding an experience can influence their perception of time. Barasch, Diehl, and Zauberman show that taking pictures during an experience creates a greater sense of immersion, a sense that time is passing quickly, and a greater subjective memory of the experience. Interestingly, taking pictures actually leads to worse objective memory perception of the experience. Zhang, Kim, Brooks, Gino, and Norton continue the explorations of how consumers' decisions to capture their experi-

ences influence time perception. They show that people forgo the option to document experiences (e.g., create a time capsule) and instead choose to partake in alternate activities. Interestingly, at a later point, people actually prefer to retrieve the documentation (vs. partaking in an alternate activities). This suggests that people have a flawed lay theory about the value of preserving their experiences in the present for future enjoyment. Given people's mispredictions about how time will affect their experiences, these papers provide useful interventions to help consumers make decisions that maximize their enjoyment of experiences.

Collectively, the four papers shed light on how time perception influences consumers' felt-age, choice, pro-social behaviors, and how one's decision to freeze time and record experiences can impact one's perception of time and the experience itself. These counterintuitive yet fun findings demonstrate that even constants like age and time can be shifted by context and "tricks."

The End-of-Decade Effect

EXTENDED ABSTRACT

Chronological age is obviously associated with the passing of time. Yet, people often fail to identify with their true age (e.g., Montepare, 2009), with younger adults feeling subjectively older than they actually are, middle-aged adults feeling roughly their own age, and older adults feeling younger than they are (Montepare & Lachman, 1989). Recent research suggests that the non-linearity of subjective age can also be found at a more granular level. Namely, Galambos, Albrecht and Jansson (2009) find that when older adolescents advance from one age-related social–developmental bracket to another, they experience a "bottom-dog phenomenon" in which they have moved from comparing themselves to a reference group of late adolescents to a reference group of older individuals. In the present paper, we suggest that such feelings occur throughout the human life span, specifically as individuals move from one personal decade to the next. We propose a model in which reaching the end of a decade is associated with increased subjective age, a greater search for meaning in life, and actions that can be either destructive or productive.

One salient driver of subjective age may be the place that people occupy within their decade. The round numbers that signify the start of a subsequent decade are common, and valued in societies that operate on base-10 systems. For example, round numbers (e.g., 10, 20) were mentioned significantly more often than other numbers in a two-year sample of Dutch op-eds (Jansen & Pollmann, 2001), and they serve as goals, whether for baseball players trying to reach a batting average of .300, or SAT takers trying to progress to the next score bracket (Pope & Simonsohn, 2011).

With a salient round number marker every ten years, people are likely to first assess their subjective age in the context of their own personal decade, and then the overall life span. To examine this possibility, we analyzed archival data in which participants were asked whether they felt younger (coded as 1), the same age (coded as 2), or older than they actually were (coded as 3). People whose age ends in a '9' felt subjectively older ($M = 1.51$, $SD = .88$) than people of other ages ($M = 1.29$, $SD = .70$), $t(931) = 3.01$, $p = .003$, and this held true even when controlling for actual age, $F(1, 930) = 4.17$, $p = .04$. As a follow-up, we had Mechanical Turk participants (N = 164; $M_{age} = 30.83$, $SD = 10.32$ years) read one of two articles that appeared

to come from the *New York Times*. Control condition participants were shown an article that suggested the presence of 3 distinct eras in the human lifetime, commencing at birth, age 7, and age 68. In the experimental condition, participants read about one additional era that commenced at their age plus one year (e.g., if the participant was 35, the next era started at 36). All participants were then asked how subjectively old they felt (3-point scale). Experimental condition participants felt subjectively older than control condition participants ($M_{experimental}$ = 2.19, SD = 0.70; $M_{control}$ = 1.86, SD = 0.66; $t(162)$ = 3.12, p < .01).

Approaching the end of a personal decade may do more than just increase feelings of subjective age. To the extent that salient endings intensify emotional experiences (Ersner-Hershfield, Mikels, Sullivan & Carstensen 2008) and promote introspection (O'Brien & Ellsworth 2012), we posit that facing the end of a decade will also be associated with a heightened search for meaning in life. To examine this idea, 155 participants were randomly assigned to one of three conditions, in which they completed a brief writing exercise and then answered questions that assessed whether they were searching for meaning in their lives (e.g., "At this moment I am thinking about my life more deeply than I normally do"; 1-7 scale). In the baseline condition, participants wrote about what they were going to do with their day tomorrow; in the control condition, participants wrote about what they thought the day before their next birthday would be like; in the experimental condition, participants wrote about what they thought the day before their last birthday in their decade would be like (e.g., 20-somethings wrote about the day before their 30th birthday). Results indicated that participants who imagined entering a new decade on their next birthday were more eager to seek meaning (M = 4.45, SD = .82) than were participants in the control (M = 4.10, SD = .72) and baseline conditions (M = 3.98, SD = .87), $F(2, 152)$ = 4.57, p = .01; only follow-up pairwise differences between the experimental and baseline condition, and experimental and control conditions, were significant, ps < .02.

Finally, when individuals face the end of a decade and search for meaning, we hypothesize that they will seek to find fulfillment in a variety of ways. Indeed, Baumeister (1991) has suggested that when a spotlight is placed on the self, people seek escape through either destructive, numbing activities or productive, transcendent ones. To this end, we examined the relationship between facing the end of a personal decade and a variety of outcomes. Across three archival datasets, compared to people with non-9-ending ages, those with an age ending in 9 were more likely to sign up for a dating site geared toward extramarital affairs, χ^2 = 28686.75, p < .001, and commit suicide, $F(1, 526)$ = 9.28, p < .01; but they were also more likely to sign up for marathons (χ^2 = 12.28, p < .001) and to run faster marathons, $t(99)$ = 3.63, p < .001.

In sum, people who are approaching a new decade in age tend to feel older, to seek out meaning more earnestly, and to commit both destructive and productive acts that signify a failed or ongoing search for meaning. These results add to a growing literature suggesting that people experience aging in fits and starts, and that the experience of advancing on a new chronological milestone activates a search for meaning.

Feeling Older and Giving Back: The Impact of Felt-Age on Pro-social Behaviors

EXTENDED ABSTRACT

"Age is just a number" is an adage used to maintain feelings of youth. But, what does it mean to dissociate your actual age from how old you feel? What are the downstream behavioral consequences?

Prior research suggests that actual age has an impact on the choices we make (e.g.,William & Drolet, 2005); surprisingly, actual age has little correlation with how old people feel (Barak & Schiffman, 1981). Despite physical and cognitive changes that come with actual age, people have to identify with a particular age for their "felt age" to align with actual age (Blau, 1956). Recent work shows that felt age can shift depending on feedback received from strength tests (Stephan et al., 2012) and memory tests (Hughes, Geraci, & De Forrest, 2013). We extend this research, and propose that, because felt age and actual age do not always align, how old people feel at the moment can drive behavior, independent of their actual age.

In this project, we examine the impact of people's felt age on their pro-social behaviors, such as saving the environment and making donations. Prior literature suggests that as people get older, there is a greater benefit to focusing on being helpful and useful to others (Krause, Herzog, & Baker, 1992). Pro-social orientation also tends to increase with age (Van Lange, Otten, De Bruin, & Joireman, 1997). We propose that, even for those within the same actual age group, subjective feelings of age – which can easily be manipulated by marketers – can influence their pro-social behaviors. Specifically, we hypothesized that relative to people who felt younger, those who felt older would focus more on the welfare of others, and thus be more likely to partake in pro-social behaviors.

We first pre-tested ways to manipulate people's felt age, to establish that felt age is indeed different from actual age, and can be influenced through various stimuli. For instance, in one stimulus we asked participants (mean$_{age}$ = 31, range$_{age}$ = 25-45) to enter their demographic information, and then show them distribution information about others who were also taking the survey – the distribution of ages either had a mean of 55 years, or a mean of 21 years. Participants then rated how old they felt. We found that seeing a distribution of previous participants' ages with the mean of 55 years old made people feel younger than a distribution with the mean of 21 years old (p < .01). In both studies 1 and 2, we used this manipulation of felt age.

Study 1 tested our main hypothesis – whether changes in felt age influence people's tendency to partake in pro-social behaviors. Participants in the same age group as the pre-test filled out demographic information, which included the felt age manipulation. Next, participants viewed an advertisement for a fictional charity called LifeNet, which provides mosquito nets to help prevent malaria. Participants then indicated on a scale, from $0 to $100, how much money they were willing to donate to the charity. We found that participants in the felt-old condition pledged more money than those in the felt-young condition (p = .04).

In study 2, we tested the proposed mechanism of focus on others. Participants entered their demographic information, which included the felt-age manipulation. Next, stated their likelihood to partake in four environmentally friendly behaviors. We employed behaviors that would impose inconvenience to the self (e.g., unplugging appliances after each use), so that taking part in these actions would suggest putting aside one's own interests. Then participants completed the self-other interest inventory to measure how much they focused on others (Gerbasi & Prentic, 2013).

We averaged the four pro-environmental behaviors in the survey (α = .62), and then submitted this composite measure to analysis. We found that participants in the felt-old condition were significantly more likely to take part in pro-environmental behaviors than those in the felt-young condition (p = .02).

More importantly, a bootstrapped mediation analysis confirmed that the effect of felt-age on people's commitment to pro-environmental behaviors was indeed due to the changes in their focus on

others (95% CI: [0.023, 0.238]). That is, participants in the felt-old (vs. felt-young) condition showed greater focus on others, and this greater focus on others led to a greater likelihood to partake in pro-environmental behaviors.

In our final study, we tested whether the observed pattern could be reversed if people who feel younger are drawn to focus on others as well. Participants read a real campaign letter from United Way. To manipulate felt-age, we presented participants with pictures of teenage volunteers (felt-old condition) or pictures of late-middle-aged volunteers (felt-young condition). Furthermore, we manipulated the self-vs-other focus through the Call to Action statement that focused on the self ("Find out how YOU can help") or on others ("Find out how to help A PERSON in need"). Our dependent measures were intentions to volunteer, donate, and share information about this charity through social media channels and word of mouth ($\alpha = .96$ across 9 measures).

Because feeling older leads to greater focus on others, we predicted that participants in the felt-old condition would not be affected by the Call to Action frame, whereas those in the felt-young condition would become more pro-social when they were led to focus on others. A significant interaction of Felt-Age x Call to Action Focus confirmed our hypothesis ($p = .03$). While participants in the felt-old condition were not influenced by the Call to Action frame, those in the felt-young condition were significantly more likely to support the organization when they read the other-focused (vs. self-focused) Call to Action statement ($p = .02$). The results suggested that the other-focused Call to Action frame successfully led participants who felt young to act like those in the felt-old conditions; that is, they became more willing to volunteer, donate, and spread the word about United Way. In summary, we provide preliminary evidence that "how old people feel" reflects more than a psychological state; it has a profound impact on whether one decides to donate money, volunteer, and save the environment.

Picturing Time: How Taking Photos Affects Time Perception and Memory

EXTENDED ABSTRACT

Until recently, pictures were taken sparsely and predominantly at special occasions (e.g., weddings, graduations); however, picture-taking has now become ubiquitous in everyday life. While consumers have different motivations for taking pictures, from strict documentation to sharing the moment with others, in some shape or form, pictures are taken in order to hold on to experiences that people want to preserve.

How will the act of taking pictures affect experiences and memory? On one hand, being behind a camera may distance individuals from the experience and shift their perspective from a participant to an observer (Storms 1972). Being less immersed in the situation, they may enjoy the experience less and time may seem to pass more slowly (Sackett et al. 2010). On the other hand, taking pictures may draw people into the event, causing them to feel more immersed. Research on mindfulness and "flow" has shown that this leads to the feeling that time seems to pass without notice (Csikszentmihalyi 1988). As such prior literature provides support for predicting that taking pictures can increase as well as decrease immersion and time perception.

Prior work on memory and photography has focused on the role pictures, once taken, can play in cueing past memories. However, one recent paper (Henkel 2014) showed that compared to simply observing, being directed to take pictures can impair object recognition. However, prior work has not investigated how freely taking pictures affects memory, particularly for non-visual information (e.g., explanations provided by guides).

In this work we examine how taking pictures will affect experiences, as well as objective and subjective memories of the event. In one field study and two lab experiments, we find that the act of taking pictures can speed up subjective experiences of time, creating the experience that time is flying. Further, people feel they remember the experience better than if they had not taken pictures, a quality of memory not previously studied. However, this boost in subjective memory is opposite to the effect picture taking has on objective memory: picture-taking actually decreases how much information one remembers in the long run.

In a field study examining the effect of photo taking, we recruited 100 individuals at a local archaeology museum. Before entering one of the galleries, half the participants were instructed to "take as many photos as possible," while the other half was instructed to "view the exhibit as you normally would." Immediately after viewing the exhibit, participants filled out a short questionnaire (Time 1). 37% also completed an online follow-up survey four days later (Time 2). An ANOVA revealed that taking photos significantly increased the extent to which participants felt immersed in the experience ($F(1,96)=8.22$, $p=.005$). Further, at time 2 we found that while participants who took photos *felt* they remembered their experience better ($F(1,35)=8.08$, $p=.002$), they were actually less likely to correctly answer a question about the exhibition ($X^2=4.50$, $p=.035$).

In order to study the act of taking pictures in the lab, we developed a unique computer interface that allows respondents to "experience" by watching a first-hand video of an event and taking pictures by clicking a button. In our studies, participants watched several sightseeing bus tours which ensured that every participant had the same experience and also exposed participants to verbal information (i.e., information provided by the tour guide) which formed the basis for our objective memory examination.

In one study 236 participants were assigned either to take pictures or to simply experience these bus tours. Measures of immersion and time perception were taken immediately after the experience. Participants were also contacted again a week later (67% response rate) and responded to subjective and objective memory questions. Replicating our findings from the field we find that taking pictures heightens feelings of immersion in the experience ($F(1,232)=22.87$, $p<.001$) and also creates the feeling that time passes more quickly ($F(1,232)=3.77$, $p=.05$). Further, taking pictures slightly increased subjective memory perceptions ($F(1,219)=2.91$, $p=.09$) but significantly reduced how many questions participants could answer correctly ($F(1,219)=7.29$, $p<.01$).

Across both studies, we find that taking pictures heightens immersion in an experience and the sensation that time flies. We predict these effects will depend on whether taking pictures is an intrusive versus seamless part of the experience. When picture-taking is intrusive (e.g., large lens camera) people may take more of an observer role: they feel less immersed and time passes more slowly. However, when taking pictures is unobtrusive (e.g., ski goggles that take pictures) taking photos may heighten immersion and speed up time perception.

In order to test this prediction, in a study with 561 participants, we tested whether the extent to which picture taking is intrusive affects immersion, time perception, and memory. In the previous study participants could take pictures by simply clicking a button. We retain that condition, as well as the "no photo" condition, and add two more intrusive photo taking conditions. In one, participants had to "drag" a camera cut-out with their mouse and align the camera's viewfinder with the center of the video. In another, in addition to

dragging the camera, participants could "delete" photos as they proceeded through the tours. Replicating our findings, taking photos, regardless of the interface, sped up time perceptions ($F(1,556)=14.89$, $p<.0001$). Moreover, taking vs. not taking photos again increased subjective memory perceptions when the photo interface was low or moderately intrusive ($F(1,556)=14.72$, $p<.0001$). However when the interface was more distracting, participants rated their memory lower and comparable to not having taken pictures ($p>.15$). For objective memory performance, a similar pattern emerges: taking photos easily or with limited disruption leads to worse objective memory performance than not having taken pictures ($F(1,556)=3.77$, $p=.05$) or when having the ability to delete photos ($F(1,556)=8.77$, $p<.01$).

In sum, across these different experimental settings we find causal evidence that taking vs. not taking pictures can heighten the extent to which people feel immersed in the experience and can create a sensation that "time is flying". Further, while taking pictures heightens the belief that one remembers more, taking pictures tends to reduce how much one actually remembers.

A "Present" for the Future: The Unexpected Value of Rediscovery

EXTENDED ABSTRACT

Many moments in everyday life, from breakfast choices to iTunes playlists, seem too mundane to be worthy of preservation, or are so salient in the moment that it seems hard to imagine forgetting them. Should we forget those mundane moments, however, documenting the present offers one clear benefit: it allows for rediscovery in the future. Across three longitudinal studies using a "time capsule paradigm," we show that individuals underestimate the future value of rediscovering today's seemingly mundane experiences. Consequently, individuals forgo opportunities to document the present, but prefer to rediscover that present in the future.

A large body of research documents a host of errors in predicting future affective reactions. People have difficulty in predicting how they will feel in the future (Gilbert, Gill, & Wilson, 2002; Gilbert, Pinel, Wilson, Blumberg, & Wheatley, 1998; Kermer, Driver-Linn, Wilson, & Gilbert, 2006; Wilson & Gilbert, 2005) and in estimating the emotional impact of both negative and positive events (Frederick & Loewenstein, 1999; Fredrickson & Kahneman, 1993; Gilbert, Morewedge, Risen, & Wilson, 2004; Gilbert et al., 1998; Wilson & Gilbert, 2005). Whereas prior research has focused on how people mispredict their affective responses to future experiences, we explore people's mispredictions of how they will feel in the future when they *rediscover past* experiences.

In Study 1, undergraduates created time capsules capturing a range of everyday experiences, including a recent conversation, three songs to which they had recently listened, and an inside joke. For each item, individuals predicted the extent to which they would be curious to read what they had documented and find their time capsules interesting in the future. Three months later, we compared these predictions to their actual reactions before and after opening their time capsules. We found that people mispredict how their future selves will feel when they rediscover their past experiences: they not only underestimate how curious they will feel to open their time capsules, but also how interesting they will find the process of rediscovery.

In Study 2, we explore whether people are more likely to underestimate the value of rediscovering the simpler, more mundane experiences of everyday life, as compared to the extraordinary experiences, which they likely expect to enjoy remembering. In a longitudinal study across seven months, participants rated the extent to which the conversation they documented was ordinary and predicted

the curiosity and interest they would feel while rediscovering these conversations. Our results reveal that the unexpected value people receive from rediscovery stems at least in part from the pleasure of reflecting on the simpler aspects of ordinary life; in contrast, the pleasure of rediscoveries is better anticipated or even overestimated for memories that are already extraordinary and memorable.

Studies 1 and 2 document when and how individuals mispredict the pleasure of rediscovering the past. In each study, however, participants were given no choice: they were required to both document and reflect on their experiences. Thus, while we have shown that people underestimate the value of rediscovery, we have not yet shown that this misprediction also leads them to forgo engaging in behaviors that allow for future rediscovery: documentation itself. Furthermore, we examined whether overconfidence in memory is a possible psychological driver of the failure to appreciate the value of rediscovery. In this longitudinal study, participants at Time 1 chose between documenting an experience and engaging in an alternative fun activity (watching an interesting video). Regardless of their choice, participants completed both tasks and then predicted the extent to which they would find the experience of opening the time capsule and watching a similar video curiosity-provoking and interesting in the future. As part of our measure of overconfidence in memory, they also predicted the percentage of the documentation they would remember. One month later (Time 2), they chose between rediscovering the experience they had documented and engaging in an alternative fun activity (watching a similarly interesting video). Regardless of their choices, participants did both and then rated their actual memory, curiosity, and interest for both the time capsule and the similar video.

Study 3 demonstrates that underestimating the joy of rediscovery leads individuals to make time-inconsistent choices: they choose to forgo opportunities to document the present, only to find themselves preferring to retrieve those past records in the future. Although they were inaccurate in predicting their enjoyment of rediscovering the past, participants did accurately predict the extent to which they would enjoy watching a similar video in the future. In sum, these results show that our participants are not universally poor predictors, but instead seem to underweight the value of rediscovery in particular. Finally, our results suggest that people's misprediction of their memory in part drives their misprediction of the pleasure from rediscovery.

Across three longitudinal studies, we find that people underestimate the extent to which they will find today's experiences curiosity-provoking and interesting, leading them to forgo the opportunity to document the present even though they later choose to rediscover it. At least in part, the phenomenon arises because individuals fail to realize that they will forget the mundane details of their current experiences, such that the misprediction of the value of rediscovery occurs particularly for ordinary, rather than extraordinary, experiences. As one participant put it: "Re-reading this event of doing mundane stuff with my daughter has certainly brightened my day. I'm glad I chose that event to write about because of the incredible joy it gives me at this moment." By recording ordinary moments today, the present can become a "present" for the future.

SESSION DESCRIPTION

Consumers are frequently uncertain about the value of product offerings and features of tasks at hand (Bettman, Luce and Payne 1998; Slovic 1995) and they often make inferences and construct meanings based on information available in the local decision context (Ariely, Loewenstein and Prelec 2003; Kardes, Posavac and Cronley 2004; Kamenica 2008; Leszczyc, Pracejus and Shen 2007 Prelec, Wernerfelt and Zettelmeyer 1997). An omnipresent feature of consumer decision context is time. From units of measurement to time limits, reference to time is a salient feature in the decision context, yet it is often arbitrary and not informative to the decision itself.

This symposium takes a close look at the relationship between references to time in the decision context, inferences constructed from them and their effects on consumers' judgment and choice. Across four papers we find that consumers over-interpret and over-weight time frames when making decisions, which biases their judgments in systematic manners. The papers document these effects using time references that range from potentially useful (coupon redemption times) to completely irrelevant (explicitly randomly assigned time limits) and across several important consumer judgments (such as budget estimates and purchase decisions).

First, Joshi and Pocheptsova show that consumers deviate from an optimal preference for deals with longer redemption windows in favor of deals that expire sooner for hedonic and highly desired products. They provide evidence that such effect is driven by perceptions of scarcity and need to justify the purchase. Zhu, Yang and Hsee continue to explore the connection between time reference and scarcity and demonstrate that consumers exhibit "urgency bias", preferring to work on tasks with shorter (vs. longer) completion window but involving smaller (vs. bigger) payoff. They find support for an attention-based account and rule out task difficulty and outcome scarcity as alternatives. Next, Goswami and Urminsky suggest that incidental time limits affect people's beliefs about tasks, such that longer time limits lead to higher estimates of the scope of the task. This leads to shifts in preferences between fixed versus variable time frames for task completion when available time is salient in the decision environment. Finally, expanding our understanding of the connection between time reference and perceptions of difficulty, Min and Ülkümen examine whether budgets elicited in one's typically used time unit vs. in a non-default unit influences the estimation difficulty and magni-

tude of budget estimates. They find that using non-default units can increase or decrease estimated budgets, depending on how consumers interpret and respond to feelings of metacognitive difficulty.

Taken together, the four papers (all in advanced stages) elucidate the nuanced relationship between time references in the decision context and consumer judgment and choice, noting when and why time references may lead to suboptimal decisions or fruitless behaviors. As the session integrates diverse research to highlight newest theoretical developments in this important yet understudied area, it is expected to appeal to a broad audience, including those interested in time perception, inference making, judgment and decision biases, planning and budgeting, and consumer preference and choice.

Too Attractive to Pass: A Peculiar Appeal of Shorter Redemption Windows of Daily Deals

EXTENDED ABSTRACT

Daily deals, such as Groupon and Living Social, have fast become a popular sensation among consumers, with both websites boasting millions of users and billions in revenues. For example, Groupon (2013) reported and active customer base of 44.9 million; and a revenue increase of 31% North America alone. Such websites typically offer a few local "daily deals" for products or services that can be purchased at a substantial discount (40-60%). For example, consumers may buy a parking pass for $12 instead of $24, or a massage for $49 instead of $115. Interestingly, such deals come with different redemption windows, ranging from as short as 30 days to as long as one year. Longer redemption windows provide clear benefits to consumers by allowing them more flexibility regarding when to use their deal and increasing opportunities for consumption. A priori, one might expect that consumers would anticipate some uncertainty regarding when they would have an occasion to redeem a particular deal, preferring deals with a longer (vs. shorter) redemption windows. . On the contrary, in a series of studies including both experimental data and data on deals from the LivingSocial website, we identify conditions under which consumers are more likely to purchase deals that have shorter rather than longer redemption windows.

We argue that consumers interpret shorter redemption windows as a signal that the deal is more scarce (see also Innman, Peter & Raghubir 1997 for a similar notion of the relationship between coupon availability time frame and perceptions of scarcity). Further, consistent with the findings that buying hedonic (vs. utilitarian) goods require more justification (Khan and Dhar 2010; Kivetz and Simonson 2002b; Kivetz and Zheng 2006; Okada 2005), we show that consumers use short redemption windows to justify the purchase of hedonic deals. Specifically, while consumers express preference for longer redemption windows for deals for utilitarian goods or services, the opposite holds for deals involving hedonic goods and services.

To test this proposition, in Study 1 ($N = 136$) we offered students an opportunity to participate (using their own money) in daily deals offered by a campus website. The participants were assigned to one of the cells in a 2 (redemption window: 1 month vs. 3 months) x 2 (deal: hedonic service vs. utilitarian service) between subjects design. As predicted, we find an interaction between the two manipulated factors ($F(132) = 3.56$, $p<.06$). Specifically, participants were more likely to purchase a deal for hedonic service when it was offered with a one month vs. three months redemption window (M_{short}

= 5.03 vs. M_{long} = 4.38), but directionally were more likely to prefer the reverse for utilitarian service (M_{short} = 6.46 vs. M_{long} = 6.64). We replicated this effect in Study 2 (N = 211, interaction effect $F(210)$ =8.63, p<.01), using a general population and varying the type of product purchased (hedonic vs. utilitarian) while keeping the service provider the same (hedonic: M_{short} = 4.26 vs. M_{long} = 3.78 and utilitarian: M_{short} = 3.77 vs. M_{long} = 5.22).

Next, we test a potential moderator of our effect – the desirability of the product. We reasoned that highly attractive hedonic products should elicit higher level of guilt and therefore would require higher level of justification before making a purchase. The products in Studies 1&2 were all highly attractive and therefore we were not able to test this hypothesis. In study 3, we analyzed purchase data of 2349 deals on Living Social (by supplementing a dataset of deals data from Byers, Mitzenmacher & Zervas 2012 with information on the redemption window for each deal). The data included the redemption window, the time that the deal was available, the level of discount and, importantly, the number of "likes" given to the product on Facebook. We used the number of likes (which ranged from 0 to 880) as proxy for desirability of the product. Two coders, blind to the hypotheses, coded the deals into hedonic vs. utilitarian category. Controlling for the factors described above, there was a significant three-way interaction between the number of "likes", the redemption window and the hedonic vs. utilitarian nature of the deal (b = -1.27, t (2348) = 8.46, p <.001). As expected, a follow-up spotlight analysis revealed that for hedonic products consumers were more likely to buy deals for highly desirable products when the redemption window was short vs. long (M_{short} = 1214.5 vs. M_{long} = 798.8, t (1657) = 9.61, p <.001), but the reverse was true for less desirable products (M_{short} = 251 vs. M_{long} = 453.7, t (1657) = 5.50, p <.001). In contrast, for utilitarian products consumers were more likely to buy deals with longer redemption windows, even for highly liked products (M_{short} = 1286 vs. M_{long} = 1074, t (678) = 4.56, p <.001).

In Study 4 (N = 80), we focused on underlying process by (a) measuring perceptions of scarcity as a function of short vs. long redemption windows and (b) by asking half of participants to justify their preference for the deal. All participants were asked to evaluate a deal from their highly preferred retailer (hedonic or utilitarian, manipulated between subjects). A three-way interaction between justification, nature of the deal and redemption window on ratings of scarcity emerged ($F(72)$ =8.63, p<.01). While redemption window had no effect on perceptions of scarcity for utilitarian deals (Fs <1), participants judged deals with shorter (vs. longer) redemption windows to be more scarce (M_{short} = 5.33 vs. M_{long} = 4.33, F(72) =6.3, p=.014). Further, this effect was even more pronounced under justification (M_{short} = 5.83 vs. M_{long} = 3.64, F(72) =11.87, p<.001) .

Across several studies, we find that consumers deviate from an optimal preference for deals with longer redemption window in favor of deals that expire sooner for hedonic and, ironically, highly desired products. We provide initial evidence that such effect is driven by perceptions of scarcity and need to justify the purchase. Our findings provide an interesting insight into how time frames can bias consumer behavior in the daily deals market.

The Urgency Bias

EXTENDED ABSTRACT

Some tasks that we face are urgent and require immediate attention and others are important and involve great significance. When faced with multiple tasks of varying urgency and importance, how do we decide which task to perform? People may prefer working on urgent rather than important tasks, because important task are often more difficult, or because important tasks are often further away from goal completion (Kivetz, Urminsky, and Zheng 2006). Additionally, the missed outcome or opportunity for an urgent task may be perceived as more scarce and valuable (Brock 1968; Cialdini 2009). Finally, urgent tasks are often dependent of each other- missing one urgent task may result in series of losses in the future.

We propose that consumers will prefer working on urgent tasks over importance tasks, even when task difficulty, goal gradient, outcome scarcity and task interdependence are held constant. We term this tendency to prefer urgency over importance as "urgency bias". Specifically, we define urgency (importance) as the state that requires immediate attention (involves great significance). Urgent tasks are characterized by short vs. long completion windows, and important tasks are characterized by big vs. small outcome magnitude. Urgency bias predicts that people are more likely to perform urgent tasks of less importance, rather than more important tasks of less urgency. Further, we propose an attention-based account to explain the urgency bias. That is, while deciding which tasks to work on, people pay more attention to urgent tasks with short completion window, instead of important tasks involving bigger outcomes.

Study 1 is designed to test the proposed main effect employing a simplified game. Participants saw one big ball and some small balls on the computer screen, and they could earn points by clicking on the balls. Relatively speaking, clicking on the small (big) balls is an urgent/not important task (important/not urgent) in the game. Specifically, participants were given one chance to click every other second throughout the 1-mintue online game. Each click on the big (small) ball gave them 8 points (6 points). In the *urgency* condition, participants were told that they could click the big ball to earn points at any time, but they could only click a small ball to earn points when the small ball was active (i.e., when there was a counting down number 5, 4, 3, 2, or 1, on it). In the *control* condition, the game was identical except that both the big and small balls were active throughout the game. All participants were told that their task was to earn as many points as possible and they would be paid 1 cent for every 5 points earned at the end of the game. We calculated cumulative probabilities of clicking the big ball every other second. A 2(Condition) x 25(the cumulative probability in each period) mixed ANOVA revealed a significant interaction, suggesting that participants in the *urgent* condition were less likely to click the big ball than those in the *control* condition, and that the likelihood of clicking the big ball increased faster over time in the *urgent* condition than in the *control* condition. These results provide an initial demonstration of urgency bias. In Study 2, we replicated these findings using a different game in which (1) we used probability rather than a countdown window to produce urgency; and (2) not working on the important task results in a bigger loss, rather than working on the important task leading to bigger gain.

Study 3 generalizes the findings from simplified games to a real-life consequential choice context. Specifically, 119 Mturkers signed up for this study for a fixed payment of 50 cents. They were told that they could choose one of two tasks to take, Task A or Task B. They were told that in both tasks they would be given 3 minutes to type as many as possible out of 100 randomly generated 6-letter strings in the reversed order. All participants were told that they would earn a bonus that would be added to their mturk account by completing either of the tasks, and the level of bonus for each task would be randomly determined by a randomizer. All participants were assigned to earn a bonus of 12 cents by completing Task A, or a bonus of 16 cents by completing Task B. In the *urgency* condition, participants were further told that the two tasks also differed in their availability which would be randomly determined. They were then shown

a dynamic randomizer which always told them that Task A would expire in 5 minutes, and Task B would expire in 50 minutes. In the *control* condition, participants were told that both tasks would expire in 50 minutes instead. As predicted, participants were significantly more likely to choose Task A (the low-payoff option) in the *urgency* condition than in the *control* condition (36.4% vs. 11.9%, p = .002).

To test the proposed attention-based account, employing the same game as in Study 1, Study 4 asked participants to indicate at the end of the game whether they thought more about the small balls or the big ball when playing the game. The indirect effect differs from zero at the 95% CI: [-.29, -.14], indicating that attention mediates the effect of urgency manipulation on the likelihood to click the big ball.

Finally, employing the same task as in Study 3, Study 5 manipulated participants' attentional focus by showing them a reminder (which reads as "Note: If you choose Task A, you will lose the opportunity to earn 16 cents. If you choose Task B, you will lose the opportunity to earn 12 cents") or not, in addition to manipulating urgency. Replicating previous findings, when no reminder was shown, participants were more likely to choose Task A (the low-payoff option) in the *urgency* condition than in the *control* condition (48.5% vs. 1.9%, p < .001). However, when the reminder was shown, no difference in choice share was found.

In sum, we find that people exhibits the urgency bias, preferring urgency over importance.

More Time, More Work: How (Incidental) Time Limits Bias Estimates of Project Time and Scope

EXTENDED ABSTRACT

People have been shown to consume more time to do a specific job when more time is available to them (e.g. "Parkinson's Law" 1955; Bryan and Locke 1966). The increased effort can lead to better objective performance in the presence of both self-imposed as well as externally-imposed deadlines (Ariely and Wertenbroch, 2002). In this research, we investigate people's beliefs about others' performance on tasks, depending on the task time limit. Across five completed studies, we find evidence that such beliefs are consistent with a general scope perception account wherein longer time limits are naively associated with a larger scope of work.

In Study 1, *judges* read about an actual pretest in which all *workers* solved a 67 piece jigsaw puzzle in an untimed condition and took 31 minutes or less. Jigsaw puzzles were chosen for this controlled experiment because it is easy to quantify the amount of work, and assuming there is only one way to 'solve' it correctly, quality of work is not relevant. In an incentive-compatible setting, *judges* estimated how long it would take the average *worker* in a new experiment assigned randomly (using a coin toss) to different timed conditions (35 minutes vs. 60 minutes) to solve the jigsaw puzzle. Between subjects, the estimated average time in the long (60 minutes) vs. short (35 minutes) time limit conditions was 34 vs. 26 minutes (p < .001), compared to 29 minutes in the control (unlimited time) condition. The results could not be explained by incidental anchors, informational or quality inferences, or intrinsic motivation.

In Study 2, *judges* were given the same background information and one of three time limits (30 mins, 45 mins, unlimited time control), but were told that the *workers* themselves would not know about the time limits as they worked on the puzzles. Again, *judges* estimated more time in the longer time limit condition (31 vs. 28 minutes, p < .05). These finding cannot be explained by the judges' anticipating the effects of time limits on workers and accurately applying Parkinson's Law.

In contrast, we propose that longer time limits are simply associated with "larger" tasks, and therefore people will estimate not only longer completion times, but also larger scope of the task. In the next two studies, *judges* were asked to estimate the number of pieces in the puzzle (as a proxy for the scope of work) and were provided with the average time (Study 3) or an exact distribution of times (Study 4) taken to solve the puzzle under untimed conditions. *Judges* estimated more puzzle pieces in the 45 minutes condition than in the 30 minutes condition (Means: 177 vs. 131, p < .05; 122 vs. 103, p < .10 respectively).

Lastly, in an incentive-compatible game *judges* budgeted for a task to be conducted by a sub-contractor who would be paid based on time spent and did not know about time limits. Judges allocated significantly more money for the task ($6.09 vs. $5.26, p < .05) when more time was available to complete it, despite having the same distribution from which the actual time would be drawn, which impacted their own earnings.

The studies suggest that people overgeneralize rules about the relationship between time limits and work, which they have learned in relevant contexts and over-apply them, resulting in systematically biased decisions. The perceived association between scope of work and time can result in suboptimal choices by an economic agent responsible for sub-contracting tasks with pre-decided time limits which are exogenously determined. This can lead to shifts in preferences for a fixed rate contract versus a variable rate contracts when available time is salient in the decision environment, and therefore can have serious financial implications.

The Effect of Default Time Units on Budge Estimation

EXTENDED ABSTRACT

Consumers are often called upon by financial institutions or advisors to estimate budgets over different recurring time intervals. For instance, a consumer who normally uses a week frame to plan her activities may be asked to provide a budget estimate in a week frame (default unit), or a month frame (non-default unit). While it is well established that judgments and decisions can be influenced by the unit in which quantitative information is expressed (e.g., Ülkümen & Thomas, 2013; Zhang & Schwarz, 2012), the specific notion of *default* units has received sparse attention (Lembregts & Pandelaere, 2013). In this project, we investigate the effect of default units on consumers' spending estimates.

We expect that estimating budgets using a non-default (versus default) unit will lead to lower budget estimates, for two reasons. First, in line with previous findings suggesting that lack of familiarity with a unit can increase estimation difficulty (e.g., Block, Hancock & Zakay, 2010), we expect non-default (versus default) units to increase the perceived *difficulty* of budget estimation. This is because providing budget estimates in a non-default (versus default) unit should make it more difficult for consumers to unpack the relevant expenses contributing to their total budget. Consequently, such inadequate unpacking of future expenses should bias estimates downward, leading to smaller budgets (Fiedler, 2007).

Second, using non-default (versus default) units may also influence the perceived *importance* of budget estimation. Specifically, we hypothesize that consumers would consider the task of estimating their budget to be less important when the estimation is done in non-default (versus default) units. Since perceived importance of a task determines the amount of effort invested (Eklöf & Nyroos, 2013), we expect non-default (versus default) units to result in less elaborate, and ultimately smaller budgets.

While we always expect smaller budgets, the process should depend on whether consumers prioritize difficulty or importance considerations. If this is the case, then we would expect construal level to determine which of the aforementioned two processes mediates the effect of default units on budget estimation. Cheema and Patrick (2008) demonstrated that the perception and interpretation of stimuli depends on construal level. Research on goals (Ülkümen & Cheema, 2011) found that goal difficulty becomes salient in low-level construal, whereas goal importance becomes salient in high-level construal. In line with this, we predict that for low-level (high-level) construers, estimation difficulty (estimation importance) would mediate the effect of non-default units, leading to smaller budget estimates.

Study 1. We asked 202 participants to estimate their total budget in a randomly assigned unit: week or month. To assess their personal default unit for budget planning, we asked them to indicate which time frame they usually use to plan their budget: weekly, monthly, or other. We categorized participants into the default (non-default) unit condition if the experimentally assigned estimation unit was consistent (inconsistent) with their personal default unit. We converted estimated budgets into a comparable, monthly basis, log-transformed, and submitted them to a 2 (Estimation unit: default, non-default) x 2 (Personal unit: week, month) ANOVA. Participants using a non-default unit provided *smaller* budget estimates ($M = \$954.4$) than those using their default unit ($M = \$1,156$), $F (1, 188) = 4.38$, $p < .05$, $\eta^2_p = 0.02$, regardless of whether their personal preference was to budget for a week or a month ($F = .87$, $p > .1$).

Study 2. To replicate the finding and explore initial evidence of estimation difficulty engendered by non-default units, we recruited 198 participants to complete a task identical to Study 1, and also included three items to assess the difficulty, confidence, and certainty they experienced while estimating their budgets ($\alpha = .87$). Replicating Study 1, participants using non-default units estimated *smaller* budgets ($M = \$1,048$) than those using default units ($M = \$1,411$), $F (1, 178) = 3.10$, $p = .08$, $\eta^2_p = 0.02$, regardless of the preferred unit ($F = .68$, $p > .1$. Moreover, participants who used non-default (versus default) units experienced *greater* cognitive difficulty ($M_{non-default} = 3.41$ vs. $M_{default} = 3.02$), $t = 1.83$, $p < .01$, d = 0.27.

Study 3. To test our underlying processes, we recruited 230 participants and manipulated construal level using a thought exercise (adapted from Freitas, Gollwitzer & Trope, 2004) where half of them in the high (low) construal level condition thought about why (how) they maintain and improve their physical health. Then, they made budget estimates as in the previous studies. Next, they responded to 7 items ($\alpha = .961$) that measure estimation difficulty (e.g., "How easy or difficult was it for you to include all relevant expenses in your budget estimate for the next week (month)?") and 5 items ($\alpha = .873$) that measure estimation importance (e.g., "How important is it for you to have a budget plan for the next week (month)?").

As well as replicating the main findings ($M_{non-default} = \$1,240$ vs. $M_{default} = \$1,480$), we found (marginally) significant moderated mediations for both estimation difficulty ($\beta = -1.049$, $p = .023$) and estimation importance ($\beta = -.52$, $p = .09$). For low-level construers, the effect was mediated by estimation difficulty (LLCI = .0086, ULCI = .3546), whereas for high-level construers, the effect was mediated by estimation importance (LLCI = -.4980, ULCI = .0218).

Three studies demonstrate whether budgets are estimated in one's default or non-default time unit influences the experienced difficulty (importance) of budget estimation, which in turn biases these estimates downward for participants in low (high) construal level. These findings help reconcile seemingly conflicting prior findings regarding the direction in which metacognitive feelings influence judgments (Fiedler, 2007; Ülkümen & Thomas, 2013). We demonstrate that estimation difficulty and importance do not influence budgets in a straightforward manner. The direction in which perceived difficulty and importance influence estimated budgets depends on the source of these metacognitions, as well as consumers' interpretation of them.

Our research is the first exploration of default units at the individual level and in the context of budgeting. In continuing research, we examine how estimation units can be used to improve accuracy of budget estimation.

SESSION OVERVIEW

Every day, consumers cope with the unpleasant experience of social exclusion. They don't get that important call, wait in line while others are bumped to the front, or learn through social-media they were not invited to the big party. Understanding social exclusion and its consequences for consumer behavior is an emerging area of interest that this session advances to the next level by showcasing the most recent work on the topic. All the papers in the proposed session seek to provide answers to the important yet understudied question: when do socially excluded people look past the sting of rejection and continue to pursue social bonds, and when does exclusion cut too deep, causing demotivation and withdrawal? The first two papers focus on personal and situational factors that determine when exclusion leads to reconnection versus withdrawal. The second set of papers tackles that question in relatively novel contexts: pro-environmental consumption and consumer-loyalty programs.

The first paper demonstrates that the reason for rejection plays a powerful role in shaping willingness to forgive and forget. When the reason for rejection is ambiguous, consumers are not hostile toward a rejecter's recommendations, so long as they have previously bolstered self-perceptions. However, if consumers know they have been rejected for personal reasons, then any recommendation made by the rejecter will be negatively viewed, regardless of prior self-affirmed. These findings suggest that, while consumers' need to connect with others generally allows them to "forgive and forget," at least when they are already in a positive state of mind, they are not so willing to overlook exclusion when it is personal.

The second paper examines how interpersonal orientation shapes consumers' reactions to social exclusion. Individuals with a relatively more independent orientation to social relationships are fairly insensitive to social exclusion. However, among individuals with a relatively more interdependent orientation, social exclusion is a serious breach of their social contract, thereby reducing their willingness to engage in impression management for the sake of so-

cial connection. These results suggest that those with the strongest desire to be accepted are the most likely to become demotivated and withdraw after exclusion.

The third paper demonstrates that exclusion reduces people's inclination to engage in pro-environmental behavior, because it makes them reluctant to incur personal costs for the benefit of others. However, when pro-environmental behavior confers direct social benefits for excluded individuals, negative effect is mitigated, suggesting that social exclusion elicits a, "What's in it for me," response, wherein consumers focus on their own needs at the expense of others.

The final paper explores loyalty programs, which while designed to build lasting bonds with consumers, inevitably exclude consumers who do not qualify for program benefits. Results demonstrate that if managers carefully match program benefits with the efforts required to achieve benefits, that excluded consumers are actually willing to exert greater effort on behalf of the excluding organization. These findings suggest that consumers can find exclusion motivating, provided the exclusion does not pose a breach of the social contract.

"Becoming More Sensitive to the Source of Social Exclusion": When Self-Affirmation and Type of Social Exclusion Influences Excluded Consumers' Preferences

EXTENDED ABSTRACT

This research examines how product recommendations by excluders (vs. non-excluders) influence excluded consumers' preferences toward a recommended product. Previous work on social exclusion has shown that excluded individuals want to avoid and be disconnected from perpetrators of exclusion (Buckley et al. 2004; Maner et al. 2007). According to this finding, we can simply predict that excluders' recommendations will negatively impact excluded consumers' product preferences. However, we suggest that excluders' recommendations do not always reduce preferences toward products. Rather, the effect of excluders' recommendation depends on consumers' sense of self and the type of exclusion.

We propose that self-affirmation (e.g. reflecting on one's long-held values) can increase sensitivity toward the type of social exclusion by reducing the focus on self-evaluative aspects of social exclusion and broadening a perspective about social cues. We examined two types of exclusion. One is intentional exclusion (e.g., excluder did not like the person), and the other is situational exclusion (e.g., the excluder had to leave early for personal reasons). Although recent studies have examined the role of self-affirmation on excluded consumers' product choice (Wan, Xu, and Ding 2014), their choice context was not related to the prior social exclusion. In contrast, the current research investigates the influence of product recommendation by excluders versus non-excluders on consumers' preferences. Moreover, in Wan et al. (2014) when the study manipulated self-affirmation, it did not inform participants about why they were excluded.

We hypothesize that when the reason for exclusion is ambiguous, non-affirmed consumers tend to focus more on self-evaluative aspects of the situation; in turn, they will be more likely to attribute social exclusion to intentional factors (e.g., "they must dislike me"). As a result, non-affirmed consumers will display a less favorable attitude toward a product when excluders (vs. non-excluders) recommend the product. However, self-affirmation will increase the

attribution to situational factors (e.g., "they misunderstood the instruction"), and accordingly reduce the negative effect of excluders' recommendation.

We also suggest that when the type of exclusion is evident (intentional or situational), affirmed consumers' preferences will be more sensitive to the type of social exclusion. More specifically, we predict that non-affirmed consumers will evaluate products recommended by excluders (vs. non-excluders) less favorably, regardless of the type of exclusion. However, affirmed participants will be able to differentiate situational exclusion from intentional exclusion and take the type of exclusion into consideration when judging the target product. We predict that for affirmed consumers excluders' recommendation will still have a negative impact on excluded consumers' preferences when the exclusion is intentional. However, for situational exclusion, excluders' recommendation will have less of a negative impact.

We tested our predictions in two studies. In study 1, we employed a 2 (affirmation: high vs. low) × 2 (product recommenders: excluders vs. non-excluders) between-subjects design. Participants first engaged in a self-affirmation manipulation task (Fein and Spencer 1997; Sherman et al. 2000; Sherman and Cohen 2006). Participants in the high affirmation conditions first ranked 12 values according to their importance. Then they wrote an essay about the most important value and why it was important and meaningful to them. In the low affirmation conditions, participants first listed food items from the previous day and wrote an essay about one specific meal. Then we manipulated social exclusion using a three-person cyber ball game. In the game, all participants were excluded from the other two players. After the game, using an open-ended question, participants were asked to write down why they thought the other two players had excluded them. Then, ostensibly for a different study, participants read information about some products and indicated their preference for each product (e.g., a toaster). Half of the participants evaluated products recommended by excluders, while the other half evaluated products recommended by non-excluders.

The content analysis of the open-ended question indicated that affirmed participants (60.6%) were more likely to attribute exclusion to situational factors (e.g., "the other two players already know each other") than non-affirmed participants (32.4%, $z = 3.4$, $p < .01$). Consistent with the attribution pattern, non-affirmed participants evaluated the products less favorably when the products were recommended by excluders (M = 5.72) than non-excluders (M = 6.41, $t(138) = 2.57$, $p = .01$). However, excluders' recommendation did not reduce the evaluation of affirmed participants ($M_{excluders} = 6.01$, $M_{non-excluders} = 5.92$, $t(138) = 0.34$, NS).

The second study examined the interactive effect of self-affirmation and exclusion type on excluded consumers' preferences. We employed a 2 (affirmation: high vs. low) × 2 (exclusion type: intentional vs. situational) × 2 (product recommenders: excluders vs. non-excluders) between-subjects design. First, participants engaged in the same self-affirmation manipulation task and then the cyber ball game, as in experiment 1. However, different from experiment 1, at the end of the game participants were informed why they had been excluded in the game. Half of the participants were told the other two players intentionally did not pass the ball because they did not consider the participants to be good co-players (intentional exclusion), while the other half were told the other two players happened to be in a bad mood and became less cooperative (situational exclusion). Then, as in experiment 1, participants evaluated products recommended by either excluders or non-excluders.

Consistent with our prediction, the findings show that for non-affirmed participants, a 2 (exclusion type: intentional vs. situational) × 2 (product recommenders: excluders vs. non-excluders) between-subjects ANOVA revealed only a main effect of product recommenders ($F(1,84) = 3.53$, $p = .06$). That is, excluders' recommendation reduced evaluation of the products regardless of the type of exclusion ($M_{excluders} = 5.87$, $M_{non-excluders} = 6.39$). More importantly, however, affirmed participants reacted to different types of exclusion differently. Excluder recommendation reduced preferences only when the exclusion was intentional ($M_{excluders} = 5.72$, $M_{non-excluders} = 6.45$, $t(171) = 2.57$, $p < .05$). Our findings indicate that, different from the previously documented buffering account, self-affirmation does not always buffer social exclusion, eliminating social exclusion effects. When exclusion is explicitly intentional, affirmed participants still respond to social exclusion negatively.

You Broke Our Contract!: Social Exclusion Differentially Influences Independent and Interdependent Consumers' Impression Management Goal Pursuit

EXTENDED ABSTRACT

The present work examines how social exclusion (vs. inclusion) influences the relation between self-construal and consumers' impression management goals. Previous research suggests that interdependents value relationships and belongingness, and dislike being isolated from their groups (e.g., Markus and Kitayama 1991; Kim and Markman 2006). Other research suggests that excluded individuals sometimes engage in more impression management to reconnect with others (Maner et al. 2007; Mead et al. 2011). If so, interdependents would be expected to intensify the pursuit of impression management following social exclusion (vs. inclusion).

Contrary to this intuitive hypothesis, we propose that social exclusion (vs. inclusion) leads interdependents to pause in pursuing impression management goals. As a result, they are less motivated to expend time, money, and effort in search of publicly (but not privately) consumed products. This pattern is not expected among independents. We base these predictions on consumers' belief in a social contract, due to which they comply with societal norms with the expectation of rewards in return.

Social contract theory delineates the relation between citizens and society (Mayer and Beltz, 1998). The theory postulates that people who behave according to the rules specified in the social contract (e.g., being socially appropriate) are provided certain benefits in exchange by society (Mayer and Beltz, 1998). Research suggests that interdependent people have a greater expectation to be included by close others than independent people (Miller et al. 1990; Triandis 1998). Hence, we propose that interdependent (vs. independent) consumers will more readily view being excluded by close others as a breach of social contract. Consequently, when excluded (vs. included), interdependent consumers are less motivated to continue upholding their side of the social contract such as managing their impression in front of others.

Four studies using a variety of operationalizations of all key variables (cultural self-construal, social exclusion, impression management) provide robust support for our hypotheses. Specifically, in the inclusion (but not exclusion) condition, interdependence was associated with the tendency to engage in impression management and the amount participants were willing to pay, the distance they were willing to travel, and the time they were willing to spend searching for publicly consumed products. In contrast, independence was not associated with these tendencies in both the inclusion and exclusion conditions (Studies 1 to 4). Hence, our findings suggest that social exclusion profoundly influences interdependent consumers' pursuit of impression management goals. Specifically, interdependent con-

sumers are less motivated to pursuit their impression management goals when excluded (vs. included) by close others. In contrast, independent consumers' impression management goal pursuit is not affected by social exclusion.

In addition, we found support for the mediating role of social contract in the interactive effect of social exclusion and self-construal on impression management goal pursuit, both by measuring social contract (Study 2) and by manipulating it (Study 3). Finally, because a social contract is an implicit agreement between a person and others in society, we theorized and found that it will affect interdependents' behavior when it has implications for how they are viewed by others (i.e., in public settings). However, when the behavior cannot be viewed by others, we did not expect and did not find social contract to influence interdependents' tendency to pursue impression management goals (Study 4).

This paper makes a number of contributions. First, we offer important qualifications to previous research which has robustly demonstrated self-construal differences in impression management goal pursuit. We conceptually replicate the general findings of Lalwani, Shavitt, and Johnson (2006) and Lalwani (2009) that interdependents are more likely to pursue impression management goals than are independents, but only when they perceive that others adhere to the social contract. When interdependents perceive that the social contract is violated (e.g., when they are socially excluded by close friends and others), they discard the pursuit of impression management goals. Second, our results dispel the notion that, when excluded, interdependent consumers more vigorously pursue impression management goals to reconnect with others. Instead, we find that exclusion causes interdependents to abandon their desire to be socially appropriate. In so doing, we shed unique insights on the mindset of the interdependent consumer, and on the extent to which they are willing to pursue their social goals. Third, we introduce social contract theory to consumer research, and contribute to that theory by unveiling how social exclusion can cause consumers to view a social contract to be breached. Fourth, while some previous research shows that excluded individuals may engage in withdrawal and avoidance behaviors (Predmore and Williams 1983; Tice et al. 2002; Williams et al. 2000), the downstream consequences of such behaviors are less clear. We identify an important consequence of exclusion, namely decreased impression management goal pursuit, and shed light on the mechanisms underlying the behavior, as well as on its implications.

Can Broken Hearts Lead to an Endangered Planet? Social Exclusion Reduces Willingness to "Go Green"

EXTENDED ABSTRACT

Consumers are lonelier than ever before. At the same time, it is becoming more pertinent than ever before to stimulate environmentally-friendly consumption. Given the prevalence of social exclusion, and given the increasing necessity of pro-environmental behavior, understanding the relationship between the two is a critical endeavor for consumer researchers.

Previous research suggests that consumers buy pro-environmental products to signal their status to others (Griskevicius, Tybur, and Van den Bergh 2010). While this costly signaling may impel some consumers toward "green" purchases, that very same process may repel yet others. A sizeable body of literature suggests that social exclusion reduces engagement in prosocial and interpersonally beneficial behaviors, in part because it reduces empathic responding (e.g., Baumeister, Brewer, Tice, and Twenge 2007). This line of research suggests, then, that social exclusion may reduce consumers'

willingness to engage in pro-environemental consumption because it reduces their empathic concern for others. However, when excluded consumers are given a viable chance for reconnection, socially excluded individuals engage in more prosocial than antisocial behavior (Maner et al. 2007; Mead et al. 2011). We therefore expected that the negative effect of exclusion on pro-environmental consumption would be attenuated in cases where green purchases confer direct social benefits for the consumer. Four experiments tested and provided support for these hypotheses.

Experiment 1 tested our basic hypothesis; it also investigated empathic responding as a potential mechanism. To manipulate social exclusion, participants were given bogus feedback about the future implications of their personality-test results (Twenge et al. 2001). Participants were told that their future would be full of social relationships (social acceptance), devoid of social relationships (social exclusion), or full of mishaps and misfortune (misfortune control). The latter group was included as a control for negative feedabck that was not social in nature.

To measure the putative mediator -- empathic concern -- participants read and responded to an essay that was ostensibly written by another student and which described a recent romantic-relationship breakup; participants indicated their feelings toward the peer using 6 adjectives (e.g., sympathetic, compassionate; Batson et al. 1995). To measure green-consumption preferences, participants indicated their preference between two backpacks that were of the same brand and price: a regular backpack, which was superior on performance, and a "green" backpack, which was environmentally superior. Willingness to sacrifice to protect the environment (WTPE) and the society (WTPS) were also measured (Stern et al. 1999).

Results supported predictions. Socially excluded participants reported a lower preference for the "green" product relative to the acceptance and control conditions; the latter groups did not differ. The same pattern emerged for measures capturing participants' willingness to make self-sacrifices for the sake of the environment and society. Additionally, empathic concern mediated the effect of exclusion on those measures. Mood was examined and could not account for obtained effects.

Results from Experiment 1 supported the hypothesis that social exclusion reduces pro-environmental concern through empathic responding. To provide convergent evidence for this possibility, Experiment 2 tested the hypothesis that social exclusion reduces green-consumption preferences among individuals low (but not high) in empathic concern. Experiment 2 therefore measured emotional empathy (Caruso and Mayer 1998) and manipulated social exclusion using a recall task (Maner et al. 2007); participants wrote about a time they were either rejected or accepted. Preference for a "green" versus a regular car was the dependent measure.

Hypotheses were tested using a series of planned simple slope tests. As predicted, social exclusion (versus acceptance) decreased preference for the "green" car, but only among low-empathy individuals. Also consistent with predictions, exclusion (versus acceptance) did not decrease pro-environmental preferences among those high in empathic concern for others.

Experiment 3 presented participants with "green" products that could or could not be used while interacting with peers and therefore could (or could not) be used as an affiliation tool. Because socially excluded individuals are particularly keen to forge bonds with others, purchase intentions for pro-environment products that facilitate interpersonal interactions should not be eroded by social exclusion. To test this hypothesis, participants were excluded or accepted using the feedback procedure described in Experiment 1. Participants then viewed either an environmentally friendly desktop computer (for

personal use at home) or a green laptop (for doing group projects with classmates at school); the products were identical on quality and performance.

Results indicated that excluded individuals were less willing to purchase the green desktop as compared to accepted individuals. However, the detrimental effect of exclusion was not apparent in the laptop condition. Looked at a different way, excluded participants reported higher purchase intentions for the publicly visible laptop than the private desktop. Among accepted participants, however, purchase intentions did not differ as a function of the product's public visibility.

In Experiment 4, we framed the same "green" product in terms of its social or utilitarian benefits, expecting that excluded consumers would be particularly interested in a "green" product when the social benefits were made salient. To test this hypothesis, we presented a green car as a fuel-efficient model whose owners were *nice, caring,* and *altruistic* (social benefits) or *economical, money-wise,* and *value-shopper* (utilitarian benefits) The social exclusion manipulation was the recall task used in Experiment 2 (Maner et al., 2007).

Results supported predictions. Participants who recalled a time they felt excluded reported higher intentions to purchase the car when the benefits were social than utilitarian. In contrast, the opposite pattern was found among participants who recalled a time of acceptance. These results emerged when controlling for individual differences in pro-environmental attitudes (Haws et al. 2010).

In summary, four experiments provide novel evidence that social exclusion has profound consequences for consumers' pro-environmental consumption. When green consumption incurred costs to the self for the benefit of others, exclusion reduced people's willingness to shoulder those costs. However, when green consumption promised the chance of social rewards, socially excluded individuals were enticed. Overall, the current work provides new insight into the complex interplay between social motivations and green consumption and suggests novel avenues for future research.

"We Don't Think You're Important": Exploring the Effects of Loyalty Programs on Those Excluded from Benefits

EXTENDED ABSTRACT

Consumer loyalty programs have been seen as an important tool for reinforcing desirable behaviors such as repeat purchase and increased brand loyalty among most valuable consumers. While previous research has explored both the benefits and pitfalls of offering loyalty programs, the focus has been on consumers who receive benefits while ignoring the impact of these programs on consumers who are excluded from receiving rewards (Henderson, Beck, and Palmatier 2011).

We focus on the impact of loyalty programs on those ineligible for reward benefits. By rewarding one group of consumers, loyalty programs, by definition, exclude another group of consumers. Social exclusion has profound, and often contradictory (Lee and Shrum 2012), effects on behavior and research on social exclusion has attempted to gain a better understanding of when exclusion results in pro- versus anti-social behaviors (Williams 2007). Managers, therefore, could benefit from knowing how to structure loyalty programs in a way to increase patronage among excluded consumers.

While there are many different facets of loyalty programs that organizations have control over, we focus on two aspects that are relevant to theory related to both social exclusion and loyalty programs: type of benefit (social vs. financial) and type of effort required to receive the reward (opting-in vs. accumulating "points").

Requiring consumers to actively opt in to a loyalty program indicates a clear desire on the part of the consumer to forge a stronger bond with the organization. At the same time, exclusion from benefits after active relational effort on the part of the consumer is likely to be perceived as rejection, which is associated with a decrease in pro-social behaviors (Twenge et al. 2007). Using effort-reward congruity (Kivetz 2005), we expect that social benefits will lead to increased motivation on the part of consumers excluded from opt-in loyalty programs because the social benefits are congruent with the social commitment made by the consumer. Exclusion from financial benefits in an opt-in system, however, will be particularly negative from the consumer's point of view, as not only has their relational effort been seemingly rejected but there is a mismatch between the effort (social) and the offered reward (financial).

In contrast, when points are accumulated automatically, with no formal opt in required, consumers may perceive inclusion or exclusion as an indication of "fit" with the company because the accumulation of "points" is a clear indication of the economic utility the consumer provides to the organization. Consequently, we expect a better fit (Kievtz 2005) between points based systems and financial rewards in which consumers see a clear relationship between their effort and potential reward. In sum, when the reward has financial benefits, we expect an accumulated points effort requirement to be more motivating than an "opt-in" effort requirement. When the reward has social benefits, we expect the opposite pattern.

Study 1 was a field experiment conducted using MTurk. MTurk has an existing reward program in which workers (those who respond to surveys or piece work requests) can earn eligibility for the "Master Workers" program based on both the frequency and quality of their work. We used this existing Master Workers program as the basis for our manipulation. After screening out potential participants who either currently are or have been Master Workers, thus ensuring that all participants were "excluded," we presented them with one of four versions of the program using a 2 (effort requirement: opt-in then earn points vs. automatically eligible once enough points have been earned) x 2 (benefit: purely financial vs. social and financial) between-subjects design.

Participants read one of the four versions of the program and then responded to a variety of measures, including how many HITs (work requests) they anticipated completing in the next 24 hours, which served as our measure of motivation. The interaction of benefit with effort requirement significantly predicted motivation ($F(1, 203) = 4.96$, $p < .03$). When the benefits included social aspects, an opt-in effort was more motivating than earning points ($M_{opt-in} = 81.33$ vs. $M_{points} = 44.48$; $F(1, 203) = 3.47$, $p < .04$, one-tailed test). When the benefits only included financial elements, however, we observed the reverse pattern ($M_{opt-in} = 33.73$ vs. $M_{points} = 59.14$; $F(1, 203) = 1.66$, $p < .10$, one-tailed test). While these results are in line with our predictions, there were two limitations to the study. First, we only looked at excluded consumers. Including included consumers as well will provide a more complete picture of how loyalty programs affect motivation. Second, the social benefit condition included a financial benefit as well. This was due to the fact that we used an established loyalty program for which the financial benefit could not be removed without arousing suspicion. Study 2 addresses these limitations.

Study 2 was conducted with undergraduate students who were randomly presented with one of four descriptions of a basketball ticket distribution method (social benefit) from a 2 (effort requirement: opt-in vs. earn points) x 2 (exclusion: yes vs. no) between-subjects design. Those in the points condition were told students must earn entries into the lottery by attending non-basketball sporting events on campus (e.g., women's softball game). Those in the

opt-in condition were told students must opt-in to the lottery before a specific date. We asked participants in the included (excluded) condition to imagine they had (not) been able to enter the lottery. Participants then completed a variety of measures, including the number of non-basketball sporting events they anticipated attending on campus next year, which served as our measure of motivation. We found a significant interaction of exclusion with effort requirement ($F(1, 129) = 6.95$, $p < .01$). In line with our predictions, exclusion resulted in greater motivation for the social benefit when the effort required was opting-in compared to earning points ($M_{opt-in} = 3.02$ vs. $M_{points} = 2.65$; $F(1, 129) = 2.62$, $p = .05$, one-tailed test). When the benefit was social and the program was structured as opt-in, exclusion led to greater motivation than inclusion ($M_{exclusion} = 3.02$ vs. $M_{inclusion} = 2.54$; $F(1, 129) = 4.79$, $p < .04$).

SESSION OVERVIEW

Emerging evidence from various streams of research supports the notion that cognition is embodied (e.g., Clark 1997; Barsalou 2008; Wilson 2002). The embodied view of cognition posits that one's bodily experience produces systematic effects on cognition (Barsalou 2008). Recent research in this area has produced a range of interesting effects, including the use of embodied metaphors. However, most of this research has been agnostic as to the processes responsible for these effects. This session presents four papers that together examine how the meanings associated with behaviors determine their impact on subsequent cognition. The four papers in this session examine different embodied behaviors and different outcomes in theorizing their results, yet the papers share an emphasis on detailing the conditions under which classic embodiment effects hold and are moderated by the meanings consumers attach to their actions.

The first paper in this session (Kim, Duhachek, Briñol and Petty) investigates whether the effect of behavior on cognition depends on the meanings consumers attach to their own behavior. Kim, Duhachek, Briñol and Petty examine whether the behavior of keeping one's self-generated thoughts in a place that has semantically different meanings influences consumers' reliance on these thoughts. Similarly, Labroo, Mukhopadhyay, and Dong examine how consumers construe the meaning of smiling behavior influences their wellbeing in different directions. The findings from these two papers suggest that the process of embodiment is largely dependent on the construal of the meaning of behavior rather than the behavior per se. The third paper by Hauser and Schwarz sheds further light on these processes by showing that embodiment effects are stronger among high need for cognition consumers, indicating the importance of the degree of thought surrounding embodied cognition and indicating that embodiment effects involve elaborative thinking. The final paper by Cai, Yang, and Wyer documents how the experience of bitter taste elicits metaphorical thinking and influences consumers' saving behavior.

Importantly, they find that mood is a key moderator in these effects, thereby demonstrating the validating role mood plays in assisting consumer ascribe meanings to their actions.

The four papers in this session offer interesting converging perspectives on how our cognition interacts with our sensorimotor experience. The papers identify meaning-based embodiment mechanisms that link behavior to cognition and highlight both the role of the type of and extent of thoughts consumers have linking their behavior with subsequent cognition.

Protect or Hide Your Thoughts: The Meanings Associated With Actions Matter

EXTENDED ABSTRACT

Previous research has shown that materializing thoughts allows consumers to lessen their influence on subsequent cognition (Briñol et al. 2012). The current research builds on this notion and identifies ways in which these materialization effects on cognition can be amplified. In so doing, we identify the role of naïve theories in driving these effects through the meanings consumers ascribe to their behaviors. In the present research, participants wrote down either positive or negative thoughts about a given object (e.g., doing exercise) and placed their written thoughts at a location (e.g., their pocket) that is tagged with semantically different meanings (e.g., safe vs. out-of-sight). Past research in consumer behavior (e.g., Roster 2001) shows that the location of a possession is correlated with its importance such that less important possessions are put at a further away or out-of-sight places (e.g., basement) whereas more important possessions are put at a nearby and more secure places (e.g., in a drawer). We hypothesize that this effect is not limited to material objects but also can be extended to immaterial entities such as our own thoughts. Further, we hypothesize that different effects can emerge from the very same behavior depending on how the behavior is construed. Specifically, our findings show that the participants embody the meaning of a place (or, the meaning of the behavior of putting their thoughts into a place) into their cognition such that placing one's thought at place that is tagged with safety amplifies the original valence of the thoughts whereas placing one's thought at a place that is tagged with insecurity attenuates the original valence of the thoughts. Since we assigned different meanings to the very same place, it is indicated that what is important in the process of embodiment is the meaning of the behavior, not the behavior per se. That is, the very same behavior can produce varying impact depending on how its meaning is construed. This research provides evidence for a driving factor in embodiment effects related to the consumers' naïve theories regarding the meanings associated with their behavior.

Our research is consistent with the recent findings of embodied cognition which show that cognitive appraisal of the behavior is important in embodiment process. Recent studies show that labelling a behavior differently can reverse the standard effect of body movement on cognition (e.g., Cesario McDonald 2013; Eder and Rothermund 2008). For example, Cesario McDonald (2013) showed that adopting an expansive body posture can actually decrease perceived power if it is construed as having different meanings (e.g., being frisked by a police). Elder and Rothermund (2008) showed that the standard arm bending and extending effect (e.g., Chen and Bargh 1999) can be reversed if the behavior is associated with different meanings. Our findings indicate that the effect of the construal

of behavior on cognition is strong such that it can even influence the thoughts that are self-generated. Our research is also consistent with the self-validation hypothesis (Petty, Briñol, and Tormala 2002) which emphasize meta-cognitive aspect of thinking. Self-validation hypothesis suggests that how consumers validate or invalidate their thoughts is an important determinant of attitude. Therefore, the extent to which placement of a thought into different locations is construed as validation or invalidation can alter the valence of thoughts as well as consumer reliance on it. In our research, placement of thoughts in a location with semantically different meanings can be characterized as validation or invalidation of one's attitude by behavior.

Study 1: Seventy six students were randomly assigned to one of the conditions in a 2 (thought valence: positive, negative) × 2 (thought treatment: disregard, expand) between subject design. Participants were first instructed to write down either positive or negative aspects of exercise and then all participants put their written thoughts into the same box. Importantly, the meaning of this behavior was randomly assigned and described as either disregarding or expanding their thoughts. The dependent measure was stated exercise intentions. As hypothesized**,** an ANOVA revealed a significant 2-way interaction ($F(1,72) = 7.96$, $p < .05$) between thought valence and thought treatment. Specifically, planned contrasts revealed that within the expand condition, those who generated positive thoughts indicated greater intentions to exercise than those who generated negative thoughts (Mpositive=7.29, Mnegative=6.13; $F(1,72)=5.02$, $p < 0.05$). However, there was no effect of valence within the disregard condition ($F(1,72)=3.04$, $p > 0.05$) indicating that classifying the embodied behavior as disregarding one's thoughts attenuates the expansion effect.

Study 2: In study 2, 127 participants were randomly assigned to one of the conditions in a 2 (thought valence: positive, negative) × 2 (thought treatment: out-of-sight, safe) between subject design. The procedure of study 2 was identical to study 1 except for the two changes. First, participants placed their thoughts into their own pocket instead of a box. Second, the meaning of box varied as either out-of-sight or safe place. Our dependent measure was a choice between a healthy and unhealthy snack (1: chocolate cake --- 9: a salad). An ANOVA revealed that the two-way interaction between through valence and through treatment is significant ($F(1,123) = 9.46$, $p < .005$). In safe condition, those who generated positive (vs. negative) thoughts indicated greater intention to choose a salad than chocolate cake (Mpositive=6.24, Mnegative=4.84; $F(1,123)=4.08$, $p < 0.05$), replicating the result of study 1. In out-of-sight condition, however, those who generated negative thoughts indicated greater intention to choose a salad than those who generated positive thoughts (Mpositive=5.22, Mnegative=6.89; $F(1,123)=5.41$, $p < 0.05$), indicating that placing the thoughts into an unsafe location can even reverse the original direction of the thought.

Discussion. Our studies show that a simple behavior of treating thoughts as a material object can change the valence of our own thoughts. This finding indicates the importance of cognitive appraisal of behavior in the process of embodiment.

Facial Feedback Hypothesis Revised: Frequent Smiling Can Reduce Wellbeing

EXTENDED ABSTRACT

Happiness boosts long-term wellbeing, improving thinking, immune health, social engagement, and coping (Lyubomirsky, King, & Diener, 2005). Happiness also boosts immediate wellbeing, because consumers interpret their positive feelings as implying that life is good (Schwarz & Clore, 1983). Nations want to improve wellbeing of their citizens, and most people want, and try, to be happy (Gross, 1998). Researchers believe simple way to increase positive feelings is to adopt a smile-like expression (Ekman & Davidson, 1993; Strack, Martin, & Stepper, 1988), because consumers infer their attitudes from their actions just as an observer might (Bem, 1972; Koriat, Ma'ayan, & Nussinson, 2006), and facial expressions provide feedback to a person regarding how he is feeling (Larsen, Kasimatis, & Frey, 1992).

We posit that the link between facial-feedback from smiling on wellbeing is moderated by consumer's naive theories regarding why they smile. Consumers believe they smile when they are happy (reactively), but also to become happy (proactively), or to mask negative emotion. Depending on which of these beliefs is momentarily or chronically accessible to a person at the time he smiles, the act of smiling may increase or reduce a person's current happiness. Smiling will increase happiness only when a person's accessible theory is that smiling is reactive. When the accessible theory is that smiling is proactive, frequent smiling will reduce happiness. Here, smiling may evoke inferences that one is experiencing negative emotion and feel physiologically unpleasant. Thus, smile-theory and smile-frequency will jointly influence current happiness. As judgments of wellbeing are constructive and assimilate with a person's momentary happiness (Schwarz & Clore, 1983), they are likely to incorporate these experiences of happiness or unhappiness caused by smiling. We tested our premise in three experiments.

Study 1 employed a longitudinal field design (n = 126). Participants completed two short 15-minute surveys exactly two weeks apart. Both surveys were identical. Participants first provided measures of smile-frequency for that day ("I smiled a lot today," "I smiled very frequently today," 1 = strongly disagree, 7 = strongly agree; rsurvey1 = .90, rsurvey2 = .95, ps < .001) and smile-theory (1 = people smile to feel good; 7 = people smile when they feel good), embedded in a series of demographic measures to reduce experimenter demand. They then reported wellbeing on the 5-item Satisfaction with Life Scale ([SWLS], Diener et al. 1985). For survey1 (n = 126), a regression analysis revealed a main effect of smile-frequency, b = .44, SE = .07, t(122) = 6.66, p < .001, and the predicted interaction between smile-theory and smile-frequency, b = .18, SE = .04, t(122) = 4.29, p < .01, $\eta2$ = .24. Among reactive-smile participants (± 1SD), frequent (M = 6.39) compared to infrequent (M = 3.12) smiling resulted in higher wellbeing, b = .54, SE = .17, t(122) = 3.26, p < .01, but among proactive-smile participants, frequent (M = 2.48) compared to infrequent (M = 5.62) smiling resulted in lower wellbeing, b = -.52, SE = .13, t(122) = -4.13, p < .001. As replication, survey2 (n = 108) regression analysis also revealed a main effect of smile-frequency, b = .44, SE = .07, t(104) = 6.01, p < .001, and the predicted interaction between smile-theory and smile-frequency, b = .12, SE = .09, t(104) = 1.32, p = .07, $\eta2$ = .10. Among reactive-smile participants, frequent (M = 5.94) compared to infrequent (M = 4.09) smiling resulted in higher wellbeing, b = .30, SE = .15, t(104) = 1.98, p < .05; among proactive-smile participants, frequent (M = 3.84) compared to infrequent (M = 4.88) smiling resulted in directionally lower wellbeing, b = -.11, SE = .07, t(104) = -1.53, p = .14. Cross-lagged panel analysis showed autocorrelation between wellbeing1 and wellbeing2, r = .45, p < .01, between interaction1 and wellbeing1, r = .18, p < .05, and between interaction2 and wellbeing2, r = .12, p = .07. Establishing our causal directionality, interaction1 predicted wellbeing2, r = .21, p < .05, but wellbeing1 did not predict interaction2, r = .04, ns.

In study 2 (N = 85), we primed smile-theory (by a recall task) and manipulated smile-action (by asking participants to engage in smile-like or not smile-like facial muscular exercises), and then

measured SWLS. An ANOVA on SWLS yielded only an interaction between theory and action, $F(1, 77) = 12.44$, $p = .001$; $\eta2 = .13$. Participants primed with reactive smile-theory reported higher well-being after smile (M = 4.99, SD = 0.95) rather than the non-smile exercise (M = 4.19, SD = 1.26), $F(1, 77) = 4.07$, $p = .04$. In contrast, participants primed with proactive smile-theory reported lower well-being after smile (M = 3.77, SD = 1.40) than non-smile exercise (M = 4.93, SD = 1.23), $F(1, 77) = 9.53$, $p = .003$. Thus, the effect of smile-like facial action on wellbeing was moderated by primed theory, as we predicted.

In study 3 (N = 63) we manipulated smile-frequency (by asking people to smile at one or ten funny ads) and measured smile-theory (same as study 1), then measured spontaneous happiness and SWLS. Regression analysis on SWLS revealed a significant interaction, b = .41, SE = .08, $t(59) = 4.95$, $p < .01$. As predicted, among participants who believe smiling is reactive (reflecting happiness), wellbeing was higher after frequent (M = 5.47) rather than infrequent (M = 4.17) smiling, b = .66, SE = .21, $t(59) = 3.15$, $p < .01$. Among proactive smilers, ironically, frequent smiling resulted in less wellbeing (M = 3.55) than infrequent smiling (M = 5.73), b = -1.10, SE = 0.19, $t(59) = -5.80$, $p < .01$. Happiness followed a similar pattern, and spontaneous happiness mediated the effect of theory × frequency on wellbeing.

As a set, these studies show that smiling increases happiness and in turn wellbeing, but only among reactive smilers. Smile-like action serves as positive affective feedback when interpreted as implying one is happy, but negative affective feedback when interpreted as unhappy. Thus, naïve theories moderate interpreting facial feedback.

Elaborative Thinkers Are More Susceptible to Metaphor-Driven Effects of Heaviness on Judgments of Importance

EXTENDED ABSTRACT

Subtle incidental sensory experiences with metaphoric relevance can affect judgments, including product evaluations (Landau, Meier, & Keefer, 2010). For instance, as suggested by expressions such as "weighty issues," the sensory experience of heaviness affects judgments related to importance. Heaviness, felt from a weighted clipboard, can prompt higher valuations of foreign currencies and judgments of increased importance of procedural justice (Jostmann, Lakens, & Schubert, 2009); it can also lead participants to judge job candidates as more qualified and social issues as more important (Ackerman, Nocera, & Bargh, 2010). That is, incidental sensory experience can activate metaphorically-linked abstract concepts and influence reasoning and evaluations in metaphor-consistent ways (for reviews, see Landau, Meier, & Keefer, 2010; Lee & Schwarz, 2014).

However, the underlying psychological processes are not yet well understood. Some researchers suggested that incidental sensory states affect judgment through heuristic, low thought processes. For example, the experience of physical heaviness may bring associated concepts of importance to mind, which affect all evaluations to which they are applicable (cf. Williams, Huang, & Bargh, 2009). The reported main effects of main effects of weight on judgments of importance are compatible with this perspective (Jostmann et al., 2009; Ackerman et al., 2010; Ijzerman, Padiotis, & Koole, 2013); but potential moderators and boundary conditions have received limited attention. Conversely, other researchers suggested that the influence of heaviness on judgment requires more elaborative reasoning processes. While heaviness may trigger thoughts of importance, those thoughts may need to be consolidated with available information through elaborative reasoning in order to exact an effect on judg-

ment. For instance, Chandler and colleagues showed a moderated weight effect, such that weighted books were judged to be more important and valuable when participants had substantive information that could support a judgment of high importance (Chandler, Reinhard, & Schwarz, 2012), but not otherwise. In their studies, only participants who had actually read the book were influenced by its weight.

These divergent perspectives lead to opposite predictions. If the influence of physical weight on judgments of importance reflects a heuristic process, it should decrease with elaborative thought; conversely, if it reflects an elaborative process, it should increase with elaborative thought. One well established variable that bears on elaborative reasoning is Need for Cognition (NFC), an individual difference variable that captures a person's tendency to engage in, and their enjoyment of, effortful elaborative thought (Cacioppo & Petty, 1982). In persuasion experiments, recipients low in NFC form judgments based on peripheral cues, whereas recipients high in NFC form judgments based on message elaboration (for a review, see Cacioppo, Petty, Feinstein, & Jarvis, 1996). Across numerous studies, low NFC individuals are associated with a tendency to use heuristic processing, while high NFC individuals are associated with a tendency to use more elaborative cognitive processes. As little is known about the mechanisms driving the effects of weight on judgments of importance and value, assessing who is more likely to display such effects could shed light on these mechanisms.

Methods Two-hundred and seventy-seven participants completed the NFC scale and evaluated the importance of an unknown book [as well as how much they were willing to pay (WTP) for two different versions of the book]. The book either did (vs did not) contain a concealed weight to make it considerably heavier. In addition, the book was either handed to participants with the front cover up (offering no substantive information) or with the back cover up, offering snippets from reviews that provided substantive information about the book.

Results Multiple regression analyses revealed a significant 3-way interaction of book weight, supporting information, and NFC on judgments of the importance and value of the book, $\beta = .009$, $t(269) = 2.249$, $p = .025$. This interaction was driven by one group of participants: only high NFC participants who saw supporting information about the book were affected by the book's weight and judged heavier books to be more important and more valuable than light books, $\beta = .198$, $t(269) = 2.36$, $p = .019$. However, weight did not influence the judgments of high NFC participants in the absence of supporting information, $p > .42$; nor did it influence the judgments of low NFC participants, independent of the presence or absence of supporting information, $ps > .22$.

These results are consistent with theories that assume that sensory experiences of metaphorical relevance are integrated into representations of the target through elaborative thought (Chandler et al., 2012). Replicating our earlier findings (Chandler et al., 2012), weight only exerted an influence when participants could draw on substantive information that could warrant a judgment of high importance. Going beyond our earlier work, only individuals who habitually engage in elaborative reasoning considered their sensory experience in forming an importance judgment, provided that they also had supportive information available. Ironically, judging a book by its weight seems to require knowledge about the book and systematic effort in arriving at a judgment. The more intuitively appealing assumption that reliance on a book's weight reflects a heuristic strategy would predict the opposite result: a high impact of weight for low NFC participants who lack substantive information. No weight effect was observed under this condition.

The Interaction Effect of Bitter Taste and Mood on Consumers' Saving Decision

EXTENDED ABSTRACT

Conceptualization A metaphor's meaning is often grounded in physical experience (Barsalou 2008). As a consequence, physical experiences can influence the application of these metaphors in making judgments to which they are relevant. Thus, the experience of physical warmth can lead people to judge a stranger to be personally warm (Williams and Bargh 2008); carrying a heavy shopping bag can influence judgment of importance (Zhang and Li 2012), and experiencing a fishy smell can influence perceptions of an experimenter's deceptiveness (Lee and Schwarz 2012).

We examined the implications of this effect for savings decisions. Harsh physical and social encounters are often characterized as "bitter;" that is, subzero temperatures are "bitter" cold, and impoverished circumstances can give rise to a "bitter" life. We conjectured that experiencing a bitter taste would activate semantic concepts of bitterness that are metaphorically associated with concepts of a "bitter" life and that if these concepts are accessible in memory at the time a saving decision was made, they would influence their saving decision.

We further speculated that mood might moderate the effect of bitter taste on saving behavior. Mood serves as information about not only individuals' reactions to the stimuli they are asked to judge (Schwarz and Clore 1996) but also other aspects of a stimulus situation (Martin, et al. 1993). For example, Wegener, Petty and Smith (1995) found that when participants receive a persuasive message, they often use the affect they are experiencing to infer the validity of their cognitive responses to the message, and this inference determines their acceptance of the message content. Thus, if the message contains strong arguments and stimulates positive thoughts about the position advocated, participants infer that these thoughts are more valid if they are happy than if they are sad and, therefore, are more persuaded by the message in the former case.

We speculated that a similar situation would obtain in the conditions we investigated. That is, suppose participants have tasted bitter drink and so thoughts of a bitter life have been activated at the time they make a decision to save or spend. They might think that these thoughts are more valid, and be more inclined to save, if they are happy than if they are sad. If participants have not tasted bitter drink, however, arguments in favor of spending may be more salient at the time they make their decision, and these arguments may be perceived as more plausible when they are happy than when they are not. Therefore, they may be less inclined to save than they would if they were sad. In short, we expected that tasting bitter drink would increase participants' saving intention if they are happy but would decrease it if they are sad.

Empirical Evidence In study 1, participants first reported their affective state, and then drank either bitter melon water or plain water. Then, after completing an unrelated task, they were told to assume that they had an additional $300 per month in income and to indicate the proportion of this amount that they would like to save. The interaction of mood and taste was significant ($F (1, 42) = 8.39$, $p < .01$). When participants felt happy, they chose to save a greater proportion of the money after tasting bitter melon water ($M = 65.5\%$) than after tasting pure water ($M = 43.5\%$; $F (1, 42) = 4.50$, $p < .05$). When participants felt sad, however, this difference was reversed (49.6% vs. 64.6%, respectively; $F (1, 42) = 4.03$, $p = .05$).

Study 2 was similar except that (a) participants' mood was experimentally induced (by recalling a happy, sad, or neutral experience), and (b) concepts associated with bitterness were activated by using a word construction task. The interaction of mood and primed concepts was significant ($F (2,148) = 4.53$, $p < .05$). Happy participants estimated they would save more when the primed concepts were related to a bitter life than when they were not (70.38% vs. 53.13%, respectively; $F (2,148) = 4.17$, $p < .05$). Sad participants, however, estimated that they would save less in the former condition than in the latter (44.11% vs. 58.65%, respectively; $F (2, 148) = 3.08$, $p < .05$). Finally, control participants' estimates were similar to those of happy participants (60.37% vs. 47.29%, respectively; $F (2,148) = 2.67$, $p = .07$). This could be attributed to the fact that participants in this condition actually felt happy; their reported mood in this condition ($M = 6.08$) was significantly above the scale midpoint of 5 ($t = 34.96$, $p < .001$).

A third study, using Chinese middle-school children as participants confirmed the effect of a bitter taste on actually savings behavior. Specifically, participants who were given ten 1-RMB coins as compensation and told they could save a portion of the money decided to save more money if they had tasted a bitter drink earlier in the study than if they had not (6.10 vs. 3.56, respectively; $F (1,45) = .62$, $p < .01$).

A fourth study confirmed the implications of our findings for actual shopping behavior. Consumers before entering a supermarket were asked to sample either bitter-tasting coffee or pure water. Upon exiting, they were asked to give us a copy of their shopping receipt for pay of RMB 20, and to indicate on the receipt the products that they had not initially intended to buy. Shoppers spent less money if they had tasted black coffee than if they had tasted water (1.54 vs.9.01, respectively; $F (1,58) = 5.20$, $p < .05$). Moreover, they indicated making fewer impulsive (unplanned) purchases in the former condition than the latter (8% vs.20%, respectively; $F(1, 58) = 3.84$, $p < .06$).

In summary, taking bitter taste or priming bitter life concepts can increases the motivation to save money rather than spending it. This effect is greater when participants are happy. However, the evidence that similar effects were evident under control conditions and in situations in which affect was not manipulated suggests that our findings generalize to situations outside the laboratory.

Paper #4: Material Words: How Sharing Material and Experiential Purchases with Others Influences Self-Esteem

Sarah G. Moore, University of Alberta, Canada

SESSION OVERVIEW

People's collected experiences form their life narratives and are intricately intertwined with their social relationships. Many of our social interactions involve sharing personal experiences or learning of others' experiences. For example, people may engage in similar experiences at different points in time, receive an experience from another person as a gift, or document and communicate their experiences to others in the form of photos and word-of-mouth. How do these various forms of sharing affect people, both during the experience and afterwards?

Most relevant research has examined how the co-presence of others affects experiences (Raghunathan and Corfman 2006; Ramanathan and McGill 2007; Caprariello and Reis 2013). There has been much less attention, however, to the broader effects of sharing experiences with others who were not present in the actual consumption experience. The four papers in this session illustrate how various forms of sharing experiences can influence social connections, self-esteem, and enjoyment and memory of experiences themselves.

The first two papers focus on the interpersonal consequences of sharing experiences. Building on work about the greater *personal* satisfaction people derive from experiences versus material goods, they show that experiences can also promote stronger *social* connections. **Kumar, Mann, and Gilovich** investigate how experiential purchases foster kinship with both others who have made similar purchases and people in general. Simply thinking about experiential purchases leads people to desire more social activities and to act more prosocially. **Chan and Mogilner** examine how receiving experiential gifts (compared to material gifts) can make recipients feel closer to the gift giver. These effects operate through the emotions evoked when an experiential gift is consumed, regardless of whether the gift is consumed together with the gift giver.

The final two papers concentrate on the intrapersonal consequences of sharing experiences. **Barasch, Diehl, and Zauberman** demonstrate that simply having the *goal* of sharing one's experience with others while taking pictures (compared to documenting the experience for oneself) can reduce enjoyment during the experience. A sharing goal also results in photos that are perceived as less authentic and enjoyable when people relive the experience. Finally, **Moore**

shows that sharing stories about experiential versus material purchases can differentially affect social dimensions of self-esteem. In particular, sharing about negative experiential and positive material purchases decreases self-esteem, but the use of explanatory language (e.g., because) can reduce the stigma associated with sharing these stories and attenuate these effects.

Individual experience and social interaction are two central elements to human existence. Together, these papers highlight the diverse ways in which these constructs can intersect. All four projects are working papers with at least three studies completed. Given the widespread applicability of the issues discussed, we expect this session to attract researchers interested in experiential versus material consumption, social connection, well-being, word-of-mouth, gift giving, picture-taking, and prosocial behavior. In the spirit of the conference theme "Back to Fun," we hope that the focus on the social aspects of experiences and the diverse approaches to studying this topic will generate a lively and fruitful discussion.

Questioning the "I" in Experience: Experiential Purchases Foster Social Connection

EXTENDED ABSTRACT

Research on experiential and material purchases (that is, money spent on *doing* versus *having*; Van Boven & Gilovich, 2003) has focused on the benefits of experiential consumption in terms of consumer satisfaction and the underlying mechanisms that produce this difference. Here, we present another downstream consequence of spending money on experiences as compared to possessions: fostering social connection. Such effects are important because of the human tendency for the need to belong (Baumeister & Leary, 1995).

In Study 1 (N = 98), we investigated whether consumers feel more connected to someone who has made the same experiential purchase as they have than to someone who has made the same material purchase. While people may feel some kinship with those who make the same purchases they do, we set out to determine whether this was especially true for experiential purchases. Participants listed a significant experiential or material purchase and then thought about another person who had made the same purchase as they had. We then asked how similar they would feel to this person and how much kinship they would feel toward the person initially. As expected, participants reported that they would feel more similar to someone who had made the same experiential purchase as they had, unequal variances $t(82.22) = 3.90$, $p < 0.001$. They also reported that they would feel more initial kinship toward the person who had purchased the same experience, unequal variances $t(86.90) = 3.61$, $p < 0.001$. Knowing that another person has made the same experiential purchase thus appears to have notable social benefits: it creates a level of closeness and kinship that shared material purchases can't match.

In Study 2 (N = 97), we extended these findings in two ways. Instead of having participants think about another person who had made the *same* purchase, they thought of someone who had made a similar, but "upgraded" purchase. We also added another dependent measure, one of longer-term kinship. Again, participants indicated that they would feel more similar to the other person in the experiential condition, $t(95) = 2.47$, $p < 0.02$, and that they would feel more initial kinship toward the other person, $t(95) = 2.03$, $p < 0.05$. Learning about someone who had made a similar, but better experiential purchase resulted in greater feelings of long-term kinship as

well, unequal variances t(87.90) = 2.44, *p* < 0.02. It seems, then, that even when a notable difference between oneself and another person making a similar purchase is made salient, experiential purchases foster more of a sense of social connection than possessions. Knowing that another person has a better version of what you have can be off-putting and can create a sense of social distance. The results of this study, however, indicate that this is less likely to be true when it comes to experiential purchases. When it comes to being "outdone" on a similar experiential purchase, the similarities appear to be more prominent or more important than the differences.

Study 3 (N = 197) examined peoples' more general feelings of connection that are aroused by the types of purchases they make (i.e., not just toward someone who has made a similar purchase). Because we asked about their sense of connection to other people in general, we thought that the predicted effect might be less strong than those documented in the aforementioned studies, and so we doubled our sample size. After participants thought about either experiential or material purchases, they filled out the Social Connectedness Scale (Lee & Robbins, 1995). In line with our hypothesis, participants reported higher levels of social connection when they reflected on their experiential purchases, t(195) = 2.05, *p* < 0.05.

When people feel connected to others, they may want to partake in other social activities and further their sense of connection. After thinking about one type of purchase or the other, participants in Study 4 (N = 80) indicated their relative preference for a variety of activities, some social and some not, adapted from Vohs, Mead, and Goode (2006). Participants were given a series of nine pairs of activities and asked which they would prefer if offered a choice between them. In each pair, one activity was inherently social (e.g. "hanging out at a café with a friend") and the other was not (e.g. "reading a favorite book alone"). Giving consumers an opportunity to think about their experiential purchases made the social activities more appealing, t(78) = 2.07, *p* < 0.05. Because we found a significant difference in purchase price between experiential and material purchases in this study, it is important to note that this difference in preference for social activities remains significant in an ANCOVA controlling for (log-transformed) average purchase price, F(1, 77) = 6.87, *p* = 0.01. While the previous studies showed that consumers feel more connected to others after thinking about their experiential purchases, this experiment demonstrated that there may be behavioral consequences that stem from this feeling. Experiences not only connect us to other people; they also provide a rich store of memories of such connection to draw on and revisit, and these memories may feed the inclination to engage even more in such activities.

By inspiring people to seek out the company of others, experiential purchases are likely to have benefits beyond the purchase itself. But do the secondary benefits of such purchases apply only to the experiencer, or do they flow outward to reach others as well, perhaps causing us to treat others better? In Study 5 (N = 48), participants were asked to recall an experiential or material purchase and then assigned the role of allocator in a dictator game. Previous research (Charness & Gneezy, 2008) has found that as social distance decreases, allocators in the dictator game become more altruistic to receivers and give them a bigger portion of the endowment. As predicted, thinking about an experiential purchase led participants to be more generous thinking about a material purchase, unequal variances t(40.46) = 2.27, *p* < 0.03.

Experiential Gifts Foster Stronger Relationships than Material Gifts

EXTENDED ABSTRACT

Occasions to give gifts tie up each year. From birthdays to religious holidays, Valentine's Day to Father's Day, each occasion is fraught with the question: What to give?! To help inform gift givers of what to give and to gain insight into the interpersonal effects of gifts, this research investigates which type of gift causes recipients to feel closer to their gift giver—material gifts (objects for the recipients to keep) or experiential gifts (events for the recipients to live through)—and why.

People seem more inclined to give material gifts. In a survey we conducted among 219 gift givers, 78% reported having most recently given a gift that was material. Four subsequent experiments testing the effect of gift type on how close gift recipients feel to their gift giver, however, reveal this tendency may be misguided.

In Experiment 1A, gift givers were recruited through a university laboratory and were provided with $10 to spend on a gift for a friend within three days. After identifying their gift recipient, gift givers were randomly assigned to purchase and give an experiential gift they jointly consumed with their recipient (shared experiential gift), an experiential gift not consumed with their recipient (non-shared experiential gift), or a material gift not consumed with their recipient (non-shared material gift). Three days later, recipients described the gift they had received and reported how receiving the gift affected their relationship with their gift giver. Recipients also rated the thoughtfulness of their gift and how much they liked the gift.

Results revealed that people who received either shared or non-shared experiential gifts consequently felt closer to their gift giver than people who received material gifts (*p*s<.05). Furthermore, experiential and material gifts did not differ in thoughtfulness or liking (*p*s>.59), suggesting that these factors do not explain the effect of gift type on closeness.

Experiment 1B extended 1A using a two-part design. We recruited pairs of friends and randomly assigned one friend to be the gift giver and the other to be the recipient. Gift givers were provided with $15 and randomly assigned to purchase either an experiential or material gift over the next three days for their friend to consume on his/her own. Recipients completed an initial survey to measure the strength of their relationship with the gift giver. The following week, recipients completed a follow-up survey in which they described the gift they had received and rated the strength of their relationship with their gift giver, the thoughtfulness of the gift, and how much they liked the gift. Relationship change was measured as the difference between the pre- and post-gift relationship ratings.

Results showed that receiving an experiential gifts made recipients feel closer to their gift giver, compared to receiving a material gift (*t*=2.06, *p*<.05). Gift type was again unrelated to thoughtfulness and liking (*p*s>.11).

Experiment 2 explored the underlying role of emotion in the effect. Participants were randomly assigned to recall a gift they had received in a 2(material vs. experiential) × 2(shared vs. non-shared) between-subjects design. Participants rated the closeness of their relationship both before and after receiving the gift, and the differences between the measures served as our measure of relationship change. Participants also rated how intensely emotional they felt at the moment they felt the most emotional from both receiving and consuming the gift, and identified which emotions they were feeling. Finally, participants rated thoughtfulness and liking.

Results showed that receiving an experiential gift resulted in a greater change in connection than receiving a material gift (*F*=6.83,

p=.009). Moreover, a non-significant main effect of whether the gift was shared (*p*=.72) and a non-significant interaction effect (*p*=.32) suggest that the connecting effect of receiving an experiential gift occurred regardless of whether the recipient consumed the gift with the gift giver. Additional analyses showed that thoughtfulness and liking did not explain the effect of gift type on consumption, nor did the emotion felt during the gift exchange. However, an analysis of the emotions that were felt while consuming the gift revealed that experiential gifts evoked more emotion when consumed than did material gifts (*F*=15.55, p<.001; the effect of sharing and the interaction effect were non-significant, *p*s>.89). Furthermore, mediation analyses showed that the emotions felt during gift consumption mediated the effect of gift type on relationship change (95%*CI*=[.03,.12]).

Experiment 3 tested whether framing a gift of a book as more experiential would make it more connecting. We further tested the underlying role of consumption emotion by manipulating whether recipients thought about the emotion they would feel while consuming the gift. Experiment 3 thus followed a 2(material vs. experiential) × 2(control vs. emotion) between-subjects design. Participants identified a friend and rated their relationship with him/her. They next imagined receiving a book from that friend and wrote about the material or experiential aspects of the book; some participants were further instructed to write about the emotions the book would make them feel. They again rated their relationship with their friend and the difference between the pre- and post-gift measures served as our measure of relationship change.

Results in the control conditions showed that the gift of a book was more connecting when recipients were reminded of the experience of reading the book, rather than its material attributes. Furthermore, in support of the underlying role of emotion, when recipients were led to think about the emotion they would feel while consuming the book, they felt greater connection regardless of gift type framing (*F*=7.60, *p*=.006).

In summary, this paper explores the effect of purchases on connections between people, finding that not all expenditures of money are equally beneficial. Indeed, people's tendency to give material gifts seems to do little to foster the relationship between a gift giver and recipient. Experiential gifts, in contrast, make recipients feel closer to the person who gave them the gift because of the emotion evoked when consuming the gift, regardless of whether the experience is consumed together. Thus, when deciding on a gift for a loved one, an experiential gift promises greater hope of connection.

When Happiness Shared is Happiness Halved: How Taking Photos to Share with Others Hurts Experiences and Memories

EXTENDED ABSTRACT

Picture-taking has become ubiquitous with technological innovation and the availability of camera phones. From eating a meal to watching a concert to skiing a mountain, hardly a situation exists these days that individuals do not feel compelled to document with the snap of a camera. While precise numbers are difficult to obtain, researchers estimate that Americans alone took 53 billion pictures in 2006 and that this number has doubled in the past seven years (National Geographic, 2012).

Consumers have different motivations for taking these pictures. One goal is to document and preserve experiences for themselves, as people gain utility from their memories (e.g., Zauberman, Ratner, & Kim, 2009). Another goal is to document and share experiences with others, as people also gain utility from connecting with others (e.g., Ramanathan & McGill, 2007). Indeed, of the billions of photos that

people take every year, millions of them are shared on social media websites each day (Facebook, 2013). Yet, prior literature has devoted little attention to understanding how one's goal for taking photos might influence their online experience and future memories. We address this question with two lab experiments and one field study.

On the one hand, it is possible that taking photos to share with others will increase enjoyment of the experience and retrospective evaluations. Sharing positive events with others provides both personal and interpersonal benefits (Reis et al., 2010; Lambert et al., 2012), and the ability to share experiences with others partially accounts for why people value experiential goods more than material goods (Caprariello & Reis, 2013). However, while people clearly gain utility from sharing experiences with others, we propose that pursuing this goal comes with a cost. People motivated to share their experience through photos become concerned with impression management and self-presentation (Leary & Kowalski, 1990; Tetlock & Manstead, 1985), which have often been associated with increased anxiety and pressure to make a good impression (Schlenker & Leary, 1982). We propose and find that taking photos to share with others can reduce online enjoyment and immersion in the experience, while also reducing enjoyment of photos themselves by hampering people's ability to fully relive their experiences.

To initially examine how one's goal in taking pictures may affect online experience, we developed a unique computer interface that allows respondents to experience a simulated event in the lab by watching a first-person-perspective video of the event. In the first two studies, participants experienced a simulation of a 4-minute city bus tour. During the simulation, participants were able to take pictures like they would during an actual experience by clicking their mouse.

In **Study 1**, 131 participants from Mechanical Turk were randomly assigned either to take photos of the bus tour so that they could preserve the memories for themselves (self condition) or to take photos so they could share the memories with their friends (share condition). A manipulation check confirmed that participants were more focused on others (versus themselves) in the share condition than the self condition (F(1,129)=6.03, p=.02). Importantly, we found that relative to the self condition, taking photos to share decreased participants' enjoyment (F(1,129)=6.21, p=.01) and immersion in the experience (F(1,129)=7.86, p<.01). Participants in the self condition also reported that their albums were better at capturing their overall tour experience (F(1,131)=5.51, p=.02).

Because Study 1 involved hypothetical sharing, **Study 2** sought to replicate these findings when individuals had to actually share their photos with others. 169 participants were assigned to the same conditions as above, except that in the sharing condition they were instructed to share their photos with a partner in the lab. Confirming the results in Study 1, participants enjoyed the experience less (F(1,167)=3.11, p=.08) and were less immersed (F(1,167)=6.10, p=.01) in the share condition than the self condition. In addition, we found initial evidence for the mechanism underlying these effects: individuals were more anxious when they were taking photos to share (F(1,167)=5.93, p=.02), which mediated the effects on immersion and enjoyment (95% CI=[-.321,-.080]).

In **Study 3**, we extended our findings from the lab into the field and also examined the effects of picture-taking goals on people's subsequent memories and evaluations of their photos. We recruited 107 students to participate in the study before they left for Christmas vacation. Half the participants were instructed to take pictures on Christmas so that they could make an album to post on Facebook, while half the participants were instructed to take pictures so that they could make an album to keep for themselves. Two days after

Christmas, participants were asked to fill out a short questionnaire and create an album based on their assigned goal (Time 1). To allow us to investigate longer-lasting consequences, they also completed an online follow-up survey one month later (Time 2; filled out by 102 out of 107 participants).

Consistent with the anxiety effects found in Study 2, participants in the share condition were more likely to report that they tried to take photos that made them look good at Time 1 ($F(1,105)=5.25$, $p=.02$). Interestingly, when asked to recall their Christmas experience and visualize the situation, participants in the share condition were more likely than those in the self condition to rate that image as being from the perspective of an observer (versus their own perspective) at both Time 1 ($F(1,105)=4.41$, $p=.03$) and Time 2 ($F(1,102)=4.10$, $p=.04$). Moreover, these effects were reflected in the photos people took: participants in the share condition were less able to relive their experience through their photos at Time 1 ($F(1,105)=6.80$, $p=.01$) and enjoyed looking at their photos less at both time points (T1: $F(1,105)=6.79$, $p=.01$; T2: $F(1,102)=4.24$, $p=.04$), compared to those in the self condition.

By demonstrating the impact of picture-taking goals on online experience and subsequent memory, the present research offers novel insights for psychology and consumer research. Given its contributions to literatures in picture-taking, sharing, and memory, we believe this research would be of interest to a wide audience at ACR.

Material Words: How Sharing Material and Experiential Purchases with Others Influences Self-Esteem

EXTENDED ABSTRACT

Consumers share word of mouth (WOM) about purchases, such as buying clothes or watching movies, daily (Carl, 2006). While sharing allows individuals to savor events (Lyubomirsky, Sousa, & Dickerhoof, 2006) and build relationships (Sprecher & Hendrich, 2004), it can also subject them to stigma (Van Boven, Campbell, & Gilovich, 2010). Thus, we examine when sharing has positive or negative consequences for consumers.

Because sharing is inherently social and self-esteem indicates relational value (Leary & Baumeister, 2000), we explore how sharing impacts social state self-esteem—the extent to which individuals feel self-conscious about their public image (Heatherton & Polivy, 1991). In general, self-esteem should be affected when individuals share purchases for which they may be stigmatized (Link & Phelan, 2001). Prior work on *material* (tangible objects) and *experiential* (intangible events) purchases shows that material purchases are stigmatized (Van Boven et al., 2010). Individuals who make material purchases are stereotyped as selfish and are evaluated unfavorably relative to those who make experiential purchases; material purchases are viewed as extrinsically motivated by factors such as status, while experiential purchases are viewed as related to the self and intrinsically motivated by factors such as personal growth and enjoyment; and conversations about material purchases are less enjoyable than conversations about experiential purchases (Caprariello & Reis, 2013; Van Boven et al., 2010).

Due to this stigma, self-esteem may decrease when sharing about material purchases, as individuals may fear being judged. Further, extending prior work, we hypothesize that purchase valence will interact with purchase type (experiential vs. material) to predict changes in self-esteem. Specifically, individuals may not fear judgment for sharing about unenjoyable, disliked material purchases, or enjoyable, liked, and fulfilling experiential purchases (Caprariello & Reis, 2013; Van Boven et al., 2010). Thus, sharing about negative material or positive experiential purchases should not influence self-

esteem. In contrast, individuals may fear judgment for sharing about enjoyable, liked material purchases or unenjoyable, disliked, and unfulfilling experiential purchases (Caprariello & Reis, 2013). Thus, sharing about positive material or negative experiential purchases may decrease self-esteem.

Importantly, we expect the language used while sharing to moderate this effect. Language influences behavior (Patrick & Hagtvedt, 2012), attitudes (Moore, 2012), and emotions (Hart, 2013). One particularly impactful type of language is explaining language (Pennebaker, 1997). Explaining may protect self-esteem because justifying stigmatized purchases should reduce individuals' fear of being judged (Lerner & Tetlock, 1999). Thus, if positive material and negative experiential purchases are not explained when sharing, self-esteem should decrease; however, if these purchases *are* explained when sharing, self-esteem should not decrease. We test these predictions in three studies.

Study 1 examined material purchases. Undergraduates (N = 169) participated in a 2 (audience: salient/not) by 2 (valence: positive/negative) by 3 (writing: control/explain/non-explain) design. They recalled an appropriate purchase (using instructions from Van Boven et al., 2010), and then wrote a review of their purchase. In the audience salient condition, participants were told their review would be shared with another participant. In the not-salient condition, participants were told their review would be stored anonymously. Control participants wrote only one or two words about their purchase, while explain and non-explain participants completed a fill-in-the-blank review (Moore, 2012). In the explain condition, half of the ten sentences contained explaining clauses (e.g., "I would ___ recommend this product to others, because ___."); the non-explain condition had similar sentences without explanation. After writing, participants completed the Social State Self-Esteem Scale (e.g., "I am worried about whether I am regarded as a success or failure," Heatherton & Polivy, 1991) and the short Material Values Scale (Richins, 2004); this was used as a covariate.

A three-way audience x valence x writing interaction predicted self-esteem ($F(2, 156) = 4.03$, $p = .02$). Self-esteem decreased only in the audience salient conditions, and only when individuals wrote about positive material purchases without explaining. Those who did not explain had lower self-esteem ($M = 2.22$) than those in the explain ($M = 2.83$, $F(1, 77) = 6.77$, $p = .01$) and control conditions ($M = 2.79$, $F(1, 77) = 3.77$, $p = .05$), which did not differ ($p = .58$).

Study 2 investigated how self-esteem was influenced by explaining (or not) material and experiential purchases, holding audience salience constant—all participants were informed that their review would be shared. We also measured global self-esteem (Rosenberg, 1965) several weeks prior to the study to use as a covariate. For the study, undergraduates (N = 157) participated in a 2 (type: material/experiential) by 2 (valence: positive/negative) by 3 (writing: control/explain/no explain) between-subjects design. The study proceeded similarly to study 1, except for the type of purchases recalled; state self-esteem and materialism were measured after writing.

Results revealed a type x valence x writing interaction on self-esteem ($F(2, 143) = 3.27$, $p = 0.04$). For positive experiential and negative material purchases, self-esteem was not influenced by writing (ps > .60). However, for negative experiential and positive material purchases, compared to control ($M_{NE} = 3.61$; $M_{PM} = 3.87$), writing without explaining decreased self-esteem ($M_{NE} = 2.85$, $F(1, 142) = 5.37$, $p = .02$; $M_{PM} = 3.36$, $F(1, 142) = 4.28$, $p = .04$), while writing with explaining did not ($M_{NE} = 3.51$, $p = 0.76$; $M_{PM} = 3.82$, $p = 0.85$).

In study 3, undergraduates (N = 91) wrote freehand about positive or negative material or experiential purchases; all were told their writing would be shared. We measured explaining word use (e.g.,

because) using the Linguistic Inquiry and Word Count (LIWC) program (Pennebaker et al., 2007). Negative material purchases were explained (M = 3.57%) more than any other type of purchase (M = 1.19%, $F(1, 89)$ = 16.02, $p < .001$).

While consistent with prior work (Wong & Weiner, 1981), study 3 suggests that consumers do not naturally share WOM in a way that protects their self-esteem. However, studies 1 and 2 demonstrate that if consumers explain their positive material or negative experiential purchases when sharing WOM, they can overcome the negative impact of sharing on their self-esteem.

Rik Pieters, Tilburg University, The Netherlands

SESSION OVERVIEW

Worldwide population is undergoing a significant shift with the increasingly growing proportion of older adults. Thus older consumers are of key interest to academics and practitioners. More work on older consumers is needed, especially at the conceptual level, given the relative paucity of prior research. This session aims to address this deficiency by tackling two overarching questions. While chronological age is obviously a critical variable in investigations of older consumers, what other age-related variables play a mediating role between chronological age and behavior. What are some explanatory variables and moderators to consider in combination with chronological age?

The four papers offer innovative approaches to these questions. The first two papers show the importance of taking into account, in addition to a consumer's current age and abilities, the experience, capabilities and knowledge accumulated over the consumer's lifetime as well as the age at which they were acquired. The third paper demonstrates the need to consider how feel-age in addition to chronological age affect product choice, and further reveals that a consumer's feel-age varies as a function of social context. The fourth paper tackles the ever thorny problem of disentangling the effects of age, cohort, and period. It demonstrates, using the example of materialism, an approach that combines a new statistical method with a sound theoretical approach.

The first paper, **"Golden or Graying? Cognitive Ability And Experience Predict Financial Outcomes Across the Lifespan,"** focuses on the complementary capabilities of fluid intelligence and crystallized intelligence. It shows how older adults may compen-

sate decline in the former with the latter: domain-specific expertise acquired over the lifetime, such as financial literacy. The authors utilize measures of consumer current cognitive ability and accumulated knowledge with real-world financial behaviors in the form of credit report data.

The second paper, **"Brand Memory And Aging: Accounting For Specific Age Reveals Superior Memory For Older Compared to Young Consumers,"** shows how both a consumer's chronological age today and specific age (defined as the consumer's age when a brand was initially launched) affect memory of brands learned over one's lifetime, and how this relationship is mediated by cognitive ability. Compared with young consumers, older consumers have worse memory for recent brands, but equivalent or better memory for brands encountered before age 30. Hence older consumers hold a biased perception of the market.

The third paper, **"Aging And Product Choice: The Effects of Feel-Age And Social Context,"** focuses on older consumers' tendency to feel younger than they actually are. It reveals that this feeling varies as a function of social context, namely of the presence of young versus older people. It then investigates how older consumers choose more youthful products in the presence of young people as a way to feel more at ease.

The fourth paper, **"The Age of Materialism: Age, Period, & Cohort Effects Across the Life Cycle,"** applies a new statistical approach (Multilevel Latent Growth model) to disentangle age, period, and cohort effects. Application to variations in materialism across the life cycle using a panel of 4700 consumers across eight waves reveals that younger and older people are more materialistic, which is partly due to younger birth cohorts being more materialistic. The statistical approach has potentially very broad applications beyond this specific case.

Golden or Graying? Cognitive Ability And Experience Predict Financial Outcomes Across the Lifespan

EXTENDED ABSTRACT

One in five Americans will be over 65-years-old by 2030. This demographic shift will be accompanied by two trends: The first is that people accumulate wealth up to retirement and subsequently face decisions about how to spend that wealth while guarding against the possibility of running out of money. Moreover, as companies shift from defined benefit retirement plans (pensions) to defined contribution plans (e.g., 401(k)s), individuals face an increasing number of important and often complex financial choices later in life.

The second age-related trend is one of the most replicable and sizeable in psychology: the brain slows with age. Studies have shown that *fluid intelligence* (G_f)—the set of abilities related to generating, transforming, and manipulating novel information—falls by nearly two standard deviations from age 20 to 70 (Salthouse 2010; Schaie 1993). Given mounting evidence that cognitive ability is a key determinant of decision-making (Agarwal et al. 2010; Agarwal and Mazumder 2013; Burks et al. 2009; Mani et al. 2013; McArdle, Smith, and Willis 2011), age-related deterioration of G_f raises the specter that people with major responsibility for financial decisions may be increasingly unable to make them. Fortunately, declining G_f is accompanied by increasing *crystallized intelligence* (G_c) (Carroll 1993;

Cattell 1987), i.e., the accumulation of knowledge and experience that increases with age into the 60s and plateaus thereafter (Horn and Cattell 1967; Li et al. 2004; Salthouse 2004, 2010). G_c may therefore represent a kind of intellectual capital that may circumvent declining G_f, producing sharp-minded octogenarians.

Importantly, the effect of age on decision quality also depends on the *relative impact* of the two types of intelligence required for the decision. Deficits in G_f might be compensated for only in situations in which the decisions can rely on the accumulated G_c. If G_c is a more important determinant of decision performance than G_f, we might even expect older adults to perform better. The opposite would be true for tasks requiring more G_f. For decisions made equally well using either or both pathways, we may see no net age effect on decision quality.

We examine whether this interaction between G_f and G_c—which we term *Complementary Capabilities* (Li et al. 2013)—affects the ability to make good financial decisions. We use a unique data set that combines extensive measurements of cognitive ability and economic phenotypes (*i.e.*, risk, loss, and time preferences) with field observations of those same individuals' economic performance.

Our cognitive data comes from a four-part study in which 478 U.S. residents between 18 and 86 completed a battery of cognitive, decision-making, and demographic measures. We obtained credit report data for these participants from a major credit bureau. Maintaining high credit scores reflects sustained ability to make good financial decisions and brings substantial benefits increased likelihood of obtaining loans at lower interest rates. To the best of our knowledge, this study is the first to combine credit report data with multiple standard measures of G_f, G_c, and economic phenotype assessments.

We conducted all analyses using structural equation modeling but present, for simplicity, the results of linear regressions using the factor scores from the SEM. We conducted multiple regressions of credit score on age and other demographic variables (Model 1), cognitive ability (Model 2), and a number of other control variables.

Model 1 shows that credit scores increase by an average of 13 points per decade of age, comparable to the effect of an additional year of education or a doubling of income. Model 2 verifies the positive relationship between credit scores and G_f but suggests that domain-general G_c is unrelated to financial decision-making ability.

We replaced the general G_c measures with a domain-specific measure of financial G_c in Model 3 and all subsequent analyses, specifically, *financial literacy (G_{c-FL})*, or the ability to understand financial information and decisions (Lusardi and Mitchell 2007). Model 3 shows that even after controlling for demographics, credit scores positively relate to G_f and G_{c-FL}. One standard deviation increase in G_f (roughly equivalent to 15 points of IQ) corresponds to a credit score increase of 18 points, whereas one standard deviation of G_{c-FL} corresponds to an increase of 66 points. In addition, the reduced age coefficient in Model 3 suggests that G_f and G_{c-FL} partly explain the effect of chronological age on credit scores.

Model 4 controls for financial experience as self-reported on 20 different financial instruments (e.g., credit cards, mortgages, mutual funds, etc.). The fact that the effect of G_{c-FL} remains significant suggests that good financial decisions require understanding financial products, not just experience using them.

We also measured individual differences in risk, loss, and time preferences using state-of-the-art adaptive measurement tasks (Toubia et al. 2013). Model 5 adds model estimates for these preferences as covariates in Model 3. Consistent with recent findings (Meier and Sprenger 2012), credit scores were higher for people with more patient time preferences. Importantly, the effect of G_f is no longer significant after controlling for time preference, consistent with a posi-

tive relationship between G_f and patient time preferences (Dohmen et al. 2010; Li et al. 2013). That is, part of the reason that people with higher G_f have higher credit scores is that they exhibit more patience in financial decisions.

Finally, we control for other important psychological factors known to influence a wide range of behaviors. Model 6 controls for the DOSPERT risk-taking scale (Weber, Blais, and Betz 2002), which has been shown to correlate with many real-world risk-taking behaviors (Brown and Braver 2007; Harrison et al. 2005; Markiewicz and Weber 2013). Model 7 controls for Big Five personality measures (Digman 1990). Both Models 6 and 7 find similar results for the effects G_f and G_{c-FL} even after controlling for these other important psychological variables.

In summary, decreasing fluid intelligence does not spell doom for older adults' financial decision-making. Instead, their improved crystallized intelligence, particularly in the financial domain, seems to provide an alternative pathway to making good financial decisions. These complementary pathways cannot be explained by other demographic differences, financial experience, economic phenotypes, or personality variables.

Brand Memory and Aging: Accounting For Specific Age Reveals Superior Memory For Older Compared to Young Consumers

EXTENDED ABSTRACT

Chronological age has a major and complex effect on the brands that a consumer knows (i.e., recognizes) and those that a consumer spontaneously recalls. These two forms of brand memory are important determinants of the composition of consideration sets, whether consumers engage in memory-based choice or stimulus-based choice. Building on previous experimental research, the present paper investigates memory for real-world brands (radio stations) that older consumers have learned about over the course of their lives.

We examine the impact of chronological age at two different times: the consumer's *age today* and the consumer's "*specific age*" relative to a brand (defined as one's age when the brand was first launched in the marketplace). Our hypotheses rely on previous research regarding age-related impairments in both encoding and retrieval processes, such as in spontaneous recall (Park et al. 2002); poorer lexical knowledge by older people of "contemporary" words compared with their knowledge of "dated" words (Worden and Sherman-Brown 1983); and declining memory of autobiographical events that occurred after the age of 30 years (Janssen, Chessa, and Murre 2005). Although our present work focuses on cognitive explanations, we acknowledge the potential effect of affective factors demonstrated in previous research that older people like older brands more (Holbrook and Schindler 1994). We do so by controlling for the differential liking of older brands and report its significant impact in many of our analyses.

Age today is important because it affects the probability that consumers spontaneously recall brands they know (i.e., recognition in an aided brand recall task). On the basis of the age-related decline in cognitive ability, we hypothesize that (H_1), compared to young consumers, older consumers are less likely to spontaneously recall the brands they know, and that (H_2), among the brands they know, older consumers are more likely to recall spontaneously those that were introduced when they were younger. Consistent with H_1, older consumers recall a smaller percentage of the stations they know. But the support for H_2 is so strong that it leads to a result that stands in contrast to H_1, depending on the age of the brand. Compared with young consumers, older consumers are *less* likely to spontaneously

recall the recent radio stations they know, but *more* likely to sponta-neously recall old radio stations they know. Thus, empirical support for H₁ when analyzing overall brand recall does not seem to apply to recall of old brands for which older consumers do better than young consumers. This result challenges the common view that older people always exhibit poorer performance on memory tasks.

Regarding the underlying process, we hypothesize (H_3) that cognitive ability today (speed of treatment) mediates the impact of age on spontaneous recall. This hypothesis holds for recent stations but not for old stations. We find no impact of cognitive decline in this latter case which constitutes another counterintuitive result.

Specific age for a given brand is important because it deter-mines the probability of knowing that brand today (assessed via recognition). We hypothesize (H_{4a}) that recognition should be high-est among consumers who were in their 20s when the brand was launched, whereas (H_{4b}) among consumers in their 30s or older at launch time, the probability of knowing the brand today should de-crease monotonically with their specific age. The results are mixed. First, for 6 of the 20 leading stations, there is no impact of specific age on current knowledge. These stations (5 old, 1 recent) include 4 of the 5 leading stations, known by almost everyone (< 97.6%). Here, older listeners perform as well as younger ones. Second, for the other 14 stations, we always obtain a strong decline of current knowledge for high values of specific age, with typically low knowl-edge for a specific age of 60 years. Recent stations targeting older listeners are no exceptions in this regard.

We further hypothesize that the total numbers of known brands (H_{5a}) and spontaneously recalled brands (H_{5b}) should decrease with a consumer's age today, and that the average age of known brands (H_{6a}) and spontaneously recalled brands (H_{6b}) should increase with consumer's age today. Because we found such notable differences between old and recent stations in our previous analyses, we as-sessed their knowledge and recall separately, and again, find mixed results. Both H_{5a} and H_{5b} received support with respect to recent sta-tions: Knowledge and spontaneous recall were worse among older respondents. However, these hypotheses are found not to hold for old stations, for which, compared with young consumers, older consum-ers know *more* and exhibit *better* spontaneously recall. Finally, we confirm that the average age of known stations (H_{6a}) and spontane-ously recalled stations (H_{6b}) increase with consumer age today.

In summary, a consumer's age significantly affects the set of brands the consumer knows, as well as the set of brands he or she recalls spontaneously, in four ways. Older consumers know more old stations and fewer recent stations. Among the stations they know, they are more likely to spontaneously recall old stations and less likely to recall recent stations. These four effects converge to show that older consumers know and recall spontaneously fewer brands and older brands. They, in turn, develop a restricted and dated view of the market, in terms of both knowledge and spontaneous recall. This produces more limited consideration sets and choices for older consumers compared to their younger counterparts. At the same time, our results serve to challenge the intuitive notion of a general decline of brand memory with age. Although older consumers, com-pared to young consumers, do have poorer memory for brands that are recently introduced as would be expected, they exhibit equiva-lent or sometimes better memory for brands that were encountered at low specific ages (i.e, when they were younger than 30).

Aging And Product Choice: The Effects of Feel-Age And Social Context

EXTENDED ABSTRACT

The increasing aging of worldwide population is an important trend for marketers. Older consumers represent a market segment that is of interest to both practitioners and academic scholars (Gui-do 2014; Yoon and Cole 2008; Yoon, Cole, and Lee 2009). Prior research has shown that older people systematically state they feel younger than they actually are (Barak 1987; Sherman, Schiffman, and Mathur 2001), and that this tendency may vary across contexts (Guido, Amatulli, and Peluso 2014). In the present paper, we seek to understand how the social context influences the tendency by older consumers to report a feel-age (i.e., the age one feels) that is lower than their chronological age. In three studies, we show that this ten-dency is magnified by the presence of young people in social con-texts, and investigate how older consumers choose more contempo-rary versus traditional products as a way to feel greater ease in such social contexts.

Study 1 tested whether the tendency by older consumers to re-port a feel-age lower than their chronological one increases when they are exposed to a young social cue rather than an old one. Eighty-six consumers aged 65 and over were intercepted close to shopping sites and randomly assigned to one of two conditions: young or old social cues. The interviewers who were blind to the study hypotheses served as social cues. Respondents in the young social cue condition were interviewed by a young interviewer, whereas those in the old social cue condition were interviewed by an older interviewer. After answering some filler questions, participants reported the age they felt at that moment and their actual date of birth.

The tendency by older consumers to state a feel-age different from their chronological age was computed as a Youth Age (YA) index which is the difference between the chronological age of re-spondents and their stated feel-age (Barak 1987). As expected, par-ticipants in the young social cue condition reported a higher YA (M = 15.90) than those in the old social cue condition (M = 7.87), p = .008.

Study 2 investigated the mechanism that might drive this ten-dency. Building on prior research (Kawakami et al. 2012; Mead et al. 2011), we theorized that being exposed to a social context perceived as chronologically distant from the self may cause older consumers not to feel at ease in that context. Thus, older consumers should feel less in harmony with a context in which other people are young. Such a lower sense of harmony, in turn, might cause older consumers to adapt by reducing the perceived distance from the young people in their context. We predicted that stating a feel-age that is lower than the chronological age is a means by which older consumers adapt the self to fit with others who are young. Thus, older consumers' sense of harmony should mediate the effect of social cue on their tenden-cy to state they feel younger (i.e., YA). Two hundred twenty-seven older consumers participated in a field study. Respondents received a questionnaire by an interviewer, who did not interact with them, close to real shopping sites typically attended by either young or older people (e.g., disco-pubs vs. senior recreation centers). Respon-dents first reported their feel-age and indicated how they perceived their context (1 = most of the people around me are old, 7 = most of the people around me are young). Then, respondents reported their sense of harmony captured via three items (e.g., "I feel at ease with people around me"; 1 = strongly disagree, 7 = strongly agree; α = .61), and their date of birth. After computing YA as in Study 1, we tested our prediction in a simple mediation model. We found a nega-tive effect of social context on sense of harmony (p < .001), a nega-tive effect of sense of harmony on youth age (p = .001), and an effect

of social context on the youth age index that became non-significant when sense of harmony was included in the model. The indirect effect of social context on youth age was positive and significant ($b = .35$, $p < .05$), thus confirming our prediction.

Study 3 tested whether being exposed to young people may lead older consumers to adapt their selves by choosing contemporary rather than traditional products. The study was designed as a 2 (respondent's age: young vs. old) × 2 (social cue: young vs. old) between-subjects experiment. Four hundred participants, both young and older consumers, were first exposed to a picture displayed either a pair of young or a pair of old people, which served as the social cue. Participants were then asked to choose an option across four different choice sets. Each choice set contained a contemporary and a traditional version of a same product. The individual tendency to prefer contemporary options was captured by the percentage of times these options were chosen across the four choice sets, which ranged from 0% (the contemporary option was never chosen) to 100% (the contemporary option was always chosen), and served as dependent variable in the analysis. We found a significant interaction between respondent's age and social cue ($p = .005$). Contrasts revealed that the tendency by old respondents to prefer contemporary options was higher when they were exposed to a young ($M = 41.55\%$) rather than an old social cue ($M = 27.91\%$), $p = .001$. The tendency by young respondents to prefer contemporary options did not vary as a function of social cue.

This present research advances our understanding of how the social context affects older consumers' tendency to state they feel younger, and elucidates the underlying processes that affect their choice behavior. Results suggest that exposing older consumers to young social cues might prompt them to choose more youth-oriented options.

The Age of Materialism: Age, Period, & Cohort Effects Across the Life Cycle

EXTENDED ABSTRACT

Do consumers become less materialistic when they grow older or do they actually become more materialistic? Likewise, are older birth cohorts of consumers, such as the Baby Boomers (born between 1946 and 1964), less materialistic than younger birth cohorts, such as Generation X (born between 1965 and 1981), or are they more materialistic? And finally, does the current period of global economic downturn prompt consumers to become more or less materialistic? These questions deal with three fundamental influences on consumers during their life cycle, namely, their age, birth cohort, and the period they live in.

The answers to these questions are of vital importance to consumer behavior theory and to public policy, because modern societies are rapidly aging, birth cohorts such as the Baby Boomers are retiring, and consumers face the challenges of a major economic downturn and restructuring period (Cole et al. 2008; Inglehart 2008; Yoon, Cole, and Lee 2009). The questions are even more pressing because materialism has been associated with a host of negative well-being and health implications, including excessive substance abuse, overeating, loneliness, depression, and even premature death (Burroughs and Rindfleisch 2002; Pieters 2013). Thus, the question is whether or not we are witnessing "The Age of Materialism," and how we know. There is surprisingly little research on the influence of age, period, and cohort (APC) in general, and in particular in consumer behavior (Cole et al. 2008). This is partly due to the initial theorizing, the challenges of collecting appropriate data, and the methodological tasks of identifying age, period and cohort effects from the data. To

unequivocally establish APC effects, the same consumers --from different birth cohorts and across different periods-- would need to be followed from birth to death. This would mean tracking thousands of consumers across a few hundred years, which is longer than the average academic tenure clock. Prior materialism research mostly had to rely on cross-sectional surveys and included age as a control variable for other factors of interest (e.g. Burroughs and Rindfleisch 2002; Chaplin and Roedder John 2007; Richins and Dawson 1992). The rare longitudinal studies covered only brief periods of just 14 months (Moschis and Moore 1982) or did not examine age, period and cohort effects (Pieters 2013). Age, period, and cohort effects cannot be disentangled without the appropriate theory, data, and model. This holds, for instance, the danger of inferring that aging consumers become less materialistic as a whole, while this is—in fact—due to certain birth cohorts getting to the older life stage, as detailed below.

The present research aims to contribute to closing the knowledge gap about age, period, and cohort effects on consumer materialism. First, it extends the Motivational Theory of Life-Span Development (Heckhausen, Wrosch, and Schulz 2010) to account for and predict the influence that age, period and cohort have on materialistic values across the life cycle. Second, it estimates a Multilevel Latent Growth model that deals with the well-known limitations of APC analysis (Yang and Land 2013; Yoon et al. 2009), by identifying the separate main and interactive effects of age, period, and cohort. Recall, that in cross-sectional designs where people of different ages are observed at one point in time, age and cohort effects are confounded (Miyazaki and Raudenbush 2000). In data from multiple time periods for the same age group, period and cohort effects are confounded. In additive statistical models, each of the factors is completely defined by the other two factors (Cohort = Period – Age), which is referred to as the APC identification problem (Mason and Fienberg 1985). As a result, traditional data and regression models cannot provide a unique solution to APC models. The methodology implemented here solves this.

Using longitudinal data (2005-2013) from a representative Dutch sample (over 4700 participants) covering a broad age span (16-90 years at the start of the study), this study employs a Multilevel Latent Growth model to disentangle the effects of age, period and cohort on materialism across the life cycle. Table 1 provides summary descriptives. Individual change in materialism over time is a function of age and period. Since the economic downturn might not influence people from all ages in the same way, the model also includes an Age x Period interaction effect. Cohort effects are captured by cohort-specific intercepts. Models are estimated for overall materialism, but also for the three subtypes of materialism: acquisition centrality, possession-defined success, and acquisition as the pursuit of happiness (Richins and Dawson 1992).

The findings reveal a U-shaped relationship between age and overall materialism, with the lowest levels of materialism around the age of 62, and higher levels before and after that age. In addition, the most recent birth cohorts (born after 1980) have higher levels of materialism. The influence of the current economic downturn on materialistic values depends on age. Whereas older people's materialism declines, younger people's materialism increases.

The U-shaped relationship between materialism and age was found for all three materialism subtypes. However, age differences in acquisition centrality and acquisition as the pursuit of happiness become insignificant after controlling for cohort effects. The observed age differences are due to the youngest birth cohorts (born after 1970 and 1975) being most materialistic. Such cohort effects are not observed for possession-defined success. The interaction effect between age and period also differs across the subtypes. For

instance, the economic downturn increases acquisition as the pursuit of happiness among both younger and older people.

Using a Multilevel Latent Growth model, this study sheds light on the effects of age, period and cohort on materialism. It finds that age differences in materialism exist but are overestimated if cohort effects are not controlled for. The relationship between materialism and age is U-shaped and driven by the subtype possession-defined success. Age differences in acquisition centrality and acquisition as the pursuit of happiness are driven by cohort effects. The influence of the economic downturn on materialism depends on one's age. These findings point to the importance of disentangling age, period and cohort effects in studying materialism and consumer behavior.

SESSION OVERVIEW

In an era of direct-to-consumer advertising, widespread Internet-based health information, and heavy reliance on self-care, consumers must take multiple steps in navigating their way toward optimal health decisions. A typical consumer investigates disease and symptom information, processes different types of health appeals, and purchases various preventive health goods. Further, if a disease becomes more serious, consumers must even make decisions regarding different types of health providers. As such, this high-stakes domain involves multiple factors that may influence each decision making stage.

Together, the papers in this special session examine four critical factors (categorization, fit with a health message, ownership, and hospital record framing) that play a role in hindering or fostering important health-related decisions such as health and risk assessment, prevention of diseases, and choice of health provider. Understanding these factors is at the root of helping consumers make normatively appropriate decisions regarding their health.

The first paper by Longoni and Menon examines the interplay of categorization-based biases and self-protection motives on health perceptions. Four studies illustrate that the mere presence (vs. absence) of a one-word label biases symptom reporting, perceived symptom intensity, and overall health risk assessment. However, decreased defensiveness when processing health information eliminates such bias.

Building on this theme of considering the role of small changes to health information in shaping health decision making, the second paper by Samper, Luce, and Purohit presents a strategy to assist consumers in overcoming feelings of low control over one's health outcomes, a typical barrier in disease prevention. Fostering a match between the focus of a health message (self- vs. other-focus) and consumers' worldviews of control (high vs. low) is associated with greater preventive behaviors.

Moving along the decision making chain to examining purchase of preventive goods, Yan and Gao examine how owning a preventive good can influence risk estimates. These studies show that merely owning a preventive product (e.g., an anti-cavity toothpaste) leads consumers to estimate the associated risk as more likely and more harmful.

Finally, the fourth paper by Jung and Kahn explores the factors that affect consumer choice of health providers. Hospital choice is influenced by data on hospital safety records, both in terms of framing (whether the hospital is categorized by mortality or survival rates), and illustration format (whether the data are animated pictographs or boxplots).

Overall, this special session illuminates key aspects of how consumers make decisions about their health, providing theoretical insights and practical applications to improve consumer decision-making in this domain. Together, these papers raise and answer interesting questions such as: What factors contribute to forming health perceptions and how can we aid accurate risk assessment? What kind of health information is best suited to engage different consumer segments? How can policy makers ensure that the right information is presented in the right way? We expect this special session to attract a wide ACR audience, in particular consumer researchers in risk assessment, health, context effects, attitudes and intentions.

Motivated Hypochondriacs: Disease Labels Shape Health Perception

EXTENDED ABSTRACT

This research looks at how disease labels might fundamentally alter health perceptions. We propose that disease labels, much like categories, lack precise and discrete membership boundaries: for a stimulus (i.e., a constellation of somatic and affective sensations at a certain point in time) to be assigned to a category (i.e., a certain illness), not all features (i.e., symptoms) need be present. In other words, symptom matching, much like feature matching, should be a flexible process of interpretation rather than exact matching. This results in a certain degree of latitude when attending to, remembering, and attributing somatic and affective states, giving rise to biases in symptom reporting and thereby affecting health perceptions. Furthermore, such disease labeling effect is susceptible to self-serving biases, whereby inaccuracies in risk estimates reflect the interaction of categorization-based errors with defensive mechanisms.

In a series of four studies, we show the following: (a) Disease labels alter symptom reporting and bias health risk estimates; (b) The direction of this bias reflects a self-protection motive: a label signaling (or interpreted as signaling) a mild ailment leads to greater symptom reporting and higher risk estimates compared to a label signaling (or interpreted as signaling) a severe ailment; (c) Reducing defensiveness eliminates this bias; (d) Perceived disease threat partially mediates the effect; (e) Disease labels do not affect risk estimates made for the general population (i.e., base-rates) or for individuals matched for age and gender (further corroborating the motivational nature of the bias); and (f) This bias holds when controlling for incidental affect, well-being, life satisfaction, and general health perception.

In Study 1, participants were handed a survey ostensibly assessing the wellness of the university community. Although all versions of the survey described the same medical condition,

the disease was labeled as Seasonality, Mild Seasonality, Severe Seasonality, or was not labeled. Participants were asked to report (a) if in the previous month they had experienced any symptoms of the disease, and if so which ones, (b) how intensely they had experienced these symptoms, and (c) risk estimates (i.e., likelihood of self-diagnosis and likelihood of contraction) for self and for another person matched for age and gender. As expected, the presence (vs. absence) of a label was associated with higher symptom recognition, higher perceived symptom intensity, and greater risk estimates. Perceived disease severity moderated the effect: symptom reporting, symptom intensity, and risk estimates were higher if the label signaled (or was interpreted as signaling) a mild (vs. severe) ailment (as measured by perceived severity ratings). Finally, labels affected risk estimates for the self but not for others. These effects held when controlling for incidental affect, well-being, life satisfaction, and general health perceptions.

In Study 2 and 3 we sought to better understand the phenomenon and identify boundary conditions. We hypothesized that the biasing effect of disease labels on health perception is due to defensive motives. If so, the effect should disappear when defensiveness is reduced, either because the person affirms alternative self-resources (Study 2), or because one's sense of perceived control is temporarily shaken (Study 3).

Building on self-affirmation theory (Steele, 1988) and on the role of self-affirmation in reducing perceived invulnerability to health risks (e.g., Sherman, Nelson and Steele 2000), in Study 2 participants were first either allowed to affirm themselves in an important domain or they were not allowed to do so. Participants were then handed a survey on the wellness of the university community containing a description of a medical condition that was either labeled or not labeled. To measure risk estimates, participants rated the likelihood they, as well as an average person of their same age and gender, would contract the disease. As predicted, defensiveness moderated the effect of labels on risk estimates, with the direction of the bias determined by participants' perception of disease severity. When participants did not engage in self-affirmation, risk estimates were biased by the presence of a label. However, when participants' defensiveness was reduced (because they engaged in self-affirmation), risk estimates were no longer biased by the presence of a label. Neither self-affirmation nor label affected risk estimates for another person, further corroborating the notion that the phenomenon reflects a self-protection bias.

Study 3 builds on research showing how high perceived control is associated with greater defensiveness and perceptions of invulnerability to negative events (e.g., DeJoy 1989; Harris 1996; Hoorens and Buunk 1993). We reasoned that we could reduce defensiveness and eliminate the biasing effect of labels by inducing perceptions of *low* control. Participants were first asked to recall and vividly describe an instance in which they felt they had high (vs. low) control, and then handed the same health survey used in Study 2, which contained the label (vs. no label) manipulation and the critical measures of risk. As expected, risk estimates of low-control participants were not biased by the presence of a label, presumably because the induction of low control tempered defensiveness; risk estimates were instead biased by the presence of a label when participants recalled an instance of high perceived control .The direction of the bias was once again determined by participants' perception of disease severity, and the effect did not apply to risk estimates for others.

Study 4 brings together the previous three studies to gain a better understanding of the process behind the phenomenon. We first manipulated the factor self-affirmation as in Study 2, and then

manipulated the factor label. The wellness survey contained measures of risk estimates and an expanded web of measures of perceived disease threat. Bootstrapping analyses revealed that perceived disease threat partially mediated the relationship between label and risk estimates, and defensiveness moderated the relationship between perceived disease threat and risk estimates.

This research is important from both a theoretical and applied perspective. Theoretically, this research elaborates on how health perceptions are formed, and presents a novel effect based on the interplay of categorization and defensive processes. From an applied perspective, this research has substantive implications for social welfare, as both preventive and care-seeking behaviors heavily rely on self-assessment.

Sleeping with One is Sleeping with Many: How Shifts in the Salience of Others' Behavior can Improve Contagious Disease Prevention

EXTENDED ABSTRACT

Low perceived control over one's health outcomes, or external Health Locus of Control (HLOC) (Wallston et al. 1976a), is associated with poorer health behaviors and outcomes, such as reduced interest in health information (Quadrel and Lau 1989) or prevention behaviors (Morrill et al. 1996). While people with more internal HLOC feel they have high control over their health, more external individuals believe that their health outcomes are a result of outside factors such as chance, God, or external authorities, and as such, feel less compelled to perform adaptive health behaviors.

Though the belief that others determine one's health is often detrimental, it may be positively leveraged when external others do, in fact, impact health outcomes. In this research, we argue that contagious disease offers such a context, and show that manipulating the focus of a health appeal to match individual worldviews of control over health can improve persuasion. Specifically, we find that individuals who feel high control over their health (health internals) increase their prevention intentions with self-focused messages, while individuals who feel less control over their health (health externals) increase these intentions with other-focused messages. We suggest that this is driven by a beneficial effect of compatibility: a self-focused message emphasizes personal control, which is easier to process for health internals, while an other-focused message emphasizes a lack of control, which is easier to process for health externals. Importantly, this is only true with contagious diseases; with noncontagious disease, this compatibility effect disappears as others have a much weaker role in the likelihood that one will be affected by disease.

In Study 1, we manipulated the message recipient's processing focus with mortality salience and control (dental pain) primes. The reminder of one's mortality has been shown to lead to an avoidance of self-focus (Arndt et al. 1998), and is often elicited in medical contexts (e.g., physician's offices, clinics, etc.). Participants in this 2 (prime: mortality salience vs. control) x HLOC (measured) experiment completed the HLOC scale (Wallston et al. 1976a) and were primed with mortality salience or dental pain. They then read a passage about HIV and rated their intentions to engage in future HIV prevention. Results revealed a significant prime x HLOC interaction: under the self-focused control prime, more internal HLOC increased intentions to engage in HIV prevention, while under the other-focused mortality prime, more external HLOC marginally increased intentions to engage in HIV prevention. Thus, we see compatibility between internal beliefs and self-focus and external beliefs and other-focus.

In Study 2, we directly examined the role of self vs. other focus in a 2 (referent: self vs. other) x HLOC (measured) experiment. Participants completed the HLOC measure and read information on HIV. Prior to reading this information, participants were asked to think about how HIV affected them (self-focused condition) or how it affected the average individual (other-focused condition). We chose this "average individual" perspective to ensure that participants focused on an anonymous individual that was neither close nor individuated (Raghubir and Menon 1998). We again took measures of disease prevention as well as message processability measures of ease of understanding. Results revealed a significant referent x HLOC interaction, such that health internals were more likely to engage in vigilance behaviors under self-focus, while health externals were more likely to engage in vigilance behaviors under other-focus, replicating Study 1. Examination of message processability also revealed a significant interaction. A bootstrapping mediation analysis revealed that message processability mediated the effects of HLOC on HIV prevention.

In Study 3, to further generalize these effects, we manipulated instead of measured HLOC, extended to a new disease context and used a public service ad to manipulate the referent. We used the threat of MERS (Middle East Respiratory Syndrome), an airborne disease that had broken out in Saudi Arabia and spread to European countries by plane. In this 2 (HLOC: internal vs. external) x 2 (referent: self vs. other) experiment, we manipulated HLOC by having participants read a passage about the controllable (internal) vs. uncontrollable (external) risks of air travel and then showed a MERS public service ad that emphasized the risk of MERS for either the self or the average person. After viewing the ad, participants rated their likelihood of engaging in air travel disease prevention behaviors (e.g., judiciously using hand sanitizer, wearing a face mask). Results revealed a significant HLOC x referent interaction on prevention whereby as before, under self focus, the internal control prime lead to increased prevention while under other focus, the external control prime did so.

Study 4 examined whether the positive effect observed with other-referencing for health externals was limited to contagious disease contexts. We only examined other (average individual) focus and manipulated contagion by presenting female participants with information about obesity described as contagious or noncontagious. This resulted in a 2 (contagion: contagious vs. noncontagious, manipulated) x 2 (Health Locus of Control: internal vs. external) design. HLOC was manipulated through a passage emphasizing the role of healthy living (internal, high control) vs. genetic factors (external, low control) in determining one's health outcomes. Analyses revealed a significant contagion x HLOC interaction on prevention. As in Study 2, when obesity was described as contagious with an other-focus, external HLOC increased disease vigilance. However, when obesity was described as noncontagious with this other-focus, external HLOC was no longer beneficial. These results replicate prior external control /other-focus compatibility effects with contagious disease, yet show that these effects do not hold when a disease is noncontagious.

In sum, we show that message compatibility effects exist between perceived control over health and the message referent to improve disease prevention. In demonstrating this, we identify a way to overcome the obstacle of external/low control individuals disengaging from their health. We also show that the benefits of message compatibility can be achieved with the subtle manipulation of other-focus in a contagious disease context and suggest that this is driven by ease of processing.

Having More But Not Feeling Better: The Effects of Merely Owning Preventive Goods on Risk Perceptions

EXTENDED ABSTRACT

Earlier literature has demonstrated the mere ownership effect where individuals evaluate an object more favorably after owning it (Beggan and Allison 1997). In some instances people acquire the products intentionally, whereas the effect is more intriguing in other circumstances where the ownership is arbitrary such as being induced by random assignment in an experiment. This mere ownership effect is often interpreted as a consequence of motivated reasoning (Festinger 1957; Kunda 1990; McGuire and McGuire 1991; Thaler 1980).

Research on mere ownership effect has been exclusively focused on the effects of mere ownership on product-related consequences such as evaluation (Beggan 1992; Strahilevitz and Loewenstein 1998), choice (Sen and Johnson 1997), pricing (Kahneman et al. 1990; Thaler 1980), and so forth. These findings could be summarized as "sweet lemon" effects. The current research, however, shifts the attention away from the lemon itself to explore whether merely owning preventive goods can influence people's risk perceptions. Preventive goods here refer to products that prevent negative outcomes from happening or reduce financial, psychological, and other loss when these events happen. Examples include sun screen, anticavity toothpaste, and insurance.

The core hypothesis of this research is that owning a preventive product leads individuals to judge the associated risk as more likely and more harmful. We propose that this effect is driven by two motivations. First, individuals want to maximize the value of their possessions. For preventive goods, their value won't be realized until negative events happen. The more frequently the associated negative event occurs, the greater value the product will have. For example, an umbrella will be more valuable if it rains frequently than infrequently. The second motive underlying our prediction is that people often have a desire to be better than others (Dunning, Perie, and Story 1991; Krueger and Mueller 2002; Kunda 1987). In the present context, such self-enhancing tendency will lead the owner of preventive goods to perceive the negative events as more likely because it will create more opportunity for owners to be better than non-owners. In addition, the superiority will become more salient if the negative event is very negative.

Four studies were conducted to examine our prediction using a variety of product categories including anticavity gum (Study 1), Apple Care (Study 2A), sun screen (Study 2B), and an advanced anti-theft lock (Study 2C). In Study 1, 137 undergraduates were randomly assigned to four conditions. Participants in the *ownership* (*control*) condition were told that they own a pack of anticavity gum (nothing). In addition to these two conditions, two more groups were included to rule out alternative explanations. First, it's possible that being merely exposed to information about preventive goods is sufficient to increase risk perceptions by making the risk concept more accessible (Raghubir and Menon 1998; Schwarz et al. 1991). Thus, we included an *information condition* in which participants were only provided with information about the preventive product. Second, it's arguable that receiving *any* gift may have the same effect. To control for this possibility, we added a *gift condition* in which participants owned a pack of whitening gum. All participants then were asked to estimate the percentage of American adults having cavity problems from "0" to "100" and to rate the harmfulness of cavity (1 = *not harmful at all*; 7 = *extremely harmful*).

The one-way ANOVA on perceived cavity pervasiveness revealed a marginally significant difference among conditions

(F(3, 133) = 2.56, p = .06). Follow-up contrast analyses indicated that, consistent with our theorizing, participants in the *ownership condition* (M = 69.93, SD = 10.61) rated cavities as more common than those in the *gift condition* (M = 61.16, SD = 14.75; t(133) = 2.10, p < .05), *information condition* (M = 59.70, SD = 21.57; t(133) = 2.53, p < .05), and *control condition* (M = 61.13, SD = 15.74; t(133) = 2.19, p < .05). No difference was found among the latter three conditions (ps > .70). The analysis on the harmfulness of cavity revealed a parallel pattern. Follow-up analyses for the significant main effect (F(3, 133) = 3.94, p < .01) indicated that participants who received a pack of anticavity gum (M = 5.90, SD = 1.09) rated cavity as more harmful than their counterparts in the *gift condition* (M = 4.97, SD = 1.18; t(133) = 2.81, p < .01), *information condition* (M = 5.05, SD = 1.60; t(133) = 2.64, p < .01), and *control condition* (M = 4.92, SD = 1.24; t(133) = 3.07, p < .01). No difference was found among the latter three conditions (ps > .65). In Studies 2A, 2B, and 2C, we replicated the above results using different product categories. The convergent support obtained from all these studies indicated that our findings are robust and generalizable.

Our findings contribute to research on mere ownership by expanding the scope from product-related evaluative judgments to more general, product unrelated perceptions. Our data can partially explain many marketing strategies such as free samples. Interestingly, our findings also suggest that offering free samples may benefit other companies. For example, as shown in Study 1, offering a free pack of anticavity gum led to higher perceptions of cavity risk, which, in turn, may increase consumers' purchase intention for anticavity products in general such as mouth wash and toothpaste. Future research is needed to directly examine such predictions.

Perceptions of Hospital Safety Records: Mean or Variance?

EXTENDED ABSTRACT

Consumers' view of hospitals should be guided by informative, accurate, and understandable hospital safety records. We attempt to understand the ways in which safety records of hospitals are processed in consumers' minds and tackle various barriers to rational choices of hospitals.

Hospitals' safety records are based on average estimates of the risks associated with surgeries (e.g., cardiovascular operation), and variance produced by the uncertainty in those estimates. Existing literature has shown that the public finds it difficult to process mean and variance simultaneously. Consumers are especially likely to overlook variance due to their lack of understanding and attention. Further, the literature on self-positivity bias and overconfidence predicts that people may have optimistic conceptions of the safety of the hospital (e.g., Taylor and Brown 1988; Harris 1996; Keller et al. 2002; Lin et al. 2003). These tendencies are possible barriers to understanding variance, because even if consumers do register the variance they may over-estimate the upside possibilities and therefore regard large variances as a chance to achieve a better outcome rather than a chance of both better and worse outcomes.

Understanding variance is especially critical for hospital selection because it directly affects the survival of patients. Generally, larger hospitals have smaller variances in estimated mean risks and may also be better equipped. Given the importance of variance, we explore how various framing and depictions of the variance affect the choice of hospitals, so that we can develop a more transparent and rational presentation format.

We conducted two surveys (Study 1: N= 239, Study 2: N = 195) using actual hospital records obtained from the 2010 US Census, American Hospital Association (AHA), and other official sources used by Medicare. The data enables us to predict the mean and variance associated with each hospital's safety for each person's health condition. We test how participants' views of safety records (as measured by their choices of hospitals) are influenced by framing effects (whether the safety records are characterized by mortality rates or by survival rates), by their health conditions (currently healthy or ill), and by how the mean and the uncertainty in the estimated mean are illustrated (by animated pictographs or boxplots). Participants make a choice between a pair of hospitals. There are four pairs of hospitals in each study – we varied whether a higher variance hospital has a lower or higher mean risk than the other hospital, and whether the mean or variance was kept the same between the two hospitals.

We hypothesize that variance is more salient when risks are illustrated by animated pictographs rather than boxplots used by Medicare websites. We also hypothesize that framing risks as survival rates trigger wishful thinking: People will seek high variance hospitals when it is an emergency rather than a non-emergency (Study 1), or when survival rates are low rather than high (Study 2), because they process variance as a chance of positive outcomes when the outlook is bad. Morality rates, however, do no trigger wishful thinking because people's mindsets are focused on negative outcomes regardless of the level of risks.

In Study 1, we found that high variance hospitals were less likely to be chosen when their safety records were illustrated by animated pictographs than boxplots in the mortality framing condition. The illustration method did not affect hospital choice in the survival framing. Emphasizing variance by animated pictographs seems to focus people's attention on variance, and presenting risks as mortality rates seems to highlight the downside possibilities of high variance hospitals. The interaction between graphic illustration (animated pictographs vs boxplots) and framing (mortality vs survival) was significant.

Consistent with our wishful thinking hypothesis, participants were more (less) likely to choose a higher variance hospital in an emergency situation as opposed to a non-emergency situation in the survival (mortality) condition. Furthermore, participants reported more confidence in their decisions and trust in the hospitals overall when the risks were framed as survival rates than mortality rates. This suggests that when risk is depicted by mortality rates, participants are less susceptible to various motivational biases, such as self-positivity bias, unrealistic optimism, and "It cannot happen to me" syndrome.

In Study 2, participants reported that they want to know the variance in the estimate of mean risk. However, the ways in which people incorporated the information about variance in their choices depended on framing effects, illustration methods, and the level of risk. We replicated the result of Study 1 that high variance hospitals were less likely to be chosen under animated pictographs than boxplots in the mortality framing condition. We also found evidence that the animation affects choices by emphasizing variance rather than de-emphasizing mean. Study 2 used two types of pictographs, one used in Study 1 and the other that depicted the mean until participants clicked a button to see the animation (i.e., variance). The two graphs did not differ in their influences on choices.

Our wishful thinking hypothesis was again supported in Study 2 that only manipulated the level of risk unlike Study 1 that manipulated the choice context (emergency or non-emergency). High variance hospitals were more likely to be chosen when the risks framed as survival rates were low (e.g., survival rate of 25%) rather than high (e.g., survival rate of 75%). Variance in survival rates is positively

perceived when risks were high. The level of risks, however, did not affect choices of high variance hospitals when the same risks were framed as mortality rates, because the variance in mortality rates is always perceived negatively when the consumer mindset is focused on deaths. Such wishful thinking was more pronounced when animated pictographs illustrate the risk because animation emphasizes variance. As found in Study 1, participants were more confident about their choices under survival than mortality framing.

Taken together, these results suggest that consumers can be nudged to a healthier and better choice of hospitals if we understand how consumers process hospital risk records.

SESSION OVERVIEW

Price and image: two critical marketing issues. This session presents four papers that each address important questions about how aspects of prices influence consumers' perceptions of the price setter. Prices serve as an important signal in the market, allowing consumers to make inferences about the appropriateness of firms' actions and motives. The objective of this session is to provide conceptual and empirical evidence of several interesting factors that influence inferences consumers make. In this session, we investigate consumer inferences related to price information, specifically examining negative inferences of firm unfairness and greed.

The first two papers both suggest more nuanced conceptualizations of the principal of dual entitlement for price unfairness (Kahnman, Knetsch & Thaler 1986a,b). Lu and colleagues provide evidence that a consumer's response to a price increase is influenced by firm power and by the consumer's power distance belief. These factors influence the extent to which a price increase leads the consumer to infer that the firm is attempting to take advantage of consumers.

In the second paper, Campbell and Carter start by examining price maintenance following a cost decrease. They show that consumers' perception of the fairness of price maintenance is influenced by perceived impact on consumer welfare. When a consumer perceives that product affordability is important to consumer welfare, price maintenance can be perceived as unfair. They further show, however, that the concern for consumer welfare is tempered by concern for firm reference profit. A price that is inferred to harm consumers is perceived as unfair unless it is necessary to maintain the firm's profit. They extend these findings to disadvantageous differential pricing.

In the third paper, David, Bearden, and Haws ask how consumers are likely to respond to customized prices and when such prices may lead to perceptions of unfairness. Three studies provide evidence that a consumer's attachment style moderates the impact of customized prices on perceptions of fairness and thus, satisfaction.

Anxiously-attached consumers perceive customized prices (as compared to non-customized or group-level prices) as unfair, even when they themselves are advantaged by the customized offer.

The fourth paper extends beyond perceptions of unfairness to perceptions of greed. Krishna, McFerran and Wan examine whether a firm's price image influences the interpretation of a firm action. Both lab and field experiments demonstrate that a firm that typically charges low (versus high) prices is more likely to be perceived to have negative motives for the same activity; specifically low price firms are more likely to be seen as motivated by "greed" than a desire to be "green." Interestingly, a firm with an image for charging high prices appears to be buffered against inferences of negative motives, and thus, perceptions of greed.

Greater understanding of factors leading to negative firm perceptions is of great practical and theoretical importance. We know from past research that such perceptions can negatively impact firm success. Each paper in this session asks how and when price actions lead to negative consumer inferences and thus, perceptions of unfairness and greed.

Firm Power, Power Distance Belief, and Consumer Price Fairness Perceptions

EXTENDED ABSTRACT

How do consumers assess fairness of a price increase? Pioneering work on the principle of dual entitlement (Kahneman, Knetsch, and Thaler 1986a,b) proposes that fairness perceptions are governed by i) a firm's entitlement to a reference profit and ii) consumers' entitlement to a reference price. Accordingly, consumers judge it fair for a firm to raise its price when justified by a reason such as cost increase (because firms are entitled to a reference profit) but unfair to take advantage of demand (because consumers are entitled to a reference price).

A natural question arises regarding the impact of firm power on consumer price fairness perceptions. Previous research has examined various factors that influence price fairness (Bolton, Warlop, and Alba 2003; Haws and Bearden 2006). Likewise, research has examined various ways in which *consumer power* influences behavior (Rucker, Galinsky, and Dubois 2012). Notably, price fairness varies by power when consumers respond to self versus other price comparisons (Jin, He, and Zhang 2014). To our knowledge, however, research has not investigated the impact of *firm power* on price fairness.

Kahneman et al. (1986a) demonstrated that consumers judge it unfair for firms to exploit monopoly power. If so, then consumers may respond negatively to higher-power firms, regardless of pricing behavior. However, we propose a more nuanced response whereby consumers are especially sensitive to firm power when firms provide justifications for price increases. Because power confers more resources and alternatives (Galinsky et al. 2008), consumers will be less accepting of a higher power firm's justification for a price increase. The high-power firm will be seen as exploiting consumers whereas the low-power firm will be seen as more entitled to the price increase. In contrast, unjustified price increases will make exploitation and lack of entitlement salient regardless of firm power.

Hypothesis₁   *With a justification, price increases will be judged less fair for high-power versus low-pow-*

er firms. When unjustified, price increases will be judged unfair regardless of firm power.

Hypothesis$_2$ *Perceived exploitation and entitlement will play a mediating role.*

Our research also explores cultural differences in price fairness perceptions. Prior research has examined the role of independence/interdependence in across-customer price comparisons (Bolton, Keh, and Alba 2010). Our research focuses on power distance belief (PDB): people with high PDB tend to accept and expect power disparity more so than people with low PDB (Hofstede 2001). We propose that PDB will moderate the impact of power; that is, consumers with higher PDB will be more sensitive to power differences and therefore more likely to respond differentially to pricing behaviors as a function of firm power.

Hypothesis$_3$ *The impact of firm power on price fairness perceptions (i.e., H$_1$) will be more likely to emerge for high- (vs. low-) PDB consumers.*

A series of studies investigate how consumers respond to price increases as a function of firm power and PDB. Studies 1-2 investigate firm power and include both un/justified price increases; studies 3-4 focus on cost justifications and assess PDB. To briefly summarize:

- Study 1 was a 3 (firm power: high, low, unspecified) x 2 (justification: cost, demand) design. The scenario was adapted from Kahneman et al. (1986a, p.729) and described a store raising the price of shovels due to a snowstorm (demand) versus wholesale costs (cost). Power was manipulated ("large major national hardware chain" vs. "small independent hardware store" vs. "hardware store"). Participants rated fairness (seven-point scales anchored by "unfair/ fair," "not at all just/just", and "unreasonable/reasonable"). ANOVA of fairness revealed a main effect of justification (F(1, 256)=10.21, $p < .01$), qualified by its interaction with firm power (F(2, 256)=2.93, $p=.06$); firm power was n.s. ($p>.10$). Raising prices due to costs was judged more fair when firm power was low/unspecified than when firm power was high (F$_{high\ vs.\ low}$(1,256)=4.04, $p< .05$; F$_{high\ vs.\ unspecified}$ (1,256)=4.68, $p< .05$). In contrast, raising prices due to demand was judged equally unfair regardless of firm power ($F<1$). These results support H$_1$.
- Study 2 was a 2 (firm power: low, high) x 2 (justification: donate, keep profit) between-subjects design. For generalizability, we examine a different scenario from Kahneman et al. (1986a, p735) that describes a firm holding a toy auction, justified (or not) by donating the profits to charity. Power was manipulated similar to study 1; fairness was measured as in study 1. Participants also rated perceptions of exploitation and entitlement (respective sample items: "The store is… taking advantage of customers", "… free to price as it wishes"). ANOVA of fairness revealed a main effect of justification (F(1,199)=79.65, $p< .01$), qualified by its interaction with firm power (F(1,199)=3.47, $p=.06$); firm power was n.s. ($p>.10$). Pricing was judged more fair with a donation justification for low vs. high power firms (F(1,199)=3.52, $p=.06$); fairness did not differ in the absence of this justification ($F<1$). Bootstrapping analyses (omitted for brevity's sake) support mediation by perceived exploitation and entitlement. These results support H$_1$-H$_2$.
- Study 3 was a 2 (firm power: high, low) x 2 (PDB Prime: high, low) between-subjects design. After PDB priming (Zhang et al.

2010), participants read a scenario describing a cost-justified price increase by a high- vs. low-power firm (adapted from study 1). Fairness and exploitation/entitlement perceptions were measured as in study 2. ANOVA of fairness revealed an interaction of PDB and firm power (F(1,79)=7.50, $p< .01$); main effects were n.s. (F's <1). When primed with high PDB, participants rated the price increase more fair for a low- vs. high-power firm (t= 2.30, $p< .05$); fairness did not differ for low PDB (t= 1.54, $p>.10$). These results (including mediation) support H$_2$ and H$_3$.
- Study 4 replicated study 3 with measured rather than manipulated PDB.

Four studies provide converging evidence that consumers respond differentially to price increases as a function of firm power and power distance belief, driven by perceptions of exploitation and entitlement. These findings provide novel insight into the role of firm power in the marketplace and have important implications for firms' pricing strategy. High-power firms must exercise caution when justifying price increases, especially in high PDB settings.

No Harm, No Foul: The Role of Inferred Harm in Perceptions of Price Fairness Under Price Maintenance

EXTENDED ABSTRACT

Much research on price fairness draws on the principle of dual entitlement and its implication that a violation of a reference price is needed for perceptions of price unfairness (Kahneman, Knetsh, and Thaler 1986a,b; KKT), and thus typically examines prices that are higher than an available reference price (e.g., Campbell 1999). However, consumers can perceive prices as unfair that are not higher than a specific reference price. For example, sometimes consumers perceive the price of pharmaceuticals to be "unfair" even though the price has not increased nor has a competitive product been offered at a lower price.

We propose that consumers' perceptions of price fairness are additionally influenced by concern for consumer welfare. Drawing on moral psychology, we propose that consumers are concerned about whether a lack of product affordability causes consumer harm. We examine whether inferences of consumer harm moderate the earlier finding that price maintenance following a cost decrease will be perceived as fair (e.g., KKT 1986b). We expect that the type of product, namely, the extent to which it is perceived as a necessity, will moderate perceptions of fairness of price maintenance after a cost decrease (H1; Study 1). We further propose that the level of consumer vulnerability moderates perceptions of the fairness of price maintenance (H2; Study 2).

While we propose that inferences of a negative impact on consumer welfare influence consumer perceptions of price fairness, the principle that a firm is allowed to protect itself from harm likewise holds. Thus, we expect that while the perceived fairness of a firm's decision to maintain a price after a cost decrease will be moderated by consumer price vulnerability, a firm's decision to increase a price after a cost increase will not be (H3; Study 3). Fairness does not require that a firm decrease its profits in order to improve the welfare of vulnerable consumers.

Lastly, we extend beyond examination of a firm's decision to maintain a price after a cost decrease. We propose that concern with consumer welfare is sufficiently important as to apply in situations in which a consumer evaluates being charged a higher price than another consumer. We propose that the extent to which a consumer infers that another consumer will be harmed by not receiving the lower price moderates the perceived fairness of a price discount for another consumer (H4; Study 4).

Studies 1 & 2 were scenario lab studies with U.S. undergraduates. Study 1 (N = 60) manipulated the importance of the product for consumer welfare, using a scenario from KKT (1986b) in which a small firm has a decrease in costs. We manipulated whether the firm produced furniture (low importance) or medicine (high importance). Product importance moderated the perceived fairness of price maintenance; the price was perceived as less fair for a product that was more (M = 4.45) versus less (M = 5.25; *p* < .01) important for consumer welfare. A bootstrapped mediation analysis indicated that the impact of product importance on perceived price fairness was mediated by inferences of harm to the consumer.

Study 2 (N = 96) manipulated consumer vulnerability by the inclusion of a description of the consumers of the product as "barely getting by." As hypothesized, maintaining the same price when costs decrease was perceived as less fair when the consumer was more vulnerable (M = 4.76) as compared to less vulnerable (M = 5.46, *t*=2.34, *p* < .02). Inferred harm to the consumer revealed the same pattern; inferred harm was higher when consumers were described as barely getting by (M = 4.42) than not (M = 3.75), *t*=3.03, *p* < .01. A bootstrapped mediation analysis indicated that the impact of the type of consumer on perceptions of price unfairness was mediated by perceived harm to the consumer.

Study 3 (N = 202 U.S. mTurk workers) examined the tradeoff between inferred harm to the consumer and harm to the firm with a 2 (Type of consumer: more vulnerable/less vulnerable) X 2 (price action: maintain with cost decrease/increase with cost increase). Using the two fair pricing conditions suggested by the principle of dual entitlement – maintaining price with a cost decrease and increasing price with a cost increase – enabled us to compare concern for consumer and firm welfare by exploring the underlying processes for each. We found a significant main effect of price action; maintaining price with a cost decrease was perceived as less fair (M = 3.6) than raising price with a cost increase (M = 4.7; *t*=4.96, *p* <.001). In line with our hypothesis, we also found a main effect of consumer type; both price actions were perceived as less fair when consumers were vulnerable (M = 3.7) than when they were less vulnerable (M = 4.6, *t*=4.00, *p* < .001). A bootstrapped mediation analysis indicated that the impact of the type of consumer on perceptions of price unfairness was mediated by perceived harm to the consumer, with an estimate for the indirect path of 0.677 and a 95% CI of .376 to 1.018. A second bootstrapped mediation analysis indicated that the impact of price action on perceptions of price unfairness was mediated by perceived potential harm to the company, with an estimate for the indirect path of 0.403 and a 95% CI of .167 to .693.

Study 4 (N = 85) extended to differential pricing, examining whether the perception of the fairness of another consumer getting a lower price than one's own price is influenced by inferred harm to the consumer. Participants read that they were in line for a movie behind an elderly consumer. We manipulated the presence of a senior discount (present/absent) and whether participants were primed to consider seniors as financially vulnerable (financially vulnerable/ financially invulnerable). A significant interaction (F(1, 81) = 11.39, *p* < .001) revealed that when senior vulnerability was primed, a senior discount was perceived as significantly fairer (M = 5.87) than no discount (M = 3.12), but that there was no effect of discount on perceived fairness with the financial invulnerability prime ($M_{discount}$ = 4.88; $M_{no\ discount}$ = 4.71).

The Role of Interpersonal Attachment Anxiety and Security on Consumer Responses to Customized Pricing

EXTENDED ABSTRACT

Advances in technology have enabled marketers to offer individual-level customized prices based upon the unique purchase patterns of consumers (Wang and Krishna 2012; Zhang and Wedel 2009). However, little is known about factors that influence consumers' evaluations of customized prices in terms of consumers' satisfaction and perceptions of fairness (Barone and Roy 2010). The present research focuses on how interpersonal attachment styles (Bowlby 1969) impact consumers' responses to customized pricing tactics, including perceptions of fairness.

In customized pricing, a consumer's purchase history is used to offer him/her an individualized discount, thus putting the consumer in an advantaged position and leaving other consumers in a less desirable position (Xia and Monroe 2010). In this regard, customized prices are similar to interpersonal relationships, in which individuals can be favored or not favored (Argo and Main 2008; Barone and Roy 2010). Thus, from an attachment theory (Bowlby 1969) perspective, consumers' evaluations of customized prices may depend on their attachment style.

Attachment theory explains that people, innately motivated to form social bonds, develop interpersonal attachment styles based on early experiences with caregivers, and these attachment styles, or psychological orientations, impact individuals' behavior throughout their lives (Ainsworth et al. 1978). Anxious attachment styles are held by individuals who have a strong need for closeness and are preoccupied with attachment, while also worrying about relationships and fearing rejection (Mikulincer and Nachshon 1991). Since anxiously attached individuals are highly sensitive to interpersonal factors and have negative expectations regarding interpersonal situations (Cassidy and Kobak 1998; Ein-Dor et al. 2011), they likely perceive customized discounts as unfair. Similarly, they are likely to be less satisfied with an advantaged price that is based on customization rather than on programs that apply to broad groups of consumers (e.g., cardholder membership programs).

Secure attachment styles are held by individuals who, based on being cared for in a responsive manner, expect that others will be available when needed (Ainsworth et al. 1978). Therefore, securely attached individuals are less likely to be concerned about interpersonal fairness (Bowlby 1973). Further, securely attached individuals often seek variety, are comfortable engaging in financial risk-taking, and have positive expectations regarding interpersonal situations (Li et al. 2012). As such, the securely-attached are likely to be open to customized pricing and interpret variations of prices offered in individualized pricing programs as having positive implications. Thus, it is likely that securely attached individuals are satisfied when they receive customized prices. We test these predictions in three studies.

Study 1 manipulated customized pricing (present/absent) and used established scales to measure participants' attachment style (Johnson et al. 2012) and satisfaction with the deal (Darke and Dahl 2003). A significant interaction between customized pricing and attachment style revealed that securely (anxiously) attached individuals reported lower (higher) satisfaction when there was no customized pricing program than when a customized pricing program was present. In addition, when a customized pricing program was present, anxiously attached individuals were less satisfied with the offered price than their more securely attached counterparts.

Study 2 examined consumer responses to customized prices that were the same versus lower (advantaged) than those charged to other customers to assess differential fairness and satisfaction (Haws

and Bearden 2006). The results indicated that secure consumers are more satisfied receiving a customized price that is lower than the price paid by other customers, but anxiously attached consumers are just as satisfied receiving a customized price that is the same as versus lower than the customized price offered to others. Similarly, securely attached individuals were more satisfied receiving an advantaged customized price than were anxiously attached individuals.

Study 3 manipulated attachment style and used a 2 (Attachment style: anxious, secure) x 2 (Program: customized, loyalty card) x 2 (Price: equal, advantaged) between-subjects design to test (1) whether the interactive effect of attachment style in the customized pricing--customer satisfaction relationship is mediated by perceptions of price fairness, and (2) the prediction that securely attached individuals report similar price evaluations after receiving a group vs. customized discount; whereas, anxiously attached individuals report more positive evaluations after receiving a group (vs. customized) deal. The results suggest that anxiously attached consumers may be highly concerned about the interpersonal factors surrounding a price discount. Specifically, in the presence of a customized pricing program, anxiously attached consumers perceived an advantaged price as being unfair; whereas, an advantaged price based on having a store loyalty card was perceived as being fair. As such, the negative effect of customized pricing on anxiously-attached consumers is reversed when the deal is based on having a loyalty card rather than on personalized customization. Further study 3 demonstrates that customers' perceptions of fairness mediate the customized pricing--customer satisfaction relationship.

Overall, our results suggest that customized pricing programs are likely effective among securely-attached consumers but not among anxiously-attached consumers. We propose that understanding the role of attachment theory in determining fairness and satisfaction responses to various marketing strategies is important both theoretically and practically. Given that attachment anxiety is negatively related to demographic variables such as age and income, managers can segment customers based on correlates of attachment style and tailor their marketing and pricing strategies accordingly. Relatedly, attachment styles can be primed through information presented in marketing communications (Gabriel et al. 2010); and, thus, marketing materials pertaining to customized prices can be designed to prime consumers with attachment security as they view information related to the customized pricing.

Perception of Environmentally-Friendly Efforts as Green or Greed

EXTENDED ABSTRACT

Consumer environmental concern is at a historical high, and many firms now offer products that are (or positioned as) friendly to the environment. Importantly, while many environmental efforts firms undertake cost additional money (e.g., using organic ingredients, making parts recyclable), others result in a cost savings for the firm (e.g., asking hotel patrons to re-use their towels, reminding consumers of saving electricity). The question we explore in this research focuses on the latter case, and examines when consumers construe a firm's efforts to be environment-saving (green) versus money-saving (greed)?

Beliefs in "green" versus "greed" are attributions made about a firm's intentions. Attribution research (e.g., Calder and Burnkrant 1977; Heider 1958) consistently shows that individuals infer the (unobservable) intentions of others based on their (observable) actions. In our context, consumers can attribute conservation efforts by firms as being of a noble (green) or more sinister (greed) motive?

We propose that the price image of the place where these efforts are practiced and the extent to which firms draw attention to the environmental effort will affect whether consumers ascribe a firm's motives as being based primarily in green (versus greed). Specifically, as there is a natural positive correlation between high price and perceived environmental friendliness (Yuan, Rajan, Krishna 2012), we expect consumers to infer more "green" motives to a firm with higher prices (versus a firm charging lower prices) (H1). Furthermore, when the higher priced firm makes consumer efforts in its green acts salient (versus not), we expect there is a greater attribution of greed (versus green) for such efforts compared to when a lower priced firm does so (H2). We also expect the effect of consumer-effort salience on green-greed attribution to be mediated by perceptions of the firm's profit orientation (H3). The green-greed attribution is important because we expect it to drive consumers' actual green behavior (H4), and the extent to which they blame (or credit) themselves (versus the firm) for green behavior (H5).

Study 1 and 2 were lab-based scenario studies in U.S. and Hong Kong. Undergraduate participants (n=197 for S1 and n=175 for S2) imagined that they had just checked into a hotel. We varied the price and whether or not a card was placed in the bathroom ("please reuse the towel to save resources"), making these 2(price: high vs. low) x 2(green effort: present vs. absent) between-subjects designs. We create a single item Green-Greed scale to measure the green versus greed attribution: "In my opinion, this hotel (1) is totally committed to going green; (4) will do green acts that will save them money; (7) is just cheap and is using "going green" as an excuse to save money." In both studies, the low-priced hotel was perceived as being greedier than high priced hotel (H1). We also found that consumers perceived the high priced hotel as being more greedy (versus green) if they had an environment card versus when they said nothing at all; for lower priced hotels, the card had no effect on attributions (H2). In study 2, we also assessed the extent to which consumers perceived the hotel to be motivated by profit. Perceived profit motivation mediated the effect of price and green effort on green-greed attribution (H3).

Studies 3 and 4 were field experiments, which took place in at a hotel chain in China. Participants (n=314 for S3 and n=281 for S4) were staff members of a large corporation participating in a training workshop. Participants were assigned to one of two hotels according to workshop themes (not performance). The two hotels, while under the same parent brand name, differ substantially in price (about US $125 vs. $37). We manipulated salience of green effort by whether or not a card was placed in the bathroom ("please reuse the towel to save resources"), making this a 2(price: high vs. low) x2 (salience of green effort: yes, no) between-subjects design. We replicated the findings in S1 and S2, again supporting H1-H3. Further, consumers tended to reuse their towels more when they perceived the hotel as being green (vs. greedy) (regression coefficient B =.20, p<0.01) (H4). Controlling for towel reuse, consumers felt that they themselves were more green when they perceived the hotel as being greedy (B=-.25, p<0.05)), suggesting a zero sum game between the firm and customer (H5).

Given the mediating role of perceived profit orientation, Study 4 examined the effect of mitigating this motive by manipulating it directly in a 2 (price: high vs. low) × 2 (salience of green effort: yes, no) × 2 (profit orientation: control vs. mitigated) between-subjects design. In the high salience green effort condition, consumers were encouraged to save electricity by turning off electrical devices and managing room temperature via a note on a small card in the room. We manipulated profit orientation by placing different types of toothbrushes in the bathroom: either a regular plastic tooth brush (control condition) in a plastic bag package (standard practice in local hotels)

or one made of bamboo, in a recycled paper-box package (mitigated condition). In the control condition, we found the same price X effort interaction pattern on greed-green attribution as in the previous studies. However, when profit orientation was mitigated, the price X effort interaction was no longer significant, leaving only the finding that the high-priced hotel was perceived as being more green than the low priced one. Additionally, the greed-green attribution predicted actual electricity usage over the guest's stay (B=-.66, p<0.01) (H4) and self credit/blame for conservation efforts (B=-.19, p<0.01) (H5). Together, our results have important implications for which firms have more to gain from green efforts, how these efforts should be made public, and how to encourage green behaviors.

Paper #4: Consumption Rituals and the Complexities of Institutional Resistance

Michelle F. Weinberger, Northwestern University, USA

SESSION OVERVIEW

The purpose of this session is to explore emerging scholarship investigating how individuals and organizations contest institutional arrangements. In the context of marketing, institutional arrangements are the formal and informal rules and norms created by actors and organizations to facilitate exchange behaviors (Carson et al. 1999, p. 115). Investigating the economic and social arrangements that exist within and between marketers, consumers, and other stakeholders has long been a central feature of marketing scholarship, historically aligned with the institutional school (Shaw and Jones 2005). Viewed ostensibly from the perspective of firms, this work, and the theorizing it supported, has tended to focus on how to effectively structure relationships between stakeholders to deal with threats such as opportunism and speculation (Bucklin 1965). This focus produced influential research into governance mechanisms, such as contracting (c.f. Bergen, Dutta, and Walker 1992; Rindfleisch and Heide 1997), designed to help marketers reduce risks and stabilize relationships and channels (Grewal and Dharwadkar 2002).

More recent work has shown that economic and social institutional arrangements can come into existence through less formalized, social processes. For example, Humphreys (2010) uses a social-constructionist perspective informed by institutional theory to show how members of the gambling industry worked to legitimate gambling in the United States. Central to the macro-level shift in views on gambling was the legitimation of both gambling as a social practice, and the organizations associated with the practice (e.g. casinos). Thomas et al. (2013) show how individuals and institutions in heterogeneous consumption communities rely on frame alignment processes to ensure continued existence of the community and its practices. Martin and Schouten (2014) chronicle how consumers provided the impetus for the emergence of a minimoto motorcycle market, through a series of pre-market and market translations among individuals and institutions. These examinations of how institutional arrangements are created through social processes raise questions concerning how market-based stakeholders might contest arrangements.

While individual and collective resistance is one form of contest (c.f. Thompson and Coskuner-Balli 2007), Scaraboto and Fischer's (2013) investigation of what they term 'frustrated fashionistas' demonstrates how consumers can alter the scope of existing institutional arrangements. The papers in this session seek to further

this line of inquiry by asking how institutional arrangements are subject to change through both formal and informal social processes, undertaken by individuals and forms of collective action. Mitchell and Handelman explore the centrality of ideology to contesting institutional arrangements, and advocate field theory to examine the interplay of individuals and institutions at various levels of analysis involved in contesting arrangements. Smith and Humphreys investigate how different professional fields seek to influence and control the structuring of an emergent field – social media – through forms of institutional work. Ertimur and Coskuner-Balli explore how markets evolve through the institutional work of actors as they appeal to, or distance themselves from, various institutional logics at play in the US yoga market. Weinberger explores how individual consumers negotiate collective consumption rituals aligned with dominant social and cultural institutions.

The Role of Ideology in Contesting Market-Based Institutional Arrangements

EXTENDED ABSTRACT

Recent scholarship in marketing and consumer research has focused on how market-based stakeholders work to bring about changes in the organization of firms and value offerings in commercial industries. For example, Humphreys (2010) demonstrates how gambling industry stakeholders worked to achieve institutional legitimacy for gambling practices and venues. Martin and Schouten (2014) investigate how consumers of minimoto motorcycles were instrumental in the creation of a new market previously overlooked by incumbent firms, such as Harley-Davidson. Similarly, Scaraboto and Fischer (2013) demonstrate how a group of marginalized female consumers, frustrated by their lack of inclusion in fashion offerings, mobilized alternative institutional logics to expand the range of available product offerings. These empirical studies demonstrate the fluid nature of rules, norms, and processes that structure social action and relationships, within and between market-based stakeholders (Carson et al. 1999). Further, these studies have directed attention to the importance of understanding processes of strategic legitimation (Suchman 1995) for understanding how such fluidity is negotiated and resolved by consumers and marketers. However, while legitimation implies a congruence between values and acceptable behavior (Dowling and Pfeffer 1975), what is not clear from this growing body of literature is the role of ideology in establishing such congruence within institutional arrangements.

While numerous definitions of ideology exist (see for example Eagleton 1991), at the core it represents a particular "configuration of ideas and attitudes in which the elements are bound together by some form of constraint or functional interdependence" (Converse 1964, p. 207). In other words, ideology represents a value system in which certain activities, beliefs, and relationships are considered to be more appropriate or desirable than alternatives.

Ideology is typically reserved for discussions of political affiliation, however it also forms an important aspect of consumption practices (Hirschman 1988; 1990), in particular as it influences meaning-making activities at the level of everyday consumption (Belk 1988; 2010; Belk et al. 1989). For example, Hirschman (1990) describes the ideology of affluence, and the ways in which wealthy consumers attempt to achieve "secular immortality" through practices consistent with values rooted in social class ideologies. Crockett et al.

(2004) show how normative political ideology influences relatively routine consumption habits of African Americans. Khan et al. (2013) show that conservative ideology may inform everyday purchasing habits implicitly or unconsciously. Luedicke et al. (2010, p. 1028) demonstrate how consumers construct moralistic identities using mythological and ideological tropes as resources. They do so by linking these moralistic identities to market-based resources, which allowed them "to venerate and validate their own ideological beliefs and values while casting different ideological views … as antagonistic threats to a sacrosanct moral order." Likewise, Kozinets and Handelman (2004) show the use of ideology to construct the identity of oppositional groups with the goal of contesting the moral order around consumption generally, in order to broker broader ideological change. Taken together, these socio-cultural investigations anchor on substantive human values (Slater 2011 p. 35), and illustrate how those values reflect ideological positions that inform one aspect of consumers' social action, namely consumption. These studies also demonstrate that the rules, processes, conventions, and accepted relations within market-based institutional environments are at least in part ideologically constituted, highlighted through consumers' attempts to legitimate reconfigurations of such arrangements.

While the studies above have investigated ideology in the context of consumption-driven meaning making at the level of consumers and consumption, what about marketers? Prior work from Holt (2002; 2004; 2010) highlights that marketers are adept at generating ideologically-informed cultural materials. Handelman et al. (2010 p. 35) demonstrate how marketers engage in ideological framing in order to overcome the limits of the fluid contexts within which strategic decisions must be made. This is consistent with the notion of marketing as a cultural technology (Slater 2011), suggesting de-centered ideological commitments on the part of marketers. Thompson and Tian (2008) and Peñaloza (2000; 2001) have built theory with respect to this position, highlighting the processes by which marketers produce cultural meanings through commercial myth-making (Peñaloza 2000 p. 82). In all of these studies, marketers commodify certain heterogeneous ideological, or mythological, identities in accordance with deliberate framing attempts (Thompson and Tian 2008; see also Thompson 2004). In this way, marketers seek to strategically legitimate particular market-based institutional designs (Carson et al. 1999) through positioning of products and services.

The variability present in market-based institutional arrangements, as chronicled in the studies discussed above, suggests that social structures represent a form of reified ideology, embodied in institutions and institutional arrangements (Friedland and Alford 1991; Meyer and Rowan 1977). Institutions are socially constructed through the beliefs and practices of individuals (Berger and Luckmann 1966/2008; Castoriadis 1987), suggesting that ideology informs the social relationships of particular institutions. Further, ideological commitments represented by institutions are malleable, particularly as they are forced to adapt and react to social disruptions (Holt and Cameron 2010). This fundamental malleability manifests in contests, undertaken by consumers and marketers, which leverage ideology as a way to establish new configurations of institutional arrangements.

Building upon earlier work in sociology and psychology, and in particular that of Pierre Bourdieu, field theory has emerged as an approach to understanding the interplay of individuals, forms of collective action, and meso/macro social structures (Fligstein and McAdam 2012; Martin 2003; 2009; 2011). While predominantly used to understand configurations of social actors with respect to particular issues (Hoffman 1999), field theory has also been used

to understand how ideology creates anchor points (Kozinets 2008; Zizek 1989/2008), around which individuals and institutions can root their identities.

This presentation will set the conceptual stage for the rest of the session by explaining and illustrating a field theoretic approach to market arrangements by examining the emergence of the 3-D printing market. This conceptual understanding and application of a field theoretic approach will help frame the empirical papers that follow in this session.

Professional Contests and the Emergence of Social Media as an Institutional Field

EXTENDED ABSTRACT

Social media is emerging as a domain of discourse and practice that potentially intersects with many industries and fields. Previous research has studied the emergence of industries and consumption practices, detailing the process through which industries (Humphreys 2010), consumption practices (Giesler 2012), and market segments (Scaraboto and Fischer 2013) become integrated with dominant norms and values. Yet most of these studies have centered around company-consumer dynamics. We aim to examine inter-field dynamics in the legitimation process. Using Abbott's (1988) theory of the system of professions, we examine the process through which different professional fields contend for control over the processes, practices, and tools broadly labeled "social media," which may be conceptualized as an emerging field (Maguire, Hardy, Lawrence 2004). How do contests between rival fields play out and what are the results of these contests for the meanings of the new domain?

Abbot argues that professions vie for control over particular fields of knowledge and defend boundaries of knowledge against outsiders. He says, "Study of organizational forms can indeed show how certain occupations control their knowledge and its application. But it cannot tell why those forms emerge when they do or why they sometimes succeed and sometimes fail. Only the study of competition can accomplish that." (1988, p. 2). The empirical question, then, is how professions vie for control over particular domains of knowledge and defend those claims against rivals. Although Abbott's framework has been used widely to understand knowledge contests in established fields as diverse as healthcare (Scott 2000), higher education (Slaughter 2004), and accounting (Greenwood and Suddaby 2006), we use it to examine dominance for knowledge over new technological processes and innovations.

The professional formations that result from these contests over new technologies have critical importance for understanding the structuring of consumer life. For example, if the field of journalism were to dominate social media, it would infuse the domain with principles based on the civil sphere, a watch-dog ethos, but perhaps also a short term, headline-driven cycle of attention. On the other hand, if marketing were to come to dominate the new field, a different set of norms and values—namely measurement, prediction of behavior, and other logics would come to the fore. That is, certain orders of worth (Boltanski and Thévenot 2006) might emerge that would have been unrealized if the contest had ended differently. For instance, Marwick (2013) shows how the norms and values of a particular tech culture shaped meanings of status and even particular functions of social media such as self-branding, functions that, in turn, can shape consumer subjectivities.

To understand the process through which professions contend over the domain of social media, we conducted a study of public discourse during the period of its emergence from 2008 to 2013. We collected all articles that mentioned "social media" in the three highest

circulation newspapers in the United States, the New York Times, Wall Street Journal, and USA Today (n=6,877). Using qualitative and quantitative content analysis, we examined the emerging logics for understanding the new phenomenon and analyzed the strategies by which different fields claimed dominion over particular aspects of the new field.

We find that various professions – including marketing, entertainment media, journalism, and information technology – as well as loosely affiliated institutional entrepreneurs, vie for some control over the emerging field of "social media." These groups engage in institutional work to stake a claim over the jurisdiction and its associated knowledge, practices, and tools. Four prominent ways in which the professions contest the field are through: professionalization attempts, issue translation, knowledge generation and assertion, and field-specific practice development.

First, the professions try to assert their place in the field through professionalization attempts such as establishing domain-relevant associations or sub-associations and forming relationships with degree granting institutions that can train people to specialize in social media. This work helps the professions to formalize and organize their approach towards the field, as well as to gain legitimacy by partnering with credible organizations such as universities. Professionalization has previously been associated with the institutionalization of fields (Lounsbury 2002).

Second, the professions stake claim to the emerging field by engaging in issue translation. That is, they demonstrate that the issues over which they hold cognitive legitimacy to professionally address are also significant in the domain of social media. For example, marketers might claim that understanding consumers is an important component of social media, or journalists might argue that public discussion is a central aspect of the field. In making such claims and translating these issues into the emerging field, professions attempt to transfer their legitimacy into the domain as well, constructing the shape of the field in the process.

Third, the professions contest the domain by generating and asserting abstract knowledge about the field. Abbott (1988) asserts that developing such knowledge is central to making legitimate claims of professional jurisdiction. The professions engage in such behavior by publishing white papers, funding academic research (e.g. MSI), providing outlets for dissemination and debate (e.g. conferences), etc.

Fourth, the professions contest their positions by engaging in field-specific practices that solve societal needs. Marketers deliver products and services to consumers via social media, journalists deliver news, the entertainment industry delivers content, etc. Abbott (1988) suggests that professions which fail to offer solutions to societal needs associated with their work risk losing relevance and control over their jurisdiction. The professions seek to avert this fate by developing practices that solve needs which are at the intersection of their traditional jurisdiction and the emerging field of social media.

Understanding professional contests can help us better understand the forces that structure consumer relationships with technology, from norms and values associated with using social media to material infrastructure of particular social media tools (e.g. presence of advertising, mobile features, etc.). Our findings have the potential contribute to consumer research on the integration of technology into consumer life (Giesler 2008; Kozinets 2008) and better understand the process of institutionalization that produces so many structuring conditions for consumer choice and practices (Martin and Schouten 2013; Scaraboto and Fischer 2013).

Market Evolution Through Shifts in Institutional Logics

EXTENDED ABSTRACT

Institutional theories in organizational theory and sociology posit that individuals and organizations exist within larger institutional environments that contain taken-for-granted social, cultural, and symbolic meaning systems that define their social reality. These environments are subject to "logics," both symbolic and material organizing principles that direct and circumscribe thoughts, decisions, and behaviors of individuals and organizations via "socially constructed, historical pattern of material practices, assumptions, values, beliefs and rules" (Friedland and Alford 1991; Thornton and Ocasio 1999, p. 804). Recent work in marketing illustrates the centrality of institutional environments and logics to understanding dynamics of markets. Scholars have shown how institutional environments impact creation and evolution of markets and how market actors may challenge as well as draw on institutional logics to change markets (Giesler 2008, 2012; Humphreys 2010; Martin and Schouten 2014; Scaraboto and Fischer 2013; Thompson and Coskuner-Balli 2007). In this article, we extend on these theoretical accounts of market dynamics by exploring how markets may become subject to multiple logics and the complex institutional work of institutional actors in augmenting/repressing these logics.

We selected the United States yoga market for our research context as it provides a vivid case of historical plurality and variation in its institutional logics. We conceptualize the yoga market as an organizational field consisting of multiple brands (yoga studios, gyms, schools, yoga gurus), consumers, and regulatory agencies (government, professional associations). Through a historical analysis of the last three decades, we seek to identify the institutional logics that guide actions and understandings in this market, understand the mechanisms by which they diffuse and shift, and the conditions that support their sustenance.

We collected data from a variety of archival sources to construct an analytical narrative of the logics guiding the yoga market. First, to study the evolution of logics constituting the market over time, we examined newspaper articles about yoga. We collected articles with the word "yoga" in the headline and the lead paragraph from the New York Times (n = 868) and the Washington Post (n = 604) published from 1980 to 2012. Following a procedure similar to one in Humphrey's (2010) study on the legitimization process of casino gambling, we began by qualitatively analyzing the newspaper articles, coding for themes and characteristics of logics. The three field level logics of spirituality, medicine, fitness and a societal logic of commodification that pervade the yoga market emerged as a result of this analysis. Then we conducted an automated quantitative content analysis of the population of articles from 1980 to 2009 using the computer program called LIWC (Pennebaker, Francis, and Booth 2007) to assess the changes in attention to logics over time.

Our analysis illustrates how the plural logics of spirituality, medicine, and fitness characterized the yoga market with the medicine and fitness logics gaining increased attention over time and how distinct market actors sought to amplify and repress these logics in line with their interests and agendas. Our qualitative analysis shows that over time institutional entrepreneurs (journals, brands, institutions) attempt to strengthen/weaken normative associations with yoga. Our findings reveal a set of institutional work that actors in this market adopt to influence organizational arrangements. These strategies range from creating normative associations (Yoga Alliance, Yoga Fit) and advocacy (Hindu American Foundation, Open Source Yoga Unity) to changing rule structures (Hindu Government) to name a few examples. (Lawrence and Suddaby 2006). The institutional

work of these distinct actors not only helps sustain the plural logics in the market but also impact the relationship amongst the logics.

Exploring the dynamics in a market with multiple logics, the contributions of our study to extant research on market evolution and change in institutional arrangements are threefold. First, our analysis documents how plural logics are created and sustained in markets. Our analysis reveals that markets do not necessarily shift from one dominant logic to another (c.f. Humphreys 2010) or are organized around two countervailing ideologies that exist in tensions with each other (c.f. Giesler 2012), but rather can be characterized by plural logics with brands with distinct interests influencing the relationality among logics that permeate the marketplace. Second, while previous marketing studies focus on managers' and media's framing strategies to account for the conflicts in markets, our analysis brings to attention how multi brand contestations undergird the balances and tensions crafted among logics in markets. Third, extending on the framing and brand revitalizing strategies, we uncover a series of institutional work that actors in pluralistic fields can adopt to legitimize particular institutional arrangements.

Consumption Rituals and the Complexities of Institutional Resistance

EXTENDED ABSTRACT

This presentation focuses on the complexities of contesting social institutions by examining a context where people do not celebrate a dominant consumption ritual in their community where the ritual elements are the primary vehicle by which community members connect. Collective rituals create "conventions that set up visible public definitions" of who one is, in what stage of life, and to what groups one belongs (Douglas and Isherwood 1979, 65). Through successful participation in collective rituals, individuals reaffirm their relationship to others in the group performing the ritual, to associated institutions, and to shared beliefs (Etzioni 2004, p. 11). They reaffirm emotional ties and group solidarity (Bell 1997; Cheal 1988; Collins 2004; Durkheim 1973; Etzioni 2000). Ritual is also a "tool for social and cultural jockeying; it is a performative medium for the negotiation of power and relationships" (Bell 1997, p. 79; Bourdieu 1977, pp. 36-37). As a result, when one makes a choice to not engage in a consumption ritual that is dominant in their community, that individual risks not reaffirming their relationship with celebrators. As such, not participating is potentially disintegrative (Etzioni 2004, p. 22) and marginalizing, because connections are not reaffirmed (Weinberger and Wallendorf 2012). Because of this, institutions like collective rituals are extremely powerful. Despite a healthy focus on collective ritual participation, particularly on gift giving, in consumer research, fewer studies have focused analytically on consumption rituals as powerful social instittuions nor resistance to these types of institutions. This presentation focuses on understanding the complex choices non-celebrants must make and the ways non-celebrants interact with ritual elements to both resist and at times engage with this dominant institution.

Recent research has examined the ways that consumers use marketplace resources to contest existing institutional arrangements based on their ideological beliefs or identity (Coskuner-Balli and Thompson 2013, Izberk-Bilgin 2012, Scaraboto and Fischer 2013, Thompson 2014). This paper builds on that work as well as research on consumption rituals (Otnes and Lowrey 2004; Rook 1985; Wallendorf and Arnould 1991) by focusing on the complexities of not celebrating dominant collective rituals, where the rituals literally dominate the social, cultural and political landscape. I use an institutional and cultural frame to build on Swidler (2001) whose research focuses on how culture is used and how institutionally informed cultural resources enable and constrain meaning making and action. As well as Lamont and Molnar's (2002) research on symbolic boundaries. While the meaning making and boundary work that occurs by celebrants of rituals has been the focus of research, here I focus on the problems created by collective consumption rituals and the implicit and explicit stategies and practices deployed to navigate around and through rituals as dominant social and cultural insititutions.

The context for this study is Christmas in America, the most dominant collective consumption ritual in the US. Unlike some rituals, it is overly inclusive, incorporating even those who prefer to not participate, what Brahm Levey (2006) describes as "smothering", meaning that at times the ritual serves to marginalize non-celebrants through failing to recognize their identities as non-celebrants. The data draws from a project where I conducted 27 interviews with and collected 20 diaries from Americans who choose for ideological reasons to *not* celebrate Christmas. Theoretical and purposive sampling techniques were used to understand a range of decisions and meanings related to Christmas practices. The participants in this study range in age and SES and are engaged in a variety of social groups in their communities (i.e. work/school, leisure, children's activities). The processes of data collection and analysis were iterative. The data were organized using the NVIVO software program, which was also used for preliminary grounded theory analysis (Spiggle 1994; Strauss and Corbin 1998). After initial grounded theory analysis of interviews with Jewish informants, additional data was collected purposively based on emergent themes and analyzed.

I find that for much of the year, boundaries that mark differences between individuals in the same community remain in the background, yet during the Christmas season, the ritual creates a meaningful divide between celebrants and non-celebrants. Most informants are not "anti-Christmas." Instead, the dominance of the institution creates a set of problems in their lives as retailers, government offices, media, workplaces and schools operate as if most participate in the non-religious consumption elements (sending cards, giving gifts, going to parties, decorating, etc), and deploy these as tools for relationship work amongst community members. While these ritual elements are not themselves religious, they are nested within ideological practices that run counter to identities and beliefs of non-celebrants.

This dominant institution creates a tension for non-celebrants between their goals of maintaining relationships with celebrators and protecting their and their children's identities as non-celebrators. To alleviate this tension between these two countervailing goals, they must actively manage the symbolic boundary between themselves and the dominant celebrating group. Thus, beyond just resisting these institutional forces, informants use dominant ritual elements as cultural resources for boundary work. I find that they contingently deploy four strategies based on these relational and identity goals: participating, disengaging, appropriating, and traversing. Participating involves not resisting and instead engaging in the ritual elements in service of relational work, backgrounding the symbolic boundary between celebrators and non-celebrators. Meanwhile disengaging means actively rejecting smothering ritual elements through everyday practices such as not attending parties. Appropriating is complex and involves using ritual elements from the dominant institution for their latent relationship purposes but stripping them of their original meaning to facilitate connections between non-celebrants, and traversing is the attempt at using ritual elements to both do relationship and identity work, maintaining and minimizing the symbolic boundary. By bringing together research on

consumption rituals, institutional resistance, and boundary work, and by focusing on the broader social context of non-celebrants lives, the presentation builds on all three areas by showing the complexities of resisting dominant social institutions.

SESSION OVERVIEW

Bourdieu refers to family as a 'social artefact' (1996: p.25). '*To understand how the family turns from nominal fiction into a real group whose members are united by intense affective bonds, one has to take account of all the practical and symbolic work that transforms the obligation to love....This work falls more particularly to the women.. perpetuated through a continuous creation of family feeling...*'(1996:p.22)

This special session focuses on the 'emotion work' of women in 'producing fun' through their food care practices. DeVault (1999) dissects their complex organisation, negotiation and planning and reveals women's efforts as creative and persistent. Much of this effort centres on creative use of food to materialize the idyllic 'happy' nuclear family. Cook (2011) suggests that mothers consume **for the family**; we focus on the 'producer mother' who consumes **to produce** the family. She is the emotion manager, who uses tools of cleaning, cooking, and creating to keep the family smiling. This production of family fun and joy is not always a easy process, but often presented as effortless in popular media (Ticknell 2005).This session examines women's constant effort, attention and 'emotion maintenance work' through food, materializing emotions that reinforce the idea of family.

We situate our session in the context of the family as a site of discourse and practice. Within this field, we study how the gendered practices of feeding as affective work integral to producing the family. We build on the work of scholars such as Murcott (1983), De Vault (1991), Sheridan (2002), Martens and Scott (2005), Chambers (2001), and Jackson (2010, 2011) ; examining how the emotion work of fun and joy in everyday food are used to materialize the emotional links of a 'ideal family'.

This session examines emotion work by which 'Family' is constructed. It brings together four papers (four countries) that examine how women materialize family emotions of fun and 'caring' through novelty around food and mealtimes.

The first paper uses ethnographic work in the Scandinavian context. It examines how mothering can be conceptualized as a practice requiring consumption. It highlights how emotions such as love and fun and its consumption must be understood as a relationship between mother and needing child.

The second paper is a visual analysis of representation of family care in women's magazines (UK and Australia) and highlights the role of women in using food and mealtimes to 'produce' happy families. The paper contextualizes media discourses and implicates advertising as a cultural intermediary that reproduces a mythic 'happy family'.

In the third paper mothers (in the UK) reconcile conflicting discourses and pressures around 'fun' foods to produce carefully negotiated 'lunch boxes' which keep both child and school happy. It details the effort and labour that goes into balancing of 'healthy' with 'fun'.

The fourth paper (from Canada) focuses on how the market helps create and sanction ideas of 'food as fun'. From traditional ideas of food as something to be taken seriously, this paper examines the evolution of the relationship between food and fun.

QUESTIONS FOR DISCUSSION

Is Food work really fun? for whom? Is it a necessary affective state for families? Is it overrated?

How has the relation fun-food- family been constructed in the marketplace? What are the implications of this relation for family collective and individual identities (i.e mothers)?

Love should be fun: Mothering as a practice

EXTENDED ABSTRACT

Consumption can be seen as a way to construct and express identity (Arnould and Thompson 2005), including that as a mother. Encoded in advertisements, brands, retail settings, and material goods, the marketplace provides the consumer with a broad range of symbolic meanings which she may tap into when constructing this identity (e.g. Hogg et al. 2011; Scott 2006). One way to conceptualize the relation between consumption and the identity as a mother supports the idea of *role embracing* (Davies et al. 2010; Hogg et al. 2004; Jennings and O'Malley 2003). Another body of literature stresses the *discourses* that women use to present themselves and act as mothers (Bugge and Almås 2006; Lupton 1996; Moisio et al. 2004). Identity can also be seen as an intersection of *practices* (Reckwitz, 2002:256) serving as the bedrock of consumption (Warde 2005:144). Even if approaching mothering as a practice is far from new in the social sciences in general (cf. Chandler 1998; O'Reilly 2009; Rich 1986; Ruddick 1995[1989]), it is still fairly unexplored in consumer research. By conceptualizing mothering as one of the practices that may constitute identity and that requires consumption to be performed (Warde 2005), this paper explores different ways in which mothering expresses love towards a needing child with the help of consumption – practice performances many times facilitated by bringing in the fun.

The paper conceptualizes mothering as a learned practice along the lines of feminist philosopher Ruddick's maternal thinking (1995[1989]) whose philosophy also goes hand-in-hand with Schatzki's notion of practices (1996: 2002). Mothering as a practice spotlights emotions and underlines that mothering must be understood as an emotional relationship that develops between a caregiving practitioner and a needing child (Ruddick 1995[1989]). The relationship does not necessarily involve the child's biological mother or father

but can be anyone prepared to step into it, while striving for overall purposes like *preserving*, *fostering*, and making the child *socially acceptable* (ibid.). The practitioners find these purposes worth striving for through their *attentive love* which keeps the practice going – a capacity that allows them to see the world from the child's perspective and care intensely about it (ibid.).

The study of love and other types of emotions has long been dealt with in sociocultural consumption research (cf. Arnould and Price 1993; Belk and Coon 2013; Belk et al. 2003; Campbell 1987; Holbrook and Hirschman 1982; Miller 1998). What has been lacking according to some scholars, however, are *analytical frameworks* that make emotions more visible in consumption (Illouz 2009; Beruchashvili and Moisio 2013) - and this is where a practice theoretical approach can help. According to practice theory, we engage in practices and strive towards certain ends because they *matter* to us, and the emotions related to these strivings are expressed through the activities composing a practice and understood only within the practice (Schatzki 1997:302). Inspired by Nussbaum (2001) attentive love can be seen as a background emotion guiding and making the practice matter, while situational emotions like joy or frustration express how the practice is going (Schatzki 1996). By approaching the relation between consumption and theories of practice along the lines of Warde's seminal work (2005), the purpose of this paper is to illustrate how mothering can be understood as an emotional practice and how the consumption and the fun that occurs in relation to it can be understood as something that this practice entails and requires. In order to pin down both the doings and sayings composing a practice, I have used an ethnographic study, including participant observations, informal conversations and attention to material artifacts, focusing on dinner consumption, an activity of utmost importance in other studies of motherhood (Charles and Kerr 1988; DeVault 1991; Lupton 1996), among nine Swedish single mothers. These women represent an extreme case of demands on combining both breadwinning and caretaking, and were, due to scarcity both time and money-wise, expected to at least express threshold activities of love.

Even though mothering may include many different activities, the analysis confirmed the everyday dinner's central role by its contribution to the practitioners' strivings to materialize mothering's rather vague purposes. It showed that the purposes can be split into a number of different dinner activities that, guided by attentive love, materializes through the goods bought, processed and thrown away, and through the child's developing body. Furthermore, the activities expressing love were not always interpreted as such by the needing child as they not necessarily meant giving the child what it wanted. Rather, the activities meant fostering it to become what was seen as being in its best interest in the long run, namely a competent member of society (cf. Ruddick 1995 [1989]). To develop a relationship with the child and to make it receptive to the various love acts performed, the practitioners "brought in the fun" in ways that not necessarily made their lives easier in the short run, but that expressed hopes for making it easier in the long. This included **fun with food** when, for example, Camilla invited her five year old to "cook" or rather "play" with food together with her, spending far more time in the kitchen than she usually would, as a way to foster the child's future cook skills. It also included **fun while food**, like when Eva promised her teenagers a greasy dinner in front of the TV – the fun – on Fridays provided they ate vegetables and helped out in the household during the rest of the week, hereby fostering responsibility and balanced eating habits. Another, more rare way was **first fun then food**, letting the play and the fun come to the foreground and be what actually guided the mothering practice. Linda, for example, spent most of her time playing with Leon. The dinner was squeezed in once the play

was finished. In short, the fun included in mothering in many ways seemed to facilitate its long term goals, mostly as a tool involved in the dinner, but the fun could also take over and be the main activity that guided the mothering practice.

Making meal times fun: Visual representation of mothers and family meals over time in Magazine Advertising

EXTENDED ABSTRACT

Drawing on a selection of food advertising and articles from Good Housekeeping (UK) this paper examines the (re)presentation of family and food through the lens of this popular women's magazine and considers the discursive meanings around food and the family over the sixty year period. Some comparison is drawn with Australian Women's weekly over the same time period.

Family life is frequently played out through domestic commensality and happy eating rituals that accompany everything from joyful festive meals such as Thanksgiving and Christmas to more mundane gatherings around the dining table (Epp and Price 2008, Jackson et. al. 2009, James et al. 2009, Marshall 2005, Bisogni et al 2007, Mosio et al 2004, Wallendorf and Arnould 1991, de Vault 1991). Within this discourse family dinnertime is seen as an important vehicle for the 'exchange of family narratives'. Providing 'proper' meals and catering to the demands of other family members, is seen as part of women's work as mothers' juggle their time and bring together these 'separate family lives' (Douglas 1972, Murcott 1982, 1995, Charles and Kerr 1987, de Vault 1991, Thompson 1996, Marshall 2005).

This idea of mother as carer and food provisioner is reinforced in popular media and food journalism which promotes the idea of 'the family meal, one prepared by housewife and mother' (Warde 1997: 137; Marshall, Hogg, Davis Schneider and Petersen 2014:125). Women are not only responsible for food provisioning but for the emotional responses of their family through this provisioning process and this is seen in the advertising images in women's magazines and early cookbooks (Burridge and Barker 2009, Burridge 2009, Hogg et al). Food advertisers, women's magazines and cookbooks reflect this idea that providing 'proper meals' is the key to building the ideal family. (Warde1997, Mosio et al 2004). There is a question over the extent to which these popular media representations might contribute to family identity management and provide scripts for these imagined happy families (Borgerson et al 2006, Heaphy 2010, Kehily and Thomson 2010).

This paper looks at a selection of family food related advertising and articles in popular women's magazines, spanning the period 1950 to 2010.Using a data sample that included one year in each decade of the two magazines (a historical slicing sample, Martens and Scott 2005) and including all advertisements around food and the family, we identify key shifts in the depiction of the mother in producing food, family and fun. Drawing on visual discourse analysis it uses a selection of food advertising and articles from Good Housekeeping (UK) to examine the (re)presentation of family and food in this popular women's magazine and consider the type of families depicted and discursive meanings around mothers, food and the family over the sixty year period. Some comparison is drawn with Australian Women's weekly over the same time period. The nature of family meals appears to be changing but not the role or responsibilities of mothers in bringing joy and fun to the family meals and in producing the idyllic 'happy family'(Chambers 2001). The changes across the six decades examined, reveals a key shift in mothers being 'givers of joy/ and creators of fun' for the family to becoming 'part of the fun of eating'. While we still see the mother as the primary

emotional worker in creating the 'fun in food for the family' we see her participating in the fun of consumption more. Thus, in the latter decades we see the mother as consuming not just on the behalf of the family but for herself as an individual.

We therefore see two distinct phases in the depiction of the mother and the family in relation to food and fun. The early phase, roughly covering the 1950s, 1960s and 1970s where the mother is the chief producer of food and fun for the family, and deriving her pleasure and 'fun' vicariously rather than directly. In the latter decades, the mother is at once the producer of food and fun as well as participant /consumer of the food and fun. Thus, in the first phase the mother produces a fun meal and serves the happy family at the table. In the second phase, she produces the meal but also consumes the food and the family fun at the table herself, directly.

This coincides with the overall construction of the mother as a producer and vicarious consumer (for the family) in the early period as described by Cook (2011) and as producer and direct consumer/participant in the latter decades. Overall however, our data shows that the mother is consistently and enduringly constructed as the person who engages in continual, ongoing labour of materializing family feeling and thus producing the family, using food as a means of channelling emotions of fun, pleasure and nurturing. Ultimately, these media representations reinforce the normative ideal of 'happy families'.

Feeding the children at school: unpacking fun food in packed lunches

EXTENDED ABSTRACT

This paper unpacks the connection between children's lunchboxes, fun food and leisure from the perspective of thirty British mothers who prepare school lunchboxes. Although fun is recognised as a key component of children's food consumption (Cook 2005), the experiences of mothers providing a leisure experience through lunchboxes has been unexplored to date.

Interpretive research looking at mothering shows how discourses of care and convenience dominate mothers' narratives of their food experiences (Moisio et al. 2004; Bugge and Almås, 2006**).** These discourses are usually described as a dichotomy (care-healthy food versus convenient-unhealthy food) symbolising resistance or surrender to the market penetration of domestic life (Moisio et al. 2004). Healthy food is described not simply in nutritional terms, but rather as food "from scratch" with a reduced intervention from the market (Bugge and Almås, 2006)**.** It symbolises "good mothering", such as mothers' self-sacrifice of preparing "good" food for their children (Cappellini and Parsons 2012). On the contrary convenient food is mainly associated with mass produced food, ready to be consumed without any (or with a minimal) intervention by mothers (Bugge and Almås, 2006; Elliott 2007).

Convenient food targeting children has been described as fun food (Cook 2005, Elliott 2007). Fun food is not classified in nutritional terms, but rather in its "appeal of fun and play" (Elliott 2008: 269). As Elliott highlights fun food "is edible entertainment, to be consumed for reasons that have little to do with sustenance or nutrition (2008: 266). *Proprietary* and *transgressive* are two dimensions of fun food (Cook 2005). Indeed this food belongs to the children's world since it refers to cartoon characters or famous games and it is re-categorised as a toy used for entertainment more than its nutritious purposes (Cook 2005; Elliott 2007).The transgressive nature of fun food makes it particularly appealing for children and renders problematic parents' attempts to reduce or forbid its consumption (Cook 2005). Feeding children with convenient and fun food is often morally condemned as a sign of "lazy", overindulgent and "un-

knowledgeable" parenting, and denounced as a cause of childhood obesity (Guber and Berry 1993; Whitman 1994).

Although these studies show the market penetration of food as promising a leisure experience, we think that they do not take into consideration mothers' own involvement in making food a leisure experience. Also seeing fun food only as a market's offer of convenient food does not take into consideration how, how often, when, where and with whom children consume food considered fun. In order to understand mothers' practices of providing food that their children will enjoy, this research adopts an intepretivist approach combining photo-elicitation interviews and a focus group discussion with thirty British mothers, recruited through a purposive sampling, from various primary schools in England. Parents with children aged between nine and eleven years old were targeted since children at this stage have well established food preferences and can negotiate their choices with adults (Roberts and Pettigrew, 2013). The aims of the interviews and focus group discussions were to investigate mothers' understandings, feelings and ideas surrounding the mundane practice of making lunchboxes for their children.

Our findings reveal that mothers prefer making a packed lunch rather than opting for a school dinner, as a lunchbox is considered a gift from home. However lunchboxes are not simply a maternal gift echoing the exiting literature on feeding the children (De Vault 1991). Seen as a way of displaying good motherhood outside the home, lunchboxes are a space of daily complex negotiations between the school's regulations, children's request for specific brands and mothers' own understanding of "good" food. Mothers' understanding of a "good" packed lunch is framed as a combination of "proper" (healthy) but also "fun food" that children can enjoy.

Mothers' understanding of fun food goes beyond the market classification of food as a convenient product. In fact three different meanings were associated with food classified as "fun". Firstly, escapism emerges as a main justification of providing food considered enjoyable, such as "adult" food commodified by mothers to accommodate children's requests. For example handmade sandwiches and pieces of fruit were shaped into stars and various animals. Secondly, enjoyable food was considered a transgression to the school's regulations. For example "sneaking in", as one mother says, food forbidden by the school (like a piece of "adult" chocolate bar), makes the experience of eating food a fun activity since it becomes a mother-child transgression of school regulations. Lastly, branded and convenient fun food is considered an "unhealthy" but crucial reward reinforcing the child's "good behaviour" in the school setting.

In unpacking mothers' experiences of making lunchboxes this research shows how Lunch boxes are "balanced culturally rather than nutritionally" (Metcalfe et al. 2008: 405). Indeed it shows that lunchboxes are a complex process of negotiating different and contrasting requests of good mother, including the school, the child and the self. Also it shows that the relation between health-care and fun-convenience is not a dichotomy as suggested by some literature (Moisio et al. 2004; Bugge and Almås, 2006**).** While mothers include convenient food in order to reward their children for having eaten the more healthy part of the lunch, they also have a wider understanding of the transgressive nature of fun through food, which goes beyond the market offering and understanding of fun. The market with its offer of convenient and ready to consume fun food seems to be excluded from the *reappropriation process* wherein mother and child transform adult food into child food and transgress school's regulations. In this process fun and healthy food are not a dichotomy but they are rather part of the same process of mother and child transformation of adult food into child's food. This research sheds new light on the relation between consumption and care, showing how they are

not a dichotomy, but they are part of the same process of 'care for the children' providing them with both enjoyable and healthy eating.

A Prize in Every Box!
From Cracker Jack to Fun da Middles

EXTENDED ABSTRACT

Fun is a powerful symbolic theme that characterizes contemporary food marketing. From PepsiCo's Fun-for-You product portfolio and Fun da Middles cupcakes to the advertising of olives as 'fun at your fingertips' and Disney Flavorz (that claim to make 'apple eating fun'), fun in terms of food marketing is becoming increasingly commonplace. Yet the everyday connection of fun with food—just like current usage of the word fun itself—is of rather recent origin. At the turn of the 19th century, the notion of 'food fun' was verboten. As American paediatrician Luther Emmett Holt sternly dictated to mothers in his manual *The Proper Care and Feeding of Children,* "young children [age 4-10] should not be allowed to play with their food, nor should the habit be formed of amusing or diverting them while eating" (1916[1894]: 147). Holt was America's most prominent child rearing expert for nearly half a century, until the emergence of the highly popular Dr. Spock (Sealander 2005: 172) who similarly suggested that child feeding was not to be an extension of the playroom (Spock 1946: 356).How, then, did fun become a commonplace and the fulcrum of foods targeted at children? (See Cook 2005, Elliott 2008, 2009, 2009a, 2010, 2012, Schor and Ford 2007) What conditions made this possible and what does this mean? In broad terms, I am interested in tracing how we move from a place where the injunction "*Don't play with your food"* transforms, with the help of commercially packaged edibles, into eating as a license to play. How did food play become acceptable and how did it become convention? And what are the implications of this kind of marketing?

Tracing back to 1912, this paper examines the rise of "fun" in connection with children's food. The analysis incorporates extensive primary research from a variety of archival sources, with particular focus on newspaper, magazine, radio and television advertisements for food products, as well research on (historical and contemporary) cultural and marketing perspectives on childhood (see Cook 2004; Cross 1997; McNeal 1969, 1992, 1999, 2007, Mechling 2000). Advertisements in popular women's magazines such as *Chatelaine,* for example, reveal how marketers first introduced the idea of packaged foods to mothers seeking to "solve the breakfast problem". "Children think they're confections," asserted a 1928 advertisement for Quaker's puffed cereal. By 1939, the idea that food could be 'fun' emerged in advertisements for Rice Krispies (i.e., an advertisement picturing a little girl asserting "Mommy, these Krispies are fun!"). This set the stage for the 1950s and 1960s dominance of child-targeted breakfast cereals—and the subsequent emergence of marketing such as Kraft Foods' 1999 campaign to promote sweetened Post Cereals to children under the slogan, "*The fun starts here.*"

I argue that the rise of food as 'fun' can be understood in three unique waves. The first wave, ***food with toy,*** can be exemplified by a range of products in which companies sought to distinguish themselves from the competition and increase sales by adding in a "prize". Cracker Jack—first mass-produced and sold at the Chicago World's Fair in 1893—was the very first company to put toy "surprises" in their packages. Starting in 1912, children could find a miniature car, animal, gun, airplane, pair of scissors, or similar item in each box. The second wave is ***food and toy,*** which is largely about modelling future gender roles and domestic labor practices for girls. It is exemplified by the Kenner Easy Bake oven. Launched in 1963, it is the first example of a toy centered around food. Ken-

ner's Easy Bake oven stood 14-inches tall and baked treats using the heat of two light bulbs. The toy was explicitly targeted at girls, with early advertisements cajoling "delight the little homemaker today", and "FUN! Safe and **educational**, just like mommy makes" In 1967 General Mills acquired Kenner and rebranded it the *Betty Crocker* Easy Bake oven, advertising miniature packaged Betty Crocker cake mixes to make the experience tastier—and "even more fun". Finally, ***food as toy*** emerges when Jell-O advertising campaigns start explicitly telling children to *play with their food* — forcing parents to relax rules around eating, at least for dessert. This "food play" marketing strategy becomes dominant in the 1990s and beyond, leading to such products as *FunSqueeze* margarine, *Fun-da-Middles* cupcakes*, FunBites* fruit snacks, *FunCheez* processed cheese, not to mention crushable yogurt tubes and fruit snacks that tattoo your tongue, or oatmeal with mini sugar dinosaur eggs that 'hatch' with the addition of boiling water. *Food as toy,* I suggest, represents a fundamental shift in strategy because the food is not accompanied by a toy but has become the toy itself.

Each 'wave' of food fun reflects particular cultural and historical preoccupations: the 'fun' of the Easy Bake oven—exemplifying *food and toy*—was rooted in accepted domestic labour practices of the 1960s, as well as a shift in which homemakers accepted packaged foods (such as cake mixes) as part of 'modern' homemaking. *Food as toy,* in contrast, reflects a far different 'everything for the child' sensibility which is often coupled with dual working parents or single parent homes.

Overall, my analysis reveals how packaged foods promised creativity and entertainment for children, and how the once transgressive notion of "playing with your food" has become increasingly acceptable, largely as a result of commercially packaged foods "specially designed" for children.

SESSION OVERVIEW

This session presents work that deals with the most subtle of marketing communication effects: language. Language is an essential feature of marketing communication that colors and changes consumers' experiences—even subtle differences in the way words are used can significantly impact consumers' reactions to marketing communications. The four papers in this session are linked by a focus on the importance of language for the success of branding and product positioning endeavors. Taken together, they demonstrate that every word matters. Nouns and verbs are not the only words that have an impact; small, seemingly unimportant words such as pronouns, prepositions, and conjunctions should be carefully chosen as well. The aim of this session is to provide a picture of current theoretical perspectives on language effects in consumer research and to explore the breadth of linguistic elements from which these effects originate.

The papers are organized by a descending order of the size of linguistic unit analysis. The first two papers consider the tone in which consumers are addressed. The first paper deals with imperative messages such as "Buy now!" Moore and colleagues show that consumers in committed brand relationships are more likely to perceive imperatives in advertisements as a threat to their freedom and experience reactance against the message. The second paper looks at the pronouns with which consumers are addressed. Lenoir and colleagues find that in languages that possess a distinction between informal and formal address pronouns (such as *tu* and *vous* in French or *tú* and *usted* in Spanish), brands that are perceived as warm, sincere, exciting or low-end benefit more from addressing consumers informally than brands that are perceived as competent, sophisticated or high-end.

In contrast, the third paper exposes small words which can be easily overlooked: prepositions and conjunctions. Patrick and Haws demonstrate how a subtle word change - using "with" instead of "and" - influences perceptions of product combinations: while "and" acts as a bridge between two different products, "with" binds products that complement each other and suggests that one item is of greater value than the other. Finally, the fourth paper arrives at the smallest unit of linguistic analysis: the sound. Kronrod and colleagues demonstrate the embodied power of the phonetic structure of brand names, showing that the movements of the organs in the mouth backward or forward when articulating brand names impact attitudes towards the brand names.

We expect this session to be of interest to a substantial proportion of the ACR community, particularly appealing to researchers working in the areas of branding and advertising. Language is a tool we all have personal experience with, and we anticipate an interesting discussion around the extent to which subtle differences in language affect consumers' responses. Because the four papers investigate different units of linguistic analysis utilizing an array of theoretical perspectives, they provide a substantive contribution to an underexplored - and fun! - field of our research discipline.

Buy Now! Brand Relationships & Consumer Responses to Imperative Advertising

EXTENDED ABSTRACT

Marketing communications often use restrictive messages that contain imperative language, such as "Call today!" or "Buy now!" Such imperative communications can be perceived as restrictions of consumers' freedom, and commonly result in negative consumer responses (Dillard, Palmer, and Kinney 1995; Goldsmith 2007; Miller et al. 2007). Yet, imperative ads are frequently used. A content analysis of America's top ten magazines showed that 72% of print ads contained at least one imperative message (e.g., "Buy Now!" and "Call Today!"), and that each ad contained, on average, two such messages. Thus, we re-examine the effectiveness of advertising that uses imperative language.

We take a novel approach by combining reactance theory with consumer-brand relationship theory. We examine two key consumer-brand relationship types—committed and uncommitted (Fournier 1998; Aaker, Fournier, and Brasel 2004)—and explore how each type impacts reactance to imperative ads. We do so by focusing on a variable that is central to reactance theory and relevant to brand relationship theory: threat perception.

Threat perception is the degree to which consumers feel that a restriction or imperative poses a meaningful threat to their freedom: the higher the perceived threat to freedom, the higher the likelihood of reactance (Brehm 1966). We suggest that consumer-brand relationship type influences threat perception. Specifically, consumer-brand relationships may influence how negatively consumers think their relationship with the brand will be impacted if they do not comply with an imperative. We argue that the negative consequences of non-compliance are greater in committed consumer-brand relationships. In committed relationships, consumers who do not comply with imperatives run the risk of violating relationship norms, experiencing negative emotions such as guilt, or damaging the relationship (Aaker

et al. 2004; Fournier 1998). In contrast, these negative consequences of non-compliance do not apply in uncommitted relationships (Aaker et al. 2004; Fournier 1998). Thus, consumers in committed relationships should view imperatives as more threatening. This higher perceived threat should create greater pressure to comply, resulting in greater reactance (Brehm 1966).

In other words, due to greater threat perception in committed (relative to uncommitted) brand relationships, pressure to comply should increase when an imperative is presented, and greater reactance should result. Due to this increased reactance, consumers should dislike imperative ads more when they come from a committed, as compared to an uncommitted, brand partner. To examine this prediction, we compare consumers' liking of imperative and non- imperative ads from both types of brand partners. In six studies, we examine when imperative ads will elicit negative responses from consumers (i.e., decreased ad liking) and when they will not. We demonstrate that reactance underlies our effects, and that these effects are mediated by threat perception and pressure to comply. We also identify and test moderating variables that attenuate our effects.

Our first studies compared consumers' reactions to imperative versus non-imperative ads.

In study 1a, participants identified a clothing brand with which they had a committed or an uncommitted relationship (using relationships definitions from Aaker, Fournier, and Brasel, 2004 and Rusbult, Martz and Agnew, 1998), and viewed an imperative or a non-imperative ad for the brand. The ads were identical except that the imperative ad included a "Buy now!" message. We found a brand-relationship by ad interaction. Participants liked the imperative ad from a committed brand partner less than the non-imperative ad from the same brand partner, while participants liked the imperative ad from the uncommitted brand partner just as well as the non- imperative ad. We replicated these findings in studies 1b and 1c using a different imperative ("Visit us!") and different dependent variables. Study 1b measured participants' likelihood of visiting the store/brand in question; study 1c asked participants to allocate $25 between a brand gift card and cash (they were entered to win their chosen allocation in a lottery).

Study 2 added a measure of individual reactance (Hong and Faedda 1996) and embedded imperative and non-imperative ads for pre-tested committed and uncommitted brand partners into a magazine that participants read. As predicted, our results replicated for high, but not low reactance individuals, suggesting that reactance underlies these findings.

In study 3, we examined threat perception as a mediator of consumers' responses to imperative ads. Participants identified a personal hygiene brand with which they had either a committed or an uncommitted relationship, and then saw an imperative ad from that brand. We measured threat perception in a two-step process: first, we assessed consumers' perceptions of the negative consequences (e.g., guilt, negative emotion) of not complying with their brand partners' imperative. We then measured consumers' likelihood of complying with their brand partners' imperative. As expected, participants who identified committed brand partners perceived greater negative consequences of non-compliance, which predicted increased likelihood of compliance. Both mediators negatively predicted ad liking. Finally, negative consequences and compliance mediated the effects of relationship type on ad liking using a two- step serial mediation model, demonstrating the hypothesized role of threat perception.

Our final two studies investigated two variables that should reduce the negative impact of imperative language from committed brand partners. In study 4, we removed the relationship threat by allowing some participants to affirm their committed or uncommit-

ted brand relationship prior to viewing an imperative or a non-imperative ad. When consumers in committed (but not uncommitted) relationships affirmed their relationships, they no longer responded negatively to imperative ads. In study 5, we used an imperative message that is already part of a committed relationship contract, and contrasted ads using "buy now" versus "buy from us" imperatives. Since consumers in committed relationships already comply with loyalty restrictions ("buy from us"), they do not react negatively to such imperative ads.

In sum, consumers respond negatively to imperative advertising from committed but not uncommitted brand partners due to differences in threat perception. The current work introduces relationship variables to reactance theory, and clarifies when and why different restrictions from different relationship partners elicit negative responses to imperative language in advertising.

What Shall I Call Thee? The Impact of Brand Personality on Consumer Response to Formal and Informal Address

EXTENDED ABSTRACT

In recent years, marketing researchers have become aware of the impact of linguistic factors on the effectiveness of marketing communication. Thus far, however, interest in sociolinguistic factors in monolingual contexts has, with some exceptions (Kronrod, Grinstein and Wathieu 2012a and 2012b; Sela, Sarial-Abi and Wheeler, 2012), been relatively limited. In particular, the impact of formal and informal address remains to be understood. In marketing communication, address choices - that is, deciding to address another person formally or informally - are everywhere. Today, English speakers rarely wonder whether it would be more appropriate to say *you* or *thou* to one another. But in many languages, different address pronouns are still used in formal and in informal situations: think for instance of the Spanish *usted* and *tu*, the French *vous* and *tu*, the German *Sie* and *Du*, the Dutch *u* en *jij*, or the Russian *vy* and *ty*. Globally, among the 10 languages counting more than 100 million native speakers - a list which includes Mandarin, Castilian Spanish, Hindi-Urdu, Bengali, Portuguese, Russian, Japanese and Punjabi - Modern English is the only one, together with some dialects of Arabic, to not possess such a distinction.

This contrast is known as the T-V distinction, after the Latin forms Tu and Vos (Brown and Gilman, 1960/2003). The T pronoun is typically used to express solidarity, directness and informality, whereas the V pronoun is used to express respect, distance, and formality. In many cases, both pronouns are used in marketing communication. This means that for billions of consumers worldwide, both formal and informal address pronouns constitute an omnipresent feature of communication in the marketplace. This is especially the case in advertising – and yet we do not understand the consequences of formal and informal address use for consumers' attitudes. On what basis should advertisers decide which type of address to use? In this paper, we explore the impact of brand positioning on consumers' expectations for, and reactions to, address pronouns.

Marketers have to decide on the most appropriate form of address for a particular communication depending on the context, taking into account language-specific norms as well as other factors such as target characteristics. We argue that address can also be chosen to reflect a brand's positioning and values - and that making address choices that are consistent with these values will have a positive impact on consumer response. We expect that informal "T" address will elicit more positive responses when the brand is perceived as warm, sincere, exciting or low-end than when it is not,

whereas formal "V" address will elicit more positive address when the brand is perceived as competent, sophisticated, or high-end than when it is not.

In study 1, we show that informal address is more consistent with the positioning of warm brands, whereas formal address is more consistent with the positioning of competent brands, as reflected in consumers' preferences. A first group of Dutch participants rated a series of brands selected among the Interbrand Best Global Brands on warmth and competence. Then, for each brand, other participants expressed their preference for either formal or informal address in the brand's communication. Both perceived warmth and competence had a significant effect on preference for formal address, with high perceived competence associated with a greater preference for formal address and higher perceived warmth associated with a greater preference for informal address.

In study 2a and 2b, we investigate the impact of brand personality on address expectations and preferences. In study 2a, we looked at the impact of a brand's association with excitement or competence. Russian participants were shown a magazine ad for a fictional jeans brand called "YourJeans", which was presented as either exciting or competent. Participants translated the brand name and the slogan into Russian. Responses were coded as using the formal (*vy*) or the informal pronoun (*ty*). A logistic regression analysis revealed a significant association between brand personality and address translation formality: in the competence condition, 29.1% of the translations used formal address. In the excitement condition, only 7.8% of the translations used formal address. In study 2b, we explored the impact of perceived sophistication and sincerity on address preferences. Chanel and Moët & Chandon (sophisticated) and Dove and Nutella (sincere) were selected by pretest. For each brand, Dutch and Dutch-speaking Belgian participants chose a slogan from a set of formal and informal slogans. A repeated-measures logistic regression revealed a significant effect of brand on address preference. Formal address was selected 58.2% of the time for Chanel and 57.5% of the time for Moët & Chandon, but only 42.9% of the time for Dove and 42.9% of the time for Nutella.

In study 3, we focus on the role of low-end and high-end positioning in moderating the effect of address on consumers' attitudes.) Participants were approached in office and public transportation settings in the Netherlands and evaluated a printed ad for a fictional low-end or high-end sunglasses brand. The address pronoun (*u* vs. *jij*) changed to implement formal or informal address. A floodlight analysis (Spiller, Fitzsimons, Lynch, and McClelland, 2013) revealed a significant interaction effect of address pronoun and positioning on purchase intention in consumers aged 29.46 and above, on attitude towards the ad in consumers aged 33.52 and above, and on attitude towards the slogan in consumers aged 47.06 and above. These results suggest that older age does not simply result in a greater preference for formal address, but rather in a greater sensitivity to address appropriateness.

In conclusion, the distinction between a formal address pronoun "V" and an informal address pronoun "T" is a feature of the marketplace for billions of consumers worldwide, and advertisers have to decide which of the two is more appropriate for a particular ad. We show that the characteristics of the target consumers are not the only factors that need to be taken into account. The brand itself matters as well. Our findings show that brand positioning is not only a predictor of address expectations, but also moderates the effect of address choice on consumers' attitudes.

"And" Bridges, "With" Bonds: A Lexical Inferencing-based Framework for Influencing Perceptions of Product Combinations

EXTENDED ABSTRACT

Will a consumer prefer eggs with ham or eggs and ham? In linguistic analysis, words can be categorized as content words (e.g. "eggs", "ham") or function words (e.g. "and", "with"; Chung and Pennebaker 2007). Function words include prepositions, articles, conjunctions, and pronouns that hold the content words together to form meaningful sentences. Function words are often considered devoid of meaning and are hence overlooked. The current research examines the conjunctions "and" and "with", and proposes that although these are used interchangeably, they differentially signal integration and therefore value when used to communicate product combinations.

Our central thesis is that the conjunction "and" bridges two products together, without necessarily integrating them (purely conjunctive role) whereas "with" goes beyond bridging and actually bonds the products together in an integrative manner. This level of product integration is of particular relevance when the products themselves are unequal in value, and the prepositional role of "with" serves to indicate both unequal valuations and better integration from having the products bundled together. Further, since individuals differ in their propensity to attend to subtle differences in language (Chung and Pennebaker 2007), we argue that an individual's processing style might explain the effect of conjunction use on the valuation of product combinations. We expect that a holistic processing style should result in less attention to the function words and the valuation they connote, while an analytic processing style should result in greater attention to the semantic meaning the conjunction conveys.

In sum, we expect that (1) the conjunction "with" connotes greater value than "and" when products are complementary, yet unequal in value (2) this effect emerges when consumers are primed to use a more analytical processing style, and 3) other cues of integration may facilitate or diminish these differences in the effectiveness of "with" and "and" in communicating value or perceived enjoyment to consumers.

In Study 1a, the 126 undergraduate participants were randomly assigned to one of four conditions following a 2 (conjunction: "with" vs. "and") X 2 (product combination: unequal value (steak/salad) vs. equal value (soup/salad)). After being presented with one of the four product combination options, they indicated their perceived value of the product combination. Results revealed significant main effects for both equal versus unequal bundles and for conjunction cue, such that "with" was higher than "and". These main effects were qualified by a significant interaction showing that while combination cue did not affect the equal value combination, "with" was perceived more favorably than "and" for the unequal value combination. As predicted, this study demonstrates that for unequal value combinations, "with" results in higher perceived value than "and". In a follow-up study (study 1b), we used non-food combinations and asked participants to evaluate an audio system and controller. Again, the product bundle connected by "with" was perceived as more attractive than the one joined by "and" again implying the enhanced value through the integrative function of "with".

In Study 2, we focused on unequal bundles only and measured processing style to test our hypothesis regarding the underlying process of our effect. The 118 participants were presented with one of two prix fixe brunch menus in which they either chose between "A: eggs with ham" and "B: eggs and bacon" OR "A: eggs and ham" and "B: eggs with bacon". The results revealed the expected main effect,

such that individuals preferred option A (eggs with ham) in the first menu and option B (eggs with bacon) in the second menu. Spotlight analysis revealed a significant interaction between conjunction use and processing style on option preference, suggesting that analytic processors were more likely to discern the differences between conjunction use.

In Study 3, 225 participants were randomly assigned to a 2 (conjunction: and vs. with) X 2 (thinking style: analytic vs. holistic) between-subjects design. Participants first completed a priming task to induce a holistic or analytic thinking style. Next participants were exposed to an advertisement for a frozen entrée product positioned as "Grilled Peppercorn Steak and/with Vegetable Medley" depending on condition. Participants responded to two items regarding their perceived satisfaction with the entrée. Results revealed a significant interaction between combination cue and thinking style. Specifically, only those participants in an analytical mindset showed increased preferences for the "with" combination, providing evidence that only when more attention is paid to the subtle language cues in one's environment does the combination cue matter.

In Study 4, 177 MTurk participants viewed a product combination of chips and salsa in which complementarity was influenced through matched or mismatched brands. Results revealed a significant interaction between conjunction and brand match/mismatch, such that when the brands were coordinated, "with" led to higher evaluations than did "and", but the opposite was true when the brands were mismatched.

Finally, in Study 5 (n = 132), we manipulated a separate cue of integration by presenting two food products (peppercorn steak and vegetable medley) either on one plate or two along with our manipulation of conjunctive cue ("with" vs. "and"). The results revealed that the visual cues were more powerful than the subtle cues of language, as the presentation of two separate plates was evaluated more favorably in conjunction with "and" rather than "with" and the typical pattern of results in which "with" was preferred to "and" was eliminated by the visual plate cues.

Overall, the current research adds to a growing literature on the powerful effects that subtle language differences have on consumer preferences. Our results underscore the importance of investigating the functioning of often-ignored function words like "and" and "with" in language use.

The Effect of Phonetic Embodiment on Attitudes towards Brand Names

EXTENDED ABSTRACT

Rising in a global culture, brand names today oftentimes lack meaning to avoid specific connotations. Therefore marketers create innovative nonsense brand names for their products. The purpose of this work is to explore the possible effects of the phonetic structure of nonsense brand names on brand attitudes. In this work we employ an innovative approach introducing research on embodiment into research on phonetic symbolism.

Research on sound symbolism has demonstrated that sounds create meaning and may affect attitudes towards brand names. For example, Sapir (1929) showed that while back vowels (e.g. mal) are associated with large size, front vowels (e.g mil) are associated with small sizes. Yorkston and Menon (2004) found that the brand name Frosh for an ice cream was preferred over the brand name Frish, as it was perceived as smoother, richer, and creamier than the Frish name. Recently, Lowrey and Shrum (2007) showed that participants prefer a fictitious brand name whose vowels are associated with attributes which are desirable for the category (e.g. sharpness for a knife).

The works on phonetic symbolism demonstrate the importance of the role played by phonetic sounds to construct meanings. However, to the best of our knowledge no previous work has inquired into the effect of the movement of the articulation organs within the space of the oral cavity while pronouncing the phonemes of a brand name. This question is the focus of the current work.

To answer this question we introduce research in embodied cognition, which ties bodily movements to the creation of, and effect on, attitudes and affect. For example, in Chen and Bargh's (1999) classic work, positive attitudes were more accessible in the participants' minds when they were pulling a lever towards them, as opposed to pushing it away.

Following the research on sound symbolism and embodied cognition, we suggest that there may be a phenomenon of phonetic embodiment, whereby the movement of the organs in the oral cavity during the articulation of a brand name may affect attitudes regarding that name. Specifically, movement from front sounds like "i" and "b" towards back sounds like "u" and "k" simulates food accepting/swallowing. To the contrary, movement of the organs from back sounds to front sounds simulates food rejection/spitting. We suggest that names with back-to-front (bf) oral movements (like Goomie) will elicit more negative attitudes than brand names where the sounds are ordered in a front-to-back (fb) direction of the articulation organs (like Meegoo), due to the movement of articulation organs inside the oral cavity.

Four studies investigate this process. In study 1 we demonstrate the basic phenomenon. Participants indicated their intent to purchase one of two brand names, based on their names only: Goomy (bf) and Feeco (fb). Then, participants indicated their preference between two companies – Picoo (fb) and Gobi (bf) – on company evaluation items, such as "has better customer support", "can sell for higher price", sounds more credible". Participants also indicated their preference to purchase one of the brand names. Consistent with our hypothesis, results suggest that for all tasks the front-to-back (fb) words, names, and brand names elicited more positive attitudes than the back-to-front (bf) words, names, and brand names. As predicted, the likelihood to purchase Feeco was significantly higher than the likelihood to purchase Goomy; and Pikoo (fb) company was more highly evaluated than Gobi (bf) company.

In study 2 we tested the possible moderation of product category for this phenomenon. Specifically, we assumed that food products, embodied as an intake motion (fb) may impact the effect we found in study 1. We compared the same tasks for food and non-food products. All food/non-food comparisons were between subjects, whereas articulation direction comparisons were within subject. Participants first evaluated the quality, popularity, and likelihood to try any of 6 items in a menu of cocktails (movies), some of which were bf (e.g. Kobim) and some fb (e.g. Megu). Next, they predicted the success of 2 new products in their category – soup (soap) – having either bf (Goven) or fb (Megu) phonetic structure direction. Finally, participants indicated their trust for two brand names (Maitoug (fb) and Kuanbei (bf)) in one of two categories (snacks or hand cream). Results replicated the findings in study 1, suggesting that brand names with a fb articulation direction elicit higher attitudes than brand names with bf articulation direction. However, this effect was attenuated and non-significant for all food products in all comparisons.

Study 3 extends the findings of study 2 by comparing non-food products (e.g. pen) with two types of food: edible (e.g. sandwich) and spoiled (e.g. molded sandwich). The purpose of this study was to further test the phonetic embodiment hypothesis in the case of food products. Results of this study support our prediction that food

products bias the phonetic embodiment effect towards always-intake: participants consistently preferred fb brand names for non-food products, had no preference for articulation direction for food products, and preference for bf brand names for spoiled food.

Finally, in study 4 we tested the mechanism of approach-avoidance associated with the phonetic embodiment effect of nonsense brand names. Participants were biased to prefer fb(bf) brand names for non-food products after viewing (un)pleasant/ approach (avoidance) pictures. These results were replicated in a physical approach-avoidance task (pushing/pulling a table top). Study 4 emphasizes the underlying mechanism responsible for the phonetic embodiment effect.

Our findings indicate that brand names which are comprised of sounds that create a movement of the articulation organs from the back(front) to the front(back) have a negative (positive) effect on attitudes, because the movement simulates food rejection(intake), which activates avoidance (approach) mechanism. In support for these results, the effect of articulation direction is attenuated in food products, as the intake embodied movement interferes with the direction of movement dictated by the sounds. Further research that will explore the effect of other product categories, as well as the combination of articulation direction and meaning, may reveal additional aspects to the question of the effect of articulation direction on attitudes towards brand names.

Joseph P. Redden, University of Minnesota, USA

SESSION OVERVIEW

Despite the fact that over 50% of Americans report wanting to lose weight (Brown 2013), the obesity rate has remained stable for nearly a decade (Cohen 2014). Regulators have attempted to aid consumers in their battle against obesity by imposing legislation to encourage more healthful eating (e.g., ban on large size sugary soft-drinks). However, many of these policies have been met with strong consumer reactance, and the effectiveness of these restrictive approaches has been questioned. In light of the limited success of these more paternalistic approaches, behavioral science has been advocated as an alternative means of nudging consumers towards more healthful consumption, since many behavioral interventions are subtle and less likely to evoke consumer reactance or resistance (Just et al. 2008; Sunstein and Thaler 2003). In addition, behavioral interventions are often easy and inexpensive to implement and have strong practical implications (Just et al. 2008). The theme of the proposed special session relates to "the behavioral science of eating" and how subtle behavioral interventions can nudge consumers towards more healthful consumption.

In the first paper, Morewedge, Garbinsky, and Shiv focus on how remembering end moments of a consumption experience can increase the interval between food consumption episodes. They find that recency effects lead consumers to remember the end (vs. initial moments) of a consumption episode. Since sensory specific satiety is higher at the end of a consumption episode, remembering the end (vs. initial moments) of consumption leads to longer interconsumption intervals. In the second paper, Cornil and Chandon identify hedonic sensory imagery as a possible means of nudging consumers towards more healthful food choices. Their results show that imagining consumption of small portions of hedonic foods leads to increased expected enjoyment of eating and can lead children and adults to choose smaller portions. Biswas, Szocs, and Inman examine how the sequential order in which consumers are exposed to healthy and unhealthy food items and the sensory mode of evaluation influence choice. They find that when consumers visually evaluate a sequence of healthy (H) and unhealthy (U) foods, preference for the healthy

option is greater for the H-U (vs. U-H) sequence. However, the effects reverse when consumers get to sample (i.e., taste) the products. Finally, Haws, Liu and Redden examine associations between consumption patterns and weight loss in a clinical weight loss trial and find that dietary variety as well as specific types of foods/beverages are associated with weight loss.

Collectively, the four papers in this session aim to address the important research question of how behavioral science can be applied to food contexts to aid consumers in making more healthful choices. The proposed special session brings together leading scholars and addresses behavioral science of eating using diverse methods (e.g., field experiments, lab experiments, and a longitudinal clinical trial) and multiple populations (e.g., adults, children, and dieters enrolled in a trial). We expect this session to have a broad appeal.

Interference of the End: Why Recency Bias in Memory Determines When a Food is Consumed Again

EXTENDED ABSTRACT

Portion sizes in the United States have been steadily increasing since the 1980s (Young & Nestle, 2002), which has affected both food intake and enjoyment. Larger portions imply larger normative amounts of food to consume, which increases overall intake. People finish the portion they are given whether it is a small or large portion (Geier, Rozin, & Doros, 2006). Increased intake also leads to greater sensory-specific satiety. As each bite of food is less pleasant than the one before it, eating more of a food reduces the average enjoyment of that food during a particular consumption experience (Rolls et al., 1981). Sensory-specific satiety is a major factor regulating food intake decisions in the present moment (e.g., Maier, Vickers, & Inman, 2007; Rolls et al., 1981), but if and how memory of past satiety affects future consumption decisions is unclear.

We suggest that a recency bias in memory leads satiety at the end of the food consumption experience to influence how long people wait until consuming that food again in the future. We argue that recency effects are especially likely to prevail in the gustatory domain because of memory interference. Interference is greater for more similar experiences, such that maximum interference occurs when experiences are identical (Oberauer & Kliegel, 2006). Eating, in many contexts, is a highly repetitive experience. A glass of juice, bowl of ice cream, or bag of potato chips contains many units of very similar stimuli that are consumed one sip or bite at a time until the entire portion has been eaten. We suggest that the repetitive nature of consumption should cause memory of the end of an experience to interfere with memory of the beginning, making the beginning less salient (Eysenck, 1977; Schank, 1982).

As memory for end moments of a consumption experience should interfere with memory for initial moments, we hypothesize that end enjoyment has a greater influence on the inter-consumption interval (ICI), defined as the number of days that pass until the consumption of a food is repeated. In this way, sensory-specific satiety influences future consumption as the more satiated a person is to a food, the lower their end enjoyment and thus the longer the interval until that food is consumed again. We report three experiments providing support for our hypothesis.

Experiment 1 examined whether recollection of initial or end enjoyment plays a greater role in determining the ICI. Controls ate a large or small portion of crackers and decided the next day when to

eat those crackers again. We used portion size to manipulate end enjoyment, as a larger portion should result in greater sensory-specific satiety at the end than a smaller portion. We also included two conditions in which participants were guided to recall a moment during their previous consumption experience before deciding when to eat the crackers again. In the end recall condition, participants recalled the end of their previous consumption experience. In the beginning recall condition, participants recalled the beginning of their previous consumption experience.

Recency effects played a larger role than did primacy effects in determining ICI. Participants in the control conditions who ate a larger portion desired a longer ICI than did participants who ate a smaller portion. Identifying the critical role of end satiety, end enjoyment of the consumption episode mediated the difference in ICI between the large and small portion conditions. Suggesting that better recollection of the end underlies this recency effect, participants in the end recall condition exhibited the same differences between conditions (and the meditating effect of end recall) as did controls. In contrast, participants in the beginning recall condition did not exhibit a difference in the desired ICI between the large and small portion conditions (so no mediation analysis could be performed).

Experiment 2 reversed the relationship between end enjoyment and amount eaten with a reset condition. *Controls* drank juice and then ate two crackers. Participants in the *reset condition* did the same, but also drank an additional sip of juice after a delay. The next day, all participants reported how soon (days until) they would like to consume the juice again. Our logic was that the crackers would partially reset adaption to the juice (Epstein et al., 1992), increasing end enjoyment for participants in the reset condition. We selected crackers to reset enjoyment because past research has shown that perceiving food as belonging to a different category is an important determinant of satiation (Redden, 2008). We found that end enjoyment rather than portion size determined ICI: Participants in the reset condition desired a shorter ICI than did controls despite having consumed more juice, and end rather then beginning enjoyment mediated this difference in ICI between conditions.

Experiment 3 directly tested whether end enjoyment is more influential because of memory interference. All participants drank 8oz of grape juice. After consuming each ounce, participants in the serial rating condition rated enjoyment on separate pages (one page per rating), whereas participants in the simultaneous rating condition rated enjoyment after each ounce on the same page (one page for all ratings). To rule out the potential influence of rating the food while consuming it (Larsen, Redden, & Elder, in press), we included a control condition that made no ratings during consumption. After consuming the juice, all participants retrospectively rated their initial enjoyment. The next day, all participants reported how soon (days until) they would like to consume the juice again.

As evidence that interference is responsible for the effect of end enjoyment on the ICI, the format of ratings in the simultaneous rating condition appeared to facilitate memory for initial enjoyment of the juice. Participants in the simultaneous rating condition better recalled their initial enjoyment of the juice than did participants in the serial condition. As we predicted, their better memory for initial enjoyment appeared to influence their desired delay: There was a shorter ICI for participants in the simultaneous condition than for participants in the serial and control conditions.

Happier with Less? Increasing the Hedonic Appeal of Smaller Portions with Enhanced Hedonic Sensory Imagery

EXTENDED ABSTRACT

Consumers generally expect that eating enjoyment increases with food quantity, especially if the food is palatable (Sorensen et al. 2003). In reality, eating a small portion is just as enjoyable as eating a large portion, and overall eating enjoyment can even decrease with larger portions (Rode et al. 2007; van Kleef et al. 2013). How can we make consumers realize that they will be happier with less food?

We know that the first bites of food are the most pleasant and that subsequent bites are decreasingly pleasant, a phenomenon called sensory-specific satiation, experienced by all individuals since infancy (Rolls et al. 1981). We also know that mentally simulating an experience makes people retrieve cognitive representations, emotions and bodily states related to that experience (Barsalou 2009). For instance, repeatedly imagining eating a food (at least 30 times) leads to a simulated state of satiety and decreases the desire to eat (Morewedge et al. 2010).

In the current research, we investigate how to lead consumers to choose smaller portions *without* satiating them or decreasing desire. We develop a new intervention, "enhanced hedonic sensory imagery", which consists in vividly imagining the taste, smell and oro-haptic sensations of three tasty foods, prior to choosing a portion size. Mentally simulating a pleasurable sensory experience should help consumers retrieve more accurate representations of the relation between sensory pleasure and food quantity. Hence it should increase the hedonic appeal of smaller portions (higher pleasure anticipations from the first few bites), and simultaneously decrease the hedonic appeal of larger portions (better anticipation of sensory satiation), promoting the choice of smaller portions without affecting desire for the chosen portion. By considering hedonic sensory imagery as an ally of healthy eating, our hypothesis contrasts with past research, which identifies spontaneous sensory imagery as the trigger of food cravings, and suggests that blocking sensory cues or imagining negative consequences on health should help consumers control their food intake (Giuliani et al. 2013; Tiggemann and Kemps 2005).

In Study 1, 55 Americans were assigned to either an enhanced sensory imagery condition (imagine vividly the hedonic eating sensations of three desserts shown on pictures) or a control condition (rate office chairs). Then, all participants provided their maximum willingness to pay (WTP) for one small and one large slices of the same cake. The sensory imagery intervention had no main effect on WTP (F<1), but significantly interacted with portion size (F(1,53)=4.1, p<.05) : sensory imagery (vs. control) increased WTP for the small slice (resp. M=$3.0 ; M=$2.3) and directionally decreased WTP for the large slice (M=$3.8 ; M=$4.0).

In Study 2, we ruled out the alternative explanation that small portions are associated with higher-quality food by assigning 41 five-year old French children to a food sensory imagery condition (similar to study 1) or a non-food sensory imagery condition, in which they imagined non-food hedonic sensations such as feeling the sun on their skin. Subsequently, the children were asked to choose stickers of different sizes representing cakes and fruit juices and to choose portions of cake and juice for an afternoon snack. Across all four replications (cake sticker, juice sticker, real cake, real juice), food sensory imagery made children choose smaller portions (all p's <.03).

Study 3 compared the effects of sensory and health imagery on both expected and experienced pleasure. We assigned 336 young French women (with heterogeneous dieting tendencies) to a food sensory imagery condition, a control condition, or a health imagery

condition in which they imagined how eating three desserts would impact their health and weight. Subsequently, one group rated the expected enjoyment of five portion sizes of brownies and chose one portion. Three other groups ate the smallest, the medium, or the largest portion and rated their actual enjoyment. We also examined moderating effects of dieting, expecting that sensory imagery would backfire in dieters, for whom hedonic thoughts about food lead to compensatory overeating (Stroebe et al. 2013). For normal eaters, both sensory imagery and health imagery led to choosing smaller portions compared to control (resp. z=-2.19, p=.03; z=-2.45, p=.01). However, health imagery decreased expected enjoyment of all portions compared to control (z=-1.89, p=.06), whereas sensory imagery increased expected enjoyment of smaller portions (z=2.4, p=.02) and decreased expected enjoyment of larger portions (z=-2.05, p=.04). Furthermore, a conditional logistic regression revealed that the choice of smaller portions was more determined by pleasure expectations in the sensory condition than in the health condition (z=5.75, p<.001). For dieters, sensory imagery backfired: it increased expected enjoyment of all portions (z=3.5, p<.001), leading to choice of larger portions (z=2.03, p=.04). Actual eating enjoyment was unaffected by the intervention and consistently decreased with size (t=-4.8, p<.001). Thus, sensory imagery led normal eaters to choose smaller portions which were, indeed, preferred before and after consumption.

In the last study, we showed that it is possible to enhance sensory imagery simply by using more vivid menu descriptions. 89 online Americans had to choose one size among six portions of cake. We provided vivid sensory information about the cake (sensory condition), information about fat and calories (health condition) or no information (control). Then, all participants chose one size among seven portions of whipped cream (no information in all conditions). Participants chose a smaller cake in both sensory and health conditions, compared to control (resp. F(1,86)=4.7, p=.03; F(1,86)=3.7 ; p=.05). The effect carried over to subsequent portion choice of cream in the sensory condition (F(1,86)=3.7 ; p=.05) but not in the health condition (F<1).

Overall, we show that enhanced hedonic sensory imagery increases the hedonic appeal of smaller (but not larger) portions, leading to moderation *without* hedonic cost. This suggests a way for food marketers to switch from a quantity business model to one focused on the quality of sensory experience. Thereby, marketers could decrease portions sizes and increase price per gram while keeping consumers satisfied. Marketers would also address the growing concerns about the contribution of increasing portion sizes to the obesity epidemic (Nestle 2003).

Making Choices when Sequentially Encountering Healthy and Unhealthy Options: The Role of Sensory Mode of Evaluation

EXTENDED ABSTRACT

Suppose while browsing through a retail store (such as Costco), a consumer first encounters a healthy item and then encounters an unhealthy item versus if she encountered the unhealthy item first and then the healthy item. Would the sequence in which she encounters the healthy and unhealthy items influence her choice? Moreover, some stores, many restaurants in food courts and even some school cafeterias give consumers the opportunity to sample food items before purchase. Would the effects of the sequence in which healthy and unhealthy items are encountered influence choice when the consumer only sees the items versus if she gets to sample (i.e., taste) them? This is the focus of our research.

Prior research examining how consumers make choices between healthy and unhealthy food options (e.g., Dhar and Wertenbroch 2012; Shiv and Fedorikhin 1999) has presented the food items simultaneously. While Chernev (2011) examined calorie estimation for sequentially encountered food items, no study has examined effects of order sequence of healthy and unhealthy items on product choices. Equally importantly, in these prior studies, participants only evaluated the products visually without actually sampling/tasting them. We argue (and our studies show) that the effects are influenced by the sensory mode of evaluation (i.e., visual vs. gustatory through actual sampling), whereby the preference pattern observed when consumers choose between visually evaluated sequence of healthy and unhealthy options *reverses* when consumers actually sample the options.

We propose that when evaluating a sequence of healthy and unhealthy options, the first stimulus tends to become the reference point for evaluation of the subsequent stimulus in the sequence (e.g., Biswas et al. 2010, 2014; Carlson et al. 2006). Thus, if the first product encountered in a sequence sets the reference point for the mode of decision making and if healthy foods are superior on cognitive dimensions while unhealthy foods are superior on affective dimensions (e.g., Shiv and Fedorikhin 1999), then for a healthy-then-unhealthy sequence (H-U), cognitive processing should dominate while for an unhealthy-then-healthy sequence (U-H), affective processing should dominate. This would imply that consumers would be more likely to trade off affective aspects of taste in favor of cognitive aspects of calorie content when options are presented in the H-U sequence. That is, we are predicting primacy effects, whereby preference for the healthy product (which is cognitively driven) will be higher for the sequence of H-U (compared to U-H). However, we also predict that actually sampling the food items will reverse this effect leading to recency effects. With taste sampling, recency effects should occur since traces from later experiences tend to erase the traces from sequentially earlier experiences (Biswas et al. 2014). We tested our hypotheses with the help of four experiments.

Study 1A was a field experiment conducted at a cafeteria style restaurant at a major theme park; the restaurant layout allowed sequential encountering of food items when standing in the cafeteria line. For the H-U condition, the healthy dessert option (fruit) was displayed at the very beginning of the food line before the unhealthy option (cheesecake), while for the U-H sequence, this was reversed. Consistent with our hypothesis, the share of the healthy item was greater on the day when the items were displayed in the H-U (vs. U-H) sequence (65.45% vs. 40.48%; $\chi^2 = 5.99$, $p < .05$).

Study 1B was a single-factor between subjects experiment with three manipulated conditions (H-U sequence vs. U-H sequence vs. control condition of simultaneous presentation). Fruit salad (chocolate cake) was used as the healthy (unhealthy) option. A higher proportion of participants preferred the healthy food item in the H-U (vs. U-H) sequence (73.21% vs. 55.17%; $\chi^2 = 4.03$, $p < .05$) as well as versus the simultaneous presentation condition (51.79%; $\chi^2 = 5.49$, $p < .05$). Preferences were similar for U-H and simultaneous presentation ($\chi^2 = .13$, $p = .72$).

In Study 2, the results of a 2 (food sequence: H-U vs. U-H) X 2 (induced processing mode: cognitive vs. affective) between subjects experiment showed an interaction effect on choice (Wald $\chi^2 = 5.89$, $p < .05$). Consistent with our theorizing, when cognitive processing mode was induced, there was greater preference for the healthy item in the H-U (vs. U-H) sequence (53.13% vs. 22.73%; $\chi^2 = 4.99$, $p < .05$) with the effects getting attenuated under affective processing (37.50% vs. 46.15%; $\chi^2 = .38$, $p = .54$).

Study 3 examined the moderating role of sensory mode of evaluation. Study 3 was a 2 (food sequence: H-U vs. U-H) X 2 (sensory mode of evaluation: visual only vs. taste sampling) between subjects design experiment. The results of a logistic regression showed a significant interaction effect (Wald $\chi^2 = 5.89$, $p < .05$). When participants visually evaluated the food items, there was greater preference for the healthy item in the H-U (vs. U-H) sequence (52% vs. 29%; $\chi^2 = 3.40$, $p < .05$). In contrast, when participants actually sampled the food items, the pattern of results reversed, whereby there was marginally greater preference for the healthy item in the U-H (vs. H-U) sequence (48% vs. 29%; $\chi^2 = 2.63$, $p < .10$).

Collectively, the results of our experiments suggest that the sequence in which consumers are exposed to healthy and unhealthy food items and the sensory mode of evaluation influences their choice between the two options. When options are visually evaluated, we find primacy effects, whereby there is greater preference for the healthy option in the H-U sequence (vs. U-H sequence or simultaneous presentation). However, when the options are taste sampled, recency effects lead to greater preference for the healthy option in the U-H (vs. H-U) sequence. Overall, our findings provide insights into preference formation when sequentially encountering healthy and unhealthy items and the role of sensory mode of evaluation. In terms of conceptual and practical implications, choices for healthy versus unhealthy items are significantly influenced by the sequential order in which they are encountered and the sensory mode of evaluating them (through visual only versus actual taste sampling).

Consumption Patterns and Weight-Loss

EXTENDED ABSTRACT

According to a recent Gallup poll, around 30% of Americans are currently trying to lose weight (Saad 2011). Of those trying to lose weight, the majority reported various dietary changes as being the most effective strategies for losing weight (Saad 2011). Yet relatively little is understood about which consumption patterns relate to greater actual weight-loss. The present study aims to fill this gap by examining the associations between different consumption patterns and weight-loss.

This study includes data from 230 participants in a clinical weight-loss trial that lasted, on average, 94 days for each participant. Some participants were assigned to consume a high-fat diet, and other participants were assigned to consume a low-fat diet. All participants were weighed at the beginning and the end of the weight-loss trial. The majority of participants completed multiple dietary recalls ($M = 6.7$), in which they provided detailed records of all of the foods and beverages that they consumed in the previous 24 hours. These records were then coded using the NCC Food and Nutrient Database.

Overall, we found that the average participant lost 11.2 pounds during the weight-loss trial. Surprisingly, the average weight-loss did not differ across participants in the low-fat and high-fat diets ($M_{lowfat} = 11.5$ vs. $M_{highfat} = 11.0$, $p = .66$), yet there was considerable variation in weight-loss across participants in both diet groups ($SD_{lowfat} = 8.6$ vs. $SD_{highfat} = 8.9$ pounds). Thus, the focus of our research is to test for associations between different consumption patterns and weight-loss, and to examine whether such associations differ depending upon diet type (low-fat versus high-fat). Below, we report some initial analyses examining (a) the association between variety in foods consumed and weight-loss; and (b) the association between types of foods consumed and weight-loss; and (c) whether these associations differ by diet type. Beyond these initial findings, we will also have conducted a range of additional analyses on this extremely rich data set well before October 2014.

We first examined the association between dietary variety and weight-loss. Although there are multiple potential ways to calculate dietary variety, we chose to focus initially on across-day dietary variety (calculated as the number of unique NCC food groups consumed divided by the number of foods consumed). We found that across-day dietary variety was negatively correlated with weight-loss, but only for participants who were assigned to consume a high-fat diet ($r = -.43$, $p < .0001$). We replicated this result using the Herfindahl index as our measure of variety ($r = .16$, $p < .07$). These findings indicate that greater dietary variety is associated with less weight-loss, particularly for those on a high-fat diet (which is what many weight-challenged people consume). This finding is consistent with research showing that variety can increase intake (Rolls, van Duijvenvoorde, & Rolls 1984), thereby potentially deterring weight-loss.

We then examined the associations between consumption of different types of food (water, meat, grains, fruits, vegetables) and weight-loss. For participants on a high-fat diet, simple bivariate correlations showed that water consumption was positively associated with weight-loss ($r = .43$, $p < .001$), meat consumption and grain consumption were negatively associated with weight-loss (meat: $r = -.38$, $p < .001$; grains: $r = -.31$, $p < .001$), and fruit and vegetable consumption were not associated with weight-loss (fruit: $r = -.10$, $p = .22$; vegetables: $r = .13$, $p = .12$). When these different types of products were entered simultaneously in a linear regression predicting weight-loss, water consumption remained positively associated with weight-loss ($\beta = .28$, $t = 2.97$, $p < .01$), meat remained negatively associated with weight-loss ($\beta = -.26$, $t = -2.99$, $p < .01$), and fruit consumption remained unassociated with weight-loss ($\beta = -.06$, $t = .82$, $p = .41$). Grain consumption was no longer associated with weight-loss ($\beta = -.03$, $t = -.33$, $p = .75$), and vegetable consumption became positively associated with weight-loss ($\beta = .19$, $t = 2.49$, $p < .02$). In contrast, for participants on a low-fat diet, simple bivariate correlations showed that consumption of the different products was not associated with weight-loss (water: $r = .01$, $p = .90$; meat: $r = -.03$, $p = .76$; grains: $r = .07$, $p = .51$; fruit: $r = .04$, $p = .70$; and vegetables: $r = .11$, $p = .31$). In addition, when these different types of food were entered simultaneously in a linear regression predicting weight-loss, consumption of the different products remained unassociated with weight-loss.

Future analyses will examine other ways of calculating dietary variety and how they relate to weight-loss. In addition, future analyses will examine whether dietary variety and different types of food may interact in their effect on weight-loss. Finally, this data set also contains data on participants' physical activity, and future analyses will examine whether physical activity is related to weight-loss, and whether physical activity and diet may interact in their impact on weight-loss.

This research offers an opportunity to examine the associations between different consumption patterns and actual weight-loss. Two key strengths of this research are that we have detailed data on what people consumed over multiple days and that we have substantial actual weight-loss (11.2 pounds on average). We anticipate that this research will help generate future research on consumption patterns that facilitate weight-loss and will be of broad interest both to consumer behavior researchers who study self-control, variety, and food, and to practitioners interested in the design of weight-loss interventions.

James Gips, Boston College, USA

SESSION OVERVIEW

A large portion of what informs our behaviors is perceived through our eyes; in fact, visual perception is such an important and complex activity that about 50% of the brain is involved with it (Bear, Connors, and Paradiso 2007). Research has demonstrated that overt attention can predict higher-order processes such as choice (e.g., Liversedge and Findlay 2000). More importantly, studying visual attention offers a detailed and unbiased measure of the consumer decision and its underlying process and often outperforms self-reported measures (Chandon et al. 2009). Surprisingly, there are few papers in marketing that use attention measures. The proposed session aims to bridge this gap by bringing together four papers that provide new insights into the role of attention in consumer behavior.

In the opening paper, **Mormann** draws on insights from several fields (neuroscience, psychology, marketing, etc.) to develop a comprehensive framework for studying visual attention in consumer research. Furthermore, the author provides valuable guidelines for using eye-tracking and discusses the unique insights that this methodology can bring to consumer researchers.

Next, **Pieters and Wedel** examine the predictive power of head position, eye fixation, and pupil size on memory. A particularly interesting finding of this paper reveals that participants had better implicit memory of the ads they saw earlier in the session when their head was positioned closer to the pictorial and farther from the text information, regardless of their viewing goals.

In a field study, **Kovacheva and Inman** examine the effect of visual attention and engagement with the category on in-store decision making and suggest several moderators. The authors also explore "failed engagements" – incidents in which the shopper actually picked up a product but eventually returned it to the shelf – and find support for their predictions that price considerations and consideration duration influence these returns.

Finally, **Brasel and Gips** explore a very relevant topic – media multitasking behaviors. They identify the individual, contextual, and stimuli-related factors that prompt switching from one media environment to another. Interestingly, they report that participants' recollections of switching behaviors were far off from their actual behaviors, thus emphasizing the importance of using objective measures of visual attention.

Overall, the papers in this session provide new insights into the role of visual attention in consumer behavior and highlight the advantages of using unobtrusive observation to obtain process measures of consumer attitudes and actions. Using diverse methods (lab experiments and field studies) and drawing on insights from different fields (neuroscience, marketing, cognitive psychology), these papers collectively aim to answer the question: How does visual attention influence and predict downstream processes such as choice, consumption, and memory? We expect that this session will appeal to a broad audience of researchers interested in visual attention, advertising, media content consumption, and consumer decision making.

Consumer Attention and Behavior: Insights from Eye-Tracking and Directions for Future Research

EXTENDED ABSTRACT

Everyone involved with marketing appreciates the importance of gaining consumers' attention (Bettman 1979; Lynch and Srull, 1982; Pieters and Wedel, 2004). In his seminal work, Bettman (1979) dedicated an entire chapter to attention and perception processes and recognized that "the particular information attended to and perceived can have a great impact on choice". He further remarked that "attention and perceptual processes have important linkages to other components in (consumer choice) theory", such as motivation, information search, memory, decision processes, and so on. Similarly, Lynch and Srull (1982) recognized that attention often affects decision outcomes by modifying the inputs that are considered. Yet, research on consumer attention is relatively scarce. Rosbergen, Pieters, and Wedel (1997; Pieters and Wedel 2004) recognized this gap in the literature and pioneered some early work on attention. Little research, however, has followed since (see Janiszewski, Kuo and Tavassoli 2013; Atalay, Bodur and Rasolofoarison 2012; Milosavljevic, Navalpakkam, Koch and Rangel 2012; Chandon, Hutchinson, Bradlow and Young 2009).

It has been suggested that the main impediments to research on attention stem from methodological challenges. Lynch and Srull (1982) recognized this lack of appropriate measurement and suggested that "[w]hen researchers introduce an equal degree of methodological sophistication to their empirical investigations [as they do to their theories], a rapid increase in the scope and depth of our understanding should result." They looked for the required "methodological sophistication" in the field of cognitive psychology. In the current review, the range of useful methodologies is further broadened to include those found in vision science. Specifically, I will here focus on eye-tracking as a critical and sophisticated methodology that allows consumer behavior researchers to fulfill the promise of Bettman's early research on attention and its effects on consumer behavior.

The current conceptual paper (1) develops a formal framework of attention and proposes future areas of research related to consumer attention and other downstream marketing processes, such as learning, memory, emotions, judgment and decision making, and (2) discusses eye-tracking as a solution to the previously identified measurement problem (Russo 1978; 2011; Payne and Venkatraman 2011) and explicate guidelines for the effective use of eye-tracking in academic consumer research.

The current framework of attention draws on a recent comprehensive review of attention found in the cognitive neuroscience lit-

erature (Knudsen 2007). Consumer attention has three fundamental components: (1) bottom-up attention, (2) top-down attention, and (3) competitive selection. First, bottom-up attention, or preattention, refers to the brain's automatic selection of the most important information that we are exposed to. This selection is based on the simple features of the environment: color, luminance, orientation, size, shape, motion. Second, top-down attention, also known as goal-driven selection, depends on the goals, expectations, and intentions of the observer. Thus, looking for a can of (classic) Coke will enhance the processing of red areas in our visual input by increasing the neuronal sensitivity for that particular color. The information that is relevant for goal attainment will be attended to more than irrelevant information. For example, when we are thirsty we pay more attention to drinks than other items (Aarts, Dijksterhuis and de Vries 2001). Finally, competitive selection refers to moving from the initial preattentive processing to focused, attentive processing. Visual selection is spatially organized, i.e., attention is allocated to a particular location in space. Once an item has been selected, top-down control determines whether to further process or not that particular information.

Building on this framework I will discuss a number of specific open questions related to consumer attention, including: which bottom-up visual features attract attention, how these features interact with top-down goal related information, and how bottom-up and top-down features interact with downstream consumer processes such as motivation, learning, memory, emotions, judgment and decision making. Specific topics for future research will be proposed for each of these categories.

In addition, drawing on 10 years of research on attention in an interdisciplinary setting (marketing, psychology, economics, vision science and cognitive neuroscience) I will develop recommendations how to effectively use eye-tracking for the study of consumer attention, answering, among others, the following questions: What are different eye-tracker options? How to design eye-tracking experiments? What is the appropriate sample size? How to obtain clean and useful data? What are the key dependent variables? How can we relate attention to other constructs of interest?

Coordination of Attention: Eye Fixations, Pupil Diameter, and Head Distance, Respond to Goals and Predict Memory

EXTENDED ABSTRACT

The visual attention system developed to protect people from being overloaded by the massive stimulation in the environment, to select stimuli from this environment that are relevant to goal pursuit, and to coordinate attention to these stimuli for successful goal completion. These functions are of even more crucial importance in todays overstimulated marketing environments. This research proposes and provides an initial test of a model of attention coordination, which focuses on the role of three key observable parameters of the visual attention system: head position, eye fixations, and pupil diameter. Prior attention research in marketing and cognitive psychology has emphasized eye fixations during exposure to stimuli such as advertising or brand packaging. Early research in marketing on the role of the pupil diameter during ad exposure had inflated and perhaps biased claims and has not yet been replicated. No research to date has examined the role of the head position during ad exposure, despite the fact that the head position is under conscious control and calibrated during goal pursuit to have optimal viewing position. The present research is the first to examine the relationships between and coordination of these three observable parameters of the visual attention system during ad exposure: eye, pupil, and head.

Two experiments are reported in which task goals were systematically varied, eye fixations, pupil dilation and the distance between the head and the stimulus were recorded, and advertising memory was subsequently measured.

A multi-level mixed response structural equation model was estimated to examine the relationships between the attention and memory measures, and their response to the task goals. The model makes it possible to disentangle relationships between the attention measures at the participant-level, due to person and goal characteristics, and relationships between the measures at the ad-levels, due to specific ad features.

Experiment 1 is a re-analysis of prior work with new measures and models. In the experiment, 220 participants saw display ads under one of five different task goal conditions, namely free viewing, brand learning, brand evaluation, ad memory, and ad attractiveness. After exposure, implicit memory was assessed with a brand identification task. Experiment 2 is new. In it, 203 participants saw display ads under one of two different task goal conditions, namely ad informativeness and ad attractiveness. After exposure, both implicit and explicit memory was assessed.

Random-ANOVA models show that, as expected, most of the variation in eye fixations is between ads. This reflects that the pictorial (intra-class coefficient rho, respectively, .330 in experiment 1, and .228 in experiment 2) and text (rho is, respectively, .311 and .219) in some ads receive much more fixations than others, independent of individual and task differences between participants. In contrast, most of the variation in head distance to the pictorial and text (rho, respectively .792 and .584 in experiment 1 and .798 and .577 in experiment 3) is between participants. Also, variation in pupil diameter is predominantly at the participant level rather than the ad level (in all cases, rho is greater than .880). This shows that in our experiments, the pupil varies only to a small extent between ads but varies mostly between participants. How goals specifically affect the attention measures, and whether the differences between ads predict down-stream communication effects was examined next.

Model estimations reveal that task goals have modest but reliable effects on the attention measures. Relative to the free viewing condition, the other task goals activate participants in experiment 1 to move the head a little closer to the ad, about one centimeter. In study 2, the informativeness goal activates participants to move the head a little closer as well. These effects are independent of the influence of task goals on eye fixations. All goals in experiment 1, and the informativeness goal in experiment 2 lead to more fixations of the text and on the picture of the ads. Pupil diameter responds less systematically to the task goals. Although no reliable task goal effect on pupil diameter was observed in experiment 1, a reliable effect was observed in experiment 2, probably due to the greater statistical power in the latter experiment. Importantly, there were reliable effects of the attention measures on implicit and explicit memory, independent of the direct goal effects. Specifically, a larger head distance to the text and a shorter head distance to the pictorial, larger fixation frequencies on the pictorial, and independent of these effects, a smaller pupil diameter all predicted better implicit memory in both experiments. Also, higher fixation frequencies and smaller pupil diameters predicted better explicit memory, even while controlling for task goals and the false alarm rate.

These findings are the first to show how three observable parameters of the visual attention system vary systematically between consumers and between ads, how they are contingent on task goals, and predictive of memory. They reveal that "attention coordination

takes place in the head" but in quite unexpected ways. A small but reliable movement of the head of about one centimeter and an even smaller change of less than a millimeter in the pupil diameter predicted better memory. The findings were obtained across a combined sample of over 400 participants and multiple ads from different categories.

Shopper Eye-Cue: Understating the In-Store Decision Process with Field Eye-Tracking Data

EXTENDED ABSTRACT

Recent research has found that the majority of grocery purchase decisions are made in the store (e.g., Inman, Winer, and Ferraro 2009). Yet, our knowledge about in-store decisions is mostly inferred from consumers' self-reports and the products listed on their receipt (but see Hui et al. 2013; Stilley, Inman, and Wakefield 2010; Hoyer 1984). We still know little about the consideration process that happens between the start and the end of the shopping trip. This paper addresses this gap by exploring the role of visual attention and engagement in in-store decisions.

Research has shown that visually attending to a stimuli increases the probability of choosing that stimuli (Janiszewski, Kuo, and Tavassoli 2013; Pieters and Warlop 1999). Drawing on the literature on choice overload (Iyengar and Lepper, 2000) and visual clutter in ads (Pieters, Wedel, and Batra 2010), we propose that perceived assortment size in the store will moderate this effect such that greater perceived variety coupled with a greater number of fixations will be associated with a lower number of unplanned purchases since it will be more difficult to make a choice as the number of considered alternatives increases. Furthermore, physically touching a product has been related to unplanned purchase conversion (Hui et al. 2013). We aim to extend this finding by suggesting that shopping enjoyment will strengthen this effect since consumers who construe shopping as fun will be more receptive to in-store stimuli. Previous research has demonstrated that, as the shopper's mental budget for the trip depletes, the number of unplanned purchases decreases as well (Stilley et al. 2010). We expect that this mechanism will hold even at the category level and suggest that the higher number planned purchases (which deplete shopper's mental account) will crowd out unplanned purchases.

To test these predictions, we analyzed a dataset containing the trips of 158 US shoppers who wore eye-tracking glasses while shopping. The field study was completed in 2012 by the Point of Purchase Advertising International (POPAI). The dataset consists of number and type of purchases (unplanned, planned, planned not purchased) for each shopper for each category considered (1034 data points), number of informational fixations (i.e. fixations related to orientation or reviewing the label), fixations on the price tag, product touches (i.e. touches to examine the product as well as to return it to the shelf), and several self-reported measures about shopper, trip and store characteristics (e.g., money pressure, perceived store variety, etc.)

Due to the nested structure of the data, we conducted a hierarchical model with number of unplanned purchases as the DV and shopper as the grouping factor. We find that shoppers who allocated more visual attention to the category had a greater number of unplanned purchases (β=.01, p<.001). More importantly, this effect is moderated by perceived product assortment – in stores rated as offering a greater abundance of products, the higher number of fixations is associated with fewer unplanned purchases (β=-.01, p<.001). This suggests that during the orientation stage, abundance of choice may cause confusion and deter choice. As expected, product engagement (i.e. number of touches) is associated with higher incidence of unplanned purchases (β=.11, p<.001) and this effect is further enhanced for shoppers who report higher enjoyment from shopping (β=.02, p=.01). Interestingly, we find a significant positive interaction between perceived assortment size and product touches (β=.04, p<.001) such that product touches have a stronger effect on purchase conversion when the store was perceived as carrying a wide selection of products. We speculate that, once the shopper has oriented herself and identified a need, assortment variety helps seal the deal by ensuring preference match. Finally, we find that the number of planned purchases in the category decreases the number of unplanned purchases (β= -.33, p<.001).

In the second part of our paper, we focus on an in-store decision making process that can only be studied by observing the shopping trip through the eyes of the shopper – failed product engagements (i.e. instances when the shopper changed her mind and returned a product to the shelf). There were 334 occurrences of failed engagement in our field data (M=2.30, SD=2.04, ranging from 1 to 13). The two categories with the highest incidence were fresh produce and refrigerated meat and seafood, suggesting that at least some of these rejected considerations may be driven by freshness concerns.

In order to explore what factors predict these returns, we ran a hierarchical model with number of returns per category as the DV and shopper as the grouping variable. We explored the effect of two main groups of factors – price salience and time resources allocated to making a decision. We hypothesized that attention to price and longer deliberation will result in more returns since they imply that the shopper processed the decision in more depth. Consistent with our predictions, we find that the number of price fixations is positively related to the number of returns (β=.16, p<.001). Furthermore, shoppers who indicated they are under greater money pressure (i.e. chronic price salience) were more likely to change their minds (β=.18, p=.05). These effects were qualified by a significant interaction such that shoppers who were chronically pressed for money and paid more attention to the price tags had more returns (β=.07, p=.01). Further, we find that the total number of fixations (a proxy for deliberation time) is positively associated with failed engagements (β=.01, p<.001). Finally, the number of purchased products (also related to time spent in the category) is positively associated with the number of returns (β= .13, p=.03).

In conclusion, our research provides unique insight into the in-store decision making process using field data. We show that visual attention and product engagement are associated with purchase conversion in a complex way – abundance of choice can decrease the positive effect of fixations during the orientation phase but enhance it during the purchase selection phase. Furthermore, we find that price saliency and time deliberation increase the number of times the shopper "changes her mind" and returns a product to the shelf.

Media Multitasking and Visual Attention: Switch Triggers in Context and Content

EXTENDED ABSTRACT

Media multitasking is fast becoming the modal form of entertainment media consumption for consumers. In Nielsen data released in 2010, 59% of respondents reported using the television and internet simultaneously, with an estimated 34% of their internet usage occurring concurrently with television. Yet there remains calls in the literature for foundational experimental work in the area (McDonald and Meng 2009, as well as observational work using natural stimuli (Jackel & Wollscheid 2007). The current research argues that before

we can begin to build models of why consumers engage in media multitasking and how multitasking affects traditional marketing outcome variables, we must first establish *what* exactly media multitasking behavior looks like. Two studies using video observation and direct eye-tracking identify multitasking attentional patterns and begin to outline a basic framework of how context and content can modify multitasking behavior.

Unfortunately, self-report measures are ill-suited to explore this issue. Media consumption is habitual with little self-awareness (Saling & Philips 2007), and routinized mental scripts guide media selection and attention (Adams 2000). Prior work has also explored 'attentional inertia' within media (Anderson, Choi & Lorch 2007), and consumers have little real-time insight into their media consumption behavior. Applied multitasking research from educational fields is of limited use in entertainment environments, as it largely focuses on switching costs and performance degradation in splitting attention between two goal-driven tasks. In addition, people overestimate their ability to multitask, as self-reported good multitaskers are less able to focus and more easily distracted by irrelevant stimuli (Ophir, Nass & Wagner 2009). This suggests that our lay theories of multitasking behavior has little relation to our actual behavior, and there remains a strong need to establish basic patterns of multitasking activity.

In the first study, 42 participants were brought into the lab, seated in from of a laptop and television with remote, and told they had 30 minutes to use both however they wanted. Their behavior was recorded using high-definition video cameras that captured whether their point-of-gaze was on the laptop monitor or television. This attentional record was then matched frame-by-frame with the content on both screens to explore how different forms of content may encourage or discourage switching. After the 30 minutes were completed, they were asked to fill out a self-report survey of their multitasking behavior.

Results show that the average gaze duration between switches was quite low, with roughly 50% of gazes lasting less than 1.5 seconds on the television and less than 5 seconds on the computer. Indeed, participants switched an average of 120 times, or over 4 switches a minute, while they only recalled 15 switches in their post-hoc survey, and post-hoc descriptions of the strategies they used to multitask had no relationship with what the video data revealed. Interestingly, switching patterns appeared no different for television or commercial content. Instead, there was evidence of a strong 'switch trigger' effect for break points either from show to commercial or vice versa, with switching rates dropping quickly after 5 seconds. This effect also occurs on the computer, with far more switches occurring within 5 seconds of a new webpage versus afterwards. The increased switching at breakpoints was also not directionally agnostic, with a strong bias towards switching to the computer from the TV regardless of whether the break point was show-to-commercial or commercial-to-show.

A second study used eye-tracker analysis to explore multitasking behavior in more detail. A single computer was used where a television show (*The Life of Birds*) was displayed on the left side of the widescreen monitor while a series of interactive spring break travel webpages were displayed on the right. Assistants coded the TV video at 30 frames per second on over 100 content variables, such as "human figure present," "movement from left to right," "camera movement," and so on. An ASL eye-tracker system recorded point-of-gaze and fixation data that could then be mapped to the stimuli. Three conditions were run across 60 participants; a multitasking condition where both the TV and web content were available, and two monotasking conditions where only the TV or web content were available.

Results show that motion in the non-attended medium encourages switching towards the media, but does not discourage switching away when the motion is taking place in the current media. TV audio was ineffectual in generating switching towards the TV, but dialogue exhibited attentional capture and discouraged switching away from the television media. Similar to the first study, natural breaks in the media guided switching; when participants clicked to load the next webpage, their eyes moved to the TV content, and remained there until the next scene change gave them freedom to move back. And compared to the monotasking conditions, simultaneous media presentation not only generated split attention, it also led to shorter fixations and increased saccadic movement within each media. Interestingly, followup analysis using Fast Fourier Transformations did not find evidence of an internal driver of switching, suggesting that switching behavior is largely in response to external media trigger rather than any internal pressure or "need to switch."

In conclusion, this work establishes a ground-level picture of media multitasking behavior through video observation and eye-tracking analysis in a controlled laboratory environment. Switching was shockingly frequent and constant, with natural breaks in the media generating large amounts of switching behavior. Switch triggers such as motion and audio cues showed differing effects in their ability to generate switches towards media versus discourage switching away from media, and media multitasking generated increased visual movement within a media in addition to attentional shifts between media. Across both studies, objective recorded behavior shared little in common with participants' post-hoc behavioral recall, suggesting that further work must maintain direct observational techniques, and traditional survey and self-report measures may be ill-suited for multitasking research.

Paper #4: The Effects of an Emergency Reserve on Self-Control Performance

Marissa A. Sharif, University of California Los Angeles, USA
Suzanne Shu, University of California Los Angeles, USA

SESSION OVERVIEW

Common wisdom suggests it is prudent to budget and save; yet, savings rates among Americans have been declining since the 1980s (Bureau of Economic Analysis 2014; Economist 2013; McCully 2011). In light of this pattern, gaining a deeper understanding of consumers' financial decision-making process grows increasingly important. Indeed, the topic has been of mounting interest to consumer researchers, practitioners, and policymakers alike (e.g., Fernandes, Lynch, and Netemeyer 2014; NEFE 2014). Accordingly, this session aims to disseminate and stimulate discussion about recent findings pertaining to causes and consequences of consumers' saving behavior—specifically, perceptions of savers (Paper 1), obstacles that may hinder saving (Papers 2 and 3), and potential strategies to encourage more prudent budgeting (Paper 2 and 4).

In paper 1, Olson and Rick suggest that saving can reap interpersonal benefits as well as financial ones. Specifically, saving enhances perceptions of self-control and hence attractiveness; consequently, people who save are more romantically appealing. Papers 2-3 examine obstacles that may prevent people from spending prudently, including attention to saving and reactions to financial shocks. Specifically, paper 2 (Sharma and Keller) suggests that temporary feelings of financial deprivation increase the perceived security gained from earning rather than saving and in turn shift people's focus from saving opportunities to earning opportunities. Further, paper 3 (Sussman and O'Brien) examines how people spend in response to negative income shocks and suggests that people are likely to spend more than necessary when they are responsible for the shocks. Fortunately, strategies exist to encourage budgeting behavior, and paper 4 (Sharif and Shu) discusses one of them. Specifically, the authors suggest that creating an emergency reserve may improve progress towards goals, and may be useful in both financial and non-financial domains which require self-control.

Thus, although saving behavior may be attractive for multiple reasons (Olson and Rick), people might not be as focused on saving opportunities when they feel worse off financially (Sharma and Keller), and when they feel personally responsible for their adverse state (Sussman and O'Brien). However, considering older age, potential emergency expenses, and the benefits of saving can boost saving tendencies (Sharma and Keller), and having an emergency reserve in a budget can improve self-control performance (Sharif and Shu). By utilizing these tactics, it may be possible to both improve the attractiveness of our financial position as well as our interpersonal standing.

Together, these papers examine a range of topics pertaining to consumer budgeting and saving, and may stimulate further questions and discussion about (1) factors that might hinder saving behavior, (2) factors that might encourage saving behavior, and (3) benefits to consumers who save. We believe this session will be of interest to researchers in many areas of study, including consumer financial decision making, economic psychology, goals, mental accounting, subjective well-being, and transformative consumer research.

A Penny Saved is a Partner Earned: The Romantic Appeal of Savers

EXTENDED ABSTRACT

What we consume conveys information about who we are. For example, in romantic contexts, men who are motivated to find a romantic partner are especially likely to buy luxury goods to signal their wealth (Griskevicius et al. 2007). This tendency echoes recent advice from the *Wall Street Journal* to (essentially) "burn a big pile of money on the first date," as a signal of wealth (Oyer 2014). Indeed, when women only have information about a single purchase, they tend to view men who recently purchased a luxury good (a Porsche) as more attractive than men who recently purchased a more basic good (a Honda), presumably because the luxury purchase is a better signal of financial viability (Sundie et al. 2011, study 4).

However, in almost any context, people will have more information about potential mates than a single purchase. The multiple consumption cues present in many contexts (e.g., clothing, accessories, phones, laptops, and cars) are likely to convey information about one's general spending habits (that is, whether one is generally a "spender" or a "saver").

We propose that people's general tendency to spend or save is likely to influence the inferences others draw about them, and thus their initial romantic appeal. Specifically, we hypothesize that savers are likely to be viewed as more attractive than spenders for both economic and psychological reasons. Economically, savers are presumably more likely to accumulate financial resources. Psychologically, savers may be viewed as possessing greater general self-control (applicable across many domains). For many people, saving requires actively suppressing the urge to spend. Individuals who possess self-control in one domain may be assumed to possess it elsewhere (e.g., savers may be assumed to be more likely to exercise and maintain a healthy diet). To the extent that general self-control makes one a better mate (e.g., by reducing the likelihood of cheating or saying hurtful things), savers should be viewed as more attractive than spenders.

Of course, our primary question of whether and why savers are viewed as more attractive is only relevant if people can accurately and easily distinguish between savers and spenders in the first place. Thus, our initial study sought to demonstrate that people can make this distinction in real time. We brought in groups of unacquainted participants to the lab and asked them to privately diagnose themselves as a saver or spender. We then asked participants to look around the room and guess, without discussion, whether the other participants were savers or spenders. Participants earned $1 per cor-

rect guess (i.e., a guess that matched the self-diagnosis). Participants were 16% more likely to correctly guess that a saver was a saver than to incorrectly guess that a spender was a saver (significantly greater than the 0% chance baseline). These snap judgments displayed accuracy on par with the accuracy of common snap judgments documented in the personality literature (cf. Vazire et al. 2008).

Next, we examined whether, why, and when savers are romantically preferred to spenders. To carefully test our hypotheses and control for confounding factors that may be correlated with saving versus spending habits, our general experimental paradigm utilized online dating profiles in which targets disclosed their saving versus spending habits. (Describing your spending habits is common on popular dating websites such as eHarmony; Lieber 2010.)

In experiment 1A, we presented participants with an opposite-sex dating profile and manipulated whether the potential mates described themselves as a "saver" or a "spender" in a variety of ways (e.g., saving described as "love to save" or "hate to spend"). Participants reported how attracted they were to the potential mate. As predicted, there was a robust preference for savers over spenders (as well as "control" targets who did not describe their spending habits), regardless of how these habits were described. Experiment 1B demonstrated that savers are romantically preferred to spenders for both dating and longer-term relationships, though this preference does not persist within the context of one-night-stands (where saving versus spending habits are not actively considered). Experiment 1C extended beyond the domain of romantic attraction to physical attraction. A novel and direct implication of our proposed underlying mechanism (perceptions of general self-control, which encourages healthy practices) is that, when there is any ambiguity about true physical attractiveness, savers should be expected to be more physically attractive and viewed through this biased lens. As predicted, savers were perceived as being more physically attractive than spenders. We also found that savers were viewed as significantly less exciting than spenders (presumably due to the prudence encouraged by general self-control), ruling out a halo effect interpretation for the physical attractiveness finding.

Experiments 2A and 2B sought to directly establish evidence for the underlying mechanism of self-control perceptions. Experiment 2A demonstrated that savers benefit from greater perceived financial viability and greater perceived general self-control, but that perceived self-control was the primary mediator between spending habits and romantic attractiveness. Experiment 2B added converging process evidence by holding spending habits constant and manipulating perceived self-control directly. Spenders who otherwise appear high in self-control were viewed as just as attractive as savers, with both types exceeding typical spenders (low in general self-control).

In experiments 3 and 4, we examined dispositional and situational factors that may moderate the romantic appeal of savers. Potential mates high in general self-control possess a number of attractive attributes, but choosing such a mate may require sacrificing stimulation. Consistent with the notion that general self-control favors prudence over fun, we found that traits (e.g., boredom susceptibility; Zuckerman 1979) and states (e.g., situational need for excitement) that increase the desire for stimulation decrease the preference for savers.

In addition to the obvious economic benefits, our work documents interpersonal benefits of saving: savers are viewed as possessing greater general self-control, which enhances both their perceived romantic and physical attractiveness. Of course, self-control is not always desired in a prospective mate: dispositional and situational forces that increase the need for stimulation attenuate the relative ap-

peal of savers. Thus, savers may win in the mating market, but only when potential mates do not crave excitement.

A Dollar Saved ≠ a Dollar Earned: Financial Deprivation Shifts Focus to Earning Over Saving

EXTENDED ABSTRACT

Many people do not save despite knowing how and why they should save, and common explanations point to demographic and individual difference variables: lower income, younger age, lower education, lower financial literacy, self-control (e.g., Karlan, Ratan, and Zinman 2014). However, these explanations cannot address why older, wealthier, and more educated people also do not save. We suggest one reason why individuals do not save (and hence why it might be challenging to encourage them to do so): People are susceptible to transient states of deprivation, which shift their focus to earning rather than saving. Five studies demonstrate that financial deprivation enhances the perceived security associated with earning rather than saving, which in turn reduces people's focus on saving opportunities in favor of earning opportunities.

Study 1 examined the correlation between perceived financial deprivation and financial security gained from earning over saving. Participants responded to the following measure: "I would feel more secure about my financial future if I" (7-pt scale; 1 = saved more, 7 = earned more) and rated their financial position using a version of Sharma and Alter's (2012) subjective financial well-being scale. The worse participants felt financially, the more they felt that earning rather than saving would provide a greater sense of financial security, $r(143) = -.29$, $p < .0001$.

In Study 2 and the subsequent studies, we manipulated financial deprivation by asking participants to describe a time they felt they did not have enough money (deprived) or had more than enough money (flush). Participants then indicated the number of hours in a day they preferred to spend on two target activities (earning, saving) and filler activities. The ratio of time participants allocated to earning versus saving was the DV. As expected, this ratio was higher among deprived (M = 3.89, SD = 2.91) than flush (M = 2.76, SD = 2.39) participants, Mann-Whitney $U = 791$, $p = .039$.

In Study 3, we manipulated financial deprivation, measured participants' selection between two jobs, and tested whether the effect of deprivation on job selection operated via feelings of financial security. The two jobs both offered a $4,000 increase in income, but differed in the source. In one job, the increase was described as coming from a bonus of $5,000 with an additional transportation expense of $1,000 (earning-framing) whereas in the other job, the increase came from a bonus of $2,000 and a $2,000 decrease in transportation expenses (saving-framing). The percentage of participants selecting the earning-framed job was marginally higher in the deprived (70.2%) than flush (59.6%) condition, $\chi^2(1, N = 268) = 3.20$, $p = .07$. In addition, perceived financial security gained from earning was higher among deprived (M = 5.50, SD = 1.48) than flush (M = 4.92, SD = 1.92) participants, F(1, 266) = 7.62, $p = .006$, and this perception mediated the effect of deprivation on job choice (95% CI: .01, .26).

In Study 4, we manipulated financial deprivation and asked participants to read about a target individual seeking to improve her family's financial position. Given that people tend to be able to save more as they grow older, we expected age to moderate the effect of deprivation on people's focus on earning over saving. Accordingly, we varied whether the target was described as younger (30 years) or older (55 years), and asked participants to indicate whether they believed the target should earn more or save more using a seven-

point scale (1 = definitely earn more, 7 = definitely save more). We found the expected interaction, $F(1, 317) = 5.83$, $p = .016$. Follow up comparisons revealed that, in the younger-target conditions, deprived (M = 4.17, SD = 2.09) participants were less likely to think the target should save rather than earn, compared to flush (M = 4.93, SD = 1.67) participants, $F(1, 317) = 8.01$, $p = .005$. However, there was no difference between deprived (M = 5.51, SD = 1.67) and flush (M = 5.30, SD = 1.70) participants' ratings in the older-target conditions, $F < 1$. Critically, the age of the target had a significant effect on deprived (but not flush) participants' focus on earning over saving: Deprived participants thought it was more important for the target to save when the target was described as older (M = 5.51, SD = 1.67) than younger (M = 4.17, SD = 2.09), $F(1, 317) = 21.99$, $p < .0001$, whereas flush participants' ratings did not differ for the older (M = 5.30, SD = 1.70) and younger (M = 4.93, SD = 1.67) target, $F(1, 317)$, 1.68, NS. These results suggest that the consideration of older age can moderate the effect of deprivation on people's 'earning-over-saving' focus.

Study 5 introduced interventions to encourage deprived people to consider the importance of saving. Since we were focused on the deprived population, we gave all participants the financial deprivation manipulation and then asked them to consider a target attempting to improve her family's financial position. A third of the participants received a scenario almost identical to that used in the younger-target condition in Study 4 (control condition), another third of participants received that control scenario plus educational information about saving ('education intervention'), and the remaining third received the control scenario plus information about unexpected emergency expenses ('emergency intervention'). The DV was the extent to which participants felt the target should focus on saving rather than earning. There was a significant effect of condition on the importance placed on saving, $p < .001$. Participants believed it was less important for the target to save in the control (M = 4.02, SD = 1.88) versus each intervention condition (M$_{saving}$ = 4.61, SD = 1.85, M$_{emergency}$ = 5.27, SD = 1.64), both ps < .01. Participants' beliefs regarding the financial security gained from earning, relative to the control condition, was significantly lower in the educational intervention condition ($p = .001$) and marginally lower in the emergency-expense intervention ($p = .075$), and feelings of deprivation (measured) affected the DV (ratings of earnings-importance) via the financial security mediator.

When One Error Elicits Another: Unnecessarily Costly Reactions to Personal Fault

EXTENDED ABSTRACT

Negative financial shocks have become both more common and more severe over time (e.g., Warren, 2003), and have even been tied to an increase in personal bankruptcy claims (e.g., Zywicki, 2005). Thus, the way that people respond to these shocks has important consequences for their financial wellbeing. Existing literature in mental accounting has examined positive shocks (windfall gains), and suggests that non-economic factors related to incurring these positive shocks can influence how people spend them (e.g., Aarkes et al., 1994; Epley, Mak, and Idson 2006; Milkman & Beshears, 2009). While prior research has examined how circumstances leading to financial windfalls and corresponding emotions impact the spending of gains (Levav & McGraw, 2009), the current paper investigates the reverse: how do circumstances leading to negative financial shocks and corresponding emotions influence the payment of associated costs? Across four studies, we examine how financially equivalent negative shocks can lead to differences in debt perceptions, take-up

and repayment decisions when coupled with variations in personal responsibility and subsequent emotional reactions. Ultimately, unnecessarily costly financial outcomes will make it even more difficult for those incurring negative financial shocks to build savings.

In Study 1, 244 participants were asked to imagine situations where they encountered a negative income shock and needed to borrow money. In two cases, participants were responsible for the expense (car accident caused by their own texting while driving; and vacation travel), and in two they were not (car accident caused by another driver texting while driving; and emergency travel). Participants reported whether they would be more likely to borrow money from their friends/family or to use a credit card (1-7 scale), as well as the interest rate they expected to pay. When participants were responsible for the expense, they reported being more likely to use a credit card (M = 4.12 vs. 3.18, $p = .005$ for car accident; M = 3.97 vs. 3.25, $p = .005$ for travel) and expecting to pay higher interest on that card (M = 10.01 vs. 7.53%, $p = .012$ for car accident; M = 9.02 vs. 6.94%, $p = .022$ for travel).

Study 2 aimed to investigate how perceptions of the scenarios differed beyond responsibility, and how these perceptions correlated with different decisions. We presented 440 participants with the same two car accident scenarios used in Study 1, and asked them to report the highest interest rate they would be willing to pay to repair the car damage, assuming they were using a credit card for the payment. Participants were willing to pay higher interest rates when they were responsible for the expense (M = 10.93 vs 9.57%, $p = .031$). They also completed the PANAS, indicating the extent to which they would feel each of 20 emotions in the situation they read about. People were most prone to associate responsibility for the accident with feelings of guilt (M = 4.02 vs 1.53, p<.001) and to associate another's responsibility with feelings of hostility (M = 2.26 vs 2.99, p<.001). Mediation analyses reveal that our measure of self-reported guilt mediates the direct effect of being in the fault condition on interest rates and our measure of hostility mediates the direct effect of being in the no fault condition.

To explore consequences of specific emotions, Study 3 manipulated them directly. Three-hundred four participants read a scenario about a costly car accident or a home break-in, and were then asked to focus on aspects of the incident that made them feel either guilty or hostile (see Small, Lerner, & Fischhoff 2006). Participants chose whether they would be more likely to borrow money to have their car fixed/possessions repurchased immediately, or wait until they had saved enough money (1-7 scale). In this situation, borrowing corresponds to a more costly behavior given associated interest payments. Participants in the guilty versus hostile condition were significantly more likely to report borrowing for an immediate remedy (M = 4.69 vs. 3.76, $p = .001$).

Finally, to gain additional insight into how perceptions of guilt and personal responsibility may be influencing subsequent financial decisions, Study 4 examined deservingness as a possible mediator. Specifically, we hypothesized that people who felt responsible for their bad financial situation would believe that they deserved additional financial punishment. To test this possibility, we presented 139 participants with the same car accident scenarios (varying personal responsibility) used in Studies 1 and 2. Participants again reported the highest interest rate they would be willing to pay to fix their car assuming credit card payment, and also rated other measures including a four-item scale that measured beliefs about deserving bad financial outcomes. Participants were again willing to pay higher interest rates when they were responsible for the expense (M = 11.67 vs 8.66%, $p = .012$). As hypothesized, beliefs that they de-

served worse financial outcomes when they caused the accident mediated this response.

Across studies, we find that personal fault can correspond to guilt about the situation and lead people to believe that they deserve subsequent negative financial outcomes. In turn, these patterns influence how people respond to identical expense shocks and differences in these responses can be financially costly beyond what economic factors would dictate. In other words, once a single misstep compromises a person's finances initially, she may be more likely to aggravate her situation by incurring additional unnecessary costs while attempting to remedy the situation, hindering her long-term ability to build savings.

The Effects of an Emergency Reserve on Self-Control Performance

EXTENDED ABSTRACT

Prior research has shown that flexibility within mental budgets allows consumers to make exceptions to budget rules in order to justify indulgent choices, thus reducing self-control (Cheema & Soman, 2006). However, other research has suggested that too stringent of mental budgets can lead to self-control failure through self-control depletion and the "what the hell" effect (Muraven, Tice, & Baumeister, 1998; Polivy & Herman, 1985) We demonstrate that including an explicitly defined emergency reserve, an extra-defined amount above an initial limitation, in mental budgets helps improve self-control performance by providing a compromise between these two extremes. In four experiments, we show that including reserves within mental budgets improves self-control performance. Additionally, we reveal a moderator of our effect, the initial level of the mental budget.

In Study 1 and 2, participants imagined that they were part of a point-based weight loss program and made a series of 28 choices between different food options over two virtual weeks. After entering their demographics, they were given a fictional number of points that the average person of their characteristics consumes in a week to lose weight. Participants were then asked to estimate how many points they would use throughout one virtual week. In the No Reserve conditions, participants only made this single point estimate of total point use. In the Constrained Aim conditions, participants were asked to set a lower number of points to aim for after their initial estimation. In the Reserve conditions, participants were given lower reference points and also asked to set aside additional points in case of an "emergency" after their initial estimation. Participants in the Reserve condition used significantly fewer points than those in the No Reserve condition, $F(1,154) = 7.19$, $p < .01$, when they had standard mental budgets, while those in the Constrained Aim condition did not use significantly fewer points than those in the No Reserve condition, $F(1,154) = 2.50$, $p > .1$. Our results suggest that the harder boundaries of the emergency reserve are contributing to the increased self-control performance rather than flexibility and lower reference points alone (which Constrained Aim participants also have). However, participants who begin with deprived (poor) mental budgets in the Reserve condition did not use a significantly lower number of points than those in the No Reserve condition, $F(1,154) = 1.38$, $p > .1$, suggesting that the effect of reserves depends on having a reasonable initial budget. Study 2 (240 participants) used the same paradigm as Study 1 and found that emergency reserves in standard mental budgets: 1) reduce of self-control depletion, 2) increase perceived flexibility while still maintaining stringency, and 3) reduce the sense of failure and associated negative emotions.

In Study 3, participants were randomly assigned a time goal to type a series of CAPTCHAs (distorted images of letters that humans can read but computers cannot). Participants' goal was to finish the task within 210 seconds in the No Reserve-Easy condition, within 210 second but aim to complete the task within 180 seconds in the Aim Condition, within 180 seconds with an additional 30 seconds of emergency time available "in case they need it" in the Reserve condition, and within 180 seconds in the No Reserve-Hard condition. Participants in the Reserve condition typed CAPTCHAs at a significantly faster rate than participants in the No Reserve-Easy condition (b = .42, $p < .05$). However, participants in the Constrained Aim condition did not type the CAPTCHAs significantly faster than participants in the No-Reserve Easy condition ($b = .32$, $p > .1$), nor did participants in the No Reserve-Hard condition ($b = .27$, $p > .1$). Study 3 thus demonstrates that participants with reserves are more motivated and thus perform better in monotonous tasks.

Studies 1-3 revealed that participants with reserves adhere more closely to the difficult reference point and perform better than participants with no reserves and an easier reference point. In study 4, we demonstrated that participants with reserves perform better than participants without reserves and the more difficult reference point if the task involves persistence in a task over time. Participants were randomly assigned a goal specifying how many days they need to complete a CAPTCHA task throughout a week. In addition to receiving $1 daily for completing the task, participants received an additional $5 bonus if they completed their goal. Participants' goal was to complete the task five days out of the week in the No Reserve-Easy condition, to complete the task five days but aim to complete the task every day in the Aim condition, and to complete the task every day of the week in the No Reserve-Hard condition. Participants' goal in the Reserve condition was to complete the task every day but they were also told "In case you need it, up to two days will be excused" and that they would still receive their bonus if they missed up to two days. Reserve participants were significantly more likely to receive their bonus than No Reserve-Easy Participants, $\chi^2(1, N = 113) = 9.02$, $p < .01$, Constrained Aim Participants, $\chi^2(1, N = 115) = 4.00$, $p < .05$, and No Reserve-Hard participants, $\chi^2(1, N = 116) = 13.40$, $p < .00$. Reserve participants were also more likely to complete the "easier" lower reference point goal (five days a week) than the No Reserve-Hard participants, $\chi^2(1, N = 116) = 5.19$, $p < .05$.

This paper presents an innovative strategy to improve self-control performance. While our studies were designed around self-control tasks that could be easily tested in a lab environment, the results suggest that emergency reserves have potential beneficial implications for other self-control goals, such as saving, budgeting, and spending. For example, individuals struggling to stay within a strict financial budget may feel less depleted and remain more motivated by knowing that they have set aside an emergency reserve, similar to the participants in our studies. However, this work also cautions that beneficial self-control strategies like emergency reserves can backfire for those with deprived mental budgets.

SESSION OVERVIEW

Consumers seek products not only for their functional properties, but also for their symbolic value (Belk 1988; Levy 1959). Indeed, consumers often use products to signal to the self and to others that they possess a desired trait or identity. For example, a person who wants to be perceived as high in status might drive a luxury car. Although consumers naturally use products that are imbued with symbolic properties, their propensity to do so intensifies when they feel threatened. After experiencing a threat, consumers have been shown to acquire, consume, and display products that boost a desired trait or identity. This broad set of behaviors is referred to as compensatory consumption (Lee and Shrum 2013; Rucker and Galinsky 2013).

Growing interest has focused on how compensatory consumption unfolds. That is, how do people use consumption to compensate for threats, and what principles guide their compensatory efforts? This session contributes to this body of research by a) investigating new triggers of compensatory consumption (Paolacci, Ordabayeva, and Stuppy; Coleman and Williams), and b) elucidating principles that guide people's compensatory efforts (Lisjak, Levav, and Rucker; Wan, Chen, and Vohs).

Paolacci and Ordabayeva examine a novel source of threat: experiencing physical shortness. They find that people who feel chronically or temporarily short (vs. tall) prefer products high in status. But, allowing these individuals to reinforce their identity buffers them against seeking status-related products. This suggests that perceived physical shortness poses a threat that consumers are motivated to repair. Coleman and Williams examine another source of threat: experiencing an emotion that is inconsistent with the emotion profile of the salient social identity. They show that when people experience an emotion that is inconsistent with their salient identity, they prefer and consume products that boost that identity, relative to individuals who experience an emotion that is consistent with their salient identity.

Lisjak and colleagues examine factors that influence how people compensate for threat. They show that when people are motivated to self-signal their self-worth following a threat, they prefer products that boost the self in the domain of the threat. In contrast, when people are motivated to signal their self-worth to others, they focus on their strengths and thus prefer products that boost the self in domains unrelated to the threat. Finally, Wan and colleagues build upon the first three papers by introducing the idea that sometimes people are motivated to compensate for a self-threat by preferring to keep rather than spend money. They show that when people feel socially excluded (vs. not) they experience a loss of their sense of personal control and save money as a means to regain control.

Together, these papers (all in advanced stages, comprising 14 completed experiments) provide value by exploring when and how people use consumption in a compensatory manner, and by providing insights that benefit consumers, marketers, and policy makers. We expect that this session will appeal to a broad audience interested in compensatory consumption, social identity, social status, goals and emotions.

Feeling Physically Short Increases Compensatory Consumption

EXTENDED ABSTRACT

Recent research has documented that physical height significantly impacts outcomes in people's personal and social life. However, no research has yet investigated whether and how the psychological experiences associated with physical height can affect people's decisions. We study whether feeling short can pose a threat to people's identity, and ultimately affect their behavior in the marketplace.

Height is a physical feature that is crucial for evolutionary fitness. In the ancestral past, being small was detrimental for survival as it entailed being inferior in the ability to gather resources and fight enemies (Freedman, 1979). Although these disadvantages are less critical today, even in modern day societies being short seems to negatively affect several life outcomes. Specifically, shorter people tend to have lower salaries, lower ranking jobs, and are generally less likely to become leaders (Egolf and Corder 1991; Frieze, Olson and Good 1990; Highman and Carment 1992; Melamed and Bozionelos 1992; Young and French 1996). Moreover, shortness triggers negative social perceptions, with studies reporting that short people are judged as less competent, confident, and successful compared to taller people (Jackson and Ervin 1992; Judge and Cable 2004; Lindeman 1999; Melamed 1994; Young and French 1996). Shorter people, finally, tend to have a more negative self-image compared to their taller peers (Brewer and Hood 1963; Riley 2009). In sum, large evidence indicates that shorter people might suffer from the actual and psychological experience of physical shortness.

In this research, we propose that feeling physically shorter than others can threaten a person's identity and social status. This feeling, that can be chronic or momentarily active, can in turn trigger compensatory behavior, such as privileging status-enhancing products in a consumption context and seeking high-power positions while interacting with others.

In Study 1 we explored whether chronic perceived height is associated with compensatory purchases of high-status products. Participants went through three scenarios in which they chose

between spending a certain amount of money on a high-status product (e.g., Armani sunglasses) and saving the money. In each scenario the participants expressed their relative preference between the two options on a scale from 1 (definitely save the money) to 7 (definitely spend the money). Afterwards the participants reported how short/tall they considered themselves to be (1 = very short, 7 = very tall) and how short/tall they felt relative to their peers (1 = much shorter, 7 = much taller). The results showed that participants who perceived themselves to be shorter had stronger preferences for spending money on high-status products as opposed to saving money. Importantly, participants also reported their actual height. Although actual height and perceived height were correlated, only perceived height predicted participants' preferences for conspicuous spending.

In Study 2 we examined the causal relationship between perceived height and compensatory behavior by considering people's preferences for a high-status role in an economic game. We manipulated perceived height by asking participants to recall three situations in which they felt short vs. tall. Participants were then explained the rules of the dictator game. These include that a sender can decide how much of her endowment to give to the receiver, who has no choice but to accept what she is given. We observed participants' preference for participating in the game as senders (a high-status role) or receivers (a low-status role). Reflecting their hypothesized stronger need to compensate, participants in the short condition were more likely to choose the role of a sender than participants in the tall condition.

In Study 3 we examined whether the opportunity to engage in self-affirmation can serve as a buffer against the identity threat induced by perceived shortness and thereby attenuate the effects of perceived shortness on compensatory consumption. We manipulated self-affirmation by asking one group of participants to rank and elaborate on personal values that are important to them in life (e.g., work, religion). Participants in the control condition were asked to rank and elaborate on several features of office chairs (e.g., cushion material, mobility). Afterwards, participants indicated their preferences for spending money on high-status products (=7) vs. low-status products (=1) in three categories (luxury vs. economy car, home decoration vs. maintenance, upscale vs. local restaurant). At the end of the survey we measured chronic perceptions of height with the measures used in Study 1. As expected, self-affirmation reduced preferences for high-status products for individuals who felt short, but not for individuals who felt tall.

Our findings contribute to the recent literature on the effects of physical and genetic traits on decision-making (Gorlin et al. 2011; Simonson and Sela 2011), by showing that physical height affects consumer decision-making. In particular, we showed that the experience of physical shortness threatens people's identity and leads to compensatory choices in the marketplace. This finding paints a less pessimistic picture of the psychological and social consequences of height. While previous work outlined that shortness seems to (inevitably) lead to detrimental life outcomes (Judge and Cable 2004), and counterproductive interpersonal coping-strategies, like aggression (Willoughby and Blount 1985), the present work illustrates compensatory strategies that are less socially harmful and could provide potent means to bolster people against the threat of feeling short. Importantly for our understanding the genetic and social causes of this phenomenon, *feeling* short affects status-seeking behaviors above and beyond *being* short. Future research should investigate the nature of the psychological process behind this effect (e.g., whether it operates with or without individuals' awareness) and whether and how the psychological experience of physical shortness

compares to other known identity threats (e.g., social exclusion). Additionally, it seems promising to identify situation- and person-dependent variables that aggravate or attenuate the threat of feeling and being physically short. This could enable researchers to suggest useful coping strategies for the consumers affected.

That's Not How I Should Feel: Emotion Profile-Inconsistent Emotions as Identity Threats

EXTENDED ABSTRACT

Individuals possess identities— group level self-labels which can activate beliefs, attitudes, emotions, and behaviors providing behavioral guidance and reinforcing identity ownership (Reed et al. 2012). Research shows that consumers prefer and consume more of identity-consistent brands and products (Ahuvia 2005; Reed 2004). Recently researchers have investigated what happens when a consumer's identity is questioned or threatened. Undermining a consumer's belief in her identity performance encourages consumption to reinforce the threatened attribute (Gao, Wheeler, and Shiv 2009), as well as preferences for products that demonstrate possession of that attribute (Rucker and Galinsky 2008). Thus, when a consumer experiences an identity threat, she may engage in behaviors to "compensate" for the perceived lack of identity enactment.

We examine a new source of identity threats: experiencing an emotion that is inconsistent with the emotion profile of that identity. Social identities contain identity-relevant emotion profiles; consumers will engage in processes of emotion regulation to seek out consistent emotions while avoiding inconsistent emotions (Coleman and Williams 2013). In this research, we argue that experiencing identity-inconsistent emotions undermines identity enactment, creating a threat. We demonstrate that, compared to consumers experiencing emotion profile-consistent emotions, experiencing identity-inconsistent emotions creates greater preference for and consumption of identity-consistent products. Additionally, when consumers self-affirm (White and Argo 2009), "buffering" against the threat, these effects are attenuated. Across 3 studies, we see effects consistent with the proposition that emotion profile-inconsistency is threatening to a consumer's identity, prompting compensatory self-verification behaviors.

Study 1 used a 3 identity (athlete, volunteer, control) by 2 emotion (anger, sadness) design, to leverage the athlete-anger and volunteer-sadness emotion profiles (Coleman and Williams 2013). Participants completed a writing task, activating their athlete or volunteer identities (Reed 2004). Participants' emotions were manipulated via facial/bodily feedback (Duclos et al. 2007), generating anger or sadness. Finally, participants evaluated pairs of products; each included an identity-relevant (e.g., Adidas t-shirt, United Way hat) and identity-neutral (e.g., sunglasses) product. Relative preference for identity-relevant products measured compensatory consumption (Rucker and Galinsky 2008). A significant interaction between identity and emotion ($F(2, 218) = 6.175$, $p < .05$) on evaluations of the athlete-relevant products emerged; when athletes experienced the emotion profile-inconsistent emotion of sadness, they had greater preference for athletic products than when they experienced anger ($p = .034$). Similarly volunteers experiencing emotion profile-inconsistent anger had greater preference for volunteerism products than those experiencing the consistent emotion of sadness ($F(2, 218) = 2.973$, $p < .05$; contrast $p = .046$).

Study 2 examines whether self-affirmation (asserting personal values) will protect individuals when experiencing identity-inconsistent emotions. The study was a 2 self-affirmation (yes, no) by

3 identity (athlete, volunteer, control) by 2 emotion (anger, sadness) design, where identity and emotion were activated as in Study 1. Prior to the identity prime, self-affirmation condition participants wrote about values (Shrira and Martin 2005). The predicted three-way interaction emerged ($F(2, 346) = 7.003$, $p = .001$); in the no self-affirmation condition, athletes experiencing sadness had a significantly greater preference for athletic products than those experiencing anger ($p = .039$), while volunteers experiencing anger engaged in greater compensatory consumption than those experiencing sadness ($p = .003$). However, individuals who had self-affirmed their values revealed no difference in preferences for identity-relevant products regardless of experienced emotion ($p = .86$).

The final study examines the implications of identity-inconsistent emotions as a threat with actual consumption, using a 3 identity (athlete, volunteer, control) by 2 emotions (anger, sadness) by 2 water brands (H_2Help, H_2Sport) design. Participants' identities were activated with the writing task, then they experienced both the emotion induction (watching a 4-minute film clip pretested to elicit anger or sadness) and the consumption opportunity. During the film, they could freely drink an 8-ounce bottle of water, labeled H_2Help (volunteer brand) or H_2Sport (athlete brand). Water consumed (grams) was the dependent variable. The predicted three-way interaction of identity, emotion, and brand ($F(2, 280) = 3.107$, $p = .046$) emerged. Athlete identity participants who viewed the identity-inconsistent sad clip consumed more of the athletic water (H_2Sport) than the volunteer water (H_2Help; $F(1, 280) = 18.176$, $p < .0001$). When they watched the identity-consistent angry clip, this disappears; they drank equal amounts of athlete and volunteer water ($F(1, 280) = 1.107$, $p > .25$). Further, those with an athlete identity and given H_2Sport consumed significantly more when experiencing sadness than anger ($F(1, 280) = 4.400$, p $<$ .05). These results indicate athletes consumed more identity-consistent (H_2Sport) water when experiencing an identity threat: viewing the sad clip.

Similarly, participants with a volunteer identity also strategically consumed water to compensate for an emotion profile-induced identity threat. Those who saw the (inconsistent) angry clip consumed more of the volunteer-oriented (H_2Help) water than athletic water ($F(1, 280) = 10.537$, $p < .001$). In contrast, when they viewed the identity-consistent (sad) clip, there was no difference in their consumption ($F(1, 280) = .084$, $p > .75$). Those with a volunteer identity given H_2Help drank more when experiencing anger than sadness ($F(1, 280) = 7.057$, $p < .01$). Within the control identity conditions, there were no differences in consumption of the water based on either emotion or brand (all $p > .2$).

Across 3 studies, with different emotion manipulations, two identities, and measures of preferences and actual consumption, we find consistent evidence that experiencing an emotion that is inconsistent with a salient identity's emotion profile can be a source of identity threat. This research demonstrates that emotion profile-inconsistency is threatening to a consumer's identity, prompting compensatory consumption. Just as with negative group stereotypes (Steele and Aronson 2995), doubting possession of an identity-associated trait (Gao, Wheeler, and Shiv 2009), or making unflattering cross-group comparisons (White and Argo 2009), emotions too can undermine identity-performance and incite compensatory consumption.

Compensatory Consumption as Self- and Social-Signaling

EXTENDED ABSTRACT

Consumers engage in signaling on a daily basis: they seek products, hold attitudes, and engage in behaviors to communicate information about themselves to others. This is referred to as social-signaling (Batra et al. 2000). Consumption can also be used to self-signal information (Quattrone and Tversky 1984). Thus, people occasionally consume in order to bolster their sense of self.

Consumers' propensity to engage in signaling behaviors increases when they feel threatened or insecure. Indeed, several studies have shown that after experiencing a self-threat, people are more likely to buy, use and display products that are associated with desirable traits, presumably in an effort to compensate for the threat (Lee and Shrum 2013; Rucker and Galinsky 2013; Wicklund and Gollwitzer 1981). Prior work has often examined how people respond when they feel insecure in private settings, such as receiving negative feedback in a lab experiment, which can be linked to a self-signaling motive—people want to affirm who they are to themselves. However, little is known about how people cope when they are made to feel insecure in public settings, which may elicit concerns both about the self and about how others view them. The objective of this research is to address this issue by examining how self- versus social-signaling influence the way people compensate for self-threats.

One approach people use to compensate for self-threats is to seek products that signal accomplishments and success in the domain of the threat. We term this approach within-domain compensation, as consumers seek to associate themselves with products or brands that signal strengths within the domain of the threat (Gao, Wheeler, and Shiv 2009; Levav and Zhu 2009; Rucker and Galinsky 2008; Stone et al. 1997). To illustrate, after participants received negative feedback about their intelligence, they were willing to pay more for products that signaled intelligence, relative to those who did not receive negative feedback (Kim and Rucker 2012). A second approach people use to compensate for self-threats is to associate themselves with products or brands that signal strengths in alternative important domains, unrelated to the threat (Steele 1988; Stone et al. 1997). We refer to this second approach as across-domain compensation. To illustrate, after receiving feedback that made salient their hypocritical behavior of practicing unsafe sex (vs. not), participants were more likely to donate money to a charity organization for homeless people in an effort to boost their views as altruistic and generous individuals (Stone et al. 1997).

We propose that when people feel insecure in private settings they will be motivated to self-signal repair and will thus prefer to compensate within-domain, relative to control participants (see also Gao et al. 2009; Stone et al. 1997). This is because within-domain compensation provides the most aligned means of addressing the threat. However, products that can self-signal repair may signal to others one's vulnerabilities. Indeed, if one were to engage in within-domain compensation others may question their competencies in the domain of the threat. Thus, we suggest that when people feel insecure in public settings, they will be more inclined to compensate across-domain because of their motivation to impress others.

Experiment 1. Participants were first threatened in the domain of intelligence either in a public or private setting. Specifically, participants were asked to recall a time in which they did not feel as intelligent as they wanted to either when they were with others or when they were alone. Participants in the control conditions were asked to recall a neutral episode that occurred either when they were with others or when they were alone. Next, as part of

an ostensibly unrelated task, participants were asked to indicate their preference between an intelligence-related product (within-domain compensation) and a status-related product (across-domain compensation). Compared to control participants, those who felt insecure about their intelligence and were in the private condition, preferred the intelligence-related product more. However, participants who felt insecure about their intelligence and were in the public condition preferred the across-domain product more, relative to control participants.

Experiment 2. Experiment 2 provides evidence for the psychological process that underlies our findings in Experiment 1 by showing that social-signaling motivates people to compensate across-domain only among those who are concerned with how they appear in front of others (i.e., high self-monitors), but not among those who are less concerned with how they appear in front of others (i.e., low self-monitors). Participants were either publicly threatened in the domain of intelligence or not. They were then asked to indicate their preference between an intelligence-related product (within-domain compensation) and a status-related product (across-domain compensation). Finally, participants completed the self-monitoring scale (Snyder and Gangestad 1986). Participants who were threatened publicly showed a greater preference for the across-domain product relative to control participants, but only when high in self-monitoring and not when low in self-monitoring.

Experiment 3. The final experiment provides further evidence for the underlying process by measuring people's concern to impress others. Participants were either publicly threatened in the domain of intelligence or not. Then, they were asked to indicate their motivation to impress others. Finally, participants indicate their preference between an intelligence-related product (within-domain compensation) and a creativity-related product (across-domain compensation). Results showed that when people experienced a threat publicly they preferred to compensate across-domain relative to control participants. Furthermore, the motivation to impress others mediated this effect in the public threat condition but not in the control condition.

As a whole, this research provides a first attempt to systematically examine the effects of self-signaling and social-signaling on compensatory consumption. The implications of this research for the broader topic of compensatory consumption and signaling are discussed.

Socially Excluded People Value Money for What it Can Do for Them—Restore Belongingness or Control

EXTENDED ABSTRACT

The experience of being socially excluded, isolated, or alone is unfortunate and pervasive in daily life (Baumeister et al. 2005; Williams 2007). The current research tests how social exclusion influences consumers' spending by presenting a comprehensive model whereby social exclusion threatens and therefore heightens needs for both belongingness and control.

Prior research has suggested that social exclusion fundamentally threatens one's need for belonging and often motivates people to engage in behavior that can yield new social relationships (Baumeister et al. 2005; Maner et al. 2007). For example, Maner et al. (2007) found that social exclusion increases people's interest in making new friends and working with others, and that this effect did not occur when the contexts lacked the opportunity for social connection. Along this line, Mead et al. (2011) found that excluded participants were more likely than non-excluded participants to use their money to purchase a product favored by their interaction

partner, and that this effect was not observed when there was little chance of interacting with the partner. However, by far the existing research is mute on whether or how social exclusion might affect money spending when purchasing does not present opportunities for social affiliation.

We departed from prior work by proposing that in fact being socially excluded has significant implications for spending, due to a shift in attitudes about money. We predicted that social exclusion would reduce spending when consumers perceive that a purchase will not provide the chance for social inclusion, and that this reduction in spending would be due to an intention to compensate for the loss in personal control because money is seen as a source for control.

As a basic human motivation, personal control is defined as the capacity to change events, and perceptions of personal control are closely related to perceptions of competence and mastery over the environment (Burger 1989; DeCharms 1968). Prior research has found that social exclusion robs people of a sense of personal control (Lee and Shrum 2012; Williams 2007) and motivates them to boost their sense of control (Warburton, Williams, and Cairns 2006). For example, Warburton et al. (2006) found that social exclusion increases aggression - a coercive tool used to restore a sense of control, and that allowing participants to fortify their sense of control in other means diminished this effect.

Money enables people to work the social system to obtain their needs and wants. Having money means having the ability to secure what one needs and in doing so to gain some mastery over life. The concept of money might be linked to the concept of control (Lea and Webley 2006). For example, Lachman and Weaver (1998) found that low-income (vs. high-income) people reported poorer health and lower life satisfaction and feelings of low personal control. Suggestive of the power of control, however, low-income people who felt a high sense of personal control reported health and well-being patterns on a par with high-income people. Price, Choi, and Vinokur (2002) found in a longitudinal study that reduced personal control statistically accounted for the adverse effects of financial strain on poor health. A diverse set of research indicates that people see money as a symbol and source of power (Tang 1995; Yamauchi and Templer 1982), a concept associated with control (Fast and Chen 2009).

Drawing on the two sets of literature, we posited that social exclusion would decrease spending because socially excluded people would hold on to their money to compensate for the threats to their personal control. Money in these cases is seen as a means for personal control. Moreover, we predicted that social exclusion would increase spending on products that are seen as helpful for achieving social affiliation. Here money is viewed as a means for acquiring social affiliation through the product. Five experiments tested and supported our hypotheses.

In Experiment 1 participants first played a Cyberball game that manipulated social exclusion versus inclusion (van Beest and Williams 2006), and then indicated their willingness to pay for a computer and for having a casual meal in a restaurant based on customer review about the computer and the restaurant. Socially excluded participants were willing to pay less than included participants for the computer (Mexclusion = HK\$3950 vs. Minclusion = HK\$5625, F(1, 36) = 11.95, p = .001) and for the meal (Mexclusion = HK\$55.55 vs. Minclusion = HK\$67.90, F(1, 36) = 5.28, p < .03).

Experiment 2 replicated the result in experiment 1 by 1) using a recall task (Pickett, Gardner, and Knowles 2004) to manipulate social exclusion and 2) assessing willingness to pay involving a genuine purchase of a snack. Socially excluded participants offered less money for the snack (Mexclusion = HK\$6.34 vs. Minclusion

= HK\$7.31, F(1, 54) = 3.85, p = .055). Experiment 2 also revealed the underlying mechanism. Excluded participants viewed money as the source of personal control more so, which mediated the effect of social exclusion on willingness to pay.

Experiment 3 tested the mechanism using a moderation approach. When participants did not fortify their personal control before spending, excluded participants were willing to pay less for a computer (Mexclusion = HK\$6685.57 vs. Minclusion = HK\$7335.33, F(1, 89) = 3.68, p = .058). However, after recalling a time in which they had personal control, this effect did not occur (Mexclusion = HK\$7630.43 vs. Minclusion = HK\$7343.35, F < 1).

Using participants recruited at Amazon's Mechanical Turk, experiment 4 demonstrated that when a picture frame provided no affiliation opporunities, excluded participants were willing to pay less (Mexclusion = US\$5.57 vs. Minclusion = US\$6.80, F(1, 152) = 4.06, p < .05). However, when this product provided the affiliation opportunity, excluded participants were willing to pay more (Mexclusion = US\$8.20 vs. Minclusion = US\$7.33, F(1, 152) = 2.89, p = .09). Participants' social affiliation aspiration mediated this moderation effect.

Experiment 5 replicated the results in experiment 4 using a measure equivalent to Becker, DeGroot, and Marschak's (1964) procedure to assess willingness to pay.

SESSION SUMMARY

In an increasingly cluttered world, marketers are working harder than ever for a share of consumers' attention. This task is made difficult by the fact that attention typically ebbs and flows amongst a multitude of stimuli, from memories of the past, to thoughts about the present, to simulations of the future, and to perceptions of a variety of environmental stimuli that may be far afield from those related to a current purchase decision. And yet, despite attention's status as a classic construct in consumer research, our understanding of attention as a fluid process that is often directed away from a focal marketing stimulus is underdeveloped. As such, the papers in this session report new findings that answer questions such as: "What are the novel consequences of consumers attending to different types and categories of stimuli?" and "What strategies can marketers use to shift consumers' attention to different targets?" In doing so, the papers collectively uncover new and important ways that attention shapes consumer behavior.

The first two papers study the antecedents and consequences of attending to a broad category of stimuli, namely those in the present moment. In the first paper, **Rahinel and Ahluwalia** conceptualize attention as occurring along a spectrum from *experiencing*, where one attends to the current physical environment, to *mind-wandering,* where one instead attends to thoughts, feelings, and daydreams. They find that an experiencing (versus mind-wandering) attention mode leads one to believe that a changeable attribute—price—is more likely to change, and subsequently attach more weight to it in their decisions. **Rudd** shows that slow controlled breathing is an effective way to shift consumers' attention to the present moment, which subsequently leads consumers to feel that time is more plentiful. This expanded perception of time, in turn, boosts creativity, life satisfaction, and procrastination.

The second two papers study the processes underlying and outcomes associated with attending to individual pieces of stimuli. Specifically, **Van Boven, Mrkva, and Westfall** study the link between attention and emotional intensity and find that merely attending to an emotionally neutral object leads it to be perceived as more emotionally evocative. This effect of attention on emotional intensity decays over time; however, the effect of attention on salience and memory does not. **Suher and Hutchinson** use a novel mobile eye-tracking

method to record exact point-of-focus and field-of-vision for consumers on grocery shopping trips. They propose a general model of consumer multi-tasking that captures visual attention that is distributed between current and future purchase decisions.

These projects, all in advanced stages, offer new and interesting insights into the broad effects of consumer attention. Notably, they also appeal to a broad audience, as they intersect with a variety of other popular areas in consumer behavior such as attribute weighting, emotion, time-perception, in-store decision making, and creativity. Finally, the novel methodologies, interesting outcomes, and fresh perspectives on the topic promise a great fit with the conference theme by bringing fun back to this central and classic consumer behavior construct.

Attention Modes and Consumer Decision Making: Merely Attending to the Physical Environment Makes Price More Important

EXTENDED ABSTRACT

At any given moment, human attention varies along a spectrum from *experiencing*, where one attends to perceptions and cognitions related to their current physical environment, to *mind-wandering* where one instead attends to thoughts, feelings, and daydreams that are decoupled from their current physical environment (Barron et al. 2011; Smallwood and Schooler 2006). In this paper, we study how such attention modes systematically alter the weight attached to price in consumer decisions. Logic from previous work suggests that being an experiencing (versus mind-wandering) mode should lead one to consider more product attributes, thus decreasing the relative weight assigned to a salient attribute like price (Chakravarti et al. 2013; Lichtenstein et al. 1988; Rao and Monroe 1988). In contrast, we find the precise opposite: that an experiencing (versus mind-wandering) mode leads one to more heavily weight price in decisions.

Our framework describes this phenomenon as a byproduct of the intersection between attention modes and the importance one places on noticing change. Since attention is allocated based on one's current goals (Pashler et al. 2001), it follows that an individual's attention mode is governed by the emphasis one presently places on environment-related vs. environment-unrelated processes. We posit here that the more relative emphasis one places on environment-related processes (leading to more relative experiencing), the more interest one places in noticing change in their environment, since change signals that one may have to modify their interactions with the environment (Rensink 2002). Building from past work (Miller and Maner, 2012; Schaller, Park, and Mueller 2003), we suggest that such interest should lead one to believe that a changeable stimulus (e.g., price) is more likely to change and, thus, assign it greater weight. Five studies support our conceptual framework.

Study 1 tests our framework in a basic context: object encoding. Participants first completed an experiencing-versus-mind-wandering (EvMW) measure, which we developed (in several preliminary studies) to capture attention mode as a trait variable. We then exposed participants to a collage that contained 12 pretested objects: four that were typically unchangeable (e.g., teddy bear), four that were typically changeable (e.g., dog), and four that were dynamically changing (e.g., animated walking man). After a seven second exposure, participants were given a recognition test that included all the items

in the collage as well as 12 foil items. As predicted, experiencers recognized more changeable objects than did mind-wanderers. There were no effects for either unchangeable or dynamically-changing objects, both of which have confirmed states of change and therefore should not show the effect. The specific pattern of means showed that experiencers treated changeable stimuli like dynamically-changing stimuli, whereas mind-wanderers treated changeable stimuli like unchangeable stimuli, thus suggesting that differences in beliefs of change likelihood may underlie the effect.

In study 2, we extended the effect to a consumer decision making context, with price as the changeable attribute. Participants completed the EvMW and then viewed an advertisement for an office chair with six attributes, including price. Participants rated whether they would consider buying the chair and, as the dependent measure, how much weight they gave to each attribute. As predicted, experiencers attached more weight to price than did mind-wanderers, and this pattern did not exist for any other attribute.

In studies 3 and 4, we tested the proposed mechanism with different categories (all-weather running shoes and desk lamps, respectively) and non-price attributes. In study 3, we manipulated attention mode by having participants read a story and put themselves in the frame of mind of the protagonist, who was described as performing an activity in either an experiencing or mind-wandering mode. We then used an ad-viewing and attribute weighting procedure, similar to that in study 2. We also measured the degree to which participants believed the price for the product would change. Results again showed that an experiencing (vs. mind-wandering) mode led to a higher weighting of price. Moreover, this effect was mediated by beliefs that the price would change. Study 4 provided more process evidence by manipulating the changeability of price. Before completing the same attention mode manipulation as in study 3, participants read a fictional *Consumer Reports* article communicating that prices were either primarily changeable or primarily unchangeable. The basic effect found in study 3 was replicated in the price-is-changeable condition, but attenuated in the price-is-unchangeable condition.

Study 5 tested the effect in a different decision making context (quality judgments), and in doing so, sought to rule out alternative explanations related to thrift motivations, construal level, and price diagnosticity. Before responding to the EvMW, participants read a description of a bottle of water and were asked to rate the quality of the water. The water was described using several attributes, with the final attribute being a low price, high price, low-reputation brand, or high-reputation brand. Results showed that experiencers predicted high-priced water to be of better quality than low-priced water, but there was no effect of price for mind-wanderers. Notably, this effect pattern did not carry over for brand (which was pretested as more diagnostic than price in this context), as b*oth* experiencers and mind-wanderers predicted that high-reputation branded water would be of higher quality than low-reputation branded water.

In sum, an experiencing (vs. mind-wandering) mode of attention leads one to believe that a changeable stimulus is indeed more likely to change and, therefore, attach more weight to it. This framework explains the weighting of price across the two attention modes, since price is a uniquely changeable attribute. Taken together, these theoretically counterintuitive findings shed new light on both price weighting and the underlying psychology of attention modes. More broadly, they also demonstrate how cognitive mechanisms built for the physical environment are co-opted for fundamental decision-making processes.

Expand Your Breath, Expand Your Time: Slow Controlled Breathing Boosts Time Affluence

EXTENDED ABSTRACT

Modern-day consumers frequently experience "time famine" (Perlow 1999): They feel there is too much to do and too little time. Unfortunately, such perceptions can take a toll on social, physical, and mental well-being (Hochschild 1997; Roxburgh 2004; Zuzanek 2004). Although science cannot expand the amount of time in each day, could it shift consumers' perceptions of how much time they have? This research examines whether engaging in slow controlled breathing would increase consumers' perceived time affluence and, consequently, impact their behavior and well-being.

Breathing can be either automatic or under voluntary control. Voluntary breathing can be performed either fast or slow and consists of conscious inhalation, retention, and exhalation (Chodzinski 2000). But, can slow controlled breathing increase perceived time affluence? Prior research and theory suggest so. For instance, a drug-induced reduction in breathing rate can reduce the perceived speed of one's internal clock (Hawkes, Joy, and Evans 1962). Moreover, activities like mindfulness meditation and yoga, which generally involve slow controlled breathing, help direct the mind's attention to the present moment (Brown and Gerbarg 2009; Brown and Ryan 2003; Kabat-Zinn et al. 1992). This is important because there is evidence that a stronger focus on the present expands time perceptions (Rudd 2013; Vohs and Schmeichel 2003). Taken together, these results suggest slow controlled breathing would increase consumers' perceived time affluence by strengthening their present-focus.

In Experiment 1, participants completed either a slow-controlled-breathing or fast-controlled-breathing exercise. Exercises differed in the breathing rate used, but took the same amount of time to complete. Posture, method of inhalation and exhalation, and depth and force of breath also did not differ across conditions. To manipulate breathing rate, participants in the slow- [fast-] controlled-breathing condition were instructed to "breathe so each complete breath (i.e., inhale plus exhale) lasts 11 counts [4 counts]" and told the inhale should last 5 [2] counts and the exhale should last 6 [2] counts. Participants in the slow- [fast-] controlled-breathing condition completed 3 "sets" of 7 eleven-count-long breaths [19 four-count-long breaths]. Because one could argue that any observed differences in time perceptions might be due to differences in arousal, feelings of arousal were measured after the breathing exercise. However, because both fast and slow controlled breathing exercises are often immediately followed by a physiological and psychological calming (Brown and Gerbarg 2005; Cappo and Holmes 1984; Kaushik et al. 2006; Khemka, Ramarao, and Nagarathna 2010), arousal was not expected to differ across conditions. The other dependent variables were temporal focus (i.e., the extent participants were currently focused on the past, present, and future) and perceived time affluence (i.e., the extent participants currently felt "pressed for time"). Consistent with the hypotheses, those who engaged in slow (vs. fast) controlled breathing were more present-focused and felt less pressed for time. Moreover, a mediation analysis revealed that slow controlled breathing expanded perceptions of time by heightening people's focus on the present. Importantly, arousal could not account for these effects.

One's sense of time availability is often an indicator of psychological health, with mental health and well-being suffering when time feels compressed (Robinson and Godbey 1997; Roxburgh 2004). Thus, Experiment 2 tested whether slow controlled breathing would boost life satisfaction by increasing perceived time affluence. Experiment 2 followed the same procedures as Experiment 1, ex-

cept this time the dependent variables were perceived time affluence (i.e., participants' current feelings of impatience) and life satisfaction (Kahneman et al. 2006). The results revealed that after engaging in slow (versus fast) controlled breathing, participants felt less impatient and more satisfied with life. Moreover, a mediation analysis demonstrated that those who engaged in slow controlled breathing experienced greater life satisfaction because they felt less impatient.

Prior research suggests feelings of time pressure can hinder creative thinking (Amabile, Hadley, and Kramer 2002; Andrews and Smith 1996). Therefore, Experiment 3 tested whether, by increasing perceived time affluence, slow controlled breathing would enhance creativity. For convergent validity, Experiment 3 added a control condition. After completing either the slow-controlled-breathing, fast-controlled-breathing, or no breathing exercise, participants reported their current feelings of time pressure and completed a divergent thinking task (in which they generated creative uses for a brick; Silvia et al. 2008). Creativity scores were determined by two independent raters and followed the scoring method outlined in Silvia et al. (2008). The results revealed that those who engaged in slow (versus fast or no) controlled breathing felt less pressed for time and were more creative. Moreover, mediation analyses demonstrated that those who engaged in slow controlled breathing were more creative because they felt less pressed for time.

A link between greater perceived time and greater procrastination is also suggested by prior research (Shu and Gneezy 2010; Vodanovich and Rupp 1999). Thus, Experiment 4 examined whether, by boosting perceived time affluence, slow controlled breathing would increase procrastination tendencies. After completing either the slow-controlled-breathing, fast-controlled-breathing, or no breathing exercise, participants reported the extent they currently felt pressed for time and the extent they would procrastinate in two scenarios (Scenario 1: They imagined they had just been assigned a 5 page paper that was due in 7 days and reported on what day they thought they would complete it; Scenario 2: They imagined they had to fill-out a 1 page form before the end of the week and reported on what day they thought they would return the completed form). The results revealed that participants who engaged in slow (versus fast or no) controlled breathing felt less pressed for time and reported a greater tendency to procrastinate in both scenarios. Moreover, mediation analyses demonstrated those who engaged in slow controlled breathing had greater procrastination tendencies because they felt less pressed for time—suggesting the consequences of expanding perceived time are not always positive.

In conclusion, slow controlled breathing strengthens one's focus on the present, and this greater present-focus can increase perceived time affluence. Importantly, this greater perceived time affluence has important consequences for consumer behavior and well-being: it boosts life satisfaction, enhances creativity, and heightens procrastination tendencies.

Attention Increases Emotional Intensity

EXTENDED ABSTRACT

A growing number of studies have shown that attention influences emotional responses. Most of these previous studies have been designed to examine whether attention is necessary to produce emotional reactions. They have shown that introducing attentional distractors, attentional load, or shifts of attention away from a task decrease emotional responses to stimuli involved in the task. Affective reactions are weaker under high and moderate levels of attentional load compared to low load (Pessoa, Padmala, and Morland 2005). We intend to address a related question with more practical significance and applications: Does focused attention increase the intensity of emotional reactions? Does this increase in emotion have downstream consequences for variables like interest, memory, and choice? Our results seek to build on work showing that emotional responses are malleable and can have important effects on memory and decision making.

Past work has examined the emotional consequences of differential attention using distractor paradigms. Raymond, Fenske, and Tavassoli (2003) randomly assigned stimuli to serve as either targets or distractors in a perception task. Stimuli which served as distractors were subsequently rated lower on self-report measures of emotional tone (i.e. "cheeriness") compared to target and neutral stimuli. Dickert and Slovic (2009) used a similar paradigm, presenting pictures of humanitarian crisis victims either as focal targets or as distractors. Participants reported less emotional sympathy for the victims assigned as distractors compared to those assigned as targets. The attention manipulation had downstream consequences. Participants were less willing to donate money to help victims who had been randomly assigned as "distractors". These previous studies all demonstrate that the emotional intensity of unattended stimuli can decrease.

The current studies extend this work in a variety of ways, showing for the first time that directed attention can increase emotional intensity, and that attention also increases perceived distinctiveness and salience. They also demonstrate that attention has long-term effects on the processing of images (study 2). Finally, study 3 demonstrates applications to person perception and decision-making.

Across three studies, directed attention increased the intensity of emotional reactions to images. Participants were presented with a slideshow of images and were exposed to each image for the same duration but were instructed to attend most closely to one randomly-assigned image. Afterwards, they rated each image on emotional valence and intensity. They also completed a free recall task to assess memory, and the perceived salience of each image was measured. Study 3 added measures of choice and judgments about the stimuli, examining whether attention influences decisions, perhaps via its effects on emotional intensity.

Following the attention manipulation, participants judged the image they attended to as more emotionally intense than other images. Images that were neutral and low-intensity at baseline showed the largest effects, increasing sharply in intensity. This attention X baseline arousal interaction was significant in both studies. Study 2 further demonstrated that attention also improves memory and the salience of the image in memory. The effect of attention on emotional intensity went away after a delay of two days. However, enhanced memory and salience of the target stimuli remained. Study 3 used a similar study design to the first two, but used images of people as stimuli and assessed whether trait judgments about each person were influenced by attention. It demonstrated that attention increases the perceived distinctiveness of each person, influences judgments of each person's trustworthiness, and may influence interest and choice.

Overall, these findings demonstrate that emotional reactions towards images and evaluations of objects are malleable, especially when those objects are initially neutral and low in emotional arousal. They also extend previous research in cognitive psychology and demonstrate that the relationship between attention and emotion is reciprocal. A large literature on attention has demonstrated that emotionally-intense stimuli capture and hold attention more than unemotional stimuli (e.g. Ohman, Flykt, and Esteves 2001), and our program of research shows that attended-to stimuli take on greater emotional intensity. These findings have clear implications for marketing and consumer research. Brand names and products which are

initially neutral can become more emotionally-intense and evoke stronger reactions in consumers after being repeatedly attended to. Advertisements which are able to best capture and direct consumers' attention towards their products and brands may be most successful, increasing the salience of the product and increasing interest.

The Multi-Tasking Shopper: Mobile Eye-Tracking and In-Store Decision Making

EXTENDED ABSTRACT

Of all the ways to read a consumer's mind during a decision making process, the most direct is to look through her eyes to see what she is seeing. This paper examines the pattern of attention to visual stimuli throughout a whole shopping trip. We conduct a grocery field study using mobile eye-tracking technology to record consumers' exact point-of-focus while navigating the store and at the point-of-purchase. Each visual fixation is classified for its spatial and temporal position along with its visual content, such as price or brand. Using these rich data, we describe the patterns of attention throughout an entire shopping trip and propose a general model of consumer multi-tasking.

Eye-tracking technology has been used extensively in scene perception research, especially in advertising contexts. This body of work provides a broad consensus that eye-movements are informative about processes such as attention, information acquisition, and choice. While this technology has been used to "see through consumers' eyes" for decades, there has been limited work on visual attention at the point-of-purchase (Chandon, Hutchinson, Bradlow, and Young 2009). The research that has examined point-of-purchase decision making has been limited to the laboratory setting. We contribute to this pool of research by using a novel data set that captures point-of-focus data in the field.

Our data consist of shopping trips made by 6 consumers in a medium-sized U.S. grocery store, including 68 purchases and eye-tracking of all visual search during each trip. Each consumer wore a mobile eye-tracking device to record her exact point-of-focus and field-of-vision throughout a complete shopping trip. To make our quantitative analyses possible, the video data was coded in two ways by video technicians. First, for each purchased product, technicians identified the start-point of the purchase and then watched the videos frame-by-frame, recording the spatial location and content of each visual fixation over time. Each fixation was mapped onto a still "snapshot" of the purchase display to make the points-of-focus spatially meaningful. The content of each fixation was categorized as picture, brand, description, price, variety, or other. Additional variables, such as product display characteristics and within and between shopper variables were also included in our database. Second, to gain greater insight into the whole shopping process, especially product categories that were considered but did not lead to a purchase, a number of scanning segments were analyzed in their entirety (i.e., including fixations while the consumer was walking and fixations on products far from the consumer's current location). For these scanning segments, video technicians recorded the content of each fixation (e.g., product category, in-store signage, shoppers, etc.) and the distance between the fixation target and the shopper.

When making a purchase, the majority of consumers' visual attention is on graphic elements of the product (26% of fixations) or brand name (25%). Textual messages and shelf edge prices together constitute another one third of the fixations (20% for text; 13% for price). The remaining visual fixations address variety or flavor (10%) and non-price shelf-edge messages (6%). Of the six types of visual fixations, the brand name or logo dominates the beginning of most

of the purchase events. Graphic images, particularly of the product, closely follow brand identity and exceed the brand attention in the latter half of the purchase process. Attention to visual content varies widely across product categories. For instance, brand information makes up 38% of visual attention for snacks and sweets, whereas it constitutes only 22% of fixations for dairy products. Purchase duration also affects the patterns of fixations. When making longer purchases, shoppers pay more attention to price and brand information and less attention to the photo and product description.

An analysis of whole shopping trips revealed that while considering a nearby shelf or making a specific purchase, consumers are continuously monitoring the shopping environment with quick glances that fixate on objects that are further away. Some scans appear to be automatic (or even reflexive), such as people entering the aisle or approaching the shopper. Others are clearly related to planning later shopping decisions, such as glancing at more distant shelf displays and signage. State transition analysis demonstrates that shoppers tend to refixate at the same distance from the shopper 26% of the time, while shoppers refixate in a new location at least 3 feet further or closer to the shopper 68% of the time. The frequent changing of fixation distance supports our conjecture that shoppers sequentially switch between multiple tasks during the shopping trip.

Finally, to illustrate the multi-tasking nature of real-world shopping, we propose a general model of consumer multi-tasking that extends current work on specific purchase (usually eye-tracking data) and store navigation (usually shopper-view video and/or RFID cart location data) by interrelating these two areas in terms of information search and decision planning. We find that a finite mixture model with three distinct distributions explains the distribution of fixation distances better than a model that assumes a single cognitive process.

SESSION SUMMARY

Consumer behavior research increasingly recognizes the importance of identity for understanding consumer cognition and choice (see, for example, the JCR research curation "Self-Identity and Consumer Behavior), and recent research has shown that people's beliefs about stability vs. change in identity can have profound consequences for consumer behavior (Bartels & Urminsky, 2011, Petrocelli, Clarkson, Tormala, & Hendrix, 2010). However, much remains to be learned about both (i) the mechanisms underlying people's beliefs about changes in identity over time and (ii) the downstream consequences of those beliefs. This session will explore both sides of this topic. Two papers, from **Urminsky and St. Louis** and **Rogers and Norton,** investigate some of the characteristics of people's beliefs about identity change and stability. **Akhar and Weeler** and **Newman, Bartels, and Smith** document some of the diverse consequences of people's beliefs about the stability of identity.

How do people think about change in their identity and the identity of others over time? **Rogers and Norton** explore people's beliefs about change in attitudes and preferences. They find that people believe that the general population will eventually grow to share their attitudes. Furthermore, they demonstrate that a motivated projection of a favorable future, rather than a projection of the current state of affairs, underlies people's belief that the attitudes and preferences of others will change into alignment with their own.

Urminsky and St. Louis examine the straightforward idea (endorsed by respondents) that if you think your most important and stable traits will change, you view your future self as less connected to the current self. However, they find people's sense of overlap with their future self—and the future oriented decisions influenced by this overlap—does not depend more on the traits rated by participants as most important for determining one's identity. Change in more peripheral or transient aspects (like one's level of happiness and life experiences) is just as destabilizing to future self connectedness and forward-looking consumer decisions as change in more important aspects of one's identity (like one's values and personality).

Akhtar and Wheeler find that general beliefs about one's own attitude immutability can have profound implications for confidence

in and motivation to advocate for a belief. These beliefs also influence one's appraisal of how those with differing beliefs would respond to such a persuasion attempt. These two effects could cancel each other out, but by changing where participants directed their focus, Akhtar and Wheeler were able to significantly influence the effect of attitude immutability on advocacy behavior. This work probes both an important pathway through which beliefs about identity change can influence behavior and the role of attention in mediating the consequences during the act.

Newman, Bartels and Smith's studies show that beliefs about human identity continuity appear to generalize to the way that people think about identity-related one-of-a-kind objects—namely, art (and not tools). Their studies find that artworks (unlike other artifacts) are restricted in the kinds of changes they can undergo and still maintain their original identity. Specifically, people care about the continuity of physical aspects of artworks because they believe the original pieces are imbued with the artist's essence. This has downstream consequences for the value that people perceive in and are willing to pay for these objects.

Taken together, these four papers address the important next questions in the literature on stability and change in identity over time: what psychological processes give rise to our beliefs about identity change or stability, and how do these beliefs then influence other judgments, motivations, and behaviors? We believe this session will be of interest to a broad audience, including consumer and decision researchers and policy practitioners interested in the potential use of identity change manipulations as an intervention. We hope this session will help the diverse group of researchers studying the antecedences and consequences of identity change and stability develop new ideas and more effective research directions.

The Belief in a Favorable Future

EXTENDED ABSTRACT

People frequently construct beliefs about the unknown in self-serving ways. People believe others agree with them more than they actually do (the false consensus effect), and that good things that are out of their control will happen to them (optimism). We explore whether people exhibit a belief in a "favorable future" – a tendency to predict that future states of the world will align with their motivations and desires, and reflect favorably on them. We find that people believe that their ideological, policy and entertainment preferences will be more common in the future than they are today. Importantly, however, people do not believe that all of their proclivities will become more common. The constructed future favors the self: people believe that their bad attributes will become more common in future but that their good attributes will become rarer – such that only people's positive aspects will stand out in the crowd.

Study 1 shows that liberals are more likely than conservatives and moderates to believe that in twenty years a greater proportion of people will identify as liberal. Conservatives, on the other hand, are more likely than liberals and moderates to believe that in twenty years a greater proportion of people will identify as conservative. Moderates demonstrate a similar pattern.

Study 2 replicates Study 1 and extends the belief in a favorable future to entertainment preferences, policy preferences, and environ-

mental beliefs. People who are fans (not fans) of the television show *American Idol* are more likely to believe that the show will be more popular (less popular) in five years; people who believe that having an abortion or being involved in a same sex marriage should be easier (harder) are more likely to believe that in twenty years having an abortion or being involved in a same sex marriage will be easier (harder); and people who believe the climate is warming (not warming) are more likely to believe that in twenty years more (fewer) people will believe the climate is warming.

Study 3 shows that the belief in a favorable future is distinct from the false consensus effect. Participants report their current ideology, the ideology they believe is most common today, and which ideology will become more common in twenty years. People believe that their current ideology will be more common in the future (favorable future). People also believe that their current ideology is the most common ideology today (false consensus). Importantly, however, the favorable future effect is substantially larger in magnitude than the false consensus effect, suggesting that beliefs about the future are magnified beyond one's (biased) perceptions of the present.

Finally, Study 4 demonstrates that the favorable future effect is motivated. People do not necessarily believe that all aspects of themselves will become more common in the future. Participants self-reported attributes about themselves that they liked and disliked, and then predicted the commonness of those attributes in twenty years. Participants believed that their disliked attributes will become more common in the future – making their faults less notable – but that their liked attributes will become less common – making their strengths more prominent. People's construction of the future appears to be not simply a projection of their current self, but a motivated projection of a favorable future.

One ironic implication of the tendency to construct a favorable future may be that it demotivates behavior in the present: if the way I want the world to be is inevitable, why bother to go out and try to change it? For example, believing that same sex marriage is inevitable may decrease one's motivation to cast a vote when same sex ballot initiatives arise.

Less Than We Know: The Effect of Trait Importance to Connectedness to the Future Self.

EXTENDED ABSTRACT

Prior research has demonstrated that people's sense of connection to their "future self" — the person they will be in the future— can substantially influence intertemporal tradeoffs, including delay discounting tasks (Bartels & Urminsky, 2011). Building on prior literature, people's future self connectedness has been operationally defined by whether the full set of features and attributes that define one's identity are shared between the present and future self. Past research has suggested that people view some traits as more important for self-identity than others (Strohminger & Nichols, 2014). We conducted three studies to identify whether ones' sense of connection to the future self rested more heavily on the believed stability of important traits. Our results indicate that while consumers believe that stability or change on important traits is relatively important for connectedness, the effect of the stability of a trait on future self connectedness was not, in fact, moderated by the importance of that trait. We show similarly that manipulating the stability (or change) in less important traits is just as effective at increasing (decreasing) revealed preferences for the well being of one's future self.

In Study 1 (n=142), we tested a comprehensive list of 49 attributes identified from prior work and pre-tests as potentially critical components of one's identity (e.g., intelligence, honesty, humor, personality, level of friendliness, values, morality, everyday experiences, memories, etc.). Participants indicated whether they believed a change on each attribute would result in a change in their personal identity. They also rated expected magnitude of change on each attribute, in the coming year.

We found that beliefs about whether a given change would impact connection to the future self were negatively correlated with beliefs about whether that change would occur. In effect, people believed that changes in stable identity traits would affect their connectedness, but would be unlike to occur, while changes in transient identity traits were likely but would not impact connectedness.

In Study 2 (n=61), we again tested participants' lay beliefs, by asking them how their connection to the future self would be differentially affected by learning that they shared transient or stable traits with the future self, using a within-subject design. We tested 12 scenarios in which participants were told about one attribute which would change and one which would remain the same over time. Participants rated how connected they believed they would feel to their future self, based on each scenario. On average, participants said that their connectedness with their future self would be 30% lower ($p<.01$) when they were asked to imagined that the stable trait would change in the future, compared to when they imagined that the transient trait would change. This suggests that participants believed that learning that their more stable traits would change would have a larger effect on their connectedness.

In Study 3 (n=473), we tested how people' connectedness to the future self and resulting decisions would actually be affected by information about the likelihood of traits changing or staying the same over time. We presented each participants with one scenario, similar to those in Study 2 but tested between-subjects. We conducted a 2x2 between subjects ANOVA, comparing how participants responded to learning that transient or stable attributes were likely to change or stay the same in the future. While we found a main effect of learning that any trait was likely to change, we did not find any evidence of interaction with the transience or stability of the trait (F=. 075). This shows that while participants said that change on stable traits would be far more devastating to connectedness than transient traits, this is not what actually happened when they were presented with information about the likelihood of the identity changing over time.

In addition, in Study 3, learning that specific attributes were likely to change significantly reduced patience in a delay-discounting task (F=5.17) indicating that people's beliefs about change on these attributes have important implications for future-oriented decision making. However, there were no significant differences in patience based on changes in transient vs. stable traits (F=1.02).

Taken together, our results suggest that that there is an important discrepancy between the attributes people believe make up the critical components of their self-identity and the way they actually use predicted change on those attributes to generate a sense of connectedness to their future self. Our evidence suggests that consumers believe they are using the relative importance of attributes in their calculations of similarity to the future self, but their actual connectedness and future oriented choice behavior do not actually evince any such calculation. This discrepancy suggests that consumer's implicit -self-identity may differ from their explicit conceptualization, leading them to underestimate the contribution of their more peripheral traits to their connection to their future self, and thus their future-oriented decision-making.

Belief in the Immutability of Attitudes Both Increases and Decreases Advocacy

EXTENDED ABSTRACT

Research on implicit theories (i.e. the beliefs people have about human characteristics) shows that people with a fixed mindset about attitudes (i.e. the belief that attitudes are relatively stable and unchanging) are more certain of their attitudes (Petrocelli, Clarkson, Tormala, & Hendrix, 2010) than are people with a growth mindset (i.e. the belief that attitudes are malleable). Separately, research on the relationship between attitude certainty and advocacy generally shows that people with greater attitude certainty are more willing to express their opinions and try to persuade others (Visser, Krosnick, & Simmons, 2003; Akhtar, Paunesku, & Tormala, 2013). A synthesis of these literatures would suggest that people with a fixed mindset about attitudes are more certain of their own attitudes and consequently more willing to try to persuade others to their beliefs. However, it is also conceivable that people with a fixed mindset about attitudes may be more likely to perceive *others'* attitudes as difficult to change, rendering people with a fixed mindset less willing to try to persuade others. Across four studies, we show that both of these countervailing effects occur simultaneously, resulting in the absence of an overall direct relationship between implicit theories of attitudes and advocacy. By shifting whom people focus on (themselves or others) or how advocacy is framed (as sharing, persuading, or defending), implicit theories can directly influence willingness to advocate.

Study 1. Participants were told that we were conducting public opinion research on a variety of issues. All participants reported their attitude, likelihood of trying to persuade others, and perceived persuadability of others regarding the death penalty. After completing a ten-minute filler task of personality scales, participants completed the eight-item implicit theory of attitude stability (ITAS) scale (from Petrocelli et. al, 2010). Results indicated that a higher score on the ITAS scale (i.e. a fixed mindset) was inversely correlated with perceived persuadability of others but uncorrelated with likelihood of trying to persuade others. However, as expected, there was a negative indirect effect of ITAS on advocacy through perceived persuadability of others. These results provide initial correlational evidence that a fixed mindset leads to lower likelihood of trying to persuade others because of lower perceived persuadability of others, but that another, opposing mediator may be canceling out the direct effect.

Study 2. Study 2 was designed to (1) allow for causal claims by manipulating implicit theories, (2) replicate the indirect effect from Study 1, (3) replicate the effect of implicit theories on attitude certainty from Petrocelli et al. (2010), and (4) simultaneously identify attitude certainty as an opposing mediator contributing to the nonsignificant direct effect of implicit theories on advocacy. Participants were told that they would be completing two unrelated tasks. The first task was an implicit theories of attitudes manipulation under the guise of a reading comprehension test (adapted from Chiu, Hong, & Dweck, 1997). For the second task, participants reported their attitude, attitude stability, attitude certainty, perceived persuadability of others, and willingness to try to persuade others regarding the death penalty. First, replicating previous research, we confirmed that a fixed mindset led to greater perceived attitude stability, which led to more certainty of one's own attitude. Replicating Study 1, we also found that a fixed mindset decreased perceived persuadability of others but had no direct effect on willingness to try to persuade others. A bootstrapped multiple mediation analysis (Preacher & Hayes, 2008) confirmed that implicit theories indirectly affected advocacy through the opposing forces of attitude certainty and perceived persuadability of others. Thus, people with a fixed mindset are simultaneously more likely to advocate because they are more certain of their attitudes and less likely to advocate because they perceive others to be less persuadable, rendering the direct impact of implicit theories on advocacy inert.

Study 3. Participants were involved in a 2 (mindset: fixed vs. growth) × 2 (focus: self vs. others) between-subjects design in which they wrote about life experiences in which they (or others) have changed (or have not changed) their attitudes over time. Participants then completed an ostensibly unrelated second task in which they reported their attitude and willingness to try to change the opinions of others regarding the death penalty. Results showed a significant interaction. Consistent with the notion that people with a fixed mindset are motivated to advocate because of their own attitude certainty, people with a fixed mindset were more willing to advocate when they focused on their own attitudes rather than others' attitudes. Those with a growth mindset, on the other hand, were more willing to advocate when they focused on others' attitudes rather than their own.

Discussion. Taken together, these findings reveal that implicit theories can play an important role in motivating advocacy, even if there appears to be no direct relationship between the two. A fixed mindset about attitudes simultaneously motivates and demotivates advocacy through greater certainty in one's own attitudes and lower perceived persuadability of others, respectively. Thus, although greater attitude certainty generally leads to greater advocacy, this is not necessarily the case when that certainty is derived from a fixed mindset about attitudes. However, people with a fixed mindset actually can become more or less willing to advocate than people with a growth mindset, depending on whom they focus their attention. Implications for understanding implicit theories of attitudes, multiple mediation analysis, and determinants of advocacy are discussed.

Are Artworks More Like People than Artifacts? Individual Concepts and Their Extensions

EXTENDED ABSTRACT

The literature on concepts has typically focused on general concepts—concepts like PERSON, CAT, or PAINTING. However, our concepts of individuals, such as my brother *Robert*, my cat *Jack*, or Van Gogh's *Starry Starry Night*, play a key role in how we interpret the world around us.

The majority of the research on this topic has examined how people track the persistence of humans. For example, how people decide whether Jim is still *Jim* across time or various transformations. Previous research suggests that people's beliefs about the continuity of persons tend to be dualistic: People believe that the continuity of an individual's mental states (their thoughts, memories, and personality traits) is necessary for identity continuity, but at the same time, they also seem to place considerable importance on the continuity of the person's physical *stuff* (e.g., Blok et al., 2001). Moreover, continuity judgments about persons seem to be somewhat unique in this respect—for example, people are more likely to say that a molecule-for-molecule copy of a hammer *is* the same individual hammer (provided that the original is destroyed when it is duplicated).

Here we extend research on continuity judgments for persons to examine a second domain in which people seem to place considerable importance on the continuity of the same physical stuff—namely, one-of-a-kind artifacts. For example, like persons (and unlike hammers) people do not tend to believe that an identical duplicate of a painting is the *same* painting, and they view duplicates as considerably less valuable than the original (Newman & Bloom 2012). To explain this pattern, we draw on the notions of the 'extended self '(James, 1890; Belk, 1988; Olson, 2011), which proposes that the

self concept goes beyond a person's physical body to include certain artifacts that are seen as extensions of the self. Therefore, we suggest that observers may place special emphasis on original artwork, because the original is thought to physically contain some part of the person who created it (which cannot be duplicated).

The goal of the Study 1 was to examine whether people's continuity judgments are more materialist for artworks than comparable artifacts. Participants read hypothetical scenarios in which an artwork or a tool was duplicated and the original was destroyed. In all cases, participants were told that the original artwork [tool] was made by a college student (to control for potential differences in value), and were given specific information about how it was made (e.g., using a mold and poured plastic), which was the same in both cases. We hypothesized that duplicate artworks should be *less likely* to be seen as continuers of the original compared to duplicate tools.

To test the notion of the extended self we also varied whether the duplicate object was made by the original creator or by another person. Specifically, participants read scenarios in which the original creator "*agrees to make an exact duplicate*" and scenarios in which he "*agrees to have someone else make an exact duplicate.*"

As predicted, we observed that duplicate artworks were *less likely* to be seen as continuers of the original compared to duplicate tools. Additionally, there was a main effect of creator such that objects made by the same individual were *more likely* to be seen as continuers of the original compared to objects made by someone else. However, this effect marginally interacted with object type, such that there was an effect of the creator for artworks, but not for the tools.

The goal of Study 2 was to explore some of the reasons why people may be more materialist when reasoning about the continuity of art versus other types of artifacts.

In this study, participants were asked to read a scenario about a painting. Between subjects we manipulated information about the painting, varying the dimensions of contagion (whether it was made by the original artist or an assistant), creativity (whether it was an original design or not) and personal attachment (whether the artist was personally attached to the artwork). In each condition, participants were told that painting was duplicated and the original was destroyed. Then, they indicated the extent to which they thought the resulting (duplicate) object was the same painting.

Overall, participants were more likely to agree that the duplicate was *not* the same painting when the artist painted it himself versus when it was painted by his assistant (contagion). The other factors, however, did not produce significant main effects or interactions. Thus, in this study, the central factor seemed to be whether or not the artist physically created it himself. This result is consistent with the results of the first study and our hypothesis that people might be more materialist about artworks because the original pieces are imbued with the artist's essence. Some participants even spontaneously referenced this idea in their justifications.

In sum, when reasoning about the continuity of art, people appear place greater emphasis on the sameness of 'physical stuff' (i.e., materialism), because the original possesses an essence that cannot be duplicated. The first study demonstrated that even when all other information is held constant (the artist is unknown, the objects are not valuable, etc.) the mere categorization of an object as 'art' versus a 'tool' makes the duplicate artwork *less* likely to be seen as a continuer of the original object. And, the results from both Studies 1 and 2 provide further support for this proposal by demonstrating that physical contact with the original artist seems to play a crucial role in these judgments. Thus, in terms of judgments about identity continuity, the present studies demonstrate that there are important ways in which judgments about art appear to be more similar to judgments about persons (in their reliance on sameness of substance) than judgments about other kinds of artifacts

SESSION OVERVIEW

Hearing has been described as "The Universal Sense" (Horowitz 2012). Sound is our constant companion, and provides us with a tremendous amount of information about the world around us. As a sense, hearing is unique. Sight captures only what is illuminated, unobstructed, and directly in front of us. Taste and touch both require physical contact. Even smell is somewhat limited in human beings. We can hear, however, in any direction, for a considerable distance, and with no deliberative effort on our part. This session brings together four rather novel papers that explore the impact of sound on human perceptions and preferences. In addition, underscoring the pervasive influence of sound, the set of papers address a variety of important outcomes including preferences, feelings of safety, perceptions of size, and risk taking behaviors—all clearly relevant to consumption.

Music has long been employed by marketers in practice, but music is only one of a vast array of sounds that, intentionally or unintentionally, may affect consumer psychology and behavior. Even music itself is simply a structured combination of sounds that can be studied individually along various dimensions. Accordingly, the papers in this session examine more fundamental questions relating to the components and/or nature of sound. Specifically, all four papers address the question, "How do various individual, identifiable dimensions of sound – whether from music, voices, or environments – alter consumer cognitions and behavior?"

Due to the focus on deconstructing sound into unique elements in order to link specific dimensions of sound with cognitive and behavioral responses, these papers all apply a theoretical rigor to understanding sound that has often been overlooked in prior research. We organize the session's papers from more high-level components to more low-level components of sound. In the first paper by Sayin et al., the social presence afforded by sounds of human or human-like animal voices provides enhanced perceptions of safety as compared to instrumental only or no sound. The second paper by Nunes and Ordanini deconstructs sound in a musical context to examine how timbre affects the popularity of a song, demonstrating the most ef-

fective ways to combine various sound elements to enhance musical popularity. The final two papers both examine effects based on the pitch of a given sound. The third paper demonstrates the cross-modal effects that affect consumer's perceptions of a product's physical size and strength using both music and voices (Lowe and Haws), while the final paper by Loveland et al. uses an evolutionary perspective to demonstrate that the pitch of an environmental noise affects consumer risk aversion.

Overall, the session adds to the literature on sensory experience in marketing and attempts to broaden marketer's consideration of sound and music to include new sound sources, new contexts, as well as a more thorough application of psychoacoustic theory. We feel that this session will lead to interesting discussion regarding the way in which music and sounds impact consumers throughout a wide-range of daily experiences.

"Sound and Safe": The Effect of Ambient Sound on Perceived Safety of Public Spaces

EXTENDED ABSTRACT:

People are frequently exposed to crime in news programs, books, movies and television series. After such exposure, they often feel fearful of being alone in public places. Thus, many public spaces such as car parks, subway stations, and bus stops are considered "anxiogenic" (Loukaitou-Sideris, 2006). Such anxiety results in avoidance of places that are perceived as unsafe (Warr, 2000). For example, if people do not feel safe at the underground park of a mall, they may not to go to that mall. However, such anxiety about public spaces may be mitigated by using appropriate environmental cues (Pain, 2000).

In this research, we focus on "ambient sound" as one such environmental cue that can influence perceived safety in public areas. Much research has shown that music (as an ambient sound) can affect mood, perceptions and behaviors of individuals (Hui, Dube, and Chebat, 1997; Mattila and Wirtz, 2001; Yalch and Spangenberg, 1988). Music has also been shown to reduce anxiety (Tansik and Routhieaux 1999). The aforementioned research on the effect of music is mainly on instrumental music. However, vocal sounds can also impact individuals' emotional states (Juslin and Laukka, 2003). Social presence literature suggests that vocal sounds are potent social cues that "enhance the illusion of interaction with a social entity" (Lombard and Ditton, 1997). The presence of others has a soothing effect under imminent threat and provides a sense of security (Mikulincer, Shaver, and Pereg, 2003). Interestingly, bird songs closely resemble human language. Both rely on specific arrangements of vocal elements in a sequence to communicate with others (Kuhl, 2003; Lipkind et al., 2013). Accordingly, we expect when individuals are exposed to vocal sounds (whether human or bird sounds), these sounds will create a sense of social presence and people will feel safer.

Building upon the "sound and emotion" and "sound and social presence" literatures, we propose that ambient sound which gives the impression of having a social presence will positively affect perceived safety. Additionally, vocal sounds (whether human or bird) will be more effective than instrumental sounds in reducing anxiety because they will convey a greater sense of social presence. Furthermore, perceived social presence will mediate the effect of ambient sound on perceived safety.

We test our hypotheses in three experiments – one in the field and two in a laboratory setting. In study 1, we test the effect of ambient sound (instrumental, animal vocal, control) on perceived safety in a real car park in a European metropolitan city (field study). We got permission from the management of the car park to broadcast ambient sounds in the stairwells of the car park (human vocal sounds were not approved). All people parking in this car park need to use to the stair wells to exit the car park. People were exposed to the sound conditions, after they parked their cars, and before they were approached by the experimenters. We found a significant main effect of the sound conditions on perceived safety. Simple contrast tests showed that animal vocal sounds had a significant effect on increasing perceived safety versus instrumental sounds (and versus no sound).

In study 2, we repeated the field experiment in a laboratory environment where we created and used a video of an indoor car park. The video was recorded from the viewer's perspective with the intention to create an environment where participants could imagine that they were actually in the car park. Thus, the body of the participant was not visible and she could hear (her own) footsteps in the video. The same ambient sounds used in the field study were incorporated into this video. The results of the field study were replicated.

Study 3 was also a laboratory study to see how robust the results of the first two studies were, and also to see if perceived social presence mediates the effect of sound on perceived safety. Furthermore, we added human vocal sounds as a fourth ambient sound condition. We used the same video as in study 2, but changed the sounds. While we controlled for sound volume across the sound conditions in studies 1 and 2, in study 3, we also controlled for tempo and rhythm. The instrumental and human vocal sounds were selected to be different versions of the same music (the music was either played with only instruments, or was created by human voices alone).

We found a significant main effect of ambient sound on perceived safety. Simple contrasts demonstrated that both vocal sounds (human and animal) had a significantly higher effect on perceived safety compared to instrumental sound or no sound. Additionally, human vocal sounds had the highest effect on social presence, followed by animal vocal sound, instrumental sound and no sound. Simple contrasts demonstrated that human vocal and animal vocal sounds had similar effects on perceived social presence, and that both these vocal sounds increased perceived social presence more than the non-vocal sound (instrumental) or no sound. Furthermore, as proposed we found that perceived social presence mediated the effect of ambient sound on perceived safety.

To the best of our knowledge, this is the first study to systematically investigate the connection between auditory input, social presence and safety perception. Our results have important implications for managers of public areas that might be perceived as unsafe.

I Like the Way It Sounds: The Influence of Which Instruments and How Many Instruments are Audible on Music Preferences

EXTENDED ABSTRACT

Why do people like some songs more than others? We know very little about why people like the music they do and how different aspects of music shape their preferences. When asked, people often refer to a song's seemingly ineffable combination of instruments and vocals, described simply as *the way it sounds*. A major determinant of the way a song sounds is the specific combination of instruments audible to the listener. Each type of instrument has a distinctive and recognizable sound known as its timbre. Combinations of instru-

ments (e.g., a guitar with a piano) are identifiable as timbre mixtures. This research investigates how preferences for popular music depend on a song's timbre mixture, or the particular combination of instruments employed.

Timbre mixtures play a critical role in people's perceptions of music. They enable listeners to identify, classify and categorize pieces of music, suggesting common perceptual mechanisms are at work whether the listener is processing polyphonic or monophonic instrument sounds. In fact, Schellenberg, Iverson, & McKinnon (1999) have shown song recognition depends on timbre. Participants in their studies were able to identify popular songs from excerpts of only 100 and 200 milliseconds, leading them to conclude the timbral qualities of everyday music appear to trigger memory in ways rhythm, pitch, and tonality cues cannot. Some psychoacoustic scholars have gone as far as arguing timbre is "the most important and ecologically relevant feature of auditory events" (Menon et al., 2002, p. 1742).

Our work documents the relationship between the type of instruments and the number of instruments audible in a song on music preferences under ecologically valid conditions. We extrapolate song preferences from weekly popularity rankings on *Billboard*'s Hot 100 singles chart by comparing songs that reached #1 (hereafter Top songs) with a comparison set of songs that, while making it onto the Hot 100, never climbed above the #90 spot (hereafter Bottom songs). By restricting our sample as such, we control for exogenous factors that might facilitate or inhibit a song from attaining national exposure; once on the Hot 100, a song's relative ranking reflects market preferences.

We apply two different analytic techniques to the data, drawn from the United States' most popular songs from the past 55 years. First, we employ crisp-set qualitative comparative analysis (QCA) to examine specific combinations of instruments and their impact on preferences Ragin 2000). The premise underlying QCA is that for certain types of outcomes, the best causal explanation involves complex combinations of the causal variables. For these types of outcomes, the direct impact of single variables is not informative (as they might be the case in a typical regression); instead, the outcome depends on how the variables are combined, creating one or more specific "recipes." Methodologically, QCA allows the researcher to derive which bundles or combinations lead to which specific outcomes (being a Top versus Bottom song in our data). Next we use logit regression to test the relationship between the number of different instrument types audible and the probability of being a Top versus a Bottom song.

We identify three specific configurations sufficient for a song to make it to the top of the chart (77% of songs with these instruments account for nearly 20% of all Top songs). Common across all three is the inclusion of background vocals. The three core sufficient configurations include: (1) background vocals with a synthesizer and a clean guitar; (2) background vocals with a synthesizer and distorted guitar, or (3) background vocals with an electronic piano and no synthesizer. We also identify three specific configurations that lead a song to be more likely to stagnate at the bottom of the charts as opposed to climb to the top (86% of songs with these instruments account for 13% of all Bottom songs). Predicated on the absence of background vocals, one recipe for a less "successful" song is: (1) the presence of a bass guitar and synthesizer without any other guitar and without an electric piano. The two other configurations include are predicated on there being no background vocals and no strings (orchestral) audible, but do include; (2) the presence of an electric piano and an acoustic guitar; or (3) the presence of an electric piano with a clean electric guitar. We should emphasize that there are always exceptions, but that our analysis reveals historically these com-

binations have led to these outcomes. In other words, some combinations have been far more likely to find their way to the bottom of the charts while others have been far more likely to find their way to the top of the charts.

Our configurations define the set of "core" instruments, but it is important to note that other instruments can be layered on top without changing the result. For this reason, we also examine how the number of distinct instrument types perceptible in a song impacts its popularity. Logit regression reveals a positive curvilinear effect such that the likelihood of being a Top song as opposed to a Bottom song increases more than proportionally as the number of instruments audible in a song increases. If we consider the typical song in our data includes five instruments ($\mu = 5.3$), we have strong evidence that people prefer more than the average number of instrument sounds. Taken together, the results suggest strong underlying preferences among the specific timbre mixtures identified in popular music.

Music critics frequently lament the perceived homogenization of popular music. On the one hand, our findings regarding the impact of specific instrument configurations on preferences could be viewed as consistent with this commentary. There is enough overlap in core configurations to provide us with three combinations that characterize Top as opposed to Bottom songs. On the other hand, our findings also point to a need for artists to make their sound distinct. Our results suggest the artist is free to, and should, add additional instrument sounds, perhaps considering them a personal embellishment in a generic recipe.

Sounds Big: The Cross-Modal Effects of Auditory Pitch on Product Perceptions

EXTENDED ABSTRACT

Whether from music in a commercial or store, the voice of a spokesperson or salesman, the sound of a product itself or the variety of sounds in a shopping environment, sound can influence consumer cognitions, perception and behavior in various ways. While researchers have explored several mechanisms explaining precisely how sound influences consumer thought and behavior, including mood (Bruner 1990), semantically-related meaning (Zhu and Meyers-Levy 2005), and phonetic or sound symbolism (Yorkston and Menon 2004, Klink 2000), there is a sensory mechanism by which sound may affect consumer cognitions that has not yet been explored by marketers – cross-modal correspondence.

"Cross-modal correspondence" is the perceptual compatibility of a stimulus experienced by one sense (in this case, hearing) with a sensory experience of a different sensory modality (Spence 2011). Almost every human experience is multisensory in nature. Our various senses so often work in symphony with each other that associations are formed between particular attributes of a stimulus in one sense and attributes pertaining to other senses. For example, correspondences have been identified between sound and color (Marks 1975), shape and taste (Ramachandran and Hubbard 2003), physical texture and taste (Bult, de Wijk and Hummel 2007) and several others. Thus, in the realm of audition, a particular attribute of a sound may influence consumer beliefs and behaviors by virtue of the fact that it is intrinsically associated with other physical characteristics unrelated to sound. We propose that a single dimension of sound, that is pitch, can affect consumer perceptions of product size. In addition, because individuals naturally make additional size-based inferences about products, we propose that the effects of pitch may have downstream effects beyond affecting perceptions of just product size.

Study 1. Participants (N=205) were seated at individual computer stations and were told that they would be listening to a radio advertisement for new product. All participants heard one of the two versions (high voice vs. low voice) of an advertisement for the new "Southwest Turkey Club" sandwich at "Cosmo's" – a fictitious sandwich chain. Half of the participants also saw an image of the advertised product while listening to the ad, while the other half did not. Participants responded to measures regarding their perceptions of and interest in the sandwich.

Participants believed the product was bigger in the low-pitch condition, even when they had seen an image of the product ($F(1,204)=8.814$, $p<.01$). There was no significant difference in perceptions of product size between participants who saw the product image and those who did not. Auditory pitch affected perceptions of size even when the product was visible.

Study 2. The purpose of study 2 was to further examine the effect of pitch on size perceptions and to see how they might affect product evaluation and preference. Undergraduate students (N=167) participated in exchange for course credit and again the study took place at private computer stations in a behavioral laboratory. Participants were told that for this particular study they would hear the audio from a recent television advertisement for a laptop computer and that the voice-over had been removed, leaving only the background music. Participants heard one of two versions (high pitch vs. low pitch) of a 60-second segment of an obscure instrumental rock song. Following the song, participants were asked to use 7-point scales to rate the advertised laptop on six dimensions; size, power, durability, weight ("lightweight"), technological sophistication, and ease of use. Participants also indicted their own personal preference for laptop characteristics and indicated their interest in owning the advertised laptop.

Consistent with study 1, the main effect of music pitch on size perceptions was significant ($M_{Low}=4.95$, $M_{Low}=4.11$; $F(1,165)=12.91$, $p<.001$). Lower pitch, even in background music, cross-modally communicated greater physical size. There was also a significant interaction between pitch condition and participants' stated dimension preferences when predicting interest in the product, such that participants who preferred a larger and more powerful laptop showed more interest in the product in the low-pitch condition.

In addition, perceptions of size mediate several other differences in product perception that occur between pitch conditions, demonstrating the "downstream" effects of cross-modal correspondence.

Study 3. The purpose of study 3 was to examine the effects of pitch on the credibility of various ad claims. Participants (N=255) heard one of two versions of an ad for a laundry detergent. One version of the ad made product claims regarding gentility while the other version made claims regarding strength. These ads were played in one of two pitch conditions (high or low pitch). Participants were then asked questions indicating how much they believed the claims of the advertisement. There was a significant interaction between ad claims and pitch condition when predicting ad credibility, $F(1, 242)=3.884$, $p<.05$), such that the low voice was seen as more credible in the "strong" ad ($M_{Strong/High}=4.89$, $M_{Strong/Low}=5.09$), and the high voice was more credible in the "gentle" ad ($M_{Gentle/High}=5.08$, $M_{Gentle/Low}=4.68$). These differences were again tied to a significant difference in product (container) size ($M_{High} = 4.25$, $M_{Low} = 4.61$, $F(1, 244) = 9.251$, $p<.01$).

In summary, the cross-modal effects of pitch in advertising dramatically altered product perceptions and preferences in several different domains. This introduces yet another means through which sound can affect consumer psychology and behavior in a way that is significant to both theory and practice.

Pitch, Threat and Risk Aversion

EXTENDED ABSTRACT

Part of the evolutionary purpose of audition in humans and animals alike is to serve as a warning of danger, alerting a listener to the presence of a potential threat (Davies and Halliday 1978). When interpreting a sound as threatening or non-threatening, there are likely various structural elements of that sound that are relied upon. Pitch, for example, has reliably been associated with size, such that lower pitch communicates larger size and higher pitch indicates smaller size (Parise and Spence 2009). From an evolutionary standpoint, the presence of something large could certainly be associated with threat. Anecdotally speaking, everyone who has paid attention to the sound design in a horror film has undoubtedly noticed the frequent usage of deep, menacing tones to heighten the tension (see Horowitz 2012, Huron et al. 2006). Furthermore, low pitch in voice has been associated with greater power and dominance in both human beings (Puts et al. 2006) and other animals alike (Morton and Page 1992). If a low pitch indeed elicits fear due to the imagined presence of an unseen threat, or makes us feel powerless by signaling the presence of a dominant counterpart, we should anticipate a decreased willingness on the part of a consumer to accept additional risk (Anderson and Galinsky 2006; Lopes 1987).

However, it is possible that males and females may respond differently to high and low pitches in an environment. For example, if the source of the pitch is perceived as a threat, females may be more likely than males to engage in "tend and befriend" behaviors, in an attempt to build and strengthen social bonds for safety's sake (Taylor et al. 2000, Turton and Campbell 2005). Thus, both risk aversion and affiliation behaviors may be affected by the presence of a low auditory pitch.

Study 1. The purpose of study 1 was to test how the presence of a low pitched sound in an environment would influence both risk taking and affiliation behaviors. The study involved 98 individuals participating in a lab session in exchange for course credit. Participants were taken 2 at a time (matched on gender and race) into an interview room to play a gambling game. For half of the dyads a hidden subwoofer played a very low pitched tone (60hz sine wave) at a very low volume, while the subwoofer was turned off for the other half of the dyads (control condition). Sitting facing away from one another, and using real money provided them, each participant wrote down one amount for a "self" wager and another for a shared "communal" wager. After wagers were recorded, participants moved their chairs to a table where the game would be played. The distance between their chairs was recorded as a measure of affiliation.

Results show that, compared to the control, participants wagered less of their money when there was a low pitched tone present in the room ($M_{LowTone}$=84.8¢, $M_{Control}$=93.7¢; $F(1, 97)$=4.38, p<.05). There was no effect on the amount placed in the communal bet. However, there was a significant interaction between gender and pitch-condition on the physical distance participants put between chairs ($F(1,97)$=4.29, p<.05) such that, compared to the control, males distanced themselves directionally, but not significantly, further apart when there was a low pitched tone present ($M_{LowTone}$=41.9in, $M_{Control}$=40.5in, NS) whereas females sat closer together when there was a low pitched tone present ($M_{LowTone}$=34.9in, $M_{Control}$=38.0in, $F(1,94)$=3.61, p = .06).

Study 2. Whereas study 1 compared risk aversion between low-pitch tone and no-tone conditions, study 2 compares risk aversion between low-pitch tone and high-pitch tone conditions. It is possible that any environmental sound with an ambiguous source will cause increased risk aversion; thus, the purpose of study 2 is to demonstrate that risk aversion will only increase if the sound is low pitched, and consequently associated with "something large" that poses a potential threat.

Undergraduates participating in exchange for course credit (N=376) sat at individual computer stations with privacy partitions in an on-campus behavioral laboratory. Speakers in the ceiling of the room consistently played a sine wave of either a relatively low pitch (80hz) or a relatively high pitch (720hz), alternating randomly across lab sessions (5 sessions each). During the session, participants worked on various computer-based tasks, one of which was specifically related to risk. Participants made a series of 50 dichotomous financial choices between a smaller, certain payoff and a chance at a larger payoff (see Griskevicius et al. 2011 for details). The primary dependent variable was the sum total of "risks" each participant preferred relative to the smaller certain payoff.

Participants in the low-pitch tone condition opted to take significantly fewer financial risks than those in the high-pitch tone condition ($M_{LowTone}$=13.8, $M_{HighTone}$=15.7, $F(1,375)$=8.66, p<.01) suggesting that our findings from study one are due specifically to the presence of a low pitched sound, rather than to the presence of an ambiguous sound per se.

Study 3. The purpose of study 3 was to directly measure our proposed mediator of anxiety or fear. Participants (N=130) entered a lab where either a low pitched tone (80 hz) or no tone (control condition) were playing at a very low volume through ceiling speakers. Participants completed a computer-based word identification task. After an ostensibly masked word flashed on the screen for an imperceptible amount of time, participants were asked to identify the word from a list of 4 possibilities. Of the 17 trials, 7 lists contained words related to anxiety or fear. The dependent variable was the total number of target words selected.

Overall, participants selected significantly more fear/anxiety related words when the low pitch was present ($M_{LowTone}$=2.35, $M_{Control}$=1.77, $F(1,129)$=7.77, p<.01)

In two studies, the presence of a low pitch decreased study participants' willingness to take risks while a third study linked this risk aversion to increased anxiety or fear. In addition, different social behaviors were observed based on gender. Researchers and practitioners alike can benefit from better understanding the effects that a sound may have on real-world behavior.

SESSION OVERVIEW

The objective of this session is to investigate how consumers embrace change in their lives. All four papers focus on processes of change, and describe the obstacles, emotions, and challenges of making changes. Much consumer research addresses the power of consumer habits and goal striving and how they affect consumer welfare (c.f. Verplanken and Wood 2006; Baumgartner and Pieters 2008). Research has also focused on understanding goal striving and persistence and how they are shaped by cultural discourses (Fisher, Otnes and Tuncay 2007). In addition, a variety of consumer research uncovers the important role of goal directed activities and goal persistence on wellbeing (for example, Fishbach and Dhar 2005; Seligman 2006). By contrast, our session focuses on the less commonly explored domain of whether and how consumers change directions and establish new goals and patterns of behavior and how this relates to a meaningful life (Feldman 2013; Mukhopadhyay and Johar 2005). Only a small amount of consumer research has focused on these processes of letting go and moving forward in a different direction (Schouten 1991; McAlexander 1991, Schau, Gilly and Wolfinbarger 2009). This is extremely important because persistent pursuit of personal goals is only part of healthy human adaptation (Wrosch, Scheier, Miller, Schulz and Carver 2003, Miller and C'De Baca 2001). When is it time to embrace change? How does this change unfold? How do consumers disengage from their past and their ideas of what would be, and engage with creating their new lives? Explicit in all four papers is an examination of the resolve to embrace a change that involves leaving something else behind—an important life goal, family and community, or a cultural narrative of

the birth of a new family member. The first paper explores consumers' ideas of the construct "Fresh Start." The second paper investigates goal disengagement and engagement with a new goal in the context of single mothers of choice. The third paper picks up on the themes of leaving things behind and engaging with a new community. The fourth explores how the shattering of a treasured imagined future eventually can lead to a new narrative being embraced across obstacles and constraints. All four papers speak to changes in consumption and consumer behavior patterns that accompany these changes, sometimes as small as making a novel choice of a snack item, as in study five reported in the first paper, to complete changes in consumption realms, as described in the second and third papers. Both the second and fourth paper also investigate how an evolving, hoped for family collective is shaped and constrained by surrounding technologies and service providers. We ask in multiple complex contexts: 1. How does goal disengagement and goal re-engagement shape consumer behavior? 2. What consumer behaviors do consumers employ to navigate the transition between changed life narratives?

Embracing A "Fresh Start": How Consumers Engage to Change Their Lives

EXTENDED ABSTRACT

This paper introduces the construct, *fresh start*, which focuses on a consumer's pursuit of new goals, accomplishing new things, and creating and making a new life. In other words, our research examines consumer engagement in "life" change (Andreasen, 1984; McAlexander, 1991; Schau, Gilly & Wolfinbarger, 2009; Silver, 1996), and is at contrast with much of the literature that focuses on goal adherence, progress and velocity with regard to a specific goal (e.g., changing eating habits, losing weight, or stopping smoking). We know that consumers do change, and when they change it can have dramatic consumption consequences (Schouten, 1991). Moreover, consumption is often profoundly implicated in what consumers seek to change, including for example, their health and budgeting (Soman & Cheema, 2004; Fishbach & Dhar, 2005; Oyserman, 2007). However, with few notable exceptions, we know little about life transformations. In this paper, we explore fresh start using five studies; Studies 1, 2 and 3 focus on the explication of the construct, measurement, and nomological net, and Studies 4 and 5 examine the ability to trigger behavior by priming individuals with the idea of a fresh start.

Study 1 (n=62) used a series of open-ended questions to gain insights into how consumers think about a fresh start. Findings indicate that "fresh start" resonates with consumers, and they understand it as starting anew and pursuing new life goals and experiences, as having a future-focus. Most respondents reflected on a fresh start as involving large, sweeping life changes, but others reported on focused goals, such as taking up a new exercise routine. With regard to desired fresh starts involving sweeping life changes, many noted the uncertainty of, as well as the difficulty and perhaps even impossibility linked to getting a fresh start. Hard work and commitment are paramount to getting a fresh start. Notably, our findings document that fresh starts are encumbered with emotions, efforts and obstacles.

Study 2, using insights from Study 1, was focused on scale development for our fresh start construct. Our online survey (n=178

adults; M-Turk) participants responded to 14 (7 point Likert-scale) items focused on getting a fresh start, as well as items designed to measure the related constructs of: optimism, future temporal focus, and psychological closure. Exploratory factor analysis (oblique rotation) results facilitated identification of four items ("I am creating a new life for myself," "I am changing the way I live my life," "I am pursuing new goals," and "I am accomplishing new things") with high internal consistency (α=.88), and confirmatory factor analysis with these four items to measure fresh start demonstrated convergent and discriminant validity between fresh start and optimism, future temporal focus, and psychological closure.

Study 3, another online survey (n=236 adults; MTurk), further validates our four-item fresh start measure, extends the nomological network and advances a model of how consumers embrace a fresh start and how fresh starts translate into behavioral intentions. Our results indicate that fresh start (measured by our four items) is positively associated with engagement in new consumption choices generally, and desire to enact new behaviors, including live healthier lives and reduce spending. We find the relationship between fresh start and new consumption choices is moderated by goal reengagement, such that goal reengagement boosted the ability to enact new behaviors when getting a fresh start.

Study 4 considered the effects of priming individuals with the idea of a fresh start to assess impact of a fresh start (vs. not) relative to a recent failure on future performance. We used a 2 (fresh start, control) x 2 (self-affirmation, no self-affirmation) between subjects design (n=136 undergraduate students). Participants first engaged in the five-minute Remote Associations Test (RAT; Mednick, 1968; Vohs et al., 2012), and upon completion received (false) feedback from the computer, saying they performed worse than average on this "intelligence" task. Participants in the fresh start condition read, "Start anew" and clicked to the next page; those in the control condition simply clicked to the next page. Next, participants received our second manipulation, with half affirmed by writing about their top-ranked value and half not affirmed by writing about their 7th ranked value (from Fein & Spencer, 1997). Participants again completed a five-minute RAT, and the number of correct items served as our "performance" dependent variable. Consistent with expectations, individuals primed with getting a fresh start (vs. control) performed significantly better on the second RAT ($b = 0.70$, $p < .05$; $R^2 = .04$), suggesting that engaging the idea of getting a fresh start may cause individuals to move past failure. We note no significant difference in performance between the self-affirmed and control group ($b = 0.70$, $p > .05$; $R^2 = .04$).

Study 5 also considered the effects of priming individuals with the idea of a fresh start to assess how thinking about a fresh start would affect the choice of a novel and familiar product. Seventy-five undergraduate students participated in the fresh start prime (vs. control) lab experiment. Participants were randomly assigned to the fresh start prime condition (and asked write a short statement about opening a door to the future following acceptance to the business college) or the control condition (and asked to write a short statement the about a movie they had seen recently). Participants responded to our four-item fresh start scale as a manipulation check, and then were asked to choose between two spreads (the novel almond butter and the familiar peanut butter) to eat with their crackers. Next, they complete the grit scale items (a measure of perseverance) and answered several demographic questions. As expected, for participants with stronger (vs. weaker) grit, we find a larger percentage (57%) of the individuals primed with a fresh start (vs. control; 29%) chose the novel almond butter ($\chi^2 = 1.35$, $p < .05$), suggesting that grittier people may hold stronger to experimenting with new future selves.

Taken together, our research systematically introduces the fresh start construct and offers a set of studies that establish a valid and internally consistent measure within a nomological network. Across our discussions and surveys of consumers we learned that for the majority embracing change through a Fresh Start, while difficult, is filled with desire and promise and connected to making better and new choices, leading to a better life. Our experiments suggest that we can empower consumers to get a fresh start and change behavior.

Consuming and Consumption in Third Space Communities: Constructing Sanctuary

EXTENDED ABSTRACT

We are beginning to better understand that experiences that are associated with identity transition can extend for many years, and may never be fully accomplished (cf. Arsel and Thompson 2011; Penaloza 1994; Ustuner and Holt 2007). Although transitions have been long postulated as a linear experience, the reality for consumers is that the lived experience of change may be much more complex than the accepted "model." In recent work, we see that the experience of leaving a consumption-related community is, in some ways, like Dr. Dolittle's pushmi-pullyu character. The attendant relationships can be integral to one's life and severing these can be painful and protracted—and can last for months, years or even decades (McAlexander, DuFault, Martin and Schouten 2014; Vaughn 1986).

For the informants in the current study who are contemplating leaving or who have left an identity-central community, this exit process is preceded and accompanied by the acute awareness of a critical choice: "Do I leave to something, leave to nothing, or resign myself to staying?" This angst appears to undergird much of the decision of whether or not to leave. The majority of the informants in this study left to 'something.' This study examines the consumer behavior involved in the creation, consumption, and experiences of a new community of that 'something.' These consumers redirected the emotional and material resources they had previously poured into their former community, and used them to effectively buy membership (cf Sana 2005) into third places. In these places, they co-construct a new something with other ex-members. In addition to consuming the new community, in eschewing the practices of their old community they substitute new brands and different consumption patterns. These new consumption patterns have been the preferred consumption selections of the new community and now become important and meaningful to their new consumer life. An entire consumption realm was lost and another one gained.

Feeling the need to find an alternative to their perception and fear of the feeling of impending nothingness upon leaving, the informants we observed and interviewed largely joined alternative communities composed partly or mostly of ex-members. Parents Without Partners, ex-Mormon conventions, and online ex-Harley owner forums are just a few examples of these kinds of third places for leavers of, respectively, marriages, faith, and brands. Unintentionally in the spirit of the conference topic "Back to Fun," we found that third places for the leavers in our study include: perennially attending ex-community conferences and gatherings where "sin baskets" are given as raffle prizes; meeting at Starbucks for young atheist meetings to discuss newest transgressions of former faith tenants; weekly poker games that first began as "Drinking 101" upon initial exit; continuing to post on ex-faith member secret Facebook groups to give advice on meet-ups, dating and hook-ups for new defectors; starting transitions groups in other churches; joining a BMW enthusiasts' club after using former tithing money to buy a BMW; and ritually attending sporting events, having family outings, or power-shopping on Sundays during

former church time. In short, much of what they have moved to is social, pleasurable, and/or fun.

Oldenburg (1989) describes traditional third places as neither work nor home, where people gather and find community. In the current research we report findings that show that these transitional third place communities play a very different role than that which has been postulated before in the consumer behavior literature. Extant literature suggests that leavers pass through these exit communities on their way out as they move toward a new identity (Schouten 1991). Those third places where people come together to establish new connections with others of similar "ex" status have been viewed as liminal and temporary (Turner 1969; McAlexander and Schouten 1989; Young and Wallendorf 1989; Ozanne 1992). However, we find that these liminal spaces, on the contrary, became an important and stable part of the ex-members' transformation of their lives, not only in the initial exit stage, but throughout the exit process, and after they felt they had established their new identity. The consumption pattern changes also remained constant.

27 informants were depth interviewed on multiple occasions over a period of three years. A sub-sample of these informants and other community members were also observed and interviewed at gatherings for ex-members, ceremonial experiences, on secret online Facebook pages to which we were invited, and in various formal and informal groups specifically for ex-members of this community for two years. Our emergent findings show that these third places fill an under-reported and very important role for leavers that are far beyond the liminality of temporary community (cf Arnould and Price 1993). For leavers they can become a permanent and stable home, culturally and socially. Consequently these new consumption patterns, in addition to the resources spent on the new community, are lasting and can become as much a part of a leaver's identity as the former community. In these third place communities consumers find both community and reinforcement and validation of their agency for change, giving them a feeling of collective strength to push back against family, cultural and social resistance. They also give leavers a comfortable community with other members of the same frame of reference in regard to the community they have left. These new communities, far from being ephemerally liminal, appear stable, and continue to impact consumption choice and consumer behavior in a lasting relationship. They contribute to the leavers' well-being as they make the transition from faithful community member, to the individual they envision who has volition, agency and strength to make independent choices.

Single Mothers By Choice: Putting Aside One Life Goal and Embracing Another

EXTENDED ABSTRACT

Consumer well-being research has emphasized the adaptive role of being optimistic, believing in one's abilities and persisting in the pursuit of important life goals (Seligman 2006). However, people can't always attain their goals and hence an equally important adaptive human process that can contribute to subjective wellbeing and health is the ability to disengage from unattainable goals and re-engage with new meaningful goals (Wrosch, Scheier, Miller, Schulz and Carver 2003; Worsch, Miller, Scheier and Brun de Pontet 2007). Examining the adaptive process of giving up and moving on has received virtually no attention in consumer research, although it likely has applications in numerous domains from diet and exercise to procreation strategies (Fischer, Otnes and Tuncay 2007). When is it time to give up, and do something different? How do people reorganize their lives to pursue a different life goal? To date, we

know almost nothing about the process through which consumers move from a persistent engagement with one important life goal to reorganizing their lives, resources, networks and market behaviors to engage with pursuit of a different goal.

The purpose of this research is to uncover that process in the context of Single Mothers by Choice. An estimated 30,000 American babies are born with the help of donor sperm each year and close to 50 percent of human sperm and eggs are purchased by single women (Hundhausen 2010). Recent research suggests that for many heterosexual women this involves a process of giving up on finding a partner and shifting resources and attention to making a baby (Hertz 2006; Graham 2012). However, research has not uncovered this process or how women shift goals and mobilize networks, markets, resources and myriad behaviors from dating to procreation. This paper presents the findings from a two-phase study. Phase one is a netnographic discourse analysis of posts and blogs from select online communities of self-identified SMCs (Single Mothers by Choice) and phase two is based on depth interviews with 19 heterosexual SMCs about their disengagement from what to many of them seems the unattainable goal of finding a partner and father for their children to engaging the goal of motherhood through donor sperm (Assisted reproductive technologies—ART). In addition, we included interviews with five women who were expanding their family from one child (either born naturally or through ART) to two in order to better understand how the ideal of the nuclear family is re-negotiated and extended over time and to compare differences in process. In order to establish boundary conditions, we also sought negative cases of women who wavered and decided not to pursue ART. The data was analyzed independently through iterative readings by the two authors and emergent themes were compared and contrasted. Discrepancies were either resolved through discussion or additional data collected until a clearer picture evolved through further interpretive analysis.

Our findings illustrate how women transition their resources, networks and consumption domains as they let go of one goal and embrace another. Our informants find emotional difficulty in this transition—for many it feels like 'giving up on love.' There is also physical pain and exhaustion; the in vitro fertilization process can be grueling. On the other hand, they also describe exhilaration and joy on realizing their freedom as they embark on this new path, free of the expectations of finding a mate and empowered to take control of their own reproduction. The liminality of moving between these goals has been described in prior research (Graham 2012; Hertz 2006), however, by focusing on how the two processes of disengagement and re-engagement interplay we counter prior descriptions of liminality and theoretically inform the significant differences we find among our informants in their experience of motherhood and how they imagine their futures. For example, while the process of disengagement is sometimes demarked by the liminal process described in prior research that then leads to embracing this new goal, many of our women have a tighter and more iterative interplay and move back and forth, pursuing both goals simultaneously or sequentially (cf McAlexander , Martin, DuFault, Schouten 2014). This relative inability to successfully let go of one goal and fully engage with the pursuit of motherhood can contribute to stress and ambivalence about this new lifestyle choice and goal (Otnes, Lowry and Shrum 1997). A post on the SMC board illustrates this ubiquitous ambivalence:

> When I decided to become a single mother, I had to deal with society's notions of the perfect family, and the fact that I was choosing to have a child in a way that was not 'ideal' or 'normal' by today's standards. I had to grieve

that I did not have the white picket fence and the husband rubbing my belly while it grew with our child inside, a child we got to make the fun way. I got mad and sad that this ideal was not for me and that I had to do it differently because somehow I was not good enough for the norm. (Changes, 2014)

Our informant data in this study greatly enriches and gives depth to many aspects of this choice, including the time of birth. Most importantly, it adds to the literature by addressing more fully the resources and consumption constellation changes that are resultant from this goal disengagement. Moreover, because the move from the traditional nuclear family choice to Single Mother by Choice is fraught with stigma and structural hurdles, engagement with this new goal is full of obstacles. While this is certainly not unique to this context, and would be applicable to other consumer changes (Schouten 2014; Ruvio and Belk 2013), it adds a significant hurdle to re-engaging with the prior goal. Further, our informant data reinforces the nascent findings of other consumer behavior researchers about the iterative non-linear nature of exit transitions (Arsel and Thompson 2011; McAlexander, Martin, DuFault, Schouten 2014); Penaloza 1994; Schau and Russell 2014; Ustuner and Holt 2007).

Changing the Script: Family Collectivity Formation in the Neonatal Intensive Care Unit

EXTENDED ABSTRACT

When you're going to have a baby, it's like planning a fabulous vacation trip - to Italy...It's all very exciting. After months of eager anticipation, the day finally arrives. You pack your bags and off you go....The stewardess comes in and says, "Welcome to Holland." "Holland?!?" you say. "What do you mean Holland? I signed up for Italy! I'm supposed to be in Italy. (From "Welcome to Holland" by Emily Perl Kingsley--given to many new NICU parents)

The time of birth is a momentous change, surrounded with cultural scripts and logics that have been created and ingrained over generations by family lore, personal experience, entertainment tropes, advertising, marketing, and media hype of celebrity and royal births. Many expectant parents prepare for the new baby with common consumer behaviors: acquiring baby clothes and infant paraphernalia, making birthing plans, preparing the nursery. Parents imagine themselves holding their newborn, bringing their new baby home in accordance with the traditional narrative.

But some babies do not follow this script, and parents' imagined narrative of birth and baby is shattered as it hits the neonatal intensive care unit doors of an unexpected reality. They arrive at the bedside of the tiny human to whom they've just given birth, separated by the enclosed box of glass that is the warming isolette. Ropes of tubing and lines attach their baby to life-giving air and nutrients, hooking them to machines that randomly cry alarm. The family has arrived in Holland, not Italy. As one staff member told us:

It's like they need a guidebook: "This is our land. These are our laws. These are our customs. These are our rules. This is what's around here…You can be an active participant in this land by knowing this and learning that and speaking this language."(Sandy, NICU caregiver)

Listening to parents talk about this time of acclimation is much like watching Bill Murray in "Lost in Translation" as he navigates Tokyo without knowing Japanese, staring at flashing billboards and listening to conversations and sounds that have no meaning to him. Parents describe a sound track that falls like the noises of a foreign country's streets on uncomprehending ears: medical acronyms, beeping, chiming, flashing cacophony of alarms, overhead pages, the hiss of ventilators. How do parents create a new script to form their family collectivity?

For background, we draw upon a body of work in the nursing and medical literature about the family and sounds in the NICU (Seideman et al. 1997, Stromsweld and Ward 1997, Board 2004, Fisher et al. 2008, Pineda et al. 2013, Lahav 2014). The importance of teamwork between staff and parents has been shown to improve parent feelings of comfort (Brandon et al 2009). In the consumer behavior literature, notable works have been written about difficult decision making and end-of-life in neonatal and pediatric intensive care units (Botti, Orfali, & Iyengar 2009; Orfali and Gordon 2004; Luce, Bettman and Payne 2001). But there is still a large lacuna in our consumer behavior literature about the much more common parental hospital service scape experience of a shorter NICU stay and a happier outcome. There is similarly a lack of research into the active role that equipment has upon the family collectivity formation (Dent 2003, Agrawal et al 2009).Our research works to fill this gap. We investigate how an evolving, hoped-for family collective is shaped and constrained by unexpected events, surrounding technologies, discourses and service providers, and how the new family collective assembles, bonds and moves forward. We employ a methodological lens of assemblage and actor network theory (Latour 2005, DeLanda 2006, Deleuze and Guattari 1987, Epp and Price 2010, Epp et al. 2011, Martin and Schouten 2013) that has been used in medical contexts (Berg and Timmermans 2000; Brown and Middleton 2005). Both parents and staff describe the unit in emic language that reveals its assemblage qualities and the equipment as actors:

You don't think of it as equipment. The equipment is extensions of the child—like you think of the ventilator as the lungs of the baby outside the baby, and the tubing is just its extended trachea. (Sam, NICU caregiver)

Parents can feel as if they are intruding on the baby/staff/unit assemblage. As one informant described:

They couldn't go home until they <her twins> could "kangaroo." They literally had to spend 30 minutes trying to get them to lie right on top of me and rearrange the tubes so that the alarms wouldn't go crazy. I kept thinking, "It's me, it's my body that's wrong. They need to do this without me here." (Marianne, mother)

Using depth interviews of parents and NICU staff, observations, and netnography on NICU forums, we triangulate our findings to show that parents who increase their capacities to become part of this NICU assemblage appear to increase their feelings of empowerment over their baby's care. It appears that this is a vital component of effectively bonding as a family collectivity. Parents describe feelings of competence and pride as they increase their capacities by learning the language and mastering use of the machinery (cf Muething 2007). As one mother told us:

Finally it got to the point where I could understand the language. It was like learning French. Desats, bradycardia,

tachycardia, A's and B's...Then I could be there for rounds and participate. I was part of the team.

Parents also reveal this enhances their ability to cope. Coping further improves family bonding and leads to better decision making (Melnyk et al 2006; Wrosch et al. 2011; Robbins et al 2013). In addition to the important work of improving parent/infant bonding, this research has the potential to make an impact upon consequent parental satisfaction with the neonatal unit service scape and the hospital itself (cf Popper et al 1987, Mitchell-DiCenso et al 1996, Cescutti-Butler and Galvin 2003, Conway et al 2006).

A growing body of work suggests that there are genuine benefits to purchasing experiences, intangible purchases such as vacations and concerts, instead of purchasing material possessions, tangible goods such as clothes, trinkets, and electronics (Carter & Gilovich, 2010, 2012; Howell, Pchelin, & Iyer, in press; Nicolao, Irwin, & Goodman, 2009; Rosenzweig & Gilovich, 2011; Van Boven & Gilovich, 2003). Experiences, compared with possessions, appear to be ultimately more satisfying because they are less likely to suffer from invidious comparisons to unchosen options or new information (Carter & Gilovich, 2010), and are more central to one's self-concept (Carter & Gilovich, 2012). What's more, the general tendency to choose experiences over possessions is associated with well-being and life satisfaction (Howell et al., in press). However, as all of this work acknowledges, the categories are not very clearly defined. What makes an experience an experience? What makes a possession a possession? While there are certainly purchases that are clearly experiential (e.g. concerts) or material (e.g. clothes), there are also quite a few that cannot be so easily categorized. An mp3 player is a tangible object, but it also allows one to enjoy the experience of listening to music. How do these ambiguous purchases fit into the overall pattern of findings? What's more, what does such ambiguity say about the underlying properties that define the categories?

To start, we endeavored to examine the types of purchases that participants generated when prompted to recall a material or an experiential purchase. In Study 1, we found that independent raters were easily able to guess, based on the description provided by the participant, which type of purchase they had been assigned to recall. This suggests that, regardless of any fuzziness in the categories, most participants seemed to have little trouble using them. There were some purchases, however, that fell somewhere in the middle, and also appeared to be somewhat middling in terms of their satisfaction. Would it be possible to take advantage of that ambiguity, to take those same purchases and emphasize aspects of one category or the other, to produce the same psychological effects?

In Study 2, we again had participants recall either a material or an experiential purchase, and again found that participants in the experiential condition were more satisfied with their purchases. However, we also asked a third group of participants to recall a material purchase, but we asked them to take a moment to think about its experiential qualities. As expected, we found that this group was just as satisfied as participants in the experiential condition. While the previous study suggested that there are real differences between the categories, this finding indicates that there is a certain amount of latitude in how one thinks about a given purchase.

In the next three studies, we examined that very latitude. We took the same purchase, one that was smack in the middle of that fuzzy boundary between the two types of purchases, and emphasized either its material or its experiential qualities. Participants in Study 3 were asked to think about a boxed set of music either as part of a music collection, something one puts on a shelf, or as an experience, something one listens to. Participants who had been led to think

of it as an experience were less bothered by negative comparative information (learning it was now available for a lower price), and thought it would be more satisfying than participants who framed it as a possession.

In Study 4, participants were asked to think about a new 3-D TV as either a possession, emphasizing where it would go in their home and fit in with their other possessions, or as an experience, emphasizing experiencing television in a whole new way and how it would fit with their other activities. We then showed participants several sets of overlapping circles, as in the Inclusion of the Other in the Self scale (Aron, Aron, & Smollan, 1992), and asked them to choose which matched how much they thought the TV would be a part of their self-concept. As predicted, participants in the experiential framing condition chose circles that overlapped to a greater degree, thinking that the more experiential television would be more closely associated with their self-concept.

In Study 5, we looked at the flip side of satisfaction: regret. People tend to feel regrets of inaction about their experiences (i.e. missed opportunities) and regrets of action about their possessions (i.e. buyer's remorse). Would framing a purchase as an experience or possession produce similar patterns of regret? When a 3-D TV was described as an experience, participants felt that the regret of a missed opportunity would be stronger than the regret of buyer's remorse, but not when it was framed as a possession.

It's worth noting that reframing ambiguity may be asymmetric. That is, it may be fairly easy to think of a tangible object in terms of the experiences it affords, but rather difficult, if not impossible, to think about an intangible experience in terms of its material qualities. Fortunately, turning possessions into experiences appears to be the reframing that is most psychologically beneficial.

These studies taken together suggest the differences between the categories appear to have something to do with real, tangible differences between possessions and experiences, but also with certain psychological processes, such as comparison and regret, and perhaps it is those psychological processes that underlie what makes an experience an experience. What's more, the ambiguity in category definitions can actually be taken advantage of – producing greater satisfaction and reduced susceptibility to negative comparative information. In sum, although it's possible that the categories are largely in the mind, it may be the mind that matters.

SESSION OVERVIEW

Consumers' everyday lives are strongly affected by financial decisions large and small. Individuals and households need to successfully build cash reserves, manage investments, eliminate debts, and plan for retirement. It is no surprise that in all of these domains, consumers are influenced considerably by personal and social factors. Despite the significance and ubiquity of such factors, little is known about their effects on consumers' everyday financial decisions. The goal of this session is to present novel research demonstrating how and why consumers' financial decisions and welfare are influenced by intra and interpersonal factors. Featuring multiple methods and diverse theoretical frameworks, this session provides new insights into how financial decisions are influenced by such factors as the subjective value of money, greed, childhood environments, and social relationships.

Shah, Bettman, and Payne investigate how one's subjective value of money influences individuals' loss aversion tendencies. Using a set of behavioral experiments, the authors find that subjective value of money moderates the degree to which people experience loss aversion. Specifically, they find that less painful forms of money (e.g., credit cards) decrease sensitivity to losses and the negative associations with losing wealth.

Krekels and Pandelaere identify a previously unexplored and counterintuitive aspect of greed: a chronic focus on loss prevention (vs. pure acquisitive behavior). The results from three studies show that people higher versus lower in dispositional greed are more focused on preventing losses. For example, in an online auction paradigm, those higher in dispositional greed bid a larger amount in order to ensure not losing an endowed product.

Mittal and Griskevicius extend beyond intrapersonal factors to explore how an interpersonal factor—childhood environment—influences financial planning behavior in the face of uncertainty. Four experiments suggest that childhood resources play a moderating role on people's motivation to plan. Specifically, individuals from impoverished backgrounds planned significantly less under resource uncer-

tainty. The authors find that sense of personal control mediates this effect and that boosting people's control beliefs helps in mitigating it.

As many important financial decisions are made within the context of relationships (e.g., between spouses), **Olson and Rick** examine whether and why dyads navigate debt management decisions differently than individuals. In an incentivized game, dyads performed significantly worse than individuals and were more likely to pay off smaller debts even when larger debts had larger interest rates. Further analyses among the dyads and a simulation suggest that the partner with the least optimal preferences had greater influence on joint outcomes.

Taken together, these four papers advance our understanding of how intra (i.e., valuation of money, dispositional greed) and interpersonal factors (i.e., childhood environments, deliberation with a partner) influence consumers' financial decisions. Overall, this session offers a coherent set of novel findings that enhance the breadth of our knowledge in an emerging area of research. We expect this session to appeal to a broad, interdisciplinary audience including researchers interested in consumer welfare, decision making, financial planning, debt management, loss aversion, childhood environments, and social relationships.

Psychological Tangibility of Money Influences Loss Aversion and Propensity for Gambling

EXTENDED ABSTRACT

Loss aversion is one of the key constructs in understanding how consumers make household financial decisions, and has been a topic of great interest across a variety of academic disciplines. Loss aversion refers to the phenomenon that the disutility of experiencing a loss weighs greater on the individual than experiencing the utility of an equal amount gained. In other words, it holds that "losses loom larger than gains" (Kahneman and Tversky 1979, 279). Research has demonstrated that whereas gambling preferences for large amounts of money were consistent with loss aversion, gambling preferences for small amounts of money showed a reversal of loss aversion (Harinck et al. 2007). Individuals expected small gains to be more favorable than equivalent small losses were unfavorable. Harinck et al. demonstrate that the objective value of money can influence the degree to which individuals are loss averse.

Whereas research demonstrates that people are loss averse and are unlikely to select gambles that have an equal chance of winning or losing the same amount of money, empirically, the results indicate a different story. Casino revenues in Nevada alone for 2012 have exceeded $10.8 billion, up 1.5% from 2011, and continue to grow (Nevada Gaming Control Board 2013). Casinos regularly require patrons to use poker chips or casino tokens, a less salient and less painful form of money than cash. Furthermore, as consumers are moving toward payment forms such as debit/credit cards and even mobile payment technologies (which all decrease the salience and vividness of the payment experience), an important question emerges: Can the form of money lead individuals to be less sensitive to losses and more focused on gains?

Recent research has demonstrated systemic psychological and behavioral biases in the way individuals evaluate the value of money based on the payment form (e.g., Raghubir and Srivastava 2002; So-

man 2001). More salient forms of money (i.e., paying with cash vs. a debit or credit card) influence the amount of pain individuals feel when paying. Paying with a less painful form of money increases the propensity to spend and to evaluate products more favorably (e.g., Chatterjee and Rose 2011; Hirschman 1979). We propose and find that loss aversion is moderated not only by the objective value of money, but also the subjective value of money. Specifically, we show that less painful forms of money moderate the degree to which individuals experience loss aversion. This leads to an increased propensity to gamble, a greater likelihood in selecting gambles with a lower probability of winning or higher buy-in amount, and increased recall errors in the amount of money played and earned when gambling.

In study 1, we gave participants a chance to play as many gambles as they desired out of a set of gambles, using their own money. We varied the form of payment they gambled with (cash or plastic student card) and the number of gambles they could choose from (2, 6, 10, 14, or 18 gambles). For each of the gambles, we also manipulated the buy-in amount in order to play the gamble ($0.50 or $1), the probability of winning (10%-90%), and the amount earned if the participant won, such that the expected value of all gambles was equal to +$0.50. In each of the conditions, participants could choose to purchase and play all, some, or none of the gambles. We find that individuals gambling with a plastic, less salient form of money gambled more overall, chose lower probability gambles, and were significantly more likely to choose $1 gambles.

In study 2, we use a similar gambling paradigm but examine individuals' ability to recall the money spent gambling after a 5-minute filler task. In comparison to those gambling with cash, we find that individuals paying with plastic had higher recall errors regarding their gambling choices, underestimating the amount of money they gambled and overestimating the amount of money earned.

Our research shows that loss aversion can decrease and even reverse when the subjective value of money is attenuated, altering one's decision-making abilities under risky choice settings. Paying with a less painful form of money decreases the sensitivity to losses and the negative associations with losing wealth. These results have important theoretical and substantive implications. Theoretically, our findings indicate that the cognitive and affective components associated with risk can be influenced by the salience of the gain and loss. Individuals may be buffered more against emotions associated with financial loss when the salience of the loss is low. Cognitively, while people may want to discount negative outcomes (i.e., the hedonic principle), the psychological strategy of discounting may be more effective when the salience of the loss is reduced. Our findings also contribute to the precise understanding of the psychological underpinnings behind the pain of payment, the biases associated with payment form differences, and consumer self-regulation.

Greedy Loss Prevention in Economic Decision-Making

EXTENDED ABSTRACT

Greed is omnipresent in our current society and highly relevant to financial decisions. For instance, the media and public opinion attributed the recent financial crisis to the greediness of bankers and stockbrokers, who risked clients' money to ensure greater turnover to satisfy their greed (Papatheodorou, Rosselló, and Xiao 2010). Greed has also been related to corporate fraud (Smith 2003) and higher levels of consumer debt (Lunt and Livingstone 1991).

When people think about the concept of greed, they typically focus on acquisitive behavior (Wachtel 2003), classifying greed as an insatiable desire. Although we endorse this view of greed, we believe that an important aspect is missing from prior conceptualiza-

tions: avoiding losses might be another important characteristic of greedy people.

This dual vision on greed is often indirectly incorporated in research, where the same behavior might be explained as preventing losses in pay-offs, labeled fear, or increasing pay-offs, labeled greed (Rapoport and Eshed-Levy 1989). We believe that both labels are an essential part of dispositional greed. An initial study (N = 184, 91 males, M_{age} = 30.9, SD = 11.8) revealed a positive correlation between dispositional greed and both promotion and prevention foci (Grant and Higgins 2003; r = .25 and .26, p < .001). To further examine our predictions, we conducted three studies that investigated whether preventing losses (above and beyond acquisitive behavior) is an essential part of a greedy disposition in economically relevant contexts.

In study 1, we employed a validated measure of loss aversion borrowed from previous research (Tom et al. 2007). In this paradigm, respondents indicate their willingness to participate in a coin toss gamble with an equal chance of winning (10 - 45€, increments of 5€) or losing (5 - 25€, increments of 2.5€). These amounts were chosen because previous studies indicate that people are roughly twice as sensitive to losses as to gains (Tversky and Kahneman 1992). Next, participants completed a measure of dispositional greed (i.e., participants rated their agreement with six statements such as "Even when I am fulfilled, I often seek more"). Analyses showed that dispositional greed predicted respondents' loss aversion. Individuals high in dispositional greed (+1 SD) exhibited an average loss aversion ratio of 5.62 (SD = .59), indicating a willingness to participate in the gamble when the gain is more than five times the loss. For those lower in dispositional greed (-1 SD) this ratio was 3.82 (SD = .59). These results show that greedy people are not just oriented towards gaining more, but are also focused on preventing losses.

Study 2 featured an auction paradigm, which is common in economic research (Bajari and Hortascu 2003; Cilia and Buchmann 2002). Prior work has shown that bidding can produce a pseudo-endowment effect (Ariely and Simonson 2003), which might result in loss experiences when people do not become the final owner. A total of 471 U.S. participants (244 males, M_{age} = 32.5, SD = 11.3) imagined being in an online auction. They viewed ten items (e.g., an iPhone, a table lamp) and indicated the highest price they were willing to bid, ranging from 10% to 120% of the retail price. They also completed a measure of dispositional greed.

The results showed that greed predicted the amount respondents were willing to bid (β = .16, $F(1, 469)$ = 12.82, p < .001). A binomial logistic regression showed that greedy people were more likely to bid at least 100% of the retail price (Wald = 5.57, β = .30, p < .05). Thus, greedy people are willing to bid more in an online auction, possibly to ensure not losing the object they already feel ownership over, even if it means paying more than their value.

In study 3, we investigated the consequences of when greedy people experience losses. Previous research has shown that allocators in an ultimatum game feel ownership of the money endowed to them and experience losses when the recipient rejects their offer (Leliveld, van Dijk, and van Beest 2008). As such, 184 U.S. participants (93 males, M_{age} = 34.6, SD = 11.0) played a $1 ultimatum game with a computer programmed to reject any offer. Answers to an open-ended question ensured that respondents were unaware of this fixed response. They then indicated their feelings following this rejection on an 8-item bipolar scale (e.g. *frustrated* to *relaxed*, *disappointed* to *not disappointed*). After some filler items, they were allocated the role of proposer in a $1 dictator game with a different recipient, to exclude a punishing explanation.

Greed significantly predicted the proposed amount in the ultimatum game ($\beta = .22$, $F(1, 182) = 9.50$, $p < .01$) but not their emotions following rejection of their offer ($\beta = .08$, $F(1, 182) = 1.19$, $p = .28$). In the dictator game, both greed and their emotions associated with rejection predicted the amount people kept for themselves. Moreover, there was a significant interaction between greed and the emotions associated with rejection: Whereas non-greedy individuals' emotions predicted how much they would keep, no negative emotional response was needed to increase greedy people's portion.

In three studies, we show that loss prevention has a significant impact on greedy behavior in financial decision-making contexts. A prevention focus is an essential part of dispositional greed, and has an even larger impact than the promotion focus. We also find that when greedy people experience imagined ownership of an object, they are willing to pay more to prevent losing this object. Finally, when they are confronted with an actual monetary loss, it causes them to behave more acquisitive in later, unrelated financial decisions, possibly to make up for this imagined loss.

The Planning Paradox: Increased Economic Uncertainty Decreases Retirement Planning

EXTENDED ABSTRACT

Financial planning is pervasive in consumers' lives. Not only does it impact how we spend money in our everyday lives, but it also has a profound effect on wealth accumulation and retirement satisfaction (Ameriks, Caplan, and Leahy 2003; Elder and Rudolph 1999). Because a principal reason to plan is to have a better and more comfortable future, might uncertainties about the future change people's planning psychologies? For example, can cues indicating looming resource uncertainty and scarcity lead people to change their valuations and importance of financial planning? Would they overvalue planning or undervalue it? Would everyone respond to uncertainty cues the same way or would there be predictable individual differences among people?

Recent work indicates that people respond in adaptive and divergent ways when faced with threats of resource uncertainty based upon their childhood resource conditions (Griskevicius et al. 2013). Whereas adults raised in relatively resource-rich environments took fewer risks and became less impulsive under cues of resource uncertainty, those from relatively resource-deprived backgrounds responded to the same cues by taking more risks and becoming more impulsive. In the present work, we draw on the cost-benefit framework of life history theory to investigate the effects of resource uncertainty on people's financial planning behavior.

In study 1, we experimentally manipulated resource uncertainty by having people read either a news article about the recent economic recession or a control article. We then assessed their motivation for financial planning by using an adapted version of the propensity to plan scale (Lynch et al. 2009). The results revealed that resource uncertainty *decreased* the motivation to plan among those from poorer backgrounds but not for those from richer backgrounds.

In study 2, we sought to replicate the results of study 1 by using a behavioral measure of the value of planning. Economic uncertainty was manipulated by asking participants to recall and briefly describe a situation in which they felt that they could not financially obtain something that they wanted. In the neutral condition, there was no manipulation, meaning that people simply responded to the measure of financial planning. Then, in an ostensibly unrelated task, respondents were informed that the experimenters were interested in knowing the kinds of information people are interested in learning in the context of retirement planning. They were provided with a list of topics pertaining to retirement finances that they could choose to learn about. Importantly, they were informed that they could choose as many or as few of the topics they were interested in. The dependent measure was the amount of time respondents spent on learning about retirement planning. Findings conceptually replicated the results of study 1. Specifically, economic uncertainty led respondents who grew up with relatively lower levels of family resources to spend significantly less time on the retirement planning task. No significant differences were observed for those growing up with higher levels of family resources.

Study 3 had two goals. First, to ensure the robustness of the experimental findings in studies 1 and 2, we sought to conceptually replicate the results using a third methodology to prime uncertainty—a photo slideshow. Second, we tested whether people's sense of control could be a potential mediator of the relationship between resource uncertainty and planning. Resource uncertainty cues were manipulated by having participants view a slideshow with visual images suggestive of economic uncertainty or control images. Next, participants rated their motivation to plan and their perceived sense of control. Consistent with the results from studies 1 and 2, study 3 found that uncertainty cues significantly *decreased* the tendency to plan only for those growing with lower levels of family resources. Additionally, this effect of resource uncertainty on planning was found to be mediated by people's sense of control.

Study 4 tested an intervention strategy for buffering individuals from the negative effects of uncertainty. Given that resource uncertainty lowers sense of control for individuals from deprived childhoods, Study 4 attempted to experimentally re-affirm people's sense of control in the face of uncertainty. Participants were randomly assigned to one of three experimental conditions: uncertainty, uncertainty *plus sense of control boost*, or neutral. Uncertainty was manipulated using the same procedure as in study 2. However, prior to this manipulation, participants recalled and described either an ordinary purchase transaction or a time when they felt in complete control of a situation (Whitson and Galinsky 2008). In the neutral condition, participants simply advanced to the dependent measure. Next, all participants worked on the retirement planning task used in study 2. The time spent reading about retirement planning served as the dependent measure. Consistent with previous studies, we found that whereas uncertainty cues did not affect planning among people from wealthier backgrounds, the same cues led to significantly reduced planning among those from poorer backgrounds. Importantly, however, enhancing sense of control led to a significant increase in planning in this group. This suggests that an intervention which aims at boosting people's sense of control can help in alleviating the effects of economic uncertainty on planning among those who are most vulnerable.

These studies provide important new insights into the complex relationship between resource uncertainty and people's financial behaviors. It draws upon life history theory to explore why people from different childhood backgrounds might plan differently during uncertain times such as economic recessions. It also identifies sense of control as an important variable that guides people's subsequent behaviors pertaining to financial planning. Furthermore, it documents the ameliorating role of a sense of control in getting people from poorer backgrounds to plan more during tough times. In sum, this work has important implications for public policy professionals and others who wish to foster better financial planning behaviors in people from disadvantaged backgrounds.

Managing Debt and Managing Each Other: Debt Management Decisions in Interpersonal Contexts

EXTENDED ABSTRACT

The past few years have witnessed a surge of interdisciplinary research aimed at understanding and improving consumer financial decision-making (Lynch 2011). The vast majority of work in this area has focused on how individual consumers process information and make decisions. However, outside the lab, many important financial decisions are subject to social influence and are made within the context of relationships (e.g., between spouses and business partners; Simpson, Griskevicius, and Rothman 2012). Moreover, the outcomes of such decisions can be important determinants of relationship satisfaction (e.g., Dew 2008). Our work begins to address this important gap in the literature by examining whether and why dyads navigate a common financial decision (how to manage debt) differently than individuals.

When individuals are faced with multiple debts, they tend to repay the smallest debt first rather than the debt with the highest interest rate, a costly tendency known as debt account aversion (Amar et al. 2011). A number of psychological factors appear to contribute to debt account aversion, including the temptation of pursuing goals nearest completion and the pleasure of eliminating an obligation. However, whether debt account aversion would persist in a joint decision-making context is unclear. On the one hand, people may find it difficult to publicly defend their desire to pursue the financially suboptimal strategy of closing small debts because it is pleasurable (Lerner and Tetlock 1999). Thus, the accountability inherent in joint decision-making may encourage more financially optimal debt repayment behavior. Performance within dyads may also be enhanced because having a partner offers an additional perspective, which encourages greater discussion and may ultimately enhance decision quality (i.e., by identifying and implementing the financially optimal strategy). On the other hand, dyads may focus their discussion on attributes that are easier to understand (e.g., the number of debts, in this context; Hsee 1996) and attempt to reach agreement on how to manage those attributes. Deliberation among like-minded people can also amplify existing preferences (e.g., Schkade, Sunstein, and Hastie 2007). Thus, if most people naturally prefer to focus on closing small debts (Amar et al. 2011), joint decision-making may make this preference even more pronounced.

Based upon work in social psychology indicating that groups value harmony and conformity (sometimes to the detriment of decision quality; Asch 1956; Janis 1972), individuals may be motivated by normative pressures. Specifically, dyads might "go along to get along" and thus focus on hedonically rewarding outcomes (which may be different than financially optimal outcomes). To test whether typical repayment behavior among individuals resembles happiness-maximizing behavior, we first examined the motives underlying debt account aversion. We presented individuals with a scenario in which they could either completely repay a low-balance debt with a low interest rate (APR) or partially repay a high-balance debt with a high APR. We asked participants what they would actually do in such a situation, what they rationally should do, or what they should do to maximize their happiness. We found that participants' actual and happiness-maximizing preferences both favored paying off the small debt, whereas rational preferences favored chipping away at the high-balance, high-APR debt. The results suggest that individuals understand that, economically, they should focus on interest rates, but that the pleasure associated with eliminating debts is difficult to resist.

Our primary experiment examined whether these hedonic preferences would be enhanced or minimized in an interpersonal context. We randomly assigned 87 (previously unacquainted) participants to complete a debt management game individually or in pairs. In the game (Amar et al. 2011), participants are initially saddled with six debts varying in size and interest rates. Critically, larger debts tend to have larger interest rates, meaning participants must avoid the temptation of closing small debts to perform well. The game lasts 25 "years" (rounds), and participants receive annual salaries they must use to repay one or more debts. In addition to a show-up fee, each participant could earn up to $7.50 ($15 for each dyad) based upon his or her final debt amount at the end of the game.

We found that dyads performed significantly worse than individuals (i.e., they had significantly greater final debt levels) and were 38% *more* likely to pay off the smallest debts. Follow-up analyses among the dyads and a simulation suggest that the partner with the least optimal preferences "wins" by having greater influence on joint outcomes. We then conducted the same experiment with 25 groups of three people to examine whether the results were specifically driven by one-on-one interaction or generalize to other types of social interactions (i.e., interactions where "majority rules" and alliances were possible). The pattern among groups was virtually identical to the pattern among dyads, suggesting that any kind of social deliberation may intensify debt account aversion.

Our work challenges the generalizability of debt management research conducted among individuals. Analysis of measures collected after the experiment suggests that dyads may have been more motivated to get along than to behave optimally. If participants who advocate closing debts are more passionate about their beliefs than participants who advocate focusing on interest rates, this (combined with heightened affiliative motives) could help explain why dyads struggle. We are currently examining (among individuals) whether suboptimal preferences are indeed held more passionately than financially optimal preferences. We are also further examining the "go along to get along" hypothesis by manipulating the extent to which dyads are motivated to get along (i.e., by manipulating whether dyads are fixed for the duration of the experiment or are randomly repaired at the end of each round). We also plan to examine whether these effects replicate with real couples, as familiarity and an existing bond may increase one's willingness to challenge others' suboptimal preferences.

Jason Dana, Yale University, USA
Barbara Mellers, University of Pennsylvania, USA

SESSION OVERVIEW

"Art is the proper task of life"–Friedrich Nietzsche

Artistic expression may be an essential aspect of what makes us human. Developing and communicating tastes for art and culture is fundamental to social life. The subjective nature of taste contributes to the tremendous richness and diversity of human culture (Hirschman 1983) but also to the difficulty of conclusively understanding this area of consumer behavior. Though some prior consumer research has demonstrated that cultural tastes serve to signal identity and facilitate social behavior (e.g., Berger and Heath 2007; Levy 1959), many principal elements of the defining qualities and drivers of consumer taste remain underexplored.

For instance, how do choices and social judgments involving art and taste differ from those involving other sorts of products? What factors influence consumer preferences for art, and what standards of evaluation are applied to judgments of taste and artistic quality? The four papers in this session examine some basic underpinnings of consumer taste and judgments of artistic quality.

The first two papers examine how tastes are formed and communicated within social groups. First, **Spiller and Bologolova** investigate how viewing a choice as a matter of taste, relative to objective quality, influences how it is perceived, communicated, and enacted. **Wertenbroch, Bhattacharjee, and Barasch** then examine how including some low-quality tastes in a set of consumption choices can balance signals of good taste and authenticity, thus better indicating *true* good taste. The final two papers investigate how perceptions of the creative process undertaken by artists drive consumer judgments of artistic quality within the marketplace. **Valsesia, Nunes, and Ordanini** find that the extent of artistic ownership shapes critical evaluations but not necessarily consumer preferences. The last paper by **Bhattacharjee, Berman, Dana, and Mellers** examines how perceived artist motives shape consumer judgments of artistic quality: consumers prefer artists who create only to satisfy their own tastes, while artists who seek to satisfy the tastes of others are seen as sellouts.

Together, these papers highlight novel aspects of the antecedents and consequences of consumer taste judgments. All four presentations have at least three studies complete and manuscripts in preparation. Given the primacy of taste to social and marketplace life, we expect this session to generate interest among researchers of consumer preference, decision making, self-concept, aesthetics, creativity, culture, and social judgment.

The goal of the session is not only to provide concrete insights, but also to stimulate deeper questions about the role of cultural and artistic tastes within our lives. Why do we care so deeply about taste and how artists approach their work? How do tastes develop and come to drive important life decisions? In the spirit of the session theme, we hope these ideas will encourage reflection about the nature of consumer research: like artists, researchers are creative producers who are deeply passionate about their work. Accordingly, we hope to provoke a discussion at ACR that is both fruitful and fun.

Discrepant Beliefs About Quality Versus Taste

EXTENDED ABSTRACT

Is a cinephile's choice between a superhero movie and a romantic comedy a matter of which is better or which she likes more? Understanding whether consumers believe a choice set is a matter of taste or quality, is critical because such beliefs affect behaviors and inferences. The question of quality versus taste is a question of perceived objectivity versus subjectivity. Advice seeking differs between domains of knowledge and domains of preference (e.g., Goethals and Nelson 1973; Gorenflo and Crano 1989; Olson, Ellis and Zanna 1983), but this is typically assumed to vary by domain. Instead, we propose that in addition to domain differences in objectivity, there are individual and situational differences in perceived objectivity for a given domain. For example, in Goodwin and Darley's (2008) study of moral behaviors, they found disagreement in the perceived objectivity of domains traditionally seen as matters of taste.

Discrepant beliefs about taste and quality have important implications for how individuals reason about the world and others' preferences. We argue that because consumers who believe a choice is a matter of quality see the difference as one that exists in the world independent of their own perspective, they will perceive greater consensus than those who view the choice as a matter of taste. Moreover, because consumers who believe a choice is a matter of taste recognize the role of the match between the option and the chooser, they will be more likely to reference themselves when explaining their choice than those who believe a choice is a matter of quality. Finally, because consumers believe that quality is an acceptable reason to pay more for a product whereas idiosyncratic factors are not (Bolton, Warlop, and Alba 2003), they are more likely to be willing to pay for their preferred option when it is believed to be a matter of quality rather than a matter of taste.

Brand Evaluation. In Studies 1 and 2 (each *N*=200), participants made one brand choice from each of four categories (e.g., Coca-Cola vs. Pepsi). All participants explained their choices, reported whether each choice was a matter of quality or taste, estimated how many participants made the same choice they did, and reported willingness to pay for their preferred option over the alternative. Consumers disagreed about how to classify a given choice: across choices, the

minority representation was held by approximately 35% of participants. Believing a choice was a matter of taste (vs. quality) was associated with lower perceived consensus (by about 10 percentage points; $ps<.0001$), greater use of first-person pronouns when explaining their choices (by about 35 percent; $ps<.0001$), and lower likelihood of being willing to pay for one's preferred option (by about 30 percentage points; $ps<.0001$).

What causes such differences in the beliefs about a given domain? Reasoning about the structure of preferences affects beliefs. Prompting consumers to explain why someone else chose a different option than they did should lead them to be more likely to recognize that others have different preferences and therefore believe the choice is a matter of taste. Study 3 ($N=200$) was similar to 1 and 2 except that rather than explaining their own choices, half of the sample explained why another participant chose the same option, and the other half explained why another participant chose a different option. Explaining another's discrepant choice increased the likelihood of rating the choice as a matter of taste by about 13 percentage points ($p<.05$).

Implications for Transitivity. One way to examine how consumers' beliefs relate to their reasoning is to examine how they react after observing others' choices. First, viewing an intransitive set of others' choices (Alex chose X over Y, Ben chose Y over Z, but Christine chose Z over X) should lead to a greater likelihood of believing the domain is a matter of taste compared to viewing a transitive set of others' choices (Alex chose X over Y, Ben chose Y over Z, and Christine chose X over Z), because the second is compatible with a single rank-ordering according to quality whereas the first is not. Indeed, in Study 4 ($N=100$), participants who saw interpersonally intransitive sets were more likely than those who saw transitive sets to report that the product domain (search engines) was a matter of taste rather than quality ($p<.05$).

Second, believing a set is a matter of quality (vs. taste) should lead to a greater likelihood of making transitive out-of-sample inferences (e.g., given Alex and Ben's choices, inferring that Christine will choose X over Z) because quality differences are transitive whereas interpersonal taste differences are not. In Study 5 ($N=400$), consumers were shown a set of overlapping choice sets from different people. Those who believed the product domain was a matter of quality were more likely to make transitive out-of-sample inferences than those who believed the domain was a matter of taste ($p<.01$).

Across studies, contrary to prior research, we find that consumers show little consensus about how to classify an attribute: the minority opinion of taste vs. quality represented one third of participants. These relationships have important implications for bidding behavior, disclosure by sellers, beliefs about price fairness, and beliefs about others' choices.

Judging Good Taste: True Preference or Pretense?

EXTENDED ABSTRACT

Good taste is central to social life. Consumers' need to demonstrate good taste is strongly associated with cultural capital within social groups (Bourdieu 1984). While the costs of acquiring tastes help ensure that they are reliable signals of distinctions between groups (Berger and Heath 2007), they cannot apply to within-group judgments. Within groups, given that quality standards are shared and there are known benefits to demonstrating good taste, how can individuals tell authentic preferences from mere pretentiousness?

We propose that *authentic good taste* is a single-peaked function of the quality of chosen options across repeated choices. Relative to choosing uniformly high-quality options, including some low-quality options may help people signal authenticity to themselves and others. Hence, judgments of *true* good taste, and the corresponding social benefits, may call for a mixture of choice options that suggests an ability to discern quality independently. Supportive evidence comes from four experiments.

Study 1 demonstrates that the presence of bad tastes increases perceptions of authenticity. Undergraduate participants imagined moving into a new dorm and evaluating their new hallmates' answers to an informal "Getting to Know You" survey including lists of their favorite tastes. Participants viewed the 6 favorite magazines of four hallmates (either all male or all female) and indicated their perceptions of these new neighbors. Magazines were chosen to represent either good (e.g., The New Yorker) or bad taste (e.g., Entertainment Weekly), as confirmed using participants' ratings on follow-up measures ($t(241)=27.39$, $p<.001$). The proportion of good tastes was manipulated among the four hallmates' selections: 0 good magazines and 6 bad magazines, 2 good and 4 bad, 4 good and 2 bad, and 6 good and 0 bad (with presentation order counterbalanced). Gender had no effect and was collapsed.

As expected, perceptions of individuals' good taste increased linearly with the proportion of good magazines ($F(1,239)=258.84$, $p<.001$). However, perceived authenticity decreased linearly with more good tastes ($F(1,239)=127.56$, $p<.001$). Importantly, undergraduates' desire to socialize with hallmates (i.e., befriend and seek recommendations) varied quadratically with their proportion of high-quality reading choices ($F(1,239)=99.77$, $p<.001$), peaking for those selecting some low-quality options. In other words, participants indicated the greatest desire to befriend and solicit reading recommendations from individuals who selected 4 good tastes but also 2 bad tastes, and these individuals were significantly preferred to those with the "best" taste ($M=4.75$ vs. 4.38, $p<.001$). Results held controlling for perceived preference similarity, suggesting participants' judgments were not simply about matching preferences.

Do these effects depend on the particular social meanings of these tastes or subjective perceptions of quality? Study 2 sought to address these possibilities and further rule out potential effects of preference similarity. An online adult sample of self-described wine novices imagined attending a wine tasting event to meet new people. Attendees tried 20 different wines and selected 8 favorites. Participants viewed the wine selections of five different individuals at the event, which were manipulated to contain different proportions of good quality versus lower quality wine (as defined by Wine Advocate numerical ratings and categories): 0 good wines and 8 bad wines, 2 good and 6 bad, 4 good and 4 bad, 6 good and 2 bad, and 8 good and 0 bad (with presentation order counterbalanced).

Again, results revealed significant linear trends for both good taste ($F(1,90)=135.15$, $p<.001$), and authenticity ($F(1,90)=105.37$, $p<.001$), such that perceived good taste increased and perceived authenticity decreased with a greater proportion of good tastes. As in Study 1, participants' desire to befriend individuals and seek their recommendations exhibited a significant quadratic trend ($F(1,90)=13.24$, $p<.001$), with those selecting the most good tastes actually rated the worst on these social outcomes. A significant quadratic trend also emerged on perceptions of individuals' ability in a blind taste test, a measure of independent discernment ($F(1,90)=17.17$, $p<.001$). Judgments of true good taste peaked for those choosing some lower-quality wines, confirming that those selecting the greatest proportion of good tastes were not judged to have true good taste.

Study 3 tested our mechanism with a misattribution paradigm, using the presence of a free gift to manipulate the signal value of wine choices. Providing a gift to explain low-quality wine choices

eliminated differences in predicted blind taste performance (p=.821), but social outcomes still favored individuals choosing some low-quality wines across conditions ($F(1,178)$=40.24, p<.001 overall), underscoring the social importance of perceived authenticity.

While Studies 1, 2, and 3 demonstrate how the presence of bad tastes drives inferences of others' authenticity, Study 4 expanded our investigation to self-signals of authenticity. In particular, we manipulated concerns about good taste versus authenticity and measured the quality of the tastes expressed by participants. An online sample of self-described movie buffs reflected on their taste in movies. They wrote a paragraph discussing whether their taste is truly good, whether their taste is truly authentic, or simply describing their taste (as a control). Next, participants listed 3 movies that they would personally recommend to a friend. The main dependent variable was the quality of these movies according to Rotten Tomatoes, a website that aggregates critical reviews and combines them into one numerical rating.

Invoking authenticity concerns led participants to recommend movies with lower quality ratings (M=78.51) compared to the good taste (M=84.01, p=.018) and control conditions (M=83.94, p=.033). Analyzing recommendations categorically for the presence of bad movies (<75 rating) yielded similar results: compared to both the good taste (39%) and control (43%) conditions, a significantly greater proportion of authenticity condition recommendations included bad movies (64%, $\chi^2(1)$=6.13, p=.013). Interestingly, these participants also judged themselves as significantly more able to truly judge the quality of a given movie (M=6.11) relative to the good taste (M=5.58, p=.016) and control (M=5.47, p=.003) conditions. Hence, participants' increased selection of bad tastes may have worked as a self-signal of authenticity and actually increased self-perceptions of true good taste.

Our findings demonstrate that signals of good taste are subject to authenticity constraints. Occasional low-quality choices help consumers signal authenticity to themselves and others. True good taste may require trading some beauty for truth.

The Impact of Artistic Ownership on Aesthetic Judgment and Preference

EXTENDED ABSTRACT

This research introduces the concept of "artistic ownership," the extent to which artists both conceive of and execute their own work, to the literature on cultural goods. We document how artistic ownership impacts critical acclaim but not consumer preferences for such goods.

Experts and consumers appear to have different assessment goals, and may thus utilize different information to form evaluations. A fundamental goal of the critic is seen as establishing organized standards by which artistic value can be assessed. We argue that critics charged with providing aesthetic judgments purposefully integrate artistic ownership into their evaluations. In contrast, consumers' decisions for most cultural goods (investments exempted) depend on aesthetic preferences, or simply what they like, and thus need not be defensible. Our work nonetheless shows that ordinary consumers, as well as critics, will include information about artistic ownership when charged to make an aesthetic judgment, but not when expressing their aesthetic preferences. This research helps explain why cultural goods can be judged as superior based on criteria that have no discernible effect on consumer's subjective consumption experience.

Music is an especially suitable domain in which to study the impact of artistic ownership, as writing credits for a song (a good measure of artistic ownership) are published by reliable sources and are often known publicly. At one extreme, a song can be the product of professional lyricists and composers who subsequently turn it over to someone else to perform. This was the case with Rihanna's 2007 breakout hit "Umbrella," which was originally written for, but rejected by, Britney Spears. At the other extreme, a song can be written, composed, and performed by the same person, as is the case with "Love Story," Taylor Swift's best-selling single. In study 1A, we utilized two different real-world data sets to examine how the extent to which a song's performer was involved in the writing process impacts on both critical acclaim (reflecting aesthetic judgments) and market performance (reflecting aesthetic preferences). We first looked at all 1,029 hit singles that reached number one in the Billboard Hot 100 singles charts between 1958, when the ranking was first introduced, and 2012. We then looked at all 690 songs that made it onto Billboard's Top 40, regardless of position, from 2009 through 2012. We find songs performed by singers who write their own material are more likely to receive critical acclaim but are no more likely to achieve platinum status, an indicator of exceptional popularity and what consumers actually buy.

Consistent with these findings, artistic ownership is considered important in many creative industries. Comedians who write their own jokes are respected while those who rely on others to produce their material are frequently the object of professional contempt. Reader's Digest reports the #1 thing television chefs don't tell audiences is they don't create their own recipes. And fashion critics admire designers who can draw, cut and stitch (e.g. Yves Saint Laurent) while frequently dismissing those who cannot (e.g. Ralph Lauren). In Hollywood today, the term auteur is often used to distinguish directors who write their own screenplays. Accordingly, in study 1B, we replicate our findings in another domain, and document how film critics are more likely than filmgoers to venerate movies by directors who write their own scripts.

In study 2, we move to the lab to investigate whether observed differences between critics' and consumers' evaluations might be due to critics possessing different and perhaps more refined tastes as compared to most consumers. Thus, we manipulate whether the performer of a song is described as its sole author or whether authorship of the song is attributed to a third-party lyricist and composer. Aesthetic judgment is assessed by asking respondents which songs they deem worthy of historic recognition and would choose to put into a time capsule, while aesthetic preference is measured by liking. We find that by explicitly asking consumers to make an aesthetic judgment (i.e., basing their evaluation on the historical and cultural importance of a work) leads them to disproportionately favor songs for which the performer shows greater artistic ownership. In contrast, when the same consumers report their preferences (i.e., what they like or what they would buy), artistic ownership has no discernible effect. The goal of the task, rather than differences in taste, appears to determine whether artistic ownership is considered in the evaluative process.

Study 3 explores competing explanations for critics' positive predisposition to works with greater artistic ownership. Perceptions regarding the talent of a work's creator as well as the effort they exerted in its creation are known to play a role in the evaluation of a cultural good but have been shown to have opposing effects (Cho and Schwartz 2008). Talented artists are presumed to exert less effort and vice versa. Study 3 tests the potential mediating role of both perceptions of talent and effort on aesthetic judgment and aesthetic preference. We find perceptions of the artist's talent mediate the impact of artistic ownership on judgments, while perceptions of the artist's effort do not.

Taken together, this work introduces artistic ownership as a novel characteristic of cultural goods and documents both its influence on aesthetic judgments and its relative lack of influence on aesthetic preferences. Aesthetic judgments – the role of critics – are supposed to be dispassionate. Consequently, these types of evaluations may compel the individual to rely on standards that seem more objective. Artistic ownership is one such standard. We show that increasing artistic ownership increases perceptions of the amount of overall artistic talent that has gone into creating a cultural good, an ostensibly compelling reason to support its artistic quality. But it is not a great rationale for a positive subjective response. One can appreciate the artistic quality of a painting, a song, an entrée, or a film without really liking it. These findings help explain why critical judgments and consumer preferences often diverge.

Selling Out: Producer Motives in Markets for Art

EXTENDED ABSTRACT

Markets are founded on the premise that consumers choose products that best meet their needs. Hence, it makes sense for producers to signal a willingness to adjust their products to match consumer preferences. But consider a musical artist who conducts market research to create a song that satisfies consumer needs. Would this song be judged favorably?

Though recent work examines the role of artist identity in judgments of artistic quality (Bar-Hillel et al. 2012; Newman and Bloom 2012), and some theorists describe a disjunction between the demands of audiences and the demands of expert art critics (e.g., Hirschman 1983), this question remains largely unaddressed. Despite the prominence of art within human culture and the pervasive presence of commerce in our market society, little work has examined the psychological determinants of perceived artistic quality within markets.

We investigate consumer judgments of *selling out*, or perceptions that producers have compromised their integrity to pursue external incentives. To provide the first examination of this phenomenon, we examine the influence of perceived producer motives on consumer product evaluations. Four studies identify a key difference between markets for commercial products and artistic products. Consumers reward commercial producers who change their products to suit consumer preferences, but penalize artistic producers who do just the same. People prefer artists who satisfy their own preferences and ignore others' preferences, even those of expert critics whose preferences typically define high quality art. Artists who adjust their products to fit others' preferences are seen as selling out, destroying consumer perceptions of product quality and reducing purchase likelihood. Importantly, our results show that such artistic integrity violations affect product quality only in markets for art, and suggest that consumers apply different standards of producer integrity in commercial markets.

Study 1 demonstrates that judgments of actual experienced song quality depend on perceived producer motives. After listening to a song, participants were less willing to download it when the artist was described as motivated by consumer preferences rather than their own preferences (4.43 vs. 5.63, $t(92)=3.21$, $p=.002$). This motive reduced perceived artistic integrity (4.43 vs. 5.63, $t(92)=9.11$, $p<.001$) and was labeled as selling out (51% vs. 4%, $\chi^2(1) = 26.58$, $p<.001$). Perceptions of artistic integrity mediated the effect of producer motives on consumer perceptions of product quality.

Using the same scenario, Study 2 shows that these results hold even when artists seek to satisfy expert critics whose preferences define high-quality art. We compared artists who adjusted their products to better fit either their own changing preferences, consumer preferences, or critical preferences, relative to a no-product-change control condition. Motives significantly affected perceived quality ($F(3,167)=4.60$, $p=.004$). While changes driven by artists' own preferences had no effect on product evaluations relative to maintaining their style (5.51 vs. 5.86, $p>.288$), changes motivated by consumer preferences (4.74 vs. 5.86, $p=.001$) or critical preferences (5.05 vs. 5.86, $p=.011$) decreased perceived quality and were widely seen as selling out (75% vs. 60% vs. 13%, $\chi^2(1)=50.31$, $p<.001$). Perceived artistic integrity again mediated the effects of producer motives on perceived product quality.

Study 3 identifies an important distinction between artistic and commercial markets. Relative to a producer focusing only on their own preferences, considering customer preferences decreased perceived quality ($t(59)=-3.01$, $p=.004$) and perceived integrity ($t(59)=-7.12$, $p=.004$) within four artistic domains (novel-writing, painting, songwriting, filmmaking). In contrast, openly focusing on customer preferences increased perceived product quality ($t(59)=11.31$, $p<.001$) and integrity ($t(59)=5.67$, $p<.001$) across four commercial domains (software programming, home contracting, event planning, brand management). These results illustrate that producer integrity is defined differently within artistic versus commercial markets.

Study 4 replicates these results within the same product domain: a photographer who takes photographs intended to be used as art versus commercial products. Participants' product evaluations showed an interaction between producer motives and product usage ($F(1,156)=21.01$, $p<.001$). Relative to the producer satisfying his own preferences, product changes made to suit customer preferences reduced perceptions of artistic photograph quality (6.15 vs. 4.91, $p<.001$), but improved perceptions of commercial photograph quality (5.17 vs. 6.01, $p=.010$). Measures of artistic integrity mediated these effects on perceived product quality when photographs were meant for artistic usage, but did not affect the perceived quality of photographs meant for commercial usage. These results further confirm our theorized distinction.

Though art and commerce are both central to human society, we illustrate a fundamental difference in what individuals expect of producers within these domains. People penalize artistic producers who change their products to fit consumer tastes but reward commercial producers who do the same. Ironically, consumers most prefer artists who seem to ignore consumer preferences.

SESSION OVERVIEW

Creating distinctive, favorable brand meanings is at the heart of building brand equity—often defined as the differential effect that knowledge about brand meanings has on consumers' responses to the marketing of the brand (Keller, 1993). In the hyper-competitive markets of the 21st century, brands need to go beyond functionality to deliver emotional and symbolic benefits via the embodiment of abstract brand meanings or concepts (Monga & John, 2010). Although there seems to be consensus on the notion that creating abstract brand meanings benefits brand performance, what factors are likely to facilitate (or impair) the translation of brand meaning creation into more favorable brand evaluations? The papers in this session unite under a common theme of identifying brand- and individual-level factors that moderate the extent to which the creation of abstract brand meanings is more or less favorably received by consumers.

Stoner and colleagues distinguish between abstract brand concepts created by diversifying the product portfolio in order to appeal to high-level needs of consumers, versus those created by establishing human-like motivational and emotional meanings that resonate with consumers' self-defining values. They demonstrate that although both strategies drive favorable consumer attitudes, the latter strategy has a more favorable impact on brand evaluations, and shields the brand better from scandals.

Sayin and colleagues investigate how the level of consumer attachment impacts responses to extensions by brands with strong personalities. Findings from four studies show that, among highly attached consumers, brands with strong personalities experience greater dilution when extending to categories that are incongruent with their abstract brand meanings. These effects are driven by consumers' feelings of betrayal by the brand. Furthermore, the effects are stronger among consumers with higher (vs. lower) self-enhancement needs.

Park and colleagues study ways to reduce the negative effect of promoting prosocial images (through CSR activities) for luxury brands. They show that although consumers with high (vs. low)

self-enhancement motivation, who desire to achieve social status or wealth, view luxury brands using CSR appeals negatively, these negative effects can be attenuated via self-expansion (self-referencing, observing celebrities, or perspective taking), which induces the feeling that self-enhancement motives (associated with the luxury brand) and self-transcendence motives (triggered by CSR appeals) can be simultaneously pursued.

Finally, Paharia and Swaminathan investigate consumers' preferences for *democratic brands* (those that welcome consumer input) and *undemocratic brands* (those who maintain control) as a function of their perceptions of warmth and competence as well as consumers' social-dominance orientation (SDO). They demonstrate that greater preference for democratic brands is mediated by perceptions of warmth. However, for people high in SDO, or in situations where hierarchy is relevant, undemocratic brands are valued more, and this effect is mediated by perceptions of competence.

In keeping with the theme of the conference ("Back to Fun"), the papers in this special session uncover some of the factors that contribute to consumers' enjoyment of the abstract meanings in brands. The findings in this session should appeal specifically to scholars interested in branding, new products, and negative publicity, and more generally to those interested in the psychological processes underlying product evaluations.

The Asymmetric Effect of Portfolio- and Image-Based Abstractness for Building and Protecting Brand Equity

EXTENDED ABSTRACT

Research shows that abstract brand concepts not only elicit more favorable consumer responses (Monga and John 2010), but also affect whether judgment revision occurs following a challenge to held beliefs (Pham and Muthukrishnan 2002). However, abstractness can come from two different brand strategies. A brand could diversify its product portfolio and push upward in defining itself in terms of a high-level product denomination (referred hereafter as *portfolio abstractness*) that is better positioned to satisfy high-level consumer needs (e.g., a railroad brand is not in the railroad business but in the transportation business, Levitt 1960). Or a brand could establish abstract brand concepts on the basis of human-like motivational and emotional meanings (referred hereafter as *image abstractness*) that resonate with consumers' self-defining values (e.g., by imbuing brands with human values such as openness or self-enhancement, Torelli et al. 2012).

Surprisingly, research has yet to examine which approach is more favorable for boosting consumer evaluations and better at shielding from brand dilution in the face of a brand scandal. We draw on Action Identification Theory to demonstrate that abstract brand concepts can be identified at different levels (Vallacher and Wegner 1987) and argue that brands high in image abstractness are identified at a higher level than brands high in portfolio abstractness. Because higher levels of identification are more easily represented in terms of high-level, self-relevant values (Vallacher and Wegner 1989), we propose and find an asymmetric effect in that image abstractness boosts customer evaluations at any level of portfolio abstractness, while portfolio abstractness only helps brand concepts low in image abstractness.

If both strategies are successful at generating favorable consumer attitudes, does either have an edge in shielding the brand from dilution in the face of a brand scandal due to a new product failure? Counter to intuitions, we propose that increasing image (vs. portfolio) abstractness is a more effective strategy Based on modern portfolio theory, one could speculate that increasing portfolio abstractness under a common thread should reduce the risk in any given product failure (Lubatkin and Chatterjee 1994). In contrast, we argue that when consumers are confronted with information about a new product failure, they are less likely to revise initially favorable brand judgments when the brands are high (vs. low) in image abstractness than when they are high (vs. low) in portfolio abstractness. This is driven by the lower level of commensurability between the more "concrete" new product failure information and the higher level identification of a brand that is high in image abstractness (vs. a brand that is high in portfolio abstractness), which in turn renders the negative information less diagnostic (Pham and Muthukrishnan, 2002).

In a pilot study we tested the theory that brands could be identified at different levels. Using a within subjects design, participants were presented with four real brands that varied on their level of image and portfolio abstractness. Results showed that brands higher in image abstractness were identified at a higher level than the brands high in portfolio abstractness, as well as the brands low in both types of abstractness (see table in Appendix for means and statistics).

In study 1, participants rated Interbrand's Top 100 Global Brands on image and portfolio abstractness as well as reported their attitude toward the brand. Fitting these ratings to a linear model yielded significant coefficients for portfolio abstractness and image abstractness, suggesting a positive effect of both types of abstractness on brand evaluations. Additionally, the coefficient for the portfolio × image abstractness interaction was also significant. Compared to a baseline condition a brand strategy focused on heightening image abstractness had a more favorable impact on brand evaluation ($F(23, 1222) = 21.50$, $p < .001$, $\eta2 = .29$) than a brand strategy focused on heightening portfolio abstractness ($F(24, 1222) = 2.94$, $p < .001$, $\eta2 = .06$). See appendix for coefficients and means.

Study 2 used a 2 (portfolio abstractness: low/high) × 2 (image abstractness: low/high) between-subjects design using real technology brands. Participants reviewed information about one of the brands and then indicated their attitudes and opinions towards that brand. After a filler task, they were presented with negative information about a new product, and reported their attitudes and opinions again. Results not only displayed the same positive and asymmetric effect of portfolio and image abstractness on initial brand evaluations as found in study 1, but there was also a significant time of measure × portfolio abstractness × image abstractness interaction, $F(1, 190) = 4.57$, $p < .05$, $\eta2 = .02$ on brand attitude showing that this asymmetric effect carries over to post-exposure attitude. The favorable effect of portfolio abstractness at low levels of image abstractness completely dissipated after exposure to negative publicity about a new product failure. In contrast, image abstractness had a more favorable impact on brand evaluations both for brands low ($F(1, 190) = 39.11$, $p < .001$, $\eta2 = .17$) and high in portfolio abstractness ($F(1, 190) = 23.84$, $p < .001$, $\eta2 = .11$). See appendix for means.

Study 3 followed the same procedure in Study 2 but using a hypothetical automobile brand in a 2 (portfolio abstractness: low/high) × 2 (image abstractness: low/high) between-subjects design. In addition, this study investigated the mediating role of diagnosticity of the negative product information (measured via negativity of thoughts, Ahluwalia 2002). Results mirrored those of

Study 2. Mediation analyses further suggested a significant shielding effect of image abstractness on posterior brand attitudes through negativity of thoughts.

When "My" Brand Extends to Incongruent Categories: Effect of Lack of Fidelity on Consumers Attitudes

EXTENDED ABSTRACT

Consumers choose to establish strong relationships with brands that they can use to create, express and differentiate their actual or aspired identities (Fournier, 1998). The literature suggests that highly attached consumers of a brand will engage in relationship sustaining behaviors, and hardly revise their attitudes toward these brands. Accordingly, highly attached consumers are targeted by brands as they are more forgiving in case of a negative event. We propose, on the other hand, that brands with strong meanings and dedicated customers may be more vulnerable if customers perceive them as exploiting their relationship.

Consumers use the meanings in brands to communicate their identities to others (Griskevicius et al., 2007). They create emotional and cognitive bonds (i.e., attachment) with brands and can even see them as extensions of the self (Park et al., 2009). Their cognitive bond leads them to allocate more social resources to defend their brands (Johnson & Rusbult, 1989) and even forego self-interest to sustain their relationship (Thomson, MacInnis, &Park, 2005). Additionally, their emotional bond (i.e., their prominent and positive feelings about a brand) inhibits recall of other feelings (Alba & Chattopadhyay, 1986). For example, Fedorikhin at al. (2008) demonstrate that highly attached consumers of a brand are willing to purchase and pay more for its extensions, even when there is only moderate fit between brand and extension. Their attachment to the brand attenuates the negative effect of the moderate fit.

We believe that consumers' relationships with brands rely on the assumption that brands will continue to convey the same meaning and that this meaning will be transferred to consumers' identities. They will choose "their" brand according to its meaning, symbolic value, and ability to express the right meaning about themselves to others. If a brand behaves incongruently with its meaning (e.g. brand extension incongruent to the meaning), meaning is diluted and cannot be transferred to consumers. When an individual has a great deal of self-concept wrapped up in a relationship, any potential problem with that relationship can cause negative feelings (Davis, Shaver, & Vernon, 2003). We propose that highly attached consumers will find a brand behavior that dilutes brand meaning as a breach to their relationship and will feel betrayed.

The more consumers feel attached, the more they feel betrayed, and the more negatively they react to the brand (H1), through the mediating effect of felt betrayal (H2). Additionally, consumers with high self-enhancement need will have greater tendency to use brands to establish more favorable self-identities. Their level of self enhancement need will strengthen consumers' negative reaction (H3), when meanings of such brands are diluted after incongruent extension decision.

In a series of five studies we test these effects. Study 1 demonstrates the effect of brand extension type (congruent vs. incongruent) and attachment level (high vs. low) on feelings of betrayal toward a fictitious beverage brand that extends into an incongruent product category. Results show that among highly attached participants feelings of betrayal are greater when the brand extends to an incongruent (vs. congruent) product category. These effects are absent among consumers low in brad attachment (see table in the Appendix for means and statistics). Study 2 investigates the

effect of attachment level on feelings of betrayal and attitude change toward the parent brand (Mini Cooper) upon the introduction of an incongruent extension (station wagon-from pretests). An analysis of the indirect effect of attachment on attitude change toward the brand through feelings of betrayal, using PROCESS computational macro for SPSS (Hayes, 2012), shows significance for the indirect path (effect size = -.0777, CI: -.1754, -.0223). Thus, greater negative attitude change occurs as feelings of betrayal increase.

Using both fictitious and real brands, Studies 1 and 2 demonstrate that highly attached consumers react more negatively when brands extend to incongruent categories. In Study 3, we use the high-attachment brands reported by participants and investigate the moderating role of self-enhancement need. Participants report their self-enhancement needs and are asked to identify brands to which they are attached. After this, they are presented with brand extensions that are either congruent or incongruent using scenarios similar to those in the previous studies, and evaluate the brand. An analysis using the PROCESS computational macro (Hayes, 2012; model 8) reveals that the conditional indirect effect of brand extension type on brand attitude change is significant and in the expected direction, with effect sizes increasing with higher self-enhancement need. In Study 4, we examine the effect of attachment level and brand extension type (both manipulated) on willingness to purchase (WTP) for a fictitious clothing brand. An ANOVA shows significant main effect of brand extension type on WTP. Simple contrasts suggest that brand extension type has significant negative effect on WTP only when attachment toward the brand is high. This result suggests that highly attached consumers are more likely to revisit their purchase decision compared to consumers less attached to the brand. Additionally, inferential tests for the effect of brand extension type on WTP for different levels of self-enhancement need within the high brand attachment condition reveal that self-enhancement need strengthens the negative effect of brand extension on WTP.

Study 5 further shows that the past effects are driven not by incongruency per se but by incongruency with the reason for brand attachment. The design included an incongruent brand extension that dilutes (or not) consumers' reason of attachment to the brand, and measured change in brand attitude. Results demonstrate that highly attached consumers react more negatively toward the brand when the brand extension dilutes (vs. not) the reason of attachment. Additionally, an analysis using the PROCESS computational macro (Hayes, 2012; model 8) reveals a significant indirect effect of incongruent extension on attitude change through perceived felt betrayal (for high attachment consumers), and effect sizes are increasing with higher self-enhancement need.

Our results demonstrate that having highly attached consumers is not always beneficiary for brands. If brands move away from their existing meaning, highly attached consumers may feel betrayed and react more negatively.

Self-Expansion as a Way of Overcoming the Harmful Effects of Luxury-CSR Incongruity

EXTENDED ABSTRACT

Recent research has shown that positioning a luxury brand on CSR can dilute its favorable brand image, particularly among self-enhancement oriented consumers—who are the luxury brand's primary target market (Torelli, Monga and Kaikati 2012). They view such prosocial images as incompatible to their own motivations, thereby reducing brand evaluations. This phenomenon is a major obstacle for luxury brands engaging in CSR, and prior research offers little guidance on how to overcome such negative effects.

In our paper, we propose that self-expansion, which is a cognitive activity intended to grow and expand perspectives and identities (Aron, Norman and Aron 1998), can reduce the harmful effects of using CSR appeals for a luxury brand. Prior research has shown that self-expansion reduces incompatibilities between the self and others (Aron et al. 1991). In the beginning of a relationship, couples face challenges due to differences between the self and the partner. Thus, people, who desire to reduce this gap, incorporate aspects of their partner into the self, and such self-expanding activities lead to better relationship satisfaction (Graham 2008). Therefore, we propose that self-expanding opportunities will reduce the gap between consumers pursuing self-enhancement and a luxury brand engaging in CSR, thus mitigating the harmful effects of CSR appeals.

In study 1, we introduce a way to expand the self—*self-referencing*, which creates new linkages with aspects of the self (Burnkrant and Unnava 1995). Participants read a CSR ad about a luxury brand, Cavalli. In the ad, consumers are told that the profits of Cavalli sunglasses will be used to provide glasses for people who cannot afford them (e.g., "You can bring the gift of sight to a young boy…"). In the self-expansion (no expansion) condition, the copy used (did not use) self-relevant words, such as "you" to create linkages of self-transcendence to aspects of the self (Burnkrant and Unnava 1995). The experimental procedure is the following. After receiving the self-enhancement motivation manipulation (Maio et al. 2009), participants read the CSR ad. Then, they were asked to write their thoughts about the ad and evaluated the Cavalli sunglasses. As expected, self-expansion through self-referencing mitigated the harmful effects of using the CSR appeal. Participants in the high self-enhancement motivation condition showed more favorable attitudes toward Cavalli sunglasses in the self-expansion (vs. no self-expansion) condition (M = 4.77 vs. M = 4.19). Participants in the low self-enhancement motivation condition did not show such a difference (M = 4.55 vs. M = 4.83). Further, the results from the mediation analysis showed that the positive effect of self-expansion on attitude toward Cavalli sunglasses was mediated by the number of positive thoughts participants generated about the CSR ad.

In study 2, we extend the findings of study 1 in three ways. First, we measured self-enhancement motivation (Schwartz 1992). Second, we used a fictitious brand "Bellavista" to rule out confounds associated with pre-existing brand attitude. Finally, we introduce another approach to expand the self—*observing celebrities*. Prior research shows that people incorporate aspects of others into the self, particularly when they feel psychologically close to them (Goldstein and Cialdini 2007). We used familiar celebrities well known to pursue self-enhancement and prosocial activities simultaneously, Brad Pitt and Angelina Jolie. Participants in the self-expansion condition read a story listing the socially responsible actions of these very successful actors. Participants in the no self-expansion condition read a neutral story. The experimental procedure was the following. After completing the self-enhancement motivation measure, participants read the story of Pitt and Jolie. Then, they read a CSR ad about Bellavista. We used the no self-referencing CSR ad in study 1, but changed the brand name. Participants were then asked to evaluate the Bellavista sunglasses, and reported how important self-transcendence values were at that moment. Consistent with study 1, participants with high self-enhancement motivation showed more favorable attitudes toward Bellavista sunglasses in the self-expansion (vs. no self-expansion) condition (M = 4.63 vs. M = 4.15). Participants with low self-enhancement motivation did not show such a difference (M = 4.54 vs. M = 4.75). Further, the results from the mediation analysis showed that the positive effect of self-

expansion on attitude toward Bellavista sunglasses was mediated by enhanced importance of self-transcendence.

In study 3, we measured pre-existing brand preference, and tested it as a moderating variable. We thus used a well-established luxury brand, Rolex. Moreover, we introduce the third approach to expand the self—*perspective taking*. People can incorporate aspects of a stranger into the self if they take the perspective of the person (Davis et al. 1996). Thus, participants were asked to read a short description about person A, who is a successful business consultant, and engages in volunteering to serve the poor of New York. Participants in the self-expansion condition were asked to write an essay about a typical day of that person while imagining as if they were that individual. Participants in the no self-expansion condition were asked to write objectively without reflecting on their own life. The experimental procedure was the same as in study 2, except that we measured pre-existing brand preference at the beginning. The results were consistent with studies 1 and 2, particularly among consumers with low pre-existing brand preference. Those with high self-enhancement motivation showed more favorable attitudes toward Rolex watches in the self-expansion (vs. no self-expansion) condition (M = 6.33 vs. M = 5.34). However, such a positive effect of self-expansion was not found among consumers with high pre-existing brand preference. They showed positive attitudes toward Rolex watches, regardless of the self-expansion condition (overall mean = 6.7) because high brand loyalty buffered the harmful effects of the CSR appeal. Finally, the results from the mediation analysis showed that the positive effect of self-expansion on attitude toward Rolex watches was mediated by enhanced importance of self-transcendence.

Our findings offer different approaches to attenuate the negative effects of using CSR appeals for luxury brands, particularly when targeting consumers who pursue self-enhancement goals (who are the core customers of luxury brands). Companies can successfully use CSR appeals for luxury brands by providing self-expansion opportunities (self-referencing, observing celebrities, or perspective-taking), which helps incorporate self-transcendence into the self.

Democratic Brands: A Framework and Empirical Test

EXTENDED ABSTRACT

What do Wikipedia, Linux, and Firefox have in common? These 'open-source' brands are almost entirely manufactured, consumed, and distributed by consumers. For instance, Wikipedia *is an online encyclopedia* written collectively by anonymous Internet volunteers who write without pay. Other more traditional brands are also dabbling in "democracy", allowing consumers to have greater power in product design, "hacking" their own products, and offering feedback to the brand through social networking sites. While some brands have been open to democracy, other brands, such as Microsoft and Apple, are notorious for being undemocratic, where they ruthlessly defend their brands and intellectual property against any consumer interaction. Despite the increasing importance of brands that either allow or disallow greater consumer participation, there is surprisingly little work on the topic. A recent exception is a paper by Fournier and Avery (2011), who articulate the notion of "open-source brands" and highlight the need for additional research on this topic. Related, recent work has explored the role of co-creation on consumers' perceptions of products (e.g., Herd and Moreau 2010; Liu and Gal 2011; Moreau 2011; Fuchs et al. 2013).

In this research we investigate various moderating and mediating factors that lead to preferences for either democratic (inviting input from consumers) or undemocratic (completely controlled) brands. More specifically, we consider whether efforts to level the playing field between consumers and brands impacts (1) overall preference for a brand, (2) perceptions of the brand's warmth and competence (Fiske et al. 2002), (3) whether warmth and competence mediates brand preferences, and (4) the moderating role of social dominance orientation (SDO) (Sidanius and Pratto, 1999), an individual's preference for hierarchy within a social system. Democratic brands, organized with less hierarchy (where consumers and companies are equals), should appeal more to those who are low in SDO, whereas undemocratic brands, organized with more hierarchy (where the company controls the product), should appeal more to those who are high in SDO.

Across a series of five studies we tested the mediating role of warmth and competence for democratic and undemocratic brands, and the moderating role of SDO. In a pilot study, we first consider whether a number of well-known technology brands vary on whether they are perceived as democratic or undemocratic. We found that out of nine brands tested, Wikipedia was found to be the most democratic brand, whereas Microsoft was found to be the least democratic brand. Furthermore, Wikipedia was found to be significantly warmer than Microsoft however, the two brands did not vary on their level of perceived competence. Finally, being democratic mediated perceptions of warmth. In study 1, we extend the effect found in the pilot study with two hypothetical brands. In a between subjects design participants either read about a democratic brand, or an undemocratic brand. In the democratic condition participants read "Imagine that company A is a technology company. The company delivers an extremely high-quality product. To ensure the greatest quality, the company [has an open platform where it welcomes changes and new developments to its software from its community.]" In the undemocratic condition, the text in brackets was replaced by: "maintains complete control over the product throughout the development process." Participants preferred the democratic brand to the undemocratic brand. Furthermore, participants found the democratic brand to be higher in warmth than the undemocratic brand however, the two brands did not vary in competence. Finally, being warm mediated purchase intention (see table in the Appendix for means and statistics).

In study 2, our aim was to consider the moderating role of SDO. In this study, we used Wikipedia and Microsoft, which were the most and the least democratic brands found in our pilot study. In a between subjects design, participants indicated how often they used either brand. In addition participants indicated their level of SDO, an individual difference measuring their preference for hierarchy within a social system. While participants indicated that they used Wikipedia and Microsoft equally, we found a significant interaction with SDO. As SDO went higher, so did the use of Microsoft, while use of Wikipedia went lower.

In study 3, our aim was to replicate the effects of study 2 using hypothetical brands to control for confounds. We also considered a new product category, cheese. Between subjects, participants either read about a brand described as being democratic or undemocratic using similar narratives from study 1. Participants indicated a significantly higher purchase intention for the democratic cheese brand than the undemocratic cheese brand. Furthermore, we again found a significant interaction with SDO whereas preference for the undemocratic brand increased as SDO was higher, and preference for the democratic brand decreased.

In study 4, we replicated the moderating effects of SDO found in studies 2 and 3. In addition, though competence did not vary across the democratic and undemocratic brands, we did find a significant interaction in which those high in SDO found the undemocratic brand to be more competent. In a moderated mediation analysis, we

found that competence ratings mediated purchase intention for those who were higher in SDO.

Finally, in study 5, rather than consider SDO as an individual difference, we varied whether hierarchy was more salient in the situation (buying cheese for one's boss) vs. less salient (buying cheese for oneself). We found a significant interaction in which participants were significantly more likely to choose the undemocratic brand when hierarchy was more salient than when it was not. However, we found no significant difference between conditions for the democratic brand.

Given increasing levels of interactivity between the consumer and the firm enabled by the internet, understanding how consumers relate to brands that are either democratic or undemocratic is increasingly important. We make four contributions to the literature: (1) we conceptualize and test the concept of democratic vs. undemocratic brands, (2) we show that preference for democratic brands is mediated through greater perceptions of warmth, (3) we show that for people who value hierarchies (high in SDO), or in situations where hierarchy is relevant, democratic brands are valued less, and (4) we show that for those high in SDO, competence mediates preference for the undemocratic brands.

SESSION OVERVIEW

Consumers are curious creatures, and marketers are keen to use curiosity to whet consumer appetites—a fact evidenced by movie teaser trailers, 'find-out-how' headlines, and mystery ads. Despite the prevalence of curiosity-evoking stimuli in daily life, little is known about either the causes or the consequences of curiosity (Loewenstein 1994; Menon and Soman 2002). This session takes steps to address both these concerns, demonstrating that, across a variety of contexts, curiosity has the power to impact consumer evaluations, preferences, and behavior.

The first two papers highlight the varied consequences of curiosity on consumer behavior. The first paper, by Wang and Zhu, examines the impact of elicited curiosity on subsequent unrelated consumer choice. They demonstrate that curiosity, once evoked, serves to motivate novel reward seeking in a later choice. The second paper, by Isikman, Ülkümen, MacInnis, and Cavanaugh, instead examines the effect of curiosity on concurrent consumer evaluations. They find that curiosity can be a fickle friend, with the power to act as a distractive force that can increase or reduce enjoyment of a simultaneous consumption experience. Taken together, these papers demonstrate that the impact of consumer curiosity is wide-ranging, affecting both simultaneous and sequential consumer behavior.

While the first two papers highlight the importance of examining consumer curiosity, the second two papers explore how marketers can effectively elicit curiosity in order to leverage these effects. These papers address the paucity of research examining the situational determinants of consumer curiosity (Menon and Soman 2002). Sevilla, Meyer, and Zhao demonstrate that visual concealment arouses curiosity, resulting in improved consumer preferences. In the final paper, Ince, Thompson, and Rabino show that, holding the amount of information provided to consumers constant, curiosity can be elicited by a feature inherent to the business context itself: a speaker's accent. They find that ambiguous accents increase consumers' interest in trying new products and services.

Interestingly, these two final papers both explore the moderating role of dispositional curiosity. These investigations yielded contrasting results; the effect of visual concealment was highest for those who are naturally curious (measured by the need for cognitive closure scale), while accent-elicited curiosity was lowest for the naturally curious (measured by the curiosity exploration inventory scale). These contradicting findings support the contention that curiosity is a multidimensional construct, comprised of both a motivated drive to close informational gaps as well as interest in exploring novel and surprising stimuli (Litman 2005). We believe that this is a rich topic for discussion and fertile ground for future research.

Overall, the four papers in this session shed light on the drivers and consequences of curiosity, while revealing promising avenues for future research. We expect that this research will be of interest to researchers in areas as diverse as motivation, information processing, aesthetics, and linguistics, elucidating a construct largely overlooked in the consumer behavior literature and at ACR conferences in particular.

What Satisfies A Curious Mind? Curiosity Prompts Novel Reward Seeking

EXTENDED ABSTRACT

Curiosity is defined as "a form of cognitively induced deprivation that arises from the perception of a gap in knowledge or understanding" (Loewenstein 1994). Despite its ubiquity, curiosity has received surprisingly little attention in consumer behavior research (Menon and Soman 2002). Limited research on state curiosity mostly studies its impact on people's search for domain-specific information that closes the knowledge gap (van Dijk and Zeelenberg 2007). However, as curiosity is also an appetitive state that possesses driving forces (Blumenberg 1983; Loewenstein 1994), it is possible that curiosity could motivate reward-seeking behaviors other than information seeking.

Existing behavioral and neuroscience research on reward-seeking behaviors found that intangible cognitive and social rewards and tangible physical rewards are processed similarly in the brain. Further, this shared brain network leads to a spillover reward-seeking effect (Berridge and Kringelbach 2008; Lieberman and Eisenberger 2009). That is, deprivation in one domain motivates individuals to seek rewards in unrelated domains (Berger and Shiv 2011; Briers et al. 2006). Although these findings are intriguing, previous studies have focused on deprivation and satiation in the lower physical domain. We know little about the spillover effect in the higher cognitive or social domains.

This research investigates the impact of curiosity, a cognitive deprivation, on consumers' subsequent reward-seeking behaviors. We find that curiosity motivates people to seek rewards, particularly novel rewards, in other unrelated domains, such as physical domains (e.g., food) and social domains (e.g., social friendship, charitable donation). This effect occurs as a result of a general appetitive drive and an open mindset, both activated by curiosity. We further identify a boundary condition; when people are curious about threatening information, the spillover reward-seeking tendency is mitigated.

Study 1 tested that curiosity prompts novel reward seeking in an unrelated domain. We used a one-factor design (curious vs. incurious vs. control) and food rewards. Passengers waiting at a subway station were asked to guess what an unbranded advertisement was about. To manipulate curiosity, explanations of the advertisement were either provided (incurious condition) or not provided (curious condition). Those in the control condition were not given this task. Next, all participants were asked to choose between a familiar snack and a novel snack, which was the dependent measure. As predicted, curious participants were more likely to choose the novel food over the familiar food, compared to either incurious participants or participants in the control condition. No difference occurred between the latter two conditions.

Study 2 demonstrated that curiosity elicits an open mindset, which subsequently leads to a novel choice. We used a 2 curiosity (curious vs. incurious) x 3 word type (open-minded vs. neutral vs. non-word) mixed design. Participants first watched a two-part video. To manipulate curiosity, those in the curious condition watched only the first part without knowing the story ending, whereas those in the incurious condition watched both parts. Next, we measured participants' semantic activation of open-mindedness through reaction times in a lexical decision task. Participants were asked to identify letter strings, including open-mind related words, neutral words, and non-words, as a word or a non-word. They then chose between a novel snack and a familiar snack, which was the dependent measure. As expected, curious participants were more likely to choose the novel food over the familiar food, compared to incurious participants. Further, we found a significant two-way interaction such that curious participants responded to the open-minded words faster than incurious participants, whereas no such difference occurred for the neutral words or the non-words. More importantly, the semantic activation of open-mindedness mediated the effect of curiosity on the food choice.

Study 3 aimed to demonstrate the general appetitive mechanism. If curiosity indeed possesses a general appetitive drive, when this appetitive drive is satiated by a reward beforehand, the subsequent spillover reward-seeking tendency should diminish. This study also extended the reward to the social domain (i.e., friendship). We used a 3 satiation (none vs. information vs. food) x 2 reward (familiar vs. novel) between-subjects design. Satiation was manipulated using the same two-part video, except that those in the food satiation condition watched only the first part and were then given a chocolate bar (Berger and Shiv 2011). Next, we measured participants' interest in seeking friendship either at their own university (familiar condition) or at another local university (novel condition). As expected, we found a significant two-way interaction such that those with no-satiation (i.e., curious participants) were more interested in seeking novel than familiar friendship, whereas those with information satiation (i.e., incurious participants) and those with food satiation showed equal interest in novel and familiar friendship.

Study 4 identified a boundary condition for the effect. When people are curious about potentially threatening information, they might refrain from approaching behavior and engage in an avoidance orientation (Sweeny et al. 2010), which subsequently leads to a reduced reward-seeking tendency. This study also adopted another social reward, namely, charitable donation. We used a 3 information (threatening vs. non-threatening vs. control) x 2 charity (familiar vs. novel) mixed design. Participants were asked to complete a health survey, which was framed either as estimating heart disease risk (threatening condition) or as providing a personalized plan to reduce heart disease risk (non-threatening condition). To induce curiosity, participants were told that the survey results could not be provided right away. Participants in the control condition were not given this task. Next, all participants were asked to indicate their willingness to donate to a familiar charity and a novel charity. As anticipated, we found a main effect such that those curious about non-threatening (threatening) information were more (less) likely to donate than those in the control condition. Further, we found a significant two-way interaction such that those in the non-threatening condition were more likely to donate to the novel than the familiar charity, whereas those in the threatening or control condition showed comparable willingness to donate to both charities.

This research contributes to both the curiosity and the reward-seeking literature by investigating *whether*, *how*, and *why* curiosity, a cognitive deprivation, motivates spillover reward seeking in the social or physical domains.

Does Curiosity Kill the Cat? Incidental Curiosity Can Have Negative Consequences

EXTENDED ABSTRACT

Marketers aim to maximize enjoyment of a consumption experience since enjoyment predicts favorable outcomes like repeat purchase and positive word of mouth (e.g., Rust and Oliver 2000). Yet, consumers are often exposed to things that arouse their curiosity during consumption experiences, such as a ringing cell phone, an email notification, or a pop-up on a website. Despite the prevalence of such curiosity-evoking events, we know little about how they might impact enjoyment of a coincident consumption experience.

Prior consumer research on curiosity has focused on curiosity evoked by events that are integral to a focal experience. We examine how curiosity-evoking events that are unrelated to, yet coincident with, a focal consumption experience impact consumption enjoyment. We define curiosity as a state of interest caused by knowledge deprivation (Loewenstein 1994) and desire to resolve uncertainty.

There are multiple potential routes through which curiosity aroused by an incidental task might influence enjoyment. First, the state of interest evoked by curiosity may be inherently pleasurable, and may carry over to the consumption experience and increase its enjoyment. Alternatively, the knowledge deprivation and uncertainty involved in curiosity may be experienced as unpleasant, which could carry over to the experience and reduce its enjoyment.

However, we predict that curiosity impacts enjoyment because it motivates an impulsive search for resolution, directing attention towards the curiosity-evoking event, and sustaining it until the curiosity is resolved. When the source of curiosity is incidental (versus integral) to the consumption experience, this search for resolution becomes distracting, directing attention away from the experience and inhibiting consumers from absorbing the experiential aspects of consumption. Accordingly, we expect curiosity evoked by coincident events to *decrease* enjoyment of positive consumption experiences, but to *increase* enjoyment of negative consumption experiences.

Three experiments provide evidence consistent with these predictions, employing different manipulations of curiosity and using self-reported, indirectly assessed and behavioral measures of attention. We demonstrate that the effect of curiosity is robust across stimulating, relaxing, and cognitively engaging experiences.

In study 1, forty-six participants were recruited ostensibly to product-test a video game. They were randomly assigned to one of the two conditions (high or low curiosity). In the high curiosity condition, the experimenter covertly called the participants on their cell phones during the game. The call evoked curiosity because they were unable to check their phones as they had been instructed to leave their phones on a table which was located close by, but out of reach. In

the low curiosity condition, the experimenter remotely activated an iPod, which played a short excerpt from a song. The location of the devices, duration and the timing of the sounds were matched across conditions. We unobtrusively video-recorded the participants, and coded for the number of times they looked towards their phones or the iPod as a behavioral measure of attention diversion. Participants reported enjoying the video game less in the high curiosity compared to the low curiosity condition (M_{high} = 6.81 vs. M_{low} = 7.62, F (1, 44) = 4.19, $p < .05$). Importantly, a meditation analysis showed that curiosity caused by the incidental event reduced enjoyment because it diverted attention away from the positive consumption experience.

If curiosity reduces consumption enjoyment because it draws attention away from the focal experience, then we would expect this effect to manifest when curiosity is sustained for an extended amount of time, but to disappear when it is resolved promptly. We test this prediction in Study 2. 78 university students were randomly assigned to one of two between-subjects conditions: curiosity-sustained vs. curiosity-resolved. The consumption experience was reading a commencement speech. Midway through the reading, participants were instructed to pull out a gift box from a bag adjacent to their computer. They were told to keep the gift box in front of them but to not open it until the end of the study. In the curiosity-sustained condition, the gift box was opaque, which did not allow the participants to see its contents. In the curiosity resolved condition, the gift box was transparent, which allowed the participants to see that it contained a pen. After the reading task, participants indicated their reading enjoyment, and responded to questions about rumination and attentional conflict. Results showed that sustained (versus resolved) curiosity reduced consumption enjoyment ($M_{sustained}$ = 7.34 vs. $M_{resolved}$ = 7.97, F (1, 76) = 4.09, $p < .05$). Moreover, the negative effect of sustained curiosity on enjoyment was mediated by rumination and attentional conflict.

Study 3 aims to test the impact of curiosity-evoking events on enjoyment of negative experiences. 105 participants took part in this study with a 2 valence (positive vs. negative) X 2 curiosity (sustained vs. resolved) between-subjects design. The consumption experience involved watching a YouTube video of a song. In the positive valence condition, we used the professionally recorded video clip of the song. In the negative valence condition, we used a nonprofessional recording of a live performance of the same song, performed by the same artist, which had bad sound and picture quality. The same gift manipulation in Study 2 was used to manipulate curiosity. After viewing the clip, participants indicated their enjoyment of it. Results showed that compared to resolved curiosity, sustained curiosity reduces enjoyment of a positive experience ($M_{sustained}$ = 5.46 vs. $M_{resolved}$ = 6.82, F (1, 53) = 6.37, $p < .05$), but increases enjoyment of a negative experience ($M_{sustained}$ = 5.81 vs. $M_{resolved}$ = 4.51, F (1, 48) = 5.00, $p < .05$).

Unlike past research, we focus on how curiosity from a coincident event influences enjoyment of a main consumption experience. We show that curiosity evoked by an incidental event can either increase or decrease enjoyment, depending on the valence of the consumption experience. This research adds to our theoretical understanding of attention's role behind curiosity. Our findings contribute to the literature by revealing a more complete picture of the link between curiosity-evoking events and consumption enjoyment. Practically, our findings suggest that it is possible to strategically promote or prevent curiosity during consumption to enhance consumers' enjoyment.

Leaving Something for the Imagination: The Effect of Visual Concealment on Product Preference

EXTENDED ABSTRACT

Marketers resort to different tactics in order to attract consumer interest. One of the most popular is the "peak-a-boo" ploy, which consists of deliberately withholding from view some of the key aspects or attributes of a product. The idea underneath this practice is that consumer curiosity would be sparked when faced with an undetermined novel stimulus, something which would increase interest and search of information about the product (Menon and Soman 2002). Consistent with past literature in marketing, this search and acquisition of new information will have positive results, as consumers suffer from a phenomenon called "uncertainty aversion", which consists on heavily discounting products for which only limited information is available. This effect causes known, average options to be preferred over those with missing attribute values (e.g., Meyer 1981; Huber and McCann 1982; Johnson and Levin 1985; Jaccard and Wood 1988; Simmons and Lynch 1991; Sanbonmatsu et al., 1992).

In this research, we demonstrate that, in the case of aesthetic stimuli, the mere unavailability or concealment of key aspects or fragments may lead to higher preference. This effect will hold in cases where the attractiveness of the revealed and the concealed fragments is kept constant and where the search for new information is unavailable. We propose that this occurs because visual concealment can trigger two interrelated psychological forces that drive the effectiveness of a product fragment: a curiosity effect (see Loewenstein 1994) that draws consumers towards objects that are incompletely portrayed, and an inference effect that conditions the level of curiosity on projections about the likely value of the completed whole based on observed fragments. This indicates that consumer assessments of partially-concealed product images often—but not always--act as an inverted-U shaped function of the percentage of the object that has been revealed. Moreover, we demonstrate that the relationship between the size of a product fragment and consumer preference for the whole product is moderated by the valence of the whole stimulus, such that the inverted-U shaped relationship exists only when the whole product is positively as opposed to negatively evaluated.

We found support for our hypotheses across four laboratory experiments using different product stimuli and procedures. Experiment 1 tested the hypothesized inverted U-shape relationship between the degree of visual concealment and preference for a whole by using aesthetically driven marketing stimuli such as futuristic car images. This study showed that participants had a higher preference towards a moderate size visual revelation as opposed to a large one, which demonstrates that "more is not always better". Experiment 2 demonstrated the generalizability of the results by replicating the findings using computer generated ideally attractive male and female human faces. Given that the first study employed a within-subjects design, Experiment 2 used a between-subjects setup to rule out alternative explanations for the results of the previous experiment such as boredom, satiation and demand effects. Moreover, this study further demonstrated the effect of curiosity in preference and choice by using varied dependent measures and ruled out an alternative explanation associated with differential attractiveness between the revealed and the concealed fragments, as, in this case, each piece was representative of a prototypical, attractive human face. This demonstrates that the level of concealment participants were exposed to in this study only affected the quantity of the visual information provided and not its attractiveness. Furthermore, this study provided media-

tion evidence in favor of evoked curiosity as the determinant of the observed enhanced preference. Experiment 3 employed attractive and unattractive human faces in a between-subject setting to demonstrate that the hypothesized inverted U-shape relationship between fragment size and preference will not exist in the case of unattractive stimuli. Finally, Experiment 4 duplicated the design employed in Experiment 1 to demonstrate that the effect is moderated by Need for Cognitive Closure (NFCC). Specifically, this study showed that participants who scored lower in this construct, and who tend to be less curious, were less sensitive to the effect, due to their lower tendency to experience curiosity.

A paradoxical consequence of our findings is that the products or visual images that benefit the most from concealment are those that have the least to hide; the more attractive the completed whole, the more it may pay to leave something for the consumer's imagination. Moreover, lab results suggest the existence of an unexpected empirical regularity in the "ideal" level of revelation of an image: across a variety of stimulus domains, we find that curiosity in seeing more of objects is maximized when about one half to two-thirds of the object has been revealed—a percent large enough for the bulk of the object to be identified, yet small enough for uncertainty to still exist about the appearance of the completed image. This research informs marketers about the sensitive role that fragment size may play in consumer preference for aesthetic products in cases where these are partially revealed as part of a marketing campaign.

Guess Where I'm From: Ambiguous Accents, Curiosity and Product Evaluations

EXTENDED ABSTRACT

Though curiosity has been identified as an intense but transient motivational force, limited research has addressed the power of curiosity to engage consumers (Loewenstein 1994). In marketing contexts, previous research has demonstrated that curiosity results in stronger brand associations, greater learning of product information, and better product evaluations (Menon and Soman 2002). Despite these compelling examples, curiosity research is sparse. Little is known about the situational drivers of curiosity (Loewenstein 1994). We examine a potential new driver of curiosity: accented speech. Increasingly ubiquitous with the rise of globalization (Gluszek and Dovidio 2010), ambiguous accented speech (i.e., of indeterminate origin) may trigger consumers' curiosity about the speaker, influencing product and service evaluations.

A large body of research has examined the impact of specific foreign or regional accents (Mai and Hoffman 2014). However, ambiguous accents, or accents providing insufficient cues of geographical background and defying adequate categorization (Budner 1962), remain unexplored. Upon hearing accents, consumers spontaneously seek to classify the speakers into ethnic, national, or religious groups (Mai and Hoffman 2014). However, despite this attempt at categorization, consumers are often unable to identify foreign accents (Lindemann 2003). We argue that ambiguous accents trigger curiosity, which extends to associated products and services, thereby increasing their perceived valuation.

In three studies, we examine the impact of ambiguous accents (direct and incidental) on consumer curiosity and product evaluations. We find that ambiguous accents significantly increase consumers' interest in a target activity, agent, and product. Because curiosity is both situationally and dispositionally driven (Loewenstein 1994), we explore how individual differences such as ambiguity intolerance, ethnocentrism, and trait curiosity moderate the curiosity effects generated by ambiguous accents.

In study 1, we test the effect of an ambiguous accent on likelihood to attend a target event - a volcano exhibit - and examine the mediating role of curiosity. We also seek to rule out a disfluency account, which would predict that ambiguous accents are more unfamiliar and difficult to understand, increasing perceptions of the speaker's uniqueness and competence (Pocheptsova, Labroo, and Dhar 2010; Thompson and Ince 2013). Participants (N=111) were randomly assigned to either an accent or no accent condition. The speaker was either an American woman or a Brazilian woman; a pretest confirmed that the Brazilian accent was ambiguous (65% of the participants could not identify the accent; when asked where the speaker was from, the mean variance was three times higher in the accent vs. no accent condition). Participants were told that they would listen to a one-minute audio clip describing a new volcano exhibit and that the speaker was the exhibit's curator. Participants then reported their likelihood to attend the exhibit and their perceptions of both the speaker and the exhibit. As predicted, there was a significant main effect of accent on attendance likelihood. Those in the accent condition were more likely to attend the exhibit, and were more curious about both the speaker and the exhibit. Importantly, a sequential mediation analysis revealed that accent curiosity significantly mediated the effect of accent on exhibit curiosity, which in turn influenced the likelihood to attend the event. Accent familiarity as well as perceptions of speaker uniqueness and knowledge did not mediate the effect of accent on exhibit interest.

In study 2, we examine the effect of ambiguous accents on consumers' evaluations of a service provider. We also replicate our results with different accents and male voices and explore ambiguity intolerance as a moderator. We predict that the curiosity effect derived from an ambiguous accent will be mitigated for individuals who are highly intolerant of ambiguity. Participants (N = 113) completed a one manipulated between-subjects factor (accent vs no accent). Participants were instructed that they had been tasked with finding someone to fix a broken lamp (a family heirloom) and that they would listen to an informational audio clip about lamp restoration services from a professional lamp restorer's website. After listening to the audio clip, participants reported their willingness to pay for the service, then completed curiosity measures and a tolerance of ambiguity scale (Budner 1962). As predicted, there was a significant accent by ambiguity intolerance interaction, such that accented speech increased consumer willingness to pay, but only for those tolerant of ambiguity. A moderated mediation was also significant.

In study 3, we test the effect of ambiguous accent on willingness to try a novel product in an unrelated product choice. Recent research suggests that incidental exposure to curiosity increases likelihood of choosing a novel over a familiar reward (Wang and Zhu 2014). We replicate our results with another female accent and explore two additional boundary conditions: ethnocentrism and trait curiosity. Participants (N = 89) completed a 2 (accent vs. no accent) x 2 (novel flavor replicates: blueberry balsamic vs. ginger lavender) between subjects design. Participants were told to imagine they were at a party listening to other partygoers speak. They listened to a 30 second audio clip of a conversation in which a woman recommends a website site, Angie's List, to a friend and were asked questions about the conversation. In an ostensibly separate study, participants were told that a creamery was conducting taste tests for two flavors: vanilla and the novel flavor. Participants indicated their preference for one of the two flavors, how much they liked the novel, how likely they were to try it and how much they would enjoy it. They completed curiosity measures followed by the ethnocentrism (Shimp and Sharma 1987) and trait curiosity scales (Kashdan et al. 2009). After collapsing over the flavor replicates, we found that the effect of cu-

riosity elicited by ambiguous accents is attenuated for both individuals who view their in-group (e.g. American) as superior as well as for naturally curious consumers who are chronically predisposed to select novel products. A moderated mediation of curiosity on interest in the novel flavor was also significant.

Taken together, these results provide evidence for a new driver of consumer curiosity which can be effectively used to increase consumers' interest in seeking new products and services.

Paper #4: Louis Vuitton and Your Waistline: Using Luxury Goods Depletes Self-Regulatory Resources and Impairs Self-Control

Yajin Wang, University of Minnesota, USA
Deborah R. John, University of Minnesota, USA

SESSION OVERVIEW

Luxury consumption is an increasingly important aspect of consumer behavior, with luxury goods showing the strongest growth among 100 categories of consumer spending (Sparshott 2014). Prior research on the topic has been primarily focused on understanding consumer motivations for purchasing luxury goods, both authentic and counterfeit. This session presents a set of papers that explore the influence of the social context on the desire and consumption of genuine and counterfeit luxury goods. We explore two questions: 1) How can others influence the usage of luxury and counterfeit luxury goods? 2) How does the actual consumption experience of using a luxury or counterfeit luxury good affect a consumer's psychological state and subsequent behavior?

The first two papers examine the purchase of counterfeit luxury products. The paper by *Wang, Stoner, and John* examines the use of counterfeit luxury goods. These authors propose that interest in counterfeit luxury products is perpetuated by the process of moral disengagement, where unethical behavior such as purchasing illegal counterfeit products is rationalized. They examine the role that social feedback plays in moral disengagement and find that when counterfeit users receive a compliment from other people, they are more likely to morally disengage and desire additional counterfeits in the future. However, the opposite occurs when others question the source of the counterfeit goods. The second paper by *Hu and Lee* shows that perceptions of relative status can impact counterfeit purchases. They propose that perceptions of low or high status in relation to others interact with implicit self-esteem to lead to the desire to purchase counterfeit luxury products. They find that counterfeit luxury consumption can be driven by a discrepancy between perceived social status and implicit self-esteem.

The final two papers examine the conspicuous consumption of luxury goods. *Lee, Shrum and Yi* show that social exclusion effects

on conspicuous consumption versus pro-social (non-conspicuous) behavior are culture-dependent. They propose and find that responses to explicit and implicit exclusion differ cross-culturally because of cultural differences in communication norms. Exclusion that is communicated in a norm-congruent manner produces pro-social behavior, whereas exclusion that is communicated in a norm-incongruent manner produces conspicuous consumption. The final paper by *Wang and John* also looks at consumption of authentic luxury products. They propose and find that using luxury products in public makes consumers feel self-conscious and needing to monitor their behavior carefully in front of others. This mindfulness depletes one's self-regulatory resources and impairs self-control on subsequent tasks. Thus, the papers in this session focus attention on the influence of social factors and context on luxury consumption. This focus is unlikely to emerge in any other format than a special session, since individual luxury consumption papers appear sporadically on the conference program in sessions not devoted to the topic. Given the variety of settings and questions, this session is likely to appeal to a broad set of conference attendees interested in luxury and conspicuous consumption, branding, culture, individual differences, and ethics.

You're Not Fooling Anyone: How Social Feedback Affects Moral Disengagement and the Purchase of Counterfeit Luxury Products

EXTENDED ABSTRACT

Counterfeit products have become a major problem for luxury brands, with counterfeits accounting for nearly 10% of worldwide trade (Townsend 2013). Prior research has examined consumer motivations for purchasing counterfeits, such as the desire for status and self-enhancement. However, only one study has examined actual use of counterfeit products and the effects of using these products on beliefs and behaviors (Gino, Norton, and Ariely 2010). In this paper, we study the actual use of counterfeit luxury products, and examine how the social feedback that counterfeit users receive affect their moral beliefs about purchasing and owning counterfeits, as well as their future interest in luxury counterfeit products. We propose that certain types of social feedback encourage counterfeit users to rationalize their behavior (a process called moral disengagement), while other types of social feedback have the opposite effect. Further, we use these insights to develop communication strategies that are effective in reducing the desire for luxury counterfeit products. In four studies, we find that social feedback alters the degree of moral disengagement that takes place when consumers wear counterfeit luxury products. Receiving compliments from others increases moral disengagement, which leads to greater interest in purchasing luxury counterfeit items in the future. In contrast, questions about the source of the luxury counterfeit has the opposite effect. We use these findings in a final study, where we show that demand for counterfeit luxury products can be decreased by anti-counterfeiting ads that focus on a social sanction—other people can easily identify counterfeits.

Study 1. In this study, we examine how social feedback while wearing a counterfeit luxury product influences the likelihood that the counterfeit user will rationalize their behavior (moral disengagement). Female participants were given a Tiffany bracelet to wear

while filling out a survey of general questions unconnected with the study. They were told the bracelet was counterfeit, even though it was a real Tiffany bracelet. After filling out the survey, participants were asked to imagine themselves wearing the counterfeit Tiffany's bracelet to a shopping mall, where they are approached by a salesperson who comments on the bracelet. For one group of participants, the salesperson is complimentary ("I really like your Tiffany bracelet. It looks so cute on you!"); for the other group of participants, the salesperson is complimentary, but questions the source of the bracelet ("I really like your Tiffany bracelet. Is it real?"). Participants then completed a 3-item measure of moral disengagement (e.g. "It is okay to buy a counterfeit product especially when the authentic product is high priced.") Results showed women in the compliment condition had a higher level of moral disengagement than those in the question condition (Ms = 4.84 vs. 3.37; $F(1, 37)$ = 13.26, p <.001).

Study 2. The procedure was similar to that in study 1, except that participants imagined the social interaction occurred with another shopper. After receiving the compliment or question, participants recorded the thoughts they had about the interaction with the shopper before completing the measure of moral disengagement. Replicating the results of study 1, those in the compliment condition had a significantly higher level of moral disengagement (M = 4.58) than in the question condition (M = 3.71, $F(1, 38)$ = 4.09, p < .05). Thoughts about the interaction with the other shopper were coded for intensity of negative external thoughts, negative internal thoughts, and external positive thoughts. Only the intensity of negative externally directed thoughts (e.g., "I don't want to get caught lying.") were found to mediate the relationship between social feedback and moral disengagement.

Study 3. In this study, we incorporate actual social feedback into our experimental procedure. Participants were randomly assigned to one of three conditions: compliment, question, or no feedback (control). Each participant was brought to a private interviewing room and was asked to wear a Burberry scarf (which was labeled as a counterfeit) and complete filler tasks. After 15 minutes, a female confederate entered the room pretending to look for a lost cell phone. She made a quick comment about the Burberry scarf in the compliment and question conditions consistent with Study 1, or made no comment at all (control). After this brief interruption, participants completed a survey that included the moral disengagement measure. Finally, participants were taken to another private room which had different "counterfeit" luxury products displayed. Participants evaluated them and indicated their interest in purchasing these products in the future (1-9 scale). Results showed that participants who received a compliment when wearing a fake luxury scarf were more likely to engage in subsequent dishonest behavior involving counterfeits. Compared to participants in the question condition, participants receiving a compliment were more interested in purchasing counterfeit products in the future (M = 7.19 vs. 4.10, p < .001). Counterfeit purchase intention was also higher for participants receiving a compliment versus those in the control condition (M = 7.19 vs. 5.89, p < .05). The effect of social feedback on purchase intention was mediated by moral disengagement.

Study 4. Using insights obtained by our prior studies, we examined the effectiveness of different ads aimed at reducing desire for luxury counterfeit products. Novice users (participants who had previously purchased 1 to 5 counterfeit products) viewed either (1) an anti-counterfeiting advertisement highlighting self-sanction "When it's fake, you know it's fake," (2) an anti-counterfeiting ad highlighting social sanction "When it's fake, we ALL know it's fake" or (3) a control advertisement for candy. After answering some basic questions about the ad, participants answered questions about inten-

tions to purchase counterfeits in the future. Results revealed that participants in the social sanction condition had a significantly lower counterfeit product purchase intention than did participants in the self-sanction condition (Ms = 3.92 vs. 4.98, $t(2,42)$ = -1.86, p < .05) or participants in the control condition (Ms = 3.92 vs. 5.02, $t(2,42)$ = 1.94, p < .05). Additionally, there was no difference in purchase intention between the self-sanction condition and the control condition ($t(2,42)$ = -.08, p > .46).

Discrepancy Between Social Status and Implicit Self-Esteem Prompts Preference for Counterfeit Luxury

EXTENDED ABSTRACT

Consumers purchase counterfeit products to convey positive signals to themselves and to others (Gino, Norton, and Ariely 2010; Wilcox, Kim, and Sen 2009). Particularly in the luxury goods market, consumers knowingly purchase counterfeit products as a social signaling mechanism with low financial costs (Nia and Zaichkowsky 2000; Penz and Stottinger 2005). In this project, we explore psychological factors that underlie consumers' preference for counterfeit luxury goods.

Past studies has identified perceived social status as a predictor of counterfeit consumption. In particular, correlational evidence suggests that people who prefer counterfeit luxury are self-identified as lower in social status compared with people who prefer authentic luxury (Bloch, Bush, and Campbell 1993). Poor consumers in developing countries are also more likely to use counterfeits as a status-signaling device (Van Kempen 2003). In the current research, we examined the effect of implicit self-esteem as a potential moderator of the effect of perceived social status on counterfeit consumption.

Implicit self-esteem is thought to play an important role in predicting status-signaling behaviors as it has been shown to affect materialism, conspicuous consumption, and compulsive buying (Hanley and Wilhelm 1992; Park and John 2011; Sivanathan and Pettit 2010). In the current project, we offer a novel proposition that perceived social status and implicit self-esteem jointly influence the preference of counterfeit luxury goods. Specifically, we hypothesize that counterfeit luxury consumption can be driven by a discrepancy between perceived social status and implicit self-esteem. Recent research lends suggestive evidence for this hypothesis. In particular, Park and John (2011) has shown that a discrepancy between implicit and explicit self-esteem leads to high levels of materialism through a desire to self-enhance. Also, people with low self-esteem were found to prefer status-signaling brands when they were socially included (which creates a discrepancy between self-esteem and social acceptance) but not when socially excluded (Dommer, Swaminathan, and Ahluwalia 2013).

We hypothesize that a discrepancy between social status and self-esteem leads to heightened psychological discomfort and a need for self-enhancement to alleviate that psychological discomfort. Compared with consuming authentic luxuries, counterfeit luxury consumption can be viewed as an effective self-enhancement strategy via status signaling, but without the burden of high financial costs. Thus, we predict that people experiencing a discrepancy between social status and implicit self-esteem will have more favorable attitudes towards counterfeit luxury products. Two studies tested this core hypothesis.

Experiment 1: Louis Vuitton Study. The design of the study is a 2 (perceived social status: high vs. low)× 2 (implicit self-esteem: high vs. low) between-subject design. Eighty-five undergraduate students were recruited to participate in this lab experiment. Only

female participants were recruited due to anticipated gender differences on familiarity with Louis Vuitton handbags.

Participants' level of implicit self-esteem was measured through a 9-point single-item asking "How much do you like your name in total?". The measure was adopted from Gebauer et al. (2008) and higher preference for one's own name has been validated as a proxy for higher implicit self-esteem. Participants' level of perceived social status was manipulated via a manipulation adopted from Piff et al. (2010). In the high social-status condition, participants were asked to compare themselves to people from the bottom of the social ladder. In contrast, in the low-social status condition, participants compared themselves to people from the top of the social ladder. Participants were then asked to imagine themselves in a shopping scenario in which they tried out a Louis Vuitton handbag but learned about an opportunity to purchase a counterfeit bag that looked and felt identical to the authentic one. Participants answered questions on their attitude and preference for the counterfeit Louis Vuitton handbag.

Results showed a significant two-way interaction on attitude towards the counterfeit LV bag ($b = -.29$, $t(85) = 2.71$, $p = .008$). Spotlight analysis revealed that among participants with low implicit self-esteem (-2SD), those who were high in perceived social-status had more favorable attitudes toward the counterfeit LV bag compared with participants who were low in perceived social status ($b = -.64$, $t(85) = 2.67$, $p = .009$). In contrast, among participants with high implicit self-esteem (+2SD), it was those low in perceived social status who had more favorable attitudes toward the counterfeit bag compared with participants high in perceived social status ($b = .52$, $t(85) = 2.18$, $p = .03$). Similar patterns were also observed for an additional DV asking participants how often they would use the counterfeit bag had they bought it ($b = -.27$, $t(85) = 2.48$, $p = .02$). The results of the current study support our core hypothesis that a discrepancy in people's implicit self-esteem and perceived social status leads to a preference for counterfeit luxury goods.

Experiment 2: Rolex Study. Ninety-nine participants recruited via MTurk participated in this online study. Similar to experiment 1, the design of the current study is a 2 (perceived social status: high vs. low)× 2 (implicit self-esteem: high vs. low) between-subject design. Rolex watches were used as the central stimulus brand, and only male participants were recruited. The procedures of the current study were similar to experiment 1.

Results show a significant two-way interaction on attitude towards a counterfeit Rolex watch similar to the pattern shown in experiment 1 ($b = -.29$, $t(99) = 2.90$, $p = .005$). Among participants with low implicit self-esteem (-2SD), high social status led to more favorable attitude towards a counterfeit Rolex watch ($b = .49$, $t(99) = 2.25$, $p = .03$). The contrast reversed for those with high implicit self-esteem (+2SD) ($b = 1.75$, $t(99) = 2.76$, $p = .007$).

Conclusion and Contributions. The current findings shed light on the psychological factors that dictate the consumption of counterfeit products and have important implications for managing luxury brands and products in the marketplace.

Cultural Influence on Conspicuous Consumption and Pro-Social Behavior in Response to Social Exclusion and the Role of Communication Norms

EXTENDED ABSTRACT

Recent research suggests that differences in how social exclusion is communicated have large effects on responses because implicit and explicit social exclusion threaten different needs (Lee and Shrum 2012). Implicit exclusion (e.g., being ignored) threatens efficacy needs (e.g., power), which results in attention-getting responses such as conspicuous consumption, whereas explicit exclusion (e.g., being rejected) threatens relational needs (e.g., self-esteem), which results in pro-social responses such as helping (non-conspicuous behavior).

Although the previous research provides insights into the mechanisms underlying exclusion effects, at least two questions remain unanswered: 1) whether responses to social exclusion are universal or culture-specific, and 2) why implicit and explicit communication of social exclusion threatens different needs. In the present research, we address both questions. Specifically, we propose that responses to explicit and implicit types of exclusion differ cross-culturally, and that these differences are related to the ways in which social exclusion is communicated. To support these propositions, we build on Hall's (1976) conceptualization of high- versus low-context communication cultures. In low-context cultures (e.g., the U.S., some European countries), the normative way of communication occurs through explicit statements, and is relatively context-free. In high-context cultures (e.g., Korea, Japan, China), the normative way of communication occurs through implicit, nonverbal cues such as facial expressions and silence, and people often draw true meaning from the social context.

In three experiments, we test the general proposition that reactions to social exclusion depend on whether social exclusion is communicated in a norm-congruent or norm-incongruent manner. We contrast Korean and American cultures, which differ in their communication norms, and show that Koreans and Americans react to explicit and implicit types of social exclusion in essentially opposite ways. Further, we document three interrelated processes that underlie these effects: 1) implicit and explicit types of social exclusion threaten different needs for Koreans and Americans, 2) threats to different needs produce different compensatory responses, and 3) the culturally opposing responses to the two types of social exclusion arise from cultural differences in communication norms. This general set of relations is presented in Figure 1.

In all experiments, participants wrote about experiences of either being ignored or rejected (Molden et al. 2009) and indicated their preferences for conspicuous logos and for willingness to help (operationalizations were varied). Means and standard deviations are summarized in Table 1. Experiment 1, using a Korean sample, examined the effect of being rejected versus ignored on conspicuous consumption and helping. We included a control condition in which participants described their college campus. Recall that in Lee and Shrum (2012), being ignored increased conspicuous consumption, whereas being rejected increased helping. However, for Korean participants, the results were the opposite. Being ignored increased helping relative to the rejected ($F(1, 59) = 6.22$, $p < .05$) and control ($F(1, 58) = 4.99$, $p < .05$) conditions, whereas being rejected increased conspicuous consumption relative to the ignored ($F(1, 59) = 4.50$, $p < .04$) and control ($F(1, 57) = 7.75$, $p < .01$) conditions.

Experiment 2, using a Korean sample, examined the underlying process that reactions to exclusion depend on which needs are threatened in Korea. We manipulated the process by boosting either self-esteem or power (moderation-of-process; Spencer, Zanna, and Fong 2005). The design was a 2 (rejected vs. ignored) × 3 (self-esteem boost vs. power boost vs. no boost) between-subjects factorial. The interaction was significant for helping ($F(2, 215) = 4.54$, $p < .05$) and for conspicuous consumption ($F(2, 215) = 5.69$, $p < .01$). For helping, the self-esteem boost reduced the effects of being ignored, relative to the no-boost ($F(1, 215) = 5.78$, $p < .05$) and power boost ($F(1, 215) = 10.19$, $p < .01$) conditions. Thus, being ignored threatened self-esteem but not power. For conspicuous consumption, the power boost reduced the effects of being rejected, relative to the

no-boost ($F(1, 215) = 17.08$, $p < .001$) and self-esteem boost ($F(1, 215) = 14.18$, $p < .001$) conditions. Thus, being rejected threatened power, but not self-esteem.

Experiment 3, using both Korean and American samples, tested our prediction that the culturally opposite responses were mediated by communication norms. The design was a 2 (Koreans vs. Americans) × 2 (rejected vs. ignored) between-subjects factorial. The interaction was significant for helping ($F(1, 128) = 11.23$, $p < .01$) and for conspicuous consumption ($F(1, 128) = 9.43$, $p < .01$). Ignored Koreans increased helping relative to rejected Koreans ($F(1, 74) = 4.77$, $p < .05$), but rejected Koreans increased conspicuous consumption relative to ignored Koreans ($F(1, 74) = 4.88$, $p < .05$). The results were opposite for Americans. Ignored Americans increased conspicuous consumption relative to rejected Americans ($F(1, 54) = 5.15$, $p < .05$), but rejected Americans increased helping relative to ignored Americans ($F(1, 54) = 5.67$, $p < .05$). This interaction was mediated by communication norms (95% CI = .0053 to .4394 for conspicuous consumption; 95% CI = .0057 to .6823 for helping).

In conclusion, our research demonstrates that compensatory responses (conspicuous consumption and helping behavior) to explicit and implicit types of exclusion were opposite between high- and low-context cultures and that these effects depended on which needs were threatened and were explained by cultural differences in communication norms.

Louis Vuitton and Your Waistline: Using Luxury Goods Depletes Self-Regulatory Resources and Impairs Self-Control

EXTENDED ABSTRACT

Whereas past research in luxury and conspicuous consumption has looked at motivations for desiring luxury goods, this paper looks at the actual experience of using luxury goods and examines the negative psychological costs of luxury consumption. We propose that using a luxury item in public makes consumers feel more self-conscious, and more mindful of needing to watch their behaviors in public. We further propose that being at such mindset requires self-regulatory resources to manage, depletes one's self-regulatory resources, and therefore impairs consumers' ability to exert self-control in subsequent situations (e.g., resisting candy). We test these hypotheses in four experiments.

Experiment 1 tests the basic theory. Eighty-four female students were randomly assigned to use a luxury handbag (Louis Vuitton, retail price: $730) or a non-luxury handbag (retail price: $75). After using the handbag in public for 15 minutes, participants returned to the lab and completed a survey, with a small bowl of M&Ms candy provided nearby as a complimentary snack. The survey asked participants to recall their experiences using the assigned handbag, including questions about whether they felt they were in the spotlight during the experience: "When you walked around with the handbag, to what extent did you feel you: (1) attracted attention from others, (2) were being noticed by others, (3) needed to be more careful in front of others, and (4) felt self-conscious about carrying the handbag" (1=not at all, 7=very much)." The four items were averaged to form a Spotlight Index ($\alpha = .68$). After completing the survey, participants were dismissed and the weight of the M&M's they consumed was measured (in grams). As expected, participants in the luxury condition consumed significantly more M&M's than participants in the control condition ($Ms = 26.19$ vs. 15.21, $t(82) = 2.11$, $p = .02$). Similarly, participants in the luxury condition also had stronger feelings of being in a spotlight ($Ms = 4.19$ vs. 3.42, $t(82) = 1.99$, $p = .025$). Finally, we found that the effect of luxury product use on M&M's consump-

tion was mediated by the Spotlight Index (95% bias-corrected, CI = [.0007, .0956]).

Study 2 provides further process evidence by comparing food consumption contexts that require self-control (unhealthy food) versus those that do not (healthy food). We predicted that the luxury depletion effects should only occur for unhealthy food. Study 2 had a 2 (Product Type: Luxury vs. Control) by 2 (Food Type: Healthy vs. Unhealthy) between-subjects design and used a procedure similar to study 1. Our analysis showed a significant interaction effect ($F(1, 84) = 3.88$, $p = .05$). Specifically, participants in the Luxury condition ate significantly more unhealthy food than participants in the control condition ($Ms = 40.45$ vs. 28.31, $t(84) = 1.78$, $p = .035$). However, there was no difference for healthy food consumption cross conditions ($p = .31$). Furthermore, the interaction effect was mediated by the Spotlight Index (95% bias-corrected, CI = [-8.52, -.45]). Study 2 also ruled out mood and power/status as alternative explanations.

In study 3, we varied luxury consumption to be public or private. If feelings of being in a spotlight are responsible for the luxury depletion effect, we should observe the effect for the public, but not the private, consumption context. To add to our process evidence, we add a third condition where we directly manipulate the spotlight mindset. For this condition, prior to participants use luxury handbags privately, we prime them with a message about how others are always watching them and how they need to be careful about their behavior in public, which is consistent with how luxury users feel when using these goods in public. Thus, we expect that participants using the luxury handbag in private will exhibit the same spotlight feelings as participants using the luxury handbag in public. Eighty female students were randomly assigned to one of the three conditions: Luxury Public vs. Luxury Private vs. Luxury Private with Spotlight Mindset Prime. As predicted, participants in the Luxury Public condition and Luxury Private with Spotlight Mindset Prime conditions had similar spotlight feelings ($M = 4.32$ vs. 4.19, $t(77) = .29$, $p = .77$), and both had significantly greater spotlight feelings than participants in the Luxury Private condition ($M = 3.20$, $ts > 2.10$, $ps < .02$). Participants in the Luxury Public condition consumed significant more candy than participants in the Luxury Private condition ($Ms = 24.11$ vs. 14.68, SD = 15.97, $t(77) = 1.90$, $p = .031$). Finally, participants in the Luxury Private with Spotlight Mindset Prime condition also ate significant more candy than participants in the Luxury Private condition ($Ms = 28.70$ vs. 14.68, $t(77) = -2.42$, $p = .01$).

Our final experiment tests two moderators: levels of luxury and self-control trait. Although both are luxury brands, premium luxury brands (e.g., Prada) are more exclusive than affordable luxury brands (e.g., Coach). Thus, the social spotlight effect should be more pronounced in the case of premium luxury brands, and we predicted that unhealthy food consumption would be greater in this condition. Finally, we expected the effects to be stronger for people who have lower self-control. One hundred and seven female students were randomly assigned to wear either a premium luxury bag (Prada, retail price: $1890) or an affordable luxury bag (Coach, retail price: $295). As expected, for participants with stronger self-control, using the premium luxury handbag or the affordable luxury handbag did not affect how much candy they ate ($M = 16.83$ vs. 12.95, $p = .55$). In contrast, participants with weaker self-control ate significantly more candy when they used the premium compared to the affordable luxury handbag ($M = 29.66$ vs. 13.54, $t(103) = -3.11$, $p = .001$).

In summary, four experiments demonstrate that engaging in luxury consumption in public depletes one's self-regulatory resources and therefore leads to more unhealthy food intake subsequently. To our knowledge, our work is the first to explore the psychological states and behavioral consequences of using luxury goods and makes

a number of novel and important contributions to luxury consumption, self-regulation, and consumer well-being.

SESSION OVERVIEW

When making product decisions, consumers decide whether to buy, use, forfeit, or replace some *focal* option. These decisions may be influenced by options that lie outside the decision frame and about which no decision needs to be made. These outside options may be desired but unavailable, they may provide substitutes for options in the focal decision frame, or they may have previously been rejected. The present session explores the roles that such outside options play in forfeiture and replacement decisions.

Forfeiture and replacement decisions are an important subset of the choices consumers commonly make. Consumers must decide whether to forgo attending a desired concert in bad weather or give up a working phone to obtain an upgraded replacement. Previous research finds that how consumers process information about products is affected by whether that decision is an acquisition decision or a forfeiture or replacement decision (Dhar and Wertenbroch 2000). Such decisions are often driven by factors such as the chooser's commitment to a focal option and the ease in which the chooser can replace that option (Fitzsimons 2000). Accordingly, whether people consider outside options, the type of outside options people consider, and the similarity of outside options to focal options are likely to affect forfeiture and replacement decisions.

Four papers look at different factors that prompt consumers to consider outside options and explore implications for forfeiture and replacement decisions. Weiss and Kivetz show that availability of an attractive outside option that was part of an incidental (rather than inherent) choice can make people less likely to forfeit a focal attractive option by increasing the perceived loss. Bellezza and Ackerman show that availability of an upgraded version of a product consumers own decreases consumers' attachment to the product they own, and leads them to take greater risks with that product to justify its replacement. Khan examines out-of-stock situations, where consumers seek a substitute for a desired but unavailable option. Such substitution decisions increase consumer choice of, but decrease consumer satisfaction from, options that are more (vs. less) similar to the outside option. That pattern is driven by transference of both positive (desirability) and negative (failure to find) associations from the outside option to the similar focal one. Sharif and Spiller show that outside options are less likely to affect decisions about focal options for people high on lackadaisical indecisive tendencies (but neither perfectionist nor neurotic indecisive tendencies). This is because

lackadaisical individuals seek less information about outside options and are less sensitive to their values even when they are known.

Together, the four papers help to contribute to research on outside option and on forfeiture and replacement decisions and will be of interest to researchers interested in decision processes. As a group, they raise questions about the ways that options outside the decision frame influence consumer decisions: When will outside options spontaneously be considered as part of a focal decision? Are there lingering consequences when those outside options are made focal? How does consideration of outside options affect consumer welfare?

Following-Through Opportunities: The Effects of Incidental versus Inherent Choices

EXTENDED ABSTRACT

Consumers often plan to pursue desirable opportunities yet fail to follow-through. Such lack of follow-through has negative implications for consumers, who forego opportunities for consumption and progress, as well as for marketers, who miss sales opportunities. The current research suggests that consumers are more likely to pursue an opportunity when it is chosen from a choice set that is construed as *incidental* rather than *inherent*. Consumers perceive choices as *incidental* when they arise from feasibility constraints that are exogenous to the considered opportunity set, as when a consumer receives a movie *and* a concert ticket but has to choose one because the events happen to coincide. Such incidental choices give rise to increased perceptions of loss and opportunity cost, thereby enhancing follow-through. By contrast, consumers perceive a choice as *inherent* if the set of available opportunities is intrinsically constrained, as when consumers earn a marketing incentive that requires choosing between different rewards (e.g., a movie *or* a concert ticket).

We suggest that when consumers make incidental choices, there is no "built-in" requirement to tradeoff one option for another, and thus, consumers are more likely to engage in counterfactual thinking about utilizing all of the options. Consequently, consumers feel that by failing to act on their chosen opportunity, all opportunities that were originally offered, their chosen option but also outside options they did not choose, are lost. Although this view of loss is inflated because the consumer could have actually only enjoyed one of the offered opportunities, this enhanced perception of loss (or opportunity cost) motivates consumers to pursue their chosen opportunity.

Accordingly, four studies demonstrate that consumers are more likely to follow-through with an opportunity when it was selected from an incidental choice-set, compared to when it was selected from an *inherent* choice-set. Participants in Study 1a imagined receiving a birthday gift that required them to choose between two desirable options. In the *inherent* choice condition, two of their friends jointly gave them a single gift voucher that provides a choice between two options: a fancy dinner versus an evening cruise. In the *incidental* choice condition, two of their friends, who do not know each other, each gave them a separate gift voucher: one voucher from one friend was for a fancy dinner, whereas the second voucher from the second friend was for an evening cruise. Participants than learned that the two events (dinner and cruise) took place at the same time on the Thursday following participants' birthday. Participants then chose which event they plan to attend.

Subsequently, participants imagined that they were assigned to work on the same Thursday evening. Their boss offered to cover for them in return for 10 hours that they will devote to a tedious task in the subsequent weekend. Consistent with our prediction of greater follow-through with *incidental* compared to *inherent* choices, participants in the *incidental choice* condition where more likely accept their boss' offer and following-through with their evening event (*p* < .05)

In Study 1b, following the same procedure, after choosing between dinner and cruise, participants imagined looking at the voucher(s) pondering how things could have evolved differently, and then listed three thoughts. Independent judges blind to the hypothesis coded thoughts for whether they represented desires to attend both events. Consistent with our predictions that the effect of *incidental* versus *inherent* choice on opportunity follow-through is related to counterfactual thoughts of using multiple choice options, participants who made the *incidental* choice were more likely to express desire to pursue both opportunities (*p* < .1).

In Study 2, following the same procedure, after choosing between dinner and cruise, participants' indicated WTP for using both options and responded to a maximizing/satisficing scale (Schwartz et al. 2002). Consistent with our prediction that *incidental* versus *inherent* choice will increase WTP for using all (mutually exclusive) options, but only among "maximizers" (seek the best outcome, i.e., utilizing all of the presented options) the interaction between choice-type and maximization was significant (*p* < .05). A spotlight analysis revealed a positive effect of *incidental* choice on WTP among maximizers (*p* < .05), but not among satisficers.

Study 3 explored a different type of feasibility constraint, budget, rather than time, limitation. Participants were informed that they have 7200 reward points. In the *inherent* choice condition, the credit card company offered participants to redeem 5000 points in return for either a massage or dinner. In the *incidental* choice condition, each reward offer was received through a separate communication from a different company, one offering the massage in return for 5000 points and the second offering the dinner also in return for 5000 points. After participants chose which reward to redeem, participants learned that their points were close to expire, and as a dependent variable, participants were asked for their WTP for an additional month in which they can use the points. Higher WTP indicates a stronger desire to follow-through with utilizing the selected reward. Subsequently, participants responded to the maximizing/satisficing scale. Consistent with our predictions, the interaction between choice-type and maximization tendency was significant (*p* < .05). We found increased WTP in the *incidental* choice condition, in which the need to choose only one reward was driven by an external constraint (i.e., insufficient amount of points), than in the *inherent* choice condition, in which the need to choose was built-in to the offer among maximizers (*p* < .05), but not among satisficers.

Consumers are less likely to imagine obtaining all of the options in a choice-set when these options are unattractive as a bundle, such as when there is less variety among options and they are perceived as "more of the same" (Sagi and Friedland 2007). In Study 4, Study 1a's design was repeated with variety among options (high: restaurant and cruise vs. low: two different restaurants) as a second factor. Because the high variety choice-set can better fit consumers' preference heterogeneity, all participants were informed they chose the same restaurant option. Consistent with the prediction that a low variety among options would attenuate the positive effect of *incidental* choice on follow-through, there was a statistically significant interaction between choice-type and variety (*p* < .05). Follow-through

was higher following *incidental* choice when variety was high (*p* < .05), but not when variety was low.

"Be Careless with That!" Availability of Product Upgrades Increases Cavalier Behavior toward Possessions

EXTENDED ABSTRACT

Product owners are often faced with the opportunity to purchase an enhanced product (e.g., a new laptop or phone), even though the device they currently own is still fully functional. We propose that individuals become less careful with owned products and less concerned about losing or damaging those products, when in the presence of attractive, though not yet attained, outside options. This careless behavior stems from a desire to justify the attainment of upgrades. Because consumers keep track of the costs and benefits of their durable purchases over time (Gourville and Soman 1998; Heath and Fennema 1996; Prelec and Loewenstein 1998; Thaler 1980), "accidentally" damaging a product allows them to write-off the residual value ante tempore and buy a new product without recording a loss or appearing wasteful.

We test our hypotheses through five studies that employ different types of upgrading manipulations (e.g., the physical presence of a better product, writing tasks, product images), investigate a wide array of consumer products (e.g., mugs, cell-phones), and examine different measures of carelessness (e.g., actual behavior, behavioral intentions). We also consider the moderating role of individual level differences in the motivation to upgrade and boundary conditions linked to the nature of the product. In particular, we find that carelessness in the presence of upgrade options is stronger for those who are particularly interested in the upgrade and is more likely to occur for products that individuals typically own one of (i.e., the newer product substitutes the current one), than for products that individuals typically own several of simultaneously (i.e., the newer product is owned in addition to the current one).

Using two conditions between-subjects designs, the first three studies test different outcomes of the overall effect: behavioral measures (study 1a), behavioral intentions (study 1b), and product perceptions (study 1c). In study 1a, we manipulated the physical availability of a preferred substitute. Participants (N. 92) were gifted with a mug and were either exposed to a better mug (upgrade condition) or not (no-upgrade condition). All participants then played the game Jenga, with the owned mug placed atop a tower of blocks. Participants removed individual blocks for payment but also attempted to prevent the tower of blocks topped by the mug from toppling down. We find that participants in the upgrade condition dropped the mug during the game in 61% of the cases, in contrast to only 37% in the no-upgrade condition (p = .02). Therefore, participants were more willing to endanger an owned product when presented with a preferred and attractive product option. In this study 1b, we recruited real laptop owners (N. 61) and examined the impact of imagining a newer laptop on willingness to take care of the currently owned device. As predicted, participants in the upgrade condition exhibited a lower willingness to take care of their current laptops than participants in the no-upgrade condition. In study 1c, we show that judgments about the extent to which a product "needs to be broken" prior to replacement are malleable. Cell phone owners (N. 60) imagined a new model of their phone about to be released (upgrade condition) or not (no-upgrade condition), and then assessed the amount of damage "needed" before replacement. We find that the replacement threshold was significantly lower for people who imagined an upgrade possibility than for those who did not. Thus, when the thought of a newer,

attractive option is prominent in participants' minds, they are willing to lower the damage threshold for an owned product.

Study 2 (N. 272) examines the moderating role of motivation to upgrade using a 2 (upgrade) x 2 (physical product condition) x 2 (iPhone ownership) between-subjects design. The study manipulated upgrade condition by asking participants to imagine that they owned an iPhone4 (old model condition) or an iPhone5 (new model condition). In addition, the study manipulated the physical state of the product by showing the image of an iPhone with an intact (undamaged condition) or cracked (damaged condition) screen. For the damaged conditions, a graphic designer created the images of the two iPhones with the same exact crack on the screens. We find that participants for whom the product is relevant (i.e., real iPhone owners) are more likely to rate the substitution of the damaged device as more necessary and to perceive an equally broken product as more damaged when the phone is an old model (iPhone4), rather than a new one (iPhone5). In contrast, the manipulation did not elicit significant differences for non-iPhone owners. Thus, study 2 demonstrates that people are motivated to create reasons for upgrading and they judge a similarly ruined product as more damaged when a more attractive option is available.

Using a 3 (upgrade) x 2 (product type) between-subjects design, study 3 (N. 356) demonstrates the mediating role of need for justification by manipulating the extent to which the upgrading is framed as necessary (i.e., low need for justification) or not necessary (i.e., high need for justification). Moreover, study 3 investigates boundary conditions linked to the substitutability of products. We find that the effect of upgrade availability is more likely to occur for products that individuals typically own one of – so called "single" products (i.e., the new product substitutes for the current one) – than for products that individuals typically own several of simultaneously – so called "cumulative" products (i.e., the new product is owned in addition to the current one). Participants thinking about product upgrades reported lower willingness to take care of their belongings when imagining "single" products (a wallet or suitcase) rather than "cumulative" products (coat or shoes).

In conclusion, our work provides novel insights into the phenomenon of consumer carelessness toward owned products and demonstrates that consumers exhibit cavalier behavior toward owned products when in the presence of attractive outside options.

How Outside Options Influence Choice of Substitutes

EXTENDED ABSTRACT

Consumers' choices and evaluations are not only affected by the alternatives present in a given choice set, but also by unavailable options (Farquhar et al. 1987; Fitzsimons 2000). A common instantiation of this problem arises in cases of product stockouts where consumers are unable to attain their desired target (Fitzsimons 2000). We refer to such desirable, out-of-stock items as *outside options*. An important question in such contexts is whether or not shoppers shift to substitute shopping and if so, which substitutes they are likely to purchase (Campo, Gijsbrechts, and Nisol 2003; Sloot, Verhoef, and Franses 2005; Breugelmans, Campo, and Gijsbrechts 2006). In the current research we undertake a complementary study of what substitutes consumers choose when their desired target is out-of-stock and how satisfied they are likely to be with their chosen option.

We demonstrate that presence of an outside option (i.e., when a desired item is out-of-stock) increases choice of substitutes that are most similar to the outside option even though it is the dissimilar substitutes that are better liked post-choice and drive greater satisfaction. We explain that consumers desire to acquire similar substitutes

due to their close association with the outside options. However, the negative feelings associated with the failed attempt to obtain the outside option also carryover more to the close substitutes consequently decreasing their liking. This notion is consistent with research showing dissociability of "wanting" and "liking" elements of value (e.g., Winkielman and Berridge 2003; Dai, Brendl, and Ariely 2010; Litt, Khan, and Shiv 2010). For example, Litt et al. (2010) showed that being thwarted from obtaining a desired outcome can increase wanting but decrease liking of that outcome. The current research extends these prior findings by examining demand and liking of substitutes rather than the outside option itself.

In Study 1, participants made a hypothetical choice between a Nikon (N) or a Canon (C) camera. Participants then imagined that a stockout prevented them from buying their chosen camera and chose a substitute camera from three available options: a Canon similar to the original Canon (C'), a Nikon similar to the original Nikon (N'), or an upgraded Canon similar to the original Canon but more expensive ($C+$). Consistent with our hypothesis that stockouts increase demand for the substitute most similar to the outside option, participants were more likely to choose the similar substitute regardless of whether they initially chose the Canon (62.32%) or the Nikon (70.18%), $ps < .01$. Next, participants read a mixed customer review of their substitute camera, and then reported their liking of their chosen substitute in light of this new information. Despite relative choice-shares favoring the similar option, choosing a similar (versus dissimilar) substitute led to less positive attitudes towards the substitute for all participants ($M_{C\to C'}$=5.44; $M_{C\to N'}$=7.70; $p<.001$) ($M_{N\to N'}$=6.05; $M_{N\to C'}$=7.42; $p<.01$). Interestingly, even choosing the ostensibly better upgraded substitute ($C+$) led to more positive attitudes only among those who had originally picked a Nikon (choosers for whom trading up is akin to trading out; $M_{N\to N'}$=6.05; $M_{N\to C+}$=7.20, p=.01) but not those who originally chose a Canon ($M_{C\to C'}$=5.44; $M_{C\to C+}$=5.62; ns).

We explain that consumers' choice and evaluation of substitutes are guided by their emotional reactions to the stockout which makes similar items more attractive by association with the outside option but at the same time reduces liking for them. If disjunctions between demand and liking of substitutes are indeed due to consumers' emotional reactions to stockouts, then disjunctions between demand and liking should be greater for individuals who have stronger affective reactions. Study 2 investigates this hypothesis using real behavior. Participants completed a laborious task to earn e-points with which they could choose products (e.g., a DVD player or a GPS) that they would receive should they win a lottery. After choosing a product, all participants learned that their chosen product (P) was out of stock. Across four conditions, participants were offered a choice between two substitutes, which were either: (1) *Both Similar:* P' and P+, (2) *Both Dissimilar:* Q and Q+, (3) *Mixed-Similarity 1:* P' and Q+, or (4) *Mixed-Similarity 2:* Q and P+. After choosing a substitute, participants evaluated their liking of their chosen substitutes after experiencing a sample of the item (e.g., sample voice directions; a movie clip played from the DVD player). Participants next completed an affect intensity measure (Larsen and Diener 1987). Finally, participants were asked if they would like to keep their chosen substitute or exchange it for a gift card of equivalent value. Consistent with Study 1, participants in both the *Mixed-Similarity* conditions were more likely to choose a similar (vs. dissimilar) substitute (78.4% and 75.7%; $ps<.01$). Despite relative choice-shares favoring the similar option, choosing a dissimilar substitute option led to greater liking in both the *Mixed-Similarity 1* condition (M_P=4.81; M_{Q+}=5.97; $p<.01$) and the *Mixed-Similarity 2* condition (M_Q=6.15; M_{P+}=4.65; $p<.01$). Additional evidence suggesting that dissimilar substitutes are better liked than similar ones comes from participants' choices at the

end of the study – participants in the *Both Similar* condition were more likely to give away the substitute than participants in the *Both Dissimilar* condition (69.73% vs. 47.30%; *p*<.01). Similarly, participants who chose the similar substitute in both *Mixed-Similarity* conditions (79.31%, 66.07%, respectively) were more likely to give away the substitute than participants who chose the dissimilar substitute (50.00%, 33.33%, respectively; *p*s<.05). As predicted, individuals who chose dissimilar substitutes (M_{Q_-}=4.20; M_Q=4.37) had higher affect intensity than individuals who chose similar substitutes (M_{P_-}=3.40; M_{P_+}=3.39; *p*s<.01). Inconsistent with a selection-bias account (which would suggest that individuals who like substitutes less also tend to select similar substitutes), liking of the chosen substitute was lower when choosing between two similar options in the *Both Similar* condition (*M*=4.92) than two dissimilar options in the *Both Dissimilar* condition (*M*=5.71), *p*<.01.

Together, these studies demonstrate that outside options resulting from stockouts can increase demand for the most similar substitutes, while decreasing liking of, and satisfaction from, those very same similar options. The findings contribute to the under-researched area of substitute selection and have important implications for demand forecasting, inventory management, customer retention, and customer satisfaction.

Indecisive Consumers and Opportunity Cost Consideration

EXTENDED ABSTRACT

Prior research has revealed that consumers often neglect their opportunity costs (Frederick et al., 2009). However, when individuals do consider their opportunity costs, they are sensitive to the value of their outside options (Spiller 2011). Tightwads, those high in propensity to plan, and those facing immediate resource constraints are more likely than others to consider their opportunity costs (Frederick et al., 2009; Spiller, 2011). Another important, but heretofore neglected individual difference that may be reflected in opportunity cost consideration is indecisiveness. Are indecisive consumers more likely to consider their outside options ad nauseam, unable to decide among their alternatives, or do they consider them to a lesser extent in an attempt to reduce the difficulty of choosing and simplify the decision-making process? We show that a specific dimension of indecisiveness, lackadaisicalness, is associated with lesser opportunity cost consideration and lower sensitivity to the value of outside options even when those outside options are made explicit and salient in the decision frame. We find that other dimensions of indecisiveness are unrelated with these behaviors.

Prior research has identified three types of indecisive individuals using the Decision Behaviors Inventory (DBI): 1) *Neurotic*, characterized by difficulty choosing when presented with a variety of different options; 2) *Perfectionistic*, characterized by excessive information-seeking before choosing; and 3) *Lackadaisical*, characterized by a lack of concern with advanced preparation (Barkley-Levenson and Fox 2014). Although these indecisive individuals have been shown to take longer to make decisions, less is known about how or why these individuals make particular choices. This research aims to further this knowledge by exploring how one important component of decision-making relates to indecisiveness.

Study 1 examines the extent that individuals exhibiting different types of indecisiveness consider opportunity costs. In a "Daily Shopping Task," 100 participants were asked to make a series of 16 choices to buy or not buy $5 gift cards over a series of four "weeks" (one opportunity to buy a $5 gift card per "day" at a cost of 2 cents, with 4 days per week, all in one sitting). Participants had the op-

portunity to view the gift cards being offered in the next three days before making their choice by clicking on black boxes representing these gift cards. Because participants had a limited weekly budget (2 cents), the gift cards available in the future were potential opportunity costs. The number of times participants looked ahead at future gift cards was our measure of opportunity cost consideration. After completing the task, participants completed the DBI. Looking ahead at future options was negatively associated with lackadaisical indecisiveness (*p* < .05), but neither neurotic nor perfectionist indecisiveness.

Study 2 examined how sensitive indecisive individuals are to the value of their outside options when they are highly salient. 100 participants completed a similar procedure as Study 1. However, participants were randomly assigned to a condition in which the next three gift cards were always displayed (Known) or never displayed (Unknown). Participants in the Known condition were more sensitive to the value of their upcoming options than were participants in the Unknown condition (*p* < .05). In other words, participants in the Known condition were less likely to buy the current option if their future options were very attractive (operationalized by aggregate choice share) than if they were unattractive, whereas those in the Unknown condition were not. More importantly, this interacted with lackadaisical indecisiveness (*p* < .05), but neither neurotic nor perfectionist indecisiveness. In the Known condition (but not the Unknown condition), sensitivity to the value of salient upcoming options decreased as lackadaisical indecisiveness increased.

Study 3 aimed to replicate the findings of Study 2 using a different paradigm and rule out the counter-explanation that lackadaisical indecisiveness is merely picking up a correlated construct. 300 participants read a scenario about a sale on their favorite DVD and decided whether to buy it or not (Frederick et al., 2009). Participants were randomly assigned to one of three conditions, in which the decision was framed as an "opportunity" (e.g., do you want to buy this DVD or not?), a "choice" (e.g., after considering what else you would buy with this money, do you want to buy this DVD or the other option you considered?), or a "mixed" condition (e.g., after considering what else you would buy with this money, do you want to buy this DVD or not?) (Jones et al., 1998). Participants generated an alternative use for their money (outside option) before their decision in the "choice" and "mixed" condition and after their decision in the "opportunity" condition. Participants reported their attitude towards the outside option and the DVD (each on three semantic-differential scales: good/bad, favorable/unfavorable, and satisfactory/unsatisfactory) and completed the DBI, Elaboration on Potential Outcome Scale (Nenkov, Inman, and Hulland 2008), and Maximization Inventory (Turner et al. 2012). We found a lackadaisical x outside option evaluation interaction on purchase behavior (*p* < .01). Low lackadaisical individuals were sensitive to the evaluation of the alternative, such that their likelihood of buying the DVD decreased as their evaluation of the outside option increased, whereas high lackadaisical individuals were insensitive to the evaluation of the alternative. This pattern was unique to lackadaisical indecisiveness and was found with neither perfectionist nor neurotic indecisiveness. This effect held even when the EPO and Maximizing Inventory subscale were included in the model and was not significantly affected by how the decision was framed (opportunity, choice, or mixed).

Study 4 replicated these findings with the addition of the Propensity to Plan scale (short-term for time and money) (Lynch et al., 2010). We found the same interaction and corresponding simple effects from Study 3 (*p* < .06). Additionally, this effect still holds when the Propensity to Plan scales are included in the model.

This research contributes both to the literature on opportunity cost consideration and indecisiveness by 1) revealing systematic individual differences in opportunity cost consideration and in sensitivity to the value of outside options, and also by 2) furthering our understanding of the decision-making processes of lackadaisical indecisive individuals.

SESSION OVERVIEW

Resource scarcity is a pervasive facet of human life. Despite increasing interest in this research topic, many open questions remain regarding the consequences of scarcity on consumers' cognitions and behavior. For example, how are consumers' cognitive processes shaped by the experience of resource scarcity? Moreover, the influence scarcity exerts on materialistic tendencies and reciprocal relationships still remain vastly unexplored. This session addresses this gap by providing new insights into how different cues of scarcity—both naturally occurring and experimentally primed—influence consumers' cognitions and behaviors.

The first paper, by **Shah, Shafir and Mullainathan**, investigates how living in a chronic state of scarcity (e.g., poverty) impacts the content of consumers' cognitions. The authors suggest that when faced with chronic resource scarcity, the resource that is scarce (e.g., money) becomes the main focus of people's cognitions. In support of this, the authors demonstrate that lower-income consumers are more likely to falsely recall hearing the word "money," have more difficulty suppressing thoughts related to costs, and are faster to identify stimuli that have been associated with money than higher-income consumers.

Having demonstrated that scarcity shapes consumers' cognitions, interesting questions arise regarding how these thoughts affect their judgment and behavior, such as their materialistic tendencies. The second paper, by **Roux, Goldsmith, Blair and Kim**, addresses this by examining whether consumers from lower socioeconomic (SES) backgrounds are more prone to materialism. Two experiments reveal that lower-SES consumers express more materialistic tendencies only when confronted with reminders of resource scarcity. The authors provide two additional experiments demonstrating evidence of the underlying psychological mechanism.

Resource scarcity-related cognitions may also have consequential implications for how consumers choose to behave in reciprocal relationships with others, which the final two papers address. In the third paper, **White, Morales and Kenrick** propose that, under resource-scarce conditions (e.g., economic recession), consumers increasingly engage in and rely upon reciprocal relationships, because such relationships confer adaptive advantages (e.g., decrease variability in resource acquisition). They provide support for this prediction in four experiments in addition to revealing important boundary conditions (e.g., the trustworthiness of the reciprocal partner).

Finally, the fourth paper, by **Durante, Griskevicius, Redden and White**, draws from evolutionary biology to study the reciprocal nature of parent-child relationships. The authors suggest that because male children have a higher likelihood of reproductive failure (i.e., producing zero offspring) than female children, parents will direct their financial resources differentially toward female children (and away from male children) when financial resources are scarce, in an effort to gain the best reproductive return on parental investment. Five experiments provide support for the predicted effect in addition to revealing theoretically relevant moderators (e.g., if the child has reached reproductive age).

Taken together, this session offers a coherent set of innovative perspectives that enhance the breath of our knowledge in the growing area of research on the implications of resource scarcity on judgment and decision making. We expect this session to appeal to a broad audience, including researchers interested in resource scarcity, poverty, cognitive processing, materialism, reciprocity, and evolutionary psychology.

Thinking About Scarcity

EXTENDED ABSTRACT

Recent research has revealed how conditions of scarcity—being short on money, time, or other resources—can directly influence cognition and behavior. Notably, this work has found that scarcity often reduces mental bandwidth (Mani, Mullainathan, Shafir, and Zhao, 2013; Spears, 2011), increases stress (Chemin, De Last, and Haushofer, 2013), constrains attention, and hurts decision making (Shah, Mullainathan, and Shafir, 2012). Meanwhile, other research has considered the ways that the scarcity mindset improves decision making (Shah, Shafir, Mullainathan, 2014; Spiller, 2011). That is, existing work focuses on how scarcity increases or decreases our cognitive capacities. But relatively little work has been done to study the broader texture of everyday thinking under conditions of scarcity. How does scarcity qualitatively alter the landscape of cognition?

In this line of research, we suggest that thoughts about a scarce resource tint even the most mundane activities. As a result, the scarce resource becomes top-of-mind. Scarcity reshapes how we organize concepts, it makes certain thoughts difficult to suppress, and it naturally grabs our attention. We explore these hypotheses with quasi-experimental designs where we examine how income variation (i.e., monetary scarcity and abundance) interacts with other factors to reshape cognition.

In Study 1a (*N*=125), we find that scarcity can make apparently unrelated items seem much more related simply because they all

place a demand on a limited budget. For example, things such as "groceries," "utilities," "phones," and "bills" may not seem like they share strong semantic connections. But we expected that lower-income individuals would see a common link between these concepts: They all require money.

To test this, we adapted a classic paradigm that assesses the semantic relatedness of concepts (Roediger and McDermott, 1995). In this paradigm, participants are shown a list of words (e.g., uncle, woman, doctor, beard) which are strongly related to a target word (e.g., man). The target word, however, is not included in the list of studied words. Participants are then asked to recall as many of the words as they can. A strikingly high number of people usually recall hearing the word "man" even though they had not. This happens because the studied words are all semantically related to the target, making it highly accessible.

In our study, participants studied a control word list (such as words related to "man") and scarcity-related word list (such as the list described above for "money"). For the first list, we found that lower-income and higher-income individuals had equal false recall rates for the target word ("man": 18% vs. 16%). However, in the second list, lower-income individuals were significantly more likely to recall hearing the target word ("money": 15% vs. 2%). In Study 1b, we replicate these results on a larger sample ($N = 478$). These results suggest that scarcity adds a tinge to even the most mundane thoughts or objects. Items that place a demand on a budget will start to feel more related when that budget is limited.

Because scarcity tints so many experiences, it might be difficult to suppress recurring thoughts of limited resources. That is, scarcity might capture the mind even as it tries to wander elsewhere. In Study 2 ($N = 437$), we adapted Wegner et al.'s (1987) "white bear" study. We asked participants to let their mind wander freely for three minutes. Some participants were asked to avoid thinking about how much they drive each month. Other participants were asked to avoid thinking about how much their monthly driving *costs* them. We recorded the number of times that participants' thoughts strayed to the topics that they were supposed to be suppressing. We found that lower-income individuals had a more difficult time suppressing thoughts about the *cost* of driving, whereas higher-income individuals did not.

If scarcity is top-of-mind and difficult to suppress, then it seems natural that we will automatically orient our attention to the limited resource. In Study 3 ($N = 94$), we tested this hypothesis using a dot-probe task. Each trial of the task began with two words presented on either side of a fixation cross. On each trial, one of the words was money-related (e.g., "cash") and the other word was not money-related, but was matched for length and pronounceability (e.g., "cane"; Shapiro & Burchell, 2012). The words then disappeared and a dot appeared where one of the words had been. Participants had to quickly indicate which side of the screen the dot appeared. We found that lower-income individuals were faster to identify the dot when it appeared on the same side as the money-related word, suggesting that monetary scarcity naturally orients attention toward money-related concepts.

Together, these results begin to paint a broader picture of how scarcity affects cognition. Instead of focusing on how scarcity affects cognitive capacity, these studies delve into the ways that scarcity changes the content of cognition.

When Those Who Have the Least Spend the Most: Understanding the Relationship Between Resource Scarcity, Socioeconomic Status and Materialism

EXTENDED ABSTRACT

"Maybe someday I'll be able to afford an iPhone like the person in front of me at the grocery store. The one paying with FOOD STAMPS!"

This remark was widely circulated on social media, generating long strings of indignant reactions regarding the inappropriateness of low-income consumers engaging in conspicuous consumption (Whitmer 2012). It illustrates the extent to which consumers can become upset, or even enraged, when they observe people who live in poverty spending their limited financial resources on unnecessary luxuries (Schechter 2011). However, to date, little academic research has directly examined if or when individuals of lower socioeconomic status (SES) might be prone to materialism.

In the current research, we argue that materialism among lower-SES consumers may represent an attempt to cope with resource scarcity. This proposition is based on the idea that by limiting one's ability to interact effectively with the environment, resource scarcity undermines consumers' perception of control. Building on past work showing that materialism helps consumers cope with uncertainty and self-doubt (Chang and Arkin 2002), we predict that consumers will likewise use materialism to cope with low perceived control stemming from resource scarcity. However, because lower-SES (vs. higher-SES) consumers already have limited means available, reminders of scarcity are likely to threaten perceived control to an even greater extent for these individuals. Consequently, we predict that the tendency for scarcity to engender materialism will be stronger for lower-SES (vs. higher-SES) consumers. Indeed, the idea that SES will moderate consumer response to scarcity is consistent with recent findings in the domain of evolutionary psychology, which has shown that SES moderates other scarcity responses such as impulsivity, self-control, and risk taking (Griskevicius et al. 2013). In sum, our theorizing suggests that materialism may not be a chronic tendency of lower-SES consumers. Rather, it may be a coping mechanism employed only when reminders of scarcity threaten their perception of control.

The goal of the first two studies is to demonstrate our proposed interaction between scarcity, SES and materialism. In study 1 (N=138), following Roux, Goldsmith and Bonezzi (2014), scarcity was primed by asking participants to list things they could not do without certain resources (e.g., water). Participants in the control condition were asked to list things that they could do with the same resources. Next, all participants completed the Envy sub-scale of Belk's (1985) Materialism Scale. Finally, all participants completed a six-item subjective SES measure (Griskevicius et al. 2013), which is also used in all subsequent studies, along with other demographic questions. In line with our prediction, we found a significant interaction between the scarcity prime and SES (p=.05). Lower-SES participants became more materialistic, expressing greater envy of other people's material possessions, when exposed to reminders of scarcity (vs. control; p=.02). Reminders of resource scarcity had no effect on higher-SES participants (p>.6). Further, no main effects emerged.

In study 2 (N=105) we examined another indicator of materialism, by testing how reminders of resource scarcity and SES affect one's belief that happiness can be achieved through material possessions. Participants in the scarcity-prime condition were asked

to recall times when they felt resources were scarce, whereas those assigned to the control condition were asked to list activities they did in the past week (Roux et al. 2014). Next, all participants completed the Happiness sub-scale of Richins' (2004) Material Values Scale. We again found a significant interaction between the scarcity prime and SES (p=.01). Specifically, lower-SES participants were more likely to indicate that happiness can be attained through material possessions after being exposed to reminders of scarcity (vs. control; p=.01), whereas reminders of resource scarcity had no effect on people from high-SES backgrounds (p>.3).

Having demonstrated support for our prediction that lower-SES consumers' materialistic tendencies are moderated by their exposure to reminders of resource scarcity, we next conducted a series of studies to provide a deeper understanding of the psychological processes underlying these effects. Study 3 (N=71) examined if the effect of SES on one's desire for control was moderated by whether or not reminders of resource scarcity were present. Participants first completed the scarcity manipulation used in study 1. Next, all participants completed a measure assessing their desire for control (Cutright 2012). In line with our predictions, results revealed a significant interaction between the scarcity prime and SES (p=.04). Lower-SES participants expressed a greater desire for control when exposed to reminders of scarcity (vs. control; p=.04), whereas reminders of scarcity had no effect on higher-SES participants (p>.4).

The final study used a different operationalization of perception of control, in order to provide convergence on our theory. Prior work has shown that being in a promotion focus tends to foster an illusion of control, or an overestimation of one's control over an outcome (Langens 2007). Study 4 (N=115) thus tested whether the effect of SES on one's regulatory orientation was moderated by whether or not reminders of resource scarcity were present. Participants first completed the scarcity manipulation task used in study 2. Next, participants' regulatory orientation was assessed using the Regulatory Focus Questionnaire (Higgins et al. 2001). Results revealed a significant interaction between the scarcity prime and SES (p=.02). Lower-SES individuals became more promotion-focused when exposed to reminders of scarcity (vs. control; p=.03), whereas reminders of scarcity had no such effect on higher-SES individuals (p>.2). These findings were replicated in an additional study conducted on participants drawn from a different pool.

In summary, although media reports may lead one to presume lower-SES individuals chronically desire materialistic luxuries beyond their means, our research suggests that lower-SES consumers may only become more materialistic when faced with reminders of resource scarcity. Further, our findings suggest that this shift in materialism may occur because lower-SES consumers experience an increased desire to regain control and take action in the face of a scarcity threat. Although further research is necessary to fully understand the boundaries of these effects, this research provides an important first step towards understanding the relationship between poverty, scarcity and materialism, and suggests important public policy implications.

Spending on Girls in Economic Recessions

EXTENDED ABSTRACT

Imagine you have two children – one boy and one girl. Which child would you favor? Deciding which child to favor is undoubtedly difficult. Yet favoring a child of one gender over the other is common practice in many cultures and across many species. We draw on theory in evolutionary biology to test the prediction that poor economic conditions should lead people to bias investment toward a daughter vs. a son.

We build on the idea that spending on children can be viewed as an investment (Becker 1991), but instead consider investment from an evolutionary perspective. A central prediction from an evolutionary model is that investment patterns in offspring should differ depending on the offspring's *reproductive value*, which is the child's ability to convert parental resources into reproductive success by having children of their own (Daly and Wilson 1988).

Theory in evolutionary biology suggests that parents should invest more in one gender over the other depending on whether resource availability is currently good or bad (Trivers and Willard 1973). The logic for this idea stems from mammalian sex differences in reproduction. Males and females are expected to produce the same number of offspring on average, but males and females have different reproductive *variances*. Females have lower variance than males (Clutton-Brock and Albon 1982; Leimar 1996). The maximum number of children a female can produce is smaller but most females produce a moderate number of offspring. By contrast, the maximum number of children that a male can produce is larger and primarily limited by the number of mates he can attract. A consequence of the sex difference in reproductive variance is that male children have been more likely than female children to produce zero offspring over evolutionary history.

Based on this logic, we propose that poor economic conditions should alter which gender provides the best reproductive return on parental investment. Poor economic conditions decrease the average number of offspring produced for both males and females. However, the sex difference in reproductive variance means that poor economic conditions will have a catastrophic consequence for many male offspring. But, most female offspring will continue to produce at least one child. Thus, we predict that poor economic conditions will lead people to prioritize spending on girls rather than boys. We tested this hypothesis in five studies.

A correlational study examined how fluctuations in U.S. GDP over the last three decades were related to retail spending on boys' versus girls' apparel. Findings revealed that GDP had a strong negative correlation with relative spending on girls versus boys (p < .001).

Experiment 1 manipulated cues to economic condition. Participants first viewed a slideshow depicting an economic upswing or an economic recession. Participants then imagined they had two children (a boy and a girl) and answered questions about how they would divide their assets between their son or daughter in a will. Consistent with predictions, economic recessions led people to bequeth more assets to daughters than to sons (p<.01).

Experiment 2 sought to replicate E1 using a different manipulation of economic condition: news articles. E2 also examined preferences for spending money on several types of child expenditures. The study also sought to rule out alternative explanations based on general affect rather than economic conditions. Replicating E1, participants bequeathed more to a girl in the economic recession condition compared to the economic upswing condition, a negative affect control condition, and a neutral control condition (ps < .05). Participants also indicated they would spend more money on a girl in the economic recession condition compared to the economic upswing condition, a negative affect control condition, and a neutral control condition (ps< .08).

The previous studies demonstrated that poor economic conditions lead people to allocate more resources to girls. We have proposed that this effect emerges because of changes in the relative reproductive value of each gender. Poor economic conditions should

make females a safer reproductive investment than males because many males will not reproduce in difficult times. We would expect that the effects of economic conditions would grow stronger as children near reproductive age. Thus, we examined how poor conditions influenced bequeathing assets to a girl versus a boy as a function of the age of both children (6 months old vs. 15 years old).

Experiment 3 had a 2 (Economic Condition; between-subject) X 2 (Children's Age; within-subject) design. Participants viewed the slideshows from E1 and indicated how they would divide assets in a will. Consistent with our prediction, participants bequeathed more assets to a girl in the economic recession condition when the children were 15 years old ($p < .03$). Participants were more likely to bequeath assets to a 15 year old girl (rather than boy) than to an infant girl (rather than boy; $p < .02$).

Experiment 4 aimed to examine the psychological mechanism. Because investing in girls is akin to investing in the sure thing or odds-on favorite, investment in girls over boys represents choosing a safe reproductive outcome rather than gambling on a riskier long shot. This suggests that risk aversion may underlie our effects. Thus, we hypothesized that the predicted effect should be stronger for individuals who are more risk averse. E4 used the same manipulation as in E2 and participants indicated how they would divide their assets in a will. To assess risk aversion, participants made a series of choices between receiving a certain monetary reward or a 50% chance of getting a larger monetary reward. Participants allocated more resources to girls in the economic recession condition ($p < .01$). Importantly, there was an interaction between economic condition and individual differences in risk aversion ($p < .01$). At +1 SD in risk aversion, recessions led people to bequeath more assets to girls compared to the upswing condition ($p < .01$). There was no effect of economic condition on bequeathing assets to a girl at -1 SD ($p > .34$).

We found that as economic conditions worsened, people chose to invest in daughters over sons. This research contributes to the literature by revealing how, why, and when resource scarcity influences spending on girls versus boys.

The Effectiveness of Reciprocity Appeals in Economic Booms and Busts

EXTENDED ABSTRACT

Reciprocity, the rule that obliges us to repay others for what we have received from them, has been observed in every human society and is one of the strongest and most pervasive social forces (Gouldner 1960; Cialdini, 1993). Why is reciprocity so prevalent, and so powerful? According to anthropological field studies of food sharing, reciprocity likely arose to help people survive in resource scarce conditions. When resources are limited, an individual or family may be unable to obtain enough resources to survive; forming reciprocal exchange relationships can be an effective means of reducing the risk of running out of food. Indeed, researchers adopting an evolutionary perspective have proposed that reciprocity norms confer several adaptive advantages in resource-scarce environments: they serve to reduce or manage variability in resource acquisition, provide stability within social systems, reinforce altruistic acts, and discourage exploitation in relationships (Gouldner 1960; Wilson and Sober 1994). Building on this research, we posit that under resource-scarce conditions, people increasingly engage in and rely upon reciprocal relationships. In a series of lab and field studies, we test the link between resource scarcity and reciprocity, and explore the processes that mediate and moderate it.

Study 1 examined the relationship between chronic concerns about resource scarcity (socioeconomic status; SES) and reciprocity. Those in the reciprocity condition received a small monetary reward and were then asked to volunteer to fill out extra survey questions. Those in the no reciprocity condition were asked to fill out the extra questions before receiving the reward. The outcome—number of extra survey questions completed—was the measure of reciprocity. Results showed a main effect of reciprocity and a reciprocity X SES interaction, $p < .001$. Low SES participants responded more strongly to the reciprocity appeal ($M_{no\ reciprocity} = 5.5$ vs. $M_{reciprocity} = 9.7$) than high SES participants ($M_{no\ reciprocity} = 5.7$ vs. $M_{reciprocity} = 7.3$).

Study 2 experimentally manipulated concerns about resource scarcity and utilized a field setting where students did not know they were part of a study. Eight thousand undergraduates were emailed a request to complete a voluntary survey about their university's admission process in a 2 (resource scarcity vs. control) X 2 (reciprocity vs. no reciprocity) between-subjects design. The reciprocity message emphasized the university's previous efforts to improve the application process, whereas the control message did not. The resource scarcity manipulation simply added a half sentence referencing "today's tough economic times" that was not included in the control. Each email ended with a survey link and the number of people completing the survey was the behavioral measure of compliance. Results indicated a main effect of reciprocity and a marginally significant resource scarcity X reciprocity interaction ($p = .09$). Students in the resource scarcity condition responded more strongly to the reciprocity appeal (reciprocity = 594 vs. no reciprocity = 447, $p < .001$) than those in the control condition (reciprocity = 531 vs. no reciprocity = 450, $p < .003$).

Study 3 tested gratitude as a potential mediator of the relationship between resource scarcity and reciprocity. Participants read a story that manipulated resource scarcity and then read a reciprocity scenario. In the reciprocity condition, participants read about being enrolled in a special valued customer program at their local department store. In the no reciprocity condition, participants read about going to their local department store. Participants also indicated how grateful and appreciative they felt. The dependent variable measured participants' willingness to buy an expensive product from the store. Analyses showed a resource scarcity X reciprocity interaction for both gratitude and willingness to buy the expensive product, $ps < .001$. The effect of reciprocity was exacerbated in the resource scarcity condition: people receiving the reciprocity benefit felt even more grateful and were even more willing to buy the expensive product. Further, gratitude mediated the relationship between resource scarcity and reciprocation, CI (.004, .41), $\beta = .12$, $SE = .10$.

Studies 4 established a boundary condition for the observed relationship between resource scarcity and reciprocation. From a functional perspective, reciprocity is beneficial to the extent that it helps establish or maintain a trusting, exchange relationship. If trust does not exist, however, attempting to enter into a reciprocal relationship may actually be dangerous—an untrustworthy relationship partner could take advantage of you, and this would be especially costly during periods of resource scarcity. Given this possibility, we hypothesize that those concerned with resource scarcity should be particularly wary of cues suggesting untrustworthiness. Study 4 tested this prediction using a 2 (resource scarcity vs. control) X 2 (reciprocity vs. no reciprocity) X 2 (persuasion knowledge active vs. not) between-subjects design. Study 4 used the same manipulation of resource scarcity as Study 3. Afterwards half of the participants read a persuasion knowledge induction describing manipulative marketing tactics (Morales 2005). All participants then read a consumer scenario in which they received an invitation

to a sales event. Half the participants read that the invitation came with a free gift (reciprocity condition). The DV was a composite of participants' reported likelihood of going to the sales event and likelihood of buying something at the sales event (r = .73). Results revealed a significant three-way resource scarcity X reciprocity X persuasion knowledge interaction, p = .005. When persuasion knowledge was not activated, results replicated previous studies. However, when persuasion knowledge was activated, a different pattern of results emerged. While there was an effect of reciprocity in the control condition, p < .00, in the resource scarcity condition, the effect of reciprocity was significantly reduced, p = .031. In fact, for those in the combined resource scarcity and persuasion knowledge conditions, there was no difference between the reciprocity and no reciprocity conditions (p = .38)—indicating an instance when reciprocity is ineffective.

Overall, these findings demonstrate when and for whom reciprocity appeals are most effective. Moreover, they highlight the usefulness of considering reciprocity from a functional evolutionary perspective and show support for a behavior strategy we characterize as strategic interdependence.

SESSION OVERVIEW

Consumers adapt to hedonic experiences, making positive experiences less enjoyable over time (Frederick and Loewenstein 1999). This adaptation occurs in a variety of contexts such as winning the lottery (Brickman, Coates, and Janoff-Bulman 1978), eating one's favorite ice cream (Kahneman and Snell 1990), listening to a well-liked song repeatedly (Galak, Kruger, and Loewenstein 2013), and receiving a salary raise (Frey and Stutzer 2002). Despite the prevalence of hedonic adaptation, consumers are poor at predicting how various hedonic experiences will make them happy over time (Kahneman 1999; Kahneman and Snell 1990), which can lead consumers to choose products that make them less happy over products that make them happier. This symposium focuses on investigating what product purchases or experiences can improve consumer happiness or well-being in the face of adaptation.

The first paper by ***Yang and Galak*** proposes sentimental value as a new component of the happiness that consumers drive from products in addition to feature-related utility. It shows that consumers adapt more slowly to products that have high sentimental value because the sentiment acts as a buffer against the decrement in feature-related utility on hedonic adaptation. These results point out that increasing the sentimental value of products can prolong consumer happiness.

The second paper by ***Lee, Cryder, and Nowlis*** demonstrates that consumers adapt less to utilitarian than hedonic products. This reduced adaptation to utilitarian products (vs. hedonic products) leads consumers to be more satisfied in the long run with their utilitarian spending. These findings suggest that simply emphasizing utilitarian or functional benefits of products may reduce hedonic adaptation and make consumers happier with their purchases.

The third paper by ***DePaoli and Khan*** shows that consumers adapt slower to products that they initially like less than products that they initially like more. Further, the paper demonstrates a boundary condition for this effect. Because liking is an affective response to products, when features or products are framed as practical, the effect no longer exists. These results imply that choosing products or experiences that are liked (but not choosing the very favorite) could lengthen consumer enjoyment.

The fourth paper by ***Yang, Gu, and Galak*** demonstrates that when consumers are unsure whether the sequence of consumption experiences will be uniformly positive or not, they tend to adapt to the sequence of experiences more slowly than when they are aware that the sequence will be uniformly positive. This effect applies only to happiness with acquisition, not happiness with consumption. These findings suggest that making consumers' upcoming experiences unpredictable can slower hedonic adaptation to the experiences.

Taken together, four papers in this special session demonstrate the recent advances in hedonic adaptation, while also offering new perspectives on improving consumer well-being. As such, we expect this special session to appeal a wide audience who is interested in hedonic adaptation and/or consumer well-being.

Love it Longer: Sentimental Value Slows Hedonic Adaptation

EXTENDED ABSTRACT

One of the ultimate goals that consumers pursue is to maximize their happiness (Russell 2012). Although any improvement in acquisition and consumption may increase the level of happiness, the increased happiness may not persist. One reason for this is hedonic adaptation, defined as a decrease in hedonic response to a stimulus over time (Frederick and Loewenstein 1999; Helson 1964).

An important question posed to consumer researchers is – how can we slow unwanted hedonic adaptation? Recent research has greatly advanced our understanding of hedonic adaptation by examining how product or experience features influence hedonic adaptation (Bar-Anan, Wilson, and Gilbert 2009; Carter and Gilovich 2010, 2012; Galak, Kruger, and Loewenstein 2013; Kurtz, Wilson, and Gilbert 2007; Nelson and Meyvis 2008; Nicolao, Irwin, and Goodman 2009; Redden 2008; Temple et al. 2008; Van Boven and Gilovich 2003; Wilson et al. 2005).

All of this work, however, makes the assumption that the sole inputs to hedonic adaptation are the product features. We suggest, instead, that the happiness a consumer derives from a product is a function of at least two components: feature-related utility and sentimental value. We define sentimental value as the value derived from the associations with a person or an entity or from the associations with an event or time in one's life. For example, a product can have sentimental value because it was received as a gift from a person one loves, or because it is a token that represents a particular life event (e.g., a souvenir from a vacation).

In four studies, we demonstrate that sentimental value slows hedonic adaptation and examine the process underlying the effect. Study 1 is an initial demonstration of the slowing effect of sentimental value on adaptation. Participants listed either all gifts they received or all purchases they made during a Christmas holiday season, and indicated happiness with each item across two time periods, shortly after acquisition and 45 days later. We found that gifts were more sentimentally valuable than their purchased counterparts, and consumers adapted to gifts more slowly than to purchases.

In Study 2, we controlled for the item in question and experimentally manipulated the sentimental value of items in the lab. Study 2 consisted of three parts spaced approximately 9 months apart. During the first part, in thanks for completing a short task, participants received a gift either from the experimenter (i.e., the low-sentimental value condition) or from their romantic partner (i.e.,

the high-sentimental value condition). Specifically, participants in the low-sentimental value condition were told: "Thank you for your participation. You also get a reward." Each male participant was then given a calendar toy and each female participant was given a man-made grass toy. In contrast, participants in the high-sentimental value condition were told: "Thank you for your participation. You also get an opportunity to choose between two gifts." The gifts were placed inside opaque boxes labeled "for myself" and "for my partner" and participants could not see inside the boxes. To ensure that participants in both conditions received the same item, male participants in the high-sentimental value condition always had the calendar toy in the box labeled "for myself" and the grass toy in the box labeled "for my partner," and female participants had the opposite. In this way, when both participants chose to have their partners receive the gift, men would always receive the calendar toy and women would always receive the grass toy, just like participants in the low-sentimental value condition. Next, if both participants chose to give the gift to their partner, the experimenter asked them to both, simultaneously, walk to the middle of the room to exchange gifts. Twenty-six out of 28 couples who were in the high-sentimental value condition, chose to give the gift to their partner. Finally, participants indicated their happiness with the gift across three time periods, shortly after acquisition, 3 months after acquisition, and 9 months after acquisition. Results showed that gifts received from participants' partners had a higher sentimental value than gifts received from the experimenter. Participants adapted to gifts received from their partners more slowly than to gifts received from the experimenter. Also, participants demanded a higher selling price for the gifts from their partners than for the rewards from the experimenter.

Study 3 examined whether objects with high sentimental value spontaneously brought to mind more associations related to a person or entity or associations to an event or time than objects with little sentimental value, and test to what extent these associations determined sentimental value and the rate of hedonic adaptation. Participants were asked to recall a good they received in the previous year which has either lots or little sentimental value to them, listed all the thoughts they had when thinking of the object, and indicated their happiness with the item at the moment they got it and now. Participants' thoughts were then coded into two categories: thoughts related to the item itself (e.g., appearance, function, specifications, price, and how they feel about the item itself), and thoughts related to associations (e.g., memories induced by the product, and how they feel about those memories). We found that participants in the high-sentimental value condition listed significantly more association-related thoughts, which then contribute to the formation of sentimental value and slow the process of hedonic adaptation.

Why does sentimental value slow hedonic adaptation? We propose that happiness with a product is a weighted sum of at least two components: feature-related utility and sentimental value. Sentimental value slows hedonic adaptation as a result of two processes. Firstly, sentimental value moderates the effect of feature-related value on happiness, such that, the higher sentimental value an object has, the lesser influence the feature-related utility exerts on happiness. Secondly, whereas feature-related value decreases with time, sentimental value does not. Study 4 tested these proposed processes simultaneously and lent support to them.

To conclude, whereas previous research focused on how product features influence hedonic adaptation, we introduce the idea of sentimental value, demonstrate that sentimental value slows hedonic adaptation, and examine the underlying process.

Jimmy Choo vs. Nike: Experienced Adaptation for Hedonic vs. Utilitarian Products

EXTENDED ABSTRACT

Humans are highly sensitive to changes in their environment, but over time, tend to adapt. Events such as romantic breakups can be experienced intensely at first, but diminish in influence more quickly than anticipated (Gilbert et al. 1998). At a perceptual level, initial changes in brightness or temperature are quite noticeable, yet can become a new normal as adaptive processes kick in. Such adaptation has been theorized to be advantageous from the perspective that if negative events persist, they are likely unchangeable and therefore are unworthy of additional attention or effort. Similarly, if positive events persist, they are unlikely to disappear and thus energy may be better directed towards new opportunities (Frederick and Loewenstein 1999). The pervasive tendency for humans to become less affected by changing circumstances has led scholars to conclude that adaptation to "new products and changing circumstances is a ubiquitous feature of human psychology" (Wang, Novemsky, and Dhar 2009).

In this paper, we investigate whether adaptation is indeed a ubiquitous feature of unvarying circumstances or whether such adaptation is relegated to particular contexts. Specifically, in the domain of consumer experience, we test whether consumers adapt uniformly to hedonic and utilitarian products. According to Sheldon and Lyubomirsky (2012), happiness coming from positive changes abates with time due to the transitory nature of intense emotions. We therefore suggest that because hedonic products are more emotionally infused, they are likely to prompt intense emotional reactions such as excitement at the time of purchase. However, this powerful emotional response is unlikely to last. Utilitarian products, in contrast, are less likely to be purchased for affective reasons, and instead have justifications that are more enduring. We propose, therefore, that because consumers have greater emotional reactions when purchasing hedonic products, consumers will exhibit a steeper rate of adaptation to hedonic relative to utilitarian products.

In Study 1, participants were asked to indicate their attitudes toward an MP3 player (hedonic product) or a printer (utilitarian product) that they bought, rating their attitudes both *prior to the purchase* (pre-attitude) and *at the time of completing the survey* (post-attitude). Participants showed a greater decline in attitudes over time with MP3 players ($M_{pre\text{-}attitude} = 5.87$ vs. $M_{post\text{-}attitude} = 4.46$; $F(1, 67) = 46.81$, $p < .001$) than with printers ($M_{pre\text{-}attitude} = 5.12$ vs. $M_{post\text{-}attitude} = 4.34$; $F(1, 71) = 16.98$, $p < .001$). Consistent with our prediction, consumers exhibited greater adaptation to hedonic than to utilitarian products.

In Study 2, we examined consumers' lay beliefs about adaptation to hedonic versus utilitarian products. Participants were asked to *predict* their attitudes toward a particular product both *prior to their purchase* (pre-attitude) and *6 months after their purchase* (post-attitude). For hedonic products, MP3 players (males) and fun dress shoes (females) were used whereas for utilitarian products, printers (males) and practical shoes (females) were used. Results showed that participants predicted the same rate of decrease in attitudes from pre-purchase to post-purchase for both hedonic and utilitarian products ($F < 1$, $p = .36$). This finding suggests that consumers do not predict differential adaptation rates for hedonic and utilitarian products.

The purpose of Study 3 was to investigate how hedonic adaptation influences consumers' regret from their purchases. Participants were asked to indicate their pre-attitudes and post-attitudes toward both a hedonic and a utilitarian product. In this study, we used a new operationalization of hedonic versus utilitarian items by manipulating price levels within the same product category: expensive shoes

in the hedonic condition and inexpensive shoes in the utilitarian condition. Our manipulation check confirmed that expensive shoes are considered significantly and substantially more hedonic than inexpensive shoes ($t(119) = 3.08$, $p < .01$) and inexpensive shoes are considered significantly more utilitarian than expensive shoes ($t(118) = -2.07$, $p < .05$). After indicating their pre-attitudes and post-attitudes, participants rated their purchase on financial wisdom scales: "To what extent would you say this purchase was money well-spent?" and "To what extent do you think the money spent on this purchase would have been better spent on something else—some other type of purchase that would have made you happier?" (Van Boven and Gilovich 2003). Consistent with the findings in Study 1, participants showed a greater decline in attitudes ($M_{difference} = 1.49$) for expensive rather than inexpensive shoes ($M_{difference} = 0.56$; $t(113) = 3.01$, $p < .01$). Importantly, the greater adaptation to expensive shoes (vs. inexpensive shoes) was associated with greater regret for their spending. Participants indicated that inexpensive shoes purchases ($M = 7.49$) represent money better spent compared with expensive shoes purchases ($M = 6.69$; $t(120) = -2.29$, $p < .05$). Participants were also more inclined to say that the money spent on expensive shoes ($M = 3.93$) could have been better spent elsewhere compared to the money spent on inexpensive shoes ($M = 2.87$; $t(120) = 2.54$, $p < .05$).

Finally, study 4 tested whether emotional excitement can mediate the effect of product type (hedonic vs. utilitarian) on attitudes. Participants were asked to indicate their pre-attitudes and post-attitudes toward either an expensive handbag (hedonic product) or an inexpensive handbag (utilitarian product) that they currently own. They were also asked to indicate their pre-excitement and post-excitement toward the handbag. Additionally, they completed the same financial wisdom scales as in Study 3. Participants showed a greater decline in attitudes over time with expensive handbags ($M_{pre-attitude} = 5.76$ vs. $M_{post-attitude} = 4.33$; $F(1, 41) = 35.94$, $p < .001$) than with inexpensive handbags ($M_{pre-attitude} = 5.30$ vs. $M_{post-attitude} = 4.60$; $F(1, 38) = 12.11$, $p < .01$), replicating our findings in previous studies. Importantly, we found that participants' excitement mediated the observed effect. Lastly, we also replicated our findings for consumer regret: once again, participants reported greater regret for expensive handbag purchases compared to inexpensive handbag purchases.

Contrary to consumers' lay beliefs that they adapt uniformly to hedonic and utilitarian products, we find that consumers adapt more to hedonic than to utilitarian products. Furthermore, we find negative consequences of hedonic purchases due to consumers' heightened regret for hedonic compared to utilitarian purchases.

Favorites Fall Faster: Greater Liking leads to Greater Satiation

EXTENDED ABSTRACT

Satiation is the process by which we get tired of good things (Coombs and Avrunin 1977; Redden 2008) or by which the intensity of our experience decreases with time (Frederick and Loewenstein 1999). Naturally, no one wants good things to go bad, so determining how this process works is of great interest.

In the current research, we investigate the role of initial product liking (i.e., how much a consumer likes a product at the beginning of a consumption experience), and its impact on satiation. We hypothesize that a higher level of initial liking will lead to a faster rate of satiation. In other words, if good things satiate, better things may satiate faster. Furthermore, because this effect is a function of "liking," which we conceptualize as an affective response to a product, we predict it is limited to hedonic (i.e. affect-rich) products (e.g., Khan, Wertenbroch, and Dhar 2004).

In four studies, we find evidence that for initially well liked products, participants satiate at a much faster rate than for initially less liked (although not disliked) products. This effect is observed when the differences in initial liking are due either to consumer preferences or to experimental manipulation.

In Study 1, participants were presented with one of two Monet paintings pretested such that our population significantly preferred one over the other ($p < .0001$). Consistent with existing procedures (e.g., Redden 2008; Galak, Redden, and Kruger 2009), participants viewed either the More-Liked or the Less-Liked painting, and rated their liking of the image (on an unmarked 100-point scale) over 10 periods. The results indicate that participants did indeed prefer the More-Liked image ($M = 71.6$, $SD = 20.9$) over the Less-Liked image ($M = 42.4$, $SD = 27.4$; $p < .0001$). More interestingly, participants viewing the More-Liked image satiated at a faster rate (i.e., their slope was steeper) than did participants viewing the Less-Liked image ($B = -3.74$, $p < .01$). Furthermore, participants across both conditions who initially liked their image more satiated more quickly ($B = -0.24$, $p < .001$), suggesting that individual preferences are also predictive of rate.

Study 2 demonstrates that this effect also occurs when initial preferences for a product are experimentally manipulated. Past research suggests that having a choice influences affective outcome evaluations (e.g., Iyengar and Lepper 2000; Botti and McGill 2011), so we manipulated initial liking using choice. All participants viewed the same image, but they were either told they could choose the stimulus they would view, or that it would be randomly assigned to them. This choice manipulation produced a significant difference in initial liking ($M_{choice} = 27.42$, $SD = 46.56$ vs. $M_{no-choice} = 46.64$, $SD = 31.91$; $p < .03$). In turn, high initial liking again predicted a faster rate of satiation ($B = -0.04$, $p < .01$). Note that the choice manipulation did not directly predict the rate of satiation ($B = .16$, ns), but had an impact by influencing the level of initial liking, which in turn predicted the rate. In other words, the results were an effect of higher initial liking, not an effect of "choice."

Studies 3 and 4 sought to demonstrate that the process of greater liking leading to faster satiation involves hedonic responses to products. Because this process hinges on "liking," which is an affective evaluation of the product, we predicted that we would only observe the effect for hedonic rather than utilitarian products (Khan et al. 2004; Alba and Williams 2013).

In Study 3, participants listened to a ringtone, and were asked to rate either their enjoyment (hedonic evaluation) or the effectiveness (utilitarian evaluation) of the ringtone over 10 periods. Participants demonstrated significantly more satiation when rating on the hedonic scale ($B = -1.90$, $p < .001$). Hedonic ratings fell significantly from $M = 57.90$ ($sd = 24.75$) to $M = 32.71$ ($sd = 26.53$; $t(117) = 5.38$, $p < .001$), whereas utilitarian ratings only fell marginally from $M = 66.26$ ($sd = 22.52$) to $M = 58.18$ ($sd = 28.97$; $t(111) = 1.70$, $p = .09$). Initial ratings were not predictive of satiation for the utilitarian scale ($B = -0.02$, $p = .21$), but were highly predictive of the rate of satiation on the hedonic scale, such that higher ratings predicted steeper slopes as hypothesized ($B = -0.08$, $p < .0001$).

Study 3 demonstrated that the effect of initial rating on satiation rate occurs when considering the hedonic but not the utilitarian aspects of a product. Study 4 sought to build on this by manipulating whether participants merely thought of a ringtone as a more hedonic or a more utilitarian product (though priming), and then asking them to simply "rate the ringtone." With this more subtle manipulation, we again found no effect on satiation rate of initial scores for the utilitarian participants ($B = -0.01$, $p = .20$), but a significant effect for the hedonic participants ($B = -0.03$, $p < .05$). We conclude that higher

initial liking of the ringtone predicts faster satiation only for products considered to be hedonic.

Besides being theoretically important to the satiation literature, our findings offer substantive insights. The effect suggests that offering hedonic consumption experiences that are too well liked may cause faster disengagement, or even disadoption, as consumers become satiated. Likewise, for consumers looking to maximize the prolonged enjoyment of their own hedonic consumption, it might be advisable to opt for goods or experiences that they like, but that are perhaps not their very favorite. Future directions for this research are focused on determining the mechanism underlying the phenomenon.

When it Could Have Been Worse, it Gets Better? The Effect of Uncertainty on Hedonic Adaptation

EXTENDED ABSTRACT

Consumption often involves positive experiences. Unfortunately, positive experiences are not always guaranteed, and experiences that were expected to be enjoyable turn sour. For example, a reliable car may fail to start one morning, a bottle of favorite wine may turn, and a chef may overcook a dish.

Consumers who are assured that they will always have positive experiences should be better off than consumers who are uncertain whether their current positive experiences will persist. That is, the negativity associated with not knowing whether an experience will be positive or negative is aversive and, thus, presumably, lowers enjoyment. Indeed, consumers spend time and money to find ways to avoid unreliable products, such as buying financially unreasonable insurance policies (Chen et al. 2009).

Contrary to this notion, we instead propose that consumers who are uncertain whether their positive experiences will persist can actually be better off, because uncertainty about the valance of individual experiences in a sequence of experiences affects the rate of hedonic adaptation. Specifically, we propose that consumers' overall happiness with an experience fades more slowly when they are unsure of whether the sequence of upcoming consumption experiences will be uniformly positive. Said otherwise, holding the actual valance of all components in a sequence of experience positive, when consumers are unaware of whether each of these components will be positive or negative, they tend to adapt to the sequence slower than when they are aware that the sequence is going to be uniformly positive.

We propose that the reason for this distinction is because happiness with an experience is comprised of at least two components: happiness with acquisition (i.e., the extent one is happy with getting to experience a stimulus), and happiness with consumption (i.e., the extent one enjoys the stimulus itself).

Happiness with acquisition is a relative construct (Hsee et al. 2009) and thus heavily depends on the alternatives that one might have acquired. When positive experiences are not guaranteed, consumers compare their current positive experiences with alternative negative experiences (i.e., counterfactuals) and, presumably, experience happiness associated with avoiding a negative alternative. In contrast, when positive experiences are guaranteed, although consumers might generate counterfactuals at the beginning, the counterfactuals become less salient overtime. Therefore, consumers are initially happy with acquiring the positive experiences, but their happiness with acquisition will fade very quickly over time. Contrarily, happiness with consumption is more inherently evaluable and less susceptible to the alternatives one might have acquired (Hsee et al. 2009; Morewedge et al. 2010; Novemsky and Ratner 2003). Therefore, consumers may derive the same level of happiness from consumption, but this happiness fades regardless of the uncertainty of future positive experiences.

We test how these two components combine to form total happiness for a product. We predict that when consumption valence over a sequence of experiences is uncertain, consumers devote more attention to the happiness with acquiring the positive experiences (e.g. "I'm so lucky! I might have gotten a worse experience."), than they do to happiness with consumption. Thus their overall happiness mainly depends on their happiness with acquisition. In contrast, when the valence of experiences within a sequence is known to be uniformly positive, more attention is paid to the happiness with consumption, which, unfortunately for consumers, fades with repetition. We test these propositions across four studies.

Study 1 served as an initial demonstration of our predictions. Participants were told that we had two photographs: a relaxing beach photo (positive experience) and a disturbing eye surgery photo (negative experience), and that they would view 10 photographs. Those in the *Certain* condition were told that they would view the beach photo 10 times in a row. Those in the *Uncertain* condition were told that they would view the beach photo at the first time and then from the second time, there would be a chance that they would view the disturbing eye surgery photo. All participants were actually shown only the beach photo 10 times, though those in the *Uncertain* condition believed that they could be shown the eye surgery photo any time after the first iteration. After each iteration, participants indicated their overall momentary level of happiness. Consistent with our hypothesis, though all participants enjoyed the photos less with each iteration, this decrease was smaller for participants in the *Uncertain* condition.

Studies 2 and 3 demonstrate that uncertainty influences the happiness with acquisition but not the happiness with consumption. Study 2 was identical to Study 1 except that participants indicated their happiness with acquiring the target photo (positive photo in all cases), happiness with the photo itself, and overall happiness (a 2 (*Certainty*) x 3 (*Measure*) full factorial between-subjects design). Consistent with our hypothesis, happiness with consumption decreased regardless of the certainty condition, but happiness with acquisition and overall happiness decreased more slowly in the *Uncertain* condition. Study 3 replicated these findings with food stimuli (using pleasant M&M chocolate candy as the positive stimulus and unpalatable vinegar water as the negative stimulus).

Study 4 was identical to Study 2 except for two critical differences. First, the three types of happiness measures were administered within-subjects. All participants indicated their overall happiness first, and then happiness associated with being exposed to the target photo and happiness with consumption (the order of the last two questions were counterbalanced). Second, participants answered the happiness questions twice, once after the first time they viewed the picture, and once after the last time. Replicating our previous findings, overall happiness with acquisition decreased more slowly in the uncertainty condition than in the certainty condition, yet the decrease in happiness with consumption was not significantly different across conditions. More importantly, regression analyses revealed that when participants were certain about their future experience, happiness with acquisition and happiness with the experience jointly predicted overall happiness. In contrast, when people were uncertain about their future experience, happiness with acquisition predicted overall happiness, but happiness with consumption did not. Further mediation analysis indicated that the decrease in happiness with acquisition, but not happiness with consumption, mediated the effect of uncertainty on hedonic adaptation.

SESSION OVERVIEW

Is bad always stronger than good? While abundant evidence suggests that ugly social interactions, negative emotions, and disruptive childhood environments often have negative impact on consumers' behaviors and well-being, four papers in this session provide novel hypotheses and surprising empirical evidence that demonstrates the upsides of negativity. This session looks at both interpersonal and intrapersonal consequences of negativity, and directly fits the theme of getting back to the fun in research (a call that responds to the prior years' negativity and volatility) – hence, a push for more upsides to our collective negativity. We explore two questions: 1) how negative emotion impacts interpersonal relationships, and 2) how negative affect and environment influence consumer goal pursuit and intrapersonal performance.

The first two papers examine how negativity, especially negative emotions, influence consumers' behaviors in an interpersonal context. *Zhang, Gino and Norton* demonstrate the surprising effectiveness of hostile mediators in resolving conflict such as they may serve as a point of comparison and decrease the division between the two negotiating parties. Across six studies, they show that negotiators who interact with hostile mediators are more willing to reach an agreement compared to those who interact with either neutral or nice mediators. The second paper by *Wu, Morales, Fitzsimons, and Chartrand* show that although disgust is often a strong distancing reaction, shared feelings of disgust surprisingly create social connection between consumers. Four studies demonstrate that when consumers experience the feeling of disgust together, they report increased feelings of similarity and closeness with group members.

The final two papers investigate how negativity can influence consumer behaviors from the intrapersonal perspective. *Wang and Vohs* test the novel consequences of negative affect on goal pursuit. Through four experiments, they show that negative emotions can lead to effortful goal pursuit because consumers implicitly recognize that their efforts could product mood improvement. Finally, *Griskevicius et al.* challenge the axiom that growing up in a poor environment is necessarily all bad. Three experiments demonstrate that poverty in

childhood doesn't not impair all styles mental function – and in fact can enhance the ability to shift between tasks flexibly and efficiently.

In sum, this session demonstrates novel and counterintuitive findings showing that the negative aspect of the life, such as bad experiences with product, interacting with a mean person, bad mood, and even poverty-stricken childhood environments, can lead to surprisingly positive outcomes. This session will appeal to a broad set of scholars interested in emotions, interpersonal relationships, consumer goal pursuit and well-being.

The Surprising Effectiveness of the Hostile Mediator

EXTENDED ABSTRACT

When negative emotions build as negotiations approach an impasse, parties in dispute commonly turn to a mediator to encourage amicable behavior and facilitate agreements. Both common sense and conflict resolution guidebooks suggest mediators should treat such situations with a gentle approach in order to mitigate negative emotions. Indeed, establishing rapport is considered a "best practice" in facilitating conflict resolution (Beardsley et al. 2006; Susskind et al. 1999). We demonstrate that while such "killing them with kindness" strategies are intuitively appealing, they can be misguided.

Mediation of disagreements is an interesting case where the documented benefits of positive emotions (Kopelman, Rosette, and Thompson 2006) and costs of negative emotions (Lelieveld et al. 2012) may reverse. In mediated conflicts—in contrast to unmediated conflicts—the mediator's behavior serves as a point of reference for negotiators to make judgments about their counterpart's behavior. Based on research documenting contrast effects in social comparisons (Rafaeli and Sutton 1991), we suggest that added mediator hostility may decrease the division between the two negotiating parties by serving as a point of comparison. Negotiators might think, "My counterpart doesn't seem so bad compared to this mediator!" Across six studies, we show that negotiators who interact with hostile mediators are more willing to reach an agreement compared to those who interact with either neutral or nice mediators.

Study 1 shows that most people predict that hostile mediators would be less effective at helping negotiators resolve conflict than nice mediators, reflecting a lay belief in the wisdom of courtesy. Evidence from Studies 2 through 5, however, suggests that these predictions do not match actual outcomes. In Study 2, participants played the role of a disputant in a negotiation, and were exposed to an audio recording of either a mean, neutral, or nice mediator who summarized the main grievances of both negotiators. Compared to those who were exposed to either a neutral or nice mediator, negotiators exposed to a hostile mediator indicated they were more willing to reach an agreement and also expected their counterpart to be more willing to compromise. Additionally, ratings of the mediator's degree of hostility mediated the effect of the mediator's style on participants' willingness to reach settlement.

In Study 3, we explore the mechanism underlying our results, examining whether participants are more willing to negotiate with their counterparts because the counterpart appears more reasonable in contrast to the hostile mediator (contrast hypothesis) or because the hostile mediator serves as a common enemy against whom negotiators can unite (common enemy hypothesis). To distinguish between these two accounts, we manipulated the target of the me-

diator's comments. In some cases, the mediator was mean or nice to the negotiators themselves; in others, the mediator was mean or nice to an individual external to the negotiation. Adding hostility to the environment had a positive effect on negotiators' willingness to reach agreements regardless of the target, supporting the contrast hypothesis.

What are the types of contrast between the mediator and counterpart that explains our effect? Study 4a replicates findings from Study 2 and demonstrates that contrasts on the dimension of warmth—but not competence—drive our finding that hostile mediators increase willingness to reach agreement. Additionally, not all contrasts that portray the counterpart as warmer generate greater willingness to reach agreement. In Study 4b, we varied not only the hostility of the mediator, but also hostility of the counterpart. We found that relevance of the comparison matters: when counterparts are hostile, added mediator hostility decreases the extent to which counterparts appear more hostile relative to the mediator, thereby increasing willingness to resolve conflict. However, when counterparts are more reasonable, this contrast is not as meaningful in that counterparts have already demonstrated the capacity to negotiate without resorting to hostility.

Whereas findings in Studies 1-4 focus on mediator's *willingness* to reach agreement, Study 5 focuses on negotiators' *ability* to resolve conflict. Negotiating dyads were incentivized to maximize personal gain and were randomly assigned to interact with a mediator through an online platform. Mediators were participants trained to follow a script of either nice or hostile remarks directed toward both negotiators; mediators received payment based on the extent to which both counterparts rated them as either hostile or nice. To address the possibility that simply the desire to avoid interactions with the mediator explains our prior findings, negotiators in this experiment also interacted through a private chat after the mediation to discuss any unresolved issues before reaching a final conclusion. Our findings show that negotiators were more likely to reach agreement after interacting with a hostile mediator compared to a nice one. Hostile mediators did not appear to force negotiators to make agreements more quickly at the expense of sacrificing agreement quality, as agreements across the two conditions did not differ on the extent to which they were integrative. However, final agreements after interactions with the hostile mediator were less equitable. Taken together, the findings show that although hostile mediators help negotiators reach outcomes that are objectively better than their next best alternative, agreements reached after exposure to a hostile mediator may involve one negotiator making more concessions than the other.

As with parents who induce their children to cease bickering by causing them to unite against an even meaner figure – for example, a parent enforcing bedtimes – hostile mediators can also induce parties in dispute to increase rapport by setting a standard of incivility against which even the worst adversary seems civil.

How Disgust Builds Social Bonds

EXTENDED ABSTRACT

Though feelings of disgust have been linked to a specific physiological state (nausea), a distinct facial expression (closed nostrils, open mouth), and a typical feeling state (revulsion), it is perhaps disgust's strong and immediate distancing reaction that is its hallmark (Rozin, Haidt, and McCauley, 2008). Indeed, research has consistently shown that feelings of disgust cause individuals to engage in distancing behaviors such as discarding existing possessions (Lerner, Small and Loewenstein, 2004), decreasing search behavior and lowering willingness to try new products (Argo, Morales and Dahl, 2006).

The fact that disgust leads individuals to distance themselves suggests that feelings of disgust should impede the formation of social bonds; social bonds typically result, after all, from feelings of closeness and attachment. Consistent with this line of reasoning, feelings of disgust have been linked to lowered evaluations of both disgust-eliciting and nearby objects (Lerner, Small and Loewenstein; Morales and Fitzsimons, 2007), suggesting that disgust may lead to lowered evaluations of others.

Research suggests, however, that emotions can lead to heightened feelings of social connection even when those emotions are negative. For instance, individuals preparing to experience a fear-provoking event prefer to wait in the company of others also about to experience the event (Schachter 1959), and individuals who experience the negative emotions of a natural disaster together express increased feelings of solidarity and group cohesion (Tyhurst 1951). These results suggest that positivity is not necessarily an essential ingredient in creating social bonds.

In the current research, we draw on research on disgust, emotion and social connection to suggest that although disgust typically leads to lowered evaluations of associated objects, it can also lead to increased feelings of social connection when feelings of disgust are shared. Specifically, we suggest that increased feelings of social bonding are most likely to occur when the feelings arise from a disgust-eliciting event that individuals experience together.

In study 1, groups of participants were randomly assigned to watch either a disgusting, scary, happy, sad or emotionally neutral film clip together. After watching the film clip, participants were asked to evaluate the clip and to indicate how socially connected they felt to other members of the group. Results revealed that relative to participants in other conditions, participants in the disgust condition had less favorable evaluations of both the film clip they watched and of the other participants in their lab session. However, relative to the control and sadness conditions, participants in the disgust condition (along with those in the fear and happiness conditions) reported increased feelings of similarity and closeness between group members, and increased feelings of being connected and bonded.

In study 2, participants were primed with disgust, fear, sadness, happiness or control (neutral) before indicating whether they would prefer to watch an upcoming film clip alone or with other participants. The emotional content of the film clip was matched to condition (e.g., disgust condition participants watched a disgusting clip, fear participants watched a scary clip). Participants then watched the film clip together as a group, evaluated it, and indicated how socially connected they felt to other group members. Consistent with study 1 results, participants in the disgust condition reported less favorable evaluations of both the film clip and other participants in their lab session but increased feelings of similarity and closeness, and of being connected and bonded. In contrast to those in the fear and happiness conditions, however, participants in the disgust condition expressed a higher preference for watching the film clip alone rather than with others. This suggests that although feelings of shared disgust can result in increased feelings of social connection, disgusted individuals do not seek out such connections.

In study 3, we focus on examining the conditions under which disgust leads to social connections. This study was a 2 (jellybean flavor) by 3 (consumption setting) between-subjects design. Participants took part in a jellybean taste test where they were randomly assigned to evaluate either a peach (neutral condition) or vomit-flavored jellybean (disgust condition) before completing measures of social connection. Participants were assigned to complete the taste

test in one of three settings: 1) all participants in the session were told together what jellybean flavor they would be tasting and then tasted the jellybean together 2) all session participants were told together what jellybean flavor they would be tasting but then tasted it separately and 3) each session participant was told individually what jellybean flavor he would be tasting and then tasted the jellybean alone. Results revealed that relative to the peach (neutral) condition, participants who tasted vomit jellybeans had lower evaluations of both the jellybean and the other session participants. Interestingly, tasting vomit jellybeans led to increased feelings of similarity and closeness only when the jellybeans were eaten together.

In study 4, we examine whether disgust has to be integral to the consumption in order to elicit the disgust bonding effect. This study was a 2 (prime) by 2 (jellybean flavor) by 2 (consumption setting) between-subjects design. Participants first viewed a series of ads that were designed to prime disgust or neutral emotion. They then tasted either a peach or vomit-flavored jellybean in either a group setting (where everyone tasted the same flavor) or alone. Results replicated those of study 3 in that participants who tasted vomit jellybeans had lower evaluations of both the jellybeans and other participants relative to those in the peach (neutral) condition. Also consistent with study 3, tasting vomit-flavored jellybeans led to increased feelings of similarity and closeness only when the jellybean flavor was announced and eaten together. There was no effect of the prime, suggesting that disgust leads to feelings of social connection only when consumers are actively sharing a disgusting experience.

Together, these studies suggest that although disgust's distancing tendencies keep individuals from wanting to connect with others, positive feelings of social connection may arise anyway when consumers are engaging in a disgust-eliciting experience together.

Negative Moods Spur Goal Attainment: A Mood Improvement Strategy

EXTENDED ABSTRACT

Consumers engage in self-control behaviors to pursue multiple goals every day. How does different affect influence consumer's goal pursuit? The literature states that people seek to change a negative mood by preferring immediate gratification (e.g., overeating; impulse buying). A different literature shows that the top outcome of goal attainment is positive mood. The current research used the latter conclusion to challenge the former by predicting and finding that effortful goal attainment is a form of emotion regulation after negative affect. We proposed that consumers experiencing negative (vs. neutral) emotion exert more effort towards achieving goals because goal accomplishment can improve mood. Four experiments tested these hypotheses and found support.

Experiment 1 tested the prediction that participants who are in a negative (vs. neutral) affect state would exert more effort to achieve a goal. We tested both anger and sadness to test types of negative affect. Participants first read that performance on verbal tasks predicts academic and career success. After working on verbal puzzles for eight minutes, they were stopped and told that the experimenter needed to assess their work in order to prepare more puzzles. While the experimenter left ostensibly to assess their work and prepare ensuing puzzles, participants completed a task that served as the mood induction. Participants were randomly assigned to watch one of three film clips, known to induce anger, sadness, or a neutral state. After the film, participants were informed that they had finished 85% of the task and were handed the last puzzle, which would complete their task. The dependent variable was effort exerted during on the last puzzle, operationalized as the speediness with which they com-

pleted the task. Consistent with predictions, participants in the anger (M=199.62) and sadness conditions (Ms =200.36) were faster than the neutral condition M=267.07; both ps<.01). Anger and sadness conditions did not differ (t<1).

Experiment 2's aim was to provide evidence for the proposed mechanism of emotion regulation using a mood freezing manipulation (Manucia, Baumann, and Cialdini1984). Participants were randomly assigned to condition in a 3 (anger vs. sadness vs. neutral) by 2 (mood-freezing vs. non-mood-freezing) between-subjects design. The mood-freezing manipulation tested whether participants experiencing negative (vs. neutral) emotions would exert effort to achieve a goal even when they believed that such efforts would not change their mood. We predicted that improved goal attainment would not hold for participants told that their mood could not change, but that we would replicate the pattern from experiment 1' among other participants. If so, this would support our proposed mechanism of (implicit) emotion regulation.

Similar to experiment 1, participants worked on word puzzles first and were stopped in order to take part in unrelated tasks that served as manipulations of mood as well as mood-freezing conditions. Next, participants went through the similar mood induction as in experiment 1. Next, as part of an ostensible marketing study on aromatherapy, all participants breathed in the scent of an essential oil. Those in the mood-freezing condition were told that the oil renders people's emotional states temporarily unchangeable. The other half were given no further information.

Next, participants worked on a last word puzzle and completed a second set of mood measures to check on the manipulation of the mood freezing manipulation.

Analyses indicated both the mood induction and mood-freezing manipulations were successful (reports available from the authors). Performance on the last puzzle conformed to predictions: As expected, among participants who did not receive the mood-freezing manipulation, those in the neutral condition took significantly longer to complete the last puzzle (M=362.33) than participants in the anger condition (M=182.54, p<.01), and sadness condition (M=192.00, p<.01). In support of the theory that those results are a sign of tacit mood regulation attempts, participants who received the mood-freezing manipulation did not differ according to condition on performance of the last task, F<1. Moreover, mediation results indicated that the combined mood induction and mood-freezing manipulations changed mood due to the effort that participants applied to achieve the goal.

Experiment 3 tested the hypothesis that fun tasks, to which people often turn in order to improve their mood, would be as effective in improving mood as effortful goal attainment – but only in the short-term; hedonic tasks would not be as effective in maintaining a boost in mood after an initial period. Participants were randomly assigned to condition in 2 (mood: negative vs. neutral) by 2 (task: challenging vs. fun) between-subjects design. After the mood induction, participants' mood was measured. Next, participants completed a challenging task (word puzzle) or a fun task (drawing and coloring), after which they completed a second affect report. After a neutral filler task, participants rated their affect again. Analyzing mood reports across measurement times, we found that while both hedonic and challenging effortful tasks improved mood in the short-run, boosts from the hedonic task do not endure, whereas the challenging task conferred longer-lasting positivity.

Experiments 1 to 3 showed that people exert effort to accomplish a challenging goal as a mean to lift their mood when in a negative state. These results raise the question of why people fail to rely on such tasks when the attainment of a challenging goal is so helpful

to mood recovery? Experiment 4 showed that when asked explicitly, people in a negative mood (induced) prefer hedonic tasks over a challenging ones – much like other work on the misprediction of future emotional states (e.g., Gilbert, 2006). In short, experiment 4 showed that people do not recognize the emotional benefits of attaining challenging goals.

In summary, people in negative, as opposed to neutral, emotional state exert more effort to conquer challenging and achievable goals. We demonstrated that this improved performance is due to efforts to improve their mood. Despite being better at achieving goals, people in a negative mood prefer that which is easy, hedonic, and short-lived over challenging and enduringly helpful tasks – an affective forecasting error.

Growing Up Poor Improves Specific Mental Abilities

EXTENDED ABSTRACT

Can growing up poor improve certain mental abilities? Evidence thus far suggests the answer is no. People who grow up in resource-deprived environments tend to score lower on tests of intelligence, language, memory, and other abilities. This reduced performance is often taken to imply that early-life deprivation impairs all forms of mental functioning.

We depart from prior work by arguing that childhood adversity shapes consumer psychology in *adaptive ways*. We hypothesized that the minds of individuals reared in resource-deprived environments should be specialized to perform tasks that are most useful in such environments.

We propose that resource deprivation should have specific consequences for mental abilities later in life. *Inhibition* is the deliberate overriding of dominant responses. Consider wanting chocolate cake when one is on a diet. Being able to overcome that urge stems from inhibition. Inhibition is central to self-control, willpower, and self-regulation — all crucial forms of being a healthy consumer. What often has been neglected in consumer psychology, however, is the essential value of shifting abilities. *Shifting* refers to flexible switching between different tasks. Shifting is central to adapting to changing situations rapidly and efficiently. Consider the consumer who needs to juggle tasks related to being a parent, online shopper, and be productive in her home office. Being able to shift successfully enables her to maintain all three roles. Shifting is essential for success in modern life.

We hypothesize that exposure to stressful early-life environments should exert *specific and opposing* effects on inhibition and shifting. Given that stressful early-life environments shape the mind toward short-term opportunism (rather than long-term investment), such environments should diminish inhibition. By contrast, stressful early-life environments should enhance shifting. The ability to shift between tasks flexibly and efficiently is essential for adapting to constantly changing environments. Because opportunities in such environment are fleeting, consumers who can adapt to change, such as by rapidly identifying new patterns and associations, are in a better position to take advantage of new opportunities before they vanish.

The current research investigated the conditions under which adult consumers raised in resource-deprived versus resource-abundant environments shower superior and inferior executive function. We hypothesized that childhood adversity is most likely to influence adult performance when consumers are tested under duress. Three experiments compared the performance of adults reared in high-stress versus low-stress environments on two types of executive function: inhibition and shifting. Critically, the performances of these two groups were compared in two different experimental contexts: stressful and non-stressful.

Inhibition was tested in Experiment 1, and shifting was tested in Experiments 2 and 3. All three studies had an experimental manipulation that induced stress in half of the participants before the executive function task. Each experiment also assessed individual differences in childhood resources. Experiments 1 and 2 involved college students, who retrospectively recalled the level of childhood resources. Experiment 3 was conducted with a diverse community sample of adults on whom we had detailed childhood environment data. This unique experiment allowed us to replicate the novel shifting finding using more objective measures of childhood environment. It also permitted us to determine which specific type of childhood stress leads people to excel at shifting.

Experiment 1. Fifty-seven consumers completed a standard executive function task assessing inhibition. First, psychological stress was elicited in half the participants by having them read a news article about worsening economic conditions. We predicted that individuals reared in resource-deprived relative to resource-abundant environments would perform worse at inhibition in the stressful context. Analyses revealed the predicted childhood resources by stressful experimental context interaction ($p = .041$). In the non-stressful experimental condition, there was no difference in performance among the two groups ($p = .79$). But in the stressful experimental condition consumers from resource-deprived childhoods performed significantly worse on the inhibition task than those from resource-abundant childhoods ($p = .003$).

Experiment 2. Experiment 2 tested whether resource-deprived childhoods can *improve* adult performance on a different executive function. Seventy-five people completed a standard executive function task assessing shifting. Analyses revealed the predicted childhood resources by stressful experimental context interaction ($p = .022$). In the non-stressful experimental condition, there was no difference in performance among the two groups ($p = .86$). But in the stressful experimental condition, individuals from resource-deprived childhoods performed significantly better at shifting than those who reported resource-abundant childhoods ($p = .035$).

Experiment 3. Experiment 3 sought to replicate the novel shifting finding from Experiment 2 with a diverse group of older participants on whom we had detailed childhood information. Fifty-one people (all age 37) performed the shifting task used in Experiment 2. Unlike Experiments 1 and 2, each participant's childhood environment in Experiment 3 had been rated by trained interviewers at multiple time-points between ages 0 and 10. This allowed us to pinpoint which environmental factor is linked to improved shifting ability.

Findings showed that superior shifting performance was directly related to growing up in an unpredictable environment. There was a childhood unpredictability by stressful experimental context interaction ($p = .038$). In the non-stressful experimental condition, there was no difference in performance among the two groups ($p = .89$). But in the stressful experimental condition, people who experienced unpredictable childhoods performed significantly better at shifting than those who experienced predictable childhoods ($p = .016$).

Can growing up in a stressful childhood environment improve certain mental abilities in adult consumers? The answer is yes—but only in stressful contexts. Three experiments revealed that consumers who had stressful childhoods were worse at inhibition, but better at shifting. Because opportunities in such environments are rapidly changing, those who can adapt to change rapidly are in a better position to take advantage of new opportunities before they disappear.

The current experiments are the first to document that stressful childhood environments do not universally impair mental function-

ing, but can actually improve specific mental abilities in adults in specific contexts.

SESSION OVERVIEW

As a pervasive aspect of human life (Booth 1984), a fundamental concept in economics (Brock 1968), and one of the most powerful instruments of influence in our society (Cialdini 2009), scarcity has attracted attention from various disciplines. Researchers have made considerable progress in understanding how scarcity of a single object enhances perceived value and demand (Brock 1968; Verhallen and Robben 1994). More recently, consumer researchers have expanded the scope beyond object specific scarcity to general perception of resource scarcity exploring situational activated scarcity (Laran and Salerno 2012; Shah, Shafir and Mullaninathan 2012) and individual differences in resource availability (Griskevicius et al. 2013). Yet, our understanding of the psychological and behavioral consequences of scarcity remains limited.

The proposed session highlights the newest research on how scarcity shapes consumers' value construction, product preferences, and daily decisions using a diverse range of theoretical frameworks, methods, and measures. In an attempt to gain better understanding of the interplay between resource scarcity and consumer behaviors, the papers examine how consumers' tradeoff, substitution, purchase, and financial decisions are influenced by experimentally-induced as well as real-life scarcity.

Zhu and Ratner examine how a uniform level of scarcity across items in a choice set impacts choices of individual items in the set. They show that overall perception of scarcity versus abundance increases arousal level, polarizes the evaluations of individual items contained in the choice set, and consequently increases (decreases) choices of the favorite (non-favorites). **Shah, Shafir and Mullainathan** argue that scarcity captures attention, makes tradeoffs more accessible and therefore makes valuation more consistent. They demonstrate that participants experiencing various forms of scarcity (including monetary, caloric, and experimentally induced time scarcity) are less susceptible to different context or framing effects. **Thompson, Hamilton and Banerji** examine the effects of perceived childhood socioeconomic status (SES) on substitution behavior. Whereas previous research indicates that experiencing childhood scarcity can make consumers more impulsive, this paper argues that when making substitution decisions, consumers with low (vs. high)

childhood SES will exhibit more patience. When the waited-for item becomes unavailable, however, the low childhood SES participants devalue it, making it easier to choose a substitute. Finally, **Mittal and Griskevicius** demonstrate that resource scarcity produces divergent control beliefs and impulsive behaviors in people as a function of their childhood environments. They hypothesize and provide evidence that resource scarcity leads individuals from relatively poorer childhood backgrounds to feel that they have less personal control, which facilitates preference for smaller sooner rewards.

Taken together, the four papers (all in advanced stages) in this session elucidate the nuanced relationship between scarcity and consumer decision making, noting when and why resource scarcity may lead to suboptimal decisions versus more fruitful behaviors. As the session integrates diverse research to highlight newest theoretical developments in this important yet understudied area, it is expected to appeal to a broad audience, including those interested in scarcity, variety seeking and compensatory choices, self-control and impulsivity, social welfare, and consumer judgment and decision making. Talks will be kept brief to allow time for audience interaction.

The Impact of Scarcity on Consumers' Choices of Multiple Items from a Product Class

EXTENDED ABSTRACT

Consumers often confront abundance or scarcity of items in a choice set. A grocery store can present large or small quantities of each type of fruit and vegetable, a clothing store can display large or small baskets of accessories, and governments can describe natural resources such as national parks as abundant or scarce. How does the degree of overall perceived scarcity of items within a choice set impact what items the consumer selects?

In spite of a rich body of literature on how scarcity of a single item enhances valuation of the specific item (Brock 1968; Verhallen and Robben 1994), how an overall level of scarcity across items from a product class affects the evaluation and choice of individual items in the choice set remains an intriguing, uninvestigated question. We build our theoretical framework based on two separate streams of research. First, it has been suggested that scarcity induces arousal (Brehm 1966; Berlyne 1969; Cialdini 2009). Second, arousal has been shown to alter attention allocation (Broadbent 1971; Easterbrook 1959; Kahneman 1973) giving rise to judgment polarization (Mano 1992; Paulhus and Lim 1994). Building upon this literature, we theorize that scarcity of multiple items from a product class induces arousal, and that the heightened arousal polarizes the evaluations of individual items contained in the choice set, consequently increasing (decreasing) choices of the most-preferred (less-preferred) items.

The objective of Study 1 is to provide support for our main thesis that scarce (vs. abundant) supply of each alternative in a choice set polarizes the liking for the favorite versus non-favorites, and increases choices of the favorite item from the set. Participants were asked to imagine that they were shopping at a grocery shop and decided to buy four yogurts as there was a "Pick Any 4 for $1" sale. They were told that the store carries a total of five different yogurt flavors including strawberry, raspberry, vanilla, peach and lemon. Participants in the abundant (scarcity) condition were told that there were many (only a few) of each flavor, approximately 50 units (5

units) of each remaining. All participants were then asked to rank the five yogurt flavors according to their preference, rate how much they like each flavor, and finally indicate which four yogurts they would choose. As predicted, we find that scarce (vs. abundant) supply of each alternative in the choice set polarized liking of the favorite versus non-favorites, and led people to select more units of their favorite item from the set.

To examine whether the mere perception of scarcity is sufficient to trigger these effects, in Study 2, participants were presented with pictures of four types of ready-to-eat vegetables. In the scarcity (abundance) condition, eight pieces of vegetables of each type were provided in four transparent large, 32 oz. (small, 8 oz.) food containers. A separate manipulation check confirmed that participants perceived the same supply level of vegetables as more limited when it was provided in the large versus small food containers. Results of Study 2 provide converging evidence for our key proposition, demonstrating that perceived (instead of actual) scarce versus abundant supply also polarized liking ratings and increased choices of the favorite. Further, in Study 2 we added popularity measures to investigate the alternative explanation of perceived popularity, and found that neither absolute nor relative popularity of the favorite was significantly different across the scarcity and abundance conditions.

We subsequently present two additional experiments to provide direct support for the arousal-based theorizing, demonstrating that the effect of scarcity versus abundance on choices between the most and less-preferred alternatives is mediated by reported arousal level (Study 3) and attenuated by experimentally induced arousal state (Study 4). In Study 3, participants were asked to pick four $25 gifts cards from five different stores, and they were told that three participants in this study would be randomly selected to receive the four $25 gift cards picked by them (total worth $100). Consistent with our theorizing, scarcity increased choices of the favorite store's gift card and the effect of supply level on gift card choices was mediated by reported arousal level. In Study 4, based on previous arousal research (Menon and Kahn 2002, Vosgerau 2010) showing that bright background color induces high-level of arousal, we manipulated a second factor, survey background color (arousing vs. control), in addition to supply level. Replicating previous results in another real choice context, subjects in the control conditions chose more pieces of their favorite candy in the scarcity versus abundance condition. Importantly, experimentally activating a high-arousal state for all participants through the bright background color eliminated the effects of the scarcity versus abundance condition on the number of pieces chosen of their favorite. Finally, Study 5 generalizes the proposed polarization effect to situations where a general sense of scarcity is activated. We find that activating the general concept of scarcity using a lexical decision task manipulation (Laran and Salerno 2012) also increased choices of the favorite item from a choice set.

To summarize, whereas prior research focused on how the scarcity of a single item impacts its attractiveness, here we examine how overall perception of scarcity across multiple items from a choice set influences choices of individual items in the set. We demonstrate that a uniform level of scarcity (vs. abundance) across items in a choice set increases choices of the most-preferred item, decreasing choices of the less-preferred items. We propose and find empirical support for an arousal-based polarization explanation.

How Scarcity Frames Value

EXTENDED ABSTRACT

Value is hard to determine. Rarely can we name an immediate price for a weekend getaway or the value of a beer on a hot sum-mer day. So we construct value from context. Our decisions might change based on which mental accounts are accessible (Thaler, 1999) or how a question is framed (Tversky & Kahneman, 1981). Indeed, much of behavioral science has been concerned with the features of the environment that introduce malleability into how we make judgments and decisions.

But here we consider how resource scarcity can frame decisions in a more stable way. We suggest that under scarcity, pressing needs capture attention (Shah, Mullainathan, Shafir, 2012). As a result, things like a utility bill or rent payment or other needs are often top-of-mind. These thoughts make tradeoffs very accessible—buying one thing means giving up another. These tradeoffs provide an internal frame of reference that more steadily guides our perception of value. As a result, valuations under scarcity are less subject to irrelevant contextual features and are instead based on these consistent, accessible tradeoffs. Across six studies, we show that scarcity makes tradeoffs more accessible and therefore makes valuation more consistent. This seems true for monetary scarcity, caloric scarcity, and experimentally induced time scarcity.

In Study 1a (N=103), participants saw a classic scenario where they named their willingness to pay for a beer that was either purchased from a convenience store or a fancy hotel (Thaler, 1985). Participants typically offer a higher price for the beer from the hotel than convenience store because the contexts have different reference prices. In this study, participants were simply asked to describe what they would think about as they came up with their willingness-to-pay. Wealthier participants were more likely to say that they would think about where the beer was being purchased (i.e., context). Poorer participants were more likely to say that they would think about items they could not buy if they bought the beer (i.e., tradeoffs). In Study 1b (N=151) participants named their willingness-to-pay. Wealthier participants replicated the classic effect, offering a higher price for the beer from the hotel. But poorer participants were less swayed by this feature of the context, instead naming prices that were nearly equivalent across both frames. In Studies 1c and 1d we replicated these results on a larger sample from the same population (N=604) and on a large, nationally representative sample (N=2015).

In Study 2a (N=705), we tested a classic demonstration of "proportional thinking" (Tversky & Kahneman, 1981). Participants indicated whether they would be willing to travel 30 minutes to save $50 on a tablet computer. The tablet was priced at $300, $500, or $1000. People are usually more willing to travel for the discount when the tablet is cheaper (i.e., a higher proportional discount). That is, to get a sense of whether $50 is worth 30 minutes, people look to the total cost. But we expected that poorer participants would value the discount more consistently. Indeed, higher-income participants were more willing to travel when the discount was proportionally larger, but lower-income participants were less sensitive to the proportional size of the discount. In Study 2b, we directly replicated these results on the nationally representative sample from Study 1d.

In Study 3 ($N = 505$), participants rated the attractiveness of one of two lotteries. One lottery simply offered a chance to win $9 (otherwise nothing). Another lottery offered the same chance of winning $9 (otherwise lose 25 cents). People typically rate the latter lottery as more attractive (even though it is dominated) because the small loss makes it easier to evaluate the worth of $9 (Slovic et al., 2002). Here, this effect holds for the rich, but not for the poor. Again, the poor have a more stable representation of value. In Study 4 (N=263), participants considered small accounts (i.e., cash in their wallet) or large accounts (i.e., money in the bank) and then rated the expensiveness of a consumer product. Typically, participants rate the product as less expensive if they have been primed to think of

the large account (Morewedge et al., 2007). This again holds for wealthier participants, but not poorer participants.

We conceptually replicated these results with different forms of scarcity in Studies 5 and 6. In Study 5 (*N*=234), dieters (those experiencing caloric scarcity) and non-dieters considered small or large caloric accounts (how many calories they consume in a day or a week) and then judged how fattening a large order of French fries felt. Non-dieters judged the fries to be less fattening when primed with a large account, but dieters provided more consistent evaluations across contexts. Finally, in Study 6 (*N*=74), we manipulated time scarcity (as in Shah et al., 2012). Participants played a game in which they were given a small time-budget (poor participants) or a large one (rich participants). Afterward, they were primed to think of a small account (time per round) or a large account (time for the whole game). Then, they were asked to imagine losing 10 seconds from a round of the game and to rate how costly that loss would feel. Time-rich participants rated the loss as less costly when primed with the large account, but time-poor participants provided more consistent evaluations across contexts.

Taken together, these studies suggest that scarcity indeed frames problems in a more stable way. These studies have the promise to resolve lingering questions in psychology and economics. Economics makes many predictions about how preferences should unfold, while behavioral science has identified several ways in which those predictions break down. But economics makes those predictions because it assumes that people regularly recognize scarcity in the world and consider the tradeoffs that it imposes. But when we experience slack, those tradeoffs recede from attention, and we can only look to the environment for guidance on what things are worth. However, it may be the case that when scarcity becomes a psychological reality, we create a context which we carry with us and which more steadily frames our perspective.

You Can't Always Get What You Want: The Effect of Childhood Scarcity on Substitution Decisions

EXTENDED ABSTRACT

One issue all consumers occasionally face is choosing a replacement for an alternative that becomes unavailable, is too expensive or is restricted in some other way (Hamilton et al. 2014). Moreover, consumers with fewer resources may be forced to forgo desired alternatives more frequently than those with more resources. Thus, consumers with fewer resources may get more practice making substitutions than consumers with more resources, potentially changing their cognitive and emotional responses when access to desired alternatives is restricted. This could be considered adaptive if the cognitive and emotional responses of low childhood SES consumers make the substitution process easier. Consistent with this idea, research on life history strategy shows that experiencing scarcity during childhood can have a lasting effect on consumer decision making. For example, research has shown that perceived childhood socioeconomic status (SES) influences risk taking and temporal discounting in response to cues about economic uncertainty (Griskevicius et al. 2013). Although seeing images of recession made high childhood SES participants more willing to delay rewards, the same cues made low childhood SES participants less willing to delay rewards (i.e., more impatient; Griskevicius et al. 2013).

In our research, we examine the effects of perceived childhood SES on substitution behavior. Although previous research suggests that experiencing childhood scarcity can make consumers more impulsive, we predict that when making substitution decisions, consumers with low childhood SES will exhibit more patience than those with high childhood SES. Specifically, due to their more extensive practice with not getting what they want, consumers with low childhood SES may have learned cognitive and emotional response strategies that make them better at regulating the negative emotions arising from these experiences, and therefore more willing to accept delays in getting a chosen item.

To better understand the process by which consumers experience substitution, we examine consumers' valuations of chosen items over time. Earlier research shows that low SES consumers exhibit a weaker cognitive dissonance reaction than high SES consumers do, and that their valuations of chosen and non-chosen alternatives do not diverge as much after choice as those of high SES consumers (Snibbe and Markus 2005). One possibility, then, is that low childhood SES consumers will devalue their chosen alternative less than high childhood SES consumers when it becomes unavailable. Another possibility, however, is that given their more extensive practice making substitutions, low childhood SES consumers will devalue their chosen alternative more when it becomes unavailable, making it easier for them to select a replacement.

We test these predictions in a series of studies using choices in two different product categories. In the first study, 256 MTurk participants were given information about three movies they could download. After rating all three movies, they chose one movie to download. After choosing their movie, participants were told that unfortunately, due to technical difficulties, the movie they had chosen was unavailable. They answered several questions about how they felt and then were asked how long they would be willing to wait for their chosen movie to become available. If they chose not to wait, participants could select a replacement from among the remaining two movies. Participants then answered questions about their perceived childhood and current SES using items from Griskevicius et al. (2013). Qualifying earlier research demonstrating that high childhood SES consumers are often more willing to delay rewards, high childhood SES Ps expressed less willingness to wait for their chosen movie than low childhood SES Ps, even though there were no differences in initial evaluations of the movies across groups.

In the second study, 485 student participants read a description of four different articles, rated the articles and then chose one of the articles for a task in which they tagged keywords. After choosing their article, all participants were told that unfortunately, the quota for the article they had selected had already been filled. Half of the participants chose among the other three articles and the other half were assigned one of the three other articles for the task. Participants answered questions about they felt, rated their chosen article again and then answered questions about their childhood and current SES (Griskevicius et al. 2013). When they were told that their chosen article was unavailable, low childhood SES Ps responded by devaluing their chosen article significantly more relative to their initial ratings than high childhood SES Ps. Notably, the devaluation effect was stronger when low childhood SES Ps chose a replacement than when they were assigned a replacement, suggesting that the devaluation was motivated by a desire to make the choice process easier.

In summary, these results suggest that consumers with low perceived childhood SES may have developed strategies to make it easier to cope with more frequent restrictions on the availability of desired alternatives. We find that consumers with low (vs. high) childhood SES are more willing to wait for an initially chosen alternative but are more likely to devalue it when it becomes unavailable, making it easier to choose a substitute. In our planned follow-up studies, we will examine the cognitive and emotional responses that lead to these outcomes.

Effects of Resource Scarcity on Perceptions of Control and Impulsivity

EXTENDED ABSTRACT

Acquisition of resources is vital for any individual's survival and well-being. Failure to successfully harness resources from the environment is a threat and is therefore undesirable. However, consistent access to resources is not a trivial task because availability of resources has been irregular since the dawn of human evolution (Chakravarthy & Booth, 2004). Even modern life is rife with inconsistencies in resource availability. Not only does the economy continue to be characterized by periods of boom and bust, but there is considerable inequality among people in access to resources at any given time. So, how does resource scarcity affect consumers' beliefs, decisions and behavior? For example, do they feel that they are in charge of their lives during tough times or do they feel that they are helpless? Might these beliefs drive their financial behaviors?

Drawing on life history theory, recent work indicates that resource scarcity leads people to respond in divergent ways as a function of their childhood environments (Griskevicius et al., 2013). In the present work, we add to this growing body of work by investigating the effects of resource scarcity on people's perceptions of control and impulsivity. We hypothesize and provide evidence that resource scarcity leads individuals from relatively poorer childhood backgrounds to feel that they have less personal control. Consequently, this psychological sense of decreased control facilitates preference for smaller sooner rewards.

We conducted four experiments to test our hypotheses. In Study 1, we examined our basic prediction that resource scarcity produces different effects on people's control beliefs depending on their childhood backgrounds and not their current economic conditions. We experimentally manipulated scarcity by having participants view a series of photos successfully used in previous research (Hill et al., 2012). In the control condition, participants viewed a series of images depicting objects commonly found in an office. We then examined their sense of control using a state version of an established measure (Lachman and Weaver, 1998). Results revealed that resource scarcity led to a *decrease* in sense of personal control among individuals who had relatively poorer childhoods. Importantly, these beliefs did not vary as function of respondents' current economic conditions.

Study 2 sought to conceptually replicate and extend the findings from the first study. If resource scarcity alters personal sense of control, as predicted by our model, then it should produce different patterns for personal and non-personal sense of control. We tested this possibility in Study 2. Participants read a news article either about the recent economic recession or a control article. Next, they responded to a six item measure of personal sense of control and a six item measure of others' sense of control adapted from a validated scale (Dew & Xiao, 2011). Study 2 conceptually replicated the very specific finding from Study 1. In addition, it showed that this effect was specific to people's *personal* sense of control rather than their more general perceptions about everyone's level of control.

In Study 3, we aimed to show that perceptions of personal control mediate the relation between resource scarcity and impulsive financial behavior. Resource scarcity was manipulated using the procedure as in Study 1. Next, sense of control was measured using the same items as in Study 1. Finally, financial impulsivity was assessed using a set of randomly presented lotteries (Green & Myerson, 2004). Results indicated continued support for our initial predictions. Resource scarcity led individuals from relatively poorer backgrounds to feel a diminished sense of control as compared to individuals from relatively wealthier backgrounds. Furthermore, our mediated moderation analyses revealed that the influence of resource scarcity on people's impulsive behavior was indeed statistically mediated by their sense of personal control.

Study 4 provided additional support for the mediating role of sense of personal control on impulsivity under resource scarcity. To provide further process evidence, we adopted a moderation-of-process experimental design in Study 4. Specifically, besides control and resource scarcity conditions, we included a third condition in which participants experienced a temporary boost in sense of control in addition to exposure to cues of resource scarcity (Whitson and Galinksy, 2008). All participants then responded to questions on impulsivity and childhood SES used in previous studies. We predicted that the observed effect of resource scarcity on impulsivity would be nullified for those experience a temporary boost in sense of control. The results were consistent with this prediction. Resource scarcity led people from poorer backgrounds to become significantly more impulsive as compared to people from poorer backgrounds. More importantly, we no longer found this effect in the condition where participants experienced a boost in sense of control despite being exposed to cues of resource scarcity.

In summary, the current research substantially extends previous work on the effects of resource scarcity on people's psychologies and behaviors. We not only show that resource scarcity produce divergent control beliefs in people as a function of their childhood environments, but we also show that these beliefs may be driving important behaviors such as impulsivity. These findings have important implications for public policy interventions that wish to improve the future life conditions among the ones that are the most susceptible to the effects of resource scarcity. Our findings suggest that infusing a sense of personal control among such individuals may help in reducing impulsive financial behaviors resulting in greater consumer welfare.

"I Regularly Weigh Up Just Getting Rid of Facebook": Exploring Restriction as a Form of Anti-consumption

Stephanie Anderson, University of Strathclyde, Glasgow, UK
Kathy Hamilton, University of Strathclyde, Glasgow, UK
Andrea Tonner, University of Strathclyde, Glasgow, UK

ABSTRACT

Recent years have witnessed increased interest in anti-consumption with various conference and journal special issues devoted to clarifying our understanding of the concept (Lee et al. 2011; Lee, Cherrier, and Belk 2013). This body of research reveals that anti-consumption is manifested in a variety of ways, some more extreme than others. Lee et al. (2011) identify three non-exclusive types of anti-consumption: reject, restrict and reclaim. A review of relevant literature reveals theoretical advancements in relation to rejection and reclamation, but restriction has received significantly less attention. To address this imbalance, this paper aims to gain a deeper understanding of restriction as a form of anti-consumption. The context for our study is Facebook. Social networking sites have been shown to facilitate anti-consumption (Hutter and Hoffman 2013), but research has yet to investigate anti-consumption of social networking sites themselves.

The contribution of our paper is twofold. First, we demonstrate that restriction may be more wide-ranging than currently acknowledged and we illustrate how restriction enables consumers to negotiate tensions between their anti-consumptive discourses and their decision to continue to consume. Second, while previous research favours more extreme examples of anti-consumption such as dumpster diving (Fernandez, Brittain, and Bennett 2011), Freeganism (Pentina and Amos 2011) and boycotting (Friedman 1999), we contribute by demonstrating how anti-consumption develops within mundane, daily practices.

Ubiquitous Facebook. Facebook consumption involves the acquisition of a user profile, usage of the site and disposition or deactivation of user profiles. User statistics reveal that consumers' engagement with social media has evolved from a novel practice to a facet of everyday life. To date there are 1.4 billion Facebook users worldwide with American users spending on average 37 minutes each day on the site (Business Insider 2014). The pervasiveness of Facebook can therefore be considered as a form of mundane, daily consumption. Mundane consumption has been defined as "consumer behaviour which occurs in situations that the consumer perceives [as] neither extraordinary nor dramatic and which are often characterised by routine" Holttinen (2014, 3). Ulver-Sneistrup, Askegaard and Kristensen (2011) suggest that exploration of mundanity allows more subtle understandings to emerge. Such consumption though unremarkable and everyday has nevertheless been theorised to be particular insightful across a range of consumer culture issue including: consumer identity (Kleine, Schultz-Kleine, and Kernan 1993), subcultural belonging (Cronin, McCarthy, and Collins 2014) and display of cultural ideals (Holttinen 2014). Miller (2011) argues that as a form of mundane consumption the consequences of Facebook are particularly far-reaching both in terms of consumer identity ("On Facebook, you find out who you are" (179) and the "expansion and transformation of social relations" (204). Miller (1998, 12) argues that researchers should pay more attention to the mundane and every day since these practices are the essential components of consumer experience and if such activities "matter to them [they] should matter to us". Such references to the pervasiveness and influence of mundane consumption such as Facebook may however conceal the contested relationship between consumers and everyday consumption and mask their anti-consumption practices.

Technology consumption has often been typified as dichotomous with consumers loving or loathing technology (Kozinets 2008; Borgmann 2000). Recent studies however have begun to consider that this oppositional approach conceals a greater complexity of emotions and interaction. Laing, Newholm and Hogg's (2009) study of online health-based forums consider the mix of anxiety, ambiguity and alienation experienced by users and members of these communities. Mick and Fournier (1998) suggest that in these negative and uncertain situations consumers employ coping strategies, some of which have anti-consumption characteristics, such as avoidance and distancing. These strategies allow consumers to negotiate their feelings of dislike, resistance and resentment (Zavestoski 2002). Within our research, we witnessed similar instances of complex and coexistent emotions specifically in relation to Facebook. Because of Facebook's ubiquity consumers considered avoidance impossible and so employed various forms of consumption restriction beyond distancing. The following section situates restriction within the broader framework of anti-consumption.

Conceptualizing Anti-Consumption. Broadly anti-consumption can be understood as a means against consumption (Zavestoski 2002; Lee, Fernandez, and Hyman 2009) which can manifest itself as both an attitude and an activity or behaviour (Cherrier 2009; Hogg, Banister, and Stephenson 2009). Anti-consumption can be oriented at the macro level and include discourses of dislike and acts of opposition to consumption in general or at the micro level where it is directed to particular consumption activities, products or brands (Cherrier, Black, and Lee 2011; Craig-Lees 2006). This distinction is present within Iyer and Muncy's (2009) typology of anti-consumption which distinguishes between 'general' (against all consumption) and 'specific' (individual brands and products) as the objects of anti-consumption, and 'societal concerns' and 'personal concerns' as the purpose of anti-consumption. According to Cherrier, Black, and Lee (2011) self-interested and socio-environmental concerns relate to a consumer's subjectivity and their desire of self-expression. This perspective is particularly relevant to social networking sites which do not correspond to any grand narrative of anti-consumption. Instead, anti-consumption of social networking sites reflects greater consumer subjectivity and personal choice. As such, considering consumer's anti-consumption from the micro lens allows us to consider individual choice. Contributing to this perspective, Cherrier, Black, and Lee (2011) introduce the concept of intentional non-consumption. This can be understood as both an act of resistance against other careless consumers and anti-consumption positioned by the consumer's own subjectivity.

Lee et al. (2011) categorise anti-consumption into three types; *reject, restrict* and *reclaim.* These three phenomena are non-exclusive and can overlap within consumption practices. Rejection occurs when consumers intentionally avoid or exclude certain products

from their consumption habits. The concept of rejection has amassed much research from boycotting behaviours to brand avoidance (see Lee, Fernandez, and Hyman 2009; Friedman 1999). In comparison to more visible displays of anti-consumption, rejection has been described as passive because it "involves products not purchased; services not accessed; and brands not chosen" (Hogg, Banister, and Stephenson 2009, 156). In relation to symbolic anti-consumption, Hogg, Banister, and Stephenson (2009) found aversion as an affective element would precede the behaviours of avoidance and abandonment. Iyer and Muncy's (2009) typology of anti-consumers focuses upon rejection, such as rejection of brands perceived as contributing to societal or environmental problems.

Reclaiming consumption occurs at the ideological level where consumers through their practices actively alter the normal consumption cycle of acquisition, use and disposal, for example by growing their own produce or upcycling products. Hunter and Hoffmann (2013, 219) offer a recent example in their investigation of carrotmobbers, who reward pro-environmental behaviour and "reclaim social and ecological responsibility from companies instead of rejecting or restricting their own consumption patterns."

Finally restricting consumption can occur when consumers reduce or lower their consumption of certain products. According to Lee et al. (2011) the reduction of certain consumption acts occurs when full rejection is not possible, such as consuming utility services. However, in comparison with rejection and reclamation, restriction has been less well researched. We argue that there is a need to better deconstruct the concept of restriction.

Importantly, Lee et al. (2011) claim anti-consumption (acts of rejection, restriction, reclamation) can overlap with consumer resistance (opposing an organisation's products, practices and partnerships). Resistance to consumption (particular or general) can be understood as an active manifestation of anti-consumption (Garcia-Bardida, Nau, and Rémy 2011). Consumer resistance is distinguished from other anti-consumption elements by opposition against the power of institutions (Penaloza and Price 1993). It has been suggested that anti-consumption attends to consumption issues whereas consumer resistance focuses upon power issues (Lee et al. 2011). As such, the blending space between anti-consumption and consumer resistance opens up the opportunity to explore consumer's consumption acts and discourses which are shaped by multiple, yet distinct consumption and power concerns. Supported by Cherrier, Black, and Lee (2011) who propose the intersection of consumer resistance and anti-consumption provides greater understanding to empirical phenomenon.

METHODS

The findings within this paper form part of a larger project concerning the consumption of social networking sites, specifically Facebook. Anti-consumption discourses and behaviours appeared as an emergent theme. This research was informed by interpretivism and used ethnographic interviews of 15 participants (aged 19-26). This demographic was selected as they are amongst the heaviest users of social networking sites and have grown-up using it since the mid-1990s (Ellison et al. 2011). As the findings emerged from a larger study participants were not selected based on their anti-consumption behaviours.

This located conversational approach to interviewing allows the researcher to gain richer understanding of consumer experiences (Sharman Heyl 2008; Holt 1997). Due to the mobile nature of social networking site consumption interviews were conducted in participants' homes, public places, restaurants and cafes. Interviews were recorded and transcribed in full.   To prompt reflection upon their

consumption practices participants were ask to display their own social networking pages (e.g. Facebook Timeline) using a laptop, tablet or smartphone device. These pages were used as an elicitation method following Heisley and Levy's (1991) account of 'autodriving' which can stimulate underlying responses and helps participants convey richer meaning. Following interview guidelines from Holt (1997) participants were encouraged to give rich descriptions of their consumption practices by recalling previous uses of social networking sites, share stories about experiences. This approach allowed participants to think deeply about their consumption practices and how it affected their lives.

The data was analysed using Stern's (1996) guidelines for deconstructive analysis. This method focuses upon revealing contradictions within texts (Derrida 1982). As such, it was particularly useful for pulling-apart the paradoxical and dichotomous assumptions which were previously imposed upon technology consumption. A close reading of each text was undertaken (Stern 1996) followed by a structuralist reading to expose recurring patterns. Finally, deconstructive stage sought multiple meanings within participants' complex narratives. This used Derrida's conceptualisation of *différance* which focuses on revealing plurality and acknowledging contradictions (Stern 1996). As such, reading for *différance* allowed the multiple meanings of anti-consumption to surface and be explored.

FINDINGS

Findings begin by exploring the mixed emotions our respondents exhibited towards Facebook consumption and then discuss the forms of restriction they employed.

Consuming Facebook: Love/Hate. For all participants, the consumption of Facebook was revealed as central to everyday life so much so that it becomes "daily routine" and "second nature", characteristics of mundane consumption (Gronow and Warde 2001). This is demonstrated by Kate, a 24 year old student, who did not consider herself a heavy user but admitted checking Facebook throughout the day:

> Kate: I check it a lot every day. I think it is becoming a bit of a habit, whenever I'm bored or if I haven't been on it for a couple of hours. I will check mine multiple times a day. It is hard to put a number on it. Like at least 20 times as day. If not every hour then every couple of hours. I generally try to have read everything on the newsfeed. So I will go down until I think I have seen that before and then I stop.

Other participants made similar comments in relation to regular daily checking of the site. The ability to connect with friends, keep up-to-date with social happenings and centralise communication in groups were viewed as the main drivers for continued consumption. These hourly, daily, weekly routines are means of consumers negotiating and enacting group belonging through their practices (Cronin, McCarthy, and Collins 2014).

However, alongside discussion on the perceived communication and social benefits of Facebook, participants would simultaneously comment on how much they disliked their behaviour, variously referred to as "tragic", "sad" or "horrible." The mixed feelings towards technology that were evident in Mick and Fournier's (1998) research are therefore equally relevant within the social networking era. Although many of our participants questioned their consumption behaviour, none of them had ever deleted Facebook or fully rejected it. Jack, a 23 year old student, came the closest to deleting his profile however he remained active on Facebook from 9am to 5pm most days.

Jack: I regularly weigh up just to get rid of Facebook. [...] I hate how I use it. [...] I have such a disdain for it that I wonder why I am even on it. [...] If you choose not to exist on Facebook, everyone always says "Aw but you can't communicate with other people!" But yes you can. It is not that hard. And I find that I have actually a great deal of respect for the people who do [delete Facebook].

While it is possible to reject Facebook, for Jack he chose to participate despite his antipathy for Facebook consumption. Along with other participants, Facebook consumption had become so mundane and embedded within daily lives they would not consider deleting it however strong their negative affective response. It stresses the importance of consumer subjectivity within anti-consumption (Cherrier, Black, and Lee 2011) as consumers choose their own position along the consumption to anti-consumption continuum. Our findings therefore support the idea that Facebook is a form of normative consumer behaviour. Much like Cherrier and Gurrieri's (2012) study of alcohol abstinence, we suggest that cultural barriers prevent total Facebook rejection. As a compromise, our participants engaged in various restrictions which we now discuss.

Restricting Facebook Consumption. We recognise that instances of anti-consumption are not always driven by motivations that are against consumption (Chatzidakis and Lee 2013). Within our data we found examples of restricted Facebook consumption explained in terms of age (those who used Facebook less as they got older) or substitution (participants who had switched to alternative social networking sites). However, here we focus specifically on participants who translated their dislike of Facebook consumption into actively restricting how they use the site.

Self-imposed Barriers: Reducing and Replacing. Our findings reveal that participants used a variety of self-imposed barriers to facilitate the restriction of Facebook consumption. Having been a heavy user of Facebook in the past, Wendy replaced her morning routine of checking Facebook before getting out of bed with checking news websites.

Wendy: I actually downloaded SkyNews as an app so I've something more productive in the morning. So now I have started looking at the news to save me going on Facebook. I'm trying to go on other things like SkyNews and Groupon to see if there are any offers on! And then I'm like "Oh 10 minutes up I need to get out of bed can't check Facebook!"

Wendy also actively restricted her Facebook consumption by putting her phone on silent until she arrived home from work. It is important to note Wendy is not rejecting Facebook as she uses the site every evening to check notifications and communicate with friends. Instead she restricts her consumption and replaces Facebook with other "more productive" media sites. A further example of a self-imposed barrier was given by Megan, a 23 year old amateur dramatics co-ordinator, who actively restricted her Facebook consumption by not buying an internet enabled phone. Instead Megan would continue her Facebook consumption by visiting the site each night on her laptop. Like Wendy, Megan has created a practical strategy which allows her to limit the amount of time spent of Facebook whilst continuing to consume Facebook in a restricted fashion. In earlier research Mick and Fournier (1998) termed similar behaviours 'coping strategies' where consumers would create practices in order to mediate their paradoxical feelings towards technology consumption. However, the strategies devised by Facebook consumers should not be understood as affective coping strategies, but instead should be viewed for their practical utility at the functional level.

Social restrictions: Deleting and Withholding. Our findings also revealed instances of restriction when participants would limit their online visibility in order to regain control over their projected selves. This relates to the concept of intentional anti-consumption where acts against consumption are directed towards other 'careless' consumers (Cherrier, Black, and Lee 2011). Participants viewed 'over-posting' as 'careless' and disliked behaviour. In response to such behaviour, participants would delete friends, erase comments and 'de-tagg' themselves from photographs in order to reduce the amount of information other 'friend' connections could see:

Kate: I have often thought I need to clear out some friends. A few weeks ago I did actually delete a few people. [...] It is more about me not wanting them to see what is going on in my life. [...] Like there is the odd horrible picture that crops up and you think oh my God why did someone feel the need to put this up? I have seen me untagg from pictures that I really don't want people to see.

For Kate, reducing the amount of people who can see information regarding her personal life, and restricting what information gets posted on Facebook allows her a degree of control over her identity. Other participants admitted concealing their birth date from Facebook to stop annual congratulations, and posting profile pictures late at night to avoid catching the attention of other users. As such, this type of restrictive behaviour allows consumers to minimize their presence and reduce their online footprint.

Interestingly, other participants actively restricted what they shared online, thereby going against the cultural norm (Cherrier and Gurrieri 2012) associated with Facebook. This is demonstrated by Jack who decided not to post his degree results on Facebook:

Researcher: Did you put your exam results up?

Jack: No. Yet again I've been doubly devious about it because by not engaging in that I am critiquing that. I am above it apparently. But I mean I see what everyone is doing because I am on Facebook. So I am essentially looking and not telling. You could argue which one is worse. I'm not sure. [...] But in reality I am still looking at it all. I am still part of the circle so I really don't have any right to that criticism. So perhaps it should be either do it and engage with it or don't do it and don't engage. [...]I am a hypocrite.

As expressed earlier, Jack considered deactivating his Facebook account, but chose not to discontinue his heavy use of the site. For Jack, limiting his actual participation on Facebook (posting, commenting, and uploading) allows him to anti-consume whilst still checking it daily, even if he remains unsettled by his consumption behaviour (*I am a hypocrite*). Withholding behaviour provides us with a nuanced form of restrictive anti-consumption which limits the expansion of social relations, deemed as central to Facebook.

Institutional Restriction: Concealing and Disguising. Findings reveal that another driver of restriction is against the commercial forces of Facebook and other data collecting corporations, indicative of the blending between anti-consumption and resistance suggested by Lee et al. (2011). Some participants believed their Facebook profiles were viewed by corporations as "marketing data". These concerns had prompted them to restrict and remove the majority of their personal information from Facebook by deleting and de-tagging:

Martin: Yeah mine is completely locked down. The threat nowadays is probably more relevant to what it has been in the past.

[...] That is one of the kind of flaws that not everyone understands how open their information is... Folk can abuse it and they do.

Jack: I don't have where I work. I don't have my current city. I don't like...that is maybe a minor quibble. I don't like that Facebook knows things about me.

Many participants shared similar concerns about how companies could manipulate their personal information. Some had even considered adopting pseudonyms to protect their identity from corporations, an adaptation they believed would enable them to continue using the site whilst simultaneously consuming against wider forces. Such restrictions could be viewed as resistant and efforts to reduce the power of institutions (Penaloza and Price 1993).

CONCLUSIONS

Although it is recognised that anti-consumption can be classified in multiple ways (Lee et al. 2011), understanding of restriction as a form of anti-consumption remains limited. Lee et al. (2011) suggest that restriction involves "cutting, lowering and limiting consumption when complete anti-consumption is not possible." This definition implies that restriction is a compromised form of anti-consumption that is only enacted if a more extreme manifestation is unachievable. Our findings suggest that motivations driving restriction are not always as straightforward as this definition implies. While Facebook can be considered as a form of mundane consumption (Holttinen 2014) it remains a context within which "complete anti-consumption" is possible. If so desired, consumers could completely avoid or reject Facebook. Although it is embedded within our participants' daily lives, they do not depend on its consumption to survive and in this respect it is far removed from the examples of "restricting electricity and water use" offered by Lee et al. (2011). Rather it is the affective and cultural aspects of mundane consumption (Cronin, McCarthy, and Collins 2014) which act as barriers (Cherrier and Gurrieri 2012) to total Facebook rejection such that rejecting Facebook completely would be a personal, social and cultural sacrifice. Hunter and Hoffman (2013) concluded that an unwillingness to make sacrifices often discourages engagement in pro-environmental behaviour. We suggest that avoidance of sacrifice is not solely limited to the ecological context but may also be applicable to other forms of anti-consumption.

Exploring mundane consumption allows a more nuanced insight (Ulver-Sneistrup, Askegaard, and Kristensen 2011) into restriction and shows how consumers adapt their pattern of consumption by creating their own self-imposed barriers, such as reducing their consumption or replacing traditional routines with new ones, withholding and concealing information from other consumers and resisting the power of institutions. We suggest that previous contributions in relation to rejection and reclamation may be extended to restriction. First our consumers exhibit characteristics of Iyer and Muncy's (2009) anti-loyal consumer (resistance to a brand (Facebook) that is driven from personal concerns). Previous research focused upon such consumers' rejection behaviour. We demonstrate that a combination of specific brand and personal concerns can also lead to restriction. Second in relation to reclamation, Fernandez, Brittain, and Bennett (2011) suggest that consumers use a variety of coping strategies to negotiate the tensions between their anti-consumption ideologies and the fact that they rely upon consumption to survive. We suggest that a similar negotiation is evident with reference to restriction: restricting consumption allows anti-consumption discourses to co-exist alongside continued consumption. We finally suggest that the definition of restriction needs to be broader: "cutting, lowering and limiting consumption when complete anti-consumption is either not possible or not desired." Future research should further explore the implications of this broader understanding of restriction across a range of consumption contexts.

TABLE OF FINDINGS

Forms of Restriction	Description	Participant Data
Self-imposed Barriers: Reducing and Replacing	Participants use a variety of self-imposed barriers to facilitate the restriction of Facebook consumption. These range from consciously reducing their participation on Facebook, to replacing Facebook with other activities.	Sarah: Sometimes I sit there [on Facebook] thinking "God…like…stop". I'll get out of bed and just take a wee walk around and start tidying things up, doing things that I am supposed to be doing.. [...] For me, when I'm not using it I'm like "Oh my God". When my phone is dead and I'm out it is actually a nice feeling. It's like I've got no one to contact me because no one can and you are a bit freer in a way. […] I like leaving my phone at home.
Social restrictions: Deleting and Withholding	Participants limit their online visibility in order to regain control over their projected selves. This includes withholding information within their online posts, deleting contacts or information posted by others.	Martin: The whole tagging situation now, you can actually de-tagg which is a good feature. Have I done it? Yeah I have. For the exact same reason as everyone is would. […] I don't think I take very good pictures. No seriously, I am not that kind of camera friendly person. […] If there is a picture I don't like…then I'll de-tagg myself.
Institutional Restriction: Concealing and Disguising	Participants restrict their online footprint as an act against the commercial forces of Facebook and other data collecting companies. Concealing and disguising their identities achieves this form of institutional restriction.	Zara: You have to be really careful about what you put on [your profile]. We talked earlier about that program about people being employed to search Facebook and Twitter for marketing purposes. For supply and demand of products. So I think social media is used by, you don't realise it is used by companies. […] Actually anything you put online you have to make sure you are happy with pretty much everyone seeing it. […] You can optimize things to make them private but then I think nothing is 100% secure. People can always hack into places. So I have my account, well I think to the best of knowledge, it is set to private, all my pictures are private. Jack: Facebook is interesting. On Facebook you are just a little, you are just a number to Facebook. All you are is just marketing information that they can sell on. Which again is why this sort of, which is why it built the way and why it encourages people to use it the way it does. Again this sort of, oh you should like things, you should attach things to your self image that is just marketing data.

50 Shades of Grey: Ancestral Consumption and Conceptual Compromise

Caroline Graham Austin, Montana State University, USA
Justin Wilder Angle, University of Montana, USA

ABSTRACT

I am as free as nature first made man,
Ere the base laws of servitude began,
When wild in woods the noble savage ran.
John Dryden (1672), "The Conquest of Grenada"

Christopher McDougall's *Born To Run* spawned tremendous interest in barefoot running. Told against the backstory of the legendary Tarahumara tribe of barefoot runners from Mexico's Copper Canyon, a central theme of the book is that modern running shoes are harmful (or at best, superfluous) instruments, sold to us by an unscrupulous shoe industry, standing in the way of happy, healthy and biomechanically-correct running. Eschewing shoes in favor of bare feet is presented as the path to running nirvana, yet in the years following *Born to Run's* publication (2009) the running shoe industry grew explosively, fueled in large part by a massive increase in so-called barefoot running shoes. Consumers interested in running without shoes began buying running shoes more frequently than ever before (Austin 2013).

The reverberations of *Born to Run* illuminate a consumer phenomenon we refer to as *ancestral consumption*, defined as the intentional engagement in behaviors aimed at approximating one's ideal, natural self (alternately referred to as seeking the *ancestral self*). The purpose of this research is to illuminate the concept of ancestral consumption and to propose a conceptual model detailing its motivations and hypothesized processes. Ancestral consumers view many mainstream technological advancements as unnatural, and possibly detrimental to both physical and mental health. They therefore attempt to revert to apparently more authentic forms of consumption, yet the concept of authenticity is so loosely defined and individually malleable that it has become mythical (Brown et al. 2013). Consider, for example, the proliferation of ancestral dietary advice in recent years. The popular Paleo diet (aka the Caveman diet) claims to be "the original human diet" (Wolff & Cordain 2010). At the same time, food writer and activist Michael Pollan instructs his readers to avoid "anything your great grandmother wouldn't recognize as food" (Pollan 2008, 149). Though both of these diet prescriptions reference the past, the temporal gap between the caveman and any current living person's grandmother is enormous. In spite of this gap, however, both ideals from the past appear pure and authentic when compared to modern industrialized food.

The construct of ancestral consumption and its relationship with authenticity have very loose borders, since they emanate from consumers' perceptions. In this research, we consider ancestral consumption to be anything that consumers determine more authentic, real, or closer to a mythical standard of idealized human existence. The marketplace is filled with examples of this phenomenon, including religious practices, such as Shamanism and sweat-lodging, home birthing, bow hunting, truffle hunting, urban foraging, home brewing, knitting, hiking, fishing and camping. The knowledge and understanding driving ancestral consumption ranges from naïve to sophisticated. Consumers might have a romanticized, wholly inaccurate view of "the way things (never) used to be" – indeed, ancestral consumers often gloss over the fact that conditions in the past frequently included maternal and infant mortality, infectious diseases, malnutrition, backbreaking physical labor, unchecked racism, sexism, and religious intolerance – or they might have scientific, ethical, and/or political motivations for choosing to consume in a more "old fashioned" way. The drivers for ancestral consumption decisions are cognitive, affective, emotional, or symbolic, or some combination thereof. In short, different motivations can lead to identical behavioral outcomes.

Yet one of the most curious aspects of ancestral consumption is its grounding within the boundaries of the contemporary marketplace. Ancestral consumers might find aspects of modern life objectionable, but rather than rejecting them outright, seek to integrate what they perceive as authenticity into their everyday consumption behaviors. Aspiring to a mythical standard of authenticity while simultaneously operating within the conventions of modern economic hegemony (Beverland & Farrelly 2010) gives rise to the paradox at the heart of ancestral consumption, a process we term *conceptual compromise*. In the case of ancestral consumption, there is conflict between the mythical and the attainable. Much of this tension arises from the often overwhelming stream of information consumers receive from marketers, self-help gurus, popular media, friends and family, salespeople, other consumers, academics, bloggers, and more. In this environment, attempting the optimal decision can become a murky estimation. Furthermore, physical reality often intrudes on people's best-laid plans. For example, runners who seek the authenticity of unshod running typically wear shoes specifically designed (and marketed) to approximate running barefoot, simply because actually running without shoes is too uncomfortable. In general, Western consumers are savvy enough to recognize that ancestral products are not entirely untainted by modernity, yet consume them nonetheless – hence, engaging in conceptual compromise.

Research on consumers' interest in extraordinary experiences (e.g., Arnould & Price 1993, Celsi, Rose & Leigh 1992, Kozinets 2002, Tumbat & Belk 2011) finds that modern life is tedious, enervating, and repetitive. Consumers seek transformation through hedonic consumption, e.g., skydiving, mountaineering, river rafting, that allows them to feel fully alive (Campbell 1987). Though motivated – in part – by similar dissatisfaction with modern conventions, ancestral consumers seek vitality through hedonic consumption that is *not* extraordinary. Rather, their focal behaviors involve everyday, routine consumption, such as diet and exercise.

Regardless of their motivations, consumers pick and choose which products and industries to avoid in favor of ancestral alternatives. For example, someone might work for a large, multinational corporation, yet consume only organic, heirloom, locally-grown foods. Very few consumers attempt to entirely avoid technological/marketing advances (Austin et al. 2007), lest they completely alienate themselves from the flow of modern life (Dobscha 1998). Given the strictures of modernity, i.e., how bound up people are with markets and technologies, including the poorest people in the world (Prahalad 2010), it is actually quite challenging for consumers to simplify their lives and still take advantage of the health and lifestyle advances of the 20th century. Conceptual compromise exists because people want to live "authentically," but only as long as the discomfort authenticity engenders is tolerable.

This conceptual investigation integrates literature from academia and the popular press to examine consumer pursuit of the ancestral self. We focus on ancestral consumers' preference for products and brands that support and reinforce their desire for au-

thenticity, but which simultaneously keep them embedded within Western socioeconomic convention (Brickman & Campbell 1971). We investigate the dimensions of two focal constructs – ancestral consumption and conceptual compromise, explore the tensions between the aspirational and normative aspects of these constructs, and present a conceptual model of decision-making in this domain.

THEORETICAL AND CONCEPTUAL BACKGROUND

The forces of both modernism and postmodernism contribute to consumers' sense of being unmoored in the marketplace. In the late 19th century, modernism ushered in "boundless opportunities for self-transformation" (Kozinets & Handelman 2004, 692), contributing to the dilemma of consumer hyperchoice (Mick, Broniarczyk & Haidt 2004). In the current, postmodern/social media era, empirical information has become fragmented and de-centered, leading consumers to see "truth" as a subjective construct (e.g., Arnould and Thompson 2005, Arias and Acebron 2001, Firat and Venkatesh 1995). When overwhelmed by complexity, consumers typically cherry-pick information to support whatever belief is most desirable or involves the least effort (Tversky & Kahneman 1974, Fiske & Taylor 1991).

Extant research describes Western consumers' tendency to seek stability, authenticity and "realness" through experiences and products that promise a return to a romantic concept of simplicity. Unlike the quest for "primitivism," which has been researched extensively, ancestral consumption does not embrace foreignness as superior to the consumer's native culture (cf. Canniford & Shankar 2007). Nor do ancestral consumers necessarily engage in cultural appropriation of "exotic," "lower" cultures (Canniford & Karababa 2012, Costa 1998) in their pursuit of more authentic lifestyles. Rather, the search for the ancestral self involves looking to a generalized (or even fictionalized) human past that offers simplified guidance for how life "should be," without disrupting how life already is.

A plausible explanation for the popularity of ancestral consumption lies in its mythic nature (Brown et al. 2013), since it accommodates a variety of consumer desires to re-create a past when humans were supposedly happier and healthier than we are now: a time and place where people were not indoors most of the time, largely sedentary, obese, disconnected from their food sources, and interacting more often with screens than with faces. Although mythical, the idea of ancestral consumption is normative, insofar as people believe that it's the way we have evolved, as organisms, to flourish. Ancestral consumers believe that although our built environment has changed radically, we are not so different from the Homo sapiens of 30,000 years ago, and should therefore consume accordingly. Hence, the appeal and success of *Born to Run* and similar titles. However, our understanding of how our ancestors lived 30,000 years ago is extremely limited; our understanding how our ancestors lived even *300* years ago is not entirely clear. Therefore, ancestral consumption, while normative on its face, is guesswork, at best. In other words, the ancestral self is a myth.

Previous research has found that myths provide salvation in times of socio-cultural and identity uncertainty (Brown et al. 2013), and acquire widespread popularity because they are both universal and singularizable. Prominent myths take hold in the public psyche because they have broad appeal, yet are vague enough to allow each individual to derive his or her own understanding of what the myth means. The mythology underlying ancestral consumption addresses consumers' unarticulated fears (Brown et al. 2013) in this case, their health and well being, and the confusing nature of an asymmetrical, technocentric, modern marketplace. ("Are my choices causing me more harm than good? How do we really know what's best? The science is always changing.") For many consumers, ancestral con-

sumption represents an unconscious flight from complexity (Simon 1957), and finding a simple and actionable coping strategy for such vexing questions is a source of relief for consumers, even if it's built on a myth.

As a mythical concept, the ancestral self is amorphous, closely linked with the zeitgeist, and therefore easily shaped, promoted and manipulated by marketers. (Consider the impact of *Born to Run* on consumers and the market, from supply chains through point of sale.) The fact that the ancestral self is a moving target, susceptible to market forces, means that the reality of pursuing it is far from simple, and not necessarily beneficial to the consumer. Given that people seeking ancestral products and experiences are not typically interested in fundamentally altering their consumption patterns, i.e., consuming less and disengage from modern economic structures, the ancestral consumer is for sale.

This has powerful implications for marketers. The paradox of "barefoot running shoes" is a case in point. In theory, barefoot running should simplify the act of running, and require less time, effort, and money than conventional running. In fact, the popularity of *Born to Run* sparked enormous consumer interest in specialized shoes. Consumers intrigued with the idea of running barefoot ironically began to believe that they needed *more* shoes in order to run "better," e.g. more efficiently, faster, with fewer injuries (Austin 2013). This effect has been so powerful that even dilettante runners are now likely to have a wardrobe of differentiated shoes.

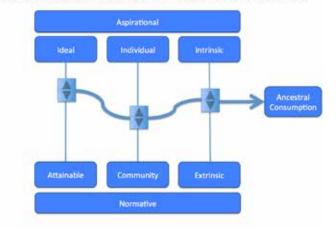
The notion that one needs to purchase additional equipment in order to run "barefoot" highlights the contradictions and compromises central to ancestral consumption. Ancestral consumers are not necessarily voluntary simplifiers (Gregg 1936), consumer rebels (Dobscha & Ozanne 2001), or activists (Kozinets & Handelman 2004) – previously studied populations with superficial similarities to ancestral consumers. Rather, ancestral consumers pursue "authenticity" without challenging or venturing beyond the normative structure of accepted/acceptable market exchanges. As Daniel Lieberman writes in *The Story of the Human Body*, "advocates of primal lifestyles are not advocating that you quit your job, move to the Kalahari Desert, and abandon all the best conveniences of modern life such as toilets, cars, and the Internet (which is essential to blog about your Stone Age experiences to other similarly minded folks)" (Lieberman 2013, 7).

Blogging aside, most manifestations of ancestral consumption are individualistic, in both philosophical orientation and in practice (Christopher & Hickinbottom 2008). This is a significant departure from other forms of alternative consumption documented in prior research, which tend to be community - or ecosystem - oriented. For example, in his examination of "consumer emancipation," Kozinets (2002) finds that consumers at the annual Burning Man celebration seek *authentic community* with their fellow participants and often carry the lessons they learn back to their "regular" lives. Dobscha and Ozanne (2001) interview environmentally focused subjects whose everyday choices reflect their desires to protect themselves, their community, and the natural environment from as many environmental adulterants as possible. Sandikci and Ger's (2010) female Turkish subjects seek a simple guiding principle that "provides a solution to the macro and micro anxieties of the modern world" (24). On the surface, these sentiments echo the desires of ancestral consumers, yet all these behaviors result in the formation of new communities. Ancestral consumers appear largely unconcerned with the community implications of their consumption. They are not hostile toward their fellow travelers (cf. Tumbat & Belk 2011), they simply co-exist. Those who socialize and exchange information related to their behavioral choices and associated conceptual compro-

mises (e.g., bloggers) could be considered a community of practice (Wenger 2011), but they are generally not cohesive enough form a brand community (Muniz & O'Guinn 2001).

Although building community is not a priority for ancestral consumers, the motivation to engage in ancestral behavior is not completely intrinsic. Promotional messages associated with this phenomenon are often based on socially oriented intrinsic motivations (Nicholls 1984), i.e., building a community of individuals. For example, Vibram, a dominant player in the barefoot running market, is currently running a "What's Your Story?" campaign, leveraging the notoriously eccentric Olympic skier Bode Miller to champion the notion of "carving [your] own path" (Vibram 2014). This appeal is in line with optimal distinctiveness theory, which holds that consumers cultivate "optimal identities" by balancing their need for uniqueness and need for affiliation (Brewer, 1991, 2003; Sheldon & Bettencourt, 2002). In general, the factors driving ancestral consumption appear to favor individualism over collectivism, while couching the appeal of the behavior in terminology that is non-threating to modern market structures.

METHODOLOGY AND MODEL

The objective of this research is not only the descriptive illumination of ancestral consumption and conceptual compromise, but also the development of a conceptual model delineating potential drivers of these consumer behaviors. Throughout the model development process, we were particularly interested in the apparent or implied contradictions at play in consumers' pursuit of ancestral consumption. These contradictions, and how consumers resolve them, are the basis for our realization that consumer compromise and ancestral consumption are inextricably linked.


We derived this model by conducting an iterative analysis (Spiggle 1994) in the constructivist paradigm (Creswell & Miller 2010). Following the protocol modeled in Tumbat & Belk (2011), both authors relied on our personal experience as runners – one as a recreational runner, the other as a competitive ultra-distance runner – to inform the initial conceptual data collection (Creswell & Miller 2010). The concept was not running-specific, and included sources such as popular media, documentary films, blogs and discussion boards, books, consumer booklists on Amazon, and survivalist television shows. Although it would be impossible to ignore our experiences as we engaged in the research process, this is not an auto-ethnography (Holt 2003). On the contrary, to limit first-person analytical bias, we consciously bracketed ourselves out of the analysis, and used qualitative analyses independently generated by a trained student research assistant familiar with the material to help assure the validity of our interpretations (Dreyfuss1982; Creswell 2007).

Examining and sorting the data, we inductively developed themes related to running in particular, then ancestral consumption and conceptual compromise more generally, that sharpened the focus of our evolving research questions (Spiggle 1994). We used theoretical lenses suggested by related research on hedonic self-seeking behaviors to inform and deepen our ongoing data collection and analysis, generating avenues for future research to test the concepts that were emerging. This inductive process produced an extensive and wide-ranging literature review (e.g., history, philosophy, economics), which further guided development of the major constructs in our model. Using these interpretive methods of data collection and analysis, i.e, "dialectical tacking" (Beverland & Farrelly 2010, 841, Geertz 1975, 52), we thus arrived at the general model of ancestral consumption and conceptual compromise presented here.

FIGURE 1

Figure 1: A Process Model of Conceptual Compromise.
Conceptual compromise is the process whereby consumers navigate between aspirational and normative consumption on X number of personally salient factors.

DISCUSSION AND IMPLICATIONS

One possible explanation for people's interest in ancestral consumption is the desire to return to a simpler, more natural way of life, yet the majority of consumers show little interest in simplifying their lives more broadly. This apparent contradiction speaks to the tensions and compromises involved in ancestral consumption. Seeking their ancestral selves, consumers run a gauntlet of marketplace dichotomies – compromising all along the way – in search of behaviors to adopt that are satisfactorily "authentic" (cf. Beverland & Farrelly 2010).

Our work extends the research on hedonic consumption, much of which is built upon on a dichotomous paradigm that frames issues around often-weighty consumer choices. Tumbat and Belk (2011), drawing on extant research (e.g., Arnould and Price 1993), explore the domains of "authentic versus commercial, community versus market, nature versus culture, extraordinary versus quotidian, sacred versus profane, liminal versus everyday, and liberating versus constraining" consumption (2011, 44). These dyads, and the consumer culture theory (CCT) work on extraordinary experiences that illuminates them, are invaluable for conceptualizing and understanding the phenomenon of conceptual compromise.

However, we hypothesize that the paired concepts in our proposed compromise model represent endpoints of fluid continuums, rather than dichotomous choices. In other words, conceptual compromise is fluid and idiosyncratic. There are examples of this type of decision-making in the literature as well. Turkish women's veiling (Sandikci and Ger 2010) is an individual choice that represents a conceptual and behavioral compromise between liberation and constraint. Similarly, shoppers at farmers' markets (Thompson & Coskuner-Balli 2007) find harmonies between community and market orientations. As they wend their way through modern life, ancestral consumers do not have to choose one side of the model or the other; rather, conceptual compromise rests on the premise of simultaneity. Consumers can decide what shade of grey best fits their individual needs and satisfies their understanding of the ancestral myth.

Conceptual compromise occurs in an environment that is rich with information and opinions – highly informed, and woefully not – and most consumers' perception of what constitutes the social construct of "authenticity" is filtered through contemporary marketing and media practices (Peterson 2005). For example, for most people, the decision to shop at farmers' markets occurs not because they grew up on farms themselves (USDA 2002), but because they have

learned – from magazines, word of mouth, online, etc. – that this food is somehow better: better for them, better for the environment, better tasting, better all around. Given that consumers' perception of ancestral consumption is similarly formed by interactions with other people (most of whom aren't scientists or historians), we posit that this construct is largely disconnected from the boundaries of time, space, and physical reality.

However, benefits do exist for ancestral consumers, even under artificial, commercialized conditions such as "extreme" obstacle racing, where they set goals, improve their dietary and exercise habits, feel the satisfaction of accomplishment, and have fun (Widdicombe 2014). Nonetheless, instead of natural consumption, ancestral consumers largely engage in *naturalistic* consumption, thanks to the compromises they make. Therefore, we must consider the strong possibility that "the usurpation of reality by the fake" (Brown et al. 2013, 603) has monetary, psychic, and physical consequences. As Sklair (1995, 504) writes,

> *Ordinary so-called 'counter-cultures' are regularly incorporated into the consumer culture and pose little threat. Indeed, by offering both real and illusory variety and choice, they are a source of great strength to the global capitalist system and of personal enrichment for those able to enjoy the abundance of cultural forms undeniably available.*

In other words, their willingness to conceptually compromise makes ancestral consumers susceptible to exploitation in an increasingly complicated marketplace

CONCLUSION

The primary limitation of this research is its conceptual nature. We do not know how large the phenomenon of ancestral consumption is, nor whether it is particularly Western, or even American (the current primary target market for ancestral consumption), or perhaps even upper-middle class white American – a solution to so-called "First World problems" (Oxford Dictionary 2014). Therefore, future research must include exploring the boundaries of such consumption, what forms it takes across populations, and the diversity of consumer desires in this domain. Additionally, since we have argued that conceptual compromise is a process occurring within individual ancestral consumers, we must also consider differences in this process across various consumer segments. Future work can build on the conceptual framework and model presented here by examining how businesses – perhaps even entire markets – emerge in response to consumer demand for ancestral human experiences. In turn, consumer responses to these market developments, both behavioral and emotional, also merit investigation.

Many consumers believe that modern humans have become domesticated to disastrous effect, and seek to reverse this process and its consequences by pursuing the ancestral self. Ironically, from a historical perspective, "the idea of a self that can determine the good through inward reflection would be incomprehensible to residents of ancient and pre-modern societies" (Christopher & Hickinbottom 2008, 567). In other words, ancestral consumers' motivations and behaviors would be unintelligible to the very types of people they are trying to emulate. Conceptual compromising allows modern, Western consumers to approximate traditional behaviors while essentially ignoring the profound philosophical underpinnings of those behaviors. Irrespective of physiology, diet, training, Westerners will never be able to run like the Tarahumara because they are not Tarahumara (McDougall 2009). Potentially more troubling is the prospect that "for many non-Western folk and indigenous psychologies, the kind of separate sense of self that is taken for granted and promoted in

Western cultures is seen as illusory, limited, and the source of suffering" (Christopher & Hickinbottom 2008, 568). By so strongly linking ancestral consumption and self-determination, consumers who seek enlightenment through these pursuits and behaviors might actually be moving further from it.

Can Sustainability be Luxurious? A Mixed-Method Investigation of Implicit and Explicit Attitudes towards Sustainable Luxury Consumption

Daisy Beckham, London School of Economics, UK

Benjamin G. Voyer, ESCP Europe Business School & London School of Economics, UK

INTRODUCTION[1]

The ecological impact of our day-to-day consumption has been called one of the greatest concerns of modern times (Randers, Meadows, Behrens, & Meadows, 1974; Turner, 2008). Existing research has addressed the issue by focusing on sustainable commoditized products, such as food (e.g. Johnston, Szabo & Rodney, 2011; Verbeke & Viaene, 1999) or cosmetics (Freestone & McGoldrick, 2008; Ngobo, 2011). Despite commodity consumption's much larger market share and environmental impact, the luxury goods market is a major influence on the consumption and production habits of lower-end goods (Kapferer, 2013). Existing studies investigating the issues of sustainability in the luxury industry are scarce, and mainly focus on advertising strategies (cf. Boenigk & Schuchardt, 2013; Steinhart, Ayalon, & Puterman, 2013). Yet many consumer sectors attempt to capitalise on consumers' desire to own luxury goods by mimicking dominant social representations surrounding the luxury sector. A notorious example is 'fast fashion' – low-cost clothing quickly produced in line with luxury trends – which tries to mimic the luxury industry's exclusivity through limited functional life, planned obsolescence, and quick turnaround of production (Fletcher, 2008; Guiltinan, 2009; Joy, Sherry, Ventakesh, Wang, & Chan, 2012).

The luxury-goods market thus fuels the extravagant expenditure and over-production which characterises mass-market consumption, and is in direct opposition of the notion of sustainability. In the present research, we explore the associations between luxury consumption and sustainability, investigating attitudes towards sustainable luxury.

LITERATURE REVIEW

Luxury and Sustainability in Socio-Historic Contexts

The social histories of luxury and sustainable consumption indicate a conceptual opposition, suggesting that the juxtaposition of the two concepts may be ill-received by consumers. For instance, Berry (1994), analysing the concept of luxury notes that its inherent values of hedonism, expense, rarity, affluence, and inessentiality mean that it has, particularly in Europe, been historically perceived as a social and moral transgression. To Plato, a luxury-consuming society was an 'unhealthy', 'fevered' polis in contrast to 'healthy' societies that limit themselves to necessities, and Hobbes (1651) argued that man's natural insatiability for luxury leads to violence and anarchy. Weber's (1930) seminal study reveals how these overtones have emerged from Europe's religious history: how Protestantism's reaction against Catholic ostentation gave rise to an enduring social context in which wealth was ethical only when industriously gained and austerely used. Luxury was seen as moral and spiritual depravity: 'idolatry of the flesh' and rebellion against the innate social order (Slater, 1997). This legacy shapes views of luxury even today (cf. Hilton, 2004).

Conversely, sustainability's inherent ethically-grounded values of altruism, restraint, and moderation contrast with luxury's inherent hedonism, aestheticism, rarity, affluence, superfluity, and its immoral socio-historical narrative (Carrier & Luetchford, 2012).

The Self, Luxury, and Power

Luxury possessions also reflect a particular manifestation of social self. There is a consensus within the literature (Bourdieu, 1984; Douglas & Isherwood, 1996; Veblen, 1899) that luxury consumption is a highly communicative act, signalling status, wealth, class and thus social and economic power (see also, Eastman, Fredenbergwe, Campbell, & Calvert, 1992). Power is commonly conceptualised as the capacity to influence others while resisting external impositions of influence (Hogg &Vaughan, 1995). Indeed, studies suggest that powerful individuals have a greater capacity to resist external normative influence, making them more likely to behave in socially-unacceptable ways (cf. Brown & Levenson, 1987; Caspi, Lynman, Mofitt, & Silva, 1993; Harnett, 2010; Magee, Gruenfeld, Keltner, & Galinsky, 2005; Xianchi & Fries, 2008). Moreover, there are indications that individuals can also gain status and power by breaking social norms. In four studies, van Kleef, Homan, Finkenauer, Gundemir, and Stamkou (2011) showed that participants perceived individuals violating norms – by, for example, dropping cigarette ash on the floor or taking food from others – as much more powerful than non-norm-violating individuals. The researchers concluded that rule-breaking aids in ascendance of power in others' eyes.

Altogether, these findings suggest that consumers use luxury consumption to enhance status and power, and that this might also result in being more likely to violate social norms related to responsible and sustainable consumption rather than actively engaging with them.

Sustainable Luxury: Mixed Findings

Although the past two years have seen a few relevant qualitative and quantitative investigations examining consumer attitudes towards sustainable luxury, these have presented a range of inconsistent or contradictory conclusions. Steinhard, et al. (2013) conclude that an environmental claim positively enhanced consumer perceptions of both utilitarian and luxury products through an experiment in which subjects were asked to imagine scenarios in a supermarket setting in which they came across toilet paper (a 'utilitarian' product) or 'fancy napkins' (their example of a luxury) that were either marked with an eco-label or not (see also Boenigk & Schuchardt, 2013). Ducrot-Lochard and Murat (2011) theorised that the luxury industry will logically evolve towards sustainability as luxury customers have extended their high quality expectations to include environmental factors. Additionally, Kapferer (2013) reasoned that luxury already possesses sustainable characteristics, calling it "the business of lasting worth" and durability.

However, other evidence suggests sustainable luxury goods are perceived more negatively, and seen as less desirable, than regular, non-sustainable luxury products. Achabou and Dekhili (2013) presented affluent male and female French participants with labels for luxury Hermès-branded shirts, some of which were described as containing recycled material. A significant negative correlation was found between the perception of the product and the presence of recycled fibres. Also, a brand's environmental commitment was the least important selection criterion in luxury purchasing decisions (with quality, price, and brand reputation the most considered; see also Joy et al., 2012). Similarly, Davies, Lee, and Ahonkai (2012) found that consumers considered sustainability and ethics much less in their luxury consumption decision-making process than in their commodity consumption decisions, although luxuries were perceived as relatively more sustainable

when compared with commodity products. Participants also perceived luxury goods as having a lesser impact on the ethical image portrayed to peers, and thus fewer social consequences.

A MIXED-METHOD APPROACH TO THE STUDY OF SUSTAINABLE LUXURY

The present research offers a mixed-method approach to the study of sustainable luxury consumption. Consumers' attitudes towards sustainable luxury consumption were explored using implicit (studies 1 and 2) and explicit attitudes measures (study 3). The notion of sustainable luxury was further explored using a focus group (study 4). The combination of quantitative and qualitative methods addresses recent calls for mixed-method research (Peracchio, Luce, & McGill, 2014), and was used as a triangulation tool to further understand the basis upon which consumers attitudes towards sustainable luxury goods are held. As previous research (e.g. Davies et al., 2012) has observed that men have a higher degree of ambivalence towards luxury consumption, only women were included in these studies.

STUDY 1: IMPLICIT ATTITUDES TOWARDS SUSTAINABLE LUXURY

The purpose of the first study was to test the hypothesis H1 that consumers will more readily associate luxury with unsustainability than with sustainability.

Method

Implicit attitudes towards sustainable luxury consumption were examined using the Go/No-Go Association Task (Nosek, & Banaji, 2001). The test investigates implicit attitudes by assessing the strength of a participant's automatic associations between mental representations by measuring response latencies in sorting words into categories. Faster responses indicate easier pairings and thus stronger implicit associations than slower or inaccurate responses. In this study the object category 'luxury' was paired with the attribute categories 'sustainable' vs. 'unsustainable' to study participants' associations of luxury and sustainability. 31 women were surveyed in a pre-test, to collate text stimuli for the attribute categories 'sustainable' and 'unsustainable. These participants wrote down as many words associated with 'sustainable' that they could in 90 seconds (e.g. green, eco-friendly…). 31 additional women aged 16-51 (M=31.16, SD =10.59) took part in the subsequent Go/No-Go association task.

Results

Subjects' scores showed a greater sensitivity to the pairing of luxury brands and words associated with unsustainability (,) than for the pairing of 'luxury' + 'sustainability' (,). A t-test revealed a statistically significant difference between consumers associations of luxury and unsustainability, compared with luxury and sustainability (. Table 1 summarizes the results.

STUDY 2: IMPLICIT ATTITUDES TOWARDS SUSTAINABLE LUXURY VS. COMMODITY

The purpose of study 2 was to further explore implicit attitudes towards sustainable luxury goods, by adding commodity consumption products as a context. Davies et al. (2012) suggest that a context of commodity consumption induces consumers to perceive luxury products as comparatively more sustainable. Study 2 therefore tested the hypothesis H2 that, when high-street brands are added as a context, luxury brands would not be associated with unsustainability.

Method

Procedures were similar to study 1, with the exception that the object categories 'luxury' vs. 'high-street' were paired with attribute categories 'sustainable' vs. 'unsustainable' to test whether a change in context affects implicit attitudes. The words for the category 'luxury' (Céline, Gucci…) were the top 18 brands from the World Luxury Index Report (2012). Eighteen well-known women's high-street brands were chosen for the 'high-street' category (Marks & Spencer, Primark…), as no equivalent report was found. Well-known mid to low-price point brands were chosen to prevent any overlap with the 'luxury' brand category. 21 women aged 22-61 (M=31.43, SD =12.41) took part in the study.

Results

No effect of pairing direction was found in Study 2, supporting hypothesis H2 that participants would not associate luxury with unsustainability against a context of high-street brands. Table 1 summarises the results.

STUDY 3: THE EFFECT OF A SUSTAINABLE LABEL OF EXPLICIT ATTITUDES TOWARDS LUXURY GOODS

The purpose of study 3 was to further explore attitudes towards sustainable luxury by looking at the effect of a sustainable product label on consumers' explicit attitudes towards luxury goods. Study 3 used a within-subject experimental design to test the hypothesis H3 that consumers will find luxury items less luxurious when labelled 'sustainable'.

Method

41 women aged 17-66 (M=29.87, SD =11.97) took part in the study. Participants taking the survey were shown six pictures of well-known luxury handbags, in randomised order, as visual stimuli. Each bag was accompanied by a short standardised description giving the bag's name and brand. Three bags were randomly labelled 'sustainable versions' by a computer, with the remaining three left unlabelled. This label was left non-specific – not clarifying what was meant by 'sustainable', as it was desired that the results give a general attitude towards sustainable luxury consumption, and providing greater detail would have limited the results' scope. Participants were then asked whether they liked each bag, how much they believed each bag to cost, how much they would pay to own each bag, and ranked how luxurious, how desirable, and how sustainable they found each bag out of 100. Each bag had a specified £1000 price range to anchor estimations of cost and ensure that they were comparable across participants (ranging from £1000-£2000 to £3500-£4500). Finally, participant's self-perceived power was measured on a 7-point scale using a measure adapted from Smith, Wigboldus, and Dijksterhuis (2008). Scores of luxury, desirability, and sustainability were normalised within participants to control for subjects' individual sensitivity to these concepts: for example, all the bags may have seemed highly luxurious to one participant, but mundane to another. To obtain this normalised ranking, each score was compared to that subject's average score across each category.

Results

A manipulation check confirmed that participants ranked bags labelled sustainable as 6.94 percentage points more sustainable than unlabelled bags (). Controlling for participants' own assessments of bags' sustainability, bags labelled sustainable were ranked on average 4.87 percentage points less luxurious than bags without such a label (), supporting hypothesis H3, that subjects would deem luxury items less luxurious when labelled sustainable. Sustainability labels did not affect bags' desirability. Additionally, although subjects rated a bag more luxurious when they were told that its price range was higher (with a £1000 increase in price range corresponding to a 4.74-point increase in luxury scores;), price had the opposite effect on assessments of

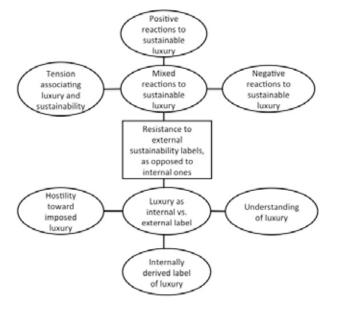
Note. Coefficients and standard errors are calculated by regressing linearly each of the four columns on the response variable above (1-4), along with responses to 'Do you like it?' and 'What do you think is the price?'. Multiple regressions on variables 'Do you like it' and 'What do you think is the price?' are not reported here as no significant effect of sustainability label, sustainability ranking and luxury ranking emerged from the analysis.

[a] This relationship is significant when 'Labelled Sustainable' is regressed on 'How luxurious…', controlling for 'How sustainable…'. (See text.)

[b] A dash indicates that this variable was excluded from analysis.

[c] These rows were regressed separately on the response variables above.

* $p < .05$. ** $p < .01$. *** $p < .005$.


sustainability (with the same £1000 increase decreasing sustainability assessments by 4.59 percentage points; ; see table 1).

Other findings indicated a more complex relationship between luxury and sustainability. For example, sustainability labels or sustainability scores did not affect how much subjects were willing to pay for the bags. There was also a positive association between subjects' own rankings of sustainability and luxury, with a one-point increase in sustainability scores corresponding to a 0.168 increase in luxury rankings . Similar positive relationships were observed between luxury scores and desirability rankings and between sustainability scores and desirability rankings (see Table 1). Furthermore, significant interaction effects of self-perceived power on the relationship between subjects' sustainability ratings and luxury and desirability ratings were found. A one-point increase in subjects' self-perceived power scores increased the coefficient of the relationship between sustainability and luxury scores by 0.209 , and increased the coefficient of the relationship between sustainability and desirability scores by 0.179 Therefore, while people with high self-perceived power scores had a strong positive relationship between sustainability and perceived luxury, and between sustainability and desirability scores, these effects decreased in size for people with lower self-perceived power scores (Table 1 summarizes the full results).

STUDY 4: A QUALITATIVE PERSPECTIVE ON SUSTAINABLE LUXURY CONSUMPTION

A focus group was used to further probe results from the three previous studies, particularly the contrasting findings on the effect of sustainability labels (whether externally-labelled sustainable, or deemed sustainable by the participant) on luxury ratings. 6 women, aged 21-25, were selected following a purposive heterogeneous sampling procedure, on the basis of including a mixture of regular and infrequent luxury customers with varying interests in sustainable practices. The focus group was transcribed and analysed using thematic analysis (Braun & Clarke, 2006, see figure 1 for thematic networks).

Figure 1: Summary of the Qualitative Study (4):
Thematic Networks

A perceived incompatibility between sustainability and luxury for luxury consumers.

Participants disagreed with the argument that luxury may already be viewed as intrinsically *sustainable* because of its higher quality and *durability*. Likewise, the conceptual differences between 'sustainability' and 'luxury' and their corresponding divergent social histories were referenced by the group. Luxury consumption's intimate connection with class, status, and social stratification was mentioned 8 times. Conversely, sustainability was spoken of as a social responsibility.

When discussed generally, sustainability and luxury were often implied to be incompatible, with participants apprehensive and uncomfortable when discussing their juxtaposition. Five of the group members opined that luxury shoppers would react negatively to sustainable luxury ("*The people who normally buy from Gucci would not be inclined to buy sustainable shoes…I think it takes away the 'special factor' for that market*", participant 1). This was also related to the notion of status, with participants implying that sustainable luxury bags do not carry as much status-increasing social capital as non-sustainable luxury bags.

However, when discussing more personal opinions, many group members had positive reactions to sustainable luxury. For example, when asked how she would feel about a sustainable version of a luxury bag she liked, one participant said: "*my opinion would change. I would be happier to buy them, but I would say that most of the people don't care*." (participant 5). This suggests that individually-held attitudes are more complex than either being positive or negative towards sustainable luxury, and that the results of the Study 1 may indicate perceived wider social belief rather than individual attitudes (cf. Olson & Fazio, 2004).

Internal vs. external labels of luxury and sustainability

Communicating status through display of luxury was described in a negative light as something predominantly that others did or that was enforced upon individuals. Participants were averse to being defined by luxury possessions and brand image, and valued luxury purchases when they were a product of internal taste rather than an externally-imposed image. This same pattern – negative perceptions of imposed definitions and positive reactions to internally-derived labels – was replicated in the group's reactions to sustainable luxury. There were 20 separate vocalisations of cynicism towards brands' own labels of sustainability on luxury items, mostly due to expectations of ulterior motives of image or profit enhancement. When discussing sustainable luxury in these terms, the group showed no desire to own it, echoing study 3's result that bags labelled sustainable were ranked less luxurious than those not labelled. However, group members spoke of desiring to own sustainable luxury when this sustainability was premised on an internally-derived belief, mirroring the survey results that if subjects themselves ranked a bag as more sustainable, they would pay more to own it and rated it more luxurious ("*I still would consider [a sustainable luxury product] better. If it's sustainable more, then it's better…It has everything I want it to be*", participant 3*). In both of these cases, attitudes towards luxury and sustainable luxury, participants cast themselves as in tension with and having opposite attitudes to the rest of society.

GENERAL DISCUSSION

The present research highlights the complexity of consumers' associations between luxury and sustainability consumption. In Study 1 participants more readily associated luxury with unsustainability than with sustainability. This was not the case when luxury was assessed against a context of high-street brands (Study 2). This latter result supports the findings of Davies, et al. (2012), that con-

sumers considered luxury products more sustainable when assessed against a context of high-street consumption. Additionally, in Study 3, subjects deemed luxury items less desirable and luxurious when labelled sustainable. Likewise, in study 4, focus group members experienced difficulty attempting to associate the two concepts, echoing established socio-historic legacies of sustainability and luxury, and voiced the belief that luxury shoppers would chose a non-sustainable luxury item over a sustainable one, as this would endow the owner more status, social power and prestige.

The present results, however, also paint a more complex picture, pointing to a contrast between internally- and externally-derived labels of luxury and sustainable luxury. In the experimental survey, subjects' own assessments of bags' sustainability were positively associated with desirability and luxury rankings, and how much subjects would pay for the bags. Similarly, when sustainable luxury was discussed from the point of view of participants themselves believing a product to be sustainable, focus group members displayed an individual preference for sustainable luxury goods, a marked difference to the cynicism which externally-imposed labels of sustainability elicited. Often, participants opined that 'everyone else' would have the opposite reaction.

The above definition of power as the ability to assert one's own influence while resisting others' (Hogg &Vaughan, 1995) appears to be an apt description of the phenomenon observed here. The negative reaction to society's impositions upon the individual – whether imposed characterisations based on inadvertent signalling of luxury status, or sustainability labels on goods – can be seen as a desire to resist society's objectification of the self, or external loci of power. Conversely, the privileging of individual taste and internally-derived labels of luxury and sustainability can be seen as a desire to retain and impose one's own power in resistance.

This interpretation of a struggle between external vs. internal *loci* of labels may be seen to be supported by, and might help reconcile, the contradictory extant research which has found both positive and negative reactions to sustainable luxury. Indeed, previous research which has asked participants to *imagine* sustainable luxury items has found positive reactions towards sustainable luxury (e.g. Steinhart et al., 2013), whereas research presenting sustainability claims on labels has found negative reactions (e.g. Achabou & Dekhili, 2013).

CONCLUSION, LIMITATIONS AND FURTHER RESEARCH

The external validity of the present study is limited to the nature of the sample used (female participants, most of which were students). In addition, the cultural Western individualist context might – at least in part – explain some of the findings, due to the socio-historical and cultural contingency of consumer practice and identities.

The small effect size and large variance from which the results of Study 1 suffered may have been due to the fact that the concepts contrasted in the GNAT were more complicated than those traditionally used in association tests (e.g., 'good/bad' and 'White/Black American') and do not necessarily elicit immediate or automatic reactions. Additionally, subjects were unlikely to have had experience with sustainable luxury goods in the past, and may have had no strong automatic associations to be measured (Bargh, Chaiken, Govender, & Pratto, 1992).

Overall, the present study provided a systematic investigation of attitudes toward sustainable luxury consumption. The apparent complexity of attitudes towards sustainable luxury lent itself well to a mixed-methods approach. From experimental research to consumer culture theory, future research on the topic should combine perspectives to account for the complexity of seizing attitudes towards luxury goods. This complexity could be further explored looking at the attitudes of different types of luxury consumers, for instance investigating whether 'patrician' vs. 'poseur' luxury consumers would express different attitudes towards sustainable luxury products (Han, Nunes, & Dreze, 2010). Additionally, a cross-cultural investigation of attitudes towards sustainable luxury consumption might reveal interesting differences between collectivist and individualist cultures.

Alternative Conceptualizations of the Extended Self

Russell Belk, York University, Canada

ABSTRACT

Belk's (1988) formulation of the extended self is an influential conceptualization of the relation between people and possessions. It has recently been updated (Belk 2013) to include digitally mediated ways of constructing, co-constructing, and expressing self. The updated conceptualization adds brand attachments and virtual possessions to the original specification of possession and person attachments as the foundation for self-extension. But this view of the relationship between the self and the material world is not the only possible view. In this paper I outline alternative formulations that have been proposed for conceptualizing the uses and effects of real and virtual objects in establishing and communicating a sense of self. To keep the task manageable I focus on four alternative conceptualizations and compare them to each other and to the formulation of the extended self by Belk:

1. The Expanded Self (e.g., Aron, Aron, Tudor, and Nelson 1991; Connell and Schau 2013)
2. The Extended Mind (e.g., Clark 2003, 2011; Clark and Chalmers 1998)
3. Multiple Narrative or Dialogic Selves (e.g., Ahuvia 2005; Bahl and Milne 2010)
4. Actor Network Theory (e.g., Callon 1986; Latour 1987, 2005).

These perspectives do not exhaust the alternative possibilities, but are arguably the most fruitful to consider with a focus on implications for consumer behavior. By examining these alternatives we can see what may be added or lost in adopting one of these different perspectives.

In order to save space I will assume familiarity with Belk (1988, 2013), but will bring in elements of this formulation as points of comparison for the other four models. By framing the four comparisons as alternatives I mean to recognize their differences from the extended self formulation, but I do not mean to imply that they are all wholly incompatible with the extended self formulation or each other. As will be seen, none of the five perspectives are simply restatements of each other and each has different implications for researching and understanding our relationship with things.

1. The Expanded Self

The formulation by Aron and Aron (1986) was initially proposed as a model of "including other in the self." That is, Aron and Aron proposed that close others such as our mother and close friends are viewed as a part of self. The inclusion of others as part of self is an element that was included in Belk's (1988) formulation as well and both perspectives were developed empirically by having people rate whether certain people were "me" or "not me." However, Belk's extended self also includes material and non-material objects and places as potential parts of self, while Aron, et al. do not. Nevertheless, as Connell and Schau (2013) observe, some consumer researchers have used the Aron and Aron(1986) framework to also include love not only for people, but also for consumer objects incorporated as a part of self (e.g., Ahuvia 2005; Fournier and Mick 1999). They also note that most consumer researchers cite Aron, et al. (1991) as only involving incorporating other people as a part of self. And they also note that when psychologists cite Belk's extended self, they only refer to the inclusion of objects in self rather than people, thus dif-ferentiating the two approaches based on whether the discussion involves objects or people.

In developing and testing their IOS (Incorporating Other in Self) scale, Aron, Aron, and Smollan (1992) had students identify their closest other. The researchers then represented self and this close other through a Venn diagram composed of two overlapping circles. The subjects were asked to respond to a series of scales pertaining to the diagrammatic representation, including "the degree to which I have expanded myself through being in the relationship with the other person" (p. 608). Reimann and Aron (2009) have recently used the self-expansion model in the realm of consumption by focusing on incorporation of brands within the self, and have developed another scale, Inclusion of the Brand in the Self (IBS). Besides its scale approach, this expansion of the self-expansion model differs from that of the extended self (Belk 1988) by only including abstract brands rather than the singularized possessions that they may become after they leave the marketplace and enter the consumer's life (see Appadarai 1986). In fact Reimann and Aron (2009) posit that the longer the consumer-brand relationship lasts the weaker it becomes (but also that the *brand* is more likely to be seen as a part of self), whereas Belk (1989) contends that for possessions to which we have become attached (e.g., a home, a pet, a wedding ring), the longer the attachment to this specific object, the stronger it becomes.

At a more basic conceptual level, Connell and Schau (2013) aptly note that while the extended self invokes a metaphor of outward extension, the expanded self invokes a metaphor of inward inclusion. Ahuvia, Batra, and Bagozzi (2009) characterize the expanded self as incorporative. As Belk (1988) recognized, the extended self is a masculine metaphor. The expanded self is characterized as a feminine metaphor by Connell and Schau (2013). Ultimately they call for a fusion of the two perspectives.

2. The Extended Mind

As Andy Clark (1997) put it in one of his earlier books on the subject, "Mind is a leaky organ, forever escaping its 'natural' confines and mingling shamelessly with body and with world" (53). He means this quite literally. Not only is the mind seen as embodied, it is seen as extended into the world around us—a phenomenon he calls embedded cognition. Imagine solving a math problem "in your head." This is the way we usually think about the brain and cognition. Now imagine solving it with the aid of counting on your fingers—an embodied example that is easily encompassed within traditional models of the mind, just as using paper and pencil would be. Now imagine solving the problem with the aid of a computer. If it seems problematic to regard this external prosthesis as a part of the mind, imagine that the computer chip that performed the calculation was embedded in your head, effectively making you a cyborg. But we are already cyborgs Clark (2003) maintains. If we read with the aid of glasses or contacts, rely on our smart phone to "remember" telephone numbers and addresses, or use Google to ascertain or verify information, are we not extending our mind with the aid of mechanical and electronic prostheses? If we remember a travel route with the aid of landmarks and road signs these too might be considered to be part of the extended mind. And if we rely on a GPS or augmented reality projected onto our glasses, the same mind extension should apply.

This version of mental extension is quite different from the extended self and the expanded self. We need not be emotionally

attached to our paper and pencil or to the road signs in order to have them be a part of the extended mind as Clark conceives of it. In his model artificial intelligence is just the latest development in a process of mind extension that began when we first learned to throw a stone or to reach the bananas with the aid of a stick. Still, it is a rather structural and cognitive model of behavior. It champions reason and instrumentality. The mind is seen as embodied and embedded in its environment, but it is rational rather than being sentimental in the way that the extended self and expanded self are. It also does not much consider other people as a part of our proximal environment. Other people are seen as components of the system in the same way that the musician uses an instrument or a car relies on its component parts. The human is seen as an adaptive responder relying on the "scaffolding" of our external physical environment to guide behavior. Even culture, language, and institutions are referred to as scaffolding for the brain and as part of the external environment that acts upon the brain. Clark (1997) describes language as "the ultimate artifact … Not only does it confer on us added powers of communication; it also enables us to reshape a variety of difficult but important tasks into formats better suited to the basic computational capacities of the human brain" (193). Call it cognitive imperialism with a dose of behavioralism.

3. Multiple and Narrative or Dialogic Selves

A quite different conception of how the self relates to objects is found among consumer researchers who maintain that the self of an individual should be conceived of as involving multiple or plural selves (e.g., Ahuvia 2005; Bahl and Milne 2010). In this view of the extended or expanded self, we harbor different selves which may feel different attractions, repulsions, attachments, and alienations with regard to a particular objects. For example, Ahuvia (2005) describes Pam whose business woman self purchased a practical dining room table and her bohemian self who loves Bugs Bunny cartoons. Tian and Belk (2005) found that the possessions in professionals' offices often reflected a tug-of-war between their home self and work selves. And Bahl and Milne (2010) find that Brad's closed self likes donuts as a comfort food while his critical self sees donuts as making him fat and unattractive to girls and his athletic self resists donuts as slowing his soccer performance.

In such conceptualizations, the self is comprised of either simultaneously or sequentially different personas that are differentially attracted to certain objects. Still, as Ahuvia (2005) sees it, there is a drive toward unity through a constructing a coherent self narrative. He finds that the conflicting selves are resolved through one of three processes: choosing one self over the others and demarcating this self through choice of loved objects; compromising selves by finding middle ground objects that are compatible with conflicting identities; or synthesizing selves by finding objects that allow each identity to be recognized and reconciled. Bahl and Milne (2010) find that different strategies are used in a dialogue between different selves in order to arrive at a meta-self. These strategies involve managing the conflict through negotiation or coalition, avoiding the conflict, for example by compartmentalizing and accepting that different selves will prevail on different occasions, or privileging a dominating self that suppresses the other selves.

If we were to diagram the conceptualization of self and consumer objects within this alternative perspective that sees the self as multiple, we might well find something like the multi-dimensional scaling representations that Bahl and Milne (2010) obtained from their informant data. Such a representation consists of the different selves surrounded by different, but sometimes overlapping, clusters of objects and activities. As Belk (1988) originally recognized, the

self is dynamic and ever changing. Likewise these multiple self perspectives also recognize the shifting and dynamic nature of the self and the objects and choices through which it is expressed and transformed. But what these perspectives also recognize along with Belk's (2013) updated model is that the idea of a singular core self is an illusion. Desirable as this illusion may be, these perspectives also recognize a more complex view of the simultaneous presence of different selves supported by different sets of objects and activities.

4. Actor Network Theory

Actor Network Theory or ANT recognizes that actions are caused by both human and non-human actants. That the human actants often engage things intentionally and the non-human actants unintentionally is not of great consequence in this perspective. La-Tour (2005) points out that the following alternative formulations of self and object interactions are not the same and the latter are difficult or impossible to imagine:

> *...hitting a nail with and without a hammer, boiling water with and without a kettle, fetching provisions with or without a basket, walking in the street with or without clothes, zapping a TV with or without a remote, slowing down a car with or without a speed-bump, keeping track of your inventory with or without a list, [or] running a company with or without bookkeeping (p. 71).*

Thus, we may properly regard these objects as acting—the hammer hits the nail, the kettle boils water, the basket holds provisions, and so forth. But it takes the whole network of actants, usually including the human for these actions to take place.

In some instances like the hammer and the builder, the musical instrument and the musician, and the computer and the hacker, the symbiosis of the person and the thing allows actions that would not otherwise be possible (Csikszentmihalyi and Rochberg-Halton 1981). In other instances however, the object takes on functions that would once have resided with the person alone. Tian and Belk (2005) found in their study of offices that "prosthetic possessions" like computers and phones, "remembered" things for consumers. Dengeri-Knott and Molesworth (2013) found that consumers used software like their Amazon wish lists to "desire" for them. That is, once they put objects on the list, they no longer had to sustain their desire in their minds because the list did it for them. As we rely on our digital devices to do more and more, they become an increasingly indispensable part of our selves. ANT also specifies that as long as networks of people and things are functioning smoothly, "punctualization" occurs—that is the individual parts of the network fades from our awareness and we concentrate only on the whole. For example, so long as our car is working properly, we remain unaware of its individual parts and even our own actions in operating it. But when the engine fails to work, depunctualization occurs and we suddenly become aware of the car and driver as a collection of parts (LaTour 1999).

Besides a person and multiple objects, actor networks are also often composed of multiple people. For instance Epp and Price (2010) chronicle the changing role of a dining room table in knitting together the lives of an extended family. This inclusion of multiple people in the human-object assemblage marks an important difference from each of the other formulations considered here. Whereas the focus of the extended self or mind is on one person or mind extending out or incorporating objects and people within itself, and the focus of multiple selves is on connecting different objects to different personas, in ANT the focus is on networks of multiple people and objects which act together in establishing the relationships between

persons and things. That is, from an ANT perspective we are not focused on the internal representation of self as much as the fact that people and things act together to cause behaviors to occur. We might in fact see the entire Internet as being the result of an unseen network of people and things (users, programmers, digital devices, routers, servers, and so forth) culminating in the vast array of information, images, games, and more that we can access online. On a narrower scale, our network of "friends" on Facebook help to co-construct our identity with posts, photos, tags, and other "metadata" that appears on our timeline (Belk 2013). Our interconnections to others are invoked and exploited when we ask online, "How do I…?" (e.g., download photos from an iPhone to my computer). Meaning too is jointly constructed. And while ANT has receive the most attention in consumer research, there are many other perspectives on empowered objects including entanglement theory, vibrant matter, alien phenomenology, postphenomenology, assemblage theory, meshwork, the political ideology of things, and trajectories of the technium.

CONCLUSIONS

We can see in these alternative formulations to the extended self an enriched and enhanced set of perspectives for construing the relationship between people and things. There is more to these differences and possibilities than I have been able to summarize here. The table below provides an even more condensed summary of these distinctions.

Table
Summary of Differences in Models of Self and Things

	Extended Self	Expanded Self	Extended Mind	Multiple Selves	ANT
Person Focus	Individual	Individual	Individual Mind	Multiple Facets of Self	Multiple Individuals
Object Focus	Possessions & Brands	Brands	Objects in the Environment	Objects & Actions	Objects & Possessions
Relation to Objects	Emotional Attachment	Love/Hate	Functional	Emotional Attachment[1]	Emotional or Functional
Relation to Self	Extension	Inclusion	Cognitive Incorporation	Inclusion[2] or Extension[3]	Behavioral Interaction

[1]Different selves may feel differential attachment or repulsion to an object
[2]Ahuvia (2005)
[3]Bahl and Milne (2010)

As noted earlier, these alternative formulations are not necessarily mutually exclusive. Ahuvia (2005) has been cited here with regard to both expanded self and multiple selves. Tian and Belk (2005) as well as Bahl and Milne (2010) have been cited in the context of both extended self and multiple selves. Connell and Schau (2013) combine extended and expanded self. And Epp and Price (2010) invoke both ANT and extended self perspectives. Nevertheless, the different mechanisms and emphases of the models summarized in the table suggest that they all bring something different to the party. Since much of the exposition of these models, including the present summary, is conceptual, what seems most rewarding and needed is empirical work that looks at the array of options available and chooses the one or ones that seems most capable of enlightening the problem at hand.

What is common in all of these models is that the self does not end with the mind and the body. People, places, and things, including virtual things, are all a part of our identity and behavior. The ways in which these entities interact is the primary focus of study in consumer research. To have such an array of options at our disposal for studying and discussing this central consumer research mission should be seen as potentially enriching the original concept of the extended self.

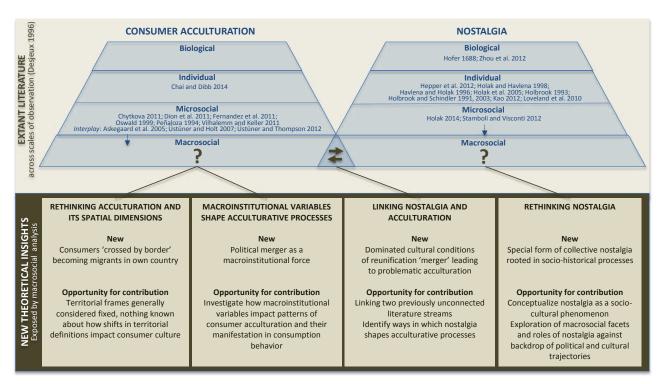
Zooming In While Zooming Out: How a Consumption Context Animates a Macro-focus Investigation and Stimulates New Opportunities for Theoretical Insights

Katja H. Brunk, ESMT European School of Management and Technology, Germany

Benjamin J. Hartmann, Jönköping University, Sweden

ABSTRACT

Consumer researchers have long recognized the power of contexts in facilitating theoretical insights (Arnould and Thompson 2005; Arnould, Price, and Moiso 2006) and have discussed the importance of historicizing (Brown, Hirschman, and Maclaran 2001), as well as the need to pay attention to the context of context (Askegaard and Linnet 2011; Earley 2014). This conceptual article further expands these discussions on how context matters by focusing attention on the predominant level of analysis linked to particular theoretical constructs. Because consumer researchers have been utilizing contexts as platforms for their theorizations, the ontological status of certain concepts reflects a particular level of analysis demanded by particular contexts. This eventually leads to an inherent link between the conventional understanding of a concept and a particular class of context and level of analysis. In this article, we illustrate and discuss how contexts can be utilized to rethink the ontological status of concepts—once derived through study within particular contexts—by highlighting the importance of a circuit of analysis that involves various levels of analysis.

We exemplify this argument by a focus on the concepts of *consumer acculturation* and *nostalgia*, and demonstrate how a particular research context—in this case a divide in consumption patterns between formerly East and West Germany—can challenge the conventional understanding of these concepts colored by prevalent individual or microsocial levels of analysis. By moving the analysis to a macrosocial level we can break free of conceptual conventions derived from earlier contexts and raise novel research questions about the interplay between different scales of observation (Desjeux 1996). This opens the door to rethinking the ontological status of consumer acculturation and nostalgia, to derive new theoretical insights, uncover complex interactions, and identify theoretical boundary conditions that have eluded us so far.


The paper is structured as follows: We start with a description of the facilitating research context before discussing how contexts can be leveraged for theory building using a multilevel circuit of analysis. We proceed with an illustration of a concrete example of this process by taking inventory of existing literature on consumer acculturation and nostalgia, and showcasing how a macrosocial level of analysis stimulates reinquiry of these concepts. This in turn fertilizes new theoretical insights and links, which are synthesized in Figure 1. We conclude with a discussion of methodological, conceptual, and theoretical contributions and implications.

FACILITATING RESEARCH CONTEXT: CONSUMPTION IN GERMANY

The research context, which serves to illustrate how a shift in the level of analysis exposes voids in previous literature and thus new theoretical connections, revolves around consumption behavior in contemporary Germany. When it comes to consumption, Germany is still a divided country: consumers of the former East (GDR) and West (FRG) differ in their purchase choices and patterns as well as the meanings they attribute to consumption overall.

FIGURE 1

Facilitating research context: Prevailing divide in East and West German Consumption Behavior

What belongs together would soon grow back together: The fall of the Berlin Wall and subsequent reunification in 1990 induced a process of adaptation and acculturation to a new market and consumption system among East Germans. A consumption culture characterized by abundance (as opposed to the ubiquitous scarcity previously experienced) was a key driver of the peaceful revolution and something East Germans had yearned for. Hence the expectation was that East German consumers would eagerly adapt and acculturate to the Western consumption culture they had fought so hard to access. However, the assumption that both consumer cultures would soon converge proved delusive. On the contrary, the sphere of consumption across the formerly separate states even today highlights the fact that considerable differences prevail. While some former GDR brands regained an 85% market share in East Germany, they remain largely unknown in the West. In some product categories the disparity appears insurmountable to the point where large Western manufacturers have started to refocus their marketing efforts by concentrating on the former Western territory only, thereby disregarding the East—a market they had once taken by storm after the Wall fell, when East German products were quickly discarded, rejected and replaced by long-desired Western goods perceived to be "the real thing" (Berdahl 1999; Veenis 1999).

Following the initial phase of hyperconsumption of Western brands, we now witness a nostalgic revival of formerly disliked GDR-associated brands, objects, practices and consumptionscapes (Merkel 2006). Formerly discontinued products reappear on supermarket shelves with retailers offering "GDR product" promotions customized only for the former GDR territory. Mail order companies selling solely GDR brands are flourishing and dispatching parcels to East Germans living inside and outside their former home base. The love and idealization for East German consumer products is accompanied by a resurgence of consumptionscapes such as GDR-themed hotels, "city safaris" in the iconic Trabant car, restaurants offering GDR cuisine, GDR product fairs, as well as consumption communities celebrating GDR consumption objects and practices in social media spaces. After 25 years of consumer adaptation and acculturation, the undiminishing disparity in consumption cultures and resurgence of formerly despised and rejected consumption objects and services surprises.

The paradoxical nature of the persistent gap in consumption behavior in a country that has been politically reunified in 1990 renders it a highly stimulating context for research. Contexts with extreme features are valuable in that they enable detection of previously uncovered construct properties, processes and relationships as well as interactions with other constructs (Arnould et al. 2006; Mook 1983). When compared to similar research contexts, such as nostalgia in Eastern Europe, the German context presents an extreme case. While the evolution from a socialist to a capitalist society took place gradually in the rest of the former Soviet Bloc, the sudden nature with which these two opposing cultures collided and had to be negotiated by East German consumers presents an ideal opportunity to rethink existing theories and their boundary conditions, as exemplified in the latter part of this paper.

The consumer acculturative processes of adapting to a new market system that followed the fall of the Wall, as well as the observed nostalgic revival of GDR-related consumption, foreground consumer acculturation and nostalgia. Comparing opposing consumption cultures and their negotiation moreover allows for a reframing of similarity and difference in fruitful ways (Arnould et al. 2006). Hence we follow the call for extraordinary research contexts which, based on their extreme features, enable us to scrutinize and expand extant theories, their boundary conditions and interactions (Mook 1983).

LEVERAGING THE CONTEXT FOR THEORY BUILDING – THE MULTILEVEL CIRCUIT OF ANALYSIS

There are several approaches to levels of analysis: be it the rigid abandoning of levels of hierarchical relationships such as those advocated by some theoretical lenses like Actor-network theory (ANT) that rely on flattening levels of analysis to derive theorizations on consumption and marketing phenomena (Bajde 2013; Giesler 2012); the recognition of the interplay between more immediate microlevel consumer experiences and more hidden macrosociological processes (Askegaard and Linnet 2011; Earley 2014); and Desjeux's (1996) scales of observation of consumption that suggest biological, individual, microsocial, or macrosocial levels of analysis as starting points for observing social reality in order to break down the complexity that emerges in attempts to observe social and cultural dimensions at once.

While Arnould and Thompson (2005, 875) state that consumer culture theoretical (CCT) research in particular strives to "systematically link individual (or idiographic) meanings to different levels of cultural processes and structure" situated "within historical and marketplace contexts," researchers have come to critique the shortcoming of CCT research to deliver the kind of integrative theorizing it set out to achieve, and pointed out that the existential-phenomenological tradition endemic in consumer research has led to an overemphasis on the individual level of analysis, and therefore neglects the macrosociological forces that shape consumption behavior (Askegaard and Linnet 2011; Earley 2014). We intend to encourage more research that takes advantage of a circuit of various levels of analysis, thereby complementing insights from one level of analysis with another one. This is grounded in Desjeux's (1996) original argument that a particular scale of observation serves merely as the entry point for analyzing consumption, followed by what we call a circuit of investigation: the subsequent, hermeneutical and triangulated use of various levels of observation. Because knowledge is co-constituted in Desjeux's (1996) terms *between* the different scales of observation—biological, individual, microsocial, macrosocial—theorizing within contexts requires a greater focus on the forces that shape the consumption phenomenon under investigation, which contextualize the predominantly used scale of observation. This means it is crucial to shed light on the meaning of the context—in Askegaard and Linnet's (2011) terms "the context of context"—and acknowledge that ontological claims about concepts are derived from the use of a particular level of analysis; albeit that these claims have to be situated vis-à-vis knowledge that is derived from the use of other levels of observation.

Our research context presented above exposes the predominantly applied foci of individual and microsocial lenses as embedded in complex larger political, institutional and cultural environments and conditions. The one-to-one transfer of West German hegemonic structures turned East Germans into largely passive receivers (vs. active co-creators) of a new political, economic and social system. The dominant manner in which systemic changes occurred sowed the seeds for later contestations. In terms of consumption, East and West Germany were characterized by opposing cultures, each with their own value grids, patterns and ideological infrastructures. While West Germany's culture of consumption was adhering to a capitalist market ideology, East Germany's culture of consumption followed a socialist ideology. This context therefore specifically foregrounds the negotiation of these two diverging consumer cultures rooted in

opposing market systems and political value systems and therefore presents an opportunity to explore as yet untouched facets of consumer acculturation and nostalgia by emphasizing the relevance of macrosocial levels of analysis. That is, the German context highlights how supposedly microsocial and individual consumption phenomena of acculturation and nostalgia have to be understood vis-à-vis the larger institutional, political and historical trajectories of which they are part.

AN INVENTORY OF EXISTING LITERATURE

Using Desjeux's (1996) scales of observation to analyze extant research on consumer acculturation and nostalgia, it becomes clear how theorizations and conceptualizations are tainted by the use of a particular level of analysis, rather than a circuit of investigation exploiting the range of different scales of observation. Predominantly, we find that individual and microsocial scales of observation are used to research nostalgia and acculturation. As argued previously, we suspect that this is related to the particular contexts chosen for studying the operation of these concepts.

Consumer acculturation. In the case of consumer acculturation, with a few exceptions that analyze the concept at the individual level of analysis, such as Chai and Dibb's (2014) recent exploration of how acculturation influences interpersonal trust, the majority of studies take a microsocial approach based on contexts of migrating groups of consumers and their adaptation to subjectively new host cultures (e.g., Chytkova 2011; Dion, Sitz, and Remy 2011; Fernandez, Veer, and Lastovicka 2011; Oswald 1999; Peñaloza 1994; Vihalemm and Keller 2011). Only a few studies explicitly address the interplay between microsocial and macrosocial levels. For example, Askegaard, Arnould, and Kjeldgaard (2005) relate the construction of ethnic identities to larger scales of global consumer culture and home/host culture, and others integrate institutional domination in acculturative processes (Üstüner and Holt 2007; Üstüner and Thompson 2012). While these recent studies have begun taking advantage of macrosocial levels of observation to inform consumer acculturation, they still conceptualize consumer acculturation primarily as a microsocial phenomenon shaped by macrosocial forces. Through the lens of the context of Germany's reunification, however, questions arise as to how consumer acculturation can be understood primarily as a macrosocial phenomenon shaped by microsocial forces, because it challenges the ontological status of acculturation involving physical migration of particular groups of consumers.

Nostalgia. As for nostalgia, a similar pattern emerges, with the individual level of observation as its predominant anchor point instead. While there are studies conceptualizing nostalgia through a biological scale of observation, such as Hofer's (1688) description of nostalgia as a medical condition linked to homesickness and melancholy and Zhou et al.'s (2012) conceptualization of nostalgia as maintaining physiological comfort and mental health by increasing perceptions of physical warmth, the majority of consumer research portrays nostalgia as an individual phenomenon. This is reflected in the conventional understanding of nostalgia as sentimental longing for the past (Holbrook and Schindler 1991) and the interpretation of this "longing" as an emotion, cognition or experience on the individual level that has either some consequences for consumption or is reflected in consumption choices. In this line of thought, prior research includes a focus on the emotional and cognitive components of nostalgia (Holak and Havlena 1998; Hepper, Ritchie, Sedikis, and Wildschut 2012), consumption preferences (Holbrook 1993; Holbrook and Schindler 2003; Loveland, Smeesters, and Mandel 2010), and proneness to nostalgia (Holak, Havlena, and Matveev 2005). Interestingly, a number of studies suggest microsocial and macro-

social facets that play a role in consumers' individual nostalgic projects (Havlena and Holak 1996; Kao 2012). However, these studies are grounded in the individualistic conceptualization of nostalgia. Only very few studies develop a perspective on nostalgia through the use of micro- or macrosocial levels of observation such as Holak's (2014) investigation of nostalgia in the context of a consumer group's diaspora (microsocial), or Stamboli and Visconti's (2012) work opening up the (macrosocial) study of nostalgia as the collective quest for cultural comfort. Yet we know surprisingly little about the operation of nostalgia on a macroscope. Comprehending nostalgia through the lens of the context described above highlights our limited understanding in terms of the macrosocial facets and roles of nostalgia against the backdrop of political and cultural trajectories.

A MACROSOCIAL SCOPE: REINQUIRING EXISTING CONCEPTS AND FERTILIZING THEORETICAL LINKS

Because previous literature indicates, but does not develop further, the role of macrosocial facets in the operation of both consumer acculturation and consumer nostalgia, these concepts invite re-examination from a macrosocial perspective. As illustrated in Figure 1, the selection of a unique research context can facilitate such shifts in scales of observation, thereby exposing limitations of conventional understandings of these concepts, which shall be briefly discussed hereafter:

Rethinking acculturation and its spatial dimensions: Consumer acculturation is generally considered as a "process of movement and adaptation to the consumer cultural environment in one country by persons from another country" (Peñaloza 1994). Hence the majority of previous consumer research frames consumer acculturation as a process of physical migration. While this is accurate for a certain class of contexts, the German case highlights another class of context for acculturative processes. Here, with the fall of the Wall, East German consumers were crossed by the border (rather than physically migrating across the border), and thereby exposed to a new cultural environment. Such acculturation without migration presents a new form of adaptation currently not captured by a microsocial definition of acculturation. Because the dominant view of acculturation holds that territorial frames are generally considered fixed, there is little known about how shifts in territorial definitions impact consumer culture. The German context exposes this boundary condition.

With territorial changes and redefinitions ongoing globally (e.g., new countries forming, borders being built and falling, ethnic groups striving for independence), this class of context presents opportunities for rethinking the spatial dimensions of consumer acculturation.

Macroinstitutional variables shape acculturative processes: As previously highlighted, prior studies focused mainly on microsocial processes of migrants. The historical instance of a political merger in Germany foregrounds the previously underexplored role of macroinstitutional forces in shaping consumers' acculturative processes and their subsequent manifestations in consumption behavior. Very little attention has been devoted to the role of macroinstitutional variables in consumer acculturation. Hence the German context presents a unique opportunity to explore how macroinstitutional variables impact patterns of consumer adaptation, and it opens the door to the study of ways in which other institutional forces (e.g., economic crises, military conflicts, globalization) may shape acculturative processes.

Exposing a conceptual link between acculturation and nostalgia: The shared goal of consumer acculturation theory is "to understand and conceptualize the various forces that define, allow,

facilitate, or complicate consumer acculturation under specific cultural conditions" (Luedicke 2011, 238). While the concepts of acculturation and nostalgia have been treated largely separately in the literature, conceptual links are suggested when the level of analysis is raised to macro perspectives. Acculturative processes still ongoing in Germany today are intertwined with nostalgia. The dominated cultural conditions of the reunification suggest that in addition to the acculturation forces identified and defined by Luedicke (2011), nostalgia is likely to be a previously unaccounted for cultural resource that shapes acculturation processes by facilitating, inhibiting or reversing adaptation. Hence the German context reveals the opportunity to study the interaction of these concepts by investigating the cultural roles of nostalgia in acculturative processes.

Rethinking nostalgia: As highlighted by the literature review, nostalgia has been primarily investigated by applying individual (and very few microsocial) scales of observation. Our context suggests that nostalgia in East Germany emerges as a special form of collective nostalgia rooted in contested sociohistorical processes. Thus it is important to conceptualize nostalgia as a sociocultural phenomenon vis-à-vis existing individualistic and microsocial conceptions and explore the macrosocial facets and roles of nostalgia against the backdrop of political and cultural trajectories.

Extant literature fails to explain the processes inherent in Germany's reunification with regard to consumer acculturation of consumers who have become migrants in their own country, and with regard to the role of nostalgia in contemporary German consumer culture against the backdrop of historical and institutional trajectories on the macroscope (Askegaard and Linnet, 2011; Brown et al. 2001). That is, the context explicitly foregrounds the interrelation of individual-level experiences with microsocial practices with the German reunification as a macrosocial process. As summarized by Figure 1, zooming out in the scale of observation (i.e, shifting attention toward these macrosocial levels) allows researchers to zoom in on new opportunities for theoretical insights by making previously undiscovered conceptual links discernible.

CONCLUDING REMARKS

Neither consumer acculturation nor nostalgia take place exclusively on biological, individual, microsocial, or macrosocial levels, and therefore should not be studied through an exclusive application of just one scale of observation. Rather, we encourage more research to take advantage of the circuit of various levels of analysis. Our contribution to the field of interpretive consumer research is threefold, namely of methodological, conceptual, as well as theoretical nature:

(1) Following Arnould et al. (2006) we contribute to a much-needed discussion on how to make unique contexts matter theoretically, by showing how a change in the scale of observation facilitates breaking free of pre-existing assumptions, leading to theoretical insights and the exposure of boundary conditions as well as conceptual interactions previously undetected.

(2) We conceptualize and substantiate our suggestion with the help of a concrete example and showcase how the unique context of a prevailing divide in East and West Germany's consumption behavior, if moved to a macrosocial level of analysis, can not only extend existing theories of consumer acculturation and nostalgia, but moreover expose conceptual links between both bodies of literature that were previously treated as separate.

(3) From a theoretical perspective, our context informs *four important extensions* to existing research on acculturation and nostalgia. Firstly, the situation presented here of consumers being "crossed by a border" rather than physically crossing the border into a new

sociocultural environment exposes a boundary condition of extant acculturation literature, namely that territorial frames are generally considered fixed and little is known about how shifts in territorial definitions impact on consumption culture. Secondly, the case of a political merger foregrounds the previously underexplored role of macroinstitutional forces in shaping consumers' acculturative processes and their subsequent manifestations in consumption behavior. Thirdly, the dominated cultural conditions of the reunification suggest that in addition to the acculturation forces identified and defined by Luedicke (2011), nostalgia is likely to be a previously unaccounted cultural resource that shapes acculturation processes. Raising the analysis to a macrosocial level exposes a complex conceptual interaction between theories of nostalgia and acculturation that has so far been largely neglected. Fourthly, in contrast to the largely biological, individual, or microsocial contexts informing the study of nostalgia thus far, nostalgia also emerges as a special form of collective, sociocultural resource that has roots in contested sociohistorical processes. Hence existing individualistic and psychological theories of nostalgia have to be complemented by sociocultural conceptions that explore the macrosocial facets and cultural roles of nostalgia against the backdrop of historical, political and cultural trajectories.

In this article, we have suggested that the application of a macrosocial scale of observation to a particular context—zooming out, in the scale of observation—is conducive to zooming in on a theoretical and conceptual level, i.e., the operation of such concepts within consumer culture. That is, we advocate zooming out as an important step in the multilevel circuit of analysis—an approach that challenges the assumption that a concept, here exemplified with nostalgia or consumer acculturation, can be accurately understood through an exclusive focus on either individual and/or microsocial levels of analysis.

The challenge ahead for consumer researchers lies in tackling the emerging complexity that goes hand-in-hand with the application of macrosocial scales of observation. For this, prior knowledge created using other (individual or microsocial) scales of observation provides important landmarks and conceptual starting points for macrosocial investigations and the subsequent exposure of theoretical voids and boundary conditions.

Nuances of Cooperation and Competition among Lower-Class Consumers

Rodrigo B. Castilhos, Universidade Federal do Rio Grande do Sul, Brazil

Hélène Gorge, Université Lille Nord de France – SKEMA Business School, France

ABSTRACT

The marketing discipline has recently displayed an increasing concern over lower-class consumers, giving rise to two overarching bodies of research. In the first, studies aim to design solutions for the alleviation of consumers' impoverished conditions, either through the market (e.g., Prahalad and Hammond, 2002), public policy (e.g. Varman, Skalén, and Belk, 2012; Viswanathan et al., 2012), or community entrepreneurship (e.g., Viswanathan, Rosa and Ruth, 2010). In the second, researchers seek to primarily understand the lived experiences of the dominated (Üstüner and Holt, 2007), vulnerable (Backer, Gentry, and Rittenburg, 2005), or simply put, poor consumers (Hill 2002). In both sets, studies attribute great importance to communal relationships and the social networks of these consumers either as a key to cope (Hill 2001; Hill and Stephens, 1997) and overcome objective conditions of deprivation (London, Anupindi and Sheth, 2010), or as the grounds from which identity projects will be produced (Üstüner and Holt, 2007). The underlying assumption is often that people experiencing similar conditions of deprivation would share a sense of collectivity and develop forms of cooperation and solidarity as belonging to the same class or "culture" (Bourdieu 1979; Hoggart 1970). However, the same social conditions that foster a sense of solidarity, can also originate tensions and competitive feelings and behaviors among social groups (Portes 1998).

Extant sociological literature has found evidences of this more "heterogeneous array of behaviors and outcomes" regarding communal relationships among poor people (Small, Harding, and Lamont, 2010: 15). Studies have shown the diverse circumstances in which they choose not to participate in communitarian projects (Small 2002), avoid help their peers (Smith 2010), and openly engage in competitive and conflictive relationships among each other (Portes and Sensenbrenner, 1993). In the same vein, but in different types of collectivities, consumer research has described tensions in communal relationships. For example, in a study of home moving practices, Marcoux (2009) has shown that consumers would rather opt to contract commercial moving services instead of asking their network of friends for favors, which would generate a need for "reciprocity". In a study of commercial climbing expeditions, Tumbat and Belk (2011) have described how the temporary community formed around a common objective was, contrary to the usual liminal camaraderie, fully permeated by competitive and individualistic feelings. As these evidences in and outside poor collectivities indicate, studies of social relationships put the attention on one side or the other, but fail to integrate both dimensions and give a more complete picture of these relations. Could cooperation and competitive dimensions be substitutable or complementary? What are the specific conditions for engaging in one or the other?

We seek to understand these apparent contradictions through the analysis of the conditions in which lower-class consumers engage in cooperative-solidarity versus competitive-individualistic relationships. Drawing from Bourdieu's conceptualization of social capital as "the aggregate of actual and/or potential resources that are linked to the possession of a durable network of more or less institutionalized relationships of mutual acquaintance and recognition" (1986: 249), we have conducted an ethnography of the daily interactions in a group of lower-class consumers living in a squatter neighborhood in Brazil. Social capital is "a system of durable obligations," which are socially constructed within any collectivity from norms of reciprocity (Mathwick, Wiertz, and Ruyter, 2008), bounded solidarity, and enforceable trust (Portes 1998). At the same time, social capital can generate both positive (e.g., help to overcome objective conditions of impoverishment) and negative (e.g., excessive claims over a few community members and restriction of personal freedom) outcomes (Portes 1998). We seek to understand how our informants frame this system of obligation and anticipate it's outcomes in the context of their daily relationships at the community level. In doing so, they engage in diverse market-mediated forms of cooperation and competition among each other. Through the thick description of each of the identified relationships, we account for the underlying moral, structural, and situational conditions of those relationships and advance on the understanding of the communal relationships among disadvantaged consumers.

This study echoes the recent calls in Transformative Consumer Research, which proposes to leverage trust and social capital in the context of poverty (Blocker et al., 2012). Our contribution is threefold: first, we challenge the dominant view of lower-class consumers as being necessarily cooperative when facing objective conditions of impoverishment; second, we enhance the understanding on the ways lower-class consumers protect and take advantage of their social network through the use of market resources; additionally, our accounting for social capital broadens the perspective of the research on sociability and reciprocity in consumer culture theory, beyond the often dyadic notions of the gift economy (Giesler 2006).

CONTEXT AND METHOD

Despite experiencing economic growth for over a decade, Brazil still faces strong social inequality. Lower-classes (those occupying the two lowest tiers in a rank with eight income-classes) vary from 36% to 42% of the households in the country, depending on the classification adopted, with a monthly income not higher than US$183 per member of the household (Kamakura and Mazzon, 2013). Beyond income classifications, the modernization process of the country has produced a deep structural gap of access to education and other kinds of relevant impersonal capitals between the lower- and middle-classes, the first composed by those individuals mainly holding positions of manual workers (Souza 2010). Over six months, we have conducted an ethnography of the daily life of six families belonging to this lower-class group, living in a squatter neighborhood in a Brazilian state capital.

Brazilian cities provide an interesting context for research on lower-class consumers for many reasons: (1) Brazilian lower-class usually faces long-term poverty, experienced during several generations, which is considered a base for the transmission of certain forms of capitals (Bourdieu 1979); (2) squatter areas are known for being dense spaces for sociability and communal relationships; and (3) lower-classes are directly benefiting from recent economic growth, objectively increasing consumption patterns, therefore having an impact in daily and communal life (Souza 2010). As our research site unites these features, it provides an extreme context that allows to foreground our theoretical argument (Price, Arnould, and Moisio, 2007).

Fieldwork was conducted by the first author. Data collection was composed of participant observation of the daily routine of six families at home, with neighbors, and in their interactions with local shops and services. During the six months of fieldwork, three to four

days a week, during different hours, were spent in the neighborhood, observing daily interactions and taking part in many dinners, birthday parties, and social gatherings inside the neighborhood. The first author also lived in the neighborhood for 15 days at the very end of the fieldwork. Four sets of in-depth interviews were conducted with the head of the families and one interview with each member of the families, totaling 43 consumer interviews. We also mapped all 49 local commerce points and interviewed the owners of the seven mains business, such as grocery and hardware stores. In total, data collection was registered in 83 single-space pages of field journal notes, 1,000 minutes of audio, transcribed in 181 single-space pages of text, 17 minutes of video, 232 pictures taken, and 30 pictures collected from informants. Data analysis followed the guidelines of the hermeneutical approach (Thompson 1997), evolving our understanding of the social relations within the neighborhood through several part-to-whole interactions, from emic to etic perspectives. As we evolved

in our interpretation of the data, we grouped the diverse communal relationships found into four distinct forms of cooperation or competition, which we further describe and discuss in the following parts of this paper.

FINDINGS

We have identified four broad dimensions of social capital relationships among our informants (see table 1). For each dimension, we depart from the description of the relationship, it's practices and discourses associated, and explain the combination of moral (norms and values), structural (durable conditions of impoverishment), and situational (immediate context of social and personal relations) conditions that make it possible in the context of the localized relationships. Finally, we understand its relations with consumption and markets, as well as the consequences at the community level. Although all forms are present among our informants, we chose to present each one through the story of a single and illustrative case.

TABLE OF RESULTS
Table 1 – Conditions of Social Capital Relationships

Dimensions of Social Capital Relationships	Conditions			Role of the market
	Moral	**Structural**	**Situational**	
Strong Reciprocity	Family reciprocal obligations	Structured family, long term conditions	Geographical proximity (household) and kinship	means
Loose Solidarity	Obligation and compassion; receiver's merit	Network of Interdependence	Personal proximity, trust	ends, replaced
Oportunism	Entitlement	Limited set of perspectives; Long term shared conditions	Necessity and opportunity	ends, undermined
Distance managing	Moral superiority	Perception of upward mobility	Personal and geographical proximity	means

Strong Reciprocity

Strong reciprocity comprehends the emotional, bodily and financial engagements directed towards the mutual improvement of life conditions, especially among family members sharing the same household. Family is a primary unit of social capital relations among the poor (Viswanathan, Sridharan, and Ritchie, 2010), as Silvia (55 years old) provides best example. She migrated from the countryside with no formal education and relied on a few friends to get her first jobs, first at the assembly line, and then as cleaning lady. Silvia incarnates the identified relationship by engaging in daily sacrifices to improve life conditions within the family core.

Now both my kids are working. But Carlo [her son] needs to change, because his job [as garbage collector] is terrible. They only give him one set of clothes and I don't have the heart to let him go with the same clothes two days in a row. I wash his clothes at the night, and at 4AM I have to dry it on iron. For me is no sacrifice, as a mother my concern is improving. You cannot give up. Do you think I bother sleeping at that mattress there [she sleeps at the mattress so her children can sleep at the bed]? I do not.

This relationship is rooted in the moral obligations among the nuclear family members (Coleman 1988). Silvia feels compelled to

support her children. This support is market-mediated in many ways, such as the daily abundance of food at home, or in the purchase of a new TV set to "conquer their heart", and in the form of the manual labor illustrated above, which fostered her purchase of a washing machine to automate the laundry task. However, not only are the sons expected to reciprocate, but they are also explicitly socialized as part of this domestic moral economy: "When the tots were still small I got widow. There was only me for everything. I had to pay for day-care. Then, when Carlo started to be able to take care of Keyla I used to say: "watch your little sister, so that will save us more [money] to buy things for you to eat"". Sharing the same household is the main situational condition for this sense of shared obligations and responsibility to arise, as closeness makes our informants more involved in each other's lives and as they all concur to the expenses of the house. Those reciprocal obligations are more likely to flourish under limited structural conditions, notably among minimally structured families facing a long term history of economic and educational deprivation. Often, in the less structured families we met, expectations of reciprocity are broken, generating tensions, mutual distrust and resentment among family members. Yet, in more structured and less economically constrained families we met, children are socialized to go to school and their reciprocal obligations move from actively helping at home to develop discipline and prospective behavior dispositions through engaging in studies, closer to middle-class patterns (Souza 2010). Thus, at the same time that strong reciprocity increases short-term access to market goods, it also limits family members' long-term improvements, especially via education (Portes 1998).

Loose Solidarity

Loose solidarity encompasses the network of favors, referrals, and trades within or outside the community (Coleman 1988). That is the most documented form of social capital relations among the poor, usually represented in a positive tone (Hill and Stephens, 1997; Weidner et al., 2010) and is close to the studies on gift economy (Giesler 2006; Sherry 1983). Lia (37) best illustrates this dimension. She also went to the city searching for job opportunities. In her migration process, she relied on the pioneer relatives to get by the hard beginnings. As Lia, most of the informants remember those favors with gratitude. She currently lives with her two boys (2 and 11) in a well-built brick and mortar house. Maybe because she has received important favors during her trajectory, she keeps helping other neighbors who "deserve it" (Smith 2010). During the field-work she referred a neighbor to her boss and helped another to buy a wardrobe by lending her personal credit, a common practice among the lower-class in Brazil (Mattoso and Rocha, 2009). She also mentioned that she had morally paid a debt to her boss, for whom she was working for less than her usual earnings after having received an important favor.

The moral underpinnings behind this narrative are (1) the sense of obligation (and entitlement) or compassion with peers (Portes 1998) and (2) the assessment of whether the receiver needs and deserves the favors in the dyadic relation (Smith 2010). Reciprocity is broadly expected and required, feeding the durable obligations among the network (Gouldner 1960). By its turn, the existence of a network of interdependence among the parties is the main structural condition that drives the loose solidarity. It stems from sharing similar objective conditions (Portes and Sensenbrenner, 1993). Additionally, solidarity is performed in priority to close neighbors, friends or employees. This personal closeness goes hand in hand with trust in the other party, which is required more as the favour become more risky, such as in cases involving credit between neighbors and local commerce.

Contrary to the first form, loose solidarity mostly replaces market solutions (donations of goods from inside and outside the communities, helping with maintenance or building of houses, helping with childcare) or increases marketplace participation (lending credit or money, referring to jobs, helping navigate public institutions). However, at the same time that it helps to objectively overcome consumers' vulnerabilities (Baker et al. 2005), it also reinforces hierarchies and structures of power inside and outside of the community.

Opportunism

The same structural interdependence that fosters loose solidarity also provides the grounds for opportunistic practices among neighbors, as well as among local commerce owners and their customers. Opportunism refers to the possibilities of free-riding, cheating and advantage-taking that our informants deal with in their communitarian daily life. Despite being rather unproblematized in consumer research, this competitive dimension is documented in different instances of communal relations (Portes 1998). Oscar, a local grocery store owner in his 50's, provides the best examples for such case. He runs the most successful grocery store of the neighborhood for more than a decade. Coming from one of the few relatively wealthy families in the neighborhood, he likes to say that he is very helpful and supportive of his neighbors, which does not spare him from being a major target of opportunism.

> *The exchanging [of goods in the shop] is a big problem: for example, I know that one can take the milk even after a month [it's expired]. You know what they say if it is expired on the very day? "The milk is rotten". Oh, it makes me mad! But, then I wonder: "What if you had bought it there at the Carrefour, would you pay the bus to go there and exchange it?" No, it's because the fool here will exchange for you. And more, we sometimes see a person stealing from the shop. The worst part is that sometimes it is and old person. But we don't speak up, you know why? Because they will make a bad face and not come back anymore. An old grandma, man, we never imagined! The woman was taking a dip in her pocket! Gee, how can a person that saw you growing, practically raised you, be stealing a dip from you? What about that person to whom you denied some credit? Like, they think that because they buy from you, you have an obligation to help them in the crunch.*

The moral justification underlying those opportunistic behaviors can be found in the feelings of entitlement among members of the community. For those engaging in opportunistic practices, sharing similar conditions would give them the right to similar outcomes. In such closed communities, the emergence of a shared normative structure allows the "less diligent members [to] enforce on the more successful all kinds of demands" (Portes 1998: 16). We witnessed numerous situations in which these claims were made. When a family got one of the first personal computers in the neighborhood for the son, their house was quickly turned into a "public cybercafé", as the parents complained. In another case, one of our informants complained after a neighbour, who she had lent money to, was caught barbecuing (a status sign in the neighborhood) the next day. Opportunity and timing are among the main situational conditions for such practices. As Oscar says, his costumers don not exchange merchandise when they buy it from the big supermarket chains in the city. Although opportunism capacitates consumption in the short term, it does so at the expense of the relationship between parties, increasing mistrust among neighbors and undermining businesses in the community.

Distance Managing

Distance managing includes the discourses of valorization of dimensions that differentiate the poor from the "inferior other", such as a stable formal work, discipline to save money, and ability to raise well-educated children; as well as practices of avoidance of potentially opportunistic or dangerous neighbors. Ilário (56), a retired office clerk, lives with his wife and younger son in a house considered big for the neighborhood. He proclaims that he is not very much part of the neighborhood. He inherited the land from his father and proudly recounts that he transformed the former small house into a big one without much help. When talking about the relationship with his neighbors he states:

We do not live together with the neighbors; we only hang out with my sister and with the guys from the market [Grocery Store owners, considered "rich"]. Other houses we have no friendship. Here the purchasing power of the people is very low, then you handle friendships here and then they do not leave your door, biting you, asking you things, disturbing you, then you'd better not have friendship with such people. Then instead of going forward you will only go backwards. Then you say "no" and people get bad face. Then if you do not have friends, you have no way they'll extort you. My sister has some friends who, now and then, are biting her. This kind of friendship that is biting you does nothing. I avoid, hence the person has no way to reach you.

The distinction Ilário quickly seeks to make between him and the other neighbors is pervasive among our informants. The discourse here is anchored in a frame of a moral superiority (Saatcioglu and Ozanne, 2013) towards those seen as undisciplined, gossipy, vagabonds, or criminals, in contrast to being an honest worker (Sarti 2005; Zaluar 2000). Structurally, this form stems from the combination of long term shared objective conditions of deprivation and individual experiences of dissonant mobility in the face of intra-class differences in the broad community. Geographical and personal proximity provide the situational conditions for the need to manage distance. The same personal closeness that fosters solidarity, on the one hand, sets the grounds for a network of social comparison, envy, and gossip at the local level, on the other hand. In this dimension the market provides the means to escape the burden of the gift economy (Marcoux 2009) and to state distinctions among peers (Üstüner and Holt, 2007). Distance managing protects individuals and increases status positions of avoiders. In the long term, however, it increases mistrust and breaks the communal mechanisms of reciprocity.

DISCUSSION AND CONCLUSION

This paper shows that among lower-class consumers, cooperation and competition can be substitutable depending on a specific combination of moral, structural, and situational conditions. Different from previous research (Hill 2002; Tumbat and Belk, 2011), the four identified dimensions are observable among people at the same collectivity. These consumers adapt and engage in one or another form of social capital in order to get the most benefit possible from their communal relations. Moreover, we observed that the same person can engage in different forms of relationship among their community, which extends Saatcioglu and Ozanne`s (2013) account of fixed moral identities among poor consumers. We demonstrated that social capital holds a complex and nuanced nature, as one can not only maintain relationships of solidarity within a group, but also perceive it`s closure as a threat or a source of opportunity, therefore avoiding to help, isolating him or herself, or even taking advantage

of other`s good will. This reinforces the idea that social capital can be best understood as a relational system (Portes 1998).

Social capital is usually regarded as a way to establish and maintain a spirit of community in a group (Bourdieu 1986). However, our study shows that collective feelings and belonging are not always desirable. This challenges the dominant view that the poor would necessarily engage in solidarity as a way to cope with and overcome objective conditions of deprivation (Hill 2002; London et al., 2010). For example, we found that opportunism can be also a way to cope and overcome these conditions. Also, social capital is supposed to facilitate collective living (Coleman 1988). However, we found that opportunism and distance managing actually complicate it, mutually reinforcing feelings of resentment and individualism. We contend that future work on lower-class consumers should take this nuanced and complex nature of social capital into account, both to better understand the lived experience of poor consumers and to elaborate solutions for poverty alleviation.

Market resources play a key role on broad social dynamics and processes of identity construction (Thompson 2013). Despite the acknowledged importance of those resources for lower-class communities (Hill 2002), extant literature has left its relationship with social capital relatively untouched. Addressing this shortcoming, we showed that markets and consumption can be (1) the means through which social relationships are constituted (2) the result of a social relationship, where cooperation or competition increase or undermine the access to markets, and (3) can be replaced by a network of favors among neighbors. So, market resources are embedded in different dimensions of communal relationships, which can bring new insights to the body of research on reciprocity in consumer culture theory. As our analysis suggests, the theorization of social capital encompasses elements of both gift-giving (Giesler 2006) and sharing (Belk 2010). Thus, future research can explore social capital as an integrative framework to understand the positive and negative possibilities at the intersection of communal relationships and consumption.

Conceptualizing the Space of Markets: How Spatiality Influences Market Dynamics

Rodrigo Castilhos, Universidade Federal do Rio Grande do Sul, Brazil
Pierre-Yann Dolbec, York University, Canada
Ela Veresiu, Witten/Herdecke University, Germany

ABSTRACT

From the emergence of Starbuck's and the coffee movement in Seattle to the role of Hollywood in Los Angeles' fashion and design markets (Molotch 2002; 2003), there is something "in the air" (Marshall 1890, 332) that explains why companies and industries tend to aggregate in certain places over others. Such localized industries benefit not only from a common talent pool and knowledge spillovers (Marshall 1890), but also from the specific culture associated with these spaces (Molotch 2002, 2003).

Space shapes the creation, disruption, and evolution of markets. For instance, prior market-level research has explored how the territory claimed by industries facilitates their legitimation (Humphreys 2010b), how a network of locales such as coffee shops serves as spaces for the performance and diffusion of consumption practices (Karababa and Ger 2010), and how the creation of a consumption infrastructure not only brings a community together, but also catalyzes market emergence (Martin and Schouten 2014). However, marketing researchers' general bias in assigning agency mostly to consumers and producers might have influenced the observed paucity of research where space would otherwise take a central and agentic role (recent exceptions include Canniford and Shankar 2013; Epp and Price 2010; Giesler 2012; Martin and Schouten 2014). To address this theoretical oversight this paper positions space as an active category in market processes.

The growing interest in joining the study of markets and space in cultural, human, and economic geography (see Boeckler and Berndt 2012), as well as in the sociology of markets (Fligstein and Dauter 2007) evidences this theoretical shortcoming in marketing. If the above-mentioned fields are particularly apt at inquiring about the ways cultural, social, and economic forces shape producers' activities and their influence on market dynamics, our field is well-positioned to contribute to understanding the role of the marketing institution (e.g., Araujo, Finch and Kjellberg 2010; Bjerrisgaard and Kjeldgaard 2012; Cayla and Arnould 2013), consumers (e.g., Martin and Schouten 2014; Scaraboto and Fischer 2013), and the interaction between producers and consumers (e.g., Thompson and Coskuner-Balli 2007) on geographically-embedded markets.

To address this shortcoming, we introduce a theoretical framework drawing on four central spatial concepts: place, territory, scale, and network (PTSN). As we will demonstrate, these concepts provide an analytical apparatus fitting to the study of market dynamics. We then discuss the agentic quality of these four theoretical constructs and highlight their contribution in our understanding of the patterning of sociospatial relations (Jessop, Brenner, and Jones 2008). We subsequently re-examine existing market dynamics research focusing on market creation at the industry-level (Humphreys 2010a, b) and at the product-level (Giesler 2012) using this sociospatial approach to highlight the benefits of our proposed framework for one of the instances of market dyanmics: market emergence. This follows the recommendations of Martin and Schouten (2014) that revisiting existing market emergence cases with a focus on object agency can reveal a richer picture of phenomena. We conclude by opening the discussion on the uses of our spatial framework and how it strengthens current explanations not only of market creation, but also of disruption and evolution, before proposing specific future research directions brought about by this new theoretical approach.

SOCIOSPATIAL CONCEPTS AND MARKETS

In this section we seek to explain how markets rely on, create, and are created by space embedded in the relationships between the many entities (objects, individuals, and institutions) that order economic and social life (Giesler 2012). To do so, we draw on the analysis of the spatial dimensions of place, territory, scale, and networks (PTSN) (Jessop et al., 2008). PTSN is an integrative framework that provides diverse entry points to understand sociospatial relations "in terms of a path-dependent, path-shaping dialectic" (Jessop et al., 2008).

Place is a concrete and limited space that is acknowledged, understood, and invested with meanings and value (Tuan 1979). When the dimension of place is at the forefront, notions of meanings, identity, symbolic exchanges, experiences, and intersubjectivities are among the most visible (Souza 2009). All social phenomena are emplaced; however, more than a mere backdrop, place mediates social life (Gieryn 2000). Place has ontological prevalence in the PTSN model. It is at the center of sociospatial relations as "more formative and generative, primal in its power, than the others" (Casey 2008, 403). Territory is a spatially bounded field of forces (Souza 1995). It is a space in which the access, purposes, or meanings are controlled by individuals, groups, or institutions (Sack 1986). The dimension of territory emerges when power relations, control, bordering, and delimitation are taken into account (Jessop et al. 2008; Souza 2009). As an empirical reality, more established territories are spatial agents that stabilize and naturalize power relations (Kärrholm 2007). Scale refers to the hierarchical ordering of the world in levels of representations, such as global, national, regional, and local, which is constantly negotiated through tensions between structural forces and the practices of human agents (Marston 2000). The ways in which the relationships at one level contribute to the formation of the other is key to scalar thinking (Marston and Smith, 2001). Networks refer to the interconnections that are established among disperse entities in horizontal relations with each other (Marston et al., 2005; Jessop et al., 2008). As such, networks conceptually contrast the notion of scale, which is based on vertical relations (Leitner 2004; Marston et al., 2005). While place and territory are as much physical and concrete realities as they are conceptualizations, scale and networks are the geographical abstractions of how the multiple forms of diverse spatial entities can relate to each other.

The four spatial dimensions are co-constituting of and co-constituted by social life, as well as by the dynamics of market systems. We contend that markets rely on and create sociospatial assemblages that (1) arrange patterns of interaction that constitute network-formation and collective action; (2) secure and grant otherwise intangible cultural norms and values, such as those implicit in the logic of the market; and (3) stabilize and give durability to socio-structural categories, differences, and hierarchies that shape market-mediated social dynamics (Gieryn 2000; Miller 2010). Simply put, markets create spaces that create markets. However, little attention has been given to the spatial dynamics of markets in consumer culture theory (CCT)-oriented research. The different combinations of place, territory, scale, and networks help to bring this dynamic to the forefront.

Combining place and scale provides an explanation on how consumption practices and markets are developed through space. For example, the market-mediated reproduction of gender relationships

at the domestic scale in American suburbs informs the social space of men and women at the job-market scale, and the relation between the two helps give rise to some of the most culturally prominent gendered myths at the national-scale: the juggling mother (Thompson 1996) and the man-of-action (Holt and Thompson 2004). Localized practices can also foster alternative explanations to processes of formation of multiple consumer cultures (Karababa and Ger 2011), to instances of localized consumer resistance (Thompson and Coskuner-Balli 2007; Giesler 2008), and glocalized consumption practices (Kjeldgaard and Askegaard 2006). In this case a sociospatial approach allows for an understanding of places as unique enablers of the emergence of discourses and practices in a particular form. The combination of place and territory allows for contextualized investigations of place-making processes (Smith 1999). Driven from different forces, interests, and alignments of agents (Gieryn 2000), markets influence the design, representations, and experiences of commercial (Kozinets 2003; Maclaran and Brown 2005) and public places (Chatzidakis, Maclaran and Bradshaw 2012; Visconti, Sherry, Borghini and Anderson 2010). At the same time, the combination of place and network helps to enhance our understanding of how markets are also created by sociospatial relationships. For instance, the existence of a broad network of localized practices can be seen as an important driver of the emergence of the mini-moto market (Martin and Schouten 2014). In the same vein, the existence of a network of localized practices can be helpful to understand why some consumption practices and discourses become accepted in mainstream markets (Sandikci and Ger 2010) while others fail (Scaraboto and Fischer 2013). The PTSN framework therefore allows for other theoretical combinations to be used in understanding diverse market dynamics. To better demonstrate our argument, we next apply this idea to two pathbreaking papers Humphreys (2010a) and Giesler (2012) that focus on one of the key aspects of market dynamics: market creation.

METHODS

Consumer researchers have recently called for a re-examination of previous market emergence studies. According to Martin and Schouten (2014, 868), "[a] disciplined look at the agency of material objects, spaces, and institutions may expand our understanding of a very differently structured market." Echoing the authors' timely and relevant imperative, we focus on sociospatial relations to reveal a "richer picture of market emergence" (Martin and Schouten 2014, 868). To pursue this goal, we adopted the re-inquiry approach previously used in marketing and consumer behavior research (e.g., Askegaard, Arnould, Kjeldgaard 2005; Garg, Inman and Mittal 2005; Murray 2002; Thompson 2002; Wilk 2001). Re-inquiries can generate valuable insights and a more complete understanding of a consumption phenomenon through the integration of different perspectives (Thompson 2002). Furthermore, to organize our findings, we use the established extended case method (e.g., Cayla and Eckhardt 2008; Holt and Thompson 2004; Holt 2002; Allen 2002). This methodological orientation is especially relevant for our research questions due to the fact that it "has become a favored methodology for researching macroscopic, often global, questions concerning market and cultures from an interpretive perspective" (Holt 2002, 73).

In particular, we chose to critically examine two influential market creation studies: the industry-level analysis of the emergence of casino gambling (Humphreys 2010a, b) and the product-level analysis of the rise of Botox Cosmetic (Giesler 2012). To do so, we first engaged in an archival search of all scholarly articles, media reports, and books with the words "Atlantic City, casino, and gambling" for the industry-level case, and "Botox Cosmetic" for the product-level case. The complete data set totaled 20 newspapers and 51 academic articles. These sources were purposively selected to highlight the emergence of the markets, which entailed us pursuing a geographically and temporally bounded sampling method. Similar to Karaba and Ger's (2010) work, we used a textual approach to data analysis and examined the sequence of events in these texts, as well as the authors' arguments, rationales, and justifications regarding the emergence of casino gambling in Atlantic City and Botox Cosmetic in the U.S. In line with the re-inquiry method, we then compared and contrasted these results with the findings provided by Humphreys' (2010a, b) and Giesler's (2012) work. Although this type of method generally approaches data from a top-down perspective rather than a bottom-up manner, an iterative and back-and-forth interpretive process nonetheless prevailed. Next, we present how a sociospatial theoretical lens can inform market creation.

RE-EXAMINING THE INFLUENCE OF SPACE ON MARKET CREATION

How do new industries emerge in a particular context? Humphreys (2010 a, b) explains the rise of the casino industry in Atlantic City as a result of central actors using framing strategies to reposition the discourses about gambling, and journalists changing the rhetorical meanings of casinos. Together, these articles provide a producer-driven and discursively-based explanation for the legitimization of Atlantic City's gambling.

Industries emerge in specific geo-historic contexts (Scott 2000). Atlantic City's growth, for example, was dependent on the emergence of the railroad industry: the city has always been a resort destination receiving influx of visitors from nearby locales (Stansfield 1978). "Changes in transport technology and recreational geography" (Stansfield 1978, 238) were responsible for the city's downfall in the sixties. The trains coming in were phased out after World War II and the narrow streets of the city and numerous pedestrian zones were at odds with the booming auto tourism. At the time casino gambling was legalized in Atlantic City, the city was in economic despair: the unemployment rate was higher than 20% and in the last 15 years, the population size had decreased by 25%, tourism and taxes revenues were steadily declining and hotels' room capacity had dropped by 40% (Braunlich 1996; Rubenstein 1984). The city needed a solution, and casino gambling was seen as a way to "facilitate the redevelopment" of the city, "encourage the replacement of lost hospitality-oriented facilities" and "attract new investments" (New Jersey Statutes Annotated 1982). More, because of the city's history as a resort destination, it benefitted from an adequate infrastructure and talent pool, as well as 50 million potential visitors in a 300-mile radius (Braunlich 1996). In the words of Martin and Sunley (2006, 398), "the context-specific, locally contingent nature of self-reinforcing economic development" made legalizing gambling the next logical step in the cycle (Stansfield 1978).

Not only does a geographical approach illuminates our understanding of the emergence of the industry, but it also benefits our comprehension of its crystallization over time: if we compare Atlantic City to its closest rival, we notice how the industry was shaped under a different network of citizens, interstate relations, and regulatory systems. "In Las Vegas, they built the city to support the casinos. But in Atlantic City, they built the casinos to support the city" (Tesker and Sur 1991, 130, citing Baker 1989). For example, in Atlantic City, casinos had to be part of a hotel, and the superficies of the casino was dependent of the room capacity of the hotel; casinos were not to be the main source of income from touristic activities; they could not have direct access to the street; they had less slot machines and more labour-intensive games than Las Vegas to keep

employment high (Braunlich 1996, 50; see also Lehne 1986). How the casino industry was defined in Atlantic City was a result of social, historical, and geographical factors unique to the city, the relation it had in a network of resort cities, and the distance it wanted to keep with Las Vegas.

In summary, a sociospatial approach places the emergence of the casino industry in Atlantic City as a contextualized phenomenon tied to a local economy, a city's infrastructure, and a state legislative framework. The sociospatial shaping of the region is perhaps more informative than a discursive approach to explain the reasons why Atlantic City became the first city in the East of the United States to legalize gambling, and why it held this monopoly for close to twenty years.

How are innovations adopted? Giesler (2012) explicates the gradual social acceptance of technological innovations, such as the Botox Cosmetic self-enhancement injection, as a conflictive, dyadic, and discursive-based process between official brand images promoted by the innovator and doppelgänger brand images (Thompson et al. 2006) publicized by other stakeholders. However, by focusing solely on rhetorical tactics, this study has overlooked the important role of spatial elements in legitimizing radical innovations.

Even though Botox had been occasionally administered in doctors' offices across the U.S. to treat wrinkles, it was not until the FDA's approval for cosmetic-use in 2002 that the innovation started to disseminate through a unique form. As Kim (2006, 8) recounts, following FDA`s approval, "[the] floodgates burst open in convivial form, giving rise to a phenomenon known as Botox Parties." Botox parties – "[a] consumption ritual taking place either in upper-class living rooms or in the practices (or homes) of exclusive Botox dermatologists" (Giesler 2012, 59) – were not part of the innovator's initial marketing campaign. Rather, they were created by medical practitioners in Los Angeles, U.S.A's plastic surgery epicenter, who saw these temporary market-spaces as an opportunity not only to save costs and make higher profits by injecting several patients at once (Zimmerman 2002), but also to introduce new customers to the innovation, and gain word-of-mouth advertising and free publicity by combining two disparate scenes: the house party with the doctor's office.

These spaces, co-created between doctors and early adopters, seamlessly integrated highbrow party elements (such as a hors d'oeuvres, champagne, and jazz music) with common medical components (including sterilized needles, vials of Botox, and consent forms). As such, they provided the safety and security of the domestic environment (McCracken 1989) in combination with the expertise of medical professionals, which gave consumers the confidence and comfort to experiment with a potentially healthy and morally risky innovation. This spatial fusion became an instant hit across the U.S., soon moving from exclusive private homes at the domestic scale to "servicescapes" (see Booms and Bitner 1981) at the public scale, when Las Vegas hotels began offering Botox spa weekends, casinos and radios gave away complementary injections at local malls, and a Botox party was held live on the popular "Entertainment Tonight" television show (Cooper 2002). Hence, the Botox party, a safe and familiar market-space, acted as a "market catalyst" (Martin and Schouten 2014) in the diffusion of the cosmetic innovation during its launch phase by fostering a brand community (Muniz and O'Guinn 2001) and evangelizing new consumers.

In sum, we found evidence that the widespread acceptance of new, illegitimate, and risky consumer practices, regardless of the institutionally powerful market actors supporting them, can be facilitated by market-mediated safe spaces.

Our sociospatial analysis of two market creation phenomena has demonstrated how spaces exert different forms of agencies over market actors and processes. At the industry-level, Atlantic City's resort structure and geographical characteristics provided the grounds to attract and legalize the city's casino industry. At the product-level, Botox parties provided a safe and controlled environment from which the innovation spread to the general public.

DISCUSSION

As we have shown, markets are emplaced and embedded within localized cultural, social, and economic forces. Places provide specific cultural, human, and material resources, as well as political and legal environments that influence the creation and evolution of markets. Temporary market spaces allow for the performance and reproduction of market practices by local social actors. Accordingly, markets are co-constituted by geography (see Shove and Pantzar 2005). Catering to the role of geographies shed a new theoretical light on micro to macro market-level processes. We show how places provide cultural, human, and material resources, as well as political and legal environments that influence the creation and evolution of markets, as well as how temporary market spaces in a domestic setting can serve as safe spaces for the diffusion of market practices and the recruitment of market actors.

So far, marketing researchers have been committed to understanding the role of actors, institutions, discourses, and practices (in order: Scaraboto and Fischer 2013; Humphreys 2010a, b; Shove and Pantzar 2005) on market dynamics, leaving space rather unexplored (some notable exceptions include Bjerrisgaard and Kjelgaard 2012; Cayla and Eckhardt 2008; Humprheys 2010b; Martin and Schouten 2013). Our proposed framework is aimed at redressing this shortcoming by offering four interlinked theoretical concepts. We suggest moving away from the overtly discursive approach to the study of markets (e.g., Giesler 2012; Humphreys 2012b; Sandicki and Ger 2010; Scaraboto and Fischer 2013) and instead focus on how the materiality of space shapes market creation, disruption, and evolution. Through our re-examination of two prominent market creation cases, we have shown how geography can extend existing approaches. The combination of the four spatial concepts allows us to provide novel research avenues addressing market dynamics. Table 1 below shows the theoretical focus brought about by the use of each concept, each combination of concepts, and the specific research questions that emerge from such a focus.

The marketing field's strength is the study of consumers and their interaction with producers. We are not suggesting that geography should overshadow an analytical focus on those actors. Rather, we believe our field is uniquely positioned to question how space impacts consumers, producers, and markets. Our spatial turn solely broadens our theoretical apparatus, and we hope that this sociospatial approach will allow for future fruitful research avenues.

Table 1. Concepts, objects of study and possible research avenues

Concept	Object of study	Application to market systems
Place	Cities, neighborhoods, regions, locales (as marketplaces)	How are markets emplaced?
Place x Territory	Core vs. periphery; places as territories	How is distance from a market center impacting a peripheral market?
Place x Scale	Global vs. local; Russian doll spatial division (home - local - national - global)	How are global markets enacted locally?
Place x Network	Network of places; Partnerships; Movements of actors	How do market actors associated across places?
Territory	Borders and boundaries	How are markets' (multiple) borders maintained or expanded upon?
Territory x Scale	Market division (local; global); Multilevel governmentality	How are market divisions sustained?
Territory x Network	Interstate market systems; Multi-territorial market alliances	How are marketing territories influencing the structuration of markets?
Scale	Hierarchies, global vs. local	How are nested market practices influencing each other?
Scale x Network	Flat ontologies; ascalar market entry	How are new markets recruited to a market system?
Network	Flows, networks	How are markets constituted across spaces?

All the Fun of the Fan:
Consuming Burlesque in an Era of Retromania

Marie-Cécile Cervellon, EDHEC Business School, France
Stephen Brown, University of Ulster, UK

ABSTRACT

Retro is often associated with a cosy, cupcaked, rose-tinted worldview. Some consumers, however, resist the comforts of capitalist commodification through retro-sexual activities. This paper studies one such community of fun-loving, fan-wielding Burlesque dancers in France, revealing their retrospective lifestyles and resistant pursuits.

The most important element in burlesque is fun. If you're having fun, the audience will feel it.

—Jo Weldon (2010: 18)

INTRODUCTION

According to Cova and Cova (2014), retromarketing is one of only four strands of Consumer Culture Theory (CCT) that have made the leap from academic contemplation to management practice. This may or may not be fair comment, but what is incontestable is that we live in a retroactive age, where throwback branding is burgeoning and newstalgia is all around (Kozinets 2013). Although there is considerable disagreement on the causes of today's yester-yearning – some attribute it to the ageing of Baby Boomers, others to the overpowering pace of technological change, yet others to consumer cocooning in an increasingly threatening world – most commentators concur that contemporary consumption is being "inundated with images of the past" (Wilson 2005, p.161).

Within marketing and consumer research, retro has had a fairly easy ride (Cova and Cova 2014). It is viewed in a positive light. Not only is it recommended as a viable branding strategy for hard-pressed marketing managers (Brown, Kozinets and Sherry, 2003), but the nostalgic feelings retro evokes are considered healthful, nothing less than rose-tinted salves that transform occasionally unpleasant memories into uniformly enjoyable reveries (Zhou, et al. 2012). The past is a palliative (Lindstrom 2011). It makes the present palatable. Whose heart doesn't lift a little when the cute, cuddly, cartoonish, child-like VW Bug cruises by? Who isn't looking forward to J.J. Abrams' reboot of *Star Wars* with most of the original cast in place?

Reading the above, it is easy to infer that retro is a soft option, the lazy response of unimaginative brand managers who rummage in their archives for languishing logos and moldering brand mascots (Walker 2008). It is cheap, it is cheesy, it is egregious, it is exploitative (Harris 2000). It is reactionary, basically (Reynolds 2011). Retro, however, can also be a site of resistance, a sequestered space where anti-commercial activities are enacted and a cheeky, counter-capitalist ethos is articulated. Drawing upon a detailed, three-year ethnographic study of Burlesque dancers, we show that, far from being dewy-eyed yester-yearners, the Burlesque dancing community regards their retro-inflected activities to be a carnivalesque challenge to commodification and consumerism. Our paper commences with an overview of latter-day retromania and its marketing manifestations, continues with a stripped-down account of the Burlesque art-form and our data gathering activities, culminates in a compact results section, which reveals the retro and resistant components of dancers' fun-filled, fan-handling pursuits, and concludes with a few words on the retro-equals-reactionary stereotype.

RETRO HO!

Way back in the dim and distant days of the mid 1990s, the provocative French philosopher Jean Baudrillard (1994) proclaimed that history had been thrown into reverse. Sensing the then-imminent millennium, when the capitalist west's "progress" would be weighed in the balance and found wanting, he announced that an age of reflection, of reminiscence, of retrospection was upon us. The overall aim of these collective recollective activities, he further averred, was to settle the score and wipe the slate clean before starting from scratch in the 21st century.

Twenty years on from Baudrillard's undeniably brilliant hindsight insights, the philosopher himself is dead and gone, but the retrospective epoch he anticipated is still going strong. Nostalgia is everywhere. Yestermania is rampant. The past is more present than ever in popular culture. Whether it be blockbuster movies (*Noah*, *Dawn of the Planet of the Apes*, *X-Men: Days of Future Past*), bestselling novels (*Bring Up the Bodies*, *Life After Life*, *Stoner*), Broadway musicals (*Wicked*, *Jersey Boys*, *Rock of Ages*), must-see TV (*Mad Men*, *Downton Abbey*, *Dallas*, alas) or indeed the ongoing financial scandals, with their unsettling echoes of the 1930s, we live at a time when the shock of the new has given way to the schlock of the old.

So retromaniacal are consumers nowadays, according to popular culture commentator Simon Reynolds (2011), the first ten years of the 21st century should not have been called the "noughties", as they often were, but nothing less than the "Re-" decade. The 2000s, he rants in an outraged 500-page tirade, were dominated by the re-prefix: revivals, reissues, remakes, re-enactments, re-launches, reformations, restorations, rehabilitations, recapitulations and non-stop retrospection, not least in the music industry and its analogous affiliates like fashion and dance.

Numerous scholars, needless to say, have tried to make sense of these developments, both with regard to the nostalgia boom in general and retro-branding in particular. Davis (1979), for instance, draws a distinction between private nostalgia and collective nostalgia; Boym (2001) contrasts restorative nostalgia with reflective nostalgia; Jameson (1991) separates traditional nostalgia and neo-nostalgia; Brown *et al*. (2003) maintain that nostalgia brands are not the same as retro brands; Maclaran (2003), de Groot (2008) and dozens of others have plumbed the depths of this retrospective impulse, using a range of qualitative and quantitative methods. For the founding father of this field, though, the most remarkable feature of the 21st century's preoccupation with the past is "Postmodern Ironic Nostalgia", which mines the past and mocks the present simultaneously (Lowenthal 2014). Instead of venerating bygone times, PIN makes fun of them and revels in contemporary anachronisms. Thus *The Onion* satirically declares that, such is the demand for revivals, America is not only running out of heritage but considering rationing what remains in order to preserve stocks of times past for future consumption!

A BRIEF HISTORY OF BURLESQUE

Burlesque, in the words of the *Oxford Reference Dictionary*, is "a variety show, often incorporating striptease." This definition, however, hardly does justice to a venerable and valuable cultural form. Burlesque is a multi-disciplinary performance art that, throughout history, has built on different theatrical traditions includ-

ing playing, singing, dancing, clowning and, since the late 19th century, stripping.

The first burlesque show, in the tradition we know today with nude and exotic dancers, took place in Paris in 1894 at the Divan Japonais and spread to celebrated cabarets like Moulin Rouge, Casino de Paris and Folies Bergeres, as well as the United States (Do Carlo, Von Berlin, and La Motta 2011). From the Roaring Twenties onward, sophisticated burlesques were performed in New York cabarets and theaters, with star strippers such as Gypsy Rose Lee, Tempest Storm, Lili St. Cyr and the peerless Betty Page (Do Carlo, et al 2011).

After a dip during the 1970s, when hardcore pornography, live sex shows, and full nudity images in the media decreased the public's appetite for top-class strip-tease, the genre was revitalized in the 1990s thanks to a number of female celebrities who revived Hollywood glamour through the New Burlesque (or Neo-Burlesque) movement, both in the US (Dita von Teese) and Europe (Immodesty Blaize). In France, for example, strip-tease classes have opened in major cities; a number of annual events have been established by dance enthusiasts; and, ever since the success of the road movie *On Tour* (which features American new burlesque performers Mimi Le Meaux, Kitten on the Keys, Dirty Martini, Julie Atlas Muz, Evie Lovelle, and Roky Roulette), the movement has featured regularly in women's magazines and its accessories are on sale in many drugstores.

METHODS AND FINDINGS

As summarized in Table 1, our three-year ethnographic study of the French burlesque community evolved through three main phases. It began with non-participant-observation of the community, originating from the lead author's vintage collecting interests. A second

phase involved deeper immersion in the subculture, when the lead researcher joined two burlesque associations, Neo Retro and Tassel Tease, and participated in their activities. The third phase necessitated full involvement in the community, though regular attendance at strip-tease classes – once per week for a year – and performing on stage in a group show, *Follie Follies* (June 30th, 2012, Mas des Escarvatiers, France). This not only offered a unique opportunity to experience the emotions created by the gaze of spectators, but it helped minimize researcher dominance and "otherness" (Madriz 2000) and facilitated the co-creation of meaning. Interviews were also conducted with burlesque art director, performer and historian Lady Flo, famous burlesque performer Cherry Lyly Darling, cabaret performer and professor La Violeta, as well as the make-up and hair-stylist Krystie Red Sugar. In addition, several trainees were interviewed (Lady Strawberry, Lady Pee, Bambi Freckles, Barbie I Doll, etc.), as were spectators at burlesque events and burlesque/vintage store managers. Field notes were taken, furthermore, as were pictures and videos during preparation for the show. In parallel, a second researcher was observing the community as an outsider. He related the analysis to existing theoretical frameworks. He also ensured that the first researcher, by dint of being deeply involved in the community, would not become blinkered by the burlesque community's beliefs and mores (Schouten and McAlexander 1995). Themes started to emerge early during the second phase of the research and were formalized thereafter, as follows:

Burlesque's Retro Aesthetic

The burlesque community is rich and varied but its members are as one in their can-do mentality. They consider femininity and beauty to be a *production*. As Dita von Teese (2006), stresses, wom-

Table 1: Overview of Methodology

	PHASE 1 (June 2010-October 2010): Non Participant Observation	PHASE 2 (October 2010-June 2011) Overt Participant-Observation as an outsider	PHASE 3 (June 2011-Dec. 2012): Participant-Observation as an insider
Data collection	Vintage Brocantes ; Vintage stores; Cabaret shows and Burlesque perfomances; Movies; Paris Burlesque Festival (Oct 2010)	Adhesion to Tassel Tease and Neo Retro; Neophyte Strip-tease classes, retro make up and hair styling classes , DIY classes (nippies) as a researcher Paris Burlesque Festival (Oct . 6-9 2011)	Weekly training to perform on stage; Nice Feria (April 2012); On stage in a collective show (June 30th 2012) French national holiday: retro 50's (July 14th 2012) Paris Burlesque Festival (Oct. 2012)
Researcher status and involvement	Spectator Collector of vintage furnitures (occasionally clothes) Fan of the 50's-60's Hollywood movies	Involvement as a researcher	Involvement as a trainee and performance on stage

en *produce* their look through exaggerated make-up and feminine attire. Not all women are born beautiful yet every woman can *become* beautiful with appropriate work involving cosmetics and costumes. In today's world of "fake naturality," where women are encouraged to use artificial means to look natural and flawless – French manicure, nude make-up, light cosmetic treatments like Botox – burlesque encourages an artificially constructed appearance that harks back to a golden age of Hollywood glamour. Burlesque women take inspiration from icons like Marilyn Monroe and Mae West, who represent the retro-feminine ideal of constructed voluptuousness. Dita von Teese's transformation from an ordinary blond girl with freckles to a glamorous, raven-haired reincarnation of pin-ups of yore illustrates both the pull of the past and its production in the present.

This neo-nostalgic outlook is likewise expressed in the costumes and accoutrements of burlesque members. Footwear and hosiery are central to the community's sense of self (Belk 2003), stockings, garters and stilettos especially. Lipstick too is integral to burlesque's retro aesthetic. In many ways, indeed, it is the signature emblem of the subculture. Despite individual differences, all burlesque looks combine bright red lips with pale powdered skin, often framed by appropriately old-fashioned hairstyles, such as the classic Victory Roll of post-war pin-ups (Weldon 2010). The vocabulary of body movement is no less nostalgic (e.g. bump 'n' grind), as are key components of stage costumes (fans, fishnets, pasties, nippies, etc.) as are grooming rituals (elaborate application of fresh lipstick) as are annual ceremonies (such as Tease-O-Rama) as are the pseudonyms adopted by burlesque dancers, which often evoke the fun-filled spirit of childhood replete with sweet treats and candy kisses (Sugar da Moore, Bambi Freckles, Lady Strawberry, Barbie I Doll, Mlle. Sweet Candy, Sucre d'Orge).

Another, rather more transgressive, throwback is the tattoo. Almost every woman encountered or interviewed had a tattoo. Their tattoos, however, tend to be the antithesis of those traditionally associated with male virility. Not only are they retro in style and imagery, but frequently depict flowers, fruits and birds as symbols of femininity and freedom. In France, lilies are an especially popular motif, a clear reference to the 15th and 16th centuries when prostitutes were marked on their skin with fleurs-de-lis (Caruchet 1981).

The retro-mindedness of community members varies considerably, admittedly. Stage performers and retro-style designers have highest status membership within the subculture. They inspire and feed groups of women who share a commitment to retro-fashions and retro activities more generally. Members at lower levels of the hierarchy do not adhere fully to the retro lifestyle on a daily basis. What they do share, though, is a rejection of contemporary consumer culture which they call the McFashion or Kleenex economy. As a rule, they prefer to invest in quality goods with historical heft. One vintage retailer explained how she got sick of Zara and H&M types of clothes and decided to invest instead in good cut, high quality, ethically produced items:

> *I was going to professional exhibitions and I was sick, season after season, to see more or less always the same stuff. The stuff the client washes maximum 5 times, and put in the garbage. One day, I discovered a stand with vintage pieces. I ordered for my boutique and it worked well. From there I extended the range. I sell authentic vintage as well as collections with a respect for both the style (vintage) and the spirit (ethical) such as for instance Brigitte Bardot line of clothes (Chantal, in her 50's, Vintage Retailer and Designer)*

Burlesque women, by and large, exit mass market consumption through nostalgic acquisitions and the celebration of authenticity (Beverland and Farrelly 2010): that is, genuine products popular in prior historical periods (Cervellon, Carey, and Harms 2012). In the burlesque world, which is regarded by some as superficial and fabricated, the genuine has special status. Community members are educated to choose vintage pieces, or make them by themselves when they are not available. They collect passionately but, unlike the typical collector, they collect in order to use. Products evocative of the "good old days" – including furniture, clothes and accessories – are used every day rather than placed on a pedestal. Women shop for vintage in specialized markets, are loyal to specialized stores, and import vintage pieces from the US through specialized websites. They replicate the look of iconic historical epochs (the 20's, the 50's, etc.) down to the finest detail in clothing, make-up and hair-styles.

Another manifestation of yester-yearning is found in the community's "home-made" or "Do-It-Yourself" ethic. Accessories and attire that cannot be purchased or borrowed from the relevant period of history are hand-made, based on original drawings. Real vintage lingerie pieces are very rare because people are reluctant to purchase second-hand underwear. For this reason, lingerie pieces tend to be sown by hand from classic patterns. Other important accessories worn in private are the pasties or nippies which hide the nipples. Again, these items are home-made. Do-it-Yourself approaches also apply to cosmetics, where mixing powders into bespoke shades is commonplace. Burlesque is the DIY of beauty and fashion. Women do their costumes themselves. Traditional crafts such as knitting and weaving are reborn. As Ferreday (2007, p.57) notes "Whereas mainstream femininity is positioned as empty consumption, and as a source of anxiety, burlesque is aligned with recycling, thrift shopping, and the revival of traditional crafts."

Burlesque's Resistant Attitude

Ferreday (2007) further notes how burlesque emerged as a subculture that promotes the construction of multiple and elaborate feminine identities. Some performers "show the girl", by placing glamour and girly attitudes at the center of their performances (e.g. Dita von Teese), meantime many other performers "burlesque the girl", emphasizing the second degree and the comic in their routines (e.g. Dirty Martini). Whatever approach is adopted, it has to be a personal and individual sense of performing femininity.

Throughout this process of "becoming a woman," burlesque resists the conventional emphasis on understatement (natural make-up, healthy tan, clothes that do not celebrate the body, et al.). It liberates from normative versions of womanhood which consider shameful the overt and excessive use of feminine artifacts. Women committed to a burlesque lifestyle embrace the glamour of Hollywood stars of the 50's, many of whom refused to exchange their stockings for new-fangled pantyhose. Burlesque women wear stockings and garters every day, as casual outfits, and set great store by bright red lipstick, noted above.

In addition to resisting oppression, burlesque women *learn* femininity. At the heart of the burlesque ethos, the dominant idea is that femininity is both *produced* and *performed*. Classes teach women how to construct their feminine self: sitting on a chair with elegance, walking on heels with allure, seducing with one eyes, moving one's hands with grace and, ultimately, undressing in a sensual manner. Femininity is always glamorous and elegant, never vulgar or nondescript. In burlesque, it must be emphasized, the "performance of femininity" is not directed at men. The vast majority of audiences at burlesque shows are female (Ferreday 2007). Attendees also tend to be well educated and independent financially. They are in a process of defining femininity (and sexuality) in a very intimate

way, regardless of male-constructed stereotypes. In this process, they subvert society's insistence on fitting in and adhering to socially-constructed roles. Implicitly, burlesquers condemn an intolerant and masculine society.

The ironic and parodic style of many burlesque performers is equally empowering. Throughout history, humor has been an instrument of resistance by the oppressed over their oppressors (e.g. Lipman 1991). It is a "survival device" (Caliskan 1995), one of the reasons why women use humor in the workplace (Martin 2004) or when engaging in male activities such as riding a motorbike (Martin, Schouten, and McAlexander, 2006). Such actions invert gender inequalities. Alongside humor, history contains many examples of women resisting forms of oppression through nudity. For instance, young Egyptian and Iranian activists post naked photos on their blogs in the name of freedom of expression. Women are willing to undress in thought-provoking ways. The burlesque community is likewise defined by nakedness, through its stress on strip-tease performance. Stripping is an individual act, going beyond one's sexual boundaries, as much as a collective defiance against a male constructed discourse of deviance (see Ronai and Cross 1998).

For many women, undressing in front of an audience is an exhibitionist act. All informants mention the thrill of going out of the boundaries of their (ordinary) sexuality through exhibiting their bodies. They consider themselves as having an anti-conformist and liberal perspective on sexuality. That said, the strip in burlesque is about sexiness and sexuality. It is not about sex, as such. During a burlesque show, participants never disrobe totally; they strip down to nippies and G-strings. They stress the tease rather than the strip in striptease. The process is more important than the outcome.

The burlesque community's resistance isn't total, however. Recent years have seen the co-option of its imagery by the luxury, fashion, beauty and beverage industries. Several haute couture houses have launched vintage inspired collections (Louis Vuitton, Miu-Miu) or recycled vintage materials and designs (YSL, Dior's revived New Look). Ralph Lauren sells vintage pieces in his London and Paris flagships along with his own creations. NARS lipstick names evoke golden age Hollywood movies (Blonde Venus, Shanghai Express) and Benefit cosmetics uses vintage and pin-up imagery on its packaging. Even Chanel embraced burlesque when Karl Lagerfeld featured Dirty Martini, one of the most famous and overweight new burlesque performers, in a photo-shoot at the iconic entrance to the brand's flagship store on rue Cambon (Sterzemien 2010). Although some purists within the community are offended by the fashion industry's exploitation of their subversive subculture – or its imagery at least – most of our informants consider this a tribute to the burlesque community's creativity and artistic accomplishments. They recognize that it provides a vehicle for conveying their ideas to a much wider public and womanhood as a whole:

> *The purists do not accept this usage of the burlesque imagery. For instance, they find insulting that women would ape their style (make-up and hair styling) and that brands would be marketed retro. I consider that we cannot live in isolation. I find positive that our ideas and creations would be put forward and inspire the marketplace (Krystie Red Sugar, 45, Hair and Make Up Artist)*

DISCUSSION AND CONCLUSION

Although consumer research studies devoted to the specifics of retro are comparatively few in number, they reveal that the nostalgia-steeped products, services and promotional activities of marketing practitioners often trigger resistance from interested parties (Brown

et al. 2003). The new Beetle, for instance, was rejected out of hand by many Love Bug lovers of old. The revived *Star Wars* franchise was castigated by movie enthusiasts who found it hard to see past the glory days of Carrie Fisher, Mark Hamill and Harrison Ford. The resisters are themselves resisted, admittedly, but just as empirical studies of nostalgia show that the bittersweet emotion is sweet for some yet bitter for others, so too retro is revered to the point of rejoicing and reviled to the point of resistance. Our ethnographic study of the Burlesque community reveals that retro can be a form of resistance in itself. By retreating into an idealized past, like the replica Mountain Men of Colorado (Belk and Costa 1998) or the stressed-out Microserfs at Burning Man (Kozinets 2002) or the old-Americana-minded riders of vintage Harley-Davidsons (Schouten and McAlexander 1995), many consumers resist and reject all that is trite and tawdry about today. Retro, in sum, isn't always a return to the hidebound past, it's also a rejection of the reactionary and a potentially revolutionary dance step into a future of postmodern ironic nostalgia.

Norms as Standards vs. Self-Descriptions:
How Dynamic Information Shifts Interpretation of Normative Messages

Sokiente W. Dagogo-Jack, University of Washington, USA
Joshua T. Beck, University of Cincinnati, USA
Nidhi Agrawal, University of Washington, USA

ABSTRACT

Social norms are widely used to promote both personally and societally beneficial behaviors. Many normative messages seek to influence the audience by presenting static information—information about the frequency, incidence, or prevalence of some behavior or condition among members of a population. For example, a *New York Times* headline "America's Diet: Too Sweet by the Spoonful" presents the norm for nutrition in static terms (Brody 2009). However, normative messages can also convey dynamic information—information about how the frequency, incidence, or prevalence of some behavior has been changing in a given population. For example, the headline, "Americans' Eating Habits Take a Healthier Turn, Study Finds," presents the norm for nutrition in dynamic terms (Beck and Schatz 2014). Although a substantial body of research has explored the mechanisms by which social norms influence behavior, this literature mainly focuses only on normative messages presenting static information (Goldstein et al., 2008; Schultz et al., 2007). The present research departs from prior work by investigating the effects of dynamic information in normative messages about exercise, a context of particular importance given a national surge in efforts to battle obesity and obesity-related illnesses.

The notion that people tend to align their behavior to social norms is well-documented in behavioral research (Bearden and Etzel 1982; Venkatesan 1966). These descriptive norms (i.e., what most people are doing) influence consumers by highlighting a potentially successful, or at least acceptable, course of action—"If everyone is doing it, it must be a sensible thing to do" (Cialdini et al. 1990, 1015). Moreover, adhering to norms often increases social approval (Fisher and Ackerman 1998; White and Simpson 2013). Thus, norms can serve as a standard to which people assimilate. However, this conclusion is predicated on research that largely examines normative messages presenting static information. What remains unknown is how people respond when normative messages also present dynamic information—specifically, information suggesting improvement.

Extant research has found that people have a general preference for improving trajectories over more stable ones (Hsee and Abelson 1991; Hsee, Abelson, and Salovey 1991; Kahneman and Tversky 1979). Furthermore, individuals tend to perceive improvement in themselves even where it has not occurred (Wilson and Ross 2001). Accordingly, we propose that when a normative message conveys improvement, the message will be aligned with people's self-views, increasing the likelihood that they interpret the message as a self-description (vs. a standard). Thus, a low (vs. high) exercise norm will be self-threatening and increase consumers' fitness intentions (Gao, Wheeler, and Shiv 2008; Taylor, Neter, and Wayment 1995). This constitutes a reversal of the effect of normative messages that only present static information.

Two experiments explore the proposed effects and examine the moderating role of implicit theories to shed light on the underlying process. Prior research on implicit theories has found that entity theorists tend to make trait attributions for their performance (Burnette 2010; Hong et al. 1999), and thus they should be most susceptible to the self-descriptive interpretation of norms fostered by dynamic information. Consistent with this, we demonstrate that the proposed reversal of effects is most pronounced for those who strongly endorse entity theories of fitness. In doing so, this research makes three contributions. First, the experiments reported here enrich the literature on social norms by providing an initial investigation of the influence of dynamic information in normative messages. Second, the preponderance of work on implicit theories and self-regulation suggests that incremental theories are more effective in promoting self-improving and self-beneficial behaviors (Burnette 2010; Burnette et al. 2013). In contrast, we demonstrate a situation in which entity theories can promote self-regulatory behavior. Lastly, this research makes a practical contribution to health marketing. Specifically, we shed light on when dynamic information in normative appeals will be effective in motivating healthy behavior and when it is likely to backfire.

SOCIAL NORMS AND STATIC INFORMATION: NORMS AS STANDARDS

Research from a variety of disciplines has demonstrated the influence of norms in numerous domains, including environmental consciousness (Goldstein, Cialdini, and Griskevicius 2008; Schultz et al., 2007; White and Simpson 2013), charitable giving (Croson, Handy, and Shang 2009; Croson and Shang 2008), volunteerism (Fisher and Ackerman 1998), and physical fitness (Christakis and Fowler 2007). Across these disparate contexts, considerable evidence suggests that individuals assimilate to salient social norms—i.e., what they believe most others are doing—for better or for worse. For example, Cialdini and colleagues (1990) found that when the norm for littering is low and salient, people reduce their littering; on the other hand, when the norm for littering is high and salient, people increase their tendency to litter. In later work, Schultz et al. (2007) demonstrated a similar effect in the context of household energy consumption. Specifically, households decreased their energy consumption when they received a message informing them that they used more electricity than the norm, and increased their consumption when they were informed the opposite. More related to the context of our study, medical research on the spread of obesity has invoked a similar norms-assimilation process to explain the spread of obesity throughout social networks (Christakis and Fowler 2007). Specifically, Christakis and Fowler suggested that close relationships with obese individuals color perceptions of fitness norms, ultimately increasing the likelihood of personal weight gain. Thus it appears that social norms are generally used as standards for behavior.

In most of the prior norms research, whether the focal norms are explicitly stated (e.g., Schultz et al. 2007; White and Simpson 2013) or merely implied (e.g., Cialdini et al. 1990; Reno, Cialdini, and Kallgren 1993), they primarily provide static information describing what others are doing presently. For example, in their research on how norms influence sustainable consumer behaviors, White and Simpson (2013) show some participants a normative message that reads, "Your neighbors are grasscycling." This norm presents static information—at this cross-section of time, people in a relevant reference group are engaging in a particular behavior—that should motivate other members of the reference group to follow suit. However, a similar normative message could have read "Your neighbors are grasscycling more than before," providing dynamic information about how sustainable behaviors have been changing.

Although it is clear that normative message conveying static information should promote behavioral assimilation, extant research is silent on what happens when these messages conveying dynamic information. Outwardly, both normative messages provide essentially the same information, as far as suggesting what other people are doing. However, for reasons delineated in the following section, we do not expect these two types of normative messages to influence consumers in the same manner.

SOCIAL NORMS AND DYNAMIC INFORMATION: NORMS AS SELF-DESCRIPTIONS

A long tradition of behavioral research has suggested that people are more sensitive to change than absolute states (Kahneman and Tversky 1979). Furthermore, research on satisfaction judgments has found that people generally prefer improvement to stability, deriving greater satisfaction from the same outcome when it has resulted from improvement than when it has not (Hsee and Abelson 1991; Hsee, Abelson, and Salovey 1991). Thus, it is likely that normative messages presenting dynamic information will have different effects from those presenting static information; however, the nature of this difference is not immediately clear.

Consistent with the general preference for improving trajectories, previous work on temporal comparisons has found that people tend to believe that they have been improving over time, and these perceptions are upheld whether or not there is any objective evidence (Wilson and Ross 2001). Across a variety of dimensions, Wilson and Ross found that people evaluated their current selves much more favorably than their past selves, and this held for students, parents, and university staff alike. Given this predilection for improvement, we propose that normative messages presenting dynamic information about improvement will be consistent with consumers' self-views. Therefore, consumers will interpret these norms as self-descriptions rather than standards for behavior. When these self-descriptions are threatening (i.e., when the norm for exercise is improving but still low), this should motivate behaviors that bolster the threatened aspect of the self (Gao, Wheeler, and Shiv 2008; Taylor et al. 1995). Thus, norms communicating dynamic information about improvement can ultimately have the opposite effect from norms that only convey static information.

Insofar as normative messages conveying improvement are interpreted as self-descriptions, the motivating effect of a low (vs. high) norm should be stronger among individuals who are more likely to be threatened by unfavorable self-descriptions. Implicit theories—whether one tends to view traits as more malleable (incremental theory) or fixed (entity theory)—have been shown to influence proneness to self-threat. Specifically, entity theorists are more likely to make trait attributions for performance and are primarily concerned with demonstrating their high level of positive attributes (Burnette 2010; Hong et al. 1999). Thus, they should be more threatened by a low norm that's interpreted as a self-description. Accordingly, we posit that when the norm for exercise is low but improving, entity (vs. incremental) theorists will be more threatened by the low norm, which to them is an unflattering self-description. Thus, rather than conforming to the low norm, entity theorists will be more likely to pursue self-beneficial behaviors to counter the threat. Moreover, this effect should be attenuated for incremental theorists, who are less likely to be threatened by negative self-descriptions and consequently less motivated to take remedial action. Importantly, this prediction opposes one based on the notion that incremental theorists believe that they can improve their fitness and thus should be more motivated by the dynamic norm than entity theorists.

STUDY 1

The goal of study 1 was to test the prediction that consumers will assimilate to fitness norms conveying static information, but this effect will be reversed when then norm also presents dynamic information about improvement. Accordingly, we manipulate the level of the static information (i.e., high vs. low exercise norm) as well as the presence of dynamic information (i.e., exercise has been increasing or control).

Design and Procedure

116 participants from Amazon's Mechanical Turk online panel completed this study for $.40. Participants were randomly assigned to one of four conditions in a 2 (static information: low vs. high) x 2 (dynamic information: increasing vs. control) design. Under the guise of a survey on fitness, participants answered filler questions about their weight and exercise tendencies. While the system supposedly recorded their responses and prepared the next portion of the survey, participants were shown a normative fitness message in which the critical manipulations were embedded. In all conditions this fitness message specified that the average American adult exercises 2 hours a week. However, to manipulate whether this was perceived as a low or high amount of exercise (i.e., static information), we described 2 hours as "an unimpressive (impressive) 20 minutes every day." Moreover, to manipulate dynamic information, the message in the increasing condition specified that Americans' weekly exercise time had increased over the past 3 years. The control condition message did not mention any changes in weekly exercise.

The dependent measures were as follows: All participants rated their anxiety about their future health (*concerned, worried, anxious*, $\alpha = .97$) on 1 (not at all) to 7 (very much) scales and their perceived need for improvement ("I need to take better care of my body," "I need to improve my fitness," "I need to devote more time to exercising," $\alpha = .92$) on a 1 to 7 Likert scale. Next, as part of a supposedly unrelated product evaluation task, participants viewed a series of advertisements for gym memberships. After viewing each ad, they rated their intentions of joining the gym (*improbable-probable, impossible-possible, unlikely-likely*, $\alpha = .96$) on 7-point scales, as well as their willingness to pay for a gym membership in U.S. dollars. Finally, participants completed a manipulation check in which they rated how much exercise American adults get on a 1 (*small amount*) to 7 (*large amount*) scale and provided basic demographic information.

Results and Discussion

A 2 (static information) x 2 (dynamic information) ANOVA on the manipulation check revealed only a main effect of static information. As expected, those in the high exercise condition ($M = 2.74$) perceived American adults to exercise more than those in the low exercise condition ($M = 1.83$, $F(1, 112) = 19.39$, $p < .001$).

Moreover, a 2 x 2 ANOVA on anxiety about future health revealed the predicted interaction ($F(1, 112) = 4.49$, $p < .05$). Simple contrasts revealed that, in the control condition, those in the high (vs. low) exercise condition had directionally but not significantly higher anxiety ($M = 4.41$ vs. 3.74, $F(1,112) = 1.90$, $p = .17$). However, when the norm for exercise was improving, those in the high (vs. low) exercise condition had directionally but not significantly lower anxiety ($M = 3.30$ vs. 4.06, $F(1,112) = 2.64$, $p = .11$). Moreover, when the weekly exercise norm was high, anxiety was lower for those in the improving condition than the control condition ($M = 3.30$ vs. 4.41, $F(1,112) = 5.35$, $p < .05$).

For perceived need for improvement, a 2 x 2 ANOVA yielded a significant interaction ($F(1, 112) = 9.79$, $p < .01$). In the control con-

dition, those in the high (vs. low) exercise condition reported a marginally higher need for improvement ($M = 6.08$ vs. 5.38, $F(1,112) = 3.26$, $p < .10$); however, in the improvement condition, those in the high (vs. low) condition reported a lower need for improvement ($M = 4.77$ vs. 5.76, $F(1,112) = 6.95$, $p = .01$). Again, when the norm was high, need for improvement was lower for those in the improving condition than the control condition ($M = 4.77$ vs. 6.08, $F(1,112) = 11.48$, $p = .001$).

Consistently, a 2 x 2 ANOVA on gym membership intentions revealed a significant interaction ($F(1, 112) = 8.61$, $p < .01$), such that in the control condition intentions were directionally (but not significantly) higher when weekly exercise was high (vs. low) ($M = 3.81$ vs. 3.23, $F(1,112) = 1.45$, NS); however, the opposite occurred in the improvement condition ($M = 2.35$ vs. 3.72, $F(1,112) = 8.87$, $p < .01$). When the weekly exercise norm was high, intentions were lower for those in the improving condition than the control condition ($M = 2.35$ vs. 3.81, $F(1,112) = 9.50$, $p < .01$). Lastly, a 2 x 2 ANOVA on willingness-to-pay (WTP) for a gym membership revealed the predicted interaction ($F(1,112) = 5.91$, $p < .05$). In the control condition, those in the high (vs. low) exercise condition reported a marginally higher WTP ($M = \$25.56$ vs. $\$18.12$, $F(1,112) = 3.04$, $p < .10$); however, in the improvement condition, this was reversed ($M = \$14.04$ vs. $\$21.00$, $F(1,112) = 2.86$, $p < .10$). Moreover, when the weekly exercise norm was high, intentions were lower for those in the improving condition than the control condition ($M = \$14.04$ vs. $\$25.56$, $F(1,112) = 7.40$, $p < .01$).

Study 1 provided initial evidence that individuals interpret norms as standards when they present static information, but as self-descriptions when they present dynamic information. Whereas consumers generally were more interested in fitness (as evidenced by self-reported need for improvement, intentions to join a gym, and willingness to pay for a gym membership) when the norm for weekly exercise time was higher, this relationship reversed when the norm was also improving. Furthermore, it appears that when the norm was higher, informing people that it had been improving had a licensing effect on their fitness intentions. Importantly, the fact that anxiety was higher in the control condition than the improvement condition for those who saw the high exercise norm suggest that the effects on WTP are not due to any self-efficacy concerns. Conceivably, consumers might disengage from fitness goals if they believe that they are too far behind others to ever catch up. However, given that those in the high exercise/improving condition actually had the lowest level of anxiety, it is unlikely that threatened self-efficacy can account for our effects. In study 2, we seek stronger evidence of the proposed process by examining the moderating role of implicit theories. Specifically, we expect the interactions obtained in study 1 to arise for those who endorse entity theories of fitness, but not for those who endorse incremental theories of fitness.

STUDY 2

Design and Procedure

101 participants from Amazon's Mechanical Turk online panel completed this study for $.40. Study 2 followed the same basic procedures from study 1 with the following changes: First, to shorten the procedure, we omitted the anxiety and need for improvement measures. Second, participants viewed both gym advertisements and advertisements about fitness-related mobile apps and reported their willingness to pay. Third, after completing the product evaluations we included a measure of implicit theories of fitness (Burnette 2010) to test the underlying process. Specifically, we predicted that the interaction obtained in study 1 would hold for entity theorists, but

not incremental theorists. Finally, we also included measures of their general interest in mobile applications and general interest in fitness centers to use as covariates.

Results and Discussion

A 2 (static information) x 2 (dynamic information) ANOVA on the manipulation check revealed only a main effect of static information. As expected, those in the high exercise condition ($M = 2.98$) perceived American adults to exercise more than those in the low exercise condition ($M = 2.02$, $F(1, 112) = 14.88$, $p < .001$).

To test the predicted three-way interaction on product evaluations, we regressed WTP for the fitness apps on a static information dummy variable ($0 = $ low, $1 = $ high), dynamic information dummy variable ($0 = $ control, $1 = $ improvement), standardized implicit theory, the interactions of these three variables, and general interest in mobile apps. This regression revealed main effects of general interest in mobile apps, ($b = .59$, $t = 5.35$, $p < .001$) and static information ($b = 1.77$, $t = 3.21$, $p < .01$); significant two-way interactions between static information and dynamic information ($b = -2.35$, $t = -2.99$, $p < .01$) and dynamic information and implicit theory ($b = -1.93$, $t = -2.29$, $p < .05$); and the hypothesized three-way static x dynamic x implicit theory interaction ($b = 1.93$, $t = 2.05$, $p < .05$). To explore the three-way interaction, we examined the two-way static x dynamic interactions at one standard deviation above and below the mean of implicit theory (with lower scores corresponding to stronger entity theories). As predicted, the two-way interaction was significant at one standard deviation below the mean ($b = -4.37$, $t = -3.35$, $p < .01$), but not at one standard deviation above the mean of implicit theories ($b = -.46$, $t = -.40$, NS). Furthermore, at -1 SD (i.e., entity theorists), the slope of static information was significant and positive for those in the control condition ($b = 1.92$, $t = 2.60$, $p < .05$), and significant and negative for those in the increasing condition ($b = -2.45$, $t = -2.28$, $p < .05$). At +1 SD, the slopes of static information were positive, and only reached significance for those in the control condition (control: $b = 1.63$, $t = 2.11$, $p < .05$; increasing: $b = 1.17$, $t = 1.31$, NS).

The same regression analyses were conducted on WTP for a gym membership, and they revealed a marginally significant three-way interaction ($b = 16.25$, $t = 1.77$, $p < .10$). Again, the static x dynamic interaction was significant at -1 SD of implicit theories ($b = -32.00$, $t = -2.60$, $p < .05$), but not at +1 SD ($b = -.02$, $t = -.002$, NS). Furthermore, at -1 SD (i.e., entity theorists), the slope of static information was significant and positive for those in the control condition ($b = 14.92$, $t = 2.14$, $p < .05$), and marginally significant and negative for those in the increasing condition ($b = -17.07$, $t = -1.68$, $p < .10$). At +1 SD, the slopes of static information were positive, but not significant (control: $b = 11.75$, $t = 1.62$, NS; increasing: $b = 11.72$, $t = 1.40$, NS).

In line with our hypothesis, implicit theories moderated the interactive effect of static and dynamic information on fitness-related behavioral intentions. Whereas the static x dynamic interaction obtained in study 1 persisted for entity theorists, who are more prone to interpreting feedback through a self-descriptive lens, this interaction was attenuated for incremental theorists.

GENERAL DISCUSSION

Across two experiments, we explore the effects of dynamic information about improvement on consumers' response to normative messages. Whereas consumers generally conformed to normative fitness messages conveying static information, the opposite occurred when these messages also included dynamic information about improvement. Furthermore, evidence suggests that this effect was

driven by differences in the interpretation of social norms presenting static versus dynamic information. While norms presenting only static information were generally interpreted as a standard, norms presenting dynamic information about improvement were interpreted as self-descriptions. Accordingly, in the absence of dynamic information, individuals were more interested in fitness-related products and services when the weekly exercise norm was framed as high (vs. low). However, when the weekly exercise norm was also improving, individuals were less interested in fitness-related products and services when the weekly exercise norm was framed as high (vs. low). Providing evidence of the underlying process, in study 2, we found that this interactive effect arose for individuals who strongly endorsed entity theories of fitness—i.e., those individuals who were more likely to be threatened by an unfavorable self-description—but did not arise for those who endorsed incremental theories of fitness.

In demonstrating these effects, we contribute to the literature on social norms by providing an initial investigation of the influence of normative messages that provide dynamic information. Despite the commonness of such messages, to the best of our knowledge, no research has investigated how their influence on behavior differs from that of more static normative messages. Here, we demonstrated that dynamic information can actually reverse the typical effects of social norms. Additionally, we contribute to research on implicit theories and self-regulatory behaviors. Previous research has suggested that entity theories tend to undermine effective self-regulation (Burnette et al. 2013; Job, Dweck, and Walton 2010; Mukhopadhyay and Johar 2005). However, our results demonstrate a situation in which entity theories will actually lead to the most adaptive responses. Indeed, in study 2, entity theorists were the only ones motivated by improving fitness norms.

Beyond these theoretical contributions, our research has practical implications for the use of normative messages. Although broadcasting a population's improvement may seem like a favorable thing to do, it can ultimately have negative consequences. Rather than motivating individuals to improve, such messages can ultimately license message recipients to disengage from the positive behaviors, to the extent that they interpret the message as self-descriptive. However, such messages can have the desired positive effects if they also highlight some shortcoming that threatens the recipient. Indeed, prior research has demonstrated how favorable self-relevant information can increase the adaptive responses to negative feedback (Sherman and Cohen 2006; Trope and Neter 1994). Thus, marketers and the media alike should exercise caution in communicating normative messages about improvement, as this might not always be as innocuous as it seems.

Although this research elucidates the process by which dynamic information about improvement alters the interpretation of normative messages, we do not explore the effects of information about decline. Based on our theorizing, these messages should not be interpreted as self-descriptions, given that people do not tend to see themselves as getting worse (Wilson and Ross 2001). Therefore, rather than reversing the effects of static information in normative messages, unfavorable dynamic information might ultimately mirror the effects of static information. We plan to explore this possibility in future research.

Networked Kids and the Formation of Contemporary Consumer Identities

Hélène de Burgh-Woodman, University of Notre Dame, Australia

ABSTRACT

Identity building has a key role to play in understanding consumer relationships with the marketplace. As technology comes to define new terrains of identity building, it is of increasing importance to understand how media such as social media and the internet come to inform new kinds of engagements and identities. While research has paid attention to concepts of the digital self and on-line personae (Belk 2013; Shau and Gilly 2003), the question of when these identities begin to evolve and at point in their lives people become aware of their personal agency in the marketplace as a result of these technologies is less clear. In this paper, it is suggested that terms such as consumer, end-user and audience, while sharing a common focus on the act of appropriating commodities and their accompanying marketing discourses, embody distinct meanings to young people or "kids" who use them to anchor their own consumption identities (Steinfield, Ellison, and Lampe 2008) and assume power in the marketplace (Acuff and Reiher 1997). Equally, this paper argues that these meanings link to a larger interpretation of the marketplace and consumer agency by the first generation of kids who have grown up with multi-platform technology such as the web and social media (Chester and Montgomery 2008). Therefore the central question this paper seeks to answer is *at what point do these terms gain resonance for kids who appropriate the market through multiple channels and network their consumption experiences via technology*? A stronger understanding of how increasingly technologically informed young consumers see themselves through these culturally embedded terms and the consequent impact on consumption practices sheds light on when (and how) market-based identities begin to form as these terms provide a roadmap or a "way in" to understanding identity formation and network building (Blais, Craig, Pepler and Connolly 2008). In doing so, this paper seeks to contribute to the increasingly nuanced dialogue in consumer research on how people, and in this context specifically young people, see themselves in relation to marketing discourse, the emerging stream of literature on web-based technology and its impact on consumption habits (Schau and Gilly, 2003; Ward and Ostram, 2006).

CONCEPTUAL FRAMEWORK

The terms consumer, end-user and audience draw from different cultural and historical trajectories. The term consumer appears primarily in Marx (1990 [1867]) and the consumer as actor in the production/consumption binary. Foregrounded by the middle classes of the late nineteenth-century (Veblen, 1990 [1899]), the consumer culture of the post-war era established the primacy of the consumer as a key element of contemporary Western society (Tadajewski and Jones, 2008). As the rich opus of consumer research indicates (Arnould and Thompson, 2005), consumers tailored their consumption habits into sophisticated indentity and meaning making acts (McCracken, 1986). In this respect, the word consumer is intrinsically linked to a cultural and social positioning as well as the focus for marketing practice. This theme of consumer as animator of consumption experiences emphasises the consumer's agentic capacity for creativity (Burroughs and Mick, 2004; Hirschman, 1980) that begins at an early age. Consumer research has captured consumer experiences and identities through such lenses as fantastical (Belk and Costa, 1998; Holbrook and Hirschman, 1982), magical (Arnould and Price, 1993), emancipatory (Firat and Venkatesh, 1995), tribal (Cova and Cova, 2002; Cova et al, 2007), subcultural (Kates, 2002;

Kozinets, 2001; Moisio and Beruchashvili, 2010) but also as resistant (Kozinets, 2002; Kozinets and Handelman, 2004; Murray and Ozanne, 1991) and ethical (Borgmann 2000; Cherrier 2004, 2005). All of these terms implicitly acknowledge the consumer's power to negotiate market discourses.

The term end-user enjoys a somewhat shorter heritage (Sewell and Teitelbaum, 1986). Hailing from product design and development (particularly in computing), this term accompanied the twentieth century rise of technological innovation, the realisation that products needed to meet practical requirements for people and a sense that products were only as good as their uptake (Doll and Torkzadeh, 1988). Linked to consumers (since consumers are also end-users), the term end-user not only points to the tactile use of products and services but also draws in questions of loyalty (Spiteri and Dion, 2004) both to company and brand, co-created value (Allee 2000; Banks 2009) and the positioning of people as participants in, and drivers of, innovation (von Hippel 2006; Banks 2009).

Finally, the term audience follows its own distinct heritage. Drawing from the significant body of work in audience theory (Mc-Quail, 2010; Schrøder, 2000, reception theory (Bennett 1997; Hall 1973; Holub 1984) and media planning (Webster et al, 2005), this term has particular resonance for the advertising sphere. Unlike end-user and consumer, audience more specifically directs us to the engagement with spectacle or visual content. While "spectacle" became laden with its own meanings in the work of the Situationists (Debord, 1995), in more contemporary contexts spectacles are endemic to an increasingly visual culture. As the following discussion demonstrates, these three terms (and the histories from which they hail) give rise to distinct interpretations and specific meanings.

METHOD

Two data sets were acquired for the basis for analysis. First, a focus group of twenty young people was conducted (Morgan, 1988; Stewart, and Shamdasani, 1990) in Australia. The age range was between eighteen and twenty years of age with an even gender split. The focus group was conducted at a University campus in familiar surroundings. The focus discussion lasted for three and a half hours. The discussion was semi-structured. The facilitator posed some initiating questions but free discussion was allowed to develop. Once discussion had evolved, the facilitator then posed specific questions. The discussion was audio-recorded with additional notes taken post hoc by the facilitator. Second, further phenomenological interviews (McCracken, 1988; Thompson et al, 1990) lasting between one and two hours interviews were conducted with ten additional participants to better explore the themes established through the focus group discussion. This interview method was selected in order to garner rich insight using participants' own language and expression and was loosely structured around the topics and questions raised during the focus group. The focus group data and the interview data were transcribed, triangulated for thematic consistency and a discourse analysis was conducted (Caruana et al, 2008; Elliot, 1996; Hackley, 2002; Mitussis and Elliot, 1999; Parsons, 2010) enabling the examination of the powers, practices and discourses to which these terms refer for young people. Table 1 offers a summary of the analysis findings

Table 1 Summary of characteristics

	Consumer	End-User	Audience
Characteristics			
Level of product/service engagement	High	High	Moderate
Level of brand engagement	Moderate	High	Moderate
Level of brand loyalty	Moderate	High	Moderate
Level of political consciousness	High	High	Low
Level of ethical consciousness	High	High	Low
Level of perceived market agency	High	High	Low

FINDINGS AND DISCUSSION

The findings confirm existing literature that suggests kids engage the marketplace for their own identity-making (Steinfield, Ellison, and Lampe 2008), and indeed wield increasing power (Acuff and Reiher 1997) but further elucidates how this consciously occur and what potential forms it takes. The dominant interpretation of the term consumer resided in its implied meaning as a force for power in the marketplace. Generally, participants agreed that they became conscious of their roles as "consumers" as children – some mentioned as early as seven or eight years. This theme of early awareness suggests that exposure to markets through technology has the effect of accelerating the formation of multiple consumer identities which have been more understood as emerging through early adulthood. The term also referenced a source of empowerment (Shaw, Newholm and Dickinson 2006) and means of assuming agentic power in the marketplace (Denegri-Knott, Zwick and Schroeder 2006). For instance, several participants spoke of their "rights as a consumer" and demonstrated their knowledge of local consumer laws in relation to product quality and service:

P1: When I buy something, I expect it to be good, you know… I don't just want something that's going to break or whatever. So, if I get something and it's bad, they're [the company] gonna hear about it for sure. That usually works and I get a refund but if it doesn't then I get the fair trading thing involved…

P2: Yep, me too.

P3: Yep, same. [Most participants nodded their heads in agreement]

P2: 'Cos everything's so expensive and like we work and everything so when you buy something…

P4: You sort of feel like the company should be good to you.

Facilitator: So you feel like you have the right to question companies as consumers?

P4: Absolutely [Collective agreement]

Facilitator: When did you start to feel this way?

P5: For ages, even when I was young… I remember as little kid I got this toy where it was "magic sand" and you could build things under water. But when you put in the water, it just collapsed. I went to my Mum and complained that it didn't work and we should take it back. We went back to the shop and told them and I remember telling the woman there that the toy was bad and that they shouldn't sell it. I was probably only eleven or twelve. [Collective laughter] I was really pumped up!

Their positionality as consumer enabled them to mobilise an assertive position in relation to the market, demanding accountability and responsiveness through a legal frame. Several participants spoke of their experiences with the office of fair trade after receiving faulty goods, using their empowered status as consumers to rectify the situation.

I4: Like, I'm not afraid to go to a company and say "hey, your product is crap". I've never been scared to do that. If they want my money then they have to do the right thing. If they don't then I'm going to do something about it because they have to do something to make it right. I've always been like that and just because I'm only one person doesn't mean they don't have to do anything. It doesn't always work the way I want but I will give it a go.

By assuming their consumer status, these participants exerted their power in their marketplace as equal agents. Interview participants nuanced this sense of power even more as some of them commented on their emerging participation on blogs, consumer community sites and online information sharing networks (Pitt, Berthon, Watson and Zinkhan 2002) to verify company credibility and product reliability.

The phrase "as a consumer" also prefaced several other statements about how these young consumers "kept companies honest" by demanding a certain level of service or after-sales responsiveness and thus flagging an ethical consumption orientation (Borgmann, 2000; Cherrier 2004):

P18: I bought a CD player ages ago. I was probably around twelve or thirteen. It was ok but after a while it stopped spinning so we took it back to the shop. They said it was something I had done like because I was young I must have broken it… Dad and I had this big thing with the shop assistant because it was still in warranty and they had to fix it. Finally, they did and it was ok but we really had to argue. But, you know, companies have to do this. If they're going to sell you something and then not look after you then you have to think about that company and whether you should buy more from them.

Facilitator: Have you bought more products from that company?

P18: No [laughter]

P3: You have to keep companies honest. They make all this money off us and then when there's a problem they don't care. So, you definitely have to make them be honest.

This also flowed through to a sense of choice in relation to brands, products and alternatives such as anti-consumption (Cherrier, 2009, 2005; Penaloza and Price, 2003; Zavestoski, 2002) where to be a consumer meant to be a highly knowledgeable, active participant in the ethics and mores of the marketplace. For instance, two interviewees mentioned that they held companies to account, suggesting they "definitely wouldn't buy from an unethical company" and that "everyone knows if a company is a bit shonky" because the internet provides that information. Again, the web had a significant role to play in networking individuals, organising them into consumption communities where information was co-opted.

Facilitator: So if you want to find out about products where do you look for information?

Several participants: The web [Collective agreement]

Facilitator: What sort of sites?

Several participants: Company ones but also blogs and user sites

Facilitator: Do you ask other people?

Several participants: Friends as well

P6: I have usually asked friends because they're the same age as me and they use things for the same reasons so they look for the same things as me. We facebook about it and share information. It's really helpful.

Facilitator: When did you start using the web and friends for information?

P6: For as long as I can remember. [Collective agreement]

Several participants spoke of their decision as consumers to buy eco products or to buy from "good" companies after talking online with other kids.

P11: When I was growing up, it was the whole Apple versus PC thing. I was a PC girl just because that's what we used in school and all that. But when I went online and heard about how good Apple was I changed. I realised that Microsoft was not a great company and that their computers weren't as reliable. The feedback from other kids my age definitely helped me go from PC to Mac.

Others spoke of their choices to change brands for product or service preference reasons. In all of these cases, the underlying empowerment derived from the status, and thus language, of the consumer identity enabled them to act as their own agents buoyed by backdrop information and networked consumer input.

The term end-user was strongly attached to a self-positioning as a participant in the production of innovation (Cova, Dalli and Zwick 2011). Collectively, the focus group agreed that they became conscious of their roles as "end-users" as older children around the age of twelve or thirteen on average when their command of technology became quite sophisticated.

P9: I have always been a computer nut even as a kid. I mean we've grown up with computers haven't we?[Collective agreement]

It's great keeping up with all the technology and with social media you can share all that knowledge with friends.

Unlike the term consumer, which was strongly linked to a sense of identity within the larger marketplace, end-user appears to reference a more intimate connection between a particular company's offerings and the use-value derived by the individual. The company Apple was discussed at length as a prime example of a company perceived as innovative for the purposes of meeting the needs of the end-user several and participants had been "talking about them" online for several years.

P9: I'm loyal to Apple. I think their products are awesome… so much better than Microsoft. It's like they really think about how we are going to use their products and it's sort of more for us.

Facilitator: By "us" you mean?

P9: Us as in younger users

Underlying this dynamic was a focus on the self as a valuable entity, a driver of innovation by constantly demanding new products that work. In this respect, there was a sense of empowerment but of a more benevolent nature.

Facilitator: Do you give companies feedback?

P9: I definitely follow certain companies and give them feedback. I like different companies on Facebook and send them messages about their products all the time.

P11: Me too

P9: I'm fairly into P2P gaming and all the companies who do stuff for that really look for feedback from us. We're all on user sites and blogs and facebook and all that. They know that they have a certain community that have good ideas and they should talk to them… and they do. Our feedback makes their stuff better and so, as end-users, we're happy because we are getting the kind of innovations we want. It also means that we stay more loyal and we want to support the company because they're supporting us.

Unlike the power derived from being a consumer, the empowerment of end-user flowed from a feeling of helping favoured companies become "even better". Being an end-user meant offering support through purchasing followed up by feedback in order to "help" the company as one would a friend. Unlike the often-assertive identity assumed by being a consumer, the end-user identity meant being a positive force for companies and a driver of innovation (Banks 2009). Again, this connection as an end-user was established from childhood and worked via technology such as online consumer feedback sites, brand community sites and blogs.

Unlike the other two terms, audience connected more with passive visual spectatorship. Participants agreed that they became conscious of their roles as "audience" as children – some mentioned

as early as seven or eight years although this was nuanced by their acknowledgement that "audience" as children meant to watch a lot of television thereby suggesting more a passive visual spectator.

> *P7: I mean when you think about it we've been an audience forever. TV has always been around and when I was really little I watched cartoons and all that so yeah we've been audience for all our lives ..*

> *P13: But it's still pretty boring... like most TV and even stuff you see on YouTube and that is pretty boring. So, even though you're all audience it doesn't really make it interesting. [Collective agreement]*

> *P7: I hate ads.*

The perception of advertising as spectacle (Debord 1995), a form of entertainment rather than a form of product or service information, was prevalent among all participants where the persuasive effects of advertising were undermined by the general perception that advertising, whether online or on TV, had limited appeal. The topic of poor advertising was covered at length where it became clear that "boring" or irrelevant advertising content was dismissed and "fun" or engaging content was regarded favourably. In a contemporary media landscape where advertising is endemic to all forms of engagement, whether it be on social media, online surfing or traditional media, these young people had developed effective self-filtering mechanisms against intrusive advertising. When asked to consider what being an audience meant to them, participants largely agreed that the term meant being passive or inert recipients of visual spectacle. Interview participants echoed this perception. When certain ads were discussed, it was clear that (as reception theory suggests) advertising content was not passively received nor did it remain uninterpreted. However, an emphasis on "not having to think too much" and just being "entertained" was the dominant element underlying one's identity as an audience member.

> *When I come home from school or uni or whatever I just want to lie on the couch and watch TV or surf the web. I don't want to have to think about stuff or be really focused. I just want to watch something that's easy and entertaining...*

In a world saturated by numerous media channels and content, having to consciously think about content was perceived as "too hard". Instead being an audience member meant assuming the luxury of being passive, laid back and entertained from afar.

CONCLUSION AND FUTURE RESEARCH DIRECTIONS

The present paper extends current understandings of marketing discourse by showing the extent to which kids increasingly engage the marketplace at a young age, network information to interpret marketing *discourse* and self-position accordingly as a consumer-agent, user or recipient of entertainment. Just as the term consumer has drawn from a long political, economic and marketing frame, these young consumers also see this term as underpinned by agentic power situated within a broader legal and economic context. Likewise, as the term end-user has emerged in parallel with an era of technological innovation, these consumers also link this term to their status as drivers of innovation – seen in largely technological arenas. Additionally, the connection between audience and spectacle has been long established. In this respect, the historical forces that frame

these terms continue to influence people as they construct their identities in relation to the marketplace.

Another contribution to emerge is the impact of technology on how kids discover information, operate in a networked context and use multiple information channels to navigate the marketplace. As technology use accelerates and, as we see from this first generation of kids who have grown up with the net, social media etc., and greater access to personal feedback, formal data and general information becomes the norm, the sense of agentic power among kids will increase. Equally, the earlier acquisition of knowledge and engagement with the global marketplace will also enable kids to form clearer identities (such as end-user, audience, consumer) at earlier stages in their lives.

The findings presented here suggest that technology is having a radical effect not just on communication but on how early kids now assume their own identity in the market and, to this extent, marketing must re-consider the traditional view of young consumers. They are not just influencers, they are information-seekers and decision-makers in their own right who have the capacity to influence a wide audience of similarly engaged kids. From a marketing perspective, this forces a thoughtful consideration of how to communicate with such a connected audience who are willing to critique firms, develop brand loyalties based on the strength of their own relationship with the brand or product and forge powerful personal identities. This study drew upon a comparatively small number of participants and, as such, its findings need further confirmation to ascertain whether the outcomes indicated here are broadly reflective of the attitudes of young people both within and beyond the Australian context. Equally, given the work done on the impact of technology on the market, a study of young kids and their current market identities would further consolidate the emerging picture described here. Nonetheless, the findings presented here suggest a fruitful path forward for expanding knowledge of how kids appropriate technology and the market for their identity and agency assuming practices.

How Immigrants Travel with their Home Brands: Brand Relationships and Acculturation

Ani Dino, Royal Holloway, University of London, UK
Benedetta Cappellini, Royal Holloway, University of London, UK

ABSTRACT

I don't know if I can explain properly how I feel about Skend-erbeu or what it means to me. What I know is that it makes me feel at home, back in my old house, in Tirana. It reminds me of my parents, who are not alive anymore. It reminds me when I was young ... I don't know if it makes any sense to you, but I am trying to tell you how it makes me feel, even just looking at the bottle. (Ilir)

Ilir is a 49-year-old Albanian immigrant living in Germany. He left Tirana 15 years ago and has very nostalgic memories about his country. Skenderbeu, an Albanian cognac, is present in Ilir's memories of his past in Albania as well as his present time in Germany. This research seeks to understand the relationship immigrants develop with their home brands when they migrate to another country. In the case of our participants, Skenderbeu is not simply one of their home brands, but to their knowledge is the only brand produced in Albania under the former communist regime. Thus, the relationship Albanian immigrants have with this brand is unique and surprisingly understudied.

In looking at the relationships immigrants develop with Skend-erbeu, this paper seeks to understand the role of home brands during immigrants' process of acculturation, examining the discourses, practices, feelings and meanings consumers develop in relation to their home brand while living in a new cultural context. It also looks at the role of such discourses, feelings and meaning in participants' acculturation process. Interpretive consumer research has looked at the roles of objects and consumption practices in the consumer acculturation process (Luedicke, 2011; Oswal, 1999; Penaloza, 1994), but surprisingly, very little has been said about the role of home brands (although see Rahman and Cherrier, 2010). Understanding how consumers relate to their home brands while living abroad is important for several reasons. Firstly, it helps in understanding the role of home brands in consumers' acculturation process. In particular it clarifies if (and if so, how) consuming home brands impacts on consumers' acculturation outcomes. Secondly, it helps in understanding how home brands travel with consumers, and if (and if so, how) consumers change their relations with such brands while living in a new cultural context.

ACCULTURATION IN CONSUMER RESEARCH

In consumer research studies acculturation is understood as a process in which people "socialized in one (minority) culture migrate and so come into continuous first-hand contact with a new (dominant) culture" (Ustuner and Holt, 2007: 41). Consumer research studies have been influenced by the seminal work of Berry (1980; 1997; 2001; 2008) highlighting how acculturation is a multimodal process combining immigrants' willingness to maintain their ethnic identity and their participation in the host culture. Following Berry, acculturation results in four different outcomes, including assimilation (immigrants do not wish to maintain their home cultural identity and seek daily interaction with the host culture), integration (immigrants wish to maintain their original culture while engaging with the host culture), separation (immigrants hold on to their original culture and interact with the host culture), and marginalisation (immigrants

have little possibility of, or interest in, cultural maintenance and little interest in having relations with the host culture).

Consumer research studies have shown how acculturation outcomes are not stable as originally conceptualised by Berry (Lu-edicke, 2011). Penaloza (1994) shows how Mexican immigrants in the US adopt some American consumption practices while maintaining some Mexican ones. In fact in public settings they consume American objects, including cars and clothes, to show their integration with American culture; while at home, food and media consumption remain typically Mexican, testifying to the maintenance of their ethnic identity. Oswald's work (1999) on upper-middle-class Haitians in the USA shows how acculturation outcomes are not fixed, and consumers swap between cultural identities depending on the consumption contexts. More recently Askegaard *et al.* (2005) show how immigrants move between different acculturation outcomes integrating home, host and global cultural consumption references. In short, these three studies show that immigrants consume objects brought from home in order to solve identity challenges and tensions arising in the new context. They also show how these objects gain new meanings, symbolising home and cultural continuity in a new context.

Positivist studies have shown how immigrants' willingness to consume some brands reflects their level of acculturation. In fact immigrants with a monocultural identity avoid brands that do not reflect consumers' distinct culture (Josiassen, 2011) and immigrants with a multicultural identity select brands which reflect the multi-cultures they have internalised (Luna and Peracchio, 2005). Although these studies offer useful insights into immigrants' decisions to purchase home or host brands, they do not unpack in depth the relationships consumers develop with such brands and with their home brands in particular. If positivist studies offer a limited understanding of the way immigrants consume their home brands, interpretive consumer research has been surprisingly silent about the role of these brands in the acculturation process (Rahman and Cherrier, 2010). An exception is the study by Rahman and Cherrier (2010) showing how international students living in Australia navigate between global, home and host country brands in an attempt to make sense of the new cultural context and maintain their consumption habits. However, as the paper claims to look at how "people who move to a new country react to the unfamiliar brandscape in general" (Rahman and Cherrier, 2010: 420), it does not fully unpack immigrants' relations with their home brands. Another exception is the work of Bengtsson *et al*. (2010) on American students visiting China and consuming American global brands. As this paper provides useful insights into the literature on brand meanings it will be referred to more fully in the next section.

BRAND MEANINGS IN INTERPRETIVE CONSUMER RESEARCH

Managerial marketing literature assumes that brand meanings are established by the brand management side and then simply transferred to the consumer side (Keller, 2003). Adopting a cultural branding approach (Cayla and Arnould, 2008), interpretive consumer research challenged this assumption, showing that the "experiential categories that consumers create for brands are not necessarily the same as the categories imposed by the marketers in charge of brand management" (Fournier, 1998: 367). In looking at how consumers

relate to their brands Fournier shows that they develop relationships with anthropomorphic traits. In fact consumers establish relationships resembling arranged marriages, casual friendship, committed partnerships, enmities and secret affairs. Others highlight how, in establishing relationships with brands, consumers "uncover and activate their own brand meanings", by reshaping meanings existing in the marketplace and creating new ones (Brown *et al.*, 2003: 29).

Interpretive research has been particularly interested in understanding how consumers attribute meanings to global brands in their local consumption contexts. Dong and Tian (2009) show how global brands in China attract enthusiastic and critical responses, since they are perceived as liberators, instruments of democracy and economic progress but also as oppressors and instruments of Western domination over China. Bengtsson *et al.* (2010) look at consumers' relations with global brands while travelling across national borders. Their findings show how American students travelling to China attribute different meanings to global brands previously consumed at home. If in the US these brands were regarded as symbols of American

imperialism and cultural homogenisation, in China the perceived brand consistency makes them synonymous with "comfort, predictability, safety, as well as national pride for home-country consumers" (Bengtsson *et al.*, 2010: 533). From these studies we understand how global brands have different meanings in relation to the context of consumption. We also understand how they are very important for travelling consumers since they symbolise safety and home in a challenging new context. What we do not know is how consumers travel with their home, non-global brands and the role of such brands in making sense of the new cultural context.

RESEARCH METHODS

Given the exploratory nature of the study, semi-structured interview were used to reveal participants' experiences, feelings and understandings of their brands in a new country. Participants were recruited through a non-probability sampling combining purposive and snowball sampling techniques (Silverman, 2006). They consist of 14 Albanians living abroad and 3 Albanians who after a long period of living abroad have now returned to their home country (see Table 1).

Table 1. Participants' profile

Name	Gender	Age	Family composition	Current Occupation	Country of Residence (abroad)	Years Residing Abroad
Adela	F	29	Single	Logistics specialist	Switzerland	1998-Present
Agim	M	63	Married to Albanian	Unemployed	Switzerland	1998-Present
Agron	M	56	Married to Albanian	Builder	France	2001-Present
Aida	F	59	Married to Albanian	Shop assistant	U.S.A	2001-Present
Andi	M	28	Single	Auditing	Italy	2003-2008
Anila	F	47	Married to Albanian	Receptionist	France	2001-Present
Besa	F	25	Single	Assistant Brand manager	Canada	1999-Present
Besnik	M	53	Married to Albanian	Self-employed	Greece	1993-Present
Eva	F	34	Married to American	Event Manager	U.S.A	2004-Present
Genta	F	29	Married to Italian	Account Manager	Italy	2001-Present
Ilir	M	49	Divorced	Construction worker	Germany	1998-Present
Mirela	F	50	Married to Albanian	Office manager	Canada	2002-Present
Mona	F	49	Married to Albanian	Unemployed	Greece	1994-Present
Nevila	F	51	Married to Albanian	Entrepreneur	Hungary	1991-1994
Sokol	M	55	Married to Albanian	Entrepreneur	Hungary	1991-1994
Tana	F	57	Married to Albanian	Shop assistant	Switzerland	1998-Present
Zana	F	60	Married to Albanian	Unemployed	Italy	1993-Present

Semi-structured interviews were conducted in Albanian by the first author during summer 2012. With participants' permission interviews were recorded, transcribed verbatim and translated into English. Participants were informed of the purpose of the research and their participation was entirely voluntary. They could withdraw at any time during the interview. In order to guarantee participants' anonymity pseudonyms are used in this paper. Interviews covered themes such as the reasons for leaving Albania and the challenges of living abroad. Participants were asked to describe their every-day routine in the new cultural context, including their consumption patterns and their consumption of Skenderbeu. Interviewees were encouraged to share their memories, ideas and feelings related to Skenderbeu. Interview transcriptions were analysed thematically following the guidelines of interpretive consumer research (Silver-man, 2006; Spiggle, 1994). The final interpretation of the data results from a continuous back and forth between authors' interpretations and a continuous back and forth between the literature and the data analysis (Thompson et al., 1994).

FINDINGS

Participants' narratives reveal how Skenderbeu is embedded in the ordinary and extraordinary events of people's lives. Indeed this brand is embedded in intimate routines as well as annual family gatherings and parties with Albanian and non-Albanian guests. In looking at these consumption occasions, we identified three different types of brand relations, each with a distinct brand meaning. These have also implications for participants' acculturation outcomes. Findings described below are summarised in the following table.

Table 2: Findings

Brand relationships	Brand meanings	Context of consumption	Acculturation outcomes
Friend form home	-Utopian past -Nostalgic memories of youth and family life -Individual memories	- Intimate home consumption with nuclear family members -Ordinary and everyday domestic consumption	Separation from the host culture
Family member	-Authenticity -Collective family memories -Domestic traditions	-Consumption with extended family -Extraordinary consumption occasions and celebrations	Maintenance of home culture
Ambassador of home culture	-Authenticity -National identity	-Gatherings with host fellow consumers and international consumers	Integration between home and host culture

1. Skenderbeu: an old friend from home

Most of our participants remember the hardship of settling in a new country. Common are anecdotes illustrating feelings of conflict, stress and misunderstanding in approaching a new culture. As Nevila says:

In Hungary everything was different. People were different, they looked so cold ... which in fact they weren't. They seemed cold to us because they were minding their own business mostly, rather than dealing with other's life, like we do in Albania. But it was not only about people, it was also about food, family relation-ships ... I don't know ... It was a totally different culture where I thought I don't fit in, and never would fit in.

Nevila's description reminds of the experiential tension charac-terising immigrants' cultural shock in experiencing a new environ-ment wherein they cannot relate to their home culture norms and conventions (Rahman and Cherrier, 2010; Winkelman, 1994). The acculturation process that Nevila and the other participants experi-enced is often described as 'hard work', characterised by the "emo-tional work involved in establishing new social networks, the stress-es of learning how to be a consumer in the new locale, and small pleasures of established routines as well as familiar surroundings and products" (Thompson and Thambyah, 1999: 221). In such a transi-tional phase familiar objects brought from home become memory in motion (Miller 2001: 69), since they help consumers deal with the sense of displacement experienced in the new and alien context.

During the intense work of making sense of a new culture, par-ticipants describe Skenderbeu as a friend from home. For example, in describing her father's relationship with the brand, Besa points out that "Every time I see my father drinking it I tell him: So, you

are with your friend again". Similarly, Anila describes the intimate relationship she and her husband developed with the brand:

Well, sometimes we find ourselves remembering our youth, our friends ... especially when the kids are not at home [referring to their two children]. France is a beautiful country of course and I am not trying to say that Albania is better, however sometimes you just miss home for the memories you have there you know. Albania reminds us that we were young once ... . So every time we drink Skenderbeu we think of home and vice versa. When we feel nostalgic about home and the years spent there we turn to Skenderbeu. At times maybe we are over-nostalgic.

From Anila's words we understand that Skenderbeu is seen as a friend from Albania with whom nostalgic moments and intimate life can be shared. As with the American students in Bengtsson *et al*. (2010), our participants see in this familiar brand a link with their life left behind. However, for Anila and her husband, Skenderbeu has nostalgic connotations since it allows them to reconnect with their home country and their youth. This process of special and temporal reconnection is activated through the consumption of Skenderbeu, a brand they "turn to" as though a friend (Fournier, 1998) with whom they might share nostalgic moments. The brand is associated with memories of a longed-for past (Davis, 1979) from which any nega-tive elements have been removed (Goulding, 1999). Interestingly, the nostalgic consumption of the brand is not orchestrated by brand management, but rather it is activated by immigrants' individual nos-talgic memories (Davis, 1979) and a longing for their personal past (Wildschut *et al*., 2006).

I remember Skenderbeu was always present in our festive tables. When I say festive, you have to think of occasions that are im-

portant for us Albanians of course, such as ... New Year's Eve ... birthdays and so on. For example ... in occasions of New Year's Eves the dining table was full of family members and relatives whom we only met occasionally throughout the year. I remember my aunt and her family always spent the New Year's Eve at our house. For me it was something extraordinary, as I loved her children, but unfortunately I could only meet them rarely; they lived in Shkoder. So ... yes, Skenderbeu brings beautiful memories to me as in days like these bottles of it were always on the table. (Aida)

As this quotation shows, the brand is commonly associated with a Utopian individual past characterised by extraordinary family occasions. Interestingly, the collective (and maybe not so joyful) experiences of the collapse of the Communist regime in the early nineties and the subsequent mass migration have never been mentioned by participants. In reconnecting participants to such a selective, Utopian and individual past, the brand also disconnects them from their present (and challenging) time in their host context. Therefore their nostalgic consumption of Skenderbeu allows participants not simply to reconnect with their past and their home country but also to disconnect from their present in the host country.

2.   Skenderbeu: an authentic Albanian family member
Skenderbeu is not simply a brand with nostalgic meanings able to disconnect participants from the present time in their host country. It is in fact a brand participants associate with collective consumption experiences wherein their family identity and their Albanian identity are celebrated. Such collective consumption experience takes the form of family gatherings where Albanian food is prepared and shared with the extended family.

We celebrate traditional Albanian holidays in family, like we used to do back in Albania ... New Year's Eve for example. For these occasions I cook traditional [Albanian] food which my mother used to cook for us, and like we used to do in those years, we always start the evening with some Skenderbeu, which the others drink while I'm preparing the table. I would want this tradition to continue even in my children's families. It is a good way to remind you who you are, where you come from and what your traditions are. (Tana)

For my sons' birthdays, Christmas or similar occasions I always invite my parents and sister's family over. I was grown up with this tradition of uniting the whole family for special occasions and now I don't want to part from it. I like to cook Albanian food and we always have some Raki [1] or Skenderbeu. Actually, the drinks are the only authentic ingredient, because I cannot find any other Albanian food in the market. So yes, I like to think that I am keeping the family tradition alive ... thank God my husband doesn't mind it. He actually likes our [Albanian] food and our traditional drinks as well (Eva)

During these occasions where Albanian identity is celebrated in a new context Skenderbeu helps consumers to re-establish and perpetuate norms and conventions (i.e. festivities, but also meal conventions).Given that the local marketplaces do not provide consumers with opportunities to acquire Albanian products, Skenderbeu seems to be the only Albanian product present in these family celebrations. Skenderbeu is considered an authentic Albanian brand not simply

1   An alcoholic drink popular in Turkey, Greece, and in the Balkan countries

for its clear geographical origins, but for the personal memories participants have of its consumption in Albania (see Beverland and Farrelly, 2010). Consuming such an authentic brand in the new environment allows participants to re-establish a sense of continuity with their home country maintaining a link with their own family traditions and conventions. Skenderbeu serves to maintain a collective and commonly shared Albanian identity as well as to reinforce personal bonds and a sense of family. In establishing this link with participants' previous life in Albania, Skenderbeu allows them to keep their ethnic and family identity alive as well as to communicate them to other family members who are non-Albanian (Eva's husband) and to the younger generation who have never lived in Albania (Eva's children).

3.   Skenderbeu: an ambassador from home
Skenderbeu is not simply a presence in Albanian celebrations and family gatherings. It is also an ambassador of Albanian culture to other consumers in the host country. For example, Sokol explains how Skenderbeu helps him to interact with Hungarians and overcome the feeling of isolation during his first months in Hungary:

We started having Hungarian friends obviously as we were living there and one of them knew about Skenderbeu cognac. Actually that was the only thing he knew about Albania, the cognac. During communism we used to export it, that's why he knew of course. For us it was something extraordinary to know that there was one thing after all that they knew about us, about Albania ... and what is more important they even liked it. So the first time my brother came to visit us, after almost one year that we were living there, he brought Skenderbeu with him. I think something like 3–4 bottles. I only kept one for us and I gave the remaining bottles to my friend. He was delighted I can still remember.

Similarly Nevila remembers taking Skenderbeu as a present when invited to some parties and offering it to guests invited for dinner. Identified as a product of Albanian culture appreciated outside their country, participants use it as a way to introduce themselves and their culture to their fellow consumers and hosts. Andi, for example, remembers using Skenderbeu as an 'ambassador' of Albanian culture. He still remembers the sense of pride in bringing to a party an Albanian product that could be appreciated by other international students. As he says:

It was a good feeling to bring something authentic Albanian. It makes you feel good, like you belong somewhere. Like your country is not just a spot on the big world map, you understand? It gave me a sense of pride. (Andi)

From Andi and Sokol we understand that Skenderbeu was used – during the first months of adaptation in a new socio-cultural (and geographic) environment – as a representative of their country, identity and culture. Becoming a consumption experience commonly shared amongst Albanians and non-Albanians, Skenderbeu was a bridge between the two (or more than two) cultures. It represents a medium through which the 'other' could be encountered, and a starting point for interacting with the host environment. Interestingly Nevila, Sokol and Andi have now returned to Albania and none of them consumes Skenderbeu anymore. This supports the literature which suggests that brands acquire different meanings when consumers cross national boarders (Bengtsson *et al.*, 2010). During the time the interviewees lived abroad, Skenderbeu was a way of reminding themselves and people around them of their ethnic identity.

Once returned to Albania they did not feel the need to make visible their ethnic identity through the assiduous consumption of Albanian brands. This is an interesting point, reminding us that often immigrants become 'hyper-immigrants', adhering to 'home' practices with more enthusiasm than non-immigrants at 'home' (Askegaard *et al.*, 2005).

DISCUSSION AND CONCLUSIONS

This paper sought to understand immigrants' relations with their home brands in a new cultural context. It contributes to the acculturation literature and the branding literature in the following ways.

In looking at the relationship consumers establish with their home brands it emerges that they establish more than one. If previous research highlights how consumers consider brands a living entity with which to establish relationships (Fournier, 1998; Shroeder and Salzer-Morling, 2006), this study confirms and extends the literature, showing how such relationships change depending on the context of consumption. Findings show that relations are not monolithic and stable, but change significantly depending on when, with whom, and how the brand is consumed. In fact, Skenderbeu is considered a friend with whom to share intimate and nostalgic memories of past times in Albania. It becomes an important guest at family celebrations and is considered a tool for authenticating family gatherings as truly Albanian. It is also important for perpetuating Albanian collective (national) and family traditions outside Albania, particularly for the younger generation who have never experienced the country directly. The brand becomes an ambassador for Albanian culture beyond the family setting. Consumed with non-Albanians the brand becomes a common terrain of interaction between immigrants and host-country consumers.

This study confirms the previous literature showing how consumers attach different meanings to brands depending on the context of consumption (Bengtsson *et al.*, 2010 Ger and Belk, 1996; Hollenbeck and Zinkhan, 2010). In fact it shows how Skenderbeu has different meanings according to the context of consumption including a nostalgic individual past, family identity and traditions, and a collective ethnic identity. It also extends the literature, showing how brand meanings change over time. Although this is not a longitudinal study, and hence we cannot claim to have found a pattern showing how brand meanings evolve over time, it shows that some meanings seem to be more prominent in the initial stage of the acculturation process and others seem to be constant over time. As participants point out, Skenderbeu becomes synonymous with national and ethnic pride and thus is proudly used in interacting with non-Albanians. Also, in an unfamiliar and challenging new cultural context, home brands become synonymous with home and comfort, with strong nostalgic overtones. Over the years it becomes synonymous with family traditions and 'authentic' ethnic identity to be maintained and perpetuated amongst family members and future generations.

Finally, this study contributes to the acculturation debate by demonstrating the central role played by home brands in consumers' acculturation process. In looking at the relationship immigrants develop with their home brand, and the meanings they impute to it, this study confirms how acculturation is a fluid process and how its outcomes are not unchanging and stable (Askegaard *et al.*, 2005). It also extends existing knowledge on acculturation, showing how Skenderbeu's polysemic brand meanings help consumers to navigate amongst different acculturation outcomes. Indeed the brand helps consumers to isolate themselves from the alienating and challenging present, and hence to disconnect from the host culture. Also, the brand allows consumers to maintain their ethnic identity by perpetuating family traditions in the host environment. Finally the brand helps consumers in integrating themselves with the new cultural context. In showing how the brand allows consumers to navigate amongst the various acculturation outcomes (maintaining their identity, integrating themselves into the new environment but at the same time disconnecting themselves from it), this study does not support positivist works claiming that consumers selection of home or host brands simply echoes stable acculturation outcomes (Luna and Peracchio, 2005). Indeed it shows how the polysemic nature of brand meanings and brand relations allows immigrants to consume a home brand for different purposes and to navigate amongst different acculturation outcomes.

A Context-Dependent View of Anchoring: The Effect of Consumer Adaptation of Incidental Environmental Anchors on Willingness to Pay

Kivilcim Dogerlioglu-Demir, Sabanci University, Turkey

Cenk Koçaş, Sabanci University, Turkey

ABSTRACT

A fairly common form of managing consumer price expectations is when companies use numbers in their marketing communications (e.g., product model numbers, numbers in product or place names, and numbers on license plates). In some cases, increasing numbers reflect better items. In others, they do not. For instance, a Canon A530 is not superior to an A460 digital camera. Likewise, Nokia 6110 is inferior to Nokia 6102. Though an average consumer is not knowledgeable about those numbers and how they are assigned to specific models (Gunasti and Ross Jr. 2010), we argue that they are there to serve a strategic mission. Those numbers potentially act as attempts at price guidance.

Consider BMW that uses car images with a European license plate displayed prominently in its print ads in Europe where the licenses are all in the format "L LL XXXX" where Ls are letters and Xs are numbers. There is clearly a correlation between the numbers in the license plates and the price of the cars. Specifically, if a zero is added to the number on the plate, the resulting number seems to be generally higher than the price for low and mid-priced models and generally lower than the price for high priced models. It is almost as if there is a not so subtle attempt at price guidance in the choice of numbers for the license plates.

This paper explores the effect of seemingly random numbers in marketing communications on consumers' willingness to pay (WTP). More specifically, we examine the differential effect of incidental environmental anchors (IEA) on consumers' WTP as a function of the product category. We suggest that although consumers are not aware of the link between the numbers and the price of the product, not only do they base their WTP on the random number but also adjust the numbers to resemble acceptable prices for a given product category. Taking a context-dependent view of anchoring, we suggest that consumers alter and adapt the anchors to fit them into appropriate value range and that range changes from context to another. In a series of experimental studies, we test and demonstrate that individuals' price expectations, thus their WTPs, are affected by those 'adapted' incidental numbers.

CONCEPTUAL FRAMEWORK

Incidental Environmental Anchoring

The idea that use of numbers as anchors to manage individuals' numerical estimates is not new. We have known for some time that when participants are given a number as an anchor and then asked to provide estimates, they are influenced by the random initial value (Tversky and Kahneman 1974). Selective accessibility framework argues that anchoring occurs in such cases because when individuals are asked a comparative question (e.g., whether the Mississippi river is shorter or longer than 70 miles), they take it as a hypothesis (Is the Mississippi river 70 miles long ?) and seek for anchor-consistent information (Mochon and Frederick 2013). Therefore, estimates are assimilated toward the anchor. Even in cases when the numerical value is not supplied by the experimenter but rather exists in the environment, numbers seem to influence judgments. For example, Krishna et al. (2006) show that consumers' price estimates are higher for a camera if they are exposed to an extreme-priced product in the catalog. Their results suggest that one extreme cue can affect the reservation price for many related items and many product categories.

In the above examples, either the experimenter or the context supplies anchors that affect subsequent judgments. If a number is provided when there is a need to make numerical judgments, consumers retrieve anchor-consistent knowledge from memory, making the estimates close to the anchor. While a substantial body of research suggests that consumers' numeric decisions are affected by experimenter or context-induced numbers that are activated before the decision is made, relatively less attention has been devoted to understanding when and how totally incidental numbers impact valuations. A recent exception is research by Critcher and Gilovich (2008) who show that even jersey numbers on football players affect the probability estimates of sacking the quarterback. Participants who saw the player wearing number 94 estimated his probability of sacking the quarterback in his next game higher than those who saw him wearing number 54. Numerical priming essentially suggests that any number in the environment at the moment of judgment may serve as an anchor. *A minimal amount of attention to incidental numbers is sufficient to anchor numerical answers to unrelated questions* (Wilson, Houston, Etling and Brekke 1996). Although Critcher and Gilovich (2008) provide important insights as to how incidental environmental anchoring (IEA) operates, their research does not discuss the potential anchor values that should be employed for different product categories to get intended reactions. The present research tries to fill this gap in the literature. Central to our hypothesis is that a consumer's WTP is affected by incidental numbers that are in no way related to the price of the product. We posit and demonstrate that anchors exert context-specific effects in consumer-generated anchors.

Context-dependent Effects on Consumer Valuations

Individuals' judgments are affected by the context of concomitant stimuli. Past research has shown that numerical values may take different meanings depending on the context and that the same number may lead to different evaluations (Parducci 1965). For instance, numerical values can be represented in alternative units and the type of unit used may impact consumers' perceptions and judgments (Pandelaere, Briers, and Lembregts 2011; Zhang and and Schwarz 2012). The unit effect postulates that when individuals come across unfamiliar units (e.g., temperatures in the unfamiliar Celsius scale for Americans); they tend to translate those units into a familiar unit (e.g., Fahrenheit) to be able to make sense of the numbers. Since this conversion is rather difficult, consumers are likely to guesstimate rather than calculate the exact values. Pandelaere, Briers, and Lembregts (2011) argue that this imprecise conversion may render consumers vulnerable to anchoring effects. For instance, consumers tend to spend less in a foreign country if the value of that currency is lower than the value of their own currency (Raghubir and Srivastava 2002).

Frederick and Mochon (2012) have also alluded that context has a big impact on the ways in which anchoring operates. If individuals are to make estimates on two different items employing the same response scale, they tend to change the use of the scale to reflect the change in the items. Therefore, in a way, anchoring effects are due to the distortion of a particular response scale. For instance, when a 70 mile anchor is presented, estimates of the length of the Mississippi

river are lower because individuals use a different number on the miles scale. In a similar vein, respondents who were first asked to estimate the weight of a wolf later judged '1000 lbs' as bigger, pointing out larger animals when asked to specify an animal that weighs around 1000 lbs. The scale distortion theory of anchoring contends that numeric anchors do not affect the beliefs about the stimulus; rather the use of the scale is altered and adapted to fit the context.

Following this logic, we argue that anchoring effect is context-dependent and taking previous research on context and unit effects a step further suggest that individuals not only change the use of the scale to fit the context but alter the numbers altogether to fit into new domains. That is, the same numerical value may serve as a lower bound for item X whereas it is taken as an upper bound for item Y. Hence, a customer may interpret 20 as an upper bound when evaluated in ounces for drinks but as a lower bound when evaluated in gallons for water tanks. The range of acceptable prices for a given product category determines the way in which the anchor value is used by the individual. Consumers adapt and distort these values to reflect a good enough anchor to base their judgments on. Though the relation between the incidental numbers and the price of the product is unknown by the consumer; when consumers' WTP is asked, they use the readily available random numbers in their environment to make estimates. However, their use of such numbers is not straightforward. These anchors are malleable. Consumers unconsciously change these values to reflect possible acceptable prices for a given product category. Thus, we formally hypothesize that

Hypothesis 1: *When acceptable prices for an expensive product are used as anchors, a lower value serves as a lower (an upper) bound for an expensive (a less expensive) product. A higher value serves as an upper (a lower) bound for an expensive (a less expensive) product.*

Hypothesis 2: *When acceptable prices for a less expensive product are used as anchors, a lower value serves as an upper (a lower) bound for an expensive (a less expensive) product. A higher value serves as a lower (an upper) bound for an expensive (a less expensive) product.*

METHOD

Study 1a and b

Study 1 a and b test H1 and H2, respectively. H1 and H2 suggest that consumers' WTP is affected by incidental numbers. Moreover, individuals interpret such values to resemble acceptable prices for different product categories. Past research has argued that the mere presence of a number is *not* sufficient to result in anchoring effects (Mussweiler and Strack 2001), especially for items with strong internal reference points (IRP) (Dogerlioglu-Demir and Koçaş forthcoming). Dogerlioglu-Demir and Koçaş (forthcoming) begin the investigation by demonstrating that consumers' WTP is affected by totally random numbers in the environment for weak IRP items. However, they note that numbers should be part of identity (e.g., product name) for IEA to work for products with stronger IRPs. Higher frequency and recency of purchases result in more focused, stronger IRPs (Mazumdar et al. 2005). Thus, it is more difficult to manage consumers' price expectations by unobvious numerical cues in the environment. Dogerlioglu-Demir and Koçaş (forthcoming) demonstrate that for a product with a strong IRP (e.g., a hamburger

meal), the IEA effect is weaker than for a product with a weak IRP (e.g., an average meal at a restaurant). When two separate numbers are used as anchors, while there is a significant difference in WTP for an average meal, there is no difference in WTP across conditions for a hamburger. The authors argue and show that numbers used as part of the product identity enhance IEA effectiveness for products with strong IRPs.

In study 1 a and b, we utilized numbers 17 and 97 as anchor values. These numbers were used in Critcher and Gilovich (2008) to represent appropriate values for an average meal at an expensive restaurant. Therefore, we expect that while 17 will pull the WTP down and 97 will pull WTP up for the meal, 17 will pull the WTP up and 97 will pull WTP down for the burger.

Study 1a

Method

Drawing 59 participants from Amazon Mturk, we had half of the respondents report their WTP for an average meal at an expensive restaurant named Studio 17 and had the other half state their WTP for an average meal at Studio 97 ("How much would you be willing to pay for your own meal at this restaurant").

Results and discussion

As hypothesized, we found a significant difference in WTP for an average meal at Studio 17 versus Studio 97 ($M_{Studio17\_meal} = 24.17$, SD = 10.32; $M_{Studio97\_meal} = 33.43$, SD = 21.94; $t(57) = -.26$, $p < 0.01$). When individuals see a restaurant named 'Studio 17', their expectations of price for an average meal is significantly lower than when they see a restaurant name 'Studio 97'. Though the numbers are utilized as part of the restaurant name and there is no obvious price connection, anchoring effect holds.

Study 1b

Method

Since consumers' WTP for a product with a strong IRP is affected by different anchor values only if the number is part of the product identity (Dogerlioglu-Demir and Koçaş forthcoming), we used numbers as part of the product name for the hamburger (the 17 vs. the 97 burger). We used 2 conditions (17 vs. 97) to test the effect of different anchors in the product names on consumers' WTP for a product with a strong IRP. We recruited 80 participants from the United States using Amazon MTurk. This time, we used a hamburger meal ad and a slogan that read "Introducing the 17 (97) burger." We specifically mentioned that "we used a random character generator to come up with such a name" to ensure that participants perceived the numbers as product names, not prices.

Results and discussion

We found a significant difference in WTP for the 17 burger versus the 97 burger ($M_{17burger} = 8.40$, SD = 3.62; $M_{97burger} = 6.24$, SD = 3.78; $t(78) = 2.59$, $p < .01$). As expected, whereas consumers interpret the number 17 as $17, they view the number 97 as $0.97 when operating in the burger domain. Therefore, 17 pulls WTP up and 97 pulls it down. As argued above, consumers tend to distort the numbers to make them look more like acceptable prices for a certain product category.

Study 2a and b

In study 1a and b, we found that the same numbers are interpreted differently depending on the context. To test whether this effect is due to the choice of numbers 17 and 97, which are more applicable to a meal than a hamburger, we conducted study 2 employing anchor

values more applicable to a hamburger meal. Dogerlioglu-Demir and Koçaş (forthcoming) show that 98% of the prices quoted as average, lower bound, or upper bound for a hamburger meal fell in the 0.99 to 19.99 range. Therefore, in study 2, we employed 099 and 1999 as anchor values. We expect that while 099 will pull the WTP down and 1999 will pull WTP up for the burger, 099 will pull the WTP up and 1999 will pull WTP down for the meal.

Study 2a

Method

We drew 44 participants from the United States using Amazon MTurk and used a 2 condition (099 and 1999) between-subjects design to test the effect of different anchors on consumers' WTP for an average meal at an expensive restaurant using the same as in Study 1a. We asked our participants "How much would you be willing to pay for your own meal at Studio 099 vs. 1999?"

Results and discussion

We found a marginal significant difference in WTP for an average meal at Studio 099 versus Studio 1999 ($M_{Studio099\_meal}$ = 41.15, SD = 35.71; $M_{Studio1999\_meal}$ = 28.08, SD = 10.96; $t(42)$ = 1.70, $p < 0.09$). As

hypothesized, while consumers interpret the number 1999 as $19.99, they view the number 099 as $99 when they are operating in the meal domain. Therefore, while 099 pulls WTP up, 1999 pulls it down, demonstrating the context-dependent nature of anchoring.

Study 2b

Method

We drew 72 participants from the United States using Amazon MTurk and used a 2 condition (099 and 1999) between-subjects design to test the effect of different anchors on consumers' WTP for a hamburger meal employing the same scenario as study 1b. We asked respondents "How much would you be willing to pay for the 099 burger vs. the 1999 burger?"

Results and discussion

We found a significant difference in WTP for the 099 burger versus the 1999 burger ($M_{099burger}$ = 5.33, SD = 2.94; $M_{1999burger}$ = 6.56, SD = 2.00; $t(70)$ = -1.96 , $p < .01$). As proposed, while 099 pulls WTP down, 1999 pulls it down, showing that consumers take 099 as the lower bound and 1999 as the upper bound when it comes to burger prices (see table 1 for results of study 1 and 2).

Table 1 Results of Study 1 and 2

Meal Domain (17&97)							
	Anchor 17		Anchor 97		Statistics		
	Mean WTP	*SD WTP*	*Mean WTP*	*SD WTP*	*N*	*t*	*p*
Meal (1a)	24.17	10.32	33.43	21.94	59	-0.26	0.01
Burger (1b)	8.40	3.62	6.24	3.78	80	2.59	0.01
Hamburger Domain (099&1999)							
	Anchor 099		Anchor 1999		Statistics		
	Mean WTP	*SD WTP*	*Mean WTP*	*SD WTP*	*N*	*t*	*p*
Meal (2a)	41.15	35.71	28.08	10.96	44	1.70	0.09
Burger (2b)	5.33	2.94	6.56	2.00	72	-1.96	0.01

CONCLUSION

Taken together, the results from this study along with previous studies provide strong support for our theorizing and hypothesized effects. Importantly, we find that consumers employ random numbers in their environment to make numerical valuations. The same numbers, however, may refer to different values depending on the context. Though unconsciously, consumers tend to alter, distort and finally adapt these numbers to make them reasonable prices for a given product category.

These findings have several important managerial implications. First, right numbers must be selected to create intended anchoring effects. Consumers have ranges of acceptable numbers especially when it comes to product prices with which they have some familiarity, and only numbers within this range are potential right numbers. Second, it is highly likely that an intended anchor may change unit in the customer's perception, and end up working as an anchor in the undesired direction. As our empirical work demonstrates, 17 is a better anchor for profit maximization than 97 in a burger domain whereas the reverse is true in a meal domain. Similarly, 099 is a better anchor for profit maximization than 1999 in a meal domain whereas the reverse is true in a burger domain. That is, WTP is higher when 1999 rather than 099 is used.

To build on this example further, we also carried out an exploratory study which we report here briefly where we consider anchors 1999, 2999, 3999 and 4999 in a burger domain (N=329) as in Study

2b . Although the numbers 1999, 2999, 3999 and 4999 are increasing nominally, these numbers are consecutively further away from the acceptable range of prices. Hence, our findings in the previous studies suggest that the larger numbers are more likely to operate as less than $10 compared to more than $10 in an anchoring context. Hence, 4999 is more likely to be perceived as $4.99 rather than $49.99, especially when compared to 3999 ($3.99 vs. $39.99) or 2999 ($2.99 vs. $29.99). Our empirical study lends some support for this prediction. Although the differences are marginally significant, there seems to be a trend in the expected direction. The mean (and SD) of WTP for anchors 1999, 2999, 3999 and 4999 are 7.70 (2.83), 7.17 (3.37), 7.23 (5.81) and 6.83 (4.01). Hence, although 2999 to 4999 may seem like better anchors for profit maximization, consumers' adaption of context-dependent prices in the range of $2.99 to $4.99 lead to a decrease in reported WTP. To conclude, we can claim that there are potentially worse anchors in the right direction that practitioners must watch for when choosing numbers to be used in marketing activities.

When Size Matters: Exploring Perceptions And Justifications Of Deviant Consumer Behavior

Paula Dootson, Queensland University of Technology, Australia
Larry Neale, Queensland University of Technology, Australia
Sam Fullerton, Eastern Michigan University, United States of America & Potchefstroom Business School, Republic of South Africa

INTRODUCTION

Deviant consumer behavior (DCB)– that which is against the law, a regulation, or violates the generally accepted norms of conduct (Fullerton and Punj 1993; Moschis and Cox 1989) – is an ongoing problem in marketplaces around the globe. Deviant consumers can cause financial, physical, or emotional harm to an organization, employees, and other consumers. While there is a growing body of research exploring *what* constitutes DCB, research investigating *why* consumers engage in DCB is sparse (Daunt and Harris 2012). This lack of understanding is reflected in the "one size fits all" approach to deterrence strategies that focus on emphasizing the need to uphold the law and/or the penalty that would apply.

This paper answers the research question *how does the size of harm caused and the size of the victim influence perceptions of DCB?* In this paper, the focus is on harm to the organization. We designed two studies to further our understanding of the complexities of DCB, to inform the development of more effective deterrence strategies. Study 1 explored how the size of harm and victim informed consumer perceptions of DCB and the neutralization techniques individuals use to rationalize DCB. Study 2 measured and examined differences in perceptions of DCB where the size of the harm and the size of the victim were manipulated. These two factors – size of harm and size of victim – have been identified as potentially significant factors influencing the perceived acceptability of consumer actions (Neale and Fullerton 2010).

LITERATURE REVIEW

Organizations largely rely on traditional deterrence strategies whereby all consumers are treated the same, and receive the same deterrence message. Deterrence theory is grounded in the classical school of criminology and the "rational choice view of human behavior" (Pratt et al. 2006, 367). It assumes that individuals weigh up the costs and benefits of a situation, and then make rational decisions based on increasing their pleasure (e.g. benefits) and decreasing their pain or harm (e.g. risk/costs) (Pratt et al. 2006). The effectiveness of this approach to understanding human behavior has been criticized, with suggestions that there are underlying psychological factors that influence human behavior beyond the rational approach (Akers 1990; Garoupa, 2003; Mazar, Amir and Ariely 2008; Mazar and Ariely 2006). Acknowledging the differences in perceptions of DCB means organizations will need to consider more tailored approaches to deterrence strategies. Perceived size of harm and size of the victim are two dimensions commonly suggested as conceptual dimensions that individuals use to distinguish between right and wrong behaviors (e.g. Fullerton and Punj 2004; Hunt and Vitell 1986; Jones 1991; Muncy and Vitell 1992; Vitell 2003). The recommendations made in this paper are the need to develop strategies tailored to deter behaviors based on the perceived size of harm caused, and the size of the victim.

Size of harm refers to how much harm the consumer perceives their DCB will cause to the organization involved. In a review of over 30 consumer ethics studies spanning from 1990 to 2003, Vitell (2003) suggested that individuals' ethical judgements were informed by the *degree of harm involved* in the behavior, alongside *how passive or active the consumer was in the act*, and whether the behavior was *perceived as legal*. These three conceptual dimensions largely reflect those originally suggested in Muncy and Vitell's (1992) Consumer Ethics Scale. Only one study known to the authors has tested the role of these conceptual dimensions in DCB. Mitchell and Chan (2002) found that severity of consequence (harm caused) played a role in the enactment of DCB. The greater the perceived size of harm, the less likely the individual would engage in DCB (Mitchell and Chan 2002). Similar conceptualisations of the size of harm dimension have been found in a number of other frameworks including Fullerton and Punj's (2004) typology of DCB, which suggests behaviors could be perceived as distinct based on *the type and degree of disruption* caused. Moreover, Hunt and Vitell's (1986) General Theory of Marketing Ethics, proposes the ethicality of a behavior reflects the *perceived consequences of each behavior alternative* and the *(un)desirability of the consequence incurred by those involved*. These two dimensions from Hunt and Vitell (1986) suggest the behavior with the greatest degree of harm to the greatest number of people would be the most unethical. In Jones' (1991) moral intensity framework of ethical decision making, the *magnitude of consequences* also provides support for the 'size of harm' dimension in that the more harm the behavior causes, the more deviant the behavior is perceived to be.

Size of victim refers to who the victim is of the DCB. In the scope of this paper, the victim considered is a small organization or a large organization. Social distance theory posits that the greater the perceived social distance between the organization and the consumer, the greater the likelihood of DCB occurring (Houston and Gassenheimer 1987). The greater the organization's size, the greater the perceptions of impersonality, and thus the greater the probability of DCB because the consumer does not feel they are harming the organization (Fullerton and Punj 2004). DCB towards a large organization can be perceived as a 'faceless crime' (Cox, Cox and Moschis 1990). If the DCB is directed towards a more identifiable victim, the victim has a greater ability to engender empathy from the individual committing the deviant act, reducing the instances of deviance (Jenni and Loewenstein 1997). Drawing on Jones' (1991) *concentration of effect* dimension of the moral intensity framework, a small organization could be perceived as a more identifiable victim than a large organization, because the concentration of effect of DCB on a small organization is greater than it would be on a large organization. Based on the conceptual dimensions identified in the literature, the following hypotheses are made:

> *Hypothesis 1:* The greater the size of harm, the more unacceptable the DCB will be perceived.

> *Hypothesis 2:* The smaller the size of the victim, the more unacceptable the DCB will be perceived.

METHOD

Two empirical studies were conducted to examine the role of the perceived size of harm and size of victim in consumer perceptions of varying types of DCB. Study 1 involved 29 semi-structured in-depth interviews with a card sort activity. The topics covered during the interview were; defining acceptable, questionable, and unacceptable behavior, exploring contradictions between categorisation of a behavior in the card sort activity and consumer perceptions of

right and wrong, and neutralization techniques employed to justify questionable and unacceptable behaviors. The sample included males and females over 18 years of age, living in Australia, who were recruited using a non-probability sampling technique of convenience and snowballing. Interviews were conducted until theoretical saturation was reached (Strauss and Corbin 1998). The interview transcripts were analyzed in Nvivo 9.2 via thematic analysis (Braun and Clarke 2006). Study 2 comprised of 815 participants recruited through an online panel in the United States. The sample contained a 50:50 gender split, and respondents offered their perceptions of the acceptability of DCB using third person scenarios and rating them on a six point Likert scale (1 = unacceptable, 6 = acceptable). Respondents did not require experience committing the DCBs given they were asked only to rate the acceptability of the actions of a third party acquaintance. The data were analyzed via four two-way ANOVAs comparing differences in the effect of size of harm and size of victim on the four DCBs examined.

STUDY 1 RESULTS

Evidence of the size of harm and size of victim constructs were identified in the qualitative data.

Size Of Harm

Size of harm referred to how much harm the consumer perceived the behavior would cause to the victim (large or small organization). The greater the perceived harm, the more likely the respondent would perceive the behavior as unacceptable. When discussing a range of behaviors, respondents reflect on various degrees of harm and how that influences how they distinguish between right and wrong behaviors:

If somebody [the waitress] has miscalculated [the bill] by a few dollars, you might not worry about it. If it was a substantial amount, say if the other bill was $100 and they charged $50, okay then, you probably would worry about it. (#6)

Yeah well, you know, [drinking a soda in the grocery store and not paying for it] a can of soda it's about three bucks so you deprive the supermarket of three dollars and it's not that big of a deal. Depending on the [public transport] fare, it could be two or three dollars as well, so that's not that big of a theft… Then you've got this dress or a power tool, and I don't know about power tools or dresses but from my understanding dresses are at least a hundred dollars and power tools same [that's unacceptable]. (#3)

Size of harm was associated with Sykes and Matza's (1957) neutralization technique of 'denial of injury', which argues that no one is being hurt by the consumer's actions:

Trying to get in to see the Mona Lisa and the Louvre or something like that if I can save a couple of bucks by claiming that she's a little bit younger [than she really is] then it wasn't going to be any skin off anybody's nose particularly with thousands of people there a day. (#11)

Respondents had arbitrary definitions for what constituted 'enough harm' to classify a behavior as unacceptable. The variability in what respondents perceived as an acceptable level of harm reflects their varying points of individual tolerance for DCB:

If you're going to a movie, um and that's only a $5 thing…but then if you're going to lie to save like $200 to go to a theme park, then it's like maybe…I shouldn't even be considering that activity, I should just be doing something else, rather than trying to lie to do it. (#10)

It would depend on how much we're talking about. If we're talking about, the value of a main course meal at $25 bucks, and I've realised, in an appropriate time frame, when we can easily point that out [the miscalculation]… I probably wouldn't be rushing back in to point out that we were supposed to pay them another $2.50. (#7)

The arbitrary definitions for what constituted 'enough harm' means organizations need to develop strategies that persuade consumers that $5 harm is just as unacceptable as $100 harm.

Size Of Victim

In the scope of this paper, DCB can be directed towards a small or large organization. When exploring insurance fraud and fraudulent returns, respondents reflect on the distinction between the two types of organizational victims:

I'd be really tempted to kind of, "yeah, just do it [commit insurance fraud]." Insurance company, they take too much money anyway…this is a chance to get something back from the money that you've paid… it's not that big of a deal…if it was like a small family based, not a multinational, high profit company then I'd probably go, "oh I don't think it's right, you know, the insurance company's owned by this family and, you know, they really need the money to be competitive...I don't think you should do that." (#24)

[Lying about why you're returning an item] I guess if it was somewhere like X or Y [two large national chain department stores]…it's not really going to hurt them as opposed to obviously returning it to like a boutique store…I mean these small businesses are trying to make a profit like they don't, it's not like a big company where they can afford to maybe, oh, someone's doing that, okay well let's hope it doesn't happen again, let's not lose out that much but it's obviously a much more smaller business would notice that as opposed to a larger business. (#13)

The quotes above highlight consumer willingness to victimise large rather than small organizations, on the basis that large organizations can financially tolerate DCB better than small organizations. In other words, the concentration of the effect of DCB on a small organization is higher than on a large organization. Another respondent expresses a similar sentiment:

Using stolen credit cards to order goods over the internet…if it's a small business, they can't necessarily afford it, and the credit card companies don't necessarily reimburse those businesses for the losses…I've had direct experience with them in the past where we sold stuff to someone in the US and it turned out to be a stolen credit card and Visa never refunded the money to the company, they said that's just a business risk that you take on. (#18)

Using another perspective, a respondent reflects that DCBs directed towards a large organization is more acceptable than directing harm at a small organization because the victim is less identifiable:

If you break something or use something at a supermarket without telling someone, changing price tags, evading fares on pub-

lic transport, these are all things that hurt a larger entity so it's not as personal. (#5)

Sykes and Matza's (1957) neutralization technique 'denial of victim' was evident under the size of victim theme:

Well look at the size of the store, look what they're charging, look at the profits, excessive profits they're making, possibly like X and Y [two large grocery chain stores] are doing it in a way that's unacceptable as a duopoly so people will convince themselves that it's acceptable to hit back. (#1)

The 'denial of victim' argument above is suggesting that the large organization's behavior is unacceptable, thus the organization deserves the harm caused by the DCB. The absence of dissonance associated with performing a DCB makes it easier for the consumer to perform the behavior and maintain a positive self-image.

To quantify the effects of size of harm and victim on perceptions of DCB, Study 2 was conducted.

STUDY 2 RESULTS

Study 2 asked respondents to rate the acceptability of four DCBs: returning used goods for a refund, lying about age in order to get a lower price, not saying anything when you buy a mispriced item, and insurance fraud. In the scenarios presented to the respondent, the size of the victim organization was large (national chain) or small (corner store/independent), and the size of the harm was also large or small in dollar amounts. A summary of the empirical results (2x2 ANOVA and means) is found in table 1.

Table 1. Summary of empirical results

Behavior	Harm	Victim	Victim small Harm small Mean	Victim small Harm large Mean	Victim large Harm small Mean	Victim large Harm large Mean
	ANOVA (significance)					
Fraudulent returns	*ns*	*ns*	2.17	2.08	2.01	1.97
Lying about age	.001	*ns*	2	2.28	2.13	2.36
Buying mispriced item	.000	.001	3.4	2.67	3.7	2.03
Insurance fraud	.000	*ns*	1.39	2.7	2.57	1.33
		N=815	N=205	N=203	N=205	N=202

Consumer perceptions of fraudulent returns were not significantly influenced by size of harm or size of victim. Consumer perceptions of lying about age to get a lower price was influenced by the size of harm, $F (1, 815) = 11.535$, $p = .001$. The size of harm also influenced consumer perceptions of insurance fraud, $F (1, 815) = 332.056$, $p = .00$. Finally, consumer perceptions of buying a mispriced item was influenced by both the size of harm, $F (1, 815) = 45.747$, $p = .000$, and by the size of the victim, $F (1, 815) = 10.417$, $p = .001$.

Manipulating the size of the harm and victim also reveals that given certain circumstances (small victim, large harm), blatantly illegal actions such as insurance fraud (2.70) was rated as slightly but not significantly more acceptable than the miscalculated bill (2.67) which is an unintentional and unplanned windfall. The data partially supports H1 and H2.

Analyzing the means reveals some interesting and contrasting results. When the victim was small, increasing the harm was perceived as *less acceptable* for fraudulent returns and buying a mispriced item, but *more acceptable* for lying about age and insurance fraud. When the victim was large, increasing the harm was perceived as *less acceptable* for fraudulent returns, buying a mispriced item, and insurance fraud, but *more acceptable* for lying about age. The variability in the outcomes suggests complexity in how underlying psychological factors and situational factors influence perceptions of DCB.

DISCUSSION

The findings of both studies illustrate that the perceived size of harm and size of victim can influence a consumer's perceptions of DCB. These dimensions can also be used as justifications to enable DCB to occur, through the 'denial of injury' and 'denial of victim' neutralization techniques. To effectively deter DCB, strategies need to challenge these neutralization techniques. Specifically, marketers should consider the need to humanise their organization. Humanizing the organization seeks to reduce the social distance between the consumer committing the deviant act and the organization being harmed, thereby reducing DCB (Cox et al. 1990; Jenni and Loewenstein 1997). Putting a 'face' to an organization makes it more difficult for the consumer to justify performing DCB at the expense of the organization because it leverages the identifiable victim effect. Identifiable victims engender a greater empathic response, making an individual more willing to engage in behavior that will reduce the harm inflicted on the victim (Jenni and Loewenstein 1997; Kogut and Ritov 2005). DCB is reduced when the individual performing the behavior can see the harm they are causing a specified victim (Small and Loewenstein 2003). Humanizing the organization may be a difficult strategy for very large, profitable organizations as the perceived social distance between the consumer and the organization is quite large.

To attempt to overcome this issue for large organizations, the humanizing recommendation would need to be used in conjunction with another deterrence recommendation such as highlighting the

negative consequences caused by the consumer's behavior. Consumers who are more likely to engage in DCB are focused on the benefit they gain from performing the behavior, as opposed to acknowledging the negative outcome incurred by others as a result of their actions (Schlenker and Forsyth 1977). Therefore, there is a need for organizations to increase awareness of the outcomes DCB causes to the victim. Implementing information campaigns that go alongside the humanization strategy could more clearly highlight the harm caused by the consumer committing the DCB.

A future research opportunity would be to develop and test interventions that reflect these recommendations to examine their effectiveness in reducing DCB. Taking a more tailored approach to deterrence strategies would overcome the limitations of deterrence theory. Humanization may also be an issue of salience as organizations increasingly implement self-serve technologies to interact with customers in order to reduce costs and attract new customers. Future researchers should explore consumer perceptions of organizational technology use from an ethical perspective.

Becoming Iconic: David Bowie from Man to Icon

Toni Eagar, Australian National University, Australia
Andrew Lindridge, Open University, United Kingdom

ABSTRACT

From Nelson Mandela to Ronald Reagan, from Steve Jobs to Sam Walton, from Oprah Winfrey to Martha Stewart, from Michael Jordan to Muhammad Ali, from Andy Warhol to Bruce Springsteen, from John Wayne to Woody Allen, cultural icons dominate our world. (Holt, 2004, p.1)

The opening of Holt's work on brands as icons highlights two important assumptions. First, that people can be icons. Second, icons are somehow different to celebrities, even though many of the people identified by Holt as icons have been studied as part of celebrity cultural studies (Crowley, 1999; Grano, 2009; Illouz, 2003) and the emerging area of human branding (Davis and Halligan, 2002; Kerrigan et al., 2011; Schroeder, 2005; Thomson, 2006). This overlapping between people who are both celebrities and icons suggests that there is a lack of theoretical distinction between these concepts. Beyond elitist judgments of celebrity as empty reproduction and icons as legitimate symbols (Alexander, 2010) there is a need to understand when a person becomes a celebrity and an icon. Such conceptual distinctions are required when developing the concept of human brands beyond its current focus on celebrities. In particular, there is a need to consider if human brand icons operate at a larger macro level than current branding and endorsement literature has considered. Using structuration theory we consider how consumers form relationships and attachments not just with the celebrity (Gabriel, 1997; Parmentier, 2010; Thomson, 2006) but also how icons become representative symbols of complex sets of societal ideas and values (Holt, 2004).

LEGITIMIZING CELEBRITIES AS ICONS

Celebrities and icons have a troubled and contentious relationship. Rojek (2001) claims that a person becomes a celebrity when media interest in their activities tranfers from the reporting of their public-self to investigating their private-self. This separation of the public- and private-self is one of the distinguishing features of celebrity discourse. Icons, in contrast, represent a person or thing that is regarded as a "compelling symbol of a set of ideas or values that a society deems important" (Holt, 2004, p.1). Celebrities and icons represent important cultural mythmaking and values, with celebrities deemed to represent the synthetic (Boorstin, 1964), the apparent (Debord, 2002), and the aspirational (Marshall, 1997). Consequently, the media and public's interest in the private lives of celebrities ensures that their fame precedes their achivements (Turner, 2004). Celebrities and icons, however, are people and objects that embody crucial cultural functions, whilst performing cultural identity myths that allow imagination, effectively repairing a damaged cultural fabric (Holt, 2004). Whether a person is considered a celebrity or an icon is often based on perceptions of greatness across time (Campbell, 1949), and whether the celebrity's cultural meaning and value is malleable to manage shifting cultural concerns (Brown et al., 2013).

Rojek's (2001) view that the celebrity represents a move from a public concern to a focus on the private self is disputed in this paper. Instead, we view celebrity as geotemporal process, where the celebrity is created through multiple associations, whether they be private or public achievements or roles (McCracken, 1989). These associations represent cultural concerns of a time period and as society shifts a celebrity's meanings may not transform. Power and fame may not

transfer then to new time periods or cultural contexts and concerns. Steve Guttenberg, a well known and popular actor in the 1980s with films such as 'Cocoon' and the 'Police Academy' series provides a good example. Despite his success in the 1980s his cultural meanings and social authority remain tied to this time period. In essence he embodies nostalgia for the 1980s rather than representing modern cultural meanings (Holbrook, 1993).

Celebrities become icons when their fame is enduring through the transformation of their cultural meaning and values that mirror changes in society (Holt, 2004). This ability to transmute their meanings, across time periods and cultural contexts, means that the person is no longer a known figure in a particular time setting (Boorstin, 1964), but rather they become an icon whose meaning is mythologised through imprecision, amorphousness and ambiguity (Brown et al., 2013). In this paper we use structuration theory to focus on how a person becomes a celebrity and an icon.

STRUCTURATION THEORY AND HUMAN BRANDS
