Preface

It was our great pleasure to co-chair the 2015 North American Conference of the Association for Consumer Research in New Orleans, from Oct. 1 to 4. This volume reports the presentations made in special sessions, competitive paper sessions, working paper session, roundtables, the film festival, and the Forums program.

This year's conference theme was "**Advancing Connections.**" It was inspired by a desire to build better connections across different research paradigms and approaches and to facilitate connections among academics, practitioners, and public policy makers, as well as to consumers. We felt strongly that there is greater need for the ACR membership to engage across methodological and theoretical divides and to connect also with key constituencies outside academia.

In keeping with this conference theme, we opted to include invited sessions spanning a broad range of topics and perspectives that offered numerous opportunities for members to gain access to knowledge/ideas that are typically not represented at ACR.

In recent years, many members of the ACR community have expressed the desire for more research endeavors that take a broader perspective and have the potential to make greater impact on theory and practice. We hoped and believed that when we individually and collectively reach across research silos and make meaningful connections it will promote rigorous and relevant work that generates important insights about consumer behavior. This year's program was intended to facilitate many opportunities to advance such connections.

The 2015 ACR conference attracted 1275 participants, 114 special session proposals (49% of which were accepted), 510 competitive paper submissions (38% accepted), 369 working paper submissions (68% accepted), 10 roundtable proposals (90% accepted) and 16 film festival submissions (87% accepted).

A few things were new to ACR this year:

- Special Symposium: This offered a unique opportunity to learn about the latest advances in memory research by three experts: Lynn Hasher, Elizabeth Kensinger, and Donna Rose Addis.
- Data Blitz: Ten working papers were selected by Claudiu Dimofte and Anirban Mukhopadhyay to be presented as a talk instead of a regular poster. Each presentation in this session provided highlights of the research in a stimulating 5-minute talk.
- Starting times for presentations: All presentations in the regular paper sessions followed the same time schedule. This enabled audience members to attend a talk in one session and then a consecutive talk in another session without having to miss parts of either talk. No more entering in the middle of the talk you came to see! Each presentation had 20 minutes including Q&A. Starting times for each talk within a session were noted in the program to easily facilitate switching.

This conference would not have been possible without the tireless efforts of many dedicated, wonderful people. We are especially grateful to Executive Director Rajiv Vaidyanathan, Conference Manager Paula Rigling, and website manager Aleksey Cherfas. We also wish to thank Membership Executive Manager Praveen Aggarwal, Communication Executive Manager Ekant Veer, and administrative coordinator Anna Potrawiak.

A big thank you to co-chairs of various tracks, including Claudiu Dimofte and Anirban Mukhopadhyay (Working Papers), Hans Baumgartner and Rebecca Hamilton (Forum Program), Marylouise Caldwell and Paul Henry (Film Festival), Amber Epp and Page Moreau (Doctoral Symposium), Stefano Puntoni and Kate White (Pre-Tenure Mid-Career Mentorship Program), Tom Meyvis, Joe Nunes, and Leif Nelson (Post-Tenure Mid-Career Mentorship Program).

We are also deeply grateful to our Program Committee, Competitive Paper Associate Editors, Competitive Paper Review Board Members, Working Paper Reviewers, Film Reviewers, to faculty who volunteered time for the Doctoral Symposium and the Mid-Career Mentorship Program, Jonathan Levav for making connections to sponsors, and countless others who advised and helped us over the past year.

Many thanks to our sponsors who generously support the mission of ACR: AMA Consumer Behavior SIG, Journal of Consumer Psychology, Journal of Consumer Research, Journal of Marketing Research, Marketing Science Institute, Qualtrics, University of Maryland, University of Michigan, University of Southern California, and University of Wisconsin.

We wish to acknowledge the enthusiastic assistance from PhD student volunteers from the University of Michigan and the University of Southern California: Stephanie Carpenter, Rebecca Chae, Chaumanix Dutton, Kathrin Hanek, He (Michael) Jia, Jennifer Lee, Bora Min, Steve Shaw, Tatiana Sokolova, Megan Subler, Arianna Uhalde, Francesca Valsesia, and Tiffany Vu.

Special thanks go to the fabulous Marketing Department at Tulane University, in particular Janet Schwartz, Mita Sujjan, Harish Sujjan, Daniel Mochon, Joon Ro, Eric Hamerman, and Emily Rosenzweig for sharing their expertise and well-kept secrets about NOLA.

Thanks to everyone who submitted their best research ensuring we could come up with a stellar program. Finally, we wish to thank Amna Kirmani, 2015 ACR President, who entrusted us with the privilege of organizing this conference.

We sincerely hope you found the conference stimulating and packed with many opportunities to make connections!

Kristin Diehl, University of Southern California, USA
Carolyn Yoon, University of Michigan, USA
ACR 2015 Conference Co-Chairs

Conference Committees & Reviewers

PRESIDENT

Amna Kirmani, University of Maryland, USA

CONFERENCE CHAIRS

Kristin Diehl, Marshall School of Business, University of Southern California, USA
Carolyn Yoon, Stephen M. Ross School of Business, University of Michigan, USA

PROGRAM COMMITTEE

Rashmi Adaval, Hong Kong University of Science and Technology, China
Soren Askegaard, University of Southern Denmark, Denmark
Russell Belk, York University, Canada
Jim Bettman, Duke University, USA
Lisa E. Bolton, Pennsylvania State University, USA
Simona Botti, London Business School, UK
Susan Broniarczyk, University of Texas at Austin, USA
Jennifer Escalas, Vanderbilt University, USA
David Faro, London Business School, UK
Rosellina Ferraro, University of Maryland, USA
Ellen Garbarino, University of Sydney, Australia
Andrew D. Gerstner, University of Texas at Austin, USA
Ayelet Gneezy, UC San Diego, USA
Ming Hsu, University of California Berkeley, USA
Chris Janiszewski, University of Florida, USA
Frank R. Kardes, University of Cincinnati, USA
Anat Keinan, Harvard University, USA
Uzma Khan, Stanford University, USA
Ellie Kyung, Dartmouth College, USA
Juliano Laran, University of Miami, USA
Robyn LeBoeuf, Washington University, USA

Leonard Lee, National University of Singapore, Singapore
Jonathan Levav, Stanford University, USA
Sidney Levy, University of Arizona, USA
Tina Lowrey, HEC Paris, France
Mary Frances Luce, Duke University, USA
Marius K. Luedicke, City University London, UK
Nina Mazar, University of Toronto, Canada
Brent McFerran, Simon Fraser University, Canada
David Mick, University of Virginia, USA
Cassie Mogilner, University of Pennsylvania, USA
Sarah Moore, University of Alberta, Canada
Andrea Morales, Arizona State University, USA
Carey Morewedge, Boston University, USA
Leif D. Nelson, University of California Berkeley, USA
Oded Netzer, Columbia University, USA
Jesper Nielsen, University of Arizona, USA
Nathan Novemsky, Yale University, USA
Cele Otnes, University of Illinois at Urbana-Champaign, USA
Andrew W. Perkins, Washington State University, USA
Hilke Plassmann, INSEAD, France
John Pracejus, University of Alberta, Canada

Priya Raghubir, New York University, USA
Scott Rick, University of Michigan, USA
Derek Rucker, Northwestern University, USA
Gad Saad, Concordia University, Canada
Jonathan Schroeder, Rochester Institute of Technology, USA
John Sherry, University of Notre Dame, USA
Suzanne Shu, University of California Los Angeles, USA
Ale Smidts, Erasmus University, The Netherlands
Oleg Urminsky, University of Chicago, USA
Erica van Herpen, Wageningen University, The Netherlands
Koert Van Ittersum, University of Groningen, The Netherlands
Stijn van Osselaer, Cornell University, USA
Kathleen Vohs, University of Minnesota, USA
Joachim Vosgerau, Bocconi University, Italy
Lawrence Williams, University of Colorado, USA
David Wooten, University of Michigan, USA
Eugenia Wu, University of Pittsburgh, USA
Eric Yorkston, Texas Christian University, USA
Gal Zauberman, University of Pennsylvania, USA
Rui (Juliet) Zhu, CKGSB, China

FORUMS (PERSPECTIVES, ROUNDTABLES, & WORKSHOPS) CHAIRS

Hans Baumgartner, Pennsylvania State University, USA

Rebecca Hamilton, Georgetown University, USA

FILM FESTIVAL CHAIRS

Marylouise Caldwell, University of Sydney, Australia

Paul Henry, University of Sydney, Australia

WORKING PAPER CHAIRS

Claudiu Dimofte, San Diego State University, USA

Anirban Mukhopadhyay, Hong Kong University of Science and Technology, China

DOCTORAL SYMPOSIUM CHAIRS

Amber Epp, University of Wisconsin-Madison, USA

Page Moreau, University of Wisconsin-Madison, USA

MID-CAREER MENTORSHIP PROGRAM CHAIRS

Pre-tenure

Stefano Puntoni, Erasmus University Rotterdam, The Netherlands
Katherine White, University of British Columbia, Canada

Post-tenure

Tom Meyvis, New York University, USA
Leif Nelson, University of California, Berkeley, USA
Joe Nunes, University of Southern California, USA

ASSOCIATE EDITORS

Katherine Burson, University of Michigan, USA
Margaret Campbell, University of Colorado, USA
Amy N. Dalton, Hong Kong University of Science and Technology, Hong Kong, China
Hope Jensen Schau, University of Arizona, USA

Dannie Kjeldgaard, University of Southern Denmark, Denmark
Robert Kozinets, York University, Canada
Prashant Malaviya, Georgetown University, USA
Cait Poyner Lamberton, University of Pittsburgh, USA

L. J. Shrum, HEC Paris, France
Hope Schau, University of Arizona, USA
Manoj Thomas, Cornell University, USA
Christian Wheeler, Stanford University, USA

SPECIAL THANKS TO

Rajiv Vaidyanathan, University of Minnesota
Duluth, USA
Paula Rigling, Conference Planner, Texas, USA
Anna Potrawiak, Ivey Business School, Western
University, Canada
Aleksey Cherfas, Chilleesys, Inc.
Aaron Christen, ACR Executive Assistant
Jessica Mendez Jeffers, ACR Executive Assistant

Marketplace Morality.	1
<i>Amna Kirmani, University of Maryland, USA</i>	

Special Session Summaries

Advances in Pay-What-You-Want Pricing	7
---	---

Chair: Stephen A. Atlas, University of Rhode Island, USA

Paper #1: Shifting Mindset in Consumer Elective Pricing

Silvia Saccardo, University of California- San Diego, USA
Charis Li, University of Florida, USA
Anya Samek, University of Wisconsin- Madison, USA
Ayelet Gneezy, University of California- San Diego, USA

Paper #2: Because We're Partners: How Social Values and Relationship Norms Influence Consumer Payments in Pay-What-You-Want Contexts

Shelle M. Santana, Harvard University, USA
Vicki Morwitz, New York University, USA

Paper #3: Paper or Plastic?: How We Pay Influences Post-Transaction Connection

Avni Shah, University of Toronto, Canada
Noah Eisenkraft, University of North Carolina- Chapel Hill, USA
Jim Bettman, Duke University, USA
Tanya Chartrand, Duke University, USA

Paper #4: Rebate-What-You-Want

Stephen Atlas, University of Rhode Island, USA

It Ain't All Positive: Frictions between Consumers and Brands.	12
--	----

Chairs: Johannes Boegershausen, University of British Columbia, Canada

Anne-Kathrin Klesse, Tilburg University, The Netherlands

Paper #1: Interpersonal Influences on Consumer-Brand Relationships: Exploring the Effect of Providing Relationship Reminders on Brand Evaluations

Mansur Khamitov, Ivey Business School, Western University, Canada
Matthew Thomson, Ivey Business School, Western University, Canada
Allison R. Johnson, Ivey Business School, Western University, Canada

Paper #2: Who Blames but Forgives When Brands Err? Applying Attachment Theory to Explain Consumer Responses to Brand Failures and Recovery Efforts

Sara Dommer, Georgia Institute of Technology, USA
Vanitha Swaminathan, University of Pittsburgh, USA
Zeynep Gürhan-Canli, Koç University, Turkey

Paper #3: The Devil You Know: Service Failures, Self-Esteem and Behavioral Loyalty

Irene Consiglio, Erasmus University Rotterdam, The Netherlands
Stijn M.J. van Osselaer, Cornell University, USA

Paper #4: The Category Spillover Effects of Brand Hatred

Johannes Boegershausen, University of British Columbia, Canada
Anne-Kathrin Klesse, Tilburg University, the Netherlands
JoAndrea Hoegg, University of British Columbia, Canada
Darren W. Dahl, University of British Columbia, Canada

**Data Quality in Online Research:
Challenges and Solutions 18**
*Chairs: Neil Brigden, Miami University, USA
Gabriele Paolacci, Erasmus University Rotterdam, The Netherlands*

Paper #1: Beyond the Turk: An Empirical Comparison of Alternative Platforms for Crowdsourcing Online Research
*Eyal Peer, Bar-Ilan University, Israel
Sonam Samat, Carnegie Mellon University, USA
Laura Brandimarte, Carnegie Mellon University, USA
Alessandro Acquisti, Carnegie Mellon University, USA*

Paper #2: Using Nonnaive Participants Can Reduce Effect Sizes
*Jesse Chandler, University of Michigan, PRIME Research, USA
Gabriele Paolacci, Erasmus University Rotterdam, The Netherlands
Eyal Peer, Bar-Ilan University, Israel
Pam Mueller, Princeton University, USA
Kate Ratliff, University of Florida, USA*

Paper #3: Research Design Decisions and Their Effects on Task Outcomes: An Illustration Using Free-sorting Experiments
*Simon J. Blanchard, Georgetown University, USA
Ishani Banerji, University of Texas at San Antonio, USA*

Paper #4: Interactivity and Data Quality in Computer-Based Experiments
Neil Brigden, Miami University, USA

The Value of Consumer Values: Explaining Value-Motivated Cognition and Behavior 23
Chair: Troy H. Campbell, University of Oregon, USA

Paper #1: How Beauty Work Affects Judgments of Moral Character
*Linyun Yang, University of North Carolina at Charlotte, USA
Adriana Samper, Arizona State University, USA
Michelle Daniels, Arizona State University, USA*

Paper #2: Cultural Diversity in Advertising and Representing Different Visions of America
*Steven Shepherd, Oklahoma State University, USA
Aaron Kay, Duke University, USA
Tanya L. Chartrand, Duke University, USA
Gavan J. Fitzsimons, Duke University, USA*

Paper #3: Global Character and Motivated Moral Decoupling Among Liberals and Conservatives
*Amit Bhattacharjee, Dartmouth College, USA
Jonathan Z. Berman, London Business School, USA
Americus Reed II, University of Pennsylvania, USA*

Paper #4: Introducing the Implication Model of the Motivated Cognition
Troy H. Campbell, University of Oregon, USA

When, Why, and How People Advocate 28
*Chairs: Lauren Cheatham, Stanford University, USA
Zakary Tormala, Stanford University, USA*

Paper #1: Finding vs. Receiving: How Content Acquisition Affects Sharing
*Zoey Chen, University of Miami, USA
S. Jonah Berger, University of Pennsylvania, USA*

Paper #2: When is Saying Believing? Sharing Sensations after Tasting New Products
*Salvador Ruiz de Maya, University of Murcia, Spain
Inés López López, University of Murcia, Spain
Sarah Moore, University of Alberta, Canada*

Paper #3: The Curvilinear Relationship between Attitude Certainty and Attitudinal Advocacy
*Lauren Cheatham, Stanford University, USA
Zakary Tormala, Stanford University, USA*

Paper #4: The Power Matching Effect: The Dynamic Interplay of Communicator and Audience Power in Persuasion
*Derek Rucker, Northwestern University, USA
David Dubois, INSEAD, France
Adam Galinsky, Columbia University, USA*

God, Luck and the World: Consequences of Consumer Beliefs On Judgment and Choice	34
<i>Chair: Yimin Cheng, Hong Kong</i>	
Paper #1: How Symbolic Fusions with Religion Imbue Products with Increased Reliability and Safety	
<i>Steven Shepherd, Oklahoma State University, USA</i>	
<i>Aaron C. Kay, Duke University, USA</i>	
<i>Richard P. Eibach, University of Waterloo, Canada</i>	
Paper #2: Do Costly Options Lead to Better Outcomes? How the Protestant Work Ethic Influences Cost-benefit Heuristics	
<i>Yimin Cheng, HKUST, Hong Kong</i>	
<i>Anirban Mukhopadhyay, HKUST, Hong Kong</i>	
<i>Rom Y. Schrift, University of Pennsylvania, USA</i>	
Paper #3: When Engaging in Luck-Rituals Reduces Risky Choice	
<i>Ping Dong, University of Toronto, Canada</i>	
<i>Aparna A. Labroo, Northwestern University, USA</i>	
Paper #4: Self and the World: Implicit Self-Theory and Biased Motivation in Human Judgment and Decision Making	
<i>Jaehwan Kwon, Baylor University, USA</i>	
<i>DJ Nayakankuppam, University of Iowa, USA</i>	
Antecedents and Consequences of Psychological Ownership	40
<i>Chair: Jaeyeon Chung, Columbia Business School, USA</i>	
Paper #1: From Tragedy to Benefit of the Commons: Increasing Shared Psychological Ownership	
<i>Suzanne Shu, UCLA, USA</i>	
<i>Joann Peck, University of Wisconsin – Madison, USA</i>	
Paper #2: Products as Self-Evaluation Standards	
<i>Weiss, Liad, University of Wisconsin – Madison, USA</i>	
<i>Gita Johar, Columbia Business School, USA</i>	
Paper #3: The Consequences of Product Ownership: Performance Handicap in a Product-unrelated Task	
<i>Jaeyeon Chung, Columbia Business School, USA</i>	
<i>Gita Johar, Columbia Business School, USA</i>	
Paper #4: Words Speak Louder: Conforming to Preferences More than Consumption	
<i>Yanping Tu, University of Chicago, USA</i>	
<i>Ayelet Fishbach, University of Chicago, USA</i>	
Expectancy and Placebo Effects of Marketing Actions	45
<i>Chair: Yann Cornil, University of British Columbia, Canada</i>	
Paper #1: How Counterfeiting Contaminates the Efficacy of Authentic Products	
<i>Moty Amar, Ono College, Israel</i>	
<i>Haiyang Yang, Johns Hopkins University, USA</i>	
<i>Ziv Carmon, INSEAD, Singapore</i>	
<i>Dan Ariely, Duke University, USA</i>	
Paper #2: Expectancy Effects of Alcohol-Energy Drink Cocktail Labeling on Subjective Intoxication, Risk-Taking, and Sexual Self-Confidence and Aggressiveness	
<i>Yann Cornil, University of British Columbia, Canada</i>	
<i>Pierre Chandon, INSEAD, France</i>	
<i>Aradhna Krishna, University of Michigan, USA</i>	
Paper #3: The Taste of a Bad Deal: The Effect of Transactional Utility on Experiential Utility	
<i>Jayson S. Jia, The University of Hong Kong</i>	
<i>Taly Reich, Yale University, USA</i>	
<i>Baba Shiv, Stanford University, USA</i>	
Paper #4: Individual Differences in Marketing Placebo Effects: Evidence from Brain Imaging and Behavioral Experiments	
<i>Hilke Plassmann, INSEAD, France</i>	
<i>Bernd Weber, University of Bonn, Germany</i>	

**Putting One’s Best Foot Forward, and Falling:
Consumers Fail to Understand How They are Perceived 51**
*Chairs: Clayton R. Critcher, University of California, Berkeley, USA
Jonah Berger, University of Pennsylvania, USA*
Paper #1: The Psychology of Humblebragging
*Ovul Sezer, Harvard Business School, USA
Francesca Gino, Harvard Business School, USA
Michael I. Norton, Harvard Business School, USA*
Paper #2: Posting Posed, Choosing Candid: Photo Posters Mispredict Audience Preferences
*Jonah Berger, University of Pennsylvania, USA
Alixandra Barasch, University of Pennsylvania, USA*
Paper #3: Passing (On) Judgment: Others Judge Us Less Extremely Than We Think
*Alice Moon, University of California, USA
Muping Gan, University of California, USA
Clayton R. Critcher, University of California, USA*
Paper #4: First Impressions and Consumer Mate Preferences in Online Dating and Speed-Dating
*Christopher Olivola, Carnegie Mellon University, USA
Paul Eastwick, University of Texas—Austin, USA
Eli Finkel, Northwestern University, USA
Ali Hortaçu, University of Chicago, USA
Dan Ariely, Duke University, USA
Alexander Todorov, Princeton University, USA*

It’s a Material World: Revisiting Established Consumer Behavior Theories From Neomaterialist Perspectives 56
*Chairs: Hope Jensen Schau, University of Arizona, USA
Beth Leavenworth DuFault, University of Arizona, USA*
Paper #1: Ontological Flattening, Vibrant Matter and Consumption: Sending Canonical Theories Back to School
*John W. Schouten, Aalto University, Finland and University of St. Gallen, Switzerland
Diane M. Martin, Aalto University, Finland
Beth Leavenworth DuFault, University of Arizona, USA*
Paper #2: Maven 2.0: The Newly Assembled Interactive Ex-Pat Market Maven
*Hope Jensen Schau, University of Arizona, USA
Beth Leavenworth DuFault, University of Arizona, USA
Yan Mandy Dang, Northern Arizona University, USA
Yulei Gavin Zhang, Northern Arizona University, USA*
Paper #3: Practice Interrupted: When Fatal Disruptions and Irreconcilable Distortions Erode Mutual Understanding and Destroy Social Order
*Paul Connell, Stony Brook University, USA
Hope Jensen Schau, University of Arizona, USA*
Paper #4: Understanding Dynamism in Consumers’ Relationships with Brands through Assemblage Theory
*Tonya Williams Bradford, University of Notre Dame, USA
John W. Schouten, Aalto University, Finland and University of St. Gallen, Switzerland*

For the Love of the Game: New Perspectives on Intrinsically Motivated Behavior 62
Chair: Jordan Etkin, Duke University, USA
Paper #1: Inspired to Create: How Awe Enhances Openness to Learning and Desire for Experiential Creation
*Melanie Rudd, University of Houston, USA
Kathleen Vohs, University of Minnesota, USA*
Paper #2: Curiosity Kills the Cat
*Chris Hsee, University of Chicago, USA
Bowen Ruan, University of Wisconsin at Madison, USA*
Paper #3: The Experience Matters More Than You Think: Weighting Intrinsic Incentives More Inside Than Outside of an Activity
*Kaitlin Woolley, University of Chicago, USA
Ayelet Fishbach, University of Chicago, USA*
Paper #4: The Cost of Quantification: Measurement Undermines Intrinsic Enjoyment
*Jordan Etkin, Duke University, USA
Jonah Berger, The Wharton School, USA*

Motivation in a Social World: Interpersonal Influences on Self-Regulatory Processes	68
<i>Chair: Jordan Etkin, Duke University, USA</i>	
Paper #1: Off My Chest and At It Again: Is Confession a Prelude to Repentance or Relapse?	
<i>Michael L. Lowe, Texas A&M University, USA</i>	
<i>Kelly L. Haws, Vanderbilt University, USA</i>	
Paper #2: Persuasion by Proxy: Vicarious Self-Control Use Increases Decision Compliance	
<i>Joshua Ackerman, University of Michigan, USA</i>	
Paper #3: In Good Company: Managing Interpersonal Resources that Support Self-Regulation	
<i>Michelle vanDellen, University of Georgia, USA</i>	
<i>James Shah, Duke University, USA</i>	
<i>N. Pontus Leander, University of Groningen, USA</i>	
<i>Julie Delose, University of Georgia, USA</i>	
<i>Jerica Bornstein, University of Georgia, USA</i>	
Paper #4: The Downside of Winning: Self-Regulatory Consequences of Competitive Standing	
<i>Szu-Chi Huang, Stanford University, USA</i>	
<i>Jordan Etkin, Duke University, USA</i>	
Time, Money, and Motivation: The Interplay between Goals and Personal Resources	74
<i>Chair: Jordan Etkin, Duke University, USA</i>	
Paper #1: Pressed for Time? Goal Conflict Shapes How Time is Seen, Spent, and Valued	
<i>Jordan Etkin, Duke University, USA</i>	
<i>Ioannis Evangelidis, Bocconi University, Italy</i>	
<i>Jennifer Aaker, Stanford University, USA</i>	
Paper #2: Impatient to Achieve or Impatient to Receive: How the Goal Gradient Effect Underlies Time Discounting	
<i>Oleg Urminsky, University of Chicago, USA</i>	
<i>Indranil Goswami, University of Chicago, USA</i>	
Paper #3: How Budgeting Helps Consumers Achieve Financial Goals	
<i>Christina Kan, Texas A&M University, USA</i>	
<i>John Lynch, University of Colorado-Boulder, USA</i>	
<i>Philip Fernbach, University of Colorado-Boulder, USA</i>	
Paper #4: Resource Slack: A Theory of Perceived Supply and Demand	
<i>John Lynch, University of Colorado-Boulder, USA</i>	
<i>Stephen Spiller, UCLA, USA</i>	
<i>Gal Zauberman, University of Pennsylvania, USA</i>	
Beyond the Choice Set: The Impact of Considering Similar Outside Options	80
<i>Chair: Liz Friedman, Yale University, USA</i>	
Paper #1: The Role of Similarity when Considering Alternatives in Purchase Decisions	
<i>Liz Friedman, Yale University, USA</i>	
<i>Jennifer Savary, Yale University, USA</i>	
<i>Ravi Dhar, Yale University, USA</i>	
Paper #2: The Impact of ‘Display Set Composition’ on Purchase Likelihood	
<i>Uma Karmarkar, Harvard Business School, USA</i>	
Paper #3: Decision-Tree Structures and their Impact on Similarity Judgment and Replacement Choices	
<i>Rom Y. Schrift, The Wharton School, USA</i>	
<i>Jeffrey R. Parker, Georgia State University, USA</i>	
<i>Gal Zauberman, The Wharton School, USA</i>	
<i>Shalena Srna, The Wharton School, USA</i>	
Paper #4: Moderating the Effect of Self on Choice	
<i>Ernest Baskin, Saint Joseph’s University, USA</i>	
<i>Nathan Novemsky, Yale University, USA</i>	
<i>Ravi Dhar, Yale University, USA</i>	

The Science of Charitable Giving and Pro-Social Behavior	85
<i>Chairs: Indranil Goswami, University of Chicago, USA</i>	
Paper #1: On Being the “Tipping Point”: Threshold Incentives Motivate Behavior	
<i>Lalin Anik, Duke University, USA</i>	
<i>Michael Norton, Harvard Business School, USA</i>	
Paper #2: “I feel your pain” The efficacy of instantiating states in charitable appeals	
<i>Carey Morewedge, Boston University, USA</i>	
<i>David Carlin, Williams College, USA</i>	
Paper #3: The Effect of Default Amounts on Charitable Donations. Evidence from a Large-Scale Field Experiment	
<i>Indranil Goswami, University of Chicago, USA</i>	
<i>Oleg Urminsky, University of Chicago, USA</i>	
Paper #4: Limits of Effective Altruism	
<i>Jonathan Berman, London Business School, UK</i>	
<i>Alixandra Barasch, The Wharton School, USA</i>	
<i>Emma Levine, The Wharton School, USA</i>	
<i>Deborah Small, The Wharton School, USA</i>	
Understanding Consumer Financial Behavior: Spending, Saving, Investing and Debt	90
<i>Chairs: Joseph Harvey, University of Colorado, USA</i>	
<i>Michal Strahilevitz, Victoria University of Wellington, New Zealand</i>	
Paper #1: The Relationship Between Frequent Stock Trading and Emotionality, Self Confidence and Self Control	
<i>Michal Strahilevitz, Victoria University of Wellington, New Zealand</i>	
<i>Joseph Harvey, University of Colorado, USA</i>	
<i>Dan Ariely, Duke University, USA</i>	
Paper #2: Piecemeal Repayment: Paying Toward Specific Purchases Promotes Higher Repayments Toward Debt Balances	
<i>Grant Donnelly, Harvard University, USA</i>	
<i>Zoe Chance, Yale University, USA</i>	
<i>Michael Norton, Harvard University, USA</i>	
Paper #3: Low-Asking Heightens Demand and High-Asking Lowers Demand	
<i>Zoe Y. Lu, University of Wisconsin, USA</i>	
<i>Christopher Hsee, University of Chicago, USA</i>	
Paper #4: Risk Management for the Future: Age, Risk, and Choice Architecture	
<i>On Amir, University of California at San Diego, USA</i>	
<i>Orly Lobel, University of San Diego, USA</i>	
All that Glitter! Motivation for Luxury Consumption from Multiple Perspectives	95
<i>Chair: JeeHye Christine Kim, INSEAD, Singapore</i>	
Paper #1: Impact of Status Maintenance Motivation and Political Ideology on Luxury Consumption	
<i>JeeHye Christine Kim, INSEAD, Singapore</i>	
<i>Brian Seongyup Park, INSEAD, Singapore</i>	
<i>David Dubois, INSEAD, Singapore</i>	
Paper #2: How Pinning Nordstrom Means Buying Macys: The Relationship of Social Media, Self-Concept, and Luxury Purchase Intentions	
<i>Lauren Grewal, University of Pittsburgh, USA</i>	
<i>Andrew Stephen, University of Pittsburgh, USA</i>	
<i>Nicole Verrochi Coleman, University of Pittsburgh, USA</i>	
Paper #3: Quenching the Desire for Luxury: Successful Lower-end Luxury Brand Extensions Satisfy Brand Desire	
<i>Vanessa Patrick, University of Houston, USA</i>	
<i>Sonja Prokopec, ESSEC Business School, USA</i>	
Paper #4: The Advantage of Low-Fit Brand Extensions: Addressing the Paradox of Luxury Brands	
<i>Silvia Bellezza, Harvard Business School, USA</i>	
<i>Anat Keinan, Harvard Business School, USA</i>	

Inferential Perspectives in Online Word-of-Mouth:

How Senders and Receivers Infer from Subtle Cues 100

Chair: Soyoung Kim, University of Alberta, Canada

Paper #1: “Don’t Buy” or “Do Not Buy”? Negation Style and Product Evaluations

*Soyoung Kim, University of Alberta, Canada
Sarah Moore, University of Alberta, Canada
Kyle Murray, University of Alberta, Canada*

Paper #2: Proximate Emotion and Distant Reason: Temporal Inference in Word-of-Mouth

*Linda Hagen, University of Michigan, USA
Ed O’Brien, University of Chicago, USA*

Paper #3: Positively Useless: Irrelevant Negative Information Enhances Positive Impressions

*Meyrav Shoham, Technion, Israel
Sarit Moldovan, Technion, Israel
Yael Steinhart, Tel Aviv University, Israel*

Paper #4: Does Sharing Lead to Sharing? Evidence from Free Product Settings

*Samuel D. Bond, Georgia Institute of Technology, USA
Stephen X. He, Manhattan College, USA
Wen Wen, University of Texas at Austin, USA*

It Is Not What It Seems:

Unexpected Influences On Doing Good For Yourself And Others 105

Chairs: Simona Botti, London Business School, United Kingdom

Anne-Kathrin Klesse, Tilburg University, the Netherlands

Paper #1: Cross-Domain Effects of Guilt on Desire for Self-Improvement Products

*Thomas Allard, Sauder School of Business, Canada
Katherine White, Sauder School of Business, Canada*

Paper #2: Choice Closure Increases Indulgence (But Only Once!)

*Yangjie Gu, HEC, France
Anne-Kathrin Klesse, Tilburg University, the Netherlands
Simona Botti, London Business School, UK
David Faro, London Business School, UK*

Paper #3: “Serves you Right”? The Dark Side of a Malleable Mindset

*Liat Levontin, Technion, Israel Institute of Technology, Israel
Gita Venkataramani Johar, Columbia Business School, USA*

Paper #4: Excusing Selfishness in Charitable Giving: The Role of Risk

Christine Exley, Stanford University, USA

iMirror/iMirror: Digital Reflections of Self-Consumption 111

Chair: Robert Kozinets, York University, Canada

Paper #1: Reflections of Self in Food Sharing Interactions and Experiences

*Robert Kozinets, York University, Canada
Rachel Ashman, University of Liverpool, UK
Anthony Patterson, University of Liverpool, UK*

Paper #2: Consumer Soveillance: Observations of the Self by Means of New Media Technologies

*Anja Dinhopf, University of Queensland, Australia
Ulrike Gretzel, University of Queensland, Australia*

Paper #3: Co-Construction of the Digital Self

Russell Belk, York University, Canada

Paper #4: Self-Transformation and Performativity of Social Media Images

Joonas Rokka, NEOMA Business School, France

Advances in Mobile Consumer Behavior:

Effects on Content Generation, Social Persuasion, Mobile Targeting and Shopping Behavior. 117

Chair: Shiri Melumad, Columbia University Graduate School of Business, USA

Paper #1: The Distinct Psychology of Smartphone Use: Smartphone-Generated Content as Emotional Expression

*Shiri Melumad, Columbia University, USA
J. Jeffrey Inman, University of Pittsburgh, USA
Michel T. Pham, Columbia University, USA*

Paper #2: In Mobile We Trust: How Mobile Reviews Can Overcome Consumer Distrust of User-Generated Reviews

*Andrew T. Stephen, University of Pittsburgh, USA
Lauren Grewal, University of Pittsburgh, USA*

Paper #3: Social and Location Effects in Mobile Advertising

*Peter Pal Zubcsek, University of Florida, USA
Zsolt Katona, UC Berkeley, USA
Miklos Sarvary, Columbia University, USA*

Paper #4: Smart Phones, Bad Calls? In-store Mobile Technology Use and Consumer Purchase Behavior

*Michael R. Sciandra, Fairfield University, USA
J. Jeffrey Inman, University of Pittsburgh, USA*

Reasoning About Advice: Inferring and Integrating the Preferences of Others 122

Chair: Rachel Meng (Columbia University)

Paper #1: Mistaking Dissimilar for Dislike: Why We Underestimate the Diversity of Others' Preferences

*Kate Barasz, Harvard University, USA
Tami Kim, Harvard University, USA
Leslie John, Harvard University, USA*

Paper #2: Valuing Dissimilarity: The Role of Diversity in Preference Predictions

*Rachel Meng, Columbia University, USA
Stephanie Y. Chen, University of Chicago, USA
Daniel M. Bartels, University of Chicago, USA*

Paper #3: Are Advice Takers Bayesian? Preference Similarity Effects on Advice Seeking and Taking

*Hang Shen, University of California, Riverside, USA
Ye Li, University of California, Riverside, USA*

Paper #4: Recommenders vs. Recommender Systems

*Mike Yeomans, Harvard University, USA
Anuj Shah, University of Chicago, USA
Sendhil Mullainathan, Harvard University, USA
Jon Kleinberg, Cornell University, USA*

How To Do, When To Do, What To Do:

The Experiential Consumption Process 127

Chair: Chadwick J. Miller, Arizona State University, USA

Paper #1: The Heart and the Head: On Choosing Experiences Intuitively and Possessions Deliberately

*Iñigo Gallo, IESE Business School, Barcelona, Spain
Sanjay Sood, University of California, USA
Thomas Mann, Cornell University, USA
Thomas Gilovich, Cornell University, USA*

Paper #2: To Do or To Have, Now or Later? The Preferred Consumption Profiles of Material and Experiential Purchases

*Amit Kumar, Cornell University, USA
Thomas Gilovich, Cornell University, USA*

Paper #3: Simply Desirable, Preferably Complex: Feature-Richness in Experiential Purchases

*Chadwick J. Miller, Arizona State University, USA
Adriana Samper, Arizona State University, USA
Naomi Mandel, Arizona State University, USA*

Paper #4: The Peculiarly Persistent Pleasantness of Bizarre Experiences

Robert Latimer, University of Toronto, Canada

What's Risky? New Perspectives on "Risk" Aversion	132
<i>Chair: Robert Mislavsky, University of Pennsylvania, USA</i>	
Paper #1: Risk is Weird	
<i>Robert Mislavsky, University of Pennsylvania, USA</i>	
<i>Uri Simonsohn, University of Pennsylvania, USA</i>	
Paper #2: Gamblers Are Fun (But They Aren't Risk Takers)	
<i>Theresa F. Kelly, University of Pennsylvania, USA</i>	
<i>Joseph P. Simmons, University of Pennsylvania, USA</i>	
Paper #3: The Unattractiveness of Hedges: Implications for the Conception of Risk Preferences	
<i>Shane Frederick, Yale University, USA</i>	
<i>Andrew Meyer, Yale University, USA</i>	
<i>Amanda Levis, Yale University, USA</i>	
Paper #4: Value Atrophy in Consumer Assessment of Risky Options	
<i>Uzma Khan, Stanford University, USA</i>	
<i>Daniella Kupor, Stanford University, USA</i>	
 Consumer Financial Decision Making:	
Understanding Savings Accumulation and Decumulation Decisions	136
<i>Chairs: Gergana Y. Nenkov, Boston College, USA</i>	
<i>Linda Court Salisbury, Boston College, USA</i>	
Paper #1: The Illusion of Wealth and Its Reversal	
<i>Dan Goldstein, Microsoft Research, USA</i>	
<i>Hal Hershfield, UCLA, USA</i>	
<i>Shlomo Benartzi, UCLA, USA</i>	
Paper #2: Solving the Annuity Puzzle: The Role of Mortality Salience in Retirement Savings Decumulation Decisions	
<i>Linda Court Salisbury, Boston College, USA</i>	
<i>Gergana Y. Nenkov, Boston College, USA</i>	
Paper #3: Psychological Factors in Savings and Decumulation Decisions	
<i>Suzanne Shu, UCLA, USA</i>	
<i>John Payne, Duke University, USA</i>	
Paper #4: Visual Depiction of Goal Structure and Financial Decisions	
<i>Min Zhao, University of Toronto, Canada</i>	
<i>Dilip Soman, University of Toronto, Canada</i>	
<i>Joonkyung Kim, University of Toronto, Canada</i>	
 Fashion Signals and Symbols: Beyond Conspicuous Consumption	 142
<i>Chair: Luke Nowlan, University of Miami, USA</i>	
Paper #1: The Devil Wears Prada? How Luxury Consumption Influences Social Behaviors	
<i>Yajin Wang, University of Minnesota, USA</i>	
<i>Deborah Roedder John, University of Minnesota, USA</i>	
<i>Vladas Griskevicius, University of Minnesota, USA</i>	
Paper #2: New Wine in Old Bottles: Vintage Consumption, Death Awareness, and the Desire to Connect the Past, Present, and Future	
<i>Gülen Sarial-Abi, Bocconi University, Italy</i>	
<i>Kathleen D. Vohs, University of Minnesota, USA</i>	
<i>Ryan Hamilton, Emory University, USA</i>	
<i>Aulona Ulqinaku, Bocconi University, Italy</i>	
Paper #3: Don't Go Broke, Go Back in Time: Vintage, an Alternative Status Symbol	
<i>Morgan Ward, Southern Methodist University, USA</i>	
<i>Claudia Townsend, University of Miami, USA</i>	
<i>Luke Nowlan, University of Miami, USA</i>	
Paper #4: The Impact of Usage Frequency on Lifestyle Branding	
<i>Jingjing Ma, Peking University, China</i>	
<i>Ryan Hamilton, Emory University, USA</i>	
<i>Alexander Chernev, Northwestern University, USA</i>	

Indulgence in Context: Within-Episode Dynamics of Indulgent Consumption.	147
<i>Chair: Ga-Eun (Grace) Oh, HKUST, China</i>	
Paper #1: The Influence of Nutrition Information on Sequential Consumption Decisions for Indulgent Food	
<i>Ga-Eun (Grace) Oh, HKUST, China</i>	
<i>Young Eun Huh, HKUST, China</i>	
<i>Anirban Mukhopadhyay, HKUST, China</i>	
Paper #2: Preference Reversal of Indulgent Rewards as A Dynamic Self-Control Mechanism	
<i>Qian Xu, Fudan University, China</i>	
<i>Liyin Jin, Fudan University, China</i>	
<i>Ying Zhang, Peking University, China</i>	
Paper #3: What's Next? Anticipated Consumption Variety: Borrowing Affect From the Future To Slow Satiation in the Present	
<i>James Mead, University of Houston – Clear Lake, USA</i>	
<i>Maura L. Scott, Florida State University, USA</i>	
<i>David Hardesty, University of Kentucky, USA</i>	
Paper #4: Too Busy to Lose Control: Impact of Busyness on Indulgent Consumption Behaviors	
<i>JeeHye Christine Kim, INSEAD, Singapore</i>	
<i>Monica Wadhwa, INSEAD, Singapore</i>	
<i>Amitava Chattopadhyay, INSEAD, Singapore</i>	
Theoretical Advances in the Sharing Economy	152
<i>Chairs: Julie L. Ozanne, University of Melbourne, Australia</i>	
<i>Samuelson Appau, Melbourne Business School, Australia</i>	
Paper #1: Designing a Sharing Economy through the Process of Market Empathization	
<i>Markus Giesler, York University, Canada</i>	
<i>Ela Veresiu, Witten/Herdecke University, Germany</i>	
<i>Anton Siebert, Witten/Herdecke University, Germany</i>	
Paper #2: Disambiguating Sharing Economies: How Economic Tropes Affect Attitudes	
<i>Cait Lambertson, University of Pittsburg, USA</i>	
<i>Alexander S. Rose, University of South Carolina, USA</i>	
<i>Randall L. Rose, University of South Carolina, USA</i>	
Paper #3: The Dark Side of Sharing: Social Exclusion within Donation Pooling	
<i>Samuelson Appau, Melbourne Business School, Australia</i>	
<i>Julie L. Ozanne, University of Melbourne, Australia</i>	
<i>Jill Klein, Melbourne Business School, Australia</i>	
Paper #4: Strategic Implications of Consumer-To-Consumer Resource Pooling	
<i>Alexander S. Rose, University of South Carolina, USA</i>	
<i>Eric J. Arnould, Southern Denmark University, Denmark</i>	
How People Talk About Products in Word of Mouth.	157
<i>Chairs: Grant Packard, Wilfrid Laurier University, Canada</i>	
<i>Jonah Berger, University of Pennsylvania, USA</i>	
Paper #1: Following the Blind: How Expertise and Endorsement Style Impact Word of Mouth Persuasion	
<i>Grant Packard, Wilfrid Laurier University, Canada</i>	
<i>Jonah Berger, University of Pennsylvania, USA</i>	
Paper #2: When and Why Paid Reviews are Bad Investments: The Impact of Monetary Incentives on Reviewer Certainty	
<i>Christiline du Plessis, Erasmus University, Netherlands</i>	
<i>David Dubois, INSEAD, France</i>	
Paper #3: Write and Write Alike: How Personality Affects the Value of Word of Mouth	
<i>Zahra Tohidinia, University of Connecticut, USA</i>	
<i>Nicholas Lurie, University of Connecticut, USA</i>	
Paper #4: Transmitting Well-Reasoned Word of Mouth Impairs Memory for Product Experiences	
<i>Zoey Chen, University of Miami, USA</i>	
<i>Ann Schlosser, University of Washington, USA</i>	

Show Me What You Can Do: Emerging Research on the Roles of Brands 163

Chair: Ryan Rahinel, University of Cincinnati, USA

Paper #1: Brand Exposure Makes Decisions Easier

Ryan Rahinel, University of Cincinnati, USA
Ashley Otto, University of Cincinnati, USA
Joshua J. Clarkson, University of Cincinnati, USA
Daniel M. Grossman, University of Cincinnati, USA

Paper #2: Sex and Status Sell to Monkeys: Social Advertising Creates Brand Preferences in Rhesus Macaques

M. Yavuz Acikalin, Stanford University, USA
Karli K. Watson, Duke University, USA
Gavan J. Fitzsimons, Duke University, USA
Michael L. Platt, Duke University, USA

Paper #3: Symbolic Brand Synergy: When 1 is Greater Than 2

Sean Coary, St. Joseph's University, USA

Paper #4: Performance Brand Placebos: How Brands Improve Performance and Consumers Take the Credit

Aaron M. Garvey, University of Kentucky, USA
Frank Germann, University of Notre Dame, USA
Lisa E. Bolton, Pennsylvania State University, USA

Understanding Prosocial Behavior Across Levels of Analysis: From the Brain to the Field 170

Chairs: Crystal Reeck, Temple University, USA

Ming Hsu, University of California Berkeley, USA

Paper #1: The Controlled Nature of Prosociality: Pharmacological Enhancement of Prosocial Behavior

Ming Hsu, University of California Berkeley, USA
Ignacio Sáez, University of California Berkeley, USA
Andrew Kayser, University of California San Francisco, USA

Paper #2: Neural Mechanisms Promoting Selflessness in Potential Conflicts of Interest

Crystal Reeck, Temple University, USA
Nina Mazar, University of Toronto, Canada
Dan Ariely, Duke University, USA
Rita Ludwig, University of Oregon, USA
Malia F. Mason, Columbia University, USA

Paper #3: Affective Mechanisms in Microlending Decisions: Using Internet Data and Neuroimaging to Predict Market-level Behavior

Alexander Genevsky, Stanford University, USA
Brian Knutson, Stanford University, USA

Paper #4: Prosocial Incentives: Limits and Benefits of Working for Others

Alex Imas, Carnegie Mellon University, USA
Elizabeth Keenan, University of California San Diego, USA
Ayelet Gneezy, University of California San Diego, USA

The Greater Good: Behavioral Research with Social Value 176

Chairs: Nicole Robitaille, Queen's University, Canada

Nina Mazar, University of Toronto, Canada

Paper #1: Setting the Record Straight on Sugary Drink Portion Cap Policies

Leslie K. John, Harvard Business School, USA
Christina Roberto, Harvard School of Public Health, USA

Paper #2: Nudging to Increase Organ and Tissue Donor Registrations

Nicole Robitaille, Queen's University, Canada
Nina Mazar, University of Toronto, Canada
Claire Tsai, University of Toronto, Canada

Paper #3: Gain without Pain: The Extended Effects of a Behavioral Health Intervention

Daniel Mochon, Tulane University, USA
Janet Schwartz, Tulane University, USA
Josiase Maroba, Discovery Vitality, USA
Deepak Patel, Discovery Vitality, USA
Dan Ariely, Duke University, USA

Paper #4: From Garbage to Gift: 'Social' Recycling Promotes Happiness

Grant E. Donnelly, Harvard Business School, USA
Cait Poynor Lambertson, University of Pittsburgh, USA
Rebecca Walker Reczek, The Ohio State University, USA
Michael I. Norton, Harvard Business School, USA

A Holistic View of Consumer-Brand Connections	181
<i>Chairs: Maria A. Rodas, University of Minnesota, USA</i>	
<i>Carlos J. Torelli, University of Minnesota, USA</i>	
Paper #1: The Self-Expanding Process of Falling in Love with a Brand	
<i>Maria A. Rodas, University of Minnesota, USA</i>	
<i>Carlos J. Torelli, University of Minnesota, USA</i>	
Paper #2: Salient Cultural Identities and Consumer Relationships with Culturally Symbolic Brands	
<i>Carlos J. Torelli, University of Minnesota, USA</i>	
<i>Rohini Ahluwalia, University of Minnesota, USA</i>	
<i>Maria A. Rodas, University of Minnesota, USA</i>	
Paper #3: When Strong Self-Brand Connections Don't Protect Brands: Achievement Mindsets and Brand Dilution	
<i>Efe Camurdan, Koç University, Turkey</i>	
<i>Zeynep Gurhan-Canli, Koç University, Turkey</i>	
<i>Alokparna Basu Monga, Rutgers University, USA</i>	
Paper #4: The Brand Company You Keep: When People Judge You by the Brands You Use	
 Sharing As a Social Phenomenon	 186
<i>Chair: Russell Belk, York University, Canada</i>	
Paper #1: Shared Moments of Sociality: Embedded Sharing within Peer-to-peer Hospitality Platforms	
<i>Katharina Hellwig, HEC Lausanne, Switzerland</i>	
<i>Russell Belk, York University, Canada</i>	
<i>Felicitas Morhart, HEC Lausanne, Switzerland</i>	
Paper #2: Sharing Difficult Choices	
<i>Tatiana Barakshina, University of Illinois at Chicago, USA</i>	
<i>Alan J. Malter, University of Illinois at Chicago, USA</i>	
Paper #3: A Social Network Analysis of Adolescent Social Standing, Sharing and Acquisition Materialism, and Life Satisfaction	
<i>Elodie Gentina, Université de Lille, France</i>	
<i>LJ Shrum, HEC Paris, France</i>	
<i>Tina M. Lowrey, HEC Paris, France</i>	
Paper #4: With Whom Do People Share? The Effects of Upward and Downward Social Comparisons on Willingness to Share Possessions	
<i>Ayalla Ruvio, Michigan State University, USA</i>	
<i>Naomi Mandel, Arizona State University, USA</i>	
<i>Elodie Gentina, Université de Lille, France</i>	
 Consumer Wellbeing: Interpreting Difficulties, Being Resilient, Extending Forgiveness, and Pursuing a “Fresh Start”	 191
<i>Chair: Linda Price, University of Arizona, USA</i>	
Paper #1: From Difficulty to Possibility: Interpretation of Experienced Difficulty, Motivation and Behavior	
<i>Daphna Oyserman, University of Southern California, USA</i>	
<i>Sheida Novin, University of Michigan, USA and Utrecht University, France</i>	
<i>George C. Smith, University of Michigan, USA</i>	
<i>Kristen Elmore, University of Michigan, USA</i>	
<i>Cecile Nurra, University of Grenoble Alpes, France</i>	
<i>Oliver Fisher, University of Southern California</i>	
<i>Neil Lewis, University of Michigan</i>	
Paper #2: Rising Every Time They Fall: The Importance and Determinants of Consumer Resilience	
<i>Joan Ball, St. John's University, USA</i>	
<i>Cait Lambertson, University of Pittsburgh, USA</i>	
Paper #3: Many Goals–One Choice: Understanding Consumer Forgiveness	
<i>Yelena Tsarenko, Monash University, Australia</i>	
<i>Yuliya Strizhakova, Rutgers University, USA</i>	
<i>Cele Otnes, University of Illinois, USA</i>	
Paper #4: Can A “Fresh Start” Help Consumers Achieve Their Goals?	
<i>Ainslie Schultz, University of Arizona, USA</i>	
<i>Linda L. Price, University of Arizona, USA</i>	
<i>Robin Coulter, University of Connecticut, USA</i>	

Sharing as Caring, Scaring, Bragging and Persuading:

Motive Inferences for Sharing Word-of-Mouth on Social Media 197

Chair: Tejvir Sekhon, Boston University, USA

Paper #1: Does Sharing Signal Caring? Asymmetric Interpretations of the Informativeness of Own and Others' Social Media Communications

Elanor F. Williams, University of California San Diego, USA

Mary Steffel, University of Cincinnati, USA

Paper #2: I Do It Out of Love! The Role of Brand Attachment Cues in Consumption Related Bragging

Tejvir Sekhon, Boston University, USA

Barbara Bickart, Boston University, USA

Remi Trudel, Boston University, USA

Susan Fournier, Boston University, USA

Paper #3: Trust Me, I Know! The Impact of Source Self-Enhancement on Persuasion in Word-of-Mouth Grant Packard, Wilfrid Laurier University, Canada

Andrew Gershoff, University of Texas at Austin, USA

David Wooten, University of Michigan, USA

Paper #4: Sharing Turns to Scaring: Explaining Apple Versus Android Brand Community Conflict

Mina Seraj, Bogazici University, Turkey

Robert Kozinets, York University, Canada

Aysegul Tokar, Bogazici University, Turkey

Illusions of Preference Construction. 203

Chair: Aner Sela, University of Florida, USA

Paper #1: "Liking Goes with Liking: An Intuitive Measure of Preferences at a Flip of a Coin"

Coby Morvinski, University of California San Diego, USA

On Amir, University of California San Diego, USA

Paper #2: "The Feeling of Preference"

Aner Sela, University of Florida, USA

Itamar Simonson, Stanford, USA

Paper #3: "Complicating Decisions: The Effort-Outcome Link and the Construction of Effortful Decision Processes"

Rom Schrift, University of Pennsylvania, USA

Ran Kivetz, Columbia University, USA

Oded Netzer, Columbia University, USA

Paper #4: "Evolving Front-runners: Choice under Gradual Construction"

Wendy Liu, University of California San Diego, USA

Itamar Simonson, Stanford, USA

Understanding and Overcoming Financial Challenges:

Process Insights, Pitfalls, and Recommendations. 208

Chairs: Rachel Meng, Columbia University, USA

Eesha Sharma, Dartmouth College, USA

Paper #1: Poverty as Helplessness: How Loss of Control Affects Impulsivity and Risk-Taking

Ayelet Gneezy, University of California San Diego, USA

Alex Imas, Carnegie Mellon University, USA

Paper #2: Thinking About Financial Deprivation: Rumination and Decision Making Among the Poor

Gita Johar, Columbia University, USA

Rachel Meng, Columbia University, USA

Keith Wilcox, Columbia University, USA

Paper #3: An Urgency Effect in Responses to Future Rate Increases

Shirley Zhang, University of Chicago, USA

Christopher Hsee, University of Chicago, USA

Abigail Sussman, University of Chicago, USA

Pragmatism and Consumer Research	212
<i>Chairs: Iain Davies, University of Bath, UK</i>	
<i>Dan Silcock, University of Bath, UK</i>	
Paper #1: Marketing Pragmatism: A Constructive Review of Pragmatic Philosophy and Implications for Consumer Research	
<i>Dan Silcock, University of Bath, UK</i>	
Paper #2: Pragmatism, New Science and Sustainability	
<i>Richard Varey, University of Waikato, New Zealand</i>	
Paper #3: “Theory” into “Knowledge”: Operationalizing consumption research into behavioural change with Pragmatism	
<i>Iain Davies, University of Bath, UK</i>	
Paper #4: Can the pragmatist logic of inquiry inform consumer led market design?	
<i>Ronika Chakrabarti, Lancaster University, UK</i>	
<i>Katy Mason, Lancaster University, UK</i>	
The Malleable Past: The Formation and Function of Memory for Experiences	218
<i>Chair: Jackie Silverman, University of Pennsylvania, USA</i>	
Paper #1: Photographic Memory: The Effects of Photo-Taking on Memory for Auditory and Visual Information	
<i>Gal Zaubergerman, University of Pennsylvania, USA</i>	
<i>Jackie Silverman, University of Pennsylvania, USA</i>	
<i>Kristin Diehl, University of Southern California, USA</i>	
<i>Alixandra Barasch, University of Pennsylvania, USA</i>	
Paper #2: Malleability of Taste Perception: Biasing Effects of Rating Scale Format on Taste Recognition, Product Evaluation, and Willingness to Pay	
<i>Antonia Mantonakis, Brock University, Canada</i>	
<i>Norbert Schwarz, University of Southern California, USA</i>	
<i>Amanda Wudarzewski, University of Waterloo, Canada</i>	
<i>Carolyn Yoon, University of Michigan, USA</i>	
Paper #3: Risk Preferences for Experiences, or How Desserts Are Like Losses	
<i>Jolie M. Martin, Pinterest, USA</i>	
<i>Martin Reimann, University of Arizona, USA</i>	
<i>Michael I. Norton, Harvard Business School, USA</i>	
Paper #4: We’ll Always Have Paris (Though We May Not Think of It): Consumers Overestimate How Often They Will Retrospect about Experiences	
<i>Stephanie Tully, University of Southern California, USA</i>	
<i>Tom Meyvis, New York University, USA</i>	
What makes you pay?	
Features of incentives and the distribution of benefits in financial behavior	224
<i>Chair: Shalena Srna, University of Pennsylvania, USA</i>	
Paper #1: Taking One for the Team: Motivating Prosocial Volunteering by Varying the Size and the (Un)Certainty of its Impact on Collective Welfare	
<i>Christopher Olivola, Carnegie Mellon University, USA</i>	
<i>Yeonjeong Kim, Carnegie Mellon University, USA</i>	
<i>Avi Merzel, Hebrew University, Israel</i>	
<i>Yaakov Kareev, Hebrew University, Israel</i>	
<i>Judith Avrahami, Hebrew University, Israel</i>	
<i>Ilana Ritov, Hebrew University, Israel</i>	
Paper #2: Using Gambling to Incentivize Prudent Financial Decisions	
<i>Abigail B. Sussman, The University of Chicago, USA</i>	
<i>Rourke L. O’Brien, Harvard University, USA</i>	
Paper #3: Lifting the Veil: The Benefits of Cost Transparency	
<i>Bhavya Mohan, Harvard Business School, USA</i>	
<i>Ryan Buell, Harvard Business School, USA</i>	
<i>Leslie John, Harvard Business School, USA</i>	
Paper #4: The impact of income tax and redistribution of tax money on productivity, satisfaction, and perceptions of fairness	
<i>Shalena Srna, University of Pennsylvania, USA</i>	
<i>Gal Zaubergerman, University of Pennsylvania, USA</i>	
<i>Schrift Rom Y., University of Pennsylvania, USA</i>	

The Pleasures and Perils of Gift-Giving	229
<i>Chairs: Mary Steffel, Northeastern University, USA</i>	
<i>Lisa Cavanaugh, University of Southern California, USA</i>	
Paper #1: Ensouling Gifts with Closeness	
<i>Evan Polman, University of Wisconsin-Madison, USA</i>	
<i>Sam J. Maglio, University of Toronto Scarborough, Canada</i>	
Paper #2: When Doing Good Is Bad in Gift Giving: Mispredicting Appreciation of Socially Responsible Gifts	
<i>Lisa A. Cavanaugh, University of Southern California, USA</i>	
<i>Francesca Gino, Harvard University, USA</i>	
<i>Gavan Fitzsimons, Duke University, USA</i>	
Paper #3: Overly Specific Gift Giving: Givers Choose Personalized but Less-Versatile and Less-Preferred Gifts	
<i>Mary Steffel, Northeastern University, USA</i>	
<i>Elanor F. Williams, University of California, San Diego, USA</i>	
<i>Robyn A. LeBoeuf, Washington University in St. Louis, USA</i>	
Paper #4: How Reasons Can Undermine the Symbolic Value of Gifts	
<i>Laurence Ashworth, Queen's School of Business, Canada</i>	
<i>Katherine White, University of British Columbia, Canada</i>	
<i>Darren Dahl, University of British Columbia, Canada</i>	
New Insights into Creative Cognition	234
<i>Chairs: Ding (Allen) Tian, Wuhan University, China</i>	
<i>Lidan Xu, University of Illinois at Urbana-Champaign, USA</i>	
Paper #1: The Light Side of Creativity: Moral Reminders Can Boost Creativity	
<i>Anne Laure Sellier, HEC Paris, France</i>	
<i>Darren W. Dahl, University of British Columbia, Canada</i>	
Paper #2: Does Self-Regulatory Resource Depletion Reduce or Enhance Creativity?	
<i>Ding (Allen) Tian, Wuhan University, China</i>	
<i>Gerald Häubl, University of Alberta, Canada</i>	
Paper #3: Good or Bad? Exploring Differential Effects of Creativity on Pro-social Behavior	
<i>Lidan Xu, University of Illinois at Urbana-Champaign, USA</i>	
<i>Ravi Mehta, University of Illinois at Urbana-Champaign, USA</i>	
Evaluations of Hedonic Experiences	239
<i>Chair: Stephanie M. Tully, University of Southern California, USA</i>	
Paper #1: Questioning the End Effect: Endings Do Not Inherently Have a Disproportionate Impact on Evaluations of Experiences	
<i>Stephanie M. Tully, University of Southern California, USA</i>	
<i>Tom Meyvis, New York University, USA</i>	
Paper #2: Experience Heterogeneity Moderates the Peak Effect in Retrospective Evaluations	
<i>Robert Latimer, University of Toronto, Canada</i>	
Paper #3: Modes of Enjoyment for Multifaceted Experiences	
<i>Michael C. Covey, University of Minnesota, USA</i>	
<i>Joseph P. Redden, University of Minnesota, USA</i>	
Paper #4: Feeling Like an Expert: Subjective Expertise and Consumption Enjoyment	
<i>Troy H. Campbell, University of Oregon, USA</i>	
<i>Dan Ariely, Duke University, USA</i>	
Experiences in the Moment	244
<i>Chair: Francesca Valsesia, University of Southern California, USA</i>	
Paper #1: Based on True Events: The Effects of Veracity on the Consumption Experience	
<i>Francesca Valsesia, University of Southern California, USA</i>	
<i>Kristin Diehl, University of Southern California, USA</i>	
<i>Joseph C. Nunes, University of Southern California, USA</i>	
Paper #2: The Revision Bias: Preferences for Revised Experiences Absent Objective Improvement	
<i>Leslie K. John, Harvard Business School, USA</i>	
<i>Michael K. Norton, Harvard Business School, USA</i>	
Paper #3: FOMO: How the Fear of Missing Out Leads to Missing Out	
<i>Jacqueline Rifkin, Duke University, USA</i>	
<i>Cindy Chan, University of Toronto, Canada</i>	
<i>Barbara Kahn, University of Pennsylvania, USA</i>	
Paper #4: My Phone is My Diary: Using Mobile Diaries for TV Viewing Measurement	
<i>Mitchell Lovett, University of Rochester, USA</i>	
<i>Renana Peres, Hebrew University of Jerusalem, Israel</i>	

Nutrition and Numerosity: The Effects of Non-Used and Non-Consumed Items on Consumption Experiences and Outcomes 249
Chair: Noah VanBergen, University of Miami, USA
Paper #1: Motivated Ignorance: The Hedonic Cost of Nutritional Information
Scott Davis, Texas A&M University, USA
Kelly L. Haws, Vanderbilt University, USA
Paper #2: The Influence of Package Formats on Consumers’ Perceptions of Product Adequacy and Efficacy Responses
Veronika Iyuk, Hofstra University, USA
Lauren Block, Baruch College, USA
Paper #3: Present but Not Consumed: The Interaction of Assortment Size and Product Familiarity on Expected and Actual Product Efficacy
Noah VanBergen, University of Miami, USA
Caglar Irmak, University of Miami, USA
Julio Sevilla, University of Georgia, USA
Paper #4: In Pieces: Food Is More Filling when Served in Several Pieces
Aner Tal, Cornell University, USA
Brian Wansink, Cornell University, USA

Access In Transition:
Understanding Evolving Marketplace Access for Stigmatized Consumers 254
Chairs: Sunaina Velagaleti, University of Wisconsin-Madison, USA
Amber M. Epp, University of Wisconsin-Madison, USA
Paper #1: Pursuing Marriage Equality in the Marketplace: Stigmatized Consumers’ Responses to Mainstream Marketplace Access
Sunaina R. Velagaleti, University of Wisconsin-Madison, USA
Amber M. Epp, University of Wisconsin-Madison, USA

**“Understanding Uncertainty:
The Mechanisms Behind the Adaptive Nature of Decision-making Under Uncertainty” 260**
Chairs: Vinod Venkatraman, Temple University, USA
Uma Karmarkar, Harvard Business School, USA
Paper #1: Development of an Individual Measure of Loss Aversion
John Payne, Duke University, USA
Suzanne Shu, University of California Los Angeles, USA
Elizabeth Webb, Columbia University, USA
Namika Sagara, Duke University, USA
Paper #2: Biases in Using Information to Evaluate Uncertain Financial Prospects
Uma Karmarkar, Harvard Business School, USA
Alexander Peysakhovich, Harvard University, USA
Paper #3: Overall Probability of Winning Heuristic in Decisions Under Uncertainty and Ambiguity
Vinod Venkatraman, Temple University, USA
Sangsuk Yoon, Temple University, USA
Khoi Vo, Temple University, USA
Paper #4: Updating Under Ambiguity: Insights from Neuroscience
Ming Hsu, University of California Berkeley, USA
Kenji Kobayashi, University of California Berkeley, USA

Inconsistent Preferences Under Risk	265
<i>Gabriele Paolacci, Erasmus University Rotterdam, The Netherlands</i>	
<i>Joachim Vosgerau, Bocconi University, Italy</i>	
Paper #1: Contextual Gambles Bias Odds in Sports Betting Markets	
<i>Andrew Meyer, Yale University, USA</i>	
<i>C. Sean Hundtofte, Yale University, USA</i>	
<i>Shane Frederick, Yale University, USA</i>	
Paper #2: When and Why Do Consumers Devalue Risky Prospects?	
<i>Alice Moon, University of California Berkeley, USA</i>	
<i>Leif Nelson, University of California Berkeley, USA</i>	
Paper #3: Malleability of Revealed Risk Preferences	
<i>Joachim Vosgerau, Bocconi University, Italy</i>	
<i>Eyal Peer, Bar-Ilan University, Israel</i>	
Paper #4: Less Likely Outcomes are Valued Less	
<i>Gabriele Paolacci, Erasmus University Rotterdam, The Netherlands</i>	
<i>Joachim Vosgerau, Bocconi University, Italy</i>	
Paying-it-Forward: How Greed, Generosity, and (un)Fairness	
Spread Through Social Networks	270
<i>Chair: Adrian F. Ward, University of Texas at Austin, USA</i>	
Paper #1: Social and Material Concerns in Paying it Forward: People are Selfish, But Only in Secret	
<i>Adrian F. Ward, University of Texas at Austin, USA</i>	
<i>Michael I. Norton, Harvard Business School, USA</i>	
<i>Kurt Gray, University of North Carolina, USA</i>	
Paper #2: When is it Better to Give or Receive? Kindness, Happiness, and Reciprocity in the Chain of Giving	
<i>Minah H. Jung, New York University, USA</i>	
<i>Silva K. Kurtisa, Georgetown University, USA</i>	
<i>Leif D. Nelson, University of California Berkeley, USA</i>	
Paper #3: Looking Forward, Looking Back: How Communal Orientation and Perceived Impact Influence Paying it Forward	
<i>Narayan Janakiraman, University of Texas at Arlington, USA</i>	
<i>Zhiyong Yang, University of Texas at Arlington, USA</i>	
<i>Karen Page Winterich, Pennsylvania State University, USA</i>	
Paper #4: Moral Responsibility and Paying it Forward: The Effects of Social Distance and Queue Length on Paying Forward Generosity	
<i>Zhiyong Yang, University of Texas at Arlington, USA</i>	
<i>Narayan Janakiraman, University of Texas at Arlington, USA</i>	
<i>Morgan K. Ward, Southern Methodist University, USA</i>	
Theorising Digital Consumption Objects	275
<i>Chair: Rebecca D. Watkins, Cardiff University, UK</i>	
Paper #1: Conceptualising the Ontology of Digital Consumption Objects	
<i>Rebecca D. Watkins, Cardiff University, UK</i>	
Paper #2: Digital Materiality – A Phenomenological Exploration	
<i>Richard Kedzior, Bucknell University, USA</i>	
Paper #3: Image and Sound in a Digital Age: The Inflation of Symbols and the Erosion of Value	
<i>Russell Belk, York University, Canada</i>	
Paper #4: Human/Digital/Material Hybrids as Consumer Mind Extensions	
<i>Janice Denegri-Knott, Bournemouth University, UK</i>

<i>Mike Molesworth, University of Southampton, UK</i>	

The Effect of Numerical Markers on Consumer Inferences and Decisions 282

Chair: Jared Watson University of Maryland, USA

Paper #1: The Effect of Reward Quantification on Actual Program Participation

*Eleanor Putnam-Farr, Massachusetts Institute of Technology, USA
Jason Riis, University of Pennsylvania, USA*

Paper #2: Swayed Away by Numbers: When Consumers Overweight the Review Counts in their Decisions

*Jared Watson, University of Maryland, USA
Anastasiya Pocheptsova, University of Maryland, USA
Michael Trusov, University of Maryland, USA*

Paper #3: “18% off the Original Price Then Another 12% off” or “12% off Then 18% off”: How Multiple Discounts Influence Consumer Evaluations

*Rajesh Bagchi, Virginia Tech, USA
Derick Davis, University of Miami, USA*

Paper #4: The Rating Polarity Effect: Overcoming the Surreptitious Influence of Implicit Numerical Associations on Consumer Judgments

*Ellie Kyung, Dartmouth College, USA
Manoj Thomas, Cornell University, USA
Aradhna Krishna, University of Michigan, USA*

Informing the Experience:

How Does Prior Information Influence Consumption Experiences 287

Chairs: Sarah Wei, University of Alberta, Canada

Anna Paley, New York University, USA

Paper #1: Sampling Traps: How the Opportunity to Sample Experiential Products Reduces Hedonic Value

*Sarah Wei, University of Alberta, Canada
Gerald Häubl, University of Alberta, Canada*

Paper #2: Enjoying the Unexpected: Prior Uncertainty Improves Hedonic Experiences

*Anna Paley, New York University, USA
Tom Meyvis, New York University, USA
Robyn A. LeBoeuf, Washington University in St. Louis, USA
Leif D. Nelson, University of California, Berkeley, USA*

Paper #3: Creating Happiness by First Inducing and Then Satisfying a Desire: The Case of Curiosity

*Christopher Hsee, University of Chicago, USA
Bowen Ruan, University of Wisconsin-Madison, USA
Zoe Y. Lu, University of Wisconsin-Madison, USA*

Paper #4: The Effect of Oral versus Manual Expression Modalities on Choice Satisfaction

*Thorsten Voß, Mannheim University, Germany
Anne Klesse, Tilburg University, The Netherlands
Caroline Goukens, Maastricht University, The Netherlands
Jonathan Levav, Stanford University, USA*

Motivating Consumer Performance:

Dynamics of Performance from Task-Dependent to Social Factors 292

Chairs: Keri L. Kettle, University of Miami, USA

Sarah Wei, University of Alberta, Canada

Paper #1: The Dynamics of Success: How Experiencing Success versus Failure Influences Subsequent Motivation

*Sarah Wei, University of Alberta, Canada
Gerald Häubl, University of Alberta, Canada*

Paper #2: Improving Consumer Performance by Merely Eliciting Goals

*Aaron M. Sackett, University of St. Thomas, USA
George Wu, University of Chicago, USA
Rebecca J. White, University of Chicago, USA
Alex B. Markle, Fordham University, USA*

Paper #3: Sharing Predictions

*Keri L. Kettle, University of Miami, USA
Gerald Häubl, University of Alberta, Canada
Isabelle Engeler, University of St. Gallen, Switzerland*

Paper #4: Is It Always Better to Be A Big Fish in A Little Pond?

*Kao Si, The Chinese University of Hong Kong, Hong Kong
Xianchi Dai, The Chinese University of Hong Kong, Hong Kong*

Consumption and Social Connections	297
<i>Chair: Hillary Wiener, Duke University, USA</i>	
Paper #1: Products as Ice Breakers: The Value of Conversation Pieces	
<i>Hillary J.D. Wiener, Duke University, USA</i>	
<i>James R. Bettman, Duke University, USA</i>	
<i>Mary Frances Luce, Duke University, USA</i>	
Paper #2: “Diet Pepsi Again?” Brand Compatibility, Power and Life Satisfaction	
<i>Danielle J. Brick, Duke University, USA</i>	
<i>Grainne M. Fitzsimons, Duke University, USA</i>	
<i>Tanya L. Chartrand, Duke University, USA</i>	
<i>Gavan J. Fitzsimons, Duke University, USA</i>	
Paper #3: Holidays as a Catalyst for Relationship Deterioration: An Examination of the Micro-Level Gift-Giving Processes in Dyads	
<i>Peter Caprariello, Stony Brook University, USA</i>	
Paper #4: Absence Dulls the Senses: How Relationship Reminders and Affective Numbing Influence Consumption Enjoyment	
<i>Jennifer K. Lee, University of Southern California, USA</i>	
<i>Lisa A. Cavanaugh, University of Southern California, USA</i>	
It Takes Two – Novel Examinations of Social Influence Within Dyads	302
<i>Chair: Freeman Wu, Arizona State University, USA</i>	
Paper #1: The Impact of Employee Appearance on Consumer Responses to Flattery	
<i>Freeman Wu, Arizona State University, USA</i>	
<i>Adriana Samper, Arizona State University, USA</i>	
<i>Andrea Morales, Arizona State University, USA</i>	
Paper #2: Power to the People: Consumer Influence Tactics in a Retail Setting	
<i>Raymond Lavoie, University of Manitoba, Canada</i>	
<i>Kelley Main, University of Manitoba, Canada</i>	
<i>Wenxia Guo, Acadia University</i>	
Paper #3: Meeting in the Middle: Social Influence Effects on the Compromise Effect	
<i>Hristina Nikolova, Boston College, USA</i>	
<i>Cait Lamberton, University of Pittsburgh, USA</i>	
Paper #4: How Do I Love Thee (And Who Should I Tell?) – The Implications of Emotional Suppression Due to Audience Size	
<i>Virginia Weber, University of Alberta, Canada</i>	
<i>Sarah Moore, University of Alberta, Canada</i>	
<i>Rihannon MacDonnell, City University London</i>	
<i>Jennifer Argo, University of Alberta, Canada</i>

2015 ACR Presidential Address

Marketplace Morality

Amna Kirmani, University of Maryland, USA

Last year, Linda Price gave an inspiring presidential address about having fun while you engage in research. This year, I am going to go 180 degrees away from fun (though I hope not from inspiration). I am going to talk about Morality. (Yes, ACR, this is the year of the superego.)

I've been thinking about moral issues for a long time. The ideas I am presenting today are part of a conceptual paper that I am preparing with two collaborators: Ajay Abraham, who is Assistant Professor at Seattle University; and In Hye Kang, who is a doctoral student at the University of Maryland.

Let me start with a couple of vignettes from my own experience.

I was born in Lahore, Pakistan, where there is a large, beautiful mosque built by a Moghul emperor in the 17th century. The mosque can accommodate 10,000 worshippers, while another 100,000 can pray in the courtyard.

Next to the mosque is an area called the Diamond Market. This is the Red Light District of the city, where the diamonds refer to women. I was always fascinated by why the Red Light District was next to the largest mosque in the city. I used to think it was just convenience: killing two birds with one stone. But what drove men to engage in prayer and prostitution in close proximity? Now I know that it could be moral licensing or moral cleansing, depending on which of the two activities came first.

Fast forward to a couple of years ago at a research seminar at the University of Maryland. A fellow marketing faculty member was giving a lecture about his research on eye-tracking to an audience of university-wide faculty and doctoral students. At the end of the talk, a member of the audience raised his hand and asked, "How can you live with yourself? Marketing is so unethical. You manipulate people to do things that they wouldn't normally do so companies can make money." There was a moment of silence. My colleague maintained his poise and gave an answer that was quite reasonable. Later, we learned that the audience member was a professor in the math department.

Now I don't know about you, but I don't like being perceived as unethical. We could dismiss these types of comments as coming from people who don't know what we really do. But we also need to do some soul searching. If this is the popular perception of marketing and what we do, perhaps there is some truth in it. Perhaps we need to see how we can change this perspective. Or perhaps we need to change how we approach consumer research so that it is more transformative and less transactional.

Both these incidents concern the issue of morality; the first is about how people reconcile engaging in moral and immoral behavior. The second is about the perception that what we do is immoral.

We make moral decisions every day in all our roles: as children, parents, friends, workers, etc. The ones relevant here are the moral decisions we make as consumers and consumer researchers.

My talk is divided into two parts. The majority of the talk will be about the morality of consumers. Then, I will address the morality of consumer researchers.

THE MORALITY OF CONSUMERS

What do I mean by the morality of consumers? The Oxford English Dictionary defines morality as "principles concerning the distinction between right and wrong or good and bad behavior."

Consumer morality would be the principles consumers have concerning the distinction between right and wrong. But not in all contexts. What matters to us as consumer researchers is consumers' beliefs about what is right and wrong in the marketplace. I call this concept

"marketplace morality."

Marketplace morality is the consumer's views on what constitutes right and wrong or good and bad behavior in marketplace situations. These might be views about consumers' own behavior as buyers or sellers, the behavior of other consumers; the behavior of entities such as firms, the government or regulatory agencies as they impact the marketplace.

The term has its roots in discussions about the moral economy, which means an economic system that is fair and just. In his introduction to the *Journal of Consumer Research's* Morality curations last year, Kent Grayson (2014) refers to the tension between the "moral economy" and the "market economy." Marketplace morality acknowledges these tensions and how consumers resolve these tensions.

I feel that consumers have a different mindset when they are in the marketplace. This mindset licenses them to act in ways they would not in their personal lives. This mindset may be due to different reasons: the type of relationship; economic self-interest; a competitive orientation; or the salience of different goals, to name some. The result is that marketplace morality may cause consumers to feel that it is okay to cheat large corporations or the government. But it is not okay to cheat nonprofit companies, family-owned businesses or others in our in-group.

Marketplace morality guides our behavior in marketing contexts. It affects our emotional reactions and actions in the moral domain. Therefore, studying marketplace morality would entail not just beliefs, but emotions and behaviors that result from these beliefs.

Let me give you some examples of marketplace morality. The first is trade-offs.

TRADE-OFFS

Consumers often make trade-offs that involve morality. They decide whether to buy clothing that is attractive, but made in a sweatshop. Whether to buy a cheaper product or a more expensive, environmentally-friendly product. Consumers also make trade-offs between competence and morality.

If I'm selling my house, should I choose a real estate agent who sells houses quickly and for a high price, but is known to cut corners? Or should I choose one who is known to be completely honest, but the houses she sells stay on the market longer and don't fetch as high a price?

This is the type of trade-off that I examine with my co-authors Rebecca Hamilton and Debora Thompson, both at Georgetown University. Do consumers use the same moral values in marketplace

2 / Marketplace Morality

contexts as in their personal contexts? It turns out they do not. In the psychology literature, which examines communal relationships among friends, family and strangers, morality concerns consistently trump competence concerns. For instance, we prefer to have friends who are honest and caring than friends who are clever and competent. In addition, we react faster to morality-related words than to competence-related words, demonstrating the primacy of morality over competence. The underlying reason is that we want to ensure that others don't harm us and that we can trust them.

What we found in the marketplace domain, however, was the opposite. In marketing contexts, such as consumers' hiring an auto mechanic, our respondents consistently preferred competent service providers over moral ones. And this was true even though they liked the moral provider more than the competent provider. Why might this be?

Consumers' goals differ in personal interactions and marketplace interactions. Whereas being moral and protecting ourselves from harm are important in the marketplace, so is achieving our purchase and consumption goal. And consumers are willing to overlook a service provider's immorality as long as the immorality does not harm them. In other words, the purchase goal subsumes the goal of behaving morally.

As reviewers pointed out when they rejected the paper (twice), you can explain all of this in terms of economic self-interest. Of course, they choose the competent service provider because they're satisfying their purchase goal. So, this is not interesting. End of story.

To fight the self-interest argument, we had to re-invent the paper. We had to come up with a situation in which people behave against their economic self-interest to favor the more moral service provider. We found that consumer preferences shifted to the less competent but more moral service provider when the provider elicited empathy. Empathy makes us more outwardly focused and less self-interested. And empathy is a moral emotion.

But I find it fascinating that so many people are willing to give up their moral conscience in the pursuit of an economic goal. Although they liked the moral agent more than the competent agent, they choose the competent agent. Purchase goals are temporary, but morality stays with you always. Why would you compromise it? What does it say about our marketplace morality? And why are we proud of it? These questions deserve further research.

CONSUMER CHEATING

The next area of marketplace morality that I want to discuss is consumer cheating. Psychologist Jonathan Haidt has done a lot of research on moral psychology. If you're interested in the topic, I recommend that you read some of his work. Haidt sees cheating as a violation of fairness or proportionality. In other words, people are entitled to the rewards of their labor, but not to undue rewards that might be obtained by others' labor (free-riding) or that might be obtained due to playing by a different set of rules from others.

According to the National Retail Federation, wardrobing (i.e., returning used clothing) cost \$8.8 billion in 2012 (Leibowitz 2013). In fact, Bloomingdales introduced a B tag to try to cut down on returns of used clothing. Other examples of cheating are false insurance claims; and consumers claiming to qualify for a benefit that they haven't earned, such as a student discount.

How do we get consumers to cheat less? In other words, how do we change their marketplace morality? Some research suggests that cheating may be reduced by making either moral identity salient or by making morality salient (Mazar, Amir, and Ariely 2008). For in-

stance, we could get people to sign an honor pledge. Or, based on my earlier research, we could induce empathy. But what else can we do?

My doctoral student at the University of Maryland, In Hye Kang, is examining consumer cheating. In Hye examines the role of construal level in cheating behavior. Prior literature on construal level and self-control has shown that abstract (vs. concrete) construal leads people to weight higher-level, longterm goals against immediate, comfortable temptations (Fujita, Trope, Liberman, and Levin-Sagi 2006). Thus, she predicts that abstract (vs. concrete) construal increases the importance given to the goal of acting honestly, which, in turn, decreases dishonest behavior. Initial studies using actual cheating behavior show support for this effect. When abstract construal was activated, consumers lied less to a firm to qualify for a paid survey, and lied less to another consumer to gain more money.

Another example of consumer cheating comes from Honest Tea. Honest Tea is a line of organic beverages positioned as healthy and honest. Each year, the company comes out with a National Honesty Index. In 27 cities in the United States, bottles of Honest Tea are sold on an honor system in kiosks like this. If you take a bottle, you put \$1 in the collection box. It appears that no one is watching, so it offers the opportunity for cheating without incurring legal consequences.

This year, 94% of the nation was honest. Atlanta was the most honest city; everyone who took a bottle paid \$1. Providence, Rhode Island was the least honest, with 17% cheating. In Washington, DC, the city of politicians who know something about being unethical, someone stole the collection box.

Actually, I was amazed at the amount of honesty shown by consumers in this situation. Until I looked at pictures of some of the kiosks and found that these kiosks are labeled as The Honest Store. Since making honesty salient tends to make us more honest, this experiment may overestimate honesty. I wonder how different the results would be if the product was Snapple, and the store was not labeled as honest.

It is clear from these examples that research on consumer cheating matters to firms (who are losing money). But it also matters to consumers (who may feel guilty or badly about themselves). Moreover, cheating hurts "Honest" consumers, who are penalized by paying more for products and services due to the costs attributable to consumer cheating behavior. Thus, doing research on this topic is beneficial to many parties.

SANCTITY/RELIGION

The next aspect of marketplace morality that I want to discuss is sanctity. In 1989, Belk, Wallendorf and Sherry made a distinction between the sacred and the profane in the consumption context. They suggested that many types of consumption have become sacralized, with rituals and meanings that go beyond the mundane and ordinary to something transcendent and extraordinary.

More recently, Jonathan Haidt and his colleagues (2009) asserted that sanctity, which refers to that which is sacred and pure, is an important moral foundation. The value on sanctity can be seen in research on contamination and moral cleansing. For example, Zhong and Liljenquist (2006) demonstrate a connection between moral purity and physical purity. Consumers who feel their moral purity is under threat are more likely to prefer cleansing products.

Purity is so important to consumers that we have marks that indicate that the product is kosher, halal, green, all natural, or vegan.

Sanctity can also be seen in recent work by McGraw, Schwartz and Tetlock (2012) on taboo trade-offs. They find that consumers disapprove of commercial practices by religious organizations and healthcare companies. In other words, consumers' marketplace mo-

rality says that sacred domains should not be commercialized. This tension between morality and money is seen in a wide variety of literature.

Increasing attention is also being paid to the role of religion in consumer behavior. In fact, there is a forthcoming review article on religion in the *Journal of Consumer Psychology*. In JCR, A fascinating paper by Sandikci and Ger (2010) describes how Turkish society is changing from secular to religious. Many Turkish women donned Islamic clothing because it gave them freedom, while outsiders saw it as a sign of oppression. Although the new clothing was associated with purity, it was also reactance against the move to ban veils. To the extent that Turkish society is becoming more religious, I wonder if the marketplace morality of Turkish society is also changing.

Thus far, I've discussed psychology, anthropology and sociology. Now let's turn to economics.

EXPERIMENTAL ECONOMICS

There is some evidence from experimental economics that market interaction lowers our moral values. In a 2013 article in *Science*, Falk and Szech ran some experiments intended to test moral behavior in markets. They asked participants to engage in a game in which they could kill a mouse to make money. The game had real consequences; participants could make 10-20 euros and a real mouse was killed.

The experiment had three conditions: individual; bilateral; and multilateral. In the individual condition, participants chose to either get 10 euros or save a mouse from being killed. In the bilateral trading market, there was one buyer and one seller in a double auction market. The seller was endowed with the mouse; the seller and buyer negotiated over how to divide up 20 euros. Either the buyer or the seller could make an offer; when the other party accepted, the mouse would be killed. The multilateral trading market worked the same way, except there were 7 buyers and 9 sellers.

The results were quite interesting. In the individual treatment, 46% of the participants chose to kill the mouse for 10 euros. In the two market conditions, however, the numbers went up to over 70%. The authors use this as evidence that markets make us behave less morally.

The question is why do people behave this way? Although the authors offer some ideas, I think this is a question that consumer researchers are ideally situated to address. This question gets to the heart of marketplace morality.

The choice between money and killing a mouse reminds me of two other markets in which morality would be interesting to understand: the human slavery market and the marriage market.

The marriage market is one of the biggest markets in South Asia. It is not a single market. It is multiple markets segmented by religion, socio-economic status, and geography. Men are in a position of power in this market, while women are bartered like commodities. Third party brokers, either for money or other payments, typically negotiate a match between two families. Money exchanges between the bride's family and the groom's family, though the flow is largely one-sided. In order to secure a husband for their daughter, the bride's family has to agree to pay a large amount of money as dowry—cash, jewelry, clothing, furniture, a house.

The exchange of money does not stop with the marriage. Sometimes, the groom's family demands more money or other resources after the marriage. If these are not forthcoming, the groom's family can send the girl back to her own home, which would bring shame and dishonor to her family. In many cases, rejected wives who do not have financial resources prefer being burnt or taking their own lives to being sent back home in dishonor.

What is the morality underlying these markets? What is the morality that forces poor people to go into a lifetime of debt in order to marry off their daughters? Is the dowry part of a fair trade? I think there is scope in consumer research to investigate these larger moral issues because they are in the context of a market of exchange and because they can be truly transformative.

Economists, psychologists, anthropologists, sociologists, ... all these disciplines, along with others, are examining the issue of morality. As I have shown, consumer researchers have also been examining this question. But I think we end up being somewhat shallow in our explanations. Rather than diving in deeply, we tend to pass marketplace immorality off as self-interest.

To summarize, marketplace morality involves examining consumers' beliefs about what is right and wrong in their marketplace interactions. It includes not just beliefs, but also the emotions and behavior that accompany those beliefs. I've only scratched the surface of the topics that might be covered. Fairness, harm, loyalty, liberty, altruism—these are all moral issues that consumers encounter in the marketplace. Many of you have been working on these topics: Dan Ariely, Darren Dahl, Jen Argo, Kate White, Americus Reed, Deb Small, Karen Winterich, to name a few. I haven't even touched on the related emotions: gratitude, disgust, anger, hope, empathy, compassion, embarrassment, guilt and shame. My basic thesis is that we can do more, much more, from the perspective of the consumer.

RESEARCH ON MORALITY IS INTERESTING AND RELEVANT.

Doing research on marketplace morality is not just an academic exercise. Research on morality is both interesting and relevant. It is relevant to consumers, public policy makers, and companies. Companies are facing morality-related issues all the time. (Think Volkswagen.)

Here's another example of how companies deal with marketplace morality. The Baltimore Ravens overlooked the immorality of their star player Ray Rice when he told them that he punched his girlfriend. His competence was too high to worry about his immorality. Then a video emerged showing him punching his girlfriend, and the video raised a public outcry; all of a sudden, both the Ravens and the NFL found Rice's actions deplorable. How did consumers react? Within a few days, consumers burned or traded in thousands of Ray Rice jerseys because they did not want to be associated with him. The Ravens had to spend a lot of money buying back those jerseys. Thus, morality can have real consequences for both companies and consumers.

CONCRETE STEPS

So, where do we go from here? Besides this call for doing research on marketplace morality, I have a few other suggestions.

First, as Editor-in-Chief of the *Journal of Consumer Psychology*, I am considering a special section or a special issue on Consumer Morality. I invite those of you who might be interested in editing such a special issue to talk to me or to SCP President Susan Broniarczyk.

My second call to action is for cross-disciplinary research on marketplace morality. One advantage of being an interdisciplinary field, is that we do not have to use a single lens to investigate a topic. As I've shown, marketplace morality can be studied with a variety of perspectives and lenses. We can look at it in a more micro fashion as well as a more holistic way. We can consider it from the view of the individual consumer as well as broader systems.

My call for multiple perspectives highlights the theme of this year's conference: Advancing Connections. This theme "was inspired by a desire to build better connections across different research paradigms and approaches." I strongly believe that multi-disciplinary research is necessary for consumer research to make significant advances. And it's our unique selling proposition. I urge you to work with someone who has a different perspective so that we can take advantage of the richness of our field. As a start, I would like to invite ethnographic researchers and empirical modelers to collaborate with me on the topic of marketplace morality.

My third call has to do with marketplace morality in the context of our profession. The marketplace for consumer research is one in which we buy and sell our ideas. This conference is one of the venues in which these ideas are exchanged. What are our moral values as we engage in the production and exchange of research? In other words, what is the morality of consumer researchers?

THE MORALITY OF CONSUMER RESEARCHERS

A few years ago, our field was hit by scandal and questions about the ethical conduct of research. Along with psychology, medicine, and the sciences, we were discovering that some researchers were not following ethical standards. Data were being fabricated; respondents were being dropped from studies; cells were being dropped from experimental designs. Some research papers were retracted from the journals; reputations of authors, co-authors, and universities were besmirched.

Conversations about ethics proliferated conferences and editorial board meetings. The Association for Consumer Research held a special plenary panel on ethics, at which leaders of the field discussed their point of view on what is and is not ethical. The American Marketing Association adopted a new set of reporting guidelines for its journals, as did the *Journal of Consumer Psychology*. Many of us raised these issues at doctoral seminars.

So, what is the current state of ethics in our field? The effect of the scandal has been increased awareness of the issues among authors, reviewers, and editors. Everyone has become more vigilant, and the bar is higher in order to publish your paper. At *JCP*, I see reviewers inquiring about details of studies they may not have asked for before. Underlying this scrutiny is the concern that the effects should be replicable.

Most of you have probably heard about the Reproducibility Project, which was an attempt to try to replicate the results of some articles published in psychology journals. As reported in *Science*, around 270 researchers attempted to replicate 100 articles in three psychology journals: *Psychological Science*; *Journal of Personality and Social Psychology*; and the *Journal of Experimental Psychology: Learning, Memory and Cognition*. The researchers worked with the original authors to get the stimuli, where possible, and to discuss the conditions under which the studies were run. They used larger sample sizes to enhance power. The results should be of concern to everyone: Only 36% of the replications showed a significant effect.

So, what should we do? In an editorial in the October issue of the *Journal of Marketing Research*, Editor-in-Chief Bob Meyer provides some guidelines for how authors should design and report studies to ensure transparency. I endorse these recommendations, and discuss some of them.

The first is the use of larger sample sizes if you are trying to show subtle, counterintuitive effects. If it's that counterintuitive, you need to have stronger evidence for it.

A second recommendation is one that many people in the field, including Michel Pham and myself, have urged: Reduce the insis-

tence on finding a single underlying process. As I have stated before, we need to embrace the notion that a single paper may not be able to identify a single best explanation. Life is messy, and so are the phenomena we study.

Another recommendation is to be more thorough in terms of what you report about studies. *JCP* has a Methodological Data Appendix, in which you can report all the study details that you may not have space for in the text. I suggest that you go beyond what is required so that reviewers don't reject a paper because there was insufficient information.

I think these are practical suggestions that should become the standard for our field.

The Association for Consumer Research has also experienced cases of ethical misconduct. Both last year and this year, we have received complaints from ACR members who have accused others of ethical misconduct, including plagiarism. This year, the ACR Board approved a policy for how to react to reports of ethical violations, and this policy has been put into practice. And yesterday, the Board considered other ethical proposals as well.

In conclusion, I hope my talk has made moral values salient to the ACR community. Next time someone says that marketing is unethical, I would like to be able to tell them how research on marketplace morality is making both consumers and consumer researchers more moral. As a result, society will benefit.

Thank you.

Special Session Summaries

Advances in Pay-What-You-Want Pricing

Chair: Stephen A. Atlas, University of Rhode Island, USA

Paper #1: Shifting Mindset in Consumer Elective Pricing

Silvia Saccardo, University of California- San Diego, USA
Charis Li, University of Florida, USA
Anya Samek, University of Wisconsin- Madison, USA
Ayelet Gneezy, University of California- San Diego, USA

Paper #2: Because We're Partners: How Social Values and Relationship Norms Influence Consumer Payments in Pay-What-You-Want Contexts

Shelle M. Santana, Harvard University, USA
Vicki Morwitz, New York University, USA

Paper #3: Paper or Plastic?: How We Pay Influences Post-Transaction Connection

Avni Shah, University of Toronto, Canada
Noah Eisenkraft, University of North Carolina- Chapel Hill, USA
Jim Bettman, Duke University, USA
Tanya Chartrand, Duke University, USA

Paper #4: Rebate-What-You-Want

Stephen Atlas, University of Rhode Island, USA

SESSION OVERVIEW

Elective pricing strategies, commonly known as pay-what-you-want pricing, offer an intriguing domain of consumer behavior where people often freely pay nonzero amounts for a product they could obtain for free (Gneezy et al. 2010). This special session aims to contribute to the literature by exploring new frameworks for understanding how and when consumers feel sufficient connection with a firm to voluntarily endow it with privately held resources. This area has received increasing interest by the behavioral community in recent years (e.g. Kim et al. 2009; 2014; Riener and Traxler 2012; Mak Zwick and Rao 2010). This session includes four papers advancing our understanding of how contextual cues, private values, and socially constructed norms influence elective payments and customer-firm relationships.

In the first paper, Saccardo, Li, Samek, and Gneezy explore how elective pricing language influences exchange/communal mindsets. These mindsets influence relative regard for self and others and willingness to contribute to elective payment opportunities, a prospect that is tested across three studies.

In the second paper, Santana and Morwitz present a model for how values and norms combine to determine voluntary payments. Norms shift how much consumers express their economic or their social motives when determining a purchase price. Additionally, the difference in voluntary contributions of pro-social and pro-selfs is wider under exchange than communal norms. Four studies and a field experiment test the specific predictions of this model.

The third paper, by Shah, Eisenkraft, Bettman, and Chartrand, explores how payment form influences consumers' connection with the products they purchase. They find, across three studies (two involving elective payments) that painful methods of payment correspond with greater connection post-transaction connection. This work indicates that one bind facing elective pricing strategy is its relative lack of painfulness.

In the fourth paper, Atlas discusses a new approach that increases elective contributions by framing them as elective rebates. He finds that consumers are more reluctant to take an elective amount of money back from an organization than to give it money directly.

Together, these four interconnected papers provide new perspectives on elective payment arrangements. Each paper will advance the field's understanding of how people respond to social norms. Another theme uniting this session is the utilization of field studies, as self-reports in this domain often diverge from incentive-compatible choices. These perspectives yield insight into consumer choice across a wide range of settings, and carry theoretical as well as practical implications for consumer research.

This session will be relevant to researchers throughout consumer behavior. In particular, it advances connections between past research on mental accounting, framing, social preferences, and charitable giving. These topics—and elective payments in particular—have attracted considerable attention in recent years and we anticipate that this session will stimulate future research. Data collection in all papers is complete and all participants have agreed to present should the session be accepted. The chair will facilitate audience discussion drawing further connections between these perspectives as well as between elective pricing and other areas of consumer research.

Shifting Mindset in Consumer Elective Pricing

EXTENDED ABSTRACT

Self-interest has been assumed to guide individuals' behavior in the marketplace. Yet, there is evidence suggesting that individuals' behavior can sometimes deviate from pure self-interest to accommodate the well-being of others (e.g. Kahneman et al., 1986; Andreoni and Miller, 2002).

Consumer elective pricing (CEP), in which consumers set their own prices for products and services, offers a unique opportunity to better understand the factors that determine the extent to which one's behavior follows market norms. Indeed, oftentimes consumers pay despite being able to get a product for free (Kim et al., 2009; Gneezy, et al. 2010; 2012; Jung et al., 2014). Notably, however, behavior under CEP doesn't always follow the same pattern. In particular, although sometimes guided by other-regarding concerns, there are occasions in which consumers' behavior is more consistent with self-interest (Leon et al., 2012), suggesting that response to CEP is context-dependent (Slovic, 1995).

In this paper, we test how a shift in mindset, shaped by contextual factors, influences payments. Building on past research on marketplace relationship norms (Fiske, 1993; Heyman and Ariely, 2004; Clark and Mills, 1993; Aggarwal, 2004), we propose that subtle changes in the presentation of a CEP offer influence the extent to which an exchange/money-market mindset is made salient. As a result, we predicted consumers would be more likely to pursue maximization of material goals (i.e., paying less) than when cued with a more communal mindset. We test our proposition in three field experiments in which we change the wording of a CEP offer to invoke self versus other-regarding mindsets.

Experiment 1 (N=525) tests mindset shifts in a charitable fundraising domain. We operated a donut stand in a Midwestern University and manipulated mindset by varying whether a CEP offer was presented as a purchase or as a donation. In one condition we sold donuts using PWYW and informed participants that we would donate all proceeds to charity. In the other, we asked customers to donate whatever amount they want (DWYW) to the charity in exchange for a donut. We expected the donation condition to make self-interested considerations less salient, increasing payments.

Among all people who made a payment for a donut, those in the DWYW condition paid more ($M_{DWYW} = \$2.05$, $M_{PWYW} = 1.65$, $t(444) = 3.02$, $p = .003$). In addition, purchase rates—the proportion of by-passers who approached the stand—was higher in the DWYW condition (DWYW=9.7%, PWYW= 7.9%; $z = 2.4$, $p = .016$). Finally, some customers (N=79) made a payment but declined to take a donut. This occurred more frequently with DWYW (77 % vs. 23%, $p < .001$, Fisher exact). These results suggest a shift in mindset led to less self-interested behavior when the transaction was framed as donation rather than as a (prosocial) purchase.

In Experiments 2a/2b we tested the proposed mindset shift and resulting behavior without coupling purchases with a charitable cause. To manipulate mindset, we used two variations of CEP: Pay-What-You-Want (PWYW) and Pay-What-You-Can (PWYC). While PWYW is more common, PWYC has been adopted by, e.g., some CEP restaurants, theatres and yoga studios. We expected individuals to follow a more self-interested mindset when asked to pay what they *want*, versus what they *can*. As a first step, we conducted a pretest in which we presented individuals (N=120) with a hypothetical scenario describing donuts offered under PWYW (PWYC), and measured the resulting mindset using two questions (adapted from Johnson and Grimm, 2010). Individuals presented with PWYC scored lower on the exchange/money-market measure (MPWYC=5.01, MPWYC=5.53, $t(118) = 2.25$, $p = .031$); the two groups did not differ on the communal/social-market measures.

Experiment 2a (N=207) tests the effect of mindset on behavior. We operated a stand in a southwestern university campus and sold donuts under CEP. We invoked mindset via signage and verbal communication, presenting customers with either a Pay-What-You-Want or a Pay-What-You-Can offer. Our results reveals that people paid more under PWYC (Exp2a: $M_{PWYC} = .82$, $M_{PWYW} = .64$, $t(205)$, $p = .002$); purchase rates were not measured.

Experiment 2b replicates this finding using a similar procedure (N=219, $M_{PWYC} = .80$, $M_{PWYW} = .65$, $t(217) = 3.03$). We did not detect differences in purchase rates (proportion of buyers out of all people who passed directly in front of the stand). After payment, participants completed a 3-question survey, which further revealed that PWYW customers viewed themselves as more selfish ($M_{PWYW} = 3.63$, $M_{PWYC} = 3.13$, $t(203)$, $p = .04$). Finally, in experiments 2a/2b the distribution of payments differed between conditions (Exp2a: $p = .004$; Exp2b: $p = .007$, Kolmogorov-Smirnov), and were shifted toward amounts smaller than \$1 (an indication of self-interested behavior) in the PWYW offer (Exp2a: 51% vs. 32%, $p = .006$; Exp2b: 57% vs. 36%, $p = .002$, χ^2).

Experiment 3 addresses two concerns. First, in experiments 2a/2b the nature of the transaction (who the seller is, what happens to profit) was not specified; subjects could have assumed the sale was associated to a charitable cause. Second, we investigate the role of identity and image concerns. Since participants paid the seller directly, their behavior could be driven by social image (Andreoni and Bernheim, 2009) or identity concerns (Bénabou and Tirole, 2006). If the high payments under pay-what-you-can are only driven by impression management considerations, we should observe no effect

in private. However, if the effects observed are due to self-signaling, the treatment effect should persist when payment is private, possibly leading to higher payments (see Gneezy et al. 2012).

Experiment 3 (N=339) took place in a for-profit context. We partnered with a business operating five coffee carts in a southwestern university, offered plain coffee under PWYW (PWYC), and crossed it with payment type (anonymous vs. seller). Our results reveal that individuals paid higher amounts under PWYC ($\beta = .289$, $p = .005$) both in private and public settings; we did not find an effect of payment type. We found no difference in the proportion of buyers out of the all of people who approached the cart across conditions. These results allow us to rule out impression management as the unique explanation for our effects.

Taken together, these studies are in line with our proposed mindset framework. Social mindset CEP offers produced higher payments, suggesting that subtle contextual cues (i.e. words) that shift mindset away from self-interest affect behavior.

Because We're Partners: How Social Values and Relationship Norms Influence Consumer Payments in Pay-What-You-Want Contexts

EXTENDED ABSTRACT

Under Pay-What-You-Want (PWYW), the prices that consumers elect to pay often vary significantly. Sometimes the variance is small and clustered around a particular reference price, while other times the variance is much larger. In both of these cases, the average price paid may be significantly above zero, yet sellers who adopt PWYW pricing may have a preference for one type of distribution versus another.

In this paper we present a conceptual model of factors that explain systematic differences in how much consumers pay in PWYW contexts. We test its predictions both in the lab and in a field experiment with actual payments. We show that buyer payments are jointly influenced by individual differences in Social Value Orientation (SVO; McClintock 1972, McClintock and Allison 1989) and the degree to which exchange or communal relationship norms are salient (Mills and Clark 1982) for the buyer when the pricing decision is made. When exchange norms are salient, pro-selfs pay less than pro-socials, and are more likely to pay \$.00. However, when communal norms are salient, pro-selfs pay more than they do than when exchange norms are salient, are less likely to pay \$.00, and the difference in payment between pro-selfs and pro-socials is attenuated. Additionally, we show that this change in payment behavior is partially mediated by a shift between economic and social motives. Finally, we show that sellers can influence communal norm salience, and by extension, buyer payment behavior, in PWYW situations in very low-cost ways.

Study 1 tests whether individual differences in SVO affect prices paid in PWYW settings. Our results showed that it did. Forty eight study participants were offered the opportunity to pay any price they wanted to purchase a pair of chocolate chip cookies using their own money, and we measured participants' SVO after they made their purchase decision and paid (if applicable). A regression of SVO on payment amount showed that for those who chose to purchase cookies (N = 22), pro-socials paid significantly more than pro-selfs ($M_{\text{pro-self}} = \$.62$ vs. $M_{\text{pro-social}} = \$ 1.22$, ($\beta = .03$, $t(20) = 3.53$, $p < .01$).

Study 2 examines the relationship between buyers' social and economic motives on payment behavior. Twenty-eight undergraduate students were given the opportunity to purchase an organic candy bar for any price they wanted to pay. For those who wanted to purchase a candy bar (N = 23), we measured their economic and social

motives after they submitted a written payment amount. We then ran two separate regression analyses with economic motive and social motive as the independent variables and payment amount as the dependent variable. Social motives had a positive effect and economic motives had a negative effect on payment amount ($\beta = .32$, $t(21) = 2.05$, $p = .05$ vs. $\beta = -.35$, $t(21) = -1.77$, $p < .10$, respectively). Study 3 builds on these findings by examining how SVO and relationship norms jointly influence these motives, which in turn influence how much consumers pay under PWYW.

Five hundred thirteen mTurk participants were told to imagine that they decided to stop in at a local coffee shop. Approximately half of the participants read a description that reflected a communal norm with the seller and the other half read one that reflected an exchange norm. They were then told that they could pay whatever they want for a 16-ounce of coffee at the shop, and were then asked to submit their purchase price. A regression analysis revealed significant main effects of SVO ($\beta = -.13$, $t(509) = -3.1$, $p < .01$) and of relationship norm ($\beta = .17$, $t(509) = 4.05$, $p < .0001$), and both of these effects were qualified by the expected SVO x relationship norm interaction ($\beta = .11$, $t(509) = 2.46$, $p < .01$). Additionally, when relative motive was included in the payment model, it had a significant effect on payment ($\beta = -.17$, $t(510) = -12.91$, $p < .0001$), and the significance of the norm x SVO effect on payment was reduced ($\beta_{\text{no med}} = .0001$, $t(510) = 2.59$, $p < .01$ vs. $\beta_{\text{med}} = .0001$, $t(4510) = 2.11$, $p < .05$, 95% CI = .0000 – .0001), indicating partial mediation.

In Study 4, we test whether merely priming relationship norms can affect payment behavior in a subsequent PWYW task (Aggarwal and Zhang 2006). 334 mTurk participants completed an SVO task and were exposed to either a communal prime or an exchange prime. They were then told to imagine that they could pay any price they wanted for a breakfast special. The subsequent regression analysis showed that pro-selfs in the exchange norm paid less (\$2.81) than pro-socials (\$3.25); however, in the communal norm condition pro-selfs (\$3.21) and pro-socials (\$3.53) paid similar amounts. A spotlight analysis (Spiller et al. 2013) showed that the difference in payments along the SVO continuum differed under the exchange prime (95% CI = -.0002, -.0001), but not under the communal prime (95% CI = -.0001, .0000). Additionally, a mediation analysis showed that when relative motive was included in the payment model, it partially mediated the effect of SVO and relationship norm on payment ($\beta_{\text{no med}} = .00$, $t(336) = 3.13$, $p < .01$), $\beta_{\text{med}} = .00$, $t(336) = 2.24$, $p < .05$).

Finally, we ran a field study in which packets of gum were sold as PWYW at a student snack bar at a large, urban university. Relationship norm was manipulated via subtle changes in promotion messaging and imagery (communal = Because We're Partners, It's Your Turn to Set the Price Today; exchange = Special Promotion, It's Your Turn to Set the Price Today) and social value orientation was measured as part of a customer satisfaction survey. The resulting analysis showed a marginal SVO x relationship norm interaction ($\beta = -.02$, $t(75) = -1.73$, $p < .09$). A floodlight analysis showed that the effect of SVO on payment was significant in the exchange norm condition (95% CI = -.003, .0452, $t(75) = 1.73$, $p < .09$), but not in the communal norm condition (95% CI = -.0398, .0177, $t(75) < 1$, $p = ns$), as expected.

'Paper or Plastic': How We Pay Influences Post-Transaction Connection

EXTENDED ABSTRACT

When you pay for something, can how you pay—e.g., whether it is by cash, credit card, or debit card—change how much you value the product that you buy or how committed you feel to the brand?

This question lies at the intersection of two fundamental shifts in consumer culture: 1) the decreasing use of cash for payment transactions, and 2) declining brand loyalty and product retention. In the 1970s, consumers could choose between about five payment forms for most transactions, with cash being the dominant form of choice (Foster, Schuh, & Zhang 2013). However, the financial landscape has changed dramatically. In today's marketplace, there are more than twenty potential methods of payment that people can use for payments (Foster, Schuh, & Zhang 2013). These payments all vary with respect to how psychologically distant they are from the consumer, and thus vary in terms of how much psychological pain an individual feels when spending with these various forms (Soman 2001, Raghuram & Srivastava 2008). Across field, laboratory, and archival studies, we examine whether payment form can influence post-transaction connection.

First, we use a field experiment selling mugs to determine whether payment method can influence post-transaction connection. The experimenter approached employees ($N=63$) of a private Southeastern university, asking each if they would like to purchase a mug. Individuals were informed that the mug normally sold for \$6.95, but was discounted to \$2 as part of a promotion. Individuals were randomly assigned to either the 'Pay by Cash' condition (a more painful form of payment) or the 'Pay by Plastic' condition (e.g., debit/credit card). Two hours following their purchase, the experimenter approached participants and asked them a series of questions. First, the experimenter asked the willingness to accept (WTA) for the mug, the amount necessary to give up their mug (i.e., the endowment effect). Participants were also asked how attached they felt to the mug and how painful it was to purchase the mug. Paying with cash increased the endowment effect ($M_{\text{Cash}} = \$6.71$, $SD_{\text{Cash}} = \$1.63$, $M_{\text{Plastic}} = \$3.83$, $SD_{\text{Plastic}} = \$1.79$, $t(60.1) = 6.67$, $p < .001$). Paying with cash also led to greater attachment to the mug ($M_{\text{Cash}} = 3.28$, $SD_{\text{Cash}} = 1.52$, $M_{\text{Plastic}} = 2.45$, $SD_{\text{Plastic}} = 1.17$, $t(58.1) = 2.42$, $p = .019$). *Pain of paying* fully mediates the relationship between payment form and post-transaction connection.

In Study 2, we used a laboratory experiment, randomly varying whether individuals donated a \$5 bill (a more painful form of money) versus a \$5 voucher to one of three charities of their choice, using someone else's money. By having individuals donate money that wasn't their own, we ruled out the possibility that wealth and income effects are driving the results. After making the donation, individuals were asked to rate how connected they felt to their chosen charity. Following their completion of the experiment, each participant was also given a ribbon lapel pin that signaled support for their chosen charity, as a thank you for the donation. We found that donating the \$5 bill led to higher post-transaction connection rating in comparison to making a donation by \$5 voucher ($M_{\text{Cash}} = 5.81$, $SD_{\text{Cash}} = 0.88$, $M_{\text{Voucher}} = 5.32$, $SD_{\text{Voucher}} = 1.29$, $t(81.0) = 2.15$, $p = .034$). One week following the completion of the experiment, individuals were asked whether they had worn the lapel pin during the week. Individuals who paid by cash were more likely to wear a lapel pin, publicly signaling support for their chosen charity ($\chi^2(1) = 8.66$, $p = .003$; $M_{\text{Cash}} = 51.3\%$, $M_{\text{Voucher}} = 13.8\%$).

In Study 3, we replicate our findings using real-world using archival donation data in which we could determine whether paying with a more (versus less) painful form of payment in a given year would increase (decrease) the probability of donating in the subsequent year. Using data from business school donations over a nine-year span, we found that paying by check (a more painful form of money) increased the likelihood of making a donation in the following year by 9.9% (i.e., 62.3% likelihood to donate in year $t + 1$ by check versus 56.7% by credit/debit card; (62.3%-

56.7%)/56.7%=9.9%, $p < .001$). Thus, Study 3 demonstrated the robustness of payment form effects on organizational commitment, even over a one-year period.

Our findings suggest that psychological pain can influence how much individuals value their chosen product, how connected they feel to it, and how committed they are over time. Our work demonstrates the potential downstream benefits of increasing the psychological pain of payment for both organizations and individuals. Individuals are more financially, psychologically, and behaviorally committed to an organization and value products more when they pay with more painful forms of payment.

Rebate-What-You-Want

EXTENDED ABSTRACT

As a strategy, elective pricing has experienced mixed success compared with fixed pricing. On one hand, elective pricing strategies allow companies to reach segments that would not pay the firm's fixed price (Mak, Zwick and Rao 2010), resulting in resulting in equal or greater profits compared with fixed pricing (Gneezy et al 2010; Riener and Traxler 2012). Yet in practice, each individual customer tends to contribute less revenue than the fixed price (Kim et al. 2009). For example, marketing research firm comScore reported that when the band Radiohead released its 2007 album, *In Rainbows*, with elective pricing, in its first month only 2 out of 5 downloaders paid a nonzero amount, netting overall only \$2.26 per record (Lipsman 2007). This project tests a simple, but novel and previously unused approach that could help make elective pricing more sustainable for firms.

Under the new strategy, customers decide how much from a fixed price to receive back, rather than choosing how much to pay. For example, under the proposed strategy, a customer would choose how much change to receive after giving \$5 for a sandwich, rather than choosing how much to pay for a sandwich with a \$5 menu price. This is analogous to choosing a rebate amount rather than paying a voluntary price amount, and accordingly it is termed Rebate-What-You-Want (RWYW).

The behavioral and economic literature provides several reasons to expect why RWYW would be more effective than traditional elective pricing. Insights from prospect theory and past research on rebates suggest RWYW may encourage customers to be more willing to pay once they have already given the money to the firm. Prospect theory suggests people tend to overvalue prospective losses to prospective gains (Kahneman and Tversky 1979; Kahneman, Knetsch, and Thaler 1990), so they may value the dollars more if it is out of their pocket (a loss) than when it is in the form of change or rebate (a gain). Similarly, taking money back from the business also involves losses in psychological satisfaction from having contributed to a social good. Consequently, voluntary payments may seem more desirable when people set the amount of money to take back than when they set the amount to pay directly. Such framing effects have not been previously tested in the domain of voluntary pricing.

A second account for why RWYW increase contributions is the rebate requires additional action beyond the purchase. Previous research suggests people intend to use rebates, but do not follow through, a phenomenon known as breakage (Pechmann and Silk, 2013). Other possible explanations include that the framing change may affect social norms, the customer's identification with the firm, or the strength of the reference price strength. This project tests the effectiveness of RWYW pricing relative to traditional elective pricing and assesses the relative strength of each explanation.

Study 1 tests the effects of RWYW framing on voluntary contributions. 127 undergraduate students imagined that they had an overdue university library book, and were asked how much they would be willing to pay in late fees. Half ($n=63$) were asked how much of a \$10 bill in their pocket they would pay with while the other half ($n=64$) were asked how much change they would want back. Participants always selected a number between 1 and 9, and for comparability, the responses in the change condition were subtracted from 10. The change group paid 46% (nearly \$2) more than the payment group ($M_{pocket} = \$3.67$, $SD = 2.57$; $M_{change} = \$5.35$, $SD = 2.48$; $F(1, 125) = 14.04$; $p < 0.001$). This result suggests that in at least one domain, RWYW pricing may be more effective than PWYW pricing.

Study 2 tests whether a rebate frame increases elective payments while controlling for several alternate explanations including for reference price, product liking, goal strength, as well as the personal traits altruism and price consciousness. 235 students were asked how much to pay or how much change to receive for a sandwich (which was again reverse-coded.) Participants reported that they were more willing to pay for the sandwich when they selected the amount to receive back ($M_{change} = \$5.02$, $SD_{change} = \$1.72$, $M_{payment} = \$4.57$, $SD_{payment} = \$1.61$, $F(1, 233) = 5.34$, $p = 0.02$), a result that also persisted after controlling for the other factors ($p < 0.01$).

Taken together, these studies suggest that framing elective payments as a rebate can increase total contributions. From one perspective, the RWYW approach offers a more sustainable model for practitioners than rebate pricing. Viewed from another perspective, this paper explores framing effects in the rebate domain, and in particular enables comparisons of the effect sizes of framing effects and rebate breakage, which are typically disconnected domains governing consumer behavior. This inquiry into why RWYW is effective provides insights to other domains of consumer choice such as framing, mental accounting, and time discounting.

SESSION OVERVIEW

How consumers connect with brands remains at the forefront for consumer researchers and managers alike. A substantial body of research examines positive consumer-firm connections manifested in consumer-brand relationships (e.g., Fournier 1998), brand engagement in consumers' self-concept (e.g., Sprott, Czellar and Spangenberg 2009), attachment (e.g., Park, Eisingerich and Park 2013; Park et al. 2010), and love (e.g., Batra, Ahuvia and Bagozzi 2012; Yim, Tse and Chan 2008). On the contrary, work on negative consumer-brand connections is comparatively scarce, possibly reflecting a "positivity bias in brand relationship research" (Fournier and Alvarez 2013, p. 260). The focus on positive consumer-brand experiences and connections is somewhat surprising given that negative experiences, connections, and emotions tend to be more impactful than their positive counterparts (Baumeister et al. 2001).

Consequently, the central purpose of this session is to shed light on 'negatives' in consumer-brand connections. To this end we have collected four exciting papers that look at frictions in consumer-brand relationships from different perspectives: first, this session highlights that consumer-brand relationships are not as positive as portrayed in prior research once measurement of these consumer-brand connections accounts for the social context which they are embedded in (Khamitov, Thomson, and Johnson). Second, this session shows that individual differences predict whether, how, and why consumers may remain in negative and troublesome brand relationships (Dommer, Swaminathan, and Gürhan-Canli; Consiglio and van Osselaer). Third, the final paper in the session shows that negative experiences and feelings towards one specific brand are likely to affect competing brands as well (Boegershausen, Klesse, Hoegg, and Dahl).

All four papers provide multifaceted insights into the negative spectrum of consumer-brand connections. Collectively, they address the following questions: (i) which types of consumers are most likely to remain in negative consumer-brand connections and (ii) whether and why do negative consumer-brand connections affect competing brands. In addition, this session reinforces the need to overcome the prevalent positivity bias in measuring and studying consumer-brand connections. A full appreciation of the potential frictions between consumers and brands can enrich our theories about consumer-brand relationships. This session is of interest to a diverse audience as it appeals to those interested in brands, consumer-brand relationships, and service failures.

Interpersonal Influences on Consumer-Brand Relationships: Exploring the Effect of Providing Relationship Reminders on Brand Evaluations

EXTENDED ABSTRACT

The current standard approaches of measuring consumer-brand relationships (CBRs) strength involves some variant of asking consumers to provide evaluations of researcher-identified brands (e.g., "To what extent do you feel personally connected to Apple iPod?", Park et al. 2010, p. 6), self-selected brands with no category constraint (e.g., "Think about a brand to which you have some degree of emotional attachment", Thomson, MacInnis and Park 2005, p. 7), or self-selected brands within a particular category (e.g., "brand you love" in the consumer electronics category, Batra, Ahuvia and Bagozzi 2012, p. 7). Yet, consumers are typically involved in an array of relationships, many involving interpersonal dyads such as with friends and family. It has been argued that only by looking at the "broader context of the consumer's life" (Fournier 2009, p. 5) can a marketer accurately gauge the functioning and importance of brand relationships. But the standard measurement approaches outlined above do not do this: they assess CBR strength in a vacuum and provide no acknowledgement of this relational array. We argue this approach may systematically overstate the vitality and meaningfulness of CBRs. To this end, we propose that contextualizing CBRs by providing interpersonal relationship reminders will lead consumers to rate CBRs as less agentic and strong. We argue this effect will be driven by the activation of relational schemas and will result in weakened consumer ratings of brand performance.

Study 1 establishes the phenomenon that providing interpersonal relationship reminders reduces consumer ratings of brand performance by lowering perceptions of agency (i.e., proximal mediator) and CBR strength (i.e., distal mediator). This study uses self-selected brands and manipulates relationship reminders both explicitly and implicitly. We find that providing relationship reminders reduces brand performance (attitudes, WOM, price premium, and willingness to defend) through our hypothesized mediators.

Study 2 replicates this effect with a different means of eliciting brands and a different measure of CBR strength. Instead of using self-selected brands, study 2 asked respondents about two pretested brands (Apple and Abercrombie & Fitch). The results of Study 2 generally replicate study 1, offering additional support for the hypothesis that respondents who receive an interpersonal relationship reminder perceive brands to be have less agency, resulting in weaker CBRs and ratings of brand performance.

Study 3 demonstrated that the effect operates with interpersonal but not other types of relationship reminders (e.g., other brands, celebrities), thus replicating the mediational pathway observed in studies 1 and 2. In addition, Study 3 reinforced the role interpersonal relationship reminders play in influencing perceptions of CBR strength by revealing an important asymmetry: interpersonal relationship strength is not affected when immediately preceded by brand questions but the reverse is not true. This result helps allay concerns that the prior results are confounded by a perceptual contrast effect.

Study 4 showed that the weakening effects of interpersonal relationship reminders on CBR strength are not driven by reduced materialism or enhanced perceived social support (alternative explanations). It also investigates if the negative effects of relationship reminders on CBR strength can be mitigated by prompting consumers to think about brands as people (Aggarwal and McGill 2012). We expect that consumers who are made to think about brands in human-like terms will be more likely to integrate the brand into their relational schemas, thereby mitigating the effect of providing interpersonal relationship reminders on perceived brand agency and CBR strength. Replicating results of previous studies, consumers who received (vs. did not receive) an interpersonal relationship reminder reported weaker scores on brand agency and strength. However, among consumers who were situationally induced to think of brands as people and thus integrate brands into relational schemas, the reminders had no little effect.

This work contributes to the CBR literature by answering the call of relationship theorists to investigate the role played by consumer's social connections in influencing CBRs (Fournier 2009), helping to draw a finer line between brand and interpersonal relationships (Swaminathan and Dommer 2012) and enhancing understanding of the way interpersonal relationship reminders operate in a branding context (Cavanaugh 2014).

To the best of our knowledge, our research is the first to demonstrate how and when reminding consumers of their interpersonal relationships impacts CBRs. While previous research referencing consumers' interpersonal relationships has suggested that marketers should improve ratings of brand performance by appealing to consumers' interpersonal relationships, such as through use of nostalgic advertising (Muehling and Pascal 2011; Zhou et al. 2012), friendship-driven brand communities (Bagozzi and Dholakia 2006), brands as facilitators of interpersonal relationships (Goode, Khamitov and Thomson 2015) and community appeals (Cutcher 2008), our results appear divergent and show that this is not necessarily the case. Our results offer insight into the role of agency in CBRs and extend a more nuanced understanding of the relationship metaphor into the brand domain (Fournier 1998), suggesting a more pervasive and complex psychological phenomenon whereby brand relationships can become affected by placing them in the broader context of consumers' lives. Indeed, this is consistent with an increasing body of social psychological research on relational schemas that finds that activating interpersonal relational schemas exerts influence on subsequent perceptions of other social experiences (Andersen and Chen 2002; Baldwin 1992; Chartrand, Dalton and Fitzsimons 2007). Thus we contribute to this research by showing that the influences of relational schemas activation extend to perceptions of consumer-brand interactions.

Who Blames but Forgives When Brands Err? Applying Attachment Theory to Explain Consumer Responses to Brand Failures and Recovery Efforts

EXTENDED ABSTRACT

In 2010, after Toyota announced a recall of cars due to a faulty gas pedal some customers swore off the brand entirely, while others went to dealerships to express their support for the brand (Audi 2010). Although transgressions weaken the consumer-brand relationship for some, others may forgive and forget.

Using a framework built on attachment theory (Bartholomew and Horowitz 1991), we examine how consumers' attachment styles affect attributions following a transgression and subsequently responses to transgressions and recovery efforts. Attachment styles refer to internal working models of interpersonal relationships based on two dimensions: anxiety and avoidance (Bartholomew and Horowitz 1991). Anxiety represents an individual's fear of abandonment in an interpersonal relationship due to a negative view of self. Avoidance represents a fear of abandonment because of a lack of trust in the relationship partner. We believe the avoidance dimension will affect consumers' stability attributions, and subsequently their brand attitudes, following a brand transgression. Because high avoidance individuals believe relationship partners are untrustworthy, they should believe in the stability of brands' transgressions and consequently lower brand attitudes.

A desire to punish the brand by spreading negative word-of-mouth (WOM) following a transgression is likely associated with both severity and controllability perceptions (Folkes 1984; McCullough, Fincham and Tsang 2003). Among individuals low in avoidance, those low in anxiety have a positive view of the self, which they can protect by attributing more control to the brand following a transgression (Burger 1981). In contrast, low avoidance-high anxiety individuals tend to blame themselves following interpersonal rejections because doing so allows them to maintain their positive views of others (Bartholomew and Horowitz 1991). High avoidance-high anxiety individuals perceive greater severity in relational transgressions (Horan 2012). High avoidance-low anxiety individuals, however, avoid relying on relationships to define who they are (Collins 1996) and likely simply withdraw from the relationship rather than punish the brand. In sum, we believe that both low avoidance-low anxiety and high avoidance-high anxiety individuals will demonstrate a greater willingness to spread negative WOM following a transgression. Furthermore, we expect controllability attributions to mediate the effect of anxiety on likelihood of spreading negative WOM among low avoidance individuals, but severity perceptions to mediate the effect of anxiety among high avoidance individuals.

In study 1, participants ($n = 198$) completed manipulations of anxiety and avoidance (Swaminathan, Stilley and Ahluwalia 2009) before reading information about a recall from GAP and responding to measures of brand attitude and likelihood of spreading negative WOM. Participants in the high avoidance conditions had significantly lower brand attitudes compared to those in the low avoidance conditions ($ps < .06$, one-tailed test). Those in the high avoidance-high anxiety and low avoidance-low anxiety conditions were more willing to spread negative WOM than those in the high avoidance-low anxiety and low avoidance-high anxiety conditions ($ps < .03$, one-tailed test). Study 2 began with participants ($n = 185$) completing Brennan et al.'s (1998) measures of anxiety and avoidance before reading information about a recall by Nike. We measured brand attitude and likelihood of spreading negative WOM as well as severity, control, and stability (Folkes, Koletsky and Graham 1987). Avoid-

ance significantly predicted brand attitude ($b = -.32$; $t(181) = 3.08$, $p < .01$) and stability mediated this effect (bootstrapped confidence interval: $-.1003$, $-.0026$). The interaction of anxiety with avoidance significantly predicted likelihood of spreading negative WOM ($b = .27$, $t(181) = 3.59$, $p < .001$). The Johnson-Neyman point estimate (Spiller et al. 2013) indicated that when avoidance (anxiety) scores averaged at or above $.7678$ ($.8020$) from the mean or at or below $-.8841$ (-1.0841) from the mean, the effect of anxiety (avoidance) was significant. Severity mediated the effect of anxiety at high levels of avoidance (indirect effect at +1 SD of avoidance: $.0595$, $.2658$) and controllability mediated the effect of anxiety at low levels of avoidance (indirect effect at -1 SD of avoidance: $-.2564$, $-.0243$). In study 3 we considered two types of recovery efforts: apology and blame redirection. Apologies are associated with interpersonal bonds (Mikulincer and Florian 1998) and thus likely unappealing to highly avoidant individuals. Blame redirection is seen as a way of shifting responsibility for the transgression incident to external causes and subsequently reducing stability and controllability attributions. While we believe a blame redirection will be successful in getting high avoidance-low anxiety individuals to restore their brand attitudes, we do not believe this will be the case for high avoidance-high anxiety individuals. Forgiveness requires a decrease in motivation to maintain estrangement from the offender (Mikulincer and Florian 1995), which these individuals are unlikely to have because they tend to avoid getting close to others (Bartholomew 1990). Participants ($n = 405$) completed the measures of anxiety and avoidance and then read a Nike transgression scenario before reporting brand attitudes. One week later 176 participants returned to complete the second study and were exposed to a recovery effort and reported their brand attitudes again. Greater avoidance was again associated with lower brand attitudes before the recovery effort ($b = -.21$; $t(172) = 2.17$, $p < .04$). The effect of recovery effort was significant among those with high avoidance-high anxiety ($b = .64$, $t(168) = 3.39$, $p < .001$) and marginally significant for those with high avoidance-low anxiety ($b = -.69$, $t(168) = 1.67$, $p < .10$). High avoidance-high anxiety individuals lowered their brand attitudes even further when the brand redirected blame compared to when they offered an apology. When high avoidance was coupled with low anxiety, a blame redirection increased brand attitudes.

This research examined how interpersonal attachment styles affect responses to brand transgressions. By illuminating the role of stability, severity, and controllability as processes governing these effects, we provide a more nuanced understanding of how interpersonal relationships of consumers impact their relationships with brands. Although recovery strategies have been shown to be influential in guiding consumer-brand relationships following transgression, our research sheds light on the moderating role of consumers' attachment styles in enabling such a recovery.

The Devil You Know: Service Failures, Self-Esteem and Behavioral Loyalty

EXTENDED ABSTRACT

Why do some consumers switch to available alternatives following service failures whilst others do not? In this research, we investigate one of the factors that might explain behavioral loyalty in face of service failures. Research suggests that individuals with low self-esteem who experience relational transgressions develop an avoidant attachment style, which impairs their interpersonal functioning and their willingness to take further interpersonal risks (Park and Maner 2009), and in particular to engage in other long-term relationships (Walker 2009). Drawing on this research, we propose

that low self-esteem (LSE) consumers who experience service failures become unwilling to commit themselves to alternative brands, even when they have the opportunity to do so, thus – paradoxically – they remain trapped in their current brand relationship. High self-esteem (HSE) consumers, instead, are more likely to switch to other available service providers when they experience service failures, as compared to when they do not experience failures. We also predict that LSE consumers who experience service failures tend to avoid new commitments *in general*, thus favoring transactions relative to long-term contracts, even in consumption domains that are unrelated to the service failure. We tested these predictions in one survey and three experiments.

In study 1a, participants completed a measure of self-esteem (Rosenberg 1989; e.g., “I have a number of good qualities”), and reported the quality of their internet connection (“Considering your Internet usage over time, what percentage of the time does your Internet connection work perfectly?” 0% = *Internet never works perfectly*, 100% = *Internet always works perfectly*.) These questions were interspersed among others in order to disguise the purpose of the study. Finally, participants indicated how likely they would be to switch to a competitor of their current Internet provider, if canceling their current contract were free of charge and the new provider did all the paperwork. As the quality of their internet connection decreased, HSE consumers were more likely to switch to a different provider. However, frequency of failures did not have an effect on LSE consumers' likelihood to switch. In study 1b, we replicated these findings in an experimental setting: HSE consumers who imagined to use an extremely faulty Internet connection were more likely to switch to an available provider as compared to their counterparts who imagined to use a perfectly functioning Internet connection; LSE consumers did not express different switching intentions between conditions.

Since we had hypothesized that the loyalty of LSE consumers in face of service failures is driven by their avoidance of new long-term relationships, in study 2 we manipulated the length of the contract offered by an alternative Internet service provider. When an alternative service provider offered a long-term contract (1 year) we replicated previous results: the two-way interaction between self-esteem and service quality was significant—HSE consumers were more likely to switch to this alternative service provider as the quality of their internet connection worsened, but LSE consumers were not. Instead, when an alternative service provider offered a short-term contract (1 month, renewable) LSE consumers were as likely as HSE consumers to switch to this provider, as revealed by the absence of an interaction between self-esteem and service quality in this condition. In fact, following a service failure, LSE consumers seemed to prefer a short-term contract relative to a long-term contract, which suggests an increased fear of committing to alternative brands. In study 3, we demonstrate that the fear of new commitments induced by service failures extends to unrelated domains. LSE consumers who imagined to use an extremely faulty Internet connection expressed a greater preference for buying a magazine at the newsstand relative to subscribing to this magazine, as compared to their counterparts who imagined to use a perfectly functioning Internet connection and participants in a negative mood condition. The preferences of HSE consumers, instead, were not affected by service failures.

In sum, these studies suggest that following service failures, HSE consumers are more likely to switch to a competitor compared to their counterparts who do not experience failures, whilst LSE consumers are not (studies 1a, 1b, and 2). Consistent with the hypothesis that service failures (vs. no failures) make LSE consumers wary of relational risks, thus rendering them avoidant of commitment with

alternative brands, LSE consumers increase their preference for low-commitment offers from competitors and decrease their preference for high-commitment offers (study 2), even in unrelated consumption domains (study 3).

This research has significant practical import for marketing and policy-making. Consumers who experience service failures can more easily escape a negative brand relationship if low-commitment alternatives are available; thus, marketers who wish to lure dissatisfied consumers from their competitors should consider diversifying their offerings and include short-term/low-commitment offers in their portfolio. Moreover, our results suggest that service failures might create generalized distrust in long-term relationships that extends to different consumption domains. In the long run, this could hurt marketing efforts to build trust and committed relationships. Finally, policy makers should take into account that behavioral loyalty is not determined only by switching costs or apathy. Lowering switching barriers to favor competition might not be enough to protect consumers' rights, but motivating brands to right their wrongs – for example by broadening the scope of class actions – might be an important additional protection for LSE consumers.

The Category Spillover Effects of Brand Hatred

EXTENDED ABSTRACT

In a recent campaign by the budget airline Spirit Airlines, more than 30,000 consumers expressed their hatred for Spirit and other American airline brands (Spirit 2014). The likely managerial motive behind Spirit's campaign is that a brand benefits when consumers hate competing brands. Such category spillover effects of brand hatred are the focus of this paper. We examine how hatred for a brand affects other brands that are close competitors (i.e., competitors in the same category such as other budget airlines) or distant competitors (i.e., competitors in a different category such as traditional full-service airlines).

Brand hatred is an extremely negative and stable emotional attitude towards a brand “including intense feelings of dislike, animosity, hostility and aversion [...]. [Brand hatred] may result from the combination of repeated experiences of anger [, contempt,] and disgust toward the hated object” (Matsumoto 2009, p. 230; cf. also Sternberg 2005; Sternberg and Sternberg 2008). Consistent with the intuition of the Spirit's managers, researchers have suggested that hatred can motivate individuals to destroy and annihilate the hated object (Ben-Ze'ev 2001; Rempel and Burris 2005). In order to do so consumers may take revenge by purchasing from the closest competitor rather than a more distant competing brand from a different category in order to maximize the harm to the hated brand. The proverb “the enemy of my enemy is my friend” resembles this logic and spillover effects of this kind have been documented in prior work on consumer revenge (e.g., Nasr Bechwati and Morrin 2003).

In contrast to this revenge-based account, hatred of a brand may activate a fundamental, evolutionary evolved self-protection motive (Griskevicius and Kenrick 2013). This motive is triggered when individuals experience threats to their physical safety or valued resources (Kenrick et al. 2010; Lisjak and Lee 2014). Once activated, the self-protective system focuses on evading potential dangers in one's social environment and makes consumers particularly vigilant and susceptible to cues signaling that they might be in danger (Griskevicius and Kenrick 2013). An active self-protection motive increases the likelihood of engagement in risk-reduction behaviors (Lisjak and Lee 2014). In the context of brand choice, if a consumer hates a particular brand, brands that are perceived as direct competitors to the hated brand (i.e., from the same category) may be viewed as more

threatening and risky than brands that are more distant. To protect themselves, consumers should thus be more inclined to purchase from a competitor from a different category than from the same one. We conduct four studies to test the competing revenge-based versus self-protection-based predictions and produce unequivocal support for the self-protection account.

Study 1a (n = 95) provides initial evidence that brand hatred spills over to shift consumers' preference away from same-category towards other-category brands. In this study, participants wrote about why they hate, love, or feel indifferent towards a specific budget airline brand (i.e., Ryanair). After completing the writing task and some manipulation check items, participants entered a lottery for a 20€ travel voucher. Our dependent measure was participants' choice of airline for the voucher: a same-category (EasyJet) or an other-category brand (British Airways). Consistent with the self-protection account, in the hatred condition, 75% of participants chose the other-category brand versus 38% of those in the indifference condition and 42% in the love condition. Study 1b (n = 136) replicates this effect and shows that the negative spillover effects to same-category brands emerge not only when consumers hate a budget brand, but also a premium brand (Lufthansa). Study 2 (n = 125) replicates the effect using fictitious brands. Moreover, to address a potential confound of studies 1a and 1b, in study 2 the same- and other-category brands in the choice set do not differ in value and price positioning. Participants imagined a detailed story about indifference- versus hatred-evoking experiences with a hotel (branded either as an independent or a chain hotel). Subsequently, participants envisioned returning to the same city and reported their willingness-to-pay for two different hotels, one same-category and one other-category brand. Willingness-to-pay (independent vs. chain) is the within-subject factor and dependent variable, and category (independent vs. chain) and emotional attitude (indifference vs. hatred) are between-subjects factors. We find a three-way interaction between category, emotional attitude, and willingness-to-pay: participants in the hatred condition were willing to pay significantly more for the chain (independent) brand when their initial hatred-evoking experience was with an independent (chain) hotel. In contrast, willingness-to-pay did not differ significantly in the indifference conditions. As the first three studies provide unanimous support for the spillover effects of brand hatred, we explicitly test the underlying self-protection mechanism of this effect in study 3 (n = 154). Building on the paradigm used in study 2, we show that brand hatred shifts perceptions of the relative safety of same- versus other-category brands: whereas participants in the indifference conditions perceive the same- and other-category brands as equally safe, participants in the hatred conditions perceive the other-category brand as significantly safer. Moderated mediation analyses reveal that the conditional indirect effect of emotional attitude (i.e., indifference versus hatred) via brand safety perceptions on the relative preference for the chain over the indifference hotel (displayed in consumers' intentions and willingness-to-pay) is significant and positive (significant and negative) when the focal brand was an independent (chain) branded hotel.

In summary, across our four studies we find consistent support that brand hatred shifts preferences away from same-category towards other-category brands in line with the self-protection hypothesis. In line with the tenets of Griskevicius and Kenrick (2013) we show that 1) reflecting on a hated brand acts as an external cue that activates the self-protection motive, 2) the activation of this fundamental motive shapes consumers' perceptions and preferences, which consequently 3) guides their choices towards favoring (safer) other-category over same-category competing brands.

SESSION OVERVIEW

Consumer researchers are increasingly relying on online samples to conduct their empirical investigations. While crowdsourcing markets and online panels (e.g., Amazon Mechanical Turk) have improved the efficiency of behavioral research, they also introduced unique and novel challenges for data quality (for recent reviews see Gosling & Mason 2015; Paolacci & Chandler 2014). In particular, both the recruitment and execution stages of research are inherently less controllable when they happen online than offline (e.g., in a physical laboratory). As a result, several questions arise that directly impact the reliability of online behavioral investigations and ultimately the trustworthiness of research findings: Is there such thing as an “online population”, or are some online samples more reliable than others? What are the consequences of research participants self-selecting into research studies as they wish? How can researchers ensure that unsupervised participants will truly engage in the tasks they perform? This session brings together four papers that assess these concerns, and suggest practical solutions for consumer researchers to ensure high data quality in their online investigations.

The first two papers focus on the recruitment stage of online research. Peer and colleagues compare a variety of online panels, finding vast differences in data quality as well as participant demographics and psychometrics. Chandler and colleagues investigate how participating twice in the same study—a phenomenon which previous research documented as prevalent—affects results, and find that including non-naive participants consistently reduces observed effect sizes. The last two papers focus on how features of the research execution can be changed to increase data quality in online research. Blanchard and Banerji comprehensively examine free sorting tasks in online research and find evidence that researcher decisions (e.g., topic, number of items, pre-task video tutorials) substantially affect both participants’ experience and the quality of

the data they provide. Brigden examines the effect of interactive study elements on participants’ attentiveness, and finds that participants’ attentiveness is significantly improved in presence of interactive elements. Altogether, the four papers highlight specific data quality concerns for online researchers, test the effectiveness of attempts to address these concerns, and identify important avenues for future research in this area.

The Internet democratized science by lowering the barriers to its consumption and dissemination. Recently, opportunities to conduct research online have allowed for a more democratic *production* of scientific knowledge. However, online data collection also has many undetected pitfalls, that this session uncovers and examines. Prior ACR sessions on crowdsourcing and online research (e.g., Goodman & Paolacci, 2014) demonstrated great interest in the community for a more thorough understanding of the consequences of relocating empirical investigations online. We expect this session to be equally successful, and to contribute substantially – by providing attendees with actionable methodological implications – to improve the practices of online data collection.

Beyond the Turk: An Empirical Comparison of Alternative Platforms for Crowdsourcing Online Research

EXTENDED ABSTRACT

In recent years, a growing number of researchers have been using Amazon Mechanical Turk (MTurk) as an efficient platform for crowdsourcing online human-subjects research. A large body of work has shown MTurk to be a reliable and cost-effective source for high-quality and representative data, for various fields and research purposes (e.g., Buhrmester, Kwang, & Gosling, 2011; Chandler, Mueller, & Paolacci, 2014; Crump, McDonnell, & Gureckis, 2013; Fort, Adda, & Cohen, 2011; Goodman, Cryder, & Cheema, 2013; Litman, Robinson, & Rosenzweig, 2014; Mason & Suri, 2012; Paolacci, & Chandler, 2014; Paolacci, Chandler, & Ipeirotis, 2010; Peer, Vosgerau, & Acquisti, 2013; Rand, 2012; Simcox, & Fiez, 2014; Sprouse, 2011). In parallel, several other alternative platforms now offer similar services, with distinct differences from MTurk: they offer access to new and more naïve populations than MTurk’s, and have fewer restrictions on the types of assignments researchers may ask participants to do (see Vakharia & Lease, 2014, for an overview). These alternative services for crowd-sourced research could be highly beneficial for researchers interested in conducting online surveys and experiments, as long as these new sites prove to provide high-quality data. We conducted an empirical investigation of the data quality (in terms of response rates, attention, dishonesty, reliability and replicability) of several alternative online crowdsourcing platforms, and compared those to both MTurk and a university-based online participants pool.

At first, we focused on six services that we found by searching for crowdsourcing websites on the web, which are similar in purpose and general design to MTurk. These services included CrowdFlower, MicroWorkers, RapidWorkers, MiniJobz, ClickWorker and ShortTask. However, we were able to run our study only on the first three sites due to various problems with the other sites (MiniJobz rejected our

study with no explanation or response to our questions; ClickWorker required a high set-up fee of about \$840 for 200 participants; and ShortTask failed to process our payment method several times and no support could be reached). In addition to the above three sites and MTurk, we also ran our study on a university-based online participant pool (CBDR) as another comparison group. We aimed to sample 200 participants from each site using a week for sampling. We obtained 200 responses from MTurk and CrowdFlower in less than 2 hours (101.01 and 108.55 responses per hour, respectively). With a considerable difference, CBDR showed the third fastest response rate (1.42 responses per hour), followed by MicroWorkers (1.08 responses per hour) and RapidWorkers (0.63 responses per hour) – from which we could only sample 105 completed responses in a week. Eventually, we obtained a total sample of 890 participants.

Our online study included several parts designed to examine different aspects of data quality. For brevity, we describe these parts here alongside their results. In one part, participants completed several validated questionnaires to examine differences in reliability between the sites: the Internet User Information Privacy Concerns scale (Malhotra, Kim, & Agarwal, 2004), the Need For Cognition scale (Cacioppo, Petty, & Kao, 1984) and the Rosenberg Self-Esteem Scale (Rosenberg, 1979). Overall, we found that MTurk participants showed the highest reliability scores on all three scales, followed by CrowdFlower participants, CBDR and Microworkers, all of whom performed adequately well on all scales (except a somewhat lower score for CrowdFlower participants on the NFC scale). RapidWorkers participants showed high reliability on the IUIPC scale, but very low reliability on the NFC and mediocre reliability on the RSES scales. We used Hakistan & Whalen's (1976) method to compare between independent reliability coefficients and found no statistically significant differences between the samples (using all participants from each sample) for the IUIPC, $\chi^2(4) = 6.63, p = .17$, but we did find statistically significant differences for the NFC and the RSES, $\chi^2(4) = 127.07, 75.69, p < .01$.

Two attention-check questions (Peer et al., 2014), embedded at different points of the study, checked participants' attention and compliance with written instructions. Whereas only 14% of MTurk participants failed both questions, almost half of the CBDR participants failed them, and the majority of the participants in all other sites failed them as well. Interestingly, CrowdFlower participants (who showed the fastest response rate) had a failure rate of almost 75%.

Another part of the study examined replicability of known findings using tasks from the judgment and decision-making literature (following Chandler et al., 2010): the Asian-disease gain vs. loss framing, the sunk-cost fallacy, and four anchoring-and-adjustment questions. We found the expected effects in both CrowdFlower and MicroWorkers, in levels comparable to MTurk, whereas RapidWorker's results were less than adequate. In another part, which used a die-throwing task, we found no differences in the propensity for dishonest behavior between the different sites.

To conclude, we found that, at the time of writing, both CrowdFlower and MicroWorkers sites, but not the RapidWorkers site, could be potential alternatives to MTurk. Additional examinations revealed that there was a very small overlap between participants from the different sites, and some individual differences between the sites. The most pronounced, and probably most practical, of those was that CrowdFlower's participants included much more Asian participants and non-U.S. citizens than MicroWorkers or MTurk. We believe additional research is required to understand the origins of these differences between the sites, and to further explore other aspects of data quality between these sites in comparison with MTurk, as well as in comparison with other, more traditional samples.

Using Nonnaive Participants Can Reduce Effect Sizes

EXTENDED ABSTRACT

When conducting a study, researchers often assume that participants are naive to the research materials, either because the pool of participants is large (e.g., Internet samples) or because participants' prior exposure to research is limited (e.g., in the case of first year college students). This assumption, however, is often violated. People can belong to a participant pool for several years, and some members are disproportionately likely to be sampled (Chandler, Mueller, & Paolacci, 2014). Moreover, researchers with overlapping interests rely on the same undergraduate subject pools, and participants may easily share information with each other (Edlund et al, 2009). People may also gain knowledge of research materials through college courses or media coverage.

Some research suggests that familiarity with research materials might impact findings. Prior knowledge may increase the likelihood of hypothesis guessing and potentially lead to demand effects (Weber & Cook, 1972). Relatedly, earlier conditions in within-subject experiments inform subsequent conditions, causing effects observed in between-subjects designs to be inflated, attenuated, or reversed (see Charness, Gneezy, & Kuhn, 2012). Recently, researchers have noted that responses to psychological measures correlate with proxies of prior participation in similar experiments, such as memory of prior participation (Greenwald & Nosek, 2001), chronological order of studies themselves (Rand et al., 2014), measures of the total number of completed experiments (Chandler et al., 2014), or naturally varying levels of prior experience with a task (Mason, Suri & Watts, 2014). Although these findings suggest that non-naivety may influence observed effect sizes more generally, this possibility has not been directly tested. To address this gap, we examine how prior exposure to study materials affects responses.

Method

We conducted a two-stage study on Amazon Mechanical Turk (for a review see Paolacci & Chandler, 2014). One thousand participants completed a set of eleven two-condition experiments in Wave 1 (W1), testing phenomena such as anchoring, framing, retrospective gambler's fallacy, etc. (full details about W1 are reported in Klein et al., 2014). In Wave 2 (W2), these participants were invited to participate in a study including the same experiments with the exclusion of two (that were not successful in W1). For each experiment, participants were randomly assigned to the same condition as in W1 or in the alternative condition. Additionally, we manipulated two factors that that should affect whether participants recall previous materials and potentially moderate the effect of non-naivety. *Visual similarity* was manipulated by randomly assigning participants to complete the experiments on the same platform as W1 or on a different, visually distinct platform. *Time Delay* was manipulated by re-contacting participants a few days, about a week, or about a month after W1. This resulted in a 3 (Time Delay) X 2 (Visual Similarity) X 2 (Condition) between-participants design.

Results

We tested the effect of non-naivety on the responses of participants who participated in both W1 and W2 (N = 638; 55% women; $M_{age} = 36, SD = 12.8$). Overall, effect sizes declined from W1 (weighted $d = 0.82$) to W2 (weighted $d = 0.63$) by $d = 0.19$, a drop of about 25%. Only one effect size increased from W1 to W2 (low vs. high scales task; Schwarz et al., 1985) and all others showed 17% to 83% declines. 9 of the 12 effects (we analyzed the four anchoring tasks separately) exhibited declines, and 5 of these declines were statistically significant.

To examine whether the attenuation of effects was stronger when recalling information from previous participation was easier, we regressed W2 effect sizes on same vs. different Condition, Visual Similarity, Time Delay, and on dummy variables for experiment (accounting for differences in attenuation across experiments). There was a significant effect of Condition, reflecting that participants exposed to different conditions demonstrated greater decline of effects from W1 to W2. There were no main effects or interactions.

After study completion, participants reported for each experiment whether they remembered participating in it. Memory for participation in each experiment depended on Time Delay and ranged between 35% and 80% of participants. We regressed W2 effect sizes on whether they represented those who did or did not report remembering the prior experiment, same vs. different condition dummy, and dummies for the different experiments. There was a significant effect of being assigned to a different condition, and neither memory of prior participation nor its interaction with same vs. different condition were significant. This suggests self-reported memory for prior participation is at best a poor indicator of whether participants will display attenuated effect sizes because of prior participation.

Our findings show that prior exposure to research materials can reduce the effect size of true research findings. Effect sizes decreased of 40% on average, although the reduction was different for different experiments. Future research should examine whether and how some paradigms (e.g., those that require participants to generate numerical estimates) are more susceptible to non-naivety. Effects were particularly attenuated when participants were exposed to alternative conditions of an experiment, highlighting that decreased might be a function of information. However, they were also attenuated among participants exposed to the same condition twice, which might be explained by repeated exposure leading to more elaboration and decreased reliance on intuition (Sherman, 1980). Self-reported participation does not identify all prior participants, or even those who demonstrated a particularly large non-naivety effect. This may be explained if participants quickly forget the source from which the information was learned, but do not forget the information itself (Johnston, Hashtroudi & Lindsay, 1993).

Non-naivety is a serious concern for behavioral researchers that cannot be solved controlling for self-reported previous participation. When directly monitoring prior participation not possible, researchers should design procedures and stimuli that differ from those known to the tested population (Chandler et al., 2014), or increase their sample size to offset the anticipated decrease in power.

Research Design Decisions and Their Effects on Task Outcomes: An Illustration Using Free-sorting Experiments

EXTENDED ABSTRACT

Numerous research areas within psychology and marketing have relied on free-sorting tasks, wherein participants allocate a set of objects into groups of their own choosing to study the natural cognitive processing of information that consumers encounter in their lives (e.g., Blanchard 2011; Ross & Murphy 1999). Unfortunately, there is little systematic empirical research that provides guidance on how researchers should design sorting tasks in order to minimize unwanted consequences such as contaminated process data, and depleted or dissatisfied participants. As different studies have provided differing recommendation, we provide an empirical investigation of sorting task researcher-driven design decisions on a variety of outcomes.

To do so, we created an experimental design that systematically varies the decisions that a researcher may face when adopting a sorting task using a fractional factorial design to test the main effect of each factor (i.e., researcher decisions) on various dependent measures (Collins, Dziak, & Runze, 2009). We then provide guidance as to best practices and potential pitfalls. The factors, along with the final design (involving 36 orthogonal tasks), are presented in a table that can be downloaded here: <http://tinyurl.com/blanchardtable>

Participants & Procedure

We requested 720 participants (20 per task) from Amazon Mechanical Turk (mTurk) for a “consumer perceptions study.” Participants were paid \$0.50 and were allocated evenly/sequentially using Qualtrics’ quota functions.

Once a participant clicked the survey link on mTurk, each participant was randomly assigned to one of the 36 task configurations via an initial Qualtrics survey whose sole purpose was to randomly assign participants. If the participant was assigned to a task design for which pre-task examples were to be provided (*Using pre-task tutorials; yes/no*), Qualtrics displayed a short video that demonstrated musical instruments being sorted along (adapted from Lickel et al., 2000). Participants then proceeded to the online sorting task interface (Cardsorting.net), which affords researchers the ability to present a varying number of objects to be sorted (*Number of objects; 20, 40, 60*), to customize instructions (*Providing a criteria for the sorts; similarity/dissimilarity*), to use either a single or a multiple cards sorting task (*Type of sorting task*), to require that participants sort all the objects at least once (*Requiring to use all the cards at least once*), and the option to ask participants to label the piles during the task, after the task, or not at all (*If and when to ask for pile labels*). After submitting their sorts, all participants proceeded to the same post-task Qualtrics survey, which contained additional dependent measures.

Results

For our analyses, we use mixed-effect linear models where the task number is a random effect and all researcher decisions are fixed effects. We provide the following recommendations:

Researchers should keep the number of objects manageable, but there is no need to severely constrain the number of objects. Although participants prefer tasks with fewer objects (20), we find no evidence that participants cannot properly follow instructions that require them to sort 40 or even 60 objects. As the number of objects increases, the biggest impact seems to be on completion time, perceptions of the effort required, and the extent to which the task was enjoyable.

Researchers should be mindful of what they are asking participants to sort. The type of objects being sorted has a significant impact. Using “groups types” instead of food objects led to a significant increase in dropout rates, completion time (for an equivalent number of objects), and participant depletion.

There’s no harm in allowing participants to sort objects into multiple piles. Even when given the option, participants were assigned objects to multiple piles only when their perceptions dictate it. Allowing participants to do so when it will not negatively impact research goals and may result in less attrition.

If researchers want labels for the piles, they should ask participants to do so after they have submitted their sorts as complete. Asking participants to name the piles during the task led to significantly greater dropout rates, a greater number of cards left unused, and higher completion times.

If researchers are trying to increase the frequency at which participants assign objects to multiple piles, they should consider providing pictures along with the objects' names. Doing so allows participants to visualize the objects, and tends to lead to a greater number of objects used more than once in the sorts.

Requiring participants to use all the cards has little effect on task and satisfaction measures. If you suspect that participants will be familiar with the majority of the objects to be sorted, then requiring they sort all objects is more likely to result in fully complete data without any detrimental effects on the sorting process or participants' experience.

Sorting interfaces are sufficiently intuitive. Expansive instructions may not be necessary. We found that participants followed the instructions, and providing them with videos that illustrated the features of the sorting interface (e.g., adding/removing objects from piles, labeling, etc.) did not have much of an impact other than to speed up the sorting process once participants got started.

General Discussion

Free-sorting is a popular data collection methodology. With online panel data and computerized platforms for free-sorting becoming more readily available, it is now possible to conduct these experiments even more easily than before. Nevertheless, researchers have many decisions to make regarding how the task should be presented to the participants and the present research shows that some of these decisions can have important consequences on the task's outcomes, and participants' perceptions of the experience.

In general, we suggest that researchers who have been wary of using sorting tasks thus far consider using online interfaces that provide a great deal of flexibility and feasibility to the researcher, while simultaneously providing participants with a reasonably pleasant and interesting task. Moreover, online interfaces allow rapid data collection thus making it possible to collect large amounts of data cheaply and quickly via online panels such as mTurk. Our findings also suggest that it may be worthwhile to revisit existing finding while varying the researchers' decisions thus introducing theoretically interesting nuances to extant literature.

Interactivity and Data Quality in Computer-Based Experiments

EXTENDED ABSTRACT

Research participants are often not as diligent and engaged as researchers would like. Instructional manipulation checks – IMCs (Oppenheimer, Meyvis, & Davidenko 2009), allow researchers to detect respondents who are not being attentive, but these checks do not address the underlying issue. Having detected inattentive respondents the researcher can discard their responses, likely reducing noise and improving statistical power, but reducing the sample size and possibly skewing the sample in the process. As an alternative, we propose that researchers might improve participant engagement by making studies more engaging, reducing the need to discard data after the fact.

The need to validate new online research pools has led to several studies examining the problem of inattentiveness among research participants. Some have suggested that the problem is comparable in magnitude (Paolacci, Chandler, & Ipeirotis, 2010), or worse among MTurk workers (Goodman, Cryder, & Cheema, 2013), while two recent studies have suggested that it is now less severe among MTurk workers than among other subject pools (Hauser & Schwarz, 2015; Klein et al., 2014).

The higher performance on IMCs among MTurk workers has multiple causes. IMCs are commonly used as a criterion for worker payment on MTurk (Chandler, Mueller, & Paolacci, 2014). Also, MTurkers in general are more experienced with these checks (Peer, Vosgerau, & Acquisti, 2013). Lastly, researchers tend to only include high reputation workers on MTurk, whereas undergraduate student samples tend to be more unfiltered (Hauser & Schwarz, 2015).

While MTurk workers generally perform better than undergraduates on IMCs, there remains room for improvement, with pass rates as low as 26% on novel IMCs (Hauser & Schwarz, 2015). Such low pass rates on these novel IMCs suggest that MTurk workers may be scanning for familiar IMCs rather than diligently reading all instructions.

Studies that are more interactive are, almost by definition, more engaging for participants. They may feature motion, sound, and choices that meaningfully change the participants' experience. These interactive elements were predicted to significantly improve participant attentiveness as measured by IMC pass rates.

Method

To assess the impact of interactivity on participant attentiveness, a meta-analysis was run on a set of 17 prior studies (total N=2384). The analysis compared IMC pass rates between studies that were either interactive or not, across three subject pools (MTurk, undergraduate students, and an in-house online panel). For the purposes of the analysis a study was only classified as interactive if it met two criteria: It had to contain audio or video and it had to feature some consequential choices. All studies included the same IMC, which asked participants to scroll down and click on a button off screen if they were reading the instructions, rather than clicking a "continue" button already visible on screen. For the MTurk studies, participation was limited to workers who had previously completed a minimum of 100 HITs with a minimum 95% approval rating.

Results

The effect on interactive elements on the pass rate for the IMC was assessed separately within each subject pool, as prior research has found dramatic differences in IMC pass rates between different subject pools. The largest difference in IMC pass rates between interactive and non-interactive studies was in the in house online subject pool, where interactive studies had a significantly higher IMC pass rate (87.3% than non-interactive studies (59.5%), $\chi^2(1, N = 415) = 229.8, p < .001, \phi = .27$). The difference was also significant in the undergraduate subject pool, where again the interactive studies had a significantly higher IMC pass rate (94.1% than non-interactive studies (78.2%), $\chi^2(1, N = 1035) = 56.8, p < .001, \phi = .24$). However, in the MTurk subject pool there was no difference in IMC pass rates between interactive studies (91.2%) and non-interactive studies (93.9%) $\chi^2(1, N = 934) = 2.1, p = .15$.

Discussion

The results indicate that more interactive studies may motivate participants to read instructions more carefully leading to better compliance. Interestingly, the improvement in attention appears to generalize to parts of the study that are not interactive. The IMC, in all studies, occurred outside of the interactive portion of the experiment.

Interactive studies were no better than non-interactive studies on MTurk. However, it may be difficult to improve on the high IMC pass rate this panel generally exhibited for this particular IMC. Further research using a novel IMC or a less restricted pool of MTurk workers may reveal differences in this subject pool as well.

Interactive elements are appealing from the researchers perspective as they increase engagement without necessarily requiring additional payments to participants. This keeps research costs down and can also avoid the issue of creating a productivity mindset, which may be counter to the objective of studying many consumption experiences that are not typically accompanied by this mindset. Interactive computer based experiments may also offer new avenues of examining consumption experience, an area with great potential for significant new discoveries within consumer research (Janiszewski, 2010).

Paper #4: Introducing the Implication Model of the Motivated Cognition

Troy H. Campbell, University of Oregon, USA

SESSION OVERVIEW

Values matter. Value conflicts trigger international wars and shape political discourse. In hopes to strategically use values' powers, firms craft value statements and design value-laden advertisements to attract employees and brands. For instance, Coca Cola's 2014 Super Bowl commercial sought to bridge the gap between the values of diversity and patriotism. Additionally, Dove's continuing #RealBeauty and #RealStrength campaigns aim to update traditional values to increase inclusiveness and authenticity. However, though policymakers, practitioners, and researchers across disciplines know the motivating power of values, more work is needed to achieve a nuanced and comprehensive understanding, and to thus ultimately effectively wield the value of consumers' values.

Currently, consumer research has only begun to connect with perspectives from neighboring disciplines that highlight values and ideologies, and integrative models unifying findings on value-motivated cognition remain scarce and nascent. Besides deepening our understanding of fundamental political values and certain under-researched values related to essential character and true self, this work can help illuminate how and when values lead to attitude change versus steadfast denial, and thus help marketers navigate value conflicts from political macro pro-social issues to personal choices on the beauty isle. This session seeks to advance connections with these outside perspectives, build an integrative theoretical foundation around values, and broaden the scope of consumer research within this key area.

The first two papers examine how values shape consumers' judgments of individuals and firms. Yang and colleagues reveal how greater effort in enhancing one's appearance threatens values about truthfully representing one's essential self. Shepard and colleagues find that diversity appeals, such as the 2014 Coca Cola ad, may have polarizing effects based on consumers' values, provoking negative reactions from those who ideologically support the current American system. Both papers demonstrate the malleability of these effects, developing message framings that affirm these values and minimize threats.

The final two papers provide perspective on how and when values lead to motivational biases in cognition. Bhattacharjee and colleagues show that due to differences in values emphasizing essential character, conservatives selectively separate immoral behaviors from professional performance less than liberals, providing one of the first demonstrations that conservative ideology can in some circumstances reduce motivated reasoning. Finally, Campbell and Kay present a parsimonious model to unify ideas from the recent explosion of research on value-based motivated cognition across fields. This integrative model provides insight into the often hidden source of motivated cognitions, the multiple paths they often take, and how to reduce these biases.

Together, these papers explore novel territory, lay a theoretical foundation in an underexplored, growing area, and stimulate deeper questions. Namely, which sorts of values are most susceptible to threat, and which tend to motivate moderation rather than polarization? When and how can values conflicts be resolved and thus reduce interpersonal conflict? Given the fundamental role values play in our lives, we expect this session to interest researchers of value and preference, motivated reasoning, culture, identity, and moral and social judgment. We hope this audience can help us ponder these questions, engage in a fruitful dialogue, further advance connections, and collectively broaden our perspectives.

How Beauty Work Affects Judgments of Moral Character

EXTENDED ABSTRACTS

Consumers devote countless hours and billions of dollars on appearance and beauty practices (i.e., beauty work, Kwan and Trautner 2009) because physical attractiveness leads to numerous positive outcomes (Langlois et al. 2000). However, an odd paradox exists: attractive people are generally perceived more favorably, but people who put a lot of effort in pursuing attractiveness are generally viewed negatively.

We propose that this occurs because an individual's appearance holds symbolic, informative value in person perception. Attractiveness is perceived as a reliable indicator of fitness, health, and reproductive value, which is largely predetermined genetically (Langlois et al. 2000). Furthermore, people tend to use attractiveness as a global, general indicator of how good or bad an individual's "true nature" is – something people are born with that they cannot change (Dion et al. 1972). Thus, by engaging in high levels of effort to upgrade or change one's appearance, one may also be perceived as masking who they truly are. We posit that extensive beauty work is perceived as indicative of poor moral character because such effort implies that one is misrepresenting one's "true essence" in order to acquire undeserved benefits. We test this effect and downstream consequences across 4 studies, focusing on the beauty work of women since they face the greatest pressure to conform to beauty standards (Fredrickson and Roberts 1997).

In study 1, we show that effort in beauty work influences judgments of moral character and perceived effectiveness in various roles. Female undergraduates were told that "Jenna" spent either 10 minutes or 2 hours getting ready to go out for an evening. When Jenna spent 2 hours getting ready, participants expected her not only to have poor moral character (moral, ethical, $r = -.70$), but also to be a worse student, friend, sister, daughter, athlete and artist (all p 's <

.01). Ratings of moral character also mediated the effect of effort on participants' judgment of Jenna, consistent with prior research finding that judgments of moral character are perceived as relevant to various domains (Blasi 2005).

In study 2, we show that the effort-morality link is unique to the beauty domain. Female undergraduates ($N=101$) read that Jenna put high or low effort into her beauty or academic work. A 2(effort: low vs. high) x 2(domain: beauty vs. academic) ANOVA revealed a two-way interaction ($p < .01$) where Jenna was rated as having poorer moral character (moral, ethical, genuine, sincere, $\alpha = .88$; Walker and Hennig 2004) when she exerted high relative to low effort on beauty work ($M_{High} = 4.11$ vs. $M_{Low} = 4.70$, $p < .05$) but not on academic effort ($M_{High} = 4.90$ vs. $M_{Low} = 4.61$, *ns*). Given that individuals also serve to gain personally with academic success, the null effect in the academic domain rules out the possibility that negative perceptions of high effort for personal gain drove our effects.

In study 3, we examine the underlying mechanism, testing whether perceptions of misrepresenting oneself drive our effects on judgments of moral character. We also examined whether this effort-morality link exists in consumers' expectations for how they themselves would be perceived by others. Female undergraduates ($N=92$) were told that they heard that a new friend spent 10 minutes or 2 hours getting ready (third person) or that a new friend learned the same information about them (first person). We measured moral character (same items as in S2, $\alpha = .90$) and misrepresentation with two items (e.g., to what extent would you believe that she is trying to put forth an image of someone she is not, $r = .83$).

A 2(effort: high vs. low) x 2(perspective: third vs. first) ANOVA found only a main effect of effort on both ratings of moral character ($p < .01$) and perceptions of misrepresentation ($p < .01$). High effort garnered more negative ratings of moral character in both the third person ($M_{High} = 4.19$ vs. $M_{Low} = 5.30$, $p < .01$) and first person condition ($M_{High} = 3.73$ vs. $M_{Low} = 5.18$, $p < .01$). High effort also led to higher ratings of misrepresentation in both the third ($M_{High} = 4.17$ vs. $M_{Low} = 2.09$, $p < .01$) and first person condition ($M_{High} = 4.55$ vs. $M_{Low} = 2.06$, $p < .01$). A bootstrapping moderated mediation analysis revealed misrepresentation mediated the effect of effort on moral character ratings in both the third (95% CI: $-.94$, $-.22$) and first person conditions (95% CI: -1.10 , $-.34$). Thus, these negative perceptions of high effort hold regardless of whether one is evaluating others or anticipating being evaluated by others.

In study 4, we use an advertising context to identify a boundary condition for our effects. We posit that extensive beauty work signals poor moral character because such behavior is perceived as misrepresenting one's "true essence." This suggests that if we can reframe the meaning of beauty work from reflecting one's true self to reflecting one's desire to enhance one's best qualities that one *already* possesses, the effect of effort should be mitigated. To test this prediction, female Mturk participants ($N=140$) were presented with an ad for "PerfectSkin" foundation that required high or low effort to use and emphasized that the product would allow their "true self" or "best self" to shine through.

A 2(effort: high vs. low) x 2(message: true self vs. best self) ANOVA found two-way interactions on both ratings of one's moral character (same items as prior studies, $\alpha = .90$, $p < .05$), and willingness to purchase PerfectSkin ($p < .05$). Participants felt that purchasing PerfectSkin would hurt their moral character more when the product required high relative to low effort, but only in the "true self" ($M_{High} = 3.23$ vs. $M_{Low} = 4.22$, $p < .01$) and not the "best self" condition ($M_{High} = 3.60$ vs. $M_{Low} = 3.71$, *ns*). Similarly, effort influenced participants' willingness to purchase PerfectSkin in the "true self" ($M_{High} = 4.19$ vs. $M_{Low} = 5.28$, $p < .05$) but not "best self" condition

($M_{High} = 4.57$ vs. $M_{Low} = 4.52$, *ns*). Further analysis confirmed that ratings of moral character mediated the effect of effort on purchase interest but only in the "true self" (95% CI: -1.09 , $-.25$) and not the "best self" condition (95% CI: $-.37$, $.55$).

Taken together, our studies provide support for the notion that high effort spent in enhancing one's attractiveness is indicative of poor moral character because such beauty work implies that one is misrepresenting oneself and preventing others from accurately judging one's "true essence."

Cultural Diversity in Advertising and Representing Different Visions of America

EXTENDED ABSTRACTS

It is important for brands to reflect the growing diversity of America in their advertising, particularly brands that reflect American culture and values. Despite this, little research has sought to understand how consumers respond to diversity in advertising. Past work has investigated how ethnic minorities respond to ads depicting individuals from their cultural group (Brumbaugh and Grier 2006; Lee, Fernandez, and Martin 2002; Ueltschy 2001). However, ads depicting cultural diversity also have the potential to reflect American society and how different cultures view America, and so consumers may respond to these ads differently depending on their views of America in general.

System justification theory (Jost & Banaji 1994) posits that there are individual differences in how satisfied one is with the current state of society and the values that it stands for. Those who are high in system confidence are satisfied with their society and its dominant ideology, whereas those low in system confidence are less supportive of their society and the values it represents. Higher system confidence predicts a preference for brands that show explicit support for one's social system (Banfield et al 2011; Cutright et al. 2011) and brands that reflect the values of the society's dominant ideology (Shepherd, Chartrand, and Fitzsimons 2015).

Hypotheses

Cultural diversity in advertising has the potential to reflect American society and embody a view of America that is either consistent or inconsistent with a consumer's beliefs and values. One way to interpret diversity in an ad is that minorities are changing America, which those high in system confidence should respond negatively to (H1). However, cultural diversity in ads may also communicate the idea that different cultures love America and American brands (e.g., Coca-Cola's "America the Beautiful" ad from the 2014 Super Bowl). Ads with culturally affirming messages such as this should be particularly appealing to consumers high in system confidence, who have favorable impressions of America and its global power and influence (H2). Finally, depicting cultural diversity in ads in the service of selling American brands to foreign countries and exporting American values should also be appealing to those high in system confidence (vs. those low in system confidence, or when the ads are for a domestic audience).

Research

In Study 1, 180 American participants first rated their level of confidence in their social system using the system justification scale (Kay and Jost 2003). They then viewed a series of ads created by the researchers (matched as closely as possible) which depicted either white and/or heterosexual actors vs. non-white or homosexual actors (i.e., cultural diversity). We found that those who were higher in system confidence (i.e., those who subscribe to America's dominant

ideology and its values) liked ads that contained cultural diversity less than the ads that did not (H1). This was in part due to their perception that minorities threaten traditional American values. The reverse was found for those lower in system confidence.

In Study 2, 200 American participants were then randomly assigned to either a baseline “no ad” condition, or our experimental condition where they viewed Coca-Cola’s “America the Beautiful” ad from the 2014 Super Bowl, depicting people from various cultures singing “America the Beautiful” in different languages (“ad condition”). The study was run shortly after the commercial aired. Participants then rated their attitude toward Coca-Cola (reflects ideal values, ethical, likeable; $\alpha = .90$). We predicted that those high in system confidence would rate Coca-Cola more favorably in the ad condition because it affirms their view of America and depicts the world as loving America (H2). First those high in system confidence rated Coca-Cola more favorably in the ad condition compared to the no ad condition, and compared to those lower in system confidence. Second, Study 3 ($n = 152$) presented participants the same ad, and found that those higher in system confidence were more likely to perceive the ad as affirming America’s greatness and that world loves America, which in turn predicted their more favorable evaluations of the brand. Thus, Studies 2 and 3 in combination provide support for H2.

Another way that cultural diversity in ads may affirm America and its values is when the ad is for a foreign (as opposed to domestic) market, thus exporting American culture and exposing the rest of the world to American brands. This should be particularly appealing to those high in system confidence (H3). We explore this in Study 4 ($n = 186$) by measuring system confidence and then presenting participants with ads that cater to different ethnic/cultural groups. Critically, the ads were presented as being for an American audience (“domestic” condition) or for a foreign audience (“foreign” condition). Consistent with H3, those higher in system confidence significantly preferred the ads in the foreign condition vs. the domestic condition. No such effect was found among those low in system confidence.

In short, cultural diversity in advertising has the potential to reflect a view of America that is either desirable, or undesirable to consumers, depending on how those consumers view America in general. We find that those who are satisfied and confident in America respond negatively to cultural diversity in ads, but respond positively to ads with cultural diversity content when the ad suggests that (i) the world loves America, or (ii) when diversity is in the service of exporting American culture and brands to other countries. Implications are discussed.

Global Character and Motivated Moral Decoupling Among Liberals and Conservatives

EXTENDED ABSTRACTS

From preferences for public policies to personal consumption decisions, political ideology is a pervasive influence on individual behavior (Khan Misra & Singh 2013).

Political issues are deeply enmeshed with powerful motivational forces like individual identity, morality, and values (Haidt 2012). Motivational biases are thus essential to understanding how consumers process information related to moral or political issues (Ditto, Pizarro and Tannenbaum 2009; Kahan et al. 2012). An influential stream of prior research suggests that political conservatism is associated with greater motivated reasoning in general (Eidelman 2012; Jost et al. 2003). Nevertheless, it may be important to investigate reasoning in specific contexts.

The current research examines how ideology affects the prevalence of consumer reasoning processes that often arise in the wake of public scandals. From Chris Christie to Brian Williams, the list of scandals involving public figures is varied and continually growing. Recent research finds that such situations can lead motivated consumers to engage in *moral decoupling*, a reasoning process by which they selectively dissociate immoral actions from judgments of professional performance (Bhattacharjee, Berman and Reed 2013).

We investigate ideological differences and motivational biases in how people judge the professional relevance of immoral personal behaviors by public figures. Three studies show that political liberalism is associated with greater moral decoupling, an effect rooted in conservatives’ greater belief that global character drives behavior across contexts. We also find clear evidence of motivational bias across the political spectrum in these judgments, and this evidence appears more robust among liberal respondents.

Study 1 examined the association between political ideology and general beliefs about the professional relevance of personal morality. On three items assessing beliefs about moral decoupling (e.g., “Judgments of job performance should remain separate from judgments of morality.”), agreement declined with individual political conservatism ($r(207) = -0.14, p = .008$). This association held in regressions controlling for demographic factors such as age, gender, and education.

To examine more contextualized judgments in Study 2, we presented a scenario (described as an excerpt from a news article) about a Democrat versus Republican governor. The article reported that the governor had been popular and effective in office, but recently admitted to either having an ongoing extramarital affair with a campaign worker or implementing legislation that increased profits for companies in which he was invested. As a proxy for ideology and a means of manipulating motivation, we recruited registered Democrat and Republican voters. Results revealed a main effect of participants’ party affiliation on judgments of professional relevance: Democrats were more likely than Republicans to decouple both types of immoral acts from performance ($M = 4.44$ vs. $3.58, F(1, 1012) = 37.41, p < .001$). A two-way interaction between participant and governor party affiliation indicated motivational bias in decoupling judgments: participants from both parties advocated separating immorality from performance more strongly when the governor’s affiliation matched their own ($F(1, 1012) = 35.09, p < .001$). In these scenarios, Democrat voters exhibited significantly greater motivational bias than Republicans ($F(1, 1012) = 4.61, p = .032$).

These results persisted when controlling for participants’ judgments of the immorality of the governor’s actions. Hence, these patterns do not seem to be driven solely by ideological variation in caring about moral violations, and judgments of professional relevance and immorality appear to be distinct. Our third study assessed this possibility more carefully and examined what drives these effects.

Prior research demonstrates that liberals tend to care relatively more about moral violations related to harm and fairness, while conservatives tend to care relatively more about violations related to ingroup loyalty, authority, and purity (Graham, Haidt and Nosek 2009). Accordingly, in Study 3 we examined violations pretested to relate to each moral foundation: harm (abusing pets, harassing overweight people), fairness (rigging art competitions, discriminating against minorities), ingroup loyalty (divulging friends’ secrets, disowning family members), authority (disrespecting parents, disrupting political ceremony), and purity (drinking urine in a performance art piece, eating a dog that died naturally). To investigate ideological variation in moral decoupling outside the political domain, we

examined how Democrat and Republican voters responded to these personal transgressions being committed by a high school principal.

As before, Democrat voters decoupled these immoral acts from professional performance more readily than Republicans ($F(1,530)=29.43, p<.001$). This effect was directionally consistent within each moral foundation, with no two-way interaction. On the contrary, party affiliation had only a marginal main effect on judgments of immorality and interacted significantly with moral foundation ($F(4,530)=5.96, p<.001$). Across the three moral foundations associated with conservatism (ingroup, authority, purity), Democrats both judged violations as less severe ($M=5.34$ vs. $6.30, p<.001$) and decoupled them more readily from performance ($M=6.09$ vs. $4.91, p<.001$). More notably, even on the two foundations associated with liberalism (harm, fairness), for which Democrats judged violations as more severe ($M=7.07$ vs. $6.48, p=.037$), they exhibited greater moral decoupling than Republicans ($M=5.08$ vs. $4.49, p=.035$). Mediation analyses found that the effects of political ideology on the extent of moral decoupling were mediated by individual belief in global character (indirect effect = $-0.029, SE=.013, 95\% CI[-0.060, -0.008]$). There were no indirect effects related to the importance of role models, moral rationalization of violations, judgments of immorality, or judgments of moral character.

While ideology affects judgments of immorality inconsistently across different sorts of violations, we find consistently greater moral decoupling among liberals compared to conservatives in both political and apolitical contexts. Our findings suggest that conservatism may not always translate to greater motivated reasoning. Emphasizing essential global character may increase motivational biases in some contexts but reduce them in others.

Introducing The Implication Model of Motivated Cognition

EXTENDED ABSTRACTS

Recently, motivated cognition research (Kunda 1990) has seen an influx of value and important belief based motivated cognition (Haidt, 2007, Jost, 2006). Conducted in fields other than consumer research, this work shows how deeply people engage in biased thinking to maintain their cherished values and important beliefs and how this can strongly influence consumer behavior and reactions to marketing appeals, such as pro-social appeals (Feygina, Jost, & Goldsmith 2010).

Though value and non-value based motivated cognition is both prevalent and important, all research literatures currently lack a parsimonious meta-level-model to explain when motivated cognition will occur, what direction it will take, and by what means (e.g. denial of fact v. denial of implication). Without such a model we problematically may often miss the true source of motivated cognition and the manner it takes.

To address this gap and need, we present for first time the Implication Model of Motivated Cognition (IMMC). The model distinctively includes a focus on the implications of a fact, not only the characteristic of the fact. For instance climate change has factual characteristics such as weather dangers but also implications beyond fact, such as the need for political solutions, of which both may bias cognition.

The following is the IMMC's "belief narrative" three-part structure: 1) a fact 2) implies 3) conclusion. In the model the "fact" doesn't necessarily need not be true, the "implies" logical, nor the "conclusion" correct. These are placeholders for information, of which alterations can greatly affect acceptance of other parts of the chain.

To illustrate, consider further the case of climate change where the dominate narrative chain is that 1) the fact: dangerous climate change exists 2) which implies 3) the conclusion: danger and enacting liberal policies to fight the danger. Here the implied conclusion may motivate certain individuals to deny the fact more. In this conservatives may deny the fact more because the solutions are particularly antithetical and threatening to their values. Note that a simple model of motivated cognition would only focus on the aspects of climate facts (e.g., the dangerous weather consequence). Such a "fact only model" would not predict differential motivations for conservatives and liberals. However, the IMMC does predict such and these predictions are support by recently published experiments from our lab (Campbell & Kay, 2014).

Next, we explain published and unpublished findings from our lab and other labs, to illustrate contribution of the IMMC framework.

Solution Aversion

As shown above in the climate change and similar climate change experiment conducted outside our lab (Feygina et al., 2010), the IMMC predicts that the associated solutions to problems can motivate denial of fact beyond the severity of the problem, in a sub pattern of the IMMC we call "solution aversion" (Campbell & Kay, 2014). Conceptually related, Ditto and Liu (2013) experimentally find people deny the factual efficacy of capital punishment, the more they see execution as deontologically aversive. *Problem Exaggeration*

The IMMC also predicts that especially desirable solutions may lead to exaggeration of problems. In a series of recent unpublished experiments conducted on Reddit.com, we find evidence of this prediction, such that when a problem (e.g. the common cold) is said to be in part solved by one's important beliefs (e.g. using one's personal scientific discipline) versus a neutral set of beliefs (e.g. another scientific discipline), people exaggerate the severity of the problem. Here, the exaggeration of the fact implies a more self-aggrandizing conclusion that one's important beliefs (values, skills, and group) are important and this accordingly motivates exaggeration.

Denial of Implication

Past work has found people will accept facts they are strongly motivated to deny when factual evidence is strong. However, we argue such "de-biasing" is not always a great cause for celebration. This is because though people may accept the fact, they may deny the implication, e.g. denying stage two in the case of a narrative we experimentally examined 1) fact: gay parents can be just as good parents, 2) this implies, 3) the conclusion: gay marriage should be legal. In a recent set of published (Friesen, Campbell, & Kay 2015) and a new line of unpublished experiments, we find people motivated to maintain certain beliefs from God to politics to consumer electronics, take a "flight from fact" and transform their beliefs to be more unfalsifiable when potentially falsifying facts seem more likely to endanger the narrative belief chain.

Accepting Conclusions

For completeness, we present another untested prediction of the IMMC: people will be more likely to accept the logical validity of a belief narrative with an undesirable conclusion, if they feel it lacks factual validity (e.g. accepting the idea that climate change *would* imply government policies, but believe the evidence does not support the fact climate change exists).

The IMMC's Future – Advancing Connections With Affirmation

Affirmation (Sherman & Cohen 2006) research has received a high level of attention in the psychology literature but less attention so in the consumer literature, especially when considering practical consumer applications. Particularly, we see affirmation as a force that can manage people's sensitivity to implied conclusions of facts.

For instance, those wishing to persuade system justifiers that America needs to be more environmental and motivated, may find success when they also emphasize that America is already quite environmental or generally a fine country, a different strategy that derogates America may work better for anti system Americans.

In sum, we encourage researchers and practitioners to be more aware of the implications of their communications and present the IMMC as a parsimonious but rich and ubiquitous model to help predict, understand, and alter motivated interpretation of fact-implication-conclusion narrative belief chains.

SESSION OVERVIEW

Although considerable research has explored the psychological antecedents and consequences of persuasion, very little attention has been paid to when, why, and how consumers choose to advocate on behalf of their own beliefs regarding issues or products. In this session, we define advocacy as either: (A) sharing or expressing one's opinion about an issue or product, or (B) making an explicit effort to persuade others toward one's opinion about an issue or product. Across four papers, we attempt to answer when, why, and how people choose to share their opinions, make recommendations, or persuade others, and we explore how those exposed to such advocacies react in a variety of contexts.

The current session will provide insight into the fundamental drivers of consumer advocacy and the myriad ways in which consumers respond to information sharing and persuasion attempts. Chen and Berger focus on sharing and word of mouth. They find important differences in the effects of receiving content from others versus finding it themselves: When people receive content from others, they share interesting but not boring content; however, when they find the content themselves, they do not discriminate and end up sharing both interesting and boring content. Moore, López, and De Maya focus primarily on how learning others' opinions influences consumers' product evaluations. Specifically, they investigate when and why consumers are influenced by others' opinions. They show that exposure to others' opinions impacts subsequent evaluations and purchase intentions of products, even when a participant has direct experience with the product and shows initial dislike. Interestingly, they also find that the type of information consumers receive shapes these effects: receiving more information in the form of an explanation reduces reliance on others' opinions compared to receiving relatively little explanation. Cheatham and Tormala explore the curvilinear relationship between attitude certainty and advocacy. Their findings suggest that being very high or very low in certainty can foster advocacy relative to having moderate certainty. The unexpected relationship between uncertainty and advocacy is attenuated by self-affirmation, suggesting that consumers express advocacy intentions as a way to compensate for feeling threatened by a lack

of certainty. Finally, Rucker, Dubois, and Galinsky demonstrate a power-matching effect in message generation and recipient responsiveness. Participants induced to high/low power are more convincing in their argument generation – and also more persuaded by others – when source-recipient power matches rather than mismatches. Their results offer a framework for understanding how power affects the communication and reception of persuasive messages.

Taken together, these papers provide deeper understanding of the specific experiential and social drivers of consumer advocacy. In so doing, this session offers new insight into an extremely important yet understudied topic. Consumer advocacy is a crucial component of the marketing mix and we expect that this session will attract a diverse audience, including researchers interested in persuasion, influence, advocacy, word of mouth, and power, among other topics. In addition, each paper will discuss practical applications, giving the session both theoretical and managerial importance.

Finding vs. Receiving: How Content Acquisition Affects Sharing

EXTENDED ABSTRACT

People often share online content with others. They email videos, forward new stories, and post status updates. Consistent with the importance of this phenomenon, a great deal of recent research has begun to examine what people share and why (Berger and Milkman 2012; Chen and Berger 2013). But might how people acquire content also influence whether or not they share it? Sometimes people find content themselves (e.g., coming across it while browsing a website), while other times people receive content from others (e.g., email forwards and retweets). Might these different methods of content acquisition impact sharing, and if so, how?

We theorize that one way acquisition method impacts sharing is by affecting how people evaluate content. People tend to associate found content with themselves and received content with others. Further, people tend to hold themselves in positive regard (e.g., high self-esteem, positive illusions about themselves) and tend to be less critical of things associated with the self. Consequently, compared to received content, people should be less likely to critically process found content and thus be less attuned to underlying content characteristics (e.g., whether it is interesting or well-written). Taken together, this suggests that when people find (vs. receive) content, characteristics of the content itself should have less of an impact on whether it gets shared.

In Study 1, participants were randomly assigned to either find or receive a more or less interesting article (2x2 between subjects design). Those in the receiving condition were told to "Imagine that someone emailed you the following article." Those in the finding condition went onto a mock online news website and flip through the newspaper by clicking the Next button located on the bottom of the page. After flipping through a couple of filler pages (which only displayed the messages "Article A/[B/C]"), participants were shown either a low or highly interesting article (pretested). After reading the content, participants indicated (1) how likely they would be to share the article and (2) how interesting they found the article.

Participants said they would be more likely to share the more interesting article, but this was moderated by acquisition method. While receivers were much more willing to share the high than the

low interest article, finders were less discriminating between the two. Moderated mediation confirms that this is driven by sensitivity to underlying content quality (interestingness in this case): While receivers were highly sensitive to content interestingness, and were thus more likely to share the high than the low interest content, finders saw less of a difference between the articles and their willingness to share was driven less by the content itself.

Study 2 provides further evidence for our theorizing in a more controlled setting. We selected one article and created high and low quality versions by adding typos. Participants followed the same finding versus receiving procedures used in study 1. Instead of rating the article on interestingness, participants indicated how well-written they found the article. Consistent with study 1, receivers were more likely to share the article without typos than the one with typos, finders were less discriminating and were equally likely to share the two. Moderated mediation shows that this is driven by finders being less sensitive to how well-written the articles were and thus making sharing decisions that are less dependent on underlying content characteristic. If our results – that finders are less sensitive to content characteristics – are indeed driven by people being less critical of things associated with themselves as we have theorized, then this effect should be attenuated among people who are more self-critical. Studies 3 and 4 test this idea.

Study 3 employs a 2 (Content quality: low vs. high interest) x self-esteem (measured) design. All participants imagined finding content and followed the same procedures used in study 1 with the addition of an implicit self-esteem measure (Bosson, Swann Jr., and Pennebaker, 2000). Not surprisingly, participants (in this case, all finders) were more willing to share the high than the low interest content, but importantly this is moderated by self-esteem. Moderated mediation shows that as finders' self-esteem decreases (i.e., as they become more critical of themselves), they become more sensitive to the underlying content characteristic (interestingness in this case), which in turn drives sharing.

Our last study further tests the role of self-esteem using a 2 (self-esteem: high vs. low) x 2 (Acquisition method: receiving vs. finding) x 2 (Content quality: low vs. high interest) between-subjects design. We manipulated self-esteem by giving participants positive or negative feedback on their performance on an unrelated task (adapted from Baumeister and Tice 1985; Forgas 1991). The rest of the study is identical to study 1. For participants in the high self-esteem condition, results were the same as the prior studies: finders' willingness to share depended less on characteristics of the content itself. Inducing low self-esteem, however, made finders look more like receivers: both finders' and receivers' willingness to share was equally sensitive to underlying content characteristics. It's only when finders are primed to be self-critical do they become more sensitive to content characteristic.

Taken together, these four studies show that *how* people acquire content affects their subsequent sharing behavior. Compared to people who received content from others, the willingness to share of people who found content themselves depended less on the characteristics of the content. Further, this was driven by people's tendency to be less critical of things associated with the self (as long as the self is seen positively). More broadly, this research contributes to understanding why people share. It is not just characteristics of the content itself, but also *how* content is acquired, that determines sharing.

When is Saying Believing? Sharing Sensations after Tasting New Products

EXTENDED ABSTRACT

Humans, as social beings and as consumers, have a strong motivation to share their understanding, emotions, beliefs, attitudes, and inner states with others—to create a shared reality (Echterhoff, Higgins and Levine 2009; Hardin and Higgins 1996; Higgins and Pittman 2008; Rimé et al. 1999). Such shared reality motivations lead individuals to communicate with others about referents such as people and products (Higgins 2005). Shared reality motivations underlie studies demonstrating the saying-is-believing effect, which show that “a message tailored to a particular audience influences a communicator's subsequent memory and impression of the message topic” (Hausmann, Levine and Higgins 2008). Such audience tuning (Higgins 1992) implies that consumers consider their audience's point of view when sending messages (Schlosser 2005), and shows that tuning messages to match the audience's point of view can impact consumers' memory and evaluations in the direction of the “tuned” message. Shared reality effects are stronger under conditions of ambiguity, where consumers lack a coherent interpretation of a situation or, conversely, are confronted with multiple plausible interpretations (Festinger 1950; Frish and Baron 1988). Consumers can deal with ambiguity by creating a shared reality with others, allowing them to construct an audience-congruent representation of the target and attain a greater sense of certainty about what the target is actually like (Kopietz et al. 2010).

The current research uses the context of new products to explore shared reality effects. In this context, ambiguity should play a significant role, since many new products are ambiguous with respect to the product categories that they belong to (Moreau, Markman and Lehmann 2001). In four studies, we examine when and how exposure to others' opinions influences consumers' evaluations and purchase intentions for new products. Theoretically, we extend previous work on shared reality and saying-is-believing to the consumer context; more importantly, we examine several marketplace-relevant variables that should increase or decrease the ambiguity of new products, and examine how these variables affect consumers' susceptibility to others' opinions. Practically, our results offer ways for marketers to understand and manage consumers' evaluations of new products.

Studies 1 and 2 used jellybeans with unidentifiable flavors to represent ambiguous new products. In both studies, undergraduates tasted the jellybeans. Some participants received information about others' opinions (95% of consumers like this flavor of jellybean), while others did not. In addition, in study 1, the timing of when participants received this information was manipulated to occur during or after the jellybean tasting. We predicted that even if participants received information after tasting, this would not be sufficient to eliminate their susceptibility to others' opinions because of ambiguity of the jellybean flavors. In study 2, the unidentifiable jellybean flavor was manipulated, based on pre-testing, such that participants tasted a liked or a disliked jellybean. We predicted that participants would show susceptibility to others' opinions' only in the disliked condition, because the desire to reduce ambiguity and increase understanding is greater for negative than for positive experiences (Wong & Weiner 1980).

Replicating prior work, both studies showed that participants “tuned” their opinions to others: receiving positive information about others' opinions increased participants' jellybean evaluations and purchase intentions. The timing manipulation in study 1 did not influence this tuning process: even when participants received

opinion information after tasting the jellybean, their evaluations were still influenced. However, the valence manipulation in study 2 revealed that participants were influenced by others' opinions only when they sampled disliked, rather than liked, jellybeans. This effect was so strong that participants' final, "tuned" evaluations of the disliked jellybean were equivalent to their evaluations of the liked jellybean. Thus, studies 1 and 2 suggest that shared reality effects in the marketplace are fairly robust. In contrast, studies 3 and 4 identify a variable that attenuates these effects and allows consumers to rely on their own evaluations rather than on others'.

Study 3 shows that explaining can decrease consumers' reliance on others' opinions. One might predict that receiving additional information—of any kind—about others' opinions should lead consumers to rely on them even more; however, we find the opposite. Compared to participants who received no information about others' opinions and to participants who received basic information about others' opinions (e.g., 95% of consumers like this muffin), those who received an explanation of others' opinions (e.g., 95% of consumers like this muffin because it is sugar free) did not "tune" their evaluations to others' opinions. We suggest that this is because the explanation decreases ambiguity enough to allow consumers to rely on—and to explain—their own experience with the product, without reference to others.

Study 4 (in progress) will further test the effects of explaining on shared reality by looking at hedonic versus utilitarian products (e.g., a gummy candy vs. a gummy vitamin) crossed with hedonic versus utilitarian explanations (I like this gummy because it's tasty vs. healthy). We predict an explanation by product type interaction (Moore 2012), where receiving hedonic reasons will reduce ambiguity for the hedonic product, and receiving utilitarian reasons will reduce ambiguity for the utilitarian product; this should decrease consumers' reliance on others' opinions and reduce the shared reality effect. We should find a shared reality effect only when others' explanations fail to reduce ambiguity—that is, when consumers receive a hedonic reason for liking a utilitarian product or a utilitarian reason for liking a hedonic product, they should still tune their evaluation to others'.

The current research provides a nuanced picture of when and why consumers are influenced by others' opinions in the marketplace. We find that shared reality motives have a strong impact on consumers' evaluations and intentions to purchase new products—even those that they have direct experience with, and even those that they dislike initially. However, these effects depend on what type of information consumers receive: ironically, receiving more information in the form of an explanation can reduce their reliance on others' opinions.

The Curvilinear Relationship between Attitude Certainty and Attitudinal Advocacy

EXTENDED ABSTRACT

From gun control to vaccinations to new product purchases, consumers are constantly advocating their beliefs. On Facebook, for example, friends bombard each other with countless posts commenting on current world events, exciting new products, or the hottest new bar. What drives a person to advocate on behalf of these beliefs? Despite a voluminous literature exploring the antecedents and consequences of persuasion more generally, surprisingly little is known about the determinants of attitudinal advocacy.

One factor that does appear to contribute to advocacy is attitude certainty. Attitude certainty refers to the subjective sense of confidence or conviction with which one holds one's attitude (Rucker,

Tormala, Petty, and Briñol 2014). Certainty traditionally has been viewed as a dimension of attitude strength in that it shapes an attitude's durability and impact. For example, attitudes held with certainty are more resistant to change and more influential over people's choices and behaviors (Tormala and Rucker 2007). Most relevant to the current research, it also has been shown to contribute to advocacy intentions and actual advocacy behavior—people generally advocate more on behalf of their own attitudes and opinions (e.g., share them with others and seek to persuade others to their views) when they hold those attitudes and opinions with certainty (Akhtar, Paunesku, and Tormala 2013; Barden & Petty, 2008; Cheatham and Tormala under review; Visser, Krosnick, & Simmons, 2003).

However, there is also reason to believe that states of low certainty can foster advocacy type behavior. According to Gal and Rucker (2010), when a consumer's confidence about a particular belief is undermined, he or she may feel threatened and engage in compensatory action that includes advocating more aggressively on behalf of the threatened belief. In a similar vein, Rios, Wheeler and Miller (2012) found that inducing people to feel *self*-uncertainty sometimes led them to express minority opinions more freely.

In short, based on past research there is potential controversy surrounding the role of attitude certainty in directing attitudinal advocacy. We propose that this difference might be explained by the fact that past research has examined attitude certainty at different points on the certainty continuum: moderate to high certainty in studies showing a positive relation between certainty and advocacy and low to moderate certainty in studies showing a negative relation. Our central hypothesis is that attitude certainty has a curvilinear relationship with attitudinal advocacy, such that people advocate more when they feel very uncertain or very certain, and advocate less when they are somewhere in between (i.e., moderate certainty). More specifically, we submit that high certainty fosters feelings of efficacy, which have been shown to promote advocacy in past work (Akhtar et al. 2013), whereas low certainty fosters compensatory motives, which lead people to advocate as a means of self-affirmation (Gal and Rucker 2010). We present 3 studies testing these relationships.

Study 1 used a correlational design to provide initial evidence of the proposed curvilinear relationship between certainty and advocacy. Participants were presented with several policy issues and asked about their attitudes, certainty, and advocacy intentions (i.e., their intentions to share their opinion with others and to persuade others to adopt their view). To test our hypothesis we conducted a hierarchical regression analysis. First, we observed a main effect of attitude certainty on sharing and persuasion intentions for each issue: the more certain people felt, the more likely they were to advocate. More importantly, we also uncovered a quadratic for both sharing and persuasion intentions, suggesting that both very uncertain and very certain participants expressed higher advocacy intentions than participants with moderate certainty.

Study 2 aimed to experimentally manipulate three levels of certainty to provide evidence of a causal role between certainty and advocacy. Participants were asked to think of an issue they were very uncertain, somewhat certain, or very certain about, followed by the same questions as in study 1 along with an open-ended behavioral question asking them to react to someone who disagreed with them. As predicted, we successfully manipulated attitude certainty at three levels. However, our core interest was in determining whether certainty had a curvilinear relationship with advocacy. Indeed, we continued to find significant evidence for the proposed curvilinear relationship between certainty and advocacy. Moreover, this pattern was replicated in our behavioral measure, such that participants actually advocated more at the low and high ends of certainty than

they did at moderate levels of certainty. Thus, study 2 provided experimental evidence of a causal role between certainty and advocacy.

Finally, in study 3 we aimed to provide evidence for the mechanism driving advocacy at low certainty. Specifically, if uncertain individuals express intentions to advocate because of a compensatory motivation to reduce feelings of threat or discomfort, their intentions to advocate should be attenuated following an affirmation manipulation. To test this hypothesis, we randomly assigned participants to a self-affirmation or non-affirmation control condition. Self-affirmation was manipulated using a procedure adapted from past research by Fein and Spencer (1997) and Martens, Greenberg and Schimel (2006). Participants were then exposed to a novel policy issue about lowering the national drinking age, followed by the same series of questions as in study 2. We found a main (linear) effect of certainty on advocacy intentions, and no main effect of affirmation condition. More importantly, there was also a significant curvilinear effect of certainty on advocacy intentions that was moderated by affirmation condition. The interaction indicated that the curvilinear relationship between certainty and advocacy was obtained in the no affirmation control condition but not in the affirmation condition. When participants were affirmed, the relationship between certainty and advocacy was linear and positive. These results suggest that uncertain individuals' advocacy is compensatory in nature, whereas highly certain individuals' advocacy is not.

In sum, 3 studies provide evidence for the proposed advocacy hypothesis: Attitude certainty has a curvilinear relationship with advocacy such that advocacy is fostered by very high and very low certainty (relative to moderate certainty), albeit through different mechanisms. Implications for understanding and eliciting advocacy in consumer contexts will be discussed.

The Power Matching Effect: The Dynamic Interplay of Communicator and Audience Power in Persuasion

EXTENDED ABSTRACT

How does power affect the type of persuasive messages communicators generate and message recipients are responsive to? Building on the proposition that high power increases individuals' tendency to be agentic and low power increases individuals' tendency to be communal (Dubois, Rucker, and Galinsky forthcoming; Rucker, Galinsky, and Dubois, 2012), we propose that states of powerlessness and power systematically affect the types of arguments communicators use and recipients value along two foundational dimensions of social judgments: competence and warmth (Cuddy et al. 2008). Where competence refers to perceptions of efficacy, skillfulness and confidence attached to a message, warmth captures the helpfulness, sincerity and friendliness contained in a message. Importantly, agency has been linked to competence and communion has been linked to warmth (see Rucker, Galinsky, and Dubois, 2012).

Because high-power states are associated with agency, we predict that communicators in a high-power state will generate messages related to competence and recipients in a high-power state will be more receptive to messages that emphasize competence. In contrast, because low-power states are associated with agency, we anticipate that communicators in a low-power state will generate messages related to warmth and recipients in a low-power state will be more receptive to messages that emphasize warmth. Taken together, we predict a power-matching effect: high-power communicators will be more persuasive to high-power recipients, whereas low-power communicators will be more persuasive to low-power recipients.

Two initial experiments find support for these effects in both oral and written contexts, with different manipulations of power. A

third experiment demonstrates how this knowledge can be used to craft marketing messages to consumers based on knowledge of consumers' power. Analyses used ANOVAs and t-tests as appropriate.

Experiment 1: Testing the dynamic interplay

Participants were assigned to the role of boss (high power) or employee (low power; Lammers et al. 2008) for a future task in the session. Their position was unknown to other participants. Next, in a different task, participants took part in a persuasion game. Participants were given the name of a remote, fictional sounding city (e.g., Lalibela) and were instructed to craft a message aimed at convincing others that this city was in a particular location of their choice (e.g., Uruguay). Participants took turns to orally convince others, and alternated in the communicator and recipient roles. As recipients, participants were asked the extent to which they believed the city was in the location the speaker talked about.

High-power communicators were overall preferred to those generated by low-power communicators. Of central importance to the power matching hypothesis, high-power recipients found messages generated by high-power communicators to be significantly more persuasive than those generated by low-power communicators, while low-power recipients found messages generated by low-power communicators more persuasive than those generated by high-power communicators.

Experiment 2: Testing the underlying mechanism hypothesis

Experiment 2 tested whether differences in warmth and competence explained the dynamic interplay between communicators' and recipients' power. In addition, a written context, as opposed to an oral context, was used. Participants were assigned to a 3(communicators' power: baseline, low, high) \times 3(recipients' power: baseline, low, high) between participant design. Both communicators' and recipients' power was manipulated through an episodic recall task where they described a time they lacked power (low-power condition), possessed power (high-power condition), or did not write anything (baseline condition, Galinsky, Gruenfeld, and Magee 2003). Communicators wrote a persuasive message aimed at promoting their university at a local high school. These messages were then randomly presented to recipients whose task was to judge the message on three dimensions: persuasiveness; perceived competence of the message; and perceived warmth of the message.

Results replicated experiment 1: high-power recipients judged the messages generated by high-power communicators as more persuasive than those generated by low-power and baseline communicators. In contrast, low-power recipients judged the messages generated by low-power communicators as more persuasive than those generated by high-power and baseline communicators. Among baseline recipients, there was no effect of power on persuasion. Further, mediation analyses found that among high-power recipients competence but not warmth mediated the effect of communicator's power on persuasiveness. In contrast, among low-power recipients warmth but not competence mediated the effect of communicators' power on persuasiveness. Thus, experiment 2 replicated experiment 1 and introduced evidence for the mediating process.

Experiment 3: Using Knowledge of Warmth and Competence to Craft Messages to Consumers

Based on experiments 1 and 2, experiment 3 examined how a communicator could craft their own messages to resonate with recipient power. That is, rather than vary communicator power, we

examine how a communicator could select content in their own message to persuade an audience.

Participants were exposed to an ad for a charity project. The ad was similar across conditions, with one exception: The project was supported by a “.org” in the warm condition, and by a “.com” in the competent condition. This manipulation has been used successfully to manipulate warmth and competence, respectively (Aaker et al. 2010). To measure power, we asked whether participants considered themselves more of a boss (high-power) or an employee (low-power) at work. The dependent variable was the amount of time in minutes they would spend to help with the project.

Results revealed a significant interaction, such that individuals who self-reported themselves as bosses (i.e., high-power) were willing to donate more time when the ad emphasized competence (i.e., .com) than when it emphasized warmth (i.e., .org). In contrast, individuals who self-reported themselves as employees (i.e., low-power) were significantly more willing to donate more time when the ad emphasized warmth than when it emphasized competence. In addition, differences in perceptions of warmth and competence in the charitable organization mediated low- and high-power individuals’ willingness to donate time. This experiment demonstrates how messages can be effectively crafted based on knowledge of recipients’ power.

Conclusion and Contributions

Altogether, these experiments offer a framework for understanding how power affects the communication and reception of persuasive messages. The findings have important theoretical implications for understanding interpersonal communication and persuasion as they provide the first evidence of the dynamic interplay between communicators’ and recipients’ power.

Paper #4: Self and the World: Implicit Self-Theory and Biased Motivation in Human Judgment and Decision Making

Jaehwan Kwon, Baylor University, USA
DJ Nayakankuppam, University of Iowa, USA

SESSION OVERVIEW

Consumers use different sources of information as inputs to judgment and decision-making. Some are stimulus-based, while others are drawn from memory (Lynch and Srull 1982). In both cases, consumers often recruit their beliefs to assess the available information (Wyer 2003). Previous literature has identified a number of important beliefs, such as implicit theories of essentialism (Molden and Dweck 2006) and the belief in a just world (Lerner 1980). In this session we investigate when and why consumers rely on different systems of beliefs, and the consequence of relying on such beliefs, especially on judgment and choice.

In the first paper, Shepherd, Kay and Eibach test whether belief in God influences consumer preferences for certain kinds of products. They posit that because religious consumers believe God is a source of order and stability, God can provide safety and security to their products by rituals such as blessing. Four studies find that the need for structure and personal control lead religious (but not non-religious) people to prefer blessed products.

In the second paper, Cheng, Mukhopadhyay and Schrif find that PWE, a belief system that was originally conceptualized to have its roots in religion (Weber 1905), influences consumer's tendency to apply cost-benefit heuristics in goal pursuit. Four studies show that people with high (vs. low) PWE are more likely to assume costlier means lead to better outcomes, regardless of their objective relationship.

People who subscribe to the Protestant Work Ethic believe that hard work leads to good outcomes, whereas some people may believe that desirable outcomes are equally a function of luck. However, while religious rituals may be beneficial for certain consumers, ordinary luck rituals may not always have desirable consumer consequences. In the third paper, Dong and Labroo find that luck rituals do not always make people feel lucky. Reconciling contradictory previous literature, they find that when losses (vs. gains) are highlighted, performing luck rituals makes people even less (vs. more) likely to engage in risky choice, but only among those who believe in luck.

A belief in luck is a belief about randomness. In the fourth paper, Kwon and Nayakankuppam investigate the extent to which consumers' beliefs about stability in the world impact their search for infor-

mation and choices. They find that entity (vs. incremental) theorists believe the nature of world is stable (vs. dynamic), and as a result entity theorists search for limited (vs. sufficient) information. Simulating the world using an innovative self-designed computer game, they find that entity (vs. incremental) theorists may outperform each other depending on the true nature of the world they inhabit.

This session discusses consumers' beliefs in God, luck, and how the world is organized, all important dimensions of an individual's worldview. We believe that it provides fresh perspectives on a high-impact area in consumer research. This session has the potential to be well attended by researchers interested in various aspects of decision-making, and we hope that a discussion held at the cross-roads of these areas will spark lively and productive debate.

How Symbolic Fusions with Religion Imbue Products with Increased Reliability and Safety

EXTENDED ABSTRACT

Marketing often involves symbolically associating a culturally resonant source domain with a novel target. Within most cultures, religion provides a rich stock of symbols to draw from for persuasive purposes (familiar examples include Chick-fil-A and In-N-Out Burger). Fusing products with religious symbols is also initiated by consumers. Indeed, 24% of respondents in a survey had purchased religious jewelry or items (i.e., decals) in the past year to attach to themselves or their personal possessions (Baylor University 2005). Catholics can have their pets blessed in remembrance of St. Francis of Assisi (Sweeney 2011). In India, cars and other products are frequently blessed by a Hindu priest.

The present research draws on compensatory control theory (Cutright 2012; Kay et al. 2008), and research on cultural laws of sympathetic magic (Frazer 1925; Rozin et al. 1986; 1990) to test a novel hypothesis regarding the kinds of symbolic fusions mentioned above, with the potential to provide new insights into the effects of symbolic associations between the sacred and consumer goods.

Maintaining perceptions of personal control is a key means of protecting one's belief that events in life are not random (Lerner 1980). How then do people maintain belief in an orderly, non-random world even when personal control is low, or when the need to see order in the world is otherwise heightened? Compensatory control theory suggests that in such instances, people turn to *extrapersonal* sources of control and order to reassure themselves that *something* provides order and control in the world.

God is often seen as an ultimate source of order in the world. While products may also offer a sense of order (Cutright 2012; Cutright and Samper 2014; Shepherd et al. 2011), they can also be risky, unpredictable, or undermine personal control (i.e., automobiles). We propose that when compensatory control needs are high (either chronically or situationally), religious consumers may view products as more reliable sources of control and order in their lives (i.e., seeing them as more safe, reliable, and less subject to randomness) when they are symbolically linked to God. Likewise, they may also place increased importance on having consumer goods symbolically associated with God. This prediction follows from compensatory control research, as well as theory and research on the culturally universal laws of sympathetic magic, which suggests that secular objects assimilate the supernatural properties of sacred objects when they come into contact (Frazer 1925; Rozin et al. 1986; 1990).

In four studies (2 correlational, 2 experiments) across two cultural contexts, we test whether or not consumer goods are increasingly imbued with control-affirming properties when compensatory control needs are high; that is, the product will be seen as more reliable, predictable, and safe from random events.

In Study 1 we used the personal need for structure scale (PNS; Neuberg and Newsom 1993) to measure the chronic need for order and control in the world (Cutright 2012). Because we recruited a Hindu sample from India via MTurk, where English is a second language, we administered a single, face-valid, representative item from the PNS scale. Participants were then asked to rate 28 items (e.g., car, boat, bicycle, toaster, television, computer, cellphone, washing machine, etc.) on how important it is for someone to have it blessed (i.e., a puja performed by a Pujari). As predicted, those with a higher need for structure placed higher importance on having consumer goods blessed. Thus, when the (chronic) need for order in the world is high, there is an increased desire to have consumer goods blessed.

In Study 2, we explore whether or not goods that are most seen as being subject to randomness corresponds with placing increased importance on having that item blessed. The same 28 items from Study 1 were presented to 78 Indian Hindu participants. Participants were asked to rate the importance of having the item blessed and also the perceived tendency for each item to break down or stop working without warning. As predicted, products that were seen as most susceptible to random processes on average were more likely to be seen as needing to be blessed ($r = .39, p = .04$).

Is there a causal link between symbolic religious fusions and perceptions of product reliability, and does this fusion help fulfill the need to see the world as orderly and controlled? In Study 3, Indian participants (Hindu, $n = 148$; non-Hindu, $n = 65$) were recruited and randomly assigned to either complete a memory task that decreases participants' sense of personal control, or not. They were then presented with an ad for a used car. In the fusion condition, the ad stated and showed (via images) that a puja will be performed by a pujari upon purchase, as is common at many Indian car dealerships. This material was removed in the no fusion condition. Participants were asked to rate the car's safety and how much they trusted the car with their family's safety. The predicted two-way interaction was significant; participants saw the blessed car as more safe, but only when personal control was threatened. This effect was unique to Hindu participants.

Study 4 replicated Study 3 with an American sample (Christian, $n = 84$; non-Christian, $n = 82$). Here, the car incidentally had a Christian symbol attached to it (i.e., an ichthys, or "Jesus fish"), or not. Again, the predicted two-way interaction was significant. As in Study 3, this effect was unique to the target religious group, suggesting that ritual/symbol relevance is important to this effect.

Companies may align themselves with a particular religion. Likewise, consumers may attach religious significance to personal possessions, sometimes explicitly to have that item and its users protected by divine forces. By examining these phenomena through the lens of compensatory control theory, four studies supported the hypothesis that secular-religious fusions can boost confidence in the safety and reliability (i.e., control affirming properties) of consumer goods, particularly when concerns about order and control in the world are heightened, either chronically or situationally (e.g., via threats to personal control).

Do Costly Options Lead to Better Outcomes? How the Protestant Work Ethic Influences Cost-benefit Heuristics

EXTENDED ABSTRACT

When people have multiple means available to achieve the same performance goal and these means differ in the level of cost involved, they often use the cost of the means to predict the benefit of the outcome. Kramer, Irmak and Block (2012) found that consumers judged a bad-tasting cough syrup to be more effective than a good-tasting one. Similarly, Labroo and Kim (2009) observed that people having an accessible goal evaluated a means more favorably if that means was more effortful (vs. easier) to process. Schriff, Netzer and Kivetz (2011) also found that when a goal was important, people proactively complicated the means as if this would ensure a better outcome. Despite the prevalence of cost-benefit heuristics in goal pursuit, their cause/origin is still unknown and little empirical work has investigated it. We propose that an individual's tendency to hold a cost-benefit heuristic may depend on the extent to which s/he subscribes to the Protestant Work Ethic (PWE).

The Protestant Work Ethic is a concept introduced by Max Weber (1905) to explain the historical rise of capitalism in Protestant countries. According to this theory, during the 16th-century Protestant reformation, Puritans deviated from the Roman Catholic Church and believed the true way of showing their faith to God was through asceticism and economic success. As a result, Puritans developed systematically stronger work ethics, which facilitated the accumulation of wealth and capitalism in Western Europe and North America rather than Mediterranean Europe. Although religion plays a less central role in modern society, the work ethic itself is still highly valued and passed on across generations through parenting, education, media, and popular culture (Giorgi and Marsh 1990; Kelvin and Jarrett 1985; McClelland et al. 1953). Hence the concept of the PWE has evolved over time. Psychologists today see it as a secular individual difference variable and have developed psychometric scales to measure it (Mirels and Garrett 1971). Research has shown, for example, that high-PWE (vs. low-PWE) people were more likely to engage in work-related activities while commuting (Greenberg 1978) and more likely to oppose taxation and blame the unemployed for their laziness (Furnham 1982, 1985).

The PWE has been regarded as one of America's core values and national character (Hsu 1972; Katz and Hass 1988), but it has largely been ignored in the Marketing literature. Because an essential component of PWE is a work-specific belief that "if you work hard, you will succeed" (Furnham 1990; Tang 1993) and people tend to protect their core beliefs and align their other cognitions to be consistent (Lerner and Miller 1978; Plaks, Grant and Dweck 2005), we propose that people with high (vs. low) PWE are (1) more likely to use cost-benefit heuristics in their consumer judgments, and (2) more likely to choose costlier means to achieve goals even in contexts where the costs do not objectively ensure better outcomes.

Study 1 measured PWE and manipulated cost as the pleasantness of taste in medicine. MTurkers ($N=152$) were shown a print ad of a cough syrup that claimed it tasted either awful or great. High-PWE participants judged the bad-tasting cough syrup to be more effective. However, low-PWE participants judged both syrups as being equally effective. Replacing PWE with need for cognition or trait self-control did not generate the same pattern.

Study 2 ($N=180$) was conducted on MTurk five days before Christmas. We manipulated high vs. low PWE in an ostensibly unrelated task (using a pretested manipulation) by asking participants to rank six quotes that either advocated or opposed the PWE. Then all participants named a person who lived far away and to whom they

would like to send a Christmas gift. Afterwards, we asked them to imagine that there were only two unfamiliar courier brands available, one charging 50% less than the other. Results showed that participants primed with high (vs. low) PWE expected that the more expensive brand was more likely to deliver their gift in time.

Study 3 (N=213) manipulated PWE the same way as in study 2. Then all participants made real choice between two filler tasks to do (one difficult and the other easy) before they worked on the main test in which they could earn money. When the filler tasks were framed as “training tasks”, priming high (vs. low) PWE made participants more likely to choose the difficult task. When the filler tasks were framed as “unrelated tasks” and hence not as means to the performance goal, priming PWE had no impact on choice. The results implied that high-PWE people’s choice of the costlier option was not driven by alternative mechanisms such as collecting special experience (Keinan and Kivetz 2011).

Study 4 (N=170) asked students to make a real choice between two health foods, of which one was sweet and the other bitter. Echoing study 3, people high (vs. low) in PWE were more likely to choose the bitter food, but only when its efficacy was ambiguous rather than ensured. Coding of open-ended protocols revealed that cost-benefit heuristics mediated the moderation effect on choice. Moreover, two self-reported behavioral cues related to PWE (i.e., how many hours do you work on the weekend; how much in advance of appointments do you set your alarm clock) predicted the same results as the PWE scale. This implies that marketers can customize their communications to high vs. low PWE consumers by identifying them through simple observation.

Work is a dominant feature of the daily life of most adults (Giorgi and Marsh 1990). This research shows that a person’s work-related core belief can spill over and influence consumption decisions. Four experiments showed that PWE is a parsimonious antecedent to the cost-benefit heuristics in goal pursuit, including taste-efficacy heuristic (study 1 and study 4), price-quality heuristic (study 2) and effort-outcome heuristic (study 3). Our results suggest that marketers may customize the strategy of using cost (e.g., high price, bitter taste) to signal quality depending on whether they target high or low PWE segments.

When Engaging in Luck-Rituals Reduces Risky Choice

EXTENDED ABSTRACT

Risky choices might prompt consumers to engage in luck rituals. But might engaging in a luck ritual also impact risky choice? How? On the one hand, research shows that engaging in a luck-ritual enhances self-esteem (Damisch et al. 2010), provides illusory-control over outcomes, and increases positive-expectancies of success, which are known to increase risky choice (Anderson and Galinsky 2006). However, other findings show that engaging in a luck-ritual can make people more conservative (Boshier 1973; Vyse 2013), reduce self-esteem (Tobacyk and Milford 1983) and remind them of low-controllability over outcomes, which are known to reduce risky choice.

While neither set of findings directly investigates the effect of engaging in luck rituals on risky choice, both sets of findings do show effects on factors that predict opposing effects on risk-taking. Thus, it is still unclear whether and how self-engaging in luck rituals would affect risky choice. The goal of our research is to directly investigate whether luck rituals increase or reduce risky choice.

We posit that one reason why some studies appear to predict that luck rituals will increase risky choice but others the opposite is that the domains of former versus latter researchers may have dif-

ferentially highlighted gains versus losses. People usually attribute good outcomes to the self (Miller and Ross 1975), and attributing outcomes to the self can increase perceived controllability over outcomes. If engaging in a luck ritual in a gain domain increases focus on potential gains and the self as agency for these gains, then people are also likely to perceive greater controllability over these outcomes, which may increase risk seeking tendency. However, when potential losses are highlighted, bad outcomes are likely to become more salient (Neumann 2000). People associate bad outcomes with external agency and external locus of control (Miller and Ross 1975), and outcomes associated with external locus of control have lower perceived controllability. People who engage in a luck ritual when potential losses are salient may infer external agency is not working for them, perceiving lower controllability over outcomes, and inferring they can end up unlucky. They may, as a result, make less risky choice. Five studies tested our propositions, underlying mechanisms, and the boundary conditions.

In Study 1 (N = 149), participants first reported frequency of engaging in luck rituals and how unlucky they consider themselves to be (embedded within demographic items). Then participants responded to a six-item scale measuring general risk aversion tendency in loss situations. As the scale focuses on losses, we find engaging frequently in luck rituals is related to avoiding risky choice, and the effect is mediated by individuals inferring that they are unlucky (95% CI: [.01, .19]). To investigate causality, we ran Study 2.

In Study 2 (N = 75), participants were asked to either engage in their favorite luck ritual or hold a pencil for the duration of the study while completing an “unrelated” survey regarding their willingness to take financial risk, highlighting potential losses as verified in a pre-test. They also indicated to what extent they felt unlucky and bad things could happen to them. Replicating the findings of Study 1, Study 2 showed that those who engage in a luck ritual indicated lower willingness to take on financial risk in loss situations compared to the controls ($M_{\text{ritual}} = 1.68, SD = .63; M_{\text{control}} = 2.16, SD = .79, F(1, 73) = 8.56, p < .01$). And the effect is driven by “feeling unlucky” (95% CI: [-.22, -.01]).

Study 3 (N = 104) investigated the moderating role of belief in luck. Participants first completed an inventory of scale items including the belief in luck scale (Darke and Freeman 1997). Participants were then randomly assigned to either a luck-ritual or a control condition. Meanwhile, participants completed a real gamble, which again highlighted potential losses (risk of not getting extra compensation; verified through pre-test). Spotlight analyses yielded that the effect of engaging in a luck ritual on risk aversion in loss domain occurred only for people who believe in luck ($M_{\text{ritual}} = .92, M_{\text{control}} = .60, b = 1.04, SE = .38, t(100) = 2.69, p < .01$) and the effect disappears for those with low belief in luck ($p > .83$).

Study 4 (N = 204) followed a similar procedure as Study 3 and conceptually replicated the finding of Study 3 by demonstrating the moderating role of internal versus external locus of control. We find engaging in a luck ritual (vs. not) increased risk aversion (reflected in their greater inclination to purchase additional product warranty; a loss choice-frame as verified in a pre-test) among participants with external locus of control ($M_{\text{ritual}} = .34, M_{\text{control}} = -.18, b = .26, SE = .06, t(196) = 4.15, p < .01$). This difference disappeared for participants with internal locus of control ($p > .80$). A moderated mediation model confirmed that perceived luck in decision-making mediated the interactive effect of luck ritual and locus of control on willingness to buy warranty (95% CI: [.01, .06]).

Finally, Study 5 (N = 200) directly manipulated gain versus loss frame and assessed participants’ risk seeking tendency. As predicted, and tying to previous findings (Block and Kramer 2009; Jiang et

al. 2009; Kramer and Block 2008) we found that in a gain domain, engaging in a luck ritual increased subjective likelihood of winning a lottery ($M_{\text{ritual}} = 4.90$, $M_{\text{control}} = 4.30$, $b = .30$, $SE = .11$, $t(194) = 2.75$, $p < .01$). In a loss domain, engaging in a luck ritual increased subjective likelihood of losing a gamble ($M_{\text{ritual}} = 5.18$, $M_{\text{control}} = 4.53$, $b = .32$, $SE = .11$, $t(194) = 2.91$, $p < .01$). These effects only appeared for people who believe in luck.

Theoretically, our findings are the first to recognize and reconcile two opposing predictions in the literature regarding the influence of engaging in a luck ritual on risky choice. These findings are important practically – as consumers engage in luck-rituals facing uncertainty, it is useful to know when and why the same action can reduce or increase risky choice.

Self and the World: Implicit Self-Theory and Biased Motivation in Human Judgment and Decision Making

EXTENDED ABSTRACT

People collect information before making judgments and decisions, the action that is accompanied by what is called search costs. Research documents that there is a great deal of heterogeneity among people with respect to search costs based on situational factors (Smith, Venkatraman, Dholakia 1999; Hauser, Urban, Weinberg 1993).

The current research examines whether there is also *chronic* motivational difference among individuals as to how much search would be necessary to make solid judgments and decisions; some individuals emphasize *efficiency* motives, while others emphasize *accuracy* motives in their judgments and decisions. We suggest that efficiency-oriented individuals, compared to accuracy-oriented individuals, are likely to desire constructing their judgments relatively quickly by processing less amount of information.

We propose that individual's implicit self-theory orientation may decide our motivations. Implicit self-theory refers to an individual's lay theory about the malleability of his/her personal traits. There are two distinct implicit self-theories identified—entity vs. incremental theory (Dweck, Chiu, and Hong 1995). Entity theorists believe that their personal traits are fixed, while incremental theorists view their personal traits as malleable. Research finds that people extend their implicit self-theories to other people and even to such non-human objects as brands/products (Park and John 2010; Yorkston, Nunes, and Matta 2010), when they are making evaluative judgments on those. We propose that beliefs in fixed traits (entity theory) reflect an efficiency motivation, whereas beliefs in malleable traits (incremental theory) reflect an accuracy motivation. We reason that given that individuals extend their beliefs about the malleability of the self to other people and things (presumably to the world), entity theorists are likely to see aspects of the world as relatively fixed and invariant, so that they may believe that relatively small amount of information can easily represent the core traits of things, which, in turn, induce efficiency motives in their judgments and decisions. In contrast, incremental theorists are likely to see aspects of the world as relatively volatile and dynamic, which, in turn, may induce accuracy motivation; consequently, they need to collect large amount of information to deal with these variant aspects of things and contexts.

Color-Tile Game: The Two Different Worlds

These lines of reasoning can yield different predictions on each theorist's search behaviors—more search for incremental theorists and less search for entity theorists. To test this idea, we designed a computer game, called the Color-Tile Game (<http://research3.its.iowa.edu/moneygame>). The game is designed as a world made up

of 100 tiles of 4 different colors. Under each tile is a certain payoff (negative or positive). Turning over a tile costs something. In addition to the cost of turning over a tile, one could also pay an amount to obtain some information about what is below the tile, which would then place one in a better position to decide whether to invest in turning over the tile or not (i.e., information cost). In the game, some colors are stable and predictable (they overwhelmingly pay well or overwhelmingly penalize the player). Other colors are unpredictable (they sometimes pay well and sometimes penalize the player). In other words, the stable colors reward efficiency motivations – the sooner an evaluative judgment is formed, the sooner one can avoid incurring the cost of information. The unpredictable colors reward accuracy motivations – you are well served by paying the cost of information because it lets you benefit from the subset of tiles that are rewarding and helps you avoid the lethal ones by paying a smaller cost (the information cost). We predicted that entity (incremental) theorists would 'do' better in the efficiency-rewarded (accuracy-rewarded) areas of the world rather than in the accuracy-rewarded (efficiency-rewarded) areas of the world.

Experiment

Ninety-six undergraduate students (Male = 63.5%, Average Age = 21.2) are participated in two (implicit self-theory: entity vs. incremental theorists) between-subjects design. Each participant was first primed with either entity or incremental theory (Chiu et al. 1997) and proceeded to Color-tile game. A one-way ANOVA on the number of the information options used confirmed that entity theorists hit less information options than incremental theorists ($M_{\text{Ent}} = 59.10$, $M_{\text{Inc}} = 79.00$, $F(1,95) = 10.81$, $p < .001$) across all colors, indicating that entity theorists were more likely to be efficiency-oriented whereas incremental theorists were more likely to be accuracy-oriented.

We predicted that as a result of these behavioral differences (i.e., number of information options used), there would be differences between entity and incremental theorists in the *sources* of earning. These effects should then emerge as a form of the interaction between implicit self-theory and the color of tiles. A 2 (implicit self-theory) X 4 (color of tiles) mixed ANOVA on rewards earned from each color demonstrated the significant interaction effect ($F(3,383) = 7.51$, $p < .001$), as well as the main effects of implicit self-theory ($F(1,383) = 3.97$, $p < .05$) and of color ($F(3,383) = 851.77$, $p < .001$). Planned analyses revealed that entity theorists earned more at red ($F(1,95) = 4.87$, $p < .05$) and yellow ($F(1,95) = 2.79$, $p = .098$) than incremental theorists, whereas incremental theorists did better at blue ($F(1,95) = 8.95$, $p < .01$) and green ($F(1,95) = 7.43$, $p < .01$) than entity theorists. These results confirmed our contention: entity theorists tried to *efficiently* earn money in the game (i.e., with less number of right-clicks), whereas incremental theorists tried to *accurately* earn money in the game (i.e. more number of right-clicks).

Conclusion

The current research provides the evidence of a stable motivational bias between these kinds of individuals. Entity theorists are biased towards emphasizing efficiency motives and this results in a tendency to make quick judgments with less number of "search" for efficient judgments and decision-making, whereas incremental theorists are biased towards emphasizing accuracy motives and this results in a reluctance to make quick judgments and in more number of "search" for accurate judgments and decisions. If we extend these findings in the game (each theorist's different strategies employed and different performances) into their daily lives, we may expect that entity theorists would do better in relatively stable and invari-

ant environments, whereas incremental theorists would do better in relatively dynamic and volatile environments.

SESSION OVERVIEW

“Ownership” is both a legal concept and a psychological state. Legally, ownership is recognized by society and thus protected by laws. Psychologically, ownership is a feeling that “a product is mine” (Peck and Shu 2009), even in the absence of legal ownership. When a consumer feels psychological ownership for a product, the product is often experienced as closely connected to the self (Turk et al. 2011) supported by activation in ventromedial pFC. Recent evidence suggests that similar self-memory advantages can be obtained under nonevaluative encoding conditions, such as when object ownership is used to evoke self-reference. Using fMRI, the current study explored the neural correlates of object ownership. During scanning, participants sorted everyday objects into self-owned or other-owned categories. Replicating previous research, a significant self-memory advantage for the objects was observed (i.e., self-owned > other-owned, or as part of the self (Weiss and Johar 2013). People experience mental synthesis between the psychologically owned object and the self because they feel that the product is part of the self (Weiss and Johar 2013).

This session aims to contribute to the growing body of research on psychological ownership by exploring antecedents and consequences of this construct. Four papers explore how feeling (vs. not feeling) psychological ownership for a product affects the way people (1) behave towards and form preference for the product as well as (2) evaluate themselves and behave in product-related and product-unrelated domains.

The **first** paper by Shu and Peck explores factors that facilitate psychological ownership over shared resources (e.g., rental cars, hotels). Two correlational studies and one field study demonstrate that increasing psychological ownership over a shared resource can increase preservation of shared resources, and reduce the “tragedy of the commons.” The **second** paper by Weiss and Johar focuses on consequences of feeling product ownership for self-judgment along product-traits, such as physical dimensions (e.g., height) or brand personalities (e.g., sincerity). Two experiments show that feeling ownership (lack of ownership) for a product leads people to judge their personal traits in assimilation (contrast) to respective product traits. The experiments demonstrate downstream implications for overall self-esteem and behavior. The **third** paper by Chung and Johar identifies consequences of feeling product ownership for behavior in product-unrelated domains. Many products (e.g., calculator) are relevant for some domains (e.g., algebra) but not for others.

Four studies show that feeling ownership over a product may impair people’s task performance when the task is portrayed as product-irrelevant compared to when it is portrayed as product-relevant. The **fourth** paper by Tu and Fishbach shows that people may experience feelings of ownership vicariously through others. Such implicit feelings of ownership for a product that others acquire was found to reduce an individual’s preference for that product, as if that individual already owned that product herself. This subsequently decreased their likelihood of choosing the same product.

These four papers raise several overarching research questions pertaining to the antecedents and consequences of psychological ownership. For instance, what is the interplay between shared feeling of ownership and personal feeling of ownership? What are the unique consequences and antecedents of each? Can the type of factors that induce such feelings affect the types of consequences that such feelings have for behavior? Comments and suggestions from the audiences will be sought so as to enhance the session’s quality and interactivity.

From Tragedy to Benefit of the Commons: Increasing Shared Psychological Ownership

EXTENDED ABSTRACT

Whenever resources are shared among multiple individuals, there is a risk that individuals will put self-interest ahead of common interest and fail to preserve those resources, an issue known as the tragedy of the commons. Recent research on psychological ownership has shown that peoples’ perceptions of ownership can increase resource valuation, even for items not legally owned. Building upon this idea, we propose that increases in psychological ownership for shared and/or not legally owned resources can lead to behaviors that better care for such resources.

We begin by examining three antecedents of psychological ownership; investing the self in the target, controlling the target, and coming to intimately know the target (Pierce, Kostova & Dirks 2001) and their relationship to psychological ownership. In the first two studies, we find that all three antecedents are correlated with psychological ownership. In our third study, we test how increases in psychological ownership affect behavior by conducting a field experiment with a hotel. We find evidence that when guests have more control (choosing their room), their feeling of ownership increases, as does their satisfaction with the hotel, their likelihood of returning, and whether they will tell others. We also find that people feeling more ownership take better care of the resource by leaving the room cleaner. Thus, efforts to increase psychological ownership do appear to increase care for non-owned resources.

Study 1: Investing the Self antecedent

Our initial two studies focus on antecedents to psychological ownership for shared resources in order to guide our creation of interventions for later studies of subsequent behavior. In Study 1, we asked 500 people to identify 3 shared objects or spaces (1,413 observations). For each item we asked: customization (investing the self), cleaning/maintenance (investing the self), number of people who shared the object/space, legal ownership, and psychological ownership. We found that, as expected, customization ($\beta = .13, p < .001$) and cleaning/maintenance ($\beta = .20, p < .001$), both requiring investing the self, were positively and significantly related to psychological ownership. Not surprisingly, legal ownership was also positively

Advances in Consumer Research
Volume 43, ©2015

related to psychological ownership ($\beta = .53, p < .001$). With psychological ownership as a dependent measure, all predicted antecedents were significant ($F(6, 2,455) = 321.60, \text{Adj } R^2 = .44$).

Study 2: Controlling the Target and Intimately Knowing the target antecedent

Our second exploratory study used natural variations in car rental procedures as a manipulation of psychological ownership. Some car rentals allow consumers to select their own car, while others assign a car. We expected that when a consumer can choose their own car, they would feel more psychological ownership compared to when the car is assigned, since the consumer has more control. We also hypothesized that if a person rents a car for a longer period of time, they will more intimately know the car and will feel more psychological ownership compared to a consumer who rents for a shorter time.

We administered a questionnaire ($n = 566$) in the context of a car rental. We asked each respondent if they had rented a car recently, whether they were allowed to select the car (control) and the length of the rental (intimately knowing). As expected, both selection of the car ($r = .30$) and length of rental ($r = .16$) were positively correlated with psychological ownership. With psychological ownership as the dependent variable, selection of the car and length of rental predicted ownership $F(3, 499) = 22.08, \text{Adj } R^2 = .11$. Whether a consumer was able to select a car was positively related to their feeling of ownership ($\beta = 1.21, p < .001$), as was the length of time that they rented the car ($\beta = .018, p < .001$).

Study 3: Hotel field study-Control antecedent

While the first two studies lend support to the relationship between the antecedents of psychological ownership and the feeling of ownership, we wanted to conduct an experiment to determine causation by directly manipulating an antecedent of ownership. This study also allows us to measure subsequent behavior and care of the shared resource. The context for this study was a hotel in a university town.

This study had two conditions: guests were either assigned a room as usual ($n = 42$) or they had a choice between 2 different rooms ($n = 39$). A survey was left in the room for the guests to fill out and return. As expected, having a choice of room resulted in a greater feeling of psychological ownership compared to not choosing ($M_{\text{choice}} = 5.49, M_{\text{no choice}} = 4.74, F(1, 79) = 7.52, p = .008$). Similarly, having a room choice resulted in significantly greater satisfaction with their hotel ($M_{\text{choice}} = 6.13, M_{\text{no choice}} = 5.76, F(1, 79) = 3.83, p = .054$) and a greater likelihood of staying at the hotel in the future ($M_{\text{choice}} = 6.15, M_{\text{no choice}} = 5.57, F(1, 79) = 5.68, p = .02$). Guests who could choose also indicated that they were more likely to tell others about the hotel in the future ($M_{\text{choice}} = 6.28, M_{\text{no choice}} = 5.64, F(1, 79) = 10.61, p = .002$). Finally, and very importantly, the hotel cleaning staff noted how clean the room was when guests checked out. The scale was 1-5 with 1-very messy, 2- messy, 3 average, 4=clean, and 5-very clean. Guests who felt more ownership left the room cleaner ($M_{\text{choice}} = 4.00, M_{\text{no choice}} = 3.57, F(1, 79) = 4.18, p = .04$).

Thus, results indicate that a subtle manipulation such as having guests choose between two hotel rooms increases both ownership and consumer behavior that preserves the resource. We propose that this relationship between greater psychological ownership for a shared resource and increased effort to preserve the resource offers a solution to the tragedy of the commons. Our ongoing work continues to test manipulations that can increase ownership for shared resources and also considers the public policy implications of such efforts.

Products as Self-Evaluation Standards

EXTENDED ABSTRACT

The self is a malleable concept and consumers frequently re-evaluate the self on different aspects relative to standards set by other people. By affecting consumers' self-evaluation, self-standards can shape consumer preferences (Aaker 1999) and thus understanding self-standards in consumption settings is a key interest for marketers.

Extending research on self-evaluation standards (Festinger 1954), the present research examines whether, when people evaluate aspects of themselves (e.g., how thin am I?), they use not only standards set by other people (e.g., how thin is this model?), but also standards set by products (e.g., how thin is this MacBook Air?). Although this idea is consistent with findings that people can use product traits as inputs for self-evaluation (Belk 1988; Park and John 2010), previous research do not suggest nor test our prediction that people may compare and contrast themselves to objects similarly to how individuals judge themselves vis-à-vis others.

It is hypothesized that products-as-standards affect consumers' self-evaluation in a direction that is modulated by product ownership: a consumer is predicted to judge her own traits in assimilation with traits of products she owns, but in contrast with traits of products she interacted with but does not own. For example, seeing an ad for a MacBook Air may lead a consumer to compare her own thinness to the slim product she does not own, and thus feel fatter and unattractive (contrast). However, receiving the Mac as a gift may make that consumer feel unity with the thin product and thus feel thinner and attractive (assimilation).

Why should products as self-standards affect how people evaluate themselves and why should ownership modulate the direction of the effect? Research on Egocentric Categorization (EC, Weiss and Johar 2013) shows that consumers spontaneously classify owned (unowned) objects as "self" ("not-self"). Once classified in this way, consumers are likely to judge the category "self" in assimilation to items that the category includes but in contrast to items the category excludes (Bless and Schwarz 2010). Thus, consumers may judge themselves in assimilation to owned products, which they classify as "self", but in contrast from unowned products, which they classify as "not-self." Notably, categorization principles predict this pattern not only for self-selected items that gained meaning over time (Belk 1988), but also for recently and arbitrarily acquired items, where the decision whether or not to own was not made by the consumer (Turk et al. 2011).

Two experiments supported the prediction that owning a product leads people to judge themselves in assimilation to that product, but interacting with an unowned product leads people to judge themselves in contrast from that product, and began testing EC as process. In Experiment 1, as part of a marketing study, participants assessed a 16oz traveling mug that was either short or tall. Participants randomly assigned to the "owned" condition received the mug they assessed as gift. Participants randomly assigned to the "unowned" condition received a different mug as a gift, and so did not own the mug they assessed. To capture participants predisposition to classify owned objects as "self" and unowned objects as "not-self," participants responded to a previously established "Mine-Me" sensitivity measure (Weiss and Johar 2013). As a first DV, participants responded to the Twenty Statement Task, where participants complete 20 self-descriptive statements ("I am ____"). Next, participants reported how they feel about their physical height between "very short" and "very tall," and subsequently completed the "Appearance" subscale of the State Self-Esteem Scale. Finally, participants coded each of their responses to the Twenty Statement Task (1) by whether they referred

to their physical appearance and (2) by whether they were relatively positive, neutral or negative.

An analysis controlling for gender and actual height in inch revealed that, consistent with our predictions, participants in the “owned” condition who assessed the short (vs. tall) mug felt shorter (assimilation). By contrast, participants in the “unowned” condition who assess that same short mug felt taller (contrast). Further, consistent with EC as the underlying process, although the effect was significant on average, this pattern was driven by participants who are predisposed to classify owned products as “self” and unowned products as “not-self,” namely “Mine-Me” sensitive individuals. Finally, a bootstrap mediation analysis revealed that feeling taller (vs. shorter) increased, in-turn, overall physical self-esteem, as manifested in both the close-ended appearance self-esteem scale, and in a physical appearance index created from the responses to the open-ended “I am...” questions.

Experiment 2 tested (1) the prediction that the pattern observed in Experiment 1 is mediated by the extent people classified owned products as “self” and (2) the generalizability of the results beyond physical traits to brand personality characteristics. As part of a marketing study, participants assessed headphones that were positioned as either sincere—authentically reproducing sound—or insincere—artificially improving sound. Participants were assigned either to own or not to own the headphones similarly to Experiment 1. As a DV, participants responded to the Social Desirability scale, which allows people to respond either honestly or in a socially desirable manner. To test whether innocuous expected effects on whether people respond in a socially desirable manner can manifest in a consequential behavior, subjects participated in a trivia contest with incentive and opportunity to artificially inflate their performance. Then, to test EC as process, participants reported the extent they classify the headphones they evaluated as “self.”

A bootstrap mediation analysis revealed that, consistent with our predictions, participants assessing the insincere (vs. sincere) headphones in the “owned” condition classified these headphones as “self,” and, in-turn, demonstrated greater social-desirability (assimilation). By contrast, participants assessing the same insincere headphones in the “unowned” condition classified these headphones as “not-self,” and, in-turn, exhibited lower social-desirability (contrast). A second bootstrap mediation analysis with two mediators operating in serial revealed that greater social-desirability predicted, in-turn, insincerity in the trivia contest.

We discuss (1) consequences for bridging literatures on self-judgment and product-judgment and (2) implications for the modern consumer, who often acquires objects without intention to do so (e.g., inheritances, gifts) and is frequently exposed to unowned products through ads.

The Consequences of Product Ownership: Performance Handicap in Product-unrelated Tasks

EXTENDED ABSTRACT

From gifts that we receive and items that we purchase from stores, we often feel that products that we own define who we are. In fact, consumers perceive themselves to share common characteristics with their products (McCracken 1986; Solomon 1983). These consumers tend to exhibit product-consistent behaviors (Belk 1988; Wheeler et al. 2007). If the feelings of psychological ownership lead these consumers to identify themselves with characteristics of the products, how would these feelings of psychological ownership affect consumers’ behaviors in product-unrelated tasks?

The present work investigates potential downstream effects of psychological ownership. Specifically, we propose that the ownership increases the feeling that the product trait is an important part-of-the self, subsequently activating product-consistent aspects of the self (Wheeler et al. 2007). Consequently, we argue that this impairs consumers’ ability to perform well in product-unrelated tasks. Past research shows that different situations and contexts can activate a certain self-concept while deactivating other aspects of the self (Hugenberg and Bodenhausen 2004). Because consumers activate the self by assimilating with the product traits, we predict that this may deactivate product-inconsistent traits of the self. We, therefore, expect that consumers who feel psychological ownership to a product may perform worse in product-unrelated tasks.

In Experiment 1, eighty students were randomly assigned to one of the four conditions: (psychological ownership: ownership/baseline × quiz: relevant/irrelevant). Half of the participants in the ownership condition saw a Google Maps app logo and described how the icon looks like to someone who has never seen it (a pre-test revealed that this increases the feelings of psychological ownership). Participants in the baseline condition summarized a short article. Next, all participants solved a quiz set (e.g., figuring out a color pattern of a 3-D cube and fitting a block into the cube) that was either framed as measuring people’s navigation skills (relevant) or visual art skills (irrelevant). The results showed that within the ownership condition, participants who solved the visual art quiz performed worse than those who solved the navigation quiz ($M_{\text{visual-art}} = 3.72$, $M_{\text{navigation}} = 5.56$; $p = .002$). Meanwhile, there was no difference between the navigation and visual art quiz scores within the baseline condition ($M_{\text{navigation}} = 4.41$, $M_{\text{visual art}} = 4.86$; $p = \text{n.s.}$).

Experiment 2 conceptually replicated the findings from Experiment 1 using another product, Play-Doh. One hundred one students were randomly assigned to one of the four conditions: (psychological ownership: ownership/baseline × quiz: relevant/irrelevant). We used the same psychological ownership manipulation identical to Experiment 1, but used Play-Doh as the product stimuli. After the manipulation, all participants solved the same quiz that was either framed as measuring individuals’ hand-crafting skills (relevant) or navigation skills (irrelevant). As expected, participants who felt psychological ownership to Play-Doh performed worse in the navigation quiz than in the hand-crafting quiz ($M_{\text{navigation}} = 3.26$, $M_{\text{hand-crafting}} = 4.64$, $p = .006$). Participants in the baseline condition did not differ in their scores across the two quiz types ($M_{\text{navigation}} = 4.21$, $M_{\text{hand-crafting}} = 4.12$; $p = \text{n.s.}$).

However, one may argue that priming a product may automatically activate prime-related contents while inhibiting prime-irrelevant contents in one’s mind. The inhibited accessibility to prime-irrelevant content may have impeded participants’ performance in product-unrelated tasks. In order to rule out this alternative explanation, we added the usage-recall condition, one of the frequently used priming methods referenced in the priming literature (Gillund and Shiffrin 1984; Neath and Saint-Aubin 2011). In Experiment 3, 117 lab participants were randomly assigned to one of the six conditions (psychological ownership: ownership/baseline/usage-recall × quiz: relevant/irrelevant). After one of the three manipulation tasks, all participants solved either the navigation skills quiz (relevant) or the pattern-recognition quiz (irrelevant). Consistent with our hypothesis, participants in the ownership condition performed worse in the pattern-recognition quiz than in the navigation quiz ($M_{\text{pattern-recognition}} = 4.12$, $M_{\text{navigation}} = 5.14$; $p = .049$) However, there was no difference in the performance within the baseline condition ($M_{\text{pattern-recognition}} = 5.63$, $M_{\text{navigation}} = 4.75$; $p = \text{n.s.}$), nor in the usage condition ($M_{\text{navigation}} = 4.82$, $M_{\text{pattern-recognition}} = 5.50$; $p = \text{n.s.}$). If the performance was im-

paired due to priming, people in the usage-recall condition should have performed well in the navigation quiz and worse in the pattern-recognition quiz. However, it was only the people in the ownership condition who showed such tendency. Therefore, this finding rules out the priming explanation, which argues that lower accessibility to the prime-irrelevant content leads to worse performance.

Experiment 4 uses a more direct way to manipulate the feelings of psychological ownership. Furthermore, we again rule out the priming explanation by exposing participants to the same product in all the conditions. M-turk participants ($N = 104$) were assigned to one of four conditions: (psychological ownership: ownership/no-ownership \times quiz: relevant/irrelevant). First, all participants described how they would find a calculator software on the desktop of their personal computer (ownership) or a public library computer (no-ownership). Next, all participants solved a quiz set (e.g., see boxes filled with arithmetic signs (+, ?, \times , =) and predict the composition of the signs in the next box), that was either framed as an algebraic quiz (relevant) or a visual sensitivity quiz (irrelevant). We also measured their involvement, effort and confidence in the quiz. The results showed that participants in the ownership condition performed worse in the visual sensitivity quiz than in the algebraic quiz ($M_{\text{algebraic}} = 4.19$, $M_{\text{visual-sensitivity}} = 3.00$; $p = .015$) but there was no difference within the no-ownership condition ($M_{\text{algebraic}} = 3.13$, $M_{\text{visual-sensitivity}} = 4.00$; $p = n.s.$). Moreover, we did not find any difference in their level of effort, involvement or confidence across the four conditions.

This research suggests that people who experience psychological ownership tend to have a biased active-self account, which may negatively affect their performance in product-irrelevant tasks. This project contributes to the current literature by introducing the downstream effect of psychological ownership and by highlighting the symbolic role of products.

Words Speak Louder: Conforming to Words More Than Consumption and the Role of Mentally Shared Consumption

EXTENDED ABSTRACT

Information on like-minded consumers' choices is readily available and engenders conformity (e.g., people buy popular products). Others' consumption choices convey two types of information: stated preference (others like it) and consumption/ownership (others already consumed/owned it). Which information engenders more conformity? Conventional wisdom suggests that actions (i.e., consumption) speak louder than words (i.e., stated preference); economic theory assumes that revealed preference (i.e., consumption) is closer to the "true preference" than stated preference. By contrast, we show lower conformity to others' consumption than preference. This is because consumers are mentally connected to each other and share each other's experiences (Ackerman et al. 2009; Wegner, Sparrow, and Winerman 2004). Whereas sharing others' preference increases one's own preference for the target item, thus increasing choice of it; sharing other's consumption makes people feel that they partially consumed/owned the target product and they do not need to consume it "again", thus decreasing choice of it. Six studies support our hypothesis.

Studies 1 and 2 demonstrated the basic effect. Study 1 recruited dyads and asked one person (1st mover) in each dyad to indicate his/her preferred chewing gum flavor (wintermint or sweetmint), and then fill out a survey on the preferred flavor without tasting it (preference condition) or after tasting it (consumption condition). The other person (2nd mover) then chose a flavor to taste. Results show that 2nd movers were less likely to choose the same flavor as 1st movers (i.e.,

conform) in the consumption (24%) than in the preference (53%) condition, $\chi^2(1) = 6.14$, $p = .013$. We conceptually replicated this effect in study 2 in a different domain: household items (e.g., hangers, lamps).

We propose that mentally sharing others' consumption/ownership underlies this effect and offer three types of evidence. First, mentally sharing other's consumption means that people would recall greater past consumption of products consumed versus merely preferred by others. In study 3, we showed participants popular food items (e.g., Lay's chips) and described them as either most-liked (preference condition) or most-consumed (consumption condition) by other consumers. We asked participants to report their purchase intention towards these products. They further rated how and how recently they consumed these products. We find lower purchase intention (i.e., lower conformity) ($M = 3.03$, $SD = 1.17$) but greater recalled past consumption (collapsed consumption frequency and recency; $r = .82$, $p < .001$) ($M = 2.97$, $SD = .91$) in the consumption condition than in the preference condition ($M = 3.48$, $SD = 1.11$, $t(143) = 2.35$, $p = .02$; $M = 2.60$, $SD = .93$, $t(143) = 2.37$, $p = .019$, respectively). Recalled past consumption further mediated the effect of information type on purchase intention.

Second, if mental sharing underlies the effect, we should expect it to be stronger for close others. Accordingly, study 4 employed a 2 (information type: preference vs. consumption) \times 2 (degree of mental sharing: high-with a friend vs. low-with a random customer) design. We asked participants to imagine choosing between two mugs after learning that their friend versus a random customer in the store likes versus intends to buy one mug. An ANOVA on purchase intention yielded the predicted interaction, $F(1, 122) = 5.25$, $p = .024$. When learning about close other, participants conformed to that person's preference ($M = 3.59$, $SD = 2.17$) more than consumption ($M = 3.07$, $SD = 2.20$), $t(60) = 3.12$, $p = .003$; whereas for distant others, there was no significant difference ($M = 3.32$, $SD = 2.17$; $M = 3.31$, $SD = 2.18$; respectively).

Third, mentally sharing others' consumption/ownership suggests that people should choose something different only if the new item complements, rather than contradicts with, the others' choice, because owning (in reality and mentally) two contradictory items is undesirable. Study 5 used a 2 (information type: preference vs. consumption) \times 2 (product relation: complementary vs. contradictory) design. We showed dyads two luggage tags that were described as having complementary or contradictory colors. Participants then indicated "which luggage tag do you like better?" (preference condition) or "Which luggage tag do you want to get for yourself as a parting gift of this study?" (consumption condition). We regressed conformity (1 = 2nd mover chose the same as 1st mover; 0 = different) on information type, product relation, and their interaction, and found an interaction, $b = 1.68$, $SE = .69$, $Wald(1) = 6.03$, $p = .014$. In support of our hypothesis, in the complementary condition, participants conformed more to their partners' preferences (74%) than consumption (39%), $\chi^2(1) = 9.05$, $p = .003$; whereas in the contradictory condition, there was no difference (41%; 46%, respectively).

Finally, in study 6, we explored choices in the online consumption domain (product choice on Amazon.com and video choice on YouTube) and found that when information on others' preferences ("ratings" and "number of likes") and consumption ("sales" and "number of views") was simultaneously available, the former had a greater impact on one's own choices than the latter.

Taken together, these results suggest that words speak louder than action—consumers conform more to other's preferences than consumption, and mentally sharing other's consumption underlies

this effect. We discuss the implications of these findings on conformity research and marketing practices.

Paper #4: Individual Differences in Marketing Placebo Effects: Evidence from Brain Imaging and Behavioral Experiments

Hilke Plassmann, INSEAD, France
Bernd Weber, University of Bonn, Germany

SESSION OVERVIEW

Expectancies are beliefs about future feelings, events or outcomes. A large body of literature in consumer research has shown that expectancies, shaped by marketing actions such as branding, labeling or pricing, influence consumers' sensory perception and enjoyment of products independently of their physical properties (e.g. Allison and Uhl 1964, McClure et al. 2004, Lee, Frederick and Ariely 2006). More recently, consumer research has shown that marketing-based expectancy effects operate as "placebo" effects and modify neural representations of experiences (Plassmann et al. 2008). Marketing placebo effects influence not only sensory perception, but also the actual efficacy of products claimed to trigger a specific behavioral response: the pricing of energy drinks influence drinkers' mental acuity (Shiv, Carmon and Ariely 2005), or the pricing of pills influence patients' resistance to pain (Waber, Shiv and Carmon 2008).

The four papers in this session—all in advanced stages of completion—aim to present novel findings on the psychological and neurological underpinnings of marketing placebo effects. These papers also present a large scope of marketing placebo effects in domains with high relevance for consumers, firms, policymakers and health authorities. **Amar, Ariely, Carmon and Yang** demonstrate how expectancies make counterfeiting particularly harmful from consumers' perspective: labeling products as fakes (counterfeit) decreases their actual efficacy. For instance golf players perform worse when playing with a club labeled as counterfeit. **Cornil, Chandon and Krishna** contribute to the debate on Alcohol Mixed with Energy Drinks by showing the critical role of expectancies: consuming a cocktail labeled as "Vodka Red Bull" (rather than "Vodka" or "Exotic Fruits") influences perceived intoxication and may trigger harmful behavioral responses such as sexual aggressiveness. Whereas most previous research on marketing placebo effects has examined how quality signals (such as price) can influence expectancies, **Jia, Reich and Shiv** show that transaction utility (for instance, the feeling of making a good or bad deal) can also shape consumers' expectancy and enjoyment of purchased products, independently of quality sig-

nals. Finally, **Plassmann and Weber** use a novel automated structural brain imaging approach to better understand individual differences in marketing placebo effects on a behavioral and neural level, and show that people high in reward-seeking, high in need for cognition, and low in somatosensory awareness are more responsive to such effects.

This session brings together leading scholars and uses diverse methods (field experiments, lab experiments, neuroimaging trials) to address important theoretical questions about marketing placebo effects such as the role of involvement and awareness, and the identification of personality traits and neural circuits involved in these effects. They also provide evidence of domain-specific placebo effects with substantive implications for business, consumer satisfaction and public health. We expect this session to have a broad appeal among consumer researchers interested in the psychology of expectancies, branding and labeling, public and health policy, and neurosciences.

How Counterfeiting Contaminates the Efficacy of Authentic Products

EXTENDED ABSTRACT

Counterfeiting is a rampant global phenomenon. The value of counterfeit and pirated products globally is estimated to be up to \$1.77 trillion in 2015 (ICC, 2015). Sales of counterfeit products have grown by 1700% in the past decade (Economist, 2010), affecting a remarkably broad range of industries (e.g., apparel, consumer electronics, beverage, food, pharmaceutical, tobacco, and even cars and heavy machinery) in both developing and developed countries around the world. While a number of studies have shed light on how counterfeits affect consumers' preference for authentic products (e.g., Gino, Norton, & Ariely, 2010; Grossman & Shapiro, 1988; Wilcox, Kim, & Sen, 2009), how counterfeiting may impact the consumption experience is not well understood. For example, might knowing that the Nike's golf clubs they have may be counterfeits impair expert golfers' game performance? Might knowing that there are counterfeit Parker ink pens on the market reduce how well one can write when she is using an authentic (non-counterfeit) Parker mechanical pencil?

This research aims to fill this gap in the literature. We argue and show in the lab and the field that counterfeiting can engender moral disgust—in a manner similar to the disgust aroused by exposure to physical contaminants (cf. Chapman, Kim, Susskind, & Anderson, 2009). Because moral disgust triggers repulsion and rejection responses (Chapman & Anderson, 2012), it can contaminate the consumption experience, dampening perception and even actual product efficacy. We further argue and demonstrate that, just like that disgusting substance can transfer infectious essence to another object (Rozin, Millman, & Nemeroff, 1986), moral disgust experienced towards a counterfeited product can contaminate the counterfeited brand in general, and thus harming the efficacy of authentic products in other categories of the brand.

In Study 1, we investigated whether perceiving that the golf club they used is a counterfeit could impair the performance of expert golfers, even though that club was an authentic product and those golfers were certified experts in the sport. Consistent with our proposition, the golfers were more successful at driving the balls into the holes when they thought they were using the authentic putter than the supposedly counterfeit one; even when they missed, they drove the balls closer to the holes. That these results emerged in the field,

with expert golfers, and manifested in objective performance differences, demonstrated the external validity of the effect.

In Study 2, we sought evidence of the psychological mechanism we proposed—whether moral disgust towards counterfeiting mediates the negative effect of counterfeiting on product efficacy, and whether exposure to a counterfeit can contaminate the efficacy of authentic products in other categories of the target brand. They were randomly assigned to one of two conditions. Those who in the authentic condition, were provided an authentic Parker pen. Those who in the counterfeit condition were given the same pen but were told that the product was a counterfeit. Participants were instructed to draw a line connecting the entrance and the exit of a small maze printed on paper, without touching the “walls” of the maze. Next, participants completed a word fragment task that unobtrusively assessed the level of moral disgust participants experienced (adapted from Jones & Fitness, 2008). After a short break, participants were asked to complete a second task that examined the infectious effect of counterfeiting on other product of the target brand. Participants were given an authentic Parker branded mechanical pencil and asked to work on the same maze task as they did with the pen. Consistent with our propositions, even though participants in both conditions used an identical pen, those in the counterfeit condition made significantly more errors on the maze task than those in the authentic condition. A mediation analysis established that the moral disgust participants experienced mediated the effect of counterfeiting on product efficacy. Further, consistent with the notion of contamination we proposed, prior exposure to the counterfeit pen significantly impacted participants’ performance when they switched to the pencil to work on the maze task; those in the counterfeit condition made significantly more mistakes on the maze task. A mediation analysis also established that the moral disgust participants experienced towards the first, counterfeit product (i.e., the pen) mediated the effect of counterfeiting on the efficacy of the second product (i.e., the mechanical pencil).

In Study 3, we directly probed whether counterfeits illicit physical repulsion, probing whether the effect we found could not be simply explained by the alternative account that consumers have lower quality expectation about counterfeited products. Participants were randomly assigned to one of two conditions: Whereas those in the authentic condition were asked to complete the session using the club they identified as authentic, those in the counterfeit condition, the one they thought was the counterfeit. The rest of the procedure was identical in both conditions. A laser pointer was attached to the handle end of the club. Participants were asked to hold the club head and point the laser beam (emitting from the pointer attached to the handle) at the bull’s eye of a round target with ten rings. The target was pinned to a vertical wall. Participants were asked to keep the laser beam on the bull’s eye as much as possible for 30 seconds. A high-resolution video camera was discretely set up in the lab room, recording the movements of the laser beam on the target area.

The overall distance the laser point ‘traveled’ on the target area—a measure of the extent to which participants were willing to firmly grip and control the club head—was used as the dependent measure. Supporting our proposition that counterfeiting triggers moral disgust and hence physical repulsion, participants in the authentic condition exhibited behavior consistent with tighter grip than those in the counterfeit condition—the former group’s laser beam traveled a shorter distance than did that of the latter group. Further, when we used the total distance the laser point traveled below the center line as the dependent measure, a significant difference was found. However, when we used the total distance the laser point traveled above the center line as the dependent measure, no signifi-

cant difference was found, indicating that the downward movements, which reflect the frequency at which participants loosened their grip, drove the effect we obtained with the total-distance-travelled measure. These findings thus suggest that the counterfeit effect we observed in this research cannot be simply explained by consumers’ lower expectation about a counterfeit’s product quality—this alternative account would not predict the difference in downward movements of the laser beam.

Taken together, the findings of the three studies provide converging support for our proposition that the notion of counterfeit engenders moral disgust towards the victimized brands, which, in term, can result in reduced product efficacy of authentic products.

Expectancy Effects of Alcohol-Energy Drink Cocktail Labeling on Subjective Intoxication, Risk-Taking, and Sexual Self-Confidence and Aggressiveness

EXTENDED ABSTRACT

More than 50% of American and European college students report consuming alcohol mixed with energy drinks (AMED), raising major public health and safety concerns. The US Food and Drug Administration has argued that mixing energy drinks with alcohol has a causal effect on risky behaviors because the caffeine in these drinks masks the effects of alcohol, decreasing perceived intoxication without actually reducing the effects of intoxication (Ferreira et al. 2006). This concern has prompted the FDA to ban premixed AMEDs in supermarkets in 2010.

In the last years however, new evidence has emerged refuting the masking hypothesis, the central argument used by the FDA. As summarized in review papers, “there is no consistent evidence that energy drinks alter the perceived level of intoxication” (Verster et al. 2012), and “the underlying mechanisms of action of alcohol–caffeine co-administration remain unknown” (Benson and Scholey 2014).

We argue that the current research on AMED, which has only investigated pharmacological effects in blind experiments, has overlooked psychological effects created by cocktail labeling. Research in consumer behavior has shown that brands or categorization labels can influence perceptions and actual behavior through expectancy (or placebo) effects (Ariely and Norton 2009; Irmak et al. 2011; Plassmann et al. 2008). Two studies have focused on the expectancy effects of energy drinks. Shiv et al. (2005) have shown that people solve more puzzles after drinking energy drinks believed to increase mental alertness. Brasel and Gips (2011) have shown that mere exposure to the Red Bull brand increased aggressive driving in video games. However, no research has, to date, examined whether AMED consumption can influence perceived intoxication and harmful behavioral responses through expectancy effects shaped by cocktail labeling.

We hypothesize that highlighting that a cocktail contains vodka and Red Bull (vs. vodka alone and vs. soft drinks) *increases* perceived intoxication through expectancy effects. This sharply contrasts with the FDA’s masking hypothesis that energy drinks *decrease* perceived intoxication through pharmacological effects. We argue that this happens because people generally believe that AMED consumption is more (rather than less) intoxicating than alcohol consumption alone (Marczinski et al. 2011; Peacock et al. 2013). We also hypothesize that higher perceived intoxication increases behaviors which are culturally associated with alcohol intoxication (MacAndrew and Edgerton 1969), such as sexual self-confidence and aggressiveness and general risk-taking. Conversely, we hypothesize that it also makes people compensate for the anticipated decrease in motor or cognitive capacities associated with alcohol intoxication

(Testa et al. 2006) and makes them take less risks in domains where risk-taking can be dangerous, such as driving. Finally, we hypothesize that these effects should be stronger among people who are less experienced with alcohol intoxication, because experienced drinkers are better able to estimate their actual level of intoxication (Monk and Heim 2013).

After prescreening heterosexual men with no alcohol disorders and at least some experience of social drinking (measured with the AUDIT test), we recruited 154 participants in Paris, France (Mean age=22.3). All participants were asked to drink the same cocktail containing 6cl of 40% Vodka (two standard drinks), 8cl of Red Bull and 16cl of a mix of exotic fruits for a target blood alcohol concentration (BAC) of 0.045g/dL. Depending on the experimental condition, participants were told it was a “vodka-Red Bull cocktail,” (high level of transparency) a “vodka cocktail,” (medium level of transparency) or an “exotic fruit cocktail” (low level of transparency).

We administered the Balloon Analogue Risk Task (BART) (Lejuez et al. 2002), a measure of general risk taking in which participants pump a virtual balloon to earn money while increasing the risk of losing money if the balloon explodes. We next measured sexual self-confidence by showing photos of attractive women and asking participants how likely they would chat these women up, and how likely it was that women would accept their advances. Then, we measured sexual aggressiveness with a validated scale (Ariely and Loewenstein 2006). We also asked participants how long they would wait before driving across different scenarios. Then, we measured perceived intoxication with a questionnaire, and actual intoxication with an electronic Breathalyzer. Before releasing participants (when their actual intoxication reached a low point), we measured participants’ beliefs that energy drinks increase or decrease alcohol intoxication.

As predicted, the level of manipulated transparency linearly increased perceived intoxication ($p < .001$), general risk-taking ($p = .02$), sexual self-confidence ($p = .01$) and sexual aggressiveness ($p = .04$): all these measures were highest when the cocktail was labeled “Vodka Red Bull”, lowest when labeled “Exotic fruits”, and in-between when labeled simply “Vodka”. Conversely, transparency increased linearly intentions to wait before driving ($p = .005$), with participants in the “Vodka-Red Bull” condition willing to wait the longest time.

To rule out mere priming effects of exposure to the Red Bull brand or Vodka label (Brasel and Gips 2011), we tested a moderated mediation model, which showed that perceived intoxication fully mediated the effect of “vodka-Red Bull” label on behavioral responses, and that this mediation was conditional upon people’s beliefs in the intoxicating effect of AMED consumption (i.e. the mediating effect of perceived intoxication significantly increased when participants more strongly believed that AMEDs increase intoxication compared with alcohol only). Another moderated mediation model showed that the mediation was stronger among participants with lower AUDIT score, that is, people with less drinking experience.

To conclude, while past research has investigated the non-pharmacological effects of energy drinks consumption (Shiv et al. 2005) or of alcohol consumption (Hull and Bond 1986), our research is the first to examine whether and how AMED consumption influences perceived intoxication and harmful behavior through expectancy. Our findings also suggest that it is important to distinguish between different risky behaviors, such as driving risk and sexual aggressiveness—which have often been bundled together. From a policy perspective, this research contributes to the current debate about the public health impact of mixing alcohol with energy drinks. Our results support the need for public authorities to regulate the branding

and advertising of AMED drinks, based on psychological rather than pharmacological mechanisms.

The Taste of a Bad Deal: The Effect of Transactional Utility on Experiential Utility

EXTENDED ABSTRACT

Can getting a bad deal on a bar of chocolate make the chocolate taste worse? Can accidentally paying twice when buying music online make a song sound worse? Our findings suggest “yes” on both accounts. This paper explores the notion that transactional utility, or enjoyment derived from the transaction or acquisition phase prior to actual consumption, can directly affect how much hedonic utility is derived from the consumption experience itself¹. This phenomenon is intuited by research from the past decade showing that that pre-experiential factors (i.e., factors that affect consumers before consumption occurs) such as price cues can change experiences’ hedonic and neurological reward values (e.g., Plassmann et al. 2007; McClure et al. 2004; Shiv, Carmon, & Ariely 2005; Tsai & Lee 2013). For example, wines with a higher price tag can trigger greater activation of reward centers of the brain (Plassmann et al. 2007); the same energy drink with a higher price tag can also improve cognitive performance in puzzle solving tasks (Shiv et al. 2005). The cognitive science behind such ‘mind over body’ effects stems from variations of the placebo effect, which relates to how our biology responds to cognitive expectations which go on to distort experiences (Shiv et al. 2005).

Whereas most previous research on marketing placebo effects has examined how factors such as price can influence expectations (e.g., price signals quality), which then affects the reward value of experiences, we explored the pure carry-over impact of transaction utility independent of such factors. In a similar vein, Tsai and Lee (2013) have shown that price promotions and getting a discount can influence post-purchase hedonic consumption experience via the improvement of mood, reduction of pain of payment, and change in consumption approach. Although price-discounts are one possible means of *increasing* transaction utility, the full extent of transaction utility’s relationship with experiential utility remains relatively unexplored. This paper, which tests the impact of *decreased* transaction utility, investigates the general effect of transaction utility on experiential utility by exploring how perceived goodness-of-deal affects motivational factors such as *wanting* which then affect the *liking* of consumer experiences (Berridge and Robinson 1998).

The challenge of this research and our experimental design was to find ways of manipulating transactional utility while keeping final price and perceived value of the products constant. Experiment 1 served as an initial exploration of the basic effect and explored how an incidental decrease in transactional utility that was independent of the product itself could affect experiential utility. In an online shopping simulation, participants ($N = 90$) were double-charged for the purchase of a music video in the treatment condition (and charged once in the control condition). These participants felt that the song’s listed price (\$2.99 in both conditions) was more expensive and reported lower transactional utility from their purchase, p ’s $< .05$. They subsequently reported (marginally) lower wanting and motivation to listen to the song, $p = .07$ and less enjoyment during the actual listening experience $p = .09$.

¹ Experiential utility should not be confused with overall satisfaction; it is not surprising that lower transactional utility can decrease overall satisfaction from the purchase, but traditional economic models do not consider that satisfaction from a purchase can change experiential factors such as enjoyment or taste perception.

Experiment 2 extended the findings to a wider range of products (chocolate chip cookies, dessert biscuits, and orange juice) in an in-lab shopping simulation that involved physical transactions (paying with tokens). All participants ($N = 130$) were endowed with both high quality tokens and low quality tokens which were ostensibly worth \$1 (participants were endowed with both to induce relative value for the money). By random assignment, participants were asked to spend either the high quality or low quality chips. Although the monetary values of the chips were equal (prices and other quality cues were also the same), the apparent disparity in quality of chips made it more painful to give up the higher quality tokens (higher quality tokens were more valued, $p < .05$, and spending them reduced transactional utility $p < .05$, although perceived objective costliness was no different, $p > .1$). This manipulation was akin to asking participants to spend an old, crumpled bill or a new, crisp bill. When tasting foods, participants who gave up the nicer token (lower transaction utility) reported reduced relative desire (wanting) for the foods, lower experiential utility, and less desire for repeat consumption or future purchases (p 's $< .05$). Furthermore, we found that the overall relationship between transaction utility and experiential utility for all three products was mediated by wanting for the products (Sobel = 5.55, $p < .01$). In other words, lower transaction utility reduced the relative desire for the products, which then reduced how much they were enjoyed.

Experiment 3 explored the mechanism of reduced wanting and tested a latitude of acceptance model of utility whereby lower transaction utility increased the 'standards' of taste (captured by a disjointed, piecewise utility function) – consumption experiences that were above that standard were unaffected by the increased scrutiny, while consumption experiences that were below the standard were negatively affected. Employing the same basic experimental paradigm as Experiment 2, we also randomized low (Hershey's) versus high quality (Ghiradelli's) branded chocolate. In the low transaction utility condition, participants liked the Hershey's chocolate less, were less interested in eating more, and less interested in future purchases (p 's $< .05$). However, there were no differences in ratings of liking, desire, or future interest for the Ghiradelli chocolate. The results supported a latitude of acceptance model (driven by differences in scrutiny at different thresholds) that is consistent with both the product quality moderation found in Plassman et al. (2007) and involvement mechanism intuited by Tsai and Lee (2013). Overall, our findings not only contribute to the understanding of how placebo effects operate in marketing and the downstream effects of pricing on consumer behavior, but also reveal intuitions on the basic understanding of reward and how cognitive and affective motivational forces can interact to change the processing of reward value.

Individual Differences in Marketing Placebo Effects: Evidence from Brain Imaging and Behavioral Experiments

EXTENDED ABSTRACT

Recent research has studied whether marketing-based expectancies such as price quality beliefs influence the consumption experience and subsequent behavior, but almost no research has examined individual differences in "marketing placebo effects" (MPE, see Plassmann & Wager 2014 for a review). In this paper, we suggest three moderators of MPE based on previous findings from the neuroscientific literature investigating traditional pain placebo effects. These are (1) dopaminergic processing linked to reward-seeking, (2) prefrontal activity linked to cognitive regulation and appraisal of emotional states and experiences (i.e., a top-down cognitive process-

ing), and (3) attention to or away from somatosensory experiences encoded in somatosensory brain areas (i.e., a bottom-up somatosensory processing linked to processing in the posterior insula and somatosensory cortices).

We tested in this paper whether individual differences in these three processes moderated MPE with a variety of different MPEs (price, brand labels, health claims) and sensory experiences (food and aesthetic consumption) following a two-step procedure: In the first step, we tested the neural predictions of our model using a structural imaging approach from neuroscience to study individual trait-related differences (study 1).

More specifically, we used automated structural Magnetic Resonance Imaging analysis to detect whether differences in gray matter volume (GMV, Ashburner & Friston 2000) can be linked to individual differences in MPE ($N = 90$). We found that the size of GMV in the ventral and dorsal striatum ($b_{\text{striatum}} = 2.38$, $SE_{\text{striatum}} = 0.9$, $p < .01$), the dorsal medial pre-frontal cortex (dmPFC, $b_{\text{dmPFC}} = 5.35$, $SE_{\text{dmPFC}} = 1.55$, $p < .001$) and the posterior insula ($b_{\text{posIns}} = -10.55$, $SE_{\text{posIns}} = 3.58$, $p < .005$) moderated the expectancy effects of price (high vs. low) and health claims (healthy vs. regular) on the experienced taste pleasantness for wine and milkshakes.

In a second step, we relied on existing evidence linking each of these brain areas with personality traits (i.e., the striatum with reward-seeking, the posterior insula with somatosensory awareness, and the dorsal medial prefrontal cortex with need for cognition) to further test the implications of our model for how personality traits moderate the placebo effects of price in behavioral experiments of wine tasting (studies 2a, 2b, and 2c) applying a similar design as done by Plassmann et al. 2008.

In study 2a ($N = 88$), we investigated whether reward sensitivity, measured using the reward-seeking subscale of the behavioral activation scale (BAS), predicts MPE and found that the BAS subscale scores amplified the effect of price on experienced utility ratings ($T(1, 87) = 2.98$, $p = .004$). In study 2b ($N = 85$), we investigated whether somatosensory awareness, measured using the private body consciousness subscale of the Body Consciousness Questionnaire (Miller, Murphy, and Buss 1981), predicts MPE and indeed found that somatosensory awareness moderated MPE ($T(1, 84) = -2.83$, $p = .006$). In study 2c ($N = 78$), we investigated whether a consumer's need to focus on cognitive cues might play an important role for MPE using the Need for Cognition Scale (Cacioppo, Petty, and Kao 1984). We found that the NFC scores in line with our hypothesis amplified the effect of price on experienced utility ratings ($T(1, 78) = 2.40$, $p = .019$).

Taken together, studies 2a, 2b, and 2c provided further evidence that participants high in reward-seeking and high in need for cognitive processing were more responsive to MPE, whereas subjects high in somatosensory awareness were less responsive to MPE.

In the last study, we tested the robustness and generalizability of our effects by studying whether reward responsiveness, somatosensory awareness, and need for cognition also jointly moderate the effects of the perceived expertise of artists (known artist vs. the experimenter, taken from Kirk et al. 2008) on subjective aesthetic experiences (study 3, $N = 492$). We found that the BAS ($T(1, 491) = 6.53$, $p < .001$) and NFC ($T(1, 491) = 2.44$, $p = .015$) scores indeed amplified expectancy effects on experienced utility ratings, whereas PBC moderated expectancy effects on experienced utility ratings ($T(1, 491) = -2.75$, $p = .006$).

To conclude, in this paper we investigated individual differences in MPE. We found converging evidence using different methodologies (brain imaging and behavioral experiments) that for a variety of marketing-based expectancies (process, brand labels, and

health claims) and different sensory consumption experiences (food and art) consumers high in reward-seeking and high in need for cognitive processing were more responsive to MPE, whereas subjects high in somatosensory awareness were less responsive to MPE. Understanding individual differences of marketing placebo effects is important for marketing researchers, public policy makers, and practitioners alike.

SESSION OVERVIEW

Consumers make decisions not merely to please themselves, but to prompt pleasing impressions in others. Saving up money for a designer purse, editing (and reediting) a witty tweet, or trying a couple dozen times to capture the perfect selfie all reflect the lengths consumers will go to in order to be viewed well by others. Although much previous research has examined how the motivation to impression manage influences consumer behavior, comparatively little research has examined whether consumers truly know what impressions they have encouraged. In this session, the papers converge in addressing a series of related questions: Do consumers realize how their actions are viewed by others? Might consumers' attempts to manage impressions ironically backfire? If consumers often err in these ways, why is this the case, and what actually does drive such social impressions?

The first two papers identify two ways that consumers fail at strategic impression management. Sezer, Gino, and Norton examine a sociocultural phenomenon that has been much discussed, but little researched: the *humblebrag*. Instead of directly touting one's own achievements (e.g., "Just published in *JCR!*"), people will hide them within a supposedly negative pronouncement (e.g., "so embarrassing...my phone keeps ringing and bothering everyone—reporters always call when I've just published in *JCR!*"). But given one's ulterior motive is so transparent, humblebrags can prompt more negative impressions than would more straightforward self-promotion. Berger and Barasch examine a failure of impression management in a different domain—on-line profile pictures. Although users of social networking and dating websites tend to post posed photos, those who peruse such profiles draw more positive inferences from candid pictures. Much like humblebrags, posed photos fail because they come across as contrived, disingenuous, and insincere. Consistent with

this account, candid photos no longer prompted an impression boost when they were known to be staged.

The final two papers examine impression management that is less deliberate, but that still reflects a disconnect between the signals consumers think they send and what others infer. In some cases, events simply befall consumers, who may then try to guess how others' impressions react. Moon, Gan, and Critcher show that focal evaluative episodes (e.g., winning or losing at a game show, being accepted or rejected by a peer) loom larger in the actor's mind than in social observers'. Although actors think they will then be judged as a genius or a dunce, a social favorite or an outcast, observers tend to see less information in these events. Olivola and colleagues complement these findings by examining situations in which observers pick up on a surprising amount of signal. In particular, they show that dating profile pictures convey not merely looks, but also personality. The latter is an important incrementally-valid predictor of the behavioral interest people receive on the dating market. Moreover, that so many consumer post photos conveying negative personality characteristics suggests they fail to appreciate these effects.

In total, session attendees will leave with a stronger understanding of what drives social impressions of consumers and consumers' (mis)estimates of those impressions.

The Psychology of Humblebragging

EXTENDED ABSTRACT

People are frequently confronted with a new type of self-praise: "Hair's not done, just rolled out of bed from a nap and still get hit on, so confusing!" "Two master degrees and I can't make a tablet work!" Such statements convey a complaint, an expression of dissatisfaction, or an unfavorable attitude (Alicke et al., 1992; Kowalski, 1996, 2002), yet simultaneously allow speakers to highlight their wonderful qualities. This kind of *humblebragging*—masking success in the guise of complaint—is increasingly common.

In this paper, we explore the psychology of humblebragging. Although humblebragging is ubiquitous, our results suggest that humblebragging fails to leave a favorable impression, and can even be worse than simply bragging—because people do not find it sincere.

Why do people brag in the first place? An extensive body of research has documented that people are motivated to manage the impressions that others form of them (Jones & Pittman, 1982; Leary & Kowalski, 1990; Schlenker, 1980). People desire to be viewed positively (Baumeister, 1982; Jones & Wortman, 1973; Schlenker & Weigold, 1992) and pay attention to how they present themselves in any given social interaction (Goffman, 1959). A commonly used impression management strategy is self-promotion, which allows individuals to bring their good qualities to others' attention (Tedeschi & Norman, 1985).

Certainly, successful impression management requires a balance. Because modesty is also a highly valued quality (Eagly & Aksen, 1971; Wosinka, Dabul, Whetstone-Dion & Cialdini, 1996), efforts to self-promote can backfire, causing the individual to be perceived as conceited or a braggart (Powers & Zuroff, 1988; Schlenker & Leary, 1982). Thus, people often seek to present their qualities and accomplishments indirectly (Schlenker & Weigold, 1992). For

instance, individuals may glorify accomplishments of their associates (Cialdini, Finch & DeNicholas, 1990), or may make modest attributions by giving credit to others (Tetlock, 1980). We suggest that humblebragging is an understudied yet ubiquitous indirect strategy that attempts to mask a brag in the guise of a complaint: to brag without seeming to be bragging.

Yet, humblebragging may not be an effective indirect way of self-promotion. Prior research has shown that the success of an impression management strategy depends on whether the person is able to hide his ulterior motive to be viewed positively (Giacalone & Rosenfeld, 1986; Jones & Pittman, 1982). If the desire to make a favorable impression seems to be the main goal of the person, the person's attempt to be viewed positively backfires, given people do not perceive the person to be genuine or sincere (Nguyen, Sears & Hartman, 2008; Turnley & Bolino, 2001). In short, perceived sincerity is one of the key ingredients that determine whether the individuals are successful in their attempt to be seen in a favorable light (Bolino, 1999; Eastman, 1994). Given these findings, we predicted that humblebragging would fail to leave a favorable impression, because masking bragging in complaint would seem insincere.

We started our exploration of this phenomenon by looking at social media. Prior research has shown that individuals share content online to communicate desired impressions (Dellarocas, 2003; Kollock, 1999; Lampel & Bhalla, 2007). This desire to signal favorable aspects of the self has given rise to a wide array of strategies for constructing a positive image online (Schau & Gilly, 2003). Thus, we started our investigation of humblebragging by analyzing a dataset of statements that are categorized as "humblebrags" on Twitter (Wittels, 2012). In Study 1, two independent raters judged 740 tweets from <https://twitter.com/humblebrag> on liking, perceived sincerity and perceived competence, and the extent to which they felt the person was humblebragging. All three metrics were negatively correlated with ratings of humblebragging, offering initial evidence for the danger of humblebragging.

In Study 2, we compared the effectiveness of humblebragging to "regular" bragging. In Study 2a, two hundred and one participants viewed either brags (e.g., "I have got so many internship offers." or humblebrags (e.g. "So many internship offers give me a headache."), and rated how much they liked the target, how competent the target seemed, and how socially attractive they found the target to be. In addition, they rated the target for their level of sincerity. Not only are humblebraggers liked less and seen as less competent and socially unattractive than braggers, but they are also seen as less sincere than braggers. In Study 2b, two hundred and one participants evaluated either a brag ("I get hit on all the time.") or a humblebrag ("Just rolled out of a bed and still get hit on all the time"). Again, humblebraggers are liked less and seen as less sincere than braggers, and also found to be less attractive than braggers. Humblebragging leads people to infer that the target possesses the trait less than regular bragging. In short, people do not like braggers, but they acknowledge that at least braggers are being straightforward. The effort to mask bragging in complaint is seen as disingenuous; moreover, these decreased ratings of sincerity are what drive lower levels of liking.

In Study 3, we examine how humblebragging compares to complaining. Prior research suggests that complaining can be used as a self-presentation tool (Kowalski, 1996). Individuals may complain to induce similarity and liking (Brehm, 1992) or to signal specific knowledge and selectivity (Alicke et al., 1992). Because bragging, complaining and humblebragging are all used in the service of creating desired impressions, we tested the relative efficacy of the three.

In Study 3, three hundred and two participants rated targets who engaged in complaining (e.g. "I am so bored."), bragging (e.g. "People

mistake me for a model."), or humblebragging (e.g. "I am so bored of people mistaking me for a model.") As in Study 2, targets who engaged in straightforward bragging were liked more than those who humblebragged; in addition, targets who engaged in straightforward complaining were also liked more than those who humblebragged. While people do not love braggers or complainers, they at least see them as more sincere than humblebraggers, and these ratings of sincerity drive liking ratings.

Posting Posed, Choosing Candid: Photo Posters Mispredict Audience Preferences

EXTENDED ABSTRACT

Photos are a ubiquitous channel of social communication. They are used to make inferences about the personalities of others and to facilitate decisions in a variety of domains. Changes in technology have only increased such reliance. Today, Web and App users share 1.8 billion photos a day. Such images allow people to keep in touch with existing social ties and generate new ones.

But do people pick correctly? That is, do people choose the photos that will lead to the most favorable impressions by others?

We examine this question in the context of posed and candid photos. Posed photos capture people in a particular position to present themselves in a certain way, usually looking directly at the camera. Candid photos, in contrast, don't involve posing, and capture people acting naturally or spontaneously.

We suggest there is an important disconnect between what people post and what observers prefer: while posters choose posed photos of themselves, observers may actually be more favorably disposed to candid ones (e.g., want to be friends with or date the person).

The notion that posters prefer posed photos is rather intuitive; posed photos allow people to shape how they come across and more effectively manage impressions.

Observers, however, may respond more favorably to candid photos because they seem more genuine. Genuineness or sincerity is a valued feature of people's personalities and interactions (Campbell & Kirmani, 2000; Tuk, Verlegh, Smidts, & Wigboldus, 2008). Seeming genuine can have positive effects on how much others like or are persuaded by an individual because they are less likely to think that person has ulterior motives. Along these lines, because candid photos capture people acting naturally or spontaneously, observers should see them as more genuine, which should elicit more favorable responses.

Twelve studies test this possibility in the lab and in the field.

Study 1a-1d examined various websites to test whether people post candid or posed photos. We coded over 2500 photos from different sources: Facebook profiles (Study 1a), OKCupid (Study 1b), the activity site Meetup.com (Study 1c), and Facebook newsfeeds (Study 1d). Across all four contexts, people overwhelmingly posted posed photos ($M_s = 87-93\%$).

To examine posters' preferences more directly, Study 2a had the same person submit both posed and candid photos and choose which one they would post as their Facebook profile picture. As predicted, participants were more likely to choose the posed photo than the candid one ($M = 85\%$ vs. 15% , $\chi^2(1) = 22.26$, $p < .001$). We find the same results when people chose which photo to post on an online dating site (Study 2b), which photo would lead people to want to date them (Study 2c), or which photo would lead people to want to be friends with them (Study 2d).

The first two studies demonstrate that people post posed photos, and think posed photos will generate desired responses. But are they correct?

Study 3a and 3b focused on observers. All participants were shown the same 30 photos (randomly chosen from Study 1a): half candid, half posed, but rated as equally attractive. As predicted, observers were more interested in being friends with ($F(1, 58) = 7.83, p = .007$) or dating ($F(1, 65) = 34.01, p < .001$) people who used candid photos rather than posed ones.

Study 4 measured the hypothesized underlying process while providing an even cleaner test of our theory by using a yoked design. Each participant was yoked to one Study 2 participant and viewed either that participant's posed or candid photo before rating how interested he or she was in getting to know that person. This allowed us to examine whether candid photos generate more positive responses while perfectly controlling for the individual pictured.

As predicted, observers were more interested in getting to know someone if that person used a candid rather than posed photo ($F(1, 91) = 5.42, p = .02$). Further, perceived genuineness mediated the impact of photo type on desire to get to know the person better (total indirect effect = .38, 95% CI [.04, .85]). Another study found similar results even when observers were considering photos of people they already knew.

A final study provided further evidence for the underlying process through moderation. Authenticity perceptions are shaped not only by a photo's image, but also by the underlying intent. Learning that someone knew a seemingly candid photo was being taken should make it seem less genuine. It might seem like the individual had ulterior motives when taking the photo and was thus not sincere (e.g., Campbell & Kirmani, 2000). As a result, intent should moderate the positive effect of candidness, and lead otherwise candid-looking photos to have the same effect as posed ones.

Study 5 found exactly this. Observers were more interested in getting to know someone when their photo was candid rather than posed ($t(110) = 2.73, p < .01$). But telling participants that the person in the photo was aware that the seemingly candid photo was being taken decreased observers' interest in getting to know that person ($t(108) = 3.51, p = .001$) to the level of the obviously posed photo ($t(111) = -.81, p = .42$). These effects were mediated by perceived genuineness.

Taken together, the present research demonstrates an important disconnect between photo posters and observers. People tend to post posed photos of themselves (Study 1a-d) and think that posed photos will generate more favorable responses (i.e., get them more dates or make them more friends, Study 2a-d). Observers, in contrast, actually respond more favorably to candid photos (Study 3-5), in part because they seem more genuine (Study 4-5).

These findings have important implications for self-presentation. People often assume that a curated, polished version of the self will generate the most favorable responses – that by smoothing rough edges and presenting one's best side will make others like them more. But as these results demonstrate, this assumption is not always correct. In some cases, observers may actually prefer an unvarnished perspective because it seems more genuine.

Passing (On) Judgment: Others Judge Us Less Extremely Than We Think

EXTENDED ABSTRACT

Consumers are interested in managing their social identities. They buy cars to be seen as higher-status, attend high-profile social occasions to be seen as popular, or recount recent visits to cultural

events to signal sophistication. But people are also thrust into situations in which the impressions they make are less controllable, but where the evaluative stakes remain (or seem) high. Company meetings, cocktail parties, or team trivia games are all circumstances in which people's competence, likeability, and intelligence feel on display. In light of people's interest in and concern with how they are viewed by others, it is natural to ask whether people are accurate in such meta-perceptions—perceptions of how others view them.

Previous research on the *spotlight effect* (Gilovich, Medvec, & Savitsky, 2000) has demonstrated that people often overestimate the extent to which their actions are *noticed*. People are sensitive to the hard-to-see coffee stain on their sleeve or the two hairs that keep moving out of place, even as others notice nothing amiss. The present work builds on this work in three ways. First, we examined if people understand how impressions of them change even when people unambiguously notice their actions. Second, we examine people's meta-perceptions not merely in circumstances when people might present poorly, but in cases when they present well. Third, we distinguish between mechanistic accounts of when and why meta-perceptions are in error.

The first three studies each test whether actors' meta-perceptions would be more reactive to focal successes or failures than observers' actual perceptions were. We tested this hypothesis in three evaluative domains: intelligence (Study 1), desirability as a dating partner (Study 2), and likeability (Study 3). In each study, actors were yoked to observers, meaning that the actors' behavior was publicly observable. They then went through a situation in which we could rig things to go well (*success* condition) or poorly (*failure* condition). We measured observers' social perceptions and actors' meta-perceptions at two times: before the focal event (*baseline*) and after it (*final*). All analyses were at the level of the dyad, such that we used a 2(Role: actor or observer) X 2 (Focal Event: success or failure) X 2(Time: baseline or final) mixed design, with the final factor measured within-subjects. In each study, we predicted a significant 3-way interaction indicating that actors' meta-perceptions (their assumptions of how the observers would view them) would be more reactive to the focal event (in a positive or negative direction when they succeeded or failed, respectively) than observers' impressions actually were.

In Study 1, 99 actor-observer pairs were contestants or viewers of a mock game show. Actors were videotaped, and observers watched the actors' experience on tape. In order to provide a context for baseline impressions, actors answered 10 dichotomous-choice trivia questions (e.g., "Which city is larger: San Antonio or Detroit?"), reasoning through their answers out loud. Actors and observers then offered baseline meta-perceptions and social perceptions of the actors' intelligence. Actors then went through the focal event—a single question that would allow the actors to double their prize or lose everything. Random assignment determined whether they were told they succeeded or failed. Actors and observers then offered their final meta-perceptions and social perceptions along the same intelligence dimension. The predicted 3-way interaction was significant, $F(1, 97) = 4.25, p = .04$. Actors assumed that observers' impressions would be more responsive to the focal success or failure than the observers' impressions actually were.

Did Study 1's asymmetry result from actors not appreciating how "sticky" observers' prior impressions are, or did actors overestimate the evaluative implications of the focal event? To disentangle these possibilities, Study 2 tested whether actors' meta-perceptions were inaccurate only concerning general impressions of the actor, or even for narrow interpretations of the focal event. If Study 1's results were driven merely by the unanticipated stickiness of observ-

ers' priors, we should not observe an actor-observer asymmetry on these more narrow measures. If instead the evaluative significance of the focal event differs for actors and observers, we should observe an actor-observer asymmetry even when (and perhaps especially when) judging the focal event.

In Study 2, 89 actor-observer pairs completed a study ostensibly about dating profiles. Actors began by introducing themselves and answering questions about their life. At this point, actors and observers offered their baseline meta-perceptions or social perceptions of the actors' dateability. Actors then went through a focal event. They answered what was supposedly a relationship IQ question, which (based on random assignment) they were said to have answered correctly (*success*) or incorrectly (*failure*). Actors and observers then offered their final impressions. But in this case, actors guessed (and observers indicated) not only how observers would judge the actors' dateability based on all they had observed, but how they would judge the actor merely based on the relationship IQ question in particular. Even when judging the focal success or failure in isolation, we observed the predicted 3-way interaction, $F(1, 87)=9.76, p=.002$. In other words, actors assumed that the same behavior would have more extreme evaluative implications for observers than observers indicated it did.

In Study 3, 114 actor-observer pairs went through a "friend date" paradigm. Actors were interviewed by someone who had to determine whether to include them or exclude them from a subsequent social interaction based on a short "get-to-know-you" interview. Actors were randomly assigned to be included (success) or excluded (failure). Baseline and final judgments focused on actors' likeability. The same 3-way interaction was significant, $F(1, 113)=10.94, p<.001$. Mediation analyses showed that actors thought that the act of being included or excluded strongly signaled their likeability to observers, whereas observers were less influenced than expected by the social acceptance or rejection.

Discussion will focus on implications for consumer welfare. Unnecessary efforts to rectify inaccurately negative meta-perceptions exact an unnecessary cost on consumers. But coasting on inaccurately positive meta-perceptions may lead to future disappointment. We will conclude by discussing a fourth study that outlines an intervention for correcting actors' meta-perceptions, that in so doing, identifies the origin of the judgment error.

First Impressions and Consumer Mate Preferences in Online Dating and Speed-Dating

EXTENDED ABSTRACT

We are all familiar with the old adage warning us not to "judge a book by its cover." And, yet, we often find ourselves forming opinions about others based on first appearances—the first thing we see when (or even before) we meet them (Todorov, Olivola, Dotsch, & Mende-Siedlecki, 2015). In today's increasingly visual media age, appearance is often the very first piece of information we receive about other people. Consequently, these first impressions can significantly impact our subsequent interpersonal judgments and decisions (Olivola, Funk, & Todorov, 2014).

Here, we examine the impact of appearance-based personality trait inferences on an important class of real-world decisions: consumer mate preferences (i.e., romantic partner choice). Today's consumers have at their disposal a variety of new ways to find romantic partners: the popularity of online dating sites remains one of the Internet's greatest success stories, and speed-dating events are now commonplace throughout the US and many other parts of the world. Using real-world data on user profiles and interactions obtained from

a major online dating site (Study 1) and from speed-dating events (Study 2), we measured the relationship between appearance-based personality trait inferences and consumers' dating success.

In our first study, we used data from a popular online dating service. The initial data consisted of a record of the self-reported characteristics and the interactions of 23,000 users in two major U.S. cities who used the service during a three-and-a-half-month period. Each user posted a personal profile to the dating site in order to provide potential partners with information about his or her characteristics. Our final target sample consisted of 729 users (380 males, 349 females). We had these users' dating profile photos rated according to the personality traits that they conveyed (e.g., how competent, likeable, etc., a person appeared to judges, based on their profile photo). We then examined whether these appearance-based trait inferences predicted users' overall dating success. Specifically, we looked at two measures of dating success for each user: (i) the number of people who contacted the user during the three month period, and (ii) the number of people who sent the user a message that indicated strong interest (e.g., by providing contact information or including certain key words).

In our second study, participants were a collection of people who participated in a speed-dating event. As with our first study, we had judges rate the speed-daters' photos on the same set of personality traits. We then examined whether these personality trait inferences—gleaned solely from the photos—predicted speed-dating success. Specifically, we defined success by two metrics: (i) the number of dating partners who, after the speed-dating event, indicated an interest in that person, and (ii) the number of dating partners with whom the speed-dater achieved *reciprocal* interest.

A similar methodology was used to obtain ratings of the daters' photos in both studies: Mean photo-based trait inferences for each target-user were measured by having judges provide independent ratings of the photos on physical attractiveness (a control variable) and ten different personality traits: ambition, competence, emotional stability, extraversion, likeability, openness to new experience, promiscuity, self-discipline, sympathy, and trustworthiness. We tried to equalize the number of male and female judges assigned to each trait. The photos were presented on a computer screen, one at a time, in the same form (identical dimensions and colors) they took on the dating site. However, they were presented in isolation, without the rest of the information in the dating-user's profile. The ordering of the photos was randomized for each judge and photos of male and female target-users were presented in separate blocks. Judges provided a rating for each photo using either the keyboard or mouse. Ratings were standardized within judges (across targets) before being averaged across judges to produce mean standardized ratings of physical attractiveness and personality traits for each target-user. The resulting attractiveness and personality trait scores were used in our analyses.

Although judges did not know the targets and all were blind to both the origin of the photos and the purpose of the study, we found that the photo-based personality trait inferences significantly—and substantially—predicted dating success (according to both measures of dating success, and in both studies). Appearing extraverted, open to new experience, emotionally stable, and likeable was positively related to success for both male and female users. In contrast, while appearing more ambitious, competent, self-disciplined, and trustworthy, was positively related to success for male users, this relationship was reversed for female users. Most of these relationships remained significant when we controlled for attractiveness, ruling out the possibility that our results can be explained simply as halo-effects of beauty. Furthermore, even after controlling for the infor-

mation provided in their profiles, appearance-based personality trait inferences still significantly predicted users' dating success. These results suggest that photo-based first impressions may influence a decision to contact a potential mate, even after learning other relevant information about the person. Moreover, the fact that consumers often post photos that convey undesirable personality characteristics suggests that they fail to anticipate how much negative impact this will have on their dating success.

We conclude by discussing the implications of our findings: what it means for consumers' social decisions to be influenced by appearances, why this "face-ism" is detrimental to optimal decision making, and why consumers may be naturally inclined to draw inferences from faces and therefore have difficulty inhibiting these tendencies.

SESSION OVERVIEW

Those who live along the San Andreas Fault in Southern California are jolted periodically by the movement of the Pacific plate and the North American plate as the two outer shell pieces slide over the Earth's mantle into new positions. Strain against resistance and release of pressure toward movement result in earthquake shock waves. This change is inexorable and even predictable. The geographical landscape is changed. But largely, residents in this fault zone stand upon what feels like stable ground, as the plates maintain their relative places until the pressure of moving in different directions builds to a breaking point. Scientific paradigms, like tectonic plates, move against each other and reach the breaking point periodically as well, and the jolts change the research landscape. We may experience small magnitude tremors and readjust our research accordingly. Rarely, "The Big One" knocks us for a loop and we have to rebuild our ontologies large scale. Frequently cited scientific philosophers Lakatos (1970), Kuhn, (1970a, b, c), Popper (1992 [34]; 88 [56]; 1970) and Laudan (1986) had differing opinions on progressions in scientific paradigms. We argue from Laudan's standpoint that different paradigms can function side by side, like tectonic plates, albeit in tension. Indeed, in the social sciences we see multiple paradigms co-existing and maintaining an uneasy stability (Laudan 1986; Walker 2010). We argue that the field at large benefits from open-mindedness toward these insights, and cooperation in reaching them, as researchers from multiple ontologies discover competing insights about the world of consumer behavior.

In the spirit of ACR 2015's theme "Advancing Connections" and breaking down paradigmatic silos, this session brings together and connects a neomaterialist ontological view (Coole and Frost 2010; DeLanda 2006; Deleuze and Guattari 1988; Dolphijn and van der Tuin 2012; Bryant 2011) with a re-envisioning of classic and

established consumer behavior theories. "Neo"—or "new"—materialism is a reinterpretation of the debate between idealism and materialism that has unfolded in sociology since Hegel Vs Marx. Thus we begin with a conceptual paper to outline the theoretical understanding of neomaterialism, as it relates to other paradigmatic studies. This paper looks at seminal papers in the interpretive vein, such as "Possessions and the Extended of Self" (Belk 1988), to see what might be gained by reexamining foundational works while holding a neomaterialist ontology. The result is a call for re-inquiry on a larger scale. What follow are three empirical papers that reexplore classic theories within an ontological framework embracing materiality, assemblages, and practices. The second paper reinvestigates the market maven concept (Feick and Price 1987) in the context of Chinese expatriotes living in the United States and acculturating to a complicated retail system. It specifically examines the active agency of language and the interactive web on mavens and "newbies." The third paper revisits practice theory with an emphasis on practices as emergent phenomena. The last paper explores the almost ubiquitous concept of consumer-brand relationships (McAlexander et al 2002; Fournier 1998) within an assemblage-theoretic framework. It reveals a more nuanced understanding of the way consumer-brand relationships evolve. The first question this session raises is: what can be gained by re-investigating seminal contexts (e.g. self) with new ontologies? The over-arching question, however, is: how can co-existing ontologies and epistemologies benefit consumer research? We expect a lively session as the values of diverse theoretical and methodological frameworks for research are discussed.

Ontological Flattening, Vibrant matter and Consumption: Sending Canonical Theories Back to School

EXTENDED ABSTRACT

A cursory examination of cultural research in the pages of marketing and consumer behavior journals in the last few years reveals a growing concern for understanding the roles of materiality in such basic areas as consumer experience and market dynamics. This same trend, fostered in part by scientific developments that have called into question our understanding of the most basic aspects of matter and existence, is sweeping through other social sciences as well (Coole and Frost 2010). Neomaterialist thinkers, although by no means completely unified in their views, agree that the idealist cultural turn in social sciences and philosophy has run out of steam. They tend to agree on other principles as well. Matter is vibrant, they say, not inert. The boundaries of bodies are porous; systems are open, not closed, and they are characterized more by complexity than by linear cause and effect. Objects have agency that resists, shapes and even defies human will. Every phenomenon is emergent, becoming, and constantly materializing. Finally, the vibrancy of matter and the agency of objects naturally lead to what DeLanda (2006) calls a flat ontology—flat in that it is non-hierarchical, flat in that it refuses to automatically prioritize human agency over that of objects or nature or other actors in a system.

This paper brings the flat ontology and object agency of neomaterialist thought to bear on key, even canonical, theories and

constructs from marketing and consumer behavior, and it poses the question: What might we gain by bringing materiality to the forefront? For example, consider the seminal article "Possessions and the Extended Self" (Belk 1988). From an ontologically flat perspective it would make just as much sense to discuss "Selves and the Extended Possession." In neomaterialist terms the reality lies somewhere in between. To plot the actual path between social construction and material structure we would begin by construing the self not as an extension of some agentic and essential individual into and through inanimate objects, but rather as an assemblage of vibrant matter of all kinds, of which the human consumer is but one (mostly) conscious manifestation and organizing force. We might argue for an alternative conceptualization along the lines of "The Assembled Self," as Belk begins to (2014)—a constantly emergent constellation of the individual consumer and all of the various other materialities and meanings with which the consumer intersects in a meaningful way. Any perceived essence of self would emanate from the assembled self's relative stability due to territorialization (Deleuze and Guattari 1988) through meanings produced by the consumer in conjunction with the consumer's cultural context, which itself is a territorialized socio-technical assemblage in a constant state of becoming.

Considering an assembled versus an extended self we might pose certain hypothetical questions. Does a consumer, for example, extend her capabilities, her power, and her public persona into the world through her choice of an automobile? Certainly, she does. But does not the automobile also choose the consumer and thus extend its power into the social world? We answer yes, for the automobile is a vibrant assemblage, not only of artfully combined materials but also of all the meanings, communications and representations focused, through a logic of market segmentation, on the consumer. The consumer's potential is enhanced by the automobile, and the automobile's potential is unleashed by the consumer — differently, we would add, than it was by the dealer or would be by subsequent owners. The consumer-plus-automobile constitutes a new assemblage that is different in both function and meaning than either of the assemblages that comprise it, or even than their sum, and it is different in every social context through which it rolls.

One specific neomaterialist epistemology, actor-network theory (ANT), would conceive of the assembled self as an actor-network, that is, as a techno-social assemblage of both humans and non-humans acting in relation to one another to co-constitute identity. Normally ANT scholars, with their background in science and technology studies, don't engage in individual identity-level research. They do however consider every actant in an assemblage to be a black box, which is itself an actor-network (Latour 1987), which opens the door to examine identity as an actor-network. Taking Callon's (1986) view of an actor-network as the product of translation, the individual would problematize identity and then enroll and mobilize identity resources in the identity construction project. The individual's consciousness would act as an obligatory point of passage for other relevant actants, including possessions broadly construed, but also ideologies and entertainment, food and drink, and all the technologies, toxins, viruses, flatteries and other forces visible and invisible, bidden or otherwise, that act upon the individual. The individual's agency would not automatically prevail, however, over the agencies of other actants in the assemblage. It would, rather, attempt continually to achieve a stable, albeit contextual, identity assemblage in the face of destabilizing actants.

Maven 2.0: The Newly Assembled Interactive Ex-Pat Market Maven

EXTENDED ABSTRACT

The market maven construct, introduced by Feick and Price in 1987, has been examined for retail markets (Abrat and Nezer 1995), for couponing (Price and Feick 1988), and in industry (Natarajan and Angur 1997). It has been tested across product categories (Slama and Williams 1990), extended into Internet activities for teen internet mavens and others (Belch et al. 2005) and looked at in WOM (word of mouth) and "what goes viral" studies (Ho and Dempsey 2010). These studies and more on the maven construct yield different findings in different retail, institutional, and especially changing media contexts. Yang and Zhou (2012a; 2012b) and Yang (2013) examine the market maven concept online for Chinese consumers. They show cultural differences further complicate this variation. When more and more extensions have to be made to fit a construct to developing trends, it may be fruitful to look at the phenomenon with a new ontology. In this paper, we examine the market maven construct with the ontology of neomaterialism, to uncover the effect of the actors, including technology, upon each other in an interactive online community of Chinese retail experts and newbies in the U.S.

With the advent of Web 2.0 (O'Reilly 2005), the Internet has become a new medium for community-based social interaction, where people share information, exchange opinions, and discuss ideas about various topics (Kozinets et al. 2010). Therefore, this medium can play an important role in maven behavior by providing a two-way communication platform to acculturation agents and new entrants. Tracing posts on a widespread Web 2.0 social vehicle (Abbasi and Chen 2008), our study focuses on a Web forum platform, where different people can initialize or join discussions to learn from, or teach others about, the American retail environment. The US marketplace is governed by a host of contradictory situational norms that can confuse even the savviest American consumers. For example, depending on the retail circumstances, consumers pay full asking price (i.e., grocers, clothing boutiques, and department stores), haggle (i.e., automobiles, and bundled goods and services), bid (i.e., antiques and eBay), barter (i.e., co-operatives), and tip (i.e., restaurants and bars). Consumers may pay in advance, pay at the time of purchase, pay in installments, pay a third party over time, or even lease. A consumer is unlikely to have perfect market information, therefore, the most favorable price or "best deal" on a given product across stores is virtually unknown (Urbany, Dickson and Sawyer 2000). Those consumers less familiar with the rules and norms of the American retail environment (e.g., immigrants, temporary residents and tourists) are at a severe disadvantage, and often use Web 2.0—that is, interactive web platforms—to understand the markets. Here, within forums and other interactive platforms, they can correspond with, or lurk and watch, online market mavens sharing their knowledge, and grow their capacities to work with the US retailing system.

Our study site is the largest, most popular and most active Web forum among the hundreds of thousands of Chinese students and professionals scattered throughout the U.S. and living elsewhere abroad. The forum is not accessible within China. The forum has a dynamic set of approximately 400 different sub-boards across many topics ranging from legal residency to child care and education. On these platforms, newbies ask questions, and experts offer help, guidance, and advice. With longitudinal archived data, we use empirical qualitative and quantitative data, including linguistic analysis, to analyze a large database of specific sub-forum posts focused on explaining the US couponing system. We demonstrate that the online forum, MITBBS (<http://www.mitbbs.com/>), serves not only as an ac-

culturation platform where Chinese immigrants and foreign nationals interact to discuss the rules and norms of American retailing, but that it also serves as a place where market mavens act as acculturation agents.

Most importantly, we revisit the market maven concept with a neomaterialist ontology to show the agency of the material as it acts upon the consumers. Web 2.0, the mavens, the couponing systems, the retailers, the newbies, and the lurkers act upon and co-create each other. By focusing on the materiality of the system, including the actant nature of language and the Web and Internet forums themselves, we find the agency of language as a collective phenomenon as it appears on the site, the agency of Web 2.0 as its features both constrain and free mavens, newbies and lurkers in their actions, and the agency of couponing bundles as their force shapes the types of interactions. We find that the medium and agency of Web 2.0 has been undertheorized in the literature of either acculturation or the market maven phenomenon. We argue that bringing a neomaterialist lens to the maven construct reveals previously hidden social dynamics by foregrounding the materiality inherent in what is a complex and emergent system.

Practice Interrupted: When Fatal Disruptions and Irreconcilable Distortions Erode Mutual Understanding and Destroy Social Order

EXTENDED ABSTRACT

Neomaterialist ontologies share the perspective that all social phenomena are emergent, in a constant state of becoming. Within studies of practice, however, there exists an assumption of stability as practices reproduce themselves through human carriers. In general, theories of practice “account poorly for change” (Southerton et al. 2012, 240) and most empirical studies do not capture temporal or cultural changes in practices (Warde 2005). This study revisits practice theory with an ethnomethodological emphasis on practices as emergent phenomena highlighting production cohort responses to breaches and replication trajectories.

Marketing scholars have historically focused on individual consumers’ brand experiences (e.g., brand loyalty), however, research revealing the complex nature of collective brand relationships has evolved (Schouten and McAlexander 1995; Muñiz and O’Guinn 2001; Cova, Kozinets and Shankar 2012; Diamond et al 2009; Arsel and Bean 2013; Canniford and Shankar 2013; Epp and Price 2010; Epp, Schau and Price 2014; Schau, Muñiz and Arnould 2009; Thomas, Price and Schau 2013). Specifically, the application of social practice theories to the marketplace has gained traction within marketing and consumer research in the last two decades. From Holt’s (1995) formative research illuminating a typology of consumption practices that explain how consumers consume, market researchers have been fascinated by practice theories as products and brands are implicated by, and in many cases embedded in, practices (Warde 2005; Schatzki 1996; Schau et al 2009; Epp et al 2014). In fact, consumers’ experience of products and brands is almost wholly comprised of practices (Brakus, Schmitt and Zarantonello 2009), especially those related to use.

Using Reckwitz’s (2002) definition of practices as manifest behaviors consisting of interconnected bodily enactments, mental activities, materials, and contextual knowledge, we affirm Warde’s (2005, 131) assertion that the basic assumption of practice theory is that “consumption occurs as items are appropriated in the course of engaging in particular practices and that being a competent practitioner requires appropriation of the requisite services, possession of appropriate tools, and devotion of a suitable level of attention to

the conduct of the practice.” For example, Thanksgiving is a practice, that is enacted annually according to broad cultural action templates within local production cohorts that involve objects (heirloom dishes), recipes (blueprints for use), brands (recipe inputs) and social norms (who participates and what their role is) (Wallendorf and Arnould 1991). Practice theorists stress practice continuity, where practices are routinely carried out by cohorts (Halkier et al. 2011; Schatzki, Cetina, and Savigny 2001; Warde 2005).

Previous literature on practice replication within kinship collectives primarily addresses intergenerational transfer of holiday and occasion rituals (Belk 1990; Escalas 1993; Wallendorf and Arnould 1991), family meals (DeVault 1991; Moio, Arnould and Price 2004), recipe transfers (Baker, Karrer, and Veeck 2005; Arnould and Epp 2006), literacy (Wagner and Spratt 1988), and obesity (Grier et al. 2007). This research is biased toward practices that replicate with minor treatment of practice interference. Moio et al (2004) discuss how meanings of practices shift between generations, and also how physical distance between family members of different generations can inhibit transmission of practices. Epp et al (2014) employ assemblage theory to understand the continuation of family practices despite physical separation and address briefly non-replication scenarios. Here, we focus on practice replication in dynamic production cohorts loosely based on kinship, not specifically intergenerational transfer, and explicitly allow for non-replication of practices.

Drawing on Garfinkel’s (1967) ground-breaking work asserting the significance of everyday taken-for-granted actions that constitute social order, we employ ethnomethodology, and specifically the focus on breaches, or disruptions, to examine the flexibility of practices and the boundary conditions that enable and inhibit practice replication among production cohorts. Here, we examine a specific form of production cohort, collectives loosely based on kinship. We focus on practices that have been replicated at relatively predictable intervals across dynamic production cohort memberships and highlight the breaches that define the boundary conditions for practice replication.

Linking ethnomethodology and practice theory, Lynch (2001, 141) treats ethnomethodology as both a “praxiology... to investigate the logic or logics of ordinary practices” and the inscribed logics themselves. Likewise, in conversation analysis, Sacks (1992) proposed that a term can be both “a general analytic concept and a contingently produced phenomenon” (142). Hilbert (1990) cites this tacking between the macro and micro levels of phenomenon (abstract and contingent) to be a key strength of ethnomethodology. Here, we wield this strength in the service of understanding the breaches when a practice failed to happen (Lynch 2001, 141) or practice non-replication.

Our data consists of 62 informants within 15 loose kinship collectives where it was possible to interview two or more members of each production cohort. Our long interview protocol was designed to access the lived experience of replicating practices, as well as those that fail to replicate. From our dataset, we were able to identify three broad practice trajectories (replication, revised replications, and non-replications) based on practice flexibility, or the elasticity of the practice to sustain mutual understanding in the face of changing circumstances and improvisation. Practice flexibility is strongest in replication, appears in a weaker form in revised replications and is stretched beyond the limits of coherence in non-replication. We find these trajectories are not static. A practice can move along one trajectory but reverse path and move along a different trajectory based on patterns of disruptions and distortions that erode mutual understanding and destroy the current social order. We identify fatal disruptions (e.g., production cohort quorum, consumption material access, and

venue) and irreconcilable distortions (e.g., competing logics regarding authenticity, performance standards, and outcomes) that erode mutual understanding, the central necessary condition for practice replication, and result in practice abandonment and/or production cohort disbandment.

Understanding Dynamism in Consumers' Relationships with Brands Through Assemblage Theory

EXTENDED ABSTRACT

Consumer-brand relationships (CBRs) are prevalent in individuals' lived experiences. Research acknowledges variations in the types of CBRs, and identifies certain trajectories within them. Prior research treats these relationships as dyadic, governed by interactions between a consumer and a brand with less consideration given to other influences that may affect them. Such a narrow focus may not provide a complete understanding of CBRs; a more systemic view is warranted. In contrast to prior research on CBRs, which privileges communications between a consumer and a brand, we explore a broader complement of influences that support the initiation, transformation, or dissolution of consumer-brand relationships.

Fournier's (1998) seminal work on CBRs employed interpersonal relationship theory to explain consumers and their relationships with brands. That groundbreaking research changed how CBRs were understood, yet that theorizing provides a limited view. We employ assemblage theory as a lens to explore aspects of consumer-brand relationships that are invisible to interpersonal relationship theory. We focus on changes in CBRs. Assemblage theory takes the stance that all social phenomena result from the relationships among the agentic actants, or forces that generate them. All assemblages are emergent; that is, everything is relational, everything changes, and change is constant—a perspective that is especially conducive to studying relationship dynamics.

In any given assemblage there are periods of greater and lesser stability. Relatively stable assemblages may be deterritorialized by new actants and relationships, leading to reterritorialization and new assemblages. Consumer brand relationships, as assemblages, inevitably change as consumers' lives, contexts and needs evolve. Brands also evolve due to factors such as the competitive environment, consumer preferences, and the needs and actions of firms. As an example, consider Meredith's relationships with brands of digital camera:

My first one or two digital cameras were [by] Kodak and I think they were good for introducing me to the world of digital photography. But then they were a little too 'beginner' for me is what I ultimately concluded. They are just a little bit bulkier and a little bit less fancy and stuff... and so I decided that I was ready to try a more heavy-duty one... I researched them online to find out what brand I was most interested in, and what-not, and then I went to the store, because they have them out, and actually felt how they felt in my hand and got an insider's perspective, I guess, from the people working there, and then went back to the internet after writing it down, and then looked at customer reviews and then ultimately decided on [a Canon] and then purchased it in-store. ~ Meredith

This single, short narrative recounts how a reasonably stable relationship with Kodak becomes deterritorialized through a complex set of interactions—among a consumer, her goals and expertise, brand messaging, product designs, competitor offerings, merchandising, retail staff and other camera users in both on- and off-line contexts—and reterritorialized as a relationship with Canon.

This study examines many such CBR assemblages with a sharp focus on the shifting relationships that shape them. We identify factors that both increase and decrease territorialization or stability. In the example cited above, the Kodak CBR was deterritorialized in part by Meredith's own growing competencies. If Kodak had participated in that growth, the brand may have been able to lead Meredith through product upgrades within a brand family where she already felt comfortable.

Other findings also promise to enhance our understanding of CBR dynamics. It seems clear that limiting analysis to the consumer-brand dyad ignores the importance of other actants in the assemblage. Meredith's relationship with Kodak, once deterritorialized, opened itself to a world of information and gave that information room to percolate. It also appears that change trajectories in CBRs are more nuanced than previous research has suggested. A CBR is embedded in a life context, and movement in that context opens many possible lines of flight for the consumer to redefine or exit the relationship. Whether that happens or not may depend on how stable or territorialized the assemblage is as well as the influence of forces upon it.

Further, brand loyalty can be conceptualized as a highly territorialized and therefore stable CBR assemblage. This is consistent with the conceptualization of McAlexander et al. (2002) of brand loyalty as integration in a brand community by way of a network of relationships among human and non-human actants, that is, with other consumers, with institutions, with branded objects and with brand symbols and narratives. Another highly territorialized type of CBR assemblage occurs in what Coupland (2005) describes as brands being sufficiently embedded in consumer rituals as to be completely taken for granted. If consumers accept brands unreflectively as natural parts of their lives, they are less likely to seek replacements.

Through this research, we advance the present understanding of CBRs through the lens of assemblage theory as we explain the means by which CBRs may change through time. Finally, we discuss implications for research and practice.

SESSION OVERVIEW

Motivation – the drive to act – is a persistent feature of human nature. Whether to work or play, to approach or avoid, to change or stay the same, people’s behavior is often energized toward some valued end. Yet while motivation may look the same from an observer’s perspective, it can arise from very different underlying sources. Generally speaking, motivation is intrinsic if a course of action is autonomously chosen and self-determined, but extrinsic if imposed by external forces (Deci and Ryan 1985; Ryan and Deci 2000). Specific behaviors can also be intrinsically motivated if done for their own sake (i.e., the inherent pleasure they bring), but extrinsically motivated if done for the instrumental benefits they provide (Fishbach and Choi 2012; Laran and Janiszewski 2011). Compared to extrinsically motivated behaviors, intrinsic motivation has many positive consequences, including enhanced performance, persistence, and creativity (Sheldon et al. 1997) heightened vitality (Nix et al. 1999), self-esteem (Deci and Ryan 1995), and general wellbeing (Ryan, Deci, and Grolnik 1995). But beyond identifying its consequences, many important questions remain about intrinsic motivation processes. This session provides new perspectives on this topic.

Four papers explore consumers’ engagement in intrinsically motivated behaviors. The first two papers focus on classic intrinsic pursuits – learning, exploration, and curiosity – examining behaviors arising from each drive. Rudd and Vohs identify a novel factor (awe) that enhances intrinsic motivation to learn and create. Four experiments demonstrate that experiencing awe increases consumers’ desire (and willingness to pay) for experiential creation. Hsee and Ruan investigate people’s innate curiosity. Their findings identify a pernicious consequence of curiosity and the intrinsic drive to resolve it: curiosity makes people seek out information with negative hedonic repercussions.

The last two papers explore factors influencing the enjoyment of intrinsically motivated behaviors. Woolley and Fishbach examine the role of timing (i.e., whether consumers evaluate an experience while they are having it versus before or after). Six studies demonstrate that intrinsic incentives matter more inside (versus outside) an activity. These incentives increase persistence by enabling a positive experience, yet people outside pursuit do not anticipate this effect. Finally, Etkin and Berger investigate how measurement shapes motivation, testing how quantification affects the enjoyment of intrinsi-

cally motivated behaviors. Three experiments show that measuring how much of an intrinsically valuable activity people do (e.g., the number of steps taken or number of pages read) leads them to enjoy the activity less.

Together these papers connect classic research on intrinsic motivation processes with modern-day phenomena, using the former as a lens to help understand the latter. Further, by identifying factors that encourage intrinsically motivated behaviors, as well as ones that thwart their enjoyment, the findings shed light on what consumers can do to enhance and protect the activities they enjoy. This session should have broad appeal to scholars interested in motivation, enjoyment, experiential consumption, and wellbeing, as well as connections between them.

Inspired to Create: How Awe Enhances Openness to Learning and Desire for Experiential Creation

EXTENDED ABSTRACT

From birth, humans are endowed with an intrinsic drive to learn and explore (Harter 1978). However, this drive is easily disrupted (e.g., by time pressure, distractions, and depletion; Ryan and Deci 2000), transforming consumers into cognitive misers (Fiske and Taylor 1984). In this research, we identify a novel remedy for consumers’ lack of intrinsic motivation to learn, demonstrating that a particular emotion—awe—can enhance consumers’ openness to learning and, consequently, increase their intrinsic desire to partake in behaviors involving experiential creation.

Awe experiences are thought to have two defining features: perceptual vastness and a need for accommodation (Keltner and Haidt 2003). This need for accommodation refers to the belief that awe experiences are overwhelming and difficult to grasp, challenging existing mental structures (Fiedler 2001). Building upon this theoretical definition of awe, we predicted that those who experienced awe would exhibit greater openness to the prospect of learning (in hopes of satisfying their need for accommodation). We also predicted this effect would have consequences for consumer behaviors involving experiential creation.

Though prior work has largely focused on how competence and autonomy motivate the undertaking of creative tasks and behaviors (Dahl and Moreau 2007; Moreau and Herd 2010; Mochon et al. 2012), learning may also be an intrinsic incentive (Dahl and Moreau 2007). Moreover, play, construction, and working with one’s hands—all common aspects of experiential creation—are primal ways of learning (Cabrera and Colosi 2010; Kendall and Sproles 1986; Piaget 1964). Therefore, we predicted that, by enhancing openness to learning, awe would increase people’s intrinsic desire to partake in experiential creation.

Our theory that openness to learning mediates awe’s effect on experiential creation led us to predict that need for closure would moderate it. When facing uncertainty or a lack of confidence in existing mental structures, individuals high (vs. low) in need for closure are more motivated to resolve this uncertainty (Kruglanski et al. 1991, 1993) and achieve the “coveted state of ‘knowledge’” (Kruglanski 1988, 122). Since awe is theorized to shake people’s confidence in their existing mental structures (Keltner and Haidt 2003)—something that should make those high (vs. low) in need for closure especially motivated to learn (Kruglanski 1988)—we predicted that

awe's ability to heighten experiential creation desires would be stronger for those high (vs. low) in need for closure.

Experiment 1 (which was conducted shortly before Valentine's Day) tested whether awe increases one's desire to partake in experiential creation. To manipulate emotions, participants watched a 60 second awe-eliciting, happiness-eliciting, or neutral commercial for an LCD television (Rudd, Vohs, and Aaker 2012) and responded to filler items. Then, as a "thanks for participating" gift, they chose to receive either "a recipe for Valentine's Day chocolates [they] could make and give to a loved one" (something involving experiential creation) or "a coupon for pre-made Valentine's Day chocolates [they] could buy and have delivered to a loved one" (something not involving experiential creation) and reported their emotions. Manipulation checks confirmed the target emotions were successfully manipulated and, as predicted, logistic regression analyses revealed those in the awe (vs. happiness or neutral) condition more frequently chose the experiential creation option: the recipe.

Experiment 2 conceptually replicated experiment 1's results using a different operationalization of experiential creation desire: willingness to pay for products with experiential creation elements. To manipulate emotions, participants watched either an awe-eliciting or happiness-eliciting slideshow. Participants subsequently reported their willingness to pay for 16 products from different categories (i.e., furniture, food, and art)—eight of these products involved experiential creation and eight did not. Importantly, although the products within each category differed in whether they did or did not involve experiential creation, they were matched on other key features. Last, participants reported their emotions. Manipulation checks confirmed the target emotions were successfully manipulated and a mixed-measures ANOVA revealed that, as predicted, those in the awe (vs. happiness) condition were willing to pay more for products that involved experiential creation. As a test of specificity, participants in the awe and happiness conditions were equally willing to pay for the control products.

Experiment 3 tested our mediation hypothesis. Emotions were manipulated as in experiment 2 and participants subsequently responded to a 7-item experiential creation desires index (e.g., "I want to create something"), five hypothetical choices between comparable meal options that either required or did not require experiential creation (e.g., make homemade soup vs. eat canned soup), a 4-item openness to learning index (e.g., "I am curious"), and reported their emotions. Manipulation checks confirmed the target emotions were successfully manipulated and one-way ANOVAs revealed that those in the awe (vs. happiness) condition reported stronger experiential creation desires, stronger preferences for experiential creation meals, and were more open to learning. Mediation analyses revealed that, as predicted, those in the awe (vs. happiness) condition exhibited greater desire for experiential creation (via both the index and the meal preferences) because they were more open to learning. (Note: A subsequent study conceptually replicated these mediations.)

Experiment 4 tested our moderation hypothesis. After completing the Need for Closure Scale (Roets and Van Hiel 2011) and the emotion manipulation from experiment 2, participants responded to the experiential creation desires index from experiment 3 and reported their emotions. Manipulation checks confirmed the target emotions were successfully manipulated. Regression and spotlight analyses also revealed a significant main effect of emotion (i.e., those in the awe vs. happiness condition expressed stronger experiential creation desires) that was qualified by the predicted interaction between need for closure and emotion. Specifically, those who experienced awe (vs. happiness) exhibited greater desires to create

things if they had a high need for closure, but not if they had a low need for closure.

In sum, our findings theoretically contribute to and connect the literature on learning, emotions, and experiential creation, offering evidence that awe is a novel way to enhance consumers' openness to learning and incentivize experiential creation. Moreover, from a practical perspective, this research highlights awe's ability to influence consumer behavior and the need for further research on this emotion.

Curiosity Kills the Cat

EXTENDED ABSTRACT

Let us start with a stylized and provocative example. Suppose you know for sure that your beloved significant other recently had an affair with your neighbor and you have decided to break up with him/her. Their intimate activities were captured vividly on a surveillance camera and you have acquired a copy of the video. The video is in front of you. The question is: Will you watch it?

The "rational" answer is probably no, because watching the video will not give you additional useful information, given that you know for a fact they had sex, and you have made up your mind to break up the relationship. Watching the video will only make you more miserable.

Yet we predict that many people under such situations will watch the video. Why? Because of curiosity.

Curiosity is one of the most deeply-rooted human desires, but relative to other basic desires, such as those for food and achievement, it is understudied (for notable exceptions, see Berlyne 1960; Golman and Loewenstein 2012; Litman 2005; Loewenstein 1994).

Curiosity is a double-sided sword. On one hand, curiosity can motivate people to explore and make important and beneficial discoveries, and give people pleasure when their curiosity gets resolved. Indeed, in another line of work, we have been examining and found such beneficial hedonic effects of curiosity. On the other hand, curiosity can drive people to seek "detrimental information" – information that they know has no functional benefits to them and will even make them unhappy. The current research explores this latter proposition.

We have conducted and completed a series of experiments showing this "perverse" side of curiosity. In one such experiment, we presented participants with the opportunity to view 24 pictures. At the beginning of the experiment, each picture was covered and had only a label on it. Participants were told that if they turned a picture labeled "DP," they would view a picture of a dog poop (pretested to be highly negative); if they turned over a picture labeled "ST," they would view a picture of a stone (pretested to be neutral), and if they turned over a picture labeled "??," they would view either the dog poop picture or the stone picture.

The experiment consisted of four between-subjects conditions: (1) Unknown Mixed: All pictures were labeled "??"; (2) Known Mixed: Some pictures were labeled "DP" and some "ST"; (3) All Dog Poop: All pictures were labeled "DP"; (4) All Stone: All pictures were labeled "ST".

The dependent variable was how many pictures Ps decided to turn over and view. The result: Those in the Unknown Mixed condition turned over and viewed more pictures (including the negative pictures) than those in any of the other conditions ($M_s = 16.4$ (Unknown Mixed) vs. 11.5 (Stone), 10.0 (Known Mixed), 3.8 (Dog Poop); all $p_s < .05$). Notably, this result cannot be attributed to variety-seeking, because if participants simply wanted variety, those in the Known-Mixed condition should have opened as many pictures.

Also notably, the result could not be attributed to wishful-thinking either, because wishful-thinking could not explain why participants in the Unknown Mixed condition viewed even more pictures than participants in the All Stone condition. It seems that curiosity, or rather, the desire to resolve curiosity, drove participants to experience what they knew was negative, in this case, the image of a disgusting dog poop.

In another experiment, we showed participants 48 buttons on a computer screen, and they could choose to click any number of them. Each button was labeled either “Water,” “Nails,” or “??.” Ps were told in advance that if they clicked a button labeled “Water,” they would hear the sound of water pouring into a jar (pretested to be neutral). If they clicked a button labeled “Nails,” they would hear the sound of nails scratching chalkboard (pretested to be highly negative). If they clicked a button labeled “??,” they would hear either the Water sound or the Nails sound.

The study consisted of two between-participants conditions: (1) Unknown Mixed: Most of the buttons were labeled “??,” with only a couple of buttons labeled as “Water” or “Nails”; (2) Known Mixed: Most of the buttons were labeled “Water” or “Nails,” with only a couple of buttons labeled as “??.”

The primary DV was how many buttons participants clicked (i.e., how many sounds they listened to). The secondary DV was their hedonic experience, which we measured every 30 seconds throughout the study.

The results: Those in the Unknown condition pressed more buttons, and hence heard more of the excruciating Nails sound, than those in the Known condition ($M_s = 39.3$ vs. 28.2 ; $p < .01$), and they also felt worse throughout the experiment ($M_s = 3.8$ vs. 4.6 ; $p < .001$). Again, curiosity drove people to expose themselves to things which they knew were unpleasant.

We have replicated these findings in other domains, and are in the process of running additional experiments to identify the boundary of these effects. This research joins a still-thin yet growing body of literature by showing the power and hedonic consequences of intrinsic desire to resolve curiosity.

The Experience Matters More Than You Think: Weighting Intrinsic Incentives More Inside Than Outside of an Activity

EXTENDED ABSTRACT

People rely on their present evaluation of future actions when making decisions that influence these actions. For example, people make travel plans or evaluate products based on what they value in the future at the moment of choice. We examine whether people differ in what they value when choosing and pursuing actions, predicting people give greater weight to intrinsic incentives during pursuit than outside pursuit of an activity.

Whereas incentive theory traditionally explores extrinsic incentives, the positive outcomes outside an activity that result from pursuing it, we focus on intrinsic incentives, which are internal to the activity and cannot be separated from it (e.g., the positive experience delivered as part of pursuing an activity; Fishbach and Choi 2012; Laran and Janiszewski 2011; Ryan and Deci 2000). For example, jobs provide salaries (extrinsic incentives) and can be challenging and interesting (intrinsic incentives).

Across six studies, we examine whether people care more for intrinsic incentives inside pursuit of an activity than outside pursuit. We predict this shift occurs because outside pursuit, people are in a cold state and do not experience intrinsic incentives as much (Loewenstein and Schkade 1999; Metcalfe and Mischel 1999; Van Boven

and Loewenstein 2003; Van Boven et al. 2012), and therefore weight them less heavily. Further, self-control research predicts immediately experienced incentives (intrinsic ones) are most salient when they are available (inside pursuit) than from a distance (outside pursuit; Ainslie 2001; Rachlin 2000).

Study 1, surveyed gym goers on the importance of intrinsic incentives (e.g., having a fun workout) and extrinsic incentives (e.g., staying in shape) during and before a workout. We find intrinsic incentives were more important during pursuit of a current workout than outside pursuit ($M_{\text{inside}} = 4.37$; $M_{\text{outside}} = 4.08$), $t(53) = 2.47$, $p = .017$, while there was no difference in importance of extrinsic incentives.

Study 2 again demonstrates intrinsic incentives are more important in the present than the future, and also finds they are more important in the present than the past. Employees rated the importance of intrinsic (e.g., being treated well at work) and extrinsic incentives (e.g., compensation) for a current, previous, or future job. Intrinsic incentives mattered more in the present ($M = 4.92$) than in the past ($M = 4.56$), $t(118) = 2.02$, $p = .046$, and in the future ($M = 4.38$), $t(118) = 2.95$, $p = .004$. However, extrinsic incentives were rated similarly in the present compared with the past or future.

Study 3 documented a shift in weighting intrinsic incentives in a more controlled experimental task. Participants completed a reading task comprised of 30 trials that they could stop at any time, but were paid based on the total trials completed. We asked about the importance of intrinsic incentives (having fun) and extrinsic incentives (getting paid) either during (inside pursuit) or before the task started (outside pursuit). Intrinsic incentives mattered more during pursuit ($M = 4.00$) than outside pursuit ($M = 2.76$), $t(100) = 3.11$, $p = .002$, with no difference in importance of extrinsic incentives.

Using the paradigm from Study 3, Study 4 examined whether intrinsic incentives increase task persistence for pursuers inside pursuit, in contrast with predictors' expected persistence outside pursuit. Assigned tasks were either high or low on intrinsic incentives (reading jokes vs. an instruction manual) and high or low on extrinsic incentives (paying more or less for each trial). While predictors did not anticipate intrinsic incentives would influence persistence, pursuers persisted longer on a high (vs. low) intrinsic incentive task, completing more trials, $F(1,195) = 21.41$, $p < .001$, and spending more time on the task, $F(1,195) = 13.67$, $p < .001$. There was no effect of extrinsic incentives on pursuers' persistence.

Study 5 provides evidence for the process underlying the impact of intrinsic incentives on persistence. Participants completed the task from Study 4, pursuing either a task high versus low on intrinsic incentives and high versus low on extrinsic incentives. Those pursuing a high intrinsic incentive task had a more positive experience ($M = 3.90$) than those pursuing a low intrinsic incentive task ($M = 1.78$), $F(1,195) = 98.38$, $p < .001$, with no effect of extrinsic incentives. Meditational analyses revealed increased persistence on an intrinsic task was driven by increased positive experience (β indirect = 1.77 , $SE = .61$; 95% C.I. = $(.67, 3.07)$).

Study 6 examined an affective marker of the shift in weighting intrinsic incentives. We predicted those outside pursuit choosing to forgo intrinsic incentives would regret this decision later, inside pursuit. We created a choice dilemma with tasks trading-off incentives (fun, low-paying task vs. boring, high-paying task). Some participants made a free choice between tasks, while others were randomly assigned a task using a forced-choice paradigm persuading them to choose one over the other. While the majority (73.33%) with free-choice opted for the extrinsic task, forgoing intrinsic incentives, those persuaded to choose this extrinsic task had a worse experience, $t(56) = 3.49$, $p < .001$, and regretted their choice more than those

choosing the intrinsic task, $t(56) = 2.52, p = .015$. A meditational analysis highlighted the role of positive experience; those persuaded to choose the intrinsic (vs. extrinsic) task had a better experience and regretted their choice less (β indirect = $-.62, SE = .24$; 95% C.I. = $(-.1.21, -.25)$).

Six studies support our theory that people value intrinsic incentives more inside than outside pursuit, and that this pattern influences evaluation, behavior and choice regret. One implication is for people to pay more attention to intrinsic incentives when making decisions outside pursuit. For example, when choosing a workout regimen, aspiring athletes should realize the positive experience of the workout will seem more important inside pursuit than outside, and can influence how long they actually persist on their workout. To increase persistence, they should choose a workout activity they will enjoy pursuing. Similarly, dieters should realize that while taste may not matter before initiating a diet, to actually persist on a diet they should choose to have a fulfilling and enjoyable (though low-calorie) eating experience.

The Cost of Quantification: Measurement Undermines Intrinsic Enjoyment

EXTENDED ABSTRACT

The era of the quantified self is upon us. From sleep, reading, sex, and energy use to devices that track exercise and monitor health, people have access to more information about their behavior than ever before. The value of personal quantification seems clear. By better understanding our behavior, we can make the necessary changes to live happier, healthier lives. But might measurement undermine how much activities are enjoyed?

By helping people see how they are doing, measurement can facilitate performance (Amir and Ariely 2008). People value being productive (Hsee, Yang, and Wang 2010; Keinan and Kivetz 2011; Reis et al. 2000) and tend to maximize measured dimensions of behavior (e.g., the number of miles earned in a frequent-flyer program; Hsee et al. 2003). Consequently, feedback on how much of something one has done (i.e., "measurement") can increase output (Hsee et al. 2013). Knowing how many steps one has accumulated during the day, for example, can encourage people to walk more.

In contrast, we argue that measurement can decrease enjoyment by transforming intrinsically valuable activities into vehicles for achievement. People often engage in activities like exercising, walking, or reading a book because they are fun to do (Fishbach and Choi 2012). These activities are pleasurable in and of themselves, so people do them for their own sake.

But because measurement provides feedback on performance, we argue that it can undermine enjoyment. Providing external rewards can reduce an activity's intrinsic value (DeCharms 1968; Deci 1971; Higgins et al. 1995). Classic research on overjustification (Lepper, Green, and Nisbett 1973), for example, found that giving children awards for coloring decreased how much they colored in the future. Even in the absence of explicit rewards, measurement *itself* may have similar effects. Focusing on what an activity achieves (i.e., its instrumentality) can make the activity less enjoyable (Fishbach and Choi 2012). By giving people feedback on how much they have done, measurement should have an analogous impact, highlighting what an activity achieves and making it seem more instrumental.

Importantly, rather than being instrumental to the specific benefits of the activity, measurement should make activities instrumental to achievement itself. Walking can be instrumental to health, for example, but it can also be instrumental to achievement more generally (i.e., how many steps can one take in a day). Merely measuring

output should transform activities once pursued for their own sake into vehicles for achievement. As a result, while measurement may encourage people to walk further or read more, it may decrease the enjoyment of engaging in those activities.

Three experiments test our predictions. Experiment 1 explored how measurement impacts enjoyment of coloring, an intrinsically rewarding activity (Lepper et al. 1973). Participants spent 10 minutes coloring simple figures, and half were assigned to receive information about how many shapes they had colored. After 10 minutes had elapsed, we measured how much participants enjoyed coloring (five items: enjoyable, boring (reverse-scored), interesting, a waste of time (reverse-scored), fun; 1 = *Not at all* to 7 = *Very much*; $\alpha = .89$). As expected, compared to those who were not measured, measured participants colored more shapes ($F(1, 103) = 6.87, p = .010$). However, at the same time, measured participants enjoyed coloring less ($F(1, 103) = 3.55, p = .062$).

Experiment 2 tested measurement's impact in the field. We gave participants pedometers to wear for a day and assigned them to either look at how many steps they walked or simply wear the pedometer (the lid was taped). To see whether the effects persist even when measurement is optional, a third group was told that they could look at the number of steps taken, but it was not a necessary part of the study. At the end of the day, we measured enjoyment ($\alpha = .81$) using the measures from Experiment 1. In addition, to test the proposed underlying process, participants indicated whether they perceived walking as instrumental (1 = *Definitely work* to 7 = *Definitely fun*). As expected, measured participants walked more than those in the control ($F(1, 97) = 11.74, p = .001$), and the same effect emerged when attending to measurement was optional ($F(1, 97) = 7.24, p = .008$). However, measured participants enjoyed walking less ($F(1, 97) = 11.01, p = .001$), even when attending to measurement was optional ($F(1, 97) = 8.73, p = .004$). Further, as predicted, perceived instrumentality drove the effect on enjoyment ($ab = -.43, 95\% CI [-.77 \text{ to } -.16]$), such that measurement reduced enjoyment by making walking more instrumental (i.e., like work). People thus voluntarily access measurement information when it is available, even though it makes the activity less intrinsically enjoyable.

Experiment 3 examined reading. Participants read an excerpt from a book, and half were assigned to view the number of pages completed. To further explore the underlying process, we manipulated how the reading task was framed. Participants either read that "reading is a useful and educational activity" (instrumental frame), "reading is a fun and relaxing activity" (enjoyable frame), or received no additional information (control). If measurement reduces enjoyment by making activities seem more instrumental, then making an activity seem instrumental to begin with should attenuate the effect. Supporting our theory, in the control condition, measured participants enjoyed reading less ($F(1, 304) = 8.89, p = .003$), and this same effect emerged when reading was framed as enjoyable ($F(1, 304) = 5.33, p = .022$). When reading was framed as instrumental, however, this effect was attenuated ($F(1, 304) = 1.59, p = .208$). Thus it is not measurement per se that makes activities less enjoyable; rather, measurement undermines the enjoyment of previously intrinsically valuable activities by making them seem instrumental.

Measurement is a powerful tool. But in addition to influencing output, it also impacts how we see and relate to various activities. Does this mean we should stop measuring our behavior? No, but it does highlight the importance of considering why people engage in a behavior before deciding whether to measure it. For intrinsically valuable activities, it's better not to know.

Paper #4: The Downside of Winning: Self-Regulatory Consequences of Competitive Standing

Szu-Chi Huang, Stanford University, USA

Jordan Etkin, Duke University, USA

SESSION OVERVIEW

Self-regulation has historically been viewed as an intrapersonal process, influenced by factors such as delay of gratification, strength of will, and self-efficacy (e.g., Baumeister, Schmeichel, and Vohs 2007). However, people do not live in a social vacuum, and a growing number of articles attest to the role of interpersonal influences in self-regulatory behaviors (Finkel and Fitzsimons 2011; Fitzsimons and Finkel 2010). For example, early research found that reminding people of significant others led them to automatically activate goals associated with those others (Fitzsimons and Bargh 2003) and that merely observing another person's behavior can trigger goal-related action (Aarts, Gollwitzer, and Hassin 2004). More recent research demonstrates that social others play a role in motivational processes. Others can have deleterious effects on self-regulation by depleting self-regulatory resources (Ackerman et al. 2009) and allowing people to outsource their efforts (Fitzsimons and Finkel 2011). They can also have positive effects through providing social support (Brunstein, Dangelmayer, and Schultheiss 1996; Uchino 2004) as well as instrumental help (Fitzsimons and Shah 2008).

While recent research highlights the critical role that interpersonal influences plays in self-regulatory processes, many questions remain. Building on these recent findings, this session provides new insight into how interpersonal influences shape motivational processes. Four papers tackle two key questions: How do other people influence individuals' self-regulatory efforts? When do social others promote versus detract from individuals' self-regulatory success?

First, Lowe and Haws examine how confessing a personal self-regulatory failure to another person influences the likelihood of repeating the same behavior. The findings show that whereas major confessions reduce the likelihood of subsequent transgressions, minor confessions license similar behaviors. Second, Ackerman takes the perspective of the observer, and explores how perceiving another person's use of self-control affects personal self-regulatory efforts. Four experiments demonstrate that vicarious self-regulation can deplete self-regulatory resources, making consumers more vulnerable to subsequent persuasion attempts. Third, vanDellen and colleagues investigate the strategies used by successful self-regulators to navigate the social environment. Five experiments show that successful

self-regulators exhibit stronger preferences for goal-supportive environments, choosing to interact and receive information from others who are also effective self-regulators. Finally, Huang and Etkin examine how others impact self-regulation in competitive contexts. The findings show that early on in a competition, receiving positive competitive feedback (i.e., that one is "winning") increases subsequent self-regulatory efforts, but later on, the same feedback reduces self-regulatory efforts.

Together these papers connect ongoing research in both marketing and psychology to inform how other people shape personal motivation processes. We hope these papers further conversations and collaborations among scholars interested in research at the intersection of motivation/self-regulation and social factors. This session should have broad appeal to scholars interested in connections between motivation, self-regulation, self-control, social influences, and interpersonal processes.

Off My Chest and At It Again: Is Confession a Prelude to Repentance or Relapse?

EXTENDED ABSTRACT

Confession is an age-old practice, and in some ways is more common than ever. Social media and other dedicated "confession" websites serve as venues for individuals to publicly disclose their various faults and failures. Confession is a common religious practice, an integral part of addiction recovery programs, a regular part of law enforcement, and a popular topic of tabloids and daytime talk shows. Across this span of contexts, confessions are an almost daily encounter for many consumers. This research examines the role of confession as a response to lapses in self-control in consumption-related contexts as it impacts future goal-directed behaviors. That is, is confession licensing, reinforcing or simply a social act without consequence?

Confessing one's missteps could serve as an act of public commitment, which could heighten goal commitment and behavioral consistency (Cialdini et al. 1993). For example, smokers who publicly committed to quit smoking were more likely to successfully adhere to that goal (Altman et al. 1987). Confession may also influence the self-view of a confessor. If confession serves as a personal reminder of high goal commitment or a lack of goal progress, it could further motivate goal adherence (Koo 2008). On the other hand, confession may serve as a way to reaffirm one's moral identity, which could have a licensing effect and actually lead to more indulgent decisions in the future (Sachdeva, Iliciev and Medin 2009). For example, social transgressions are often followed by an increased willingness to help (Tedeschi and Riordan 1981), but when confession follows a social misstep it can reduce the perceived need to make amends (Wallace and Sadalla 1966). Confession helps confessors to make sense of the event in question (Kelly and McKillop 1996) and can decrease feelings of stress regarding the event (Pennebaker 1989, 1990), which may liberate confessors to relax their standards again.

We suggest that confession may result in either licensing or reinforcement depending on the severity of the trespass being confessed, such that confessing high-guilt infractions reinforces future goal-directed behavior, while confessing a low-guilt indiscretion creates a licensing effect. In the context of prosocial behavior, Gneezy et al. (2012) find that the costliness of a prosocial behavior moderates whether the prosocial act is licensing or reinforcing, such that

“costly” or difficult prosocial actions are reinforcing while relatively “costless” prosocial behaviors create licensing effects. Similarly, Lowe and Haws (2014) find that the guilt associated with shared self-control decisions moderates the impact of that decision on social relationships. Confessing a guilt-laden self-control failure may feel very costly, and therefore heighten commitment, while a less-guilty confession would be somewhat costless and therefore lead to licensing. We test these predictions in a series of three studies, with additional studies already in progress.

In study 1, participants (87 undergraduate students) imagined coming across a personally desired item (either “major” (\$100) or “minor” (\$0.75)) and feeling tempted to secretly charge it to the company credit card. In both conditions, participants imagine dishonestly purchasing the item with the company card. Participants were then randomly assigned to either a “confess” condition in which they wrote a confession to a roommate or a control condition where they wrote about an unrelated topic. After writing, participants were asked how likely they would be to do something similar in the future. An ANOVA revealed a two-way interaction ($F(1, 81) = 4.84, p < .05$), such that confessing the major indiscretion decreased the likelihood of repeating the dishonest act in the future, whereas confessing the more minor indiscretion *increased* the likelihood of repeating the behavior.

Study 2 entailed an online panel of 83 individuals who were asked to recall an actual occasion that they spent money in a somewhat wasteful manner. Then, participants were asked to rate how guilty they felt about this occasion. Participants were then randomly assigned to either the confession or control condition. Before writing anything, participants in both conditions provided the name of an individual that would ostensibly be emailed their written responses to heighten the perceived consequences of the confession. Next, participants were asked to imagine coming across a tempting but unnecessary item costing around \$40-\$50. After listing a personally tempting item, participants were asked how likely they would be to splurge and purchase that item. The assessment of guilt was crossed with confession/control conditions in a linear regression predicting each participant’s likelihood of splurging again on the item they imagined. The interaction between level of guilt and confession was significant ($\beta = .808, t = 2.87, p < .01$) again demonstrating that, relative to the control condition, confessing incidents of major guilt was reinforcing, while confessing events of minor guilt was licensing.

Study 3 examined real behavior over time following a confession. Participants were 176 undergraduate students participating in a 2-part study. In part 1, all participants were asked to recall some of their recent unhealthy behavior. After recalling some specific instances, participants were asked how guilty they felt about the behavior. Participants were then randomly assigned to a confession or control condition. In the confession condition, participants confessed the details of their unhealthy behavior, while in the control condition, participants wrote about their current musical preferences. Two weeks later, participants were asked to recall and rate their health-related behaviors over the previous two weeks on an “extremely unhealthy” to “extremely healthy” scale. A linear regression showed a significant interaction between guilt and confession on health-related behaviors, such that confessing high-guilt indiscretions led to better health-related behavior relative to the control condition, whereas confessing low-guilt indiscretions undermined future health-related behavior relative to the control condition ($\beta = .650, t = 3.16, p < .01$).

Overall, our studies revealed a consistent pattern such that whether the severity of the indiscretion was externally manipulated (study 1) or internally perceived (studies 2 and 3), the same pattern emerged such that minor confessions (vs. keeping the behavior to

oneself) led to licensing whereas major confessions were reinforcing for goal behavior.

Persuasion by Proxy: Vicarious Self-Control Use Increases Decision Compliance

EXTENDED ABSTRACT

Research on the depleting effects of self-control has spawned a substantial literature focusing primarily on intrapersonal causes and consequences of self-regulatory failure (Baumeister 2002). For instance, people who use self-control for one purpose subsequently suffer deficits in their ability or willingness to resist especially persuasive messages (Burkley 2008). However, work on topics relating to mental connection suggests that interpersonal contexts may offer unique settings in which self-control actions could affect not only those people using self-control, but others in the social environment as well. For instance, during a group shopping trip, a friend with a sweet tooth may avoid temptation by intentionally looking elsewhere while walking by a mall chocolate shop. This simple action has implications for the friend’s subsequent self-control behavior, yet very little is known about how such actions affect an *observer’s* ability to regulate his or her behavior.

The mental connection literature establishes the possibility that, under certain conditions, perceiving another’s use of self-control can either inspire or deplete the self-control of perceivers. To test the role of self-control in social settings, I contrast predictions derived from three types of mental processes. First, perceiving others may automatically prime similar cognitions and behaviors through the process of mimicry. From this perspective, seeing a person resist a food indulgence is likely to lead an observer to resist food indulgences as well, though this may have little effect on unrelated forms of resistance (such as resisting a persuasion attempt). Second, the goal of using self-control may spread to observers through a goal contagion process. From this perspective, the observer of food resistance may be more likely resist any outcome relevant to self-control (because the underlying self-regulatory goal, and not the behavior itself, has been transmitted). Finally, mentally simulating the food resistance actions of another may evoke the entire experience of resistance, including its downstream consequences (see Decety and Grèzes 2006). From this perspective, an observer would likely feel the consequences of the other’s self-control use—depletion—even though the observer has not actually used self-control.

Four studies investigate these ideas by manipulating and measuring the degree of mental connection between actors and observers. Each study tests whether closer connection to actors results in lowered persuasion resistance within observers. In study 1, student participants either simply read about, or actively took the perspective of, a waiter who came to work at a high quality restaurant without having eaten recently and thus had to exert self-control in order to resist eating food on the job (or else risk being fired). In a second task, participants read an essay advocating changing the school grading system to one that the participants initially disliked. Simulating the perspective of the hungry waiter in the first task completely eliminated negativity towards the grading change and led to a doubling of support for this previously disliked system.

Study 2 used a similar first paradigm but measured rather than manipulated mental connection. Subsequently, participants viewed an advertisement for a shaving razor that featured either strong or weak messages. Automatically taking the perspective of the waiter was associated with increased favorability to the product. This occurred primarily when the ad messages were strong, suggesting that

participants were no longer able to effectively resist these persuasion attempts.

Study 3 expanded on these ideas by using visual observation of another's self-control use and by subtly manipulating mental connection with the actor. Participants learned that they either shared or not the same birthday as a person who, in a video, pushed himself to eat a radish rather than a tempting cookie (or the cookie instead of the radish). They then evaluated an unrelated food advertisement and performed a shopping task with several products. Participants viewing someone with whom they shared a birthday eat a radish (but not someone who ate a cookie) later expressed more favorability to the ad and purchased somewhat more products. Interestingly, having a different birthday increased resistance to the ad when the actor exhibited self-control by eating the radish, suggesting some presence of a goal contagion effect.

Finally, study 4 tested the role of self-control expectancies in a vicarious context. Participants were led to believe that self-control is either limited in capacity or not (Job, Dweck, and Walton 2010), and then they actively took the perspective or not of the actor in the radish-eating video from study 3 (only purchasing was measured as an outcome here). Taking the self-control user's perspective while also believing that self-control was a limited resource reduced advertisement resistance as indicated by an increase in purchasing of snack foods. This was not the case when participants believed that self-control was unlimited, suggesting that self-control expectancies, and not ability, drop when simulating the self-control experience of others.

In summary, the results of four studies indicate that vicarious self-regulation can deplete resistance to persuasive messages in a manner most consistent with a mental simulation account rather than mimicry or goal contagion (save for one finding from study 3). These findings raise important theoretical questions for models of depletion that rely on the exhaustion of physical resources. They also help to deepen our understanding of social consumption experiences and the situations in which consumers are likely to benefit (or not) from the presence of other consumers.

In Good Company: Managing Interpersonal Resources that Support Self-Regulation

EXTENDED ABSTRACT

Researchers increasingly recognize goal pursuit involves not only reacting to constraints and affordances as they arise but also anticipating them. Effective self-regulation involves proactively ensuring one is in the right place at the right time and with enough resources to effectively respond to those situations (e.g., Gollwitzer 1993; Moskowitz and Li 2011). Given recent work suggesting that self-regulation extends to interpersonal processes (Fitzsimons and Finkel 2011; Fitzsimons and Shah 2008), we posit that effective self-regulators marshal interpersonal resources to ease the ongoing burdens of self-regulation—that is, they look beyond themselves to consider the affordances of their social environment for goal pursuit. Thus, we propose that effective self-regulation could involve not only managing *internal* resources for goal pursuit but also the often-fleeting *interpersonal* resources that can support goal pursuit. Just as effective self-regulators are probably apt to approach goal-supportive and avoid goal-unsupportive environments (Fishbach and Shah 2006) and to preemptively manage their exposure to temptations (Hofmann et al. 2012; Imhoff, Schmidt, and Gerstenberg 2014); successful self-regulators may similarly manage the goal support they receive from others.

We propose that effective self-regulation involves more than simply rising to meet the challenge of temptations and obstacles are they are encountered; it also involves positioning oneself in social environments that make it easier to pursue goals and resist temptations in the first place. In five studies, we tested a theory of social positioning—that people who are effective self-regulators tend to position themselves in social environments that best afford self-regulatory success. We tested three hypotheses aimed at understanding dynamics behind these expected preferences for supportive social environments. First, we examined a *perceptual sensitivity* hypothesis—asking whether effective self-regulators better detect self-control in others or are simply more sensitive to others' goal-directed motivation. Second, we examined a *targeted support-seeking* hypothesis—asking whether effective self-regulators simply seek more support from anyone or whether they focus their searches for help from specific people. Third, we examined a *strategic positioning* hypothesis—expecting these stronger preferences to emerge strategically rather than incidentally (e.g., because of greater liking or similarity to others).

In all studies, participants completed measures of self-regulatory effectiveness and then evaluated friends or potential collaborators. In Study 1, participants reported how much time they wanted to spend with a new acquaintance they perceived to have either high or low self-control. In Study 2, participants interacted with confederates who displayed either high or low self-control. Participants then chose a collaborator for an upcoming task that they learned would require effort. In Study 3, participants worked on an individual word task and were asked to evaluate potential sources of help (i.e., advice or information about how a person had scored) from high or low self-regulators. In all three studies, preferences were higher to spend time with (Study 1), collaborate with (Study 2), or receive information from (Study 3) the target with high self-control/self-regulation. However, in each study, participants' own self-regulatory effectiveness moderated this effect such that preferences for the more supportive target were stronger among participants who were effective at self-regulation.

In Study 4, we examined whether evaluations of goal-supportive friends might be sensitive to changing fluctuations in need for help. Participants evaluated goal-supportive and goal-interfering friends in the context of a particular goal pursuit, performance in a statistics course. Again, effective self-regulators demonstrated stronger preferences for goal-supportive (vs. goal-interfering friends), but only when they reported a need for help (i.e., nervousness about course performance). Finally, in Study 5, we examined self-regulatory mechanisms of these effects, focusing particularly on how task-specific motivation might be driving interpersonal preferences. Again, participants evaluated potential collaborators for a joint task. Participants' self-regulatory effectiveness predicted their motivation to perform well on this task. Personal task-specific motivation predicted perceiving the collaborators as differentially motivated, and subsequently predicted preferences for the collaborator with high self-control over the collaborator with low self-control.

Across the five studies, results supported our idea that effective self-regulators show stronger preferences than less effective self-regulators for goal-supportive environments. We found limited support for a perceptual sensitivity mechanism. Participants' self-regulatory effectiveness predicted perceptions of targets' task-specific motivation (Study 5) but not targets' self-control (Studies 1 & 2). Thus, perceptual sensitivity may be related to stronger preferences to the extent that it is focused on a specific goal pursuit rather than perceiving general self-regulatory skills in others. We found consistent support for a *targeted support-seeking* hypothesis. Effective self-

regulators did not rate all support as more useful, rather they rated support from high self-regulators as more useful than support from low self-regulators. Our results also appear to support a *strategic positioning* hypothesis; the preferences of effective self-regulators were not simply explained by greater liking of supportive others who may be similar to them. In Study 2, participants reported equally liking confederates appearing to have high and low self-control. In Study 4, effective self-regulators (who reported on their friends and should therefore have equally liked them generally) reported more positive evaluations of instrumental over anti-goal friends only when they also reported feeling nervous about pursuing the relevant goal. Finally, in Study 5, task-specific motivation played a meditational role in connecting trait self-control to stronger preferences for supportive versus unsupportive collaborators.

The present research expands notions of effective self-regulation to consider not only how individuals regulate their internal resources but how they regulate their social environments to take advantage of external resources that may support their own self-regulation. In doing so, these findings support recent evidence that self-regulation involves social processes (Fitzsimons and Finkel 2010; Fitzsimons and Fishbach 2010; Vohs and Finkel 2006). Our research suggests effective self-regulators are more likely to position themselves in social environments that further their likelihood of successful outcomes and highlights a proactive component of social relationships and self-regulation that has not yet received much empirical attention. That effective self-regulators look to their social environments for potential support suggests they may be more aware of the processes that affect their success at self-regulation.

The Downside of Winning: Self-Regulatory Consequences of Competitive Standing

EXTENDED ABSTRACT

Competition - contexts where an individual can attain his ends only at the expense of others not attaining theirs (e.g., Johnson and Johnson 1974; Deutsch 1962) - is prevalent in our everyday lives. As children, we compete for better grades in school, for starting roles on sports teams, and for the lead in the school play; in business, colleagues compete for promotions, teams compete for bonus compensation, and firms enter bidding wars to earn contracts (Campbell and Furrer 1995; Deci and Ryan 1985; Epstein and Harackiewicz 1992). Competition is so pervasive in Western culture that the very language of business, politics, and education is filled with “win-lose” terms. For instance, a person “wins” a promotion, “beats” the other candidate, and “outsmarts” her peers (Stanne, Johnson, and Johnson 1999).

As prevalent as competition is, recent years have witnessed little advancement to our theoretical understanding of self-regulation in competitive contexts. In the current research, we adopt a longitudinal perspective (Gaudreau et al. 2002; Louro, Pieters, and Zeelenberg 2007) to explore the dynamic self-regulatory effects of competition-based feedback. Specifically, we propose that being ahead in a competition can both enhance and detract from subsequent self-regulation effort. Which effect emerges depends on the stage (early vs. late) of the competition in which competitive feedback is received.

A defining feature of competition is the inherent uncertainty about the outcome (Johnson and Johnson 1989). This uncertainty should be particularly pronounced at the early stages of a competition. When people first join a competition, they have little information about their opponent, which limits their ability to judge their likelihood of success. As a result, they should seek signals to help alleviate uncertainty surrounding whether they will win. Because

competitions make social comparison salient (Johnson and Johnson 1989), competitors should rely on their current standing (i.e., whether they are ahead or behind) to infer their ultimate chance of winning. Therefore, receiving feedback that one is ahead at the early stages of a competition should increase the perceived likelihood of success, thereby enhancing subsequent self-regulation.

Notably, whereas concerns about whether winning is possible should be pronounced at early competition stages, later on, the focus on what one needs to do to win would dominate. Unlike individual pursuits, in competitive contexts, successful goal attainment (i.e., “winning”) depends on one’s own and one’s opponent’s performance (Locke et al. 1981). To assess what ground remains to be covered, competitors should thus refer to the discrepancy between their current standing and their competitor’s standing. As a result, receiving feedback that one is ahead at the later stages of a competition signals a positive discrepancy, reducing the perceived amount of effort required to win, thereby reducing subsequent self-regulation.

Four experiments demonstrate that whereas positive competitive feedback enhances self-regulation effort when received early on in a competition, the same feedback received later on reduces self-regulation. All experiments involved one-on-one competitions between a participant and an opponent. We employed competitive feedback discrepancies of moderate size, given concerns that too small of a difference would fail to produce a meaningful signal and too large of a difference would suggest winning is ensured (or impossible), precluding the necessity of subsequent efforts.

Experiment 1 examines how competitive feedback impacts subsequent self-regulation at different stages of the competition. Participants ($N = 294$) competed in a five-round dice game. After two (early stage) or four (late stage) rounds, they received feedback about their current standing in the competition. Half received feedback that they were ahead of their competitor, and the remaining half received feedback that they were behind their opponent. Then, participants were given a bonus roll, in which the longer they waited to roll the dice, the more points they could earn. The time they spent waiting served as our measure of self-regulation. Results revealed the predicted interaction ($F(1, 286) = 8.65, p < .01$). After two rounds, being ahead led to greater self-regulation ($M_{\text{ahead}} = 68.33$ vs. $M_{\text{behind}} = 42.90$). After four rounds, however, being ahead led to lower self-regulation ($M_{\text{ahead}} = 50.39$ vs. $M_{\text{behind}} = 76.98$).

Experiment 2 replicated this effect and tested the underlying process. The procedure was similar to Experiment 1. After receiving competitive feedback, participants reported the perceived difficulty of winning (1 = *Not difficult at all*, 7 = *Very difficult*), as well as the number of points they needed in order to earn, and then entered the next round of the game (time spent in this round again served as our measure of self-regulation). Results revealed the predicted interaction ($F(1, 138) = 6.53, p = .01$). At the early stage, being ahead led to greater subsequent self-regulation ($M_{\text{ahead}} = 82.79$ vs. $M_{\text{behind}} = 65.27$) because of the lower perceived difficulty of winning, but at the later stage, being ahead led to lower subsequent self-regulation ($M_{\text{ahead}} = 61.22$ vs. $M_{\text{behind}} = 84.34$) due to a lower estimated discrepancy/amount of effort required.

Experiments 3 and 4 provide additional support for the underlying process through moderation. Experiment 3 focused on the early stage, manipulating the relevance of competitive feedback to the likelihood of winning; experiment 4 focused on the later stage, manipulating the presence of definitive information about the remaining discrepancy. The experiments utilized different competitive contexts (a sales competition and a memory competition) to increase the generalizability of our findings.

In sum, we adopt a dynamic, longitudinal approach to examine the self-regulatory consequences of temporary standing during a competition. Whereas being ahead increases self-regulatory efforts when a competition first begins, the same feedback conversely decreases efforts towards the competition's end. The findings connect research on social psychology, educational psychology, athletic motivation, and business management to inform how competition can help or hinder self-regulation.

SESSION OVERVIEW

Consumers' goals and personal resource are inextricably intertwined. Our goals should determine how we spend our time and money, as well as how much "slack" (Zauberman and Lynch 2005) remains. Conversely, personal resource availability should determine how we go about pursuing our goals, including what goals seem to be in conflict. Despite these apparent connections, research on goals and research on personal resources have developed relatively independently to-date. Research on goals, for instance, has explored why consumers adopt and pursue goals (e.g., Heath, Larrick, and Wu 1999; Locke and Latham 1990) as well as factors that affect the level and intensity of motivation (e.g., Bonezzi, Brendl, and Angelis 2011; Etkin and Ratner 2012; Fishbach and Dhar 2005; Kivetz, Urminsky, and Zheng 2006; Zhang and Huang 2010). Research on perceived resource abundance has identified personal and situational factors that influence how much time (e.g., Mogilner, Chance, and Norton 2012; Rudd, Vohs, and Aaker 2012; Shu and Gneezy 2010; Vohs and Schmeichel 2003; Zhao, Lee, and Soman 2012; Zhang and DeVoe 2010) and money (e.g., Shah, Mullainathan, and Shafir 2012; Sharma and Alter 2012; Sussman and Alter 2012) people feel that they have, as well as psychological consequences of focusing on time versus money (Gino and Mogilner 2013; Mogilner 2010; Vohs, Mead, and Goode 2006). While emerging work is beginning to explore how goals and personal resources relate (Fernbach, Kan, and Lynch 2014; Jhang and Lynch 2014; Spiller 2011), many open questions remain. Helping to address this gap, this session explores the interplay between goals and personal resources.

Four papers tackle the following questions: How do people's goals shape perceptions of resource abundance? How do people's judgments of resource supply influence the goals they pursue? The first two papers explore the relationship between goals and time. First, Etkin, Evangelidis, and Aaker examine the role of subjective perceptions of goal conflict in making people feel pressed for time. Four experiments demonstrate that perceiving more conflict between goals affects how time is perceived, spent, and valued. Second, Urminsky disentangles the relationship between goal gradient and temporal discounting effects. The studies show that goal gradient-like ef-

fects uniquely explain some classic time discounting findings. Next, turning to the relationship between goals and money, Kan, Lynch and Fernbach explore how and why budgeting helps people pursue financial goals. The findings show distinct effects of budget setting and budget tracking in managing financial constraints. Finally, Lynch, Spiller, and Zauberman offer a comprehensive framework for understanding interconnections between goals, time, and money resources. They discuss how people perceive resource demands and resource supplies as a function of active goals and opportunity costs.

Together, these papers further understanding of the interplay between goals and personal resources. We hope this session stimulates further exploration of the connections between resource perceptions and goal pursuit. This session should have broad appeal to scholars interested in goal pursuit, time, money, and scarcity more generally.

Pressed for Time? Goal Conflict Shapes How Time is Seen, Spent, and Valued

EXTENDED ABSTRACT

People rarely feel that they have enough time. Yet, despite growing interest in the consequences of feeling time constrained (Darley and Batson 1973; Mogilner, Chance, and Norton 2012; Robinson and Godbey 1998; Roxburgh 2004; Rudd, Vohs, and Aaker 2012; Van Boven and Gilovich 2003), little is known about what affects people's subjective sense of time in the first place. Why do people feel so pressed for time? And what consequences might this have for how consumers spend and value their time?

In this research, we propose that consumers' perceptions of goal conflict shape how time constrained they feel. We argue that, aside from the number of goals that people pursue and the objective amount of time required to pursue these goals, simply *perceiving* greater conflict between goals should make people feel that they have less time.

Goal conflict refers to the sense that pursuing one goal interferes with pursuing others (Riediger and Freund 2004). Although some goals naturally conflict more than others (Emmons and King 1988; Hofmann, Vohs and Baumeister 2012), perceptions of goal conflict are largely subjective. For example, conflict between the same goals may seem higher on some occasions than others. When missing dinner to stay late at the office, for example, one may feel more conflict between goals to succeed at work and be a good parent than when working from home.

Why would perceiving conflict between goals reduce feelings of time affluence? We argue that perceiving greater conflict between goals has an impact on experienced emotions. Prior work shows that perceiving conflict between goals is often accompanied by negative affect (Emmons and King 1988); particularly, stress and anxiety (Lazarus and Folkman 1984). Stress and anxiety, in turn, are linked to people's subjective sense of time (Lehto 1998; Robinson and Godbey 1998; Roxburgh 2004). Integrating these findings, we hypothesize that perceiving more conflict between goals should increase stress and anxiety, and consequently, make people feel more pressed for time.

Note, one might expect that perceiving more conflict between goals would decrease perceived time affluence only when goals compete for time – for example, when one has a goal to perform well at work, but also spend quality time with family. However, we reason that even when goal conflict is unrelated to time (e.g., money), per-

ceiving more of it should have a similar impact on stress and anxiety. Greater perceptions of goal conflict – both related and unrelated to demands on time – should thus make consumers feel that they have less time.

Four experiments test these predictions. Experiment 1 examined how perceiving more conflict between goals, both related and unrelated to time, affects consumers' subjective sense of time. We asked participants to consider two personal goals that either competed for their time, money, or conflicted more generally. A fourth group simply listed two of their goals. Then, we measured subjective time perceptions (5-item scale adapted from Rudd et al. 2012; 1 = *Not at all* to 7 = *Very much*; $\alpha = .89$). As expected, perceiving more conflict between goals made people feel more pressed for time ($F(3, 119) = 4.42, p < .05$), and this effect emerged regardless of whether the conflicting goals competed for time, money, or conflicted in a more general sense. Compared to the control ($M = 2.29$), participants perceived greater goal conflict in the time ($M = 5.15$), money ($M = 5.34$), and general conflict conditions ($M = 5.15$).

Experiment 2 tested the proposed underlying process. Participants considered one of the following goal-pairs: “do well at work” and “spend time with loved ones” (time conflict), “save money” and “buy nice things” (money conflict), and “be healthy” and “eat tasty foods” (non-resource conflict). To manipulate goal conflict, participants described at time when they did versus did not feel conflict between the goals. Then, we measured stress and anxiety (1 = *Very little*, 7 = *A lot*; $r = .81$) and time perceptions ($\alpha = .89$). As expected, across goal conflict types, perceiving more conflict made people feel that they had less time. Further, it also increased reports of stress and anxiety, and these heightened emotions explained why goal conflict reduced people's sense of time ($ab = -.28$; 95% CI: $-.48$ to $-.13$).

Experiment 3 examined consequences for how time is spent. Participants considered the goals “be healthy” and “have meaningful social relationships” and half also read that people often experience conflict between these goals. To assess how people spend time, we invited them to read a short popular press article and recorded how long they spent on it (Zhong and DeVoe 2010). Finally, we measured subjective time perceptions ($\alpha = .81$). As expected, perceiving more conflict between goals reduced subjective time perceptions. Further, it also reduced the amount of time participants spent reading.

Experiment 4 examined consequences for how time is valued and tested a simple intervention to mitigate goal conflict's effects. Participants listed two goals and then described a time when they did versus did not conflict. Next, some participants completed an anxiety reappraisal exercise from prior research (Brooks 2014). They repeated the statement “I am excited” three times out loud. Remaining participants either repeated the statement “my name is X” (matched control) or moved directly to the dependent measures. To assess the value of time, we measured participants' willingness to pay to expedite shipping on a recent purchase (Malkoc and Zauberan 2006). Finally, we measured subjective time perceptions ($\alpha = .89$). As expected, in the (combined) control reappraisal conditions, perceiving more conflict between goals reduced subjective time perceptions. Further, it also increased willingness to pay to expedite shipping. Reappraising anxiety as excitement, however, attenuated these effects.

In sum, despite trends documenting an increase in time pressure, little is known about what makes consumers feel pressed for time. This research demonstrates a novel pathway – perceived conflict between goals – that decreases how time affluent consumers feel and consequently, how they spend and value their time.

Impatient to Achieve or Impatient to Receive: How the Goal Gradient Effect Underlies Time Discounting

EXTENDED ABSTRACT

Research on both the goal gradient (Kivetz et al 2006) and intertemporal choice and discount rates (Frederick et al 2002, Zauberan and Urminsky 2015) has shown that outcomes are more valued when they are closer in time. While intertemporal choices have been linked to goal conflict (Urminsky and Kivetz 2011), the goal gradient and time discounting have generally either been studied separately or integrated by assuming that goal gradient effects are due to time discounting (Jain 2012). In this paper, we separate what is usually confounded in goal gradient and intertemporal choices research, the timing of achieving task completion and the timing of receiving the associated outcome. This approach allows us to separate the effects of the goal gradient (distance to completing the task needed to earn a reward) from the effects of intertemporal preferences (time until actually receiving the reward). Across eight studies, we find that choices involving tradeoffs between smaller soon and later larger goals, holding reward timing constant, parallel time discounting findings, but are not explained by the time discounting of received benefits.

In the first study (N=406), participants allocated non-substitutable resources between two hypothetical projects (10 hours of access to research resources needed for two papers). Across four between-subjects conditions, we varied when the papers were due (i.e., the goal timing: the first in three weeks and the second in three or five weeks) and when the papers would be graded (i.e., the temporally discounted outcome: both in three weeks, one in three weeks and one in five weeks, or both in five weeks). Allocations were significantly higher for the first project when the first deadline was sooner ($b = .11, p = .002$), consistent with the goal gradient, but the timing of the outcome did not have a significant effect (receiving the grade, $b = .038, p = .283$), suggesting minimal time discounting in this context. These results were replicated in two similar studies.

In Study 2a (N=380), participants allocated 10 tickets between two hypothetical lotteries with equal probabilities of winning: Lottery A, which paid \$10, or Lottery B, which paid \$14. Participants would find out whether they won in either 1, 3 or 5 weeks, and winners would receive the prize in either 1, 3 or 5 weeks, yielding nine between-subjects conditions. Thus, the two lotteries could differ in the timing of the drawing (or not) and in the timing of the payment (or not). This design allowed us to separately quantify the effect of goal completion timing (goal gradient) and prize receipt timing (time discounting), in a regression analysis predicting allocation between the two lotteries based on the differences in timing.

Participants generally split their tickets, allocating 5.7 vs. 4.3 tickets to Lotteries A vs. B, averaging across the conditions. However, for each additional week that Lottery B's drawing occurred later than Lottery A's drawing, participants allocated .26 fewer tickets to Lottery B ($p = .001$), controlling for the timing of the payoffs. In contrast, for each additional week that Lottery B's payoff was later than Lottery A's payoff, participants only allocated .15 fewer tickets to Lottery B ($p = .04$), controlling for the timing of the drawings. Thus, we found significantly stronger goal gradient effects than time discounting effects. Estimating a traditional time discounting model (which ignores the timing of goal outcomes) for the data, yielded an overly impatient estimate of the weekly time discounting factor (.89 instead of .95). Study 2b (N=379) replicated these findings, using the same nine lottery scenarios but eliciting binary choices rather than allocations.

In Study 3 (N=171), participants read a scenario about choosing between plane tickets and thereby earning points in one of two dif-

ferent frequent flyer programs. We elicited their indifference point, via a series of choices, between one program in which they earned fewer points but also needed fewer points to earn a reward and another program in which they earned more points but had a higher point requirement to earn the same reward. We found that the way people made tradeoffs involving the timing of outcome resolution (e.g., completing the requirement for a free ticket) paralleled prior findings of hyperbolic time discounting, even when the timing of receiving the reward benefit was fixed. For example, earning 500 points in the first program was equivalent to earning more points in the second program when it was the last 500 needed than when it was 500 out of 1000 ($p < .01$), even if the free flight would have been used at the same time in either case.

Lastly, in Study 4, participants ($N=72$) allocated tickets between two real lotteries, which differed by a week in the timing of the drawing, but both paid a \$50 prize at the same time. Participants varied in how far in the future the sooner drawing would be held (from 11 days away to 1 day away). Because both lotteries paid the prize at the same time, a time discounting account would predict no difference between the two lotteries. In contrast, the closer the drawings were when the participants made their choice, the more tickets they allocated to the lottery with the sooner drawing ($r=-.29, p=.01$), a goal gradient finding that parallels, but cannot be explained by, hyperbolic discounting.

In summary, in those situations where people learn about earning a reward at one time but actually receive the reward at another later time, we observe separate disassociated larger goal gradient and smaller time discounting effects. While time discounting may explain some goal gradient findings, our studies primarily find that goal gradient effects provide a substantial explanation of time discounting. Estimated discount rates are inflated when not separately accounting for goal gradient effects.

How Budgeting Helps Consumers Achieve Financial Goals

EXTENDED ABSTRACT

Many consumers experience financial constraints and struggle to achieve their financial goals, such as limiting spending, saving adequately and avoiding excessive debt. Budgeting can help people manage their financial constraints and avoid dysfunctional behaviors (Fernbach, Kan and Lynch, 2015), and a Gallup poll finds that a third of Americans do keep a household budget (Jacobe 2013). But how and why does budgeting help? Successful budgeting consists of both setting a budget and then tracking that budget. We suggest that setting budgets and tracking budgets each contribute uniquely to helping people achieve their financial goals. Budget setting increases the clarity of financial goals, while budget tracking increases pain of paying.

We hypothesize that budget setting decreases ambiguity surrounding what one can or cannot afford and increases the clarity of financial goals. An important part of successful self-regulation is having clear and specific goal standards (Baumeister 2002; Vohs, Baumeister and Tice 2008). Budgets provide numerical representations of intended expenditures that serve as concrete reference points and translate abstract goals into clear standards (Heath, Larrick and Wu 1999; Krishnamurthy and Prokopec 2010). We therefore suggest that the goal specificity provided by budget setting helps people to alleviate overspending; the more a budget clarifies one's spending goals, the more it will help to minimize overspending.

Study 1 investigated the role of goal specificity in how budget setting impacts spending behavior. Participants from mTurk com-

pleted a two-phase study over the Black Friday shopping weekend (Nov 28th to Dec 1st, 2015). During the week prior to Black Friday, participants were asked to budget for their gift shopping for each of five people for whom they planned to purchase gifts during the Black Friday shopping weekend. Depending on random assignment, participants budgeted in a manner such that the total cost of the five gifts was either clear or ambiguous. In the clear total spending condition, participants budgeted for all five gift recipients on a single page, and the total cost was automatically summed up and provided back to the participant. In the ambiguous total spending condition, participants planned for each gift recipient on a separate webpage, and total cost was not provided back to the participant. After Black Friday, participants were asked if they had finished purchasing their gifts for each recipient. If they had finished, they reported the total cost incurred for each recipient, and if not, they reported the amount spent to date plus the intended additional spending. Both groups reported spending and planning to spend more after Black Friday than they had anticipated before Black Friday, but the magnitude of overspending was significantly less for consumers whose gift spending budgets provided clear total expenditures (Interaction: $F(1, 251) = 5.873, p = .016$). This study suggests that the goal clarity provided by budget setting is a key factor in why budgeting is beneficial.

Another important component of budgeting is tracking one's expenses. In addition to providing more frequent feedback on one's goal progress, expense tracking may also serve to increase the pain associated with making payments, thus helping to curb expenditures. Purchases can vary in the extent to which costs and benefits are psychologically linked (Gourville and Soman 1998; Soman and Gourville 2001), and procedures that increase this linkage have been found to exacerbate pain of paying, and decrease subsequent purchases (Soman 2001). We propose that the explicit logging of purchases that occurs as part of expense tracking facilitates the allocation of costs to benefits, resulting in higher pain of paying and decreased enjoyment from spending, particularly under conditions of high constraint.

Study 2 explored the role of budget tracking in how financial constraints impact people's enjoyment from spending money. A different set of mTurk workers completed this two-phase study over the Black Friday shopping weekend. Prior to Black Friday, participants began by reporting their perceived level of financial constraint (1=low constraint, 11=high constraint). Next, they were randomly assigned to one of four budget setting and expense tracking conditions. Participants either 1) set a budget for their Black Friday shopping and tracked expenses for their Black Friday shopping, 2) set a budget for their Black Friday shopping and tracked expenses for their regular shopping over the weekend, 3) set a budget for their regular shopping over the weekend and tracked expenses for their Black Friday shopping, or 4) set a budget for their regular shopping over the weekend and tracked expenses for their regular shopping. After the Black Friday shopping weekend, participants listed the purchases they made in both the Black Friday and regular shopping categories, and rated their enjoyment, satisfaction and pain associated with making each purchase.

We created two new variables that represent spending enjoyment for 1) the category that is tracked versus 2) the category that is untracked. For example, the tracked spending enjoyment variable represents enjoyment for Black Friday spending for people who were told to track their Black Friday spending, and represents enjoyment for regular spending for people who were told to track their regular spending. Higher constraint was associated with less enjoyment, but the relationship was stronger for tracked than untracked spending (Interaction: $F(1, 328) = 4.89, p = .028$). Tracked spending

enjoyment decreased as constraint increased ($b = -.068, t = -2.15, p = .032$), but untracked spending enjoyment did not ($b = -.008, t = -.286, p = .775$). Taking the simple effects the other way, a floodlight analysis found that the simple effect of expense tracking was significant for all values of constraint above the Johnson-Neyman point of 8.67. For people facing higher financial constraint, tracking expenses decreased the enjoyment they derived from spending. Budget setting did not affect enjoyment, nor did it interact with constraint. This study suggests that budget tracking differs from budget setting to uniquely impact the pleasure that people receive from spending money.

Taken together, these studies provide evidence for the processes by which budgeting helps people manage monetary constraints and achieve their financial goals. Budget setting clarifies financial goals, while budget tracking limits temptations by increasing pain of paying.

Resource Slack: A Theory of Perceived Supply and Demand

EXTENDED ABSTRACT

We provide a parsimonious framework that explains a range of intertemporal phenomena, from opportunity cost consideration to different forms of planning, to discounting, procrastination, the planning fallacy, and properties of financial decision-making. Our theory explains the relations among cognitive and motivational factors that determine when one will accept a given proposal P requiring the use of some resource. We also explain why one might be more open to the same proposal for the future than for now.

Resource slack is a perception of an absence of constraint, ranging from abundance to deficit. We account for perceived slack by cognitive and motivational factors that affect recruited supply of the resource and recruited competition for the same resources. Slack perceptions are affected by how one feels about the goals associated with some proposed activity and how one feels about competing goals that make use of the same resource.

Critically, slack determines whether one engages in memory-based augmentation of the consideration set when an explicit proposal P is on the table. When a single yes or no proposal is on the table, the explicit choice is a yes or no choice ($\{P, Pnot\}$), with a yes response if P clears a sufficiently high utility threshold. When people realize P might interfere with attaining competing goals attached to competing resource use C , they transform the choice to picking one or more from the set $\{P, C\}$. If there is sufficient slack, however, even an ongoing goal may not be considered as competition C , and so the decision remains one of $\{P, Pnot\}$. Our resource slack theory explains when people spontaneously consider competition when evaluating a proposal.

When available slack seems insufficient to allow pursuit of both P and C , one sometimes spontaneously generates a counterproposal P' that involves some mutation of the original proposal P that might allow both P' and C to fit within the resources available, such as delaying the proposal. We explain the slack processes that lead this delay to be repeated, producing procrastination (Shu and Gneezy, 2010).

Sometimes a counterproposal does not involve delay, but rather involves some other form of what Fernbach et al. (2014) call efficiency planning. Here, one mutates P to P' or C to C' in order to stretch one's resources to avoid having to choose. When a perceived slack deficit is dire and slack seems clearly insufficient to cover both the proposed P and the salient competition, C , one must consider priority planning. Priority planning entails explicit consideration of

opportunity costs, sacrificing lesser priorities to attain higher ones. People are often overly optimistic about their ability to fit in both P and C , in which case, prioritization sometimes happens too late to avoid painful losses of high-priority goals.

Our theory explains how factors affecting perceived resource supply now and in the future exacerbate these tendencies. It is relatively straightforward to assess resource supply in the present. But to predict resource supply for a future time period t involves a prediction of not just the per-period income of the resource at t , but of any accumulated savings or debt of the resource between now and time t . Selective recruitment of supply also distorts slack perceptions.

It is common to perceive more resource slack in the future than in the present and therefore to sharply discount the value of the resource in the future compared to the present (Zauberman and Lynch, 2005). This pattern of slack perceptions occurs if and only if one has more salient or more motivating goals for the present than for the future. We show that people perceive much more resource slack in the future than the present when they are close to attaining some goal in the present, but pursuing an interrupting proposal P might block attainment of that goal (Jhang and Lynch, 2015). The effects of goal proximity on intertemporal discounting explain many perplexing intertemporal phenomena such as hyperbolic discounting and impatience when deprived of some visceral reward like food or sleep.

We argue that any goal associated with focal competition C can produce similar effects—even subgoals whose completion could be delayed with no consequence (Jhang and Lynch, 2015). What makes these effects perplexing and difficult to anticipate is the fact that in pursuing a goal, one thinks implementally about subgoals, but only when doing so becomes relevant. We are typically closer to a subgoal than to the overall goal of which it is a part. People have some appreciation for an overall goal-gradient effect, but do not anticipate the power of subgoals. Subgoal proximity has a strong effect on one's perception of slack now versus at some point in the future, affecting whether that goal is represented as competition C in conflict with P .

Our theory shows how implemental planning and subgoal formation cause perceptions of slack. Reciprocally, perceiving little slack triggers planning. Economic theory suggests every action bears opportunity costs and that people should consider such costs in any decision. But some recent papers have claimed broad opportunity cost neglect (e.g., Frederick et al., 2009), consistent with Slovic's (1972) concreteness principle and Kahneman's (2011) principle of What You See Is All There Is. We show opportunity cost consideration is triggered by feelings of constraint (Spiller, 2011) and by fundamental factors that affect the accessibility of both pools of resource supply and recruited competition.

When the sufficiency of slack is ambiguous and a proposal is attractive, one may make optimistic slack projections that lead to "yes" responses. Misforecasting future slack produces the "Yes... Damn!" effect of agreeing to a proposal for the future that one later regrets; one would have declined had P been proposed for the present. This "Yes...Damn!" effect makes people susceptible to a planning fallacy of underestimating time to completion of some task, particularly tasks with multiple steps. In the financial domain, resource slack theory can explain the positive effects of "Save More Tomorrow" on retirement savings, the unexpected negative effects created by payday loans, and differential spending with cash versus with credit.

SESSION OVERVIEW

Extensive choice research focuses on providing a set of alternatives to examine preferences. While several important contributions have emerged from this literature (e.g., Simonson and Tversky, 1992; Dhar and Simonson, 2003), the majority of focus to date has been on this final aspect of the decision--choosing among available alternatives-- and relatively little attention has been given to how consumers think about options that are not explicitly part of the decision. Consideration of outside options may be guided by marketers through advertising and marketing communications, shelf displays, etc., or they may be a result of the consumer's thought process (Spiller 2011). In recent years, research has begun to explore how taking into account outside options affects the decision process as compared to only evaluating the immediate choice set (Frederick et al., 2009; Parker and Schrift, 2011; Posavac et al., 2004; Pratkanis and Farquhar, 1992). However, relatively little attention has been given to how the type of option considered impacts preferences and choice, and in particular, to the importance of how the outside options relate to the immediate choice set.

The current session seeks to address the following two questions: In what ways do consumers incorporate evaluations of outside options into their decision process? How does the perceived similarity of the outside option to the current choice set affect decisions?

The first two papers examine how similar versus dissimilar outside options affect purchase interest of a focal item. Friedman, Savary and Dhar explore the impact of consumer-generated alternatives, and find that when consumers consider alternatives that are dissimilar to the target item under consideration, purchase interest is decreased more than when they consider alternatives that are similar to the target item. The authors propose that this pattern is driven by additional goals being activated when considering dissimilar alternatives, which weakens the importance of the focal goal. Karmarkar finds an overall similar pattern of results when exploring how externally provided (rather than consumer-generated) display-only alternatives affect purchase decisions. Though she finds that similar display sets increase purchase intentions for a focal item above controls, she too finds that these intentions decrease when it is displayed with dissimilar items. In addition, she demonstrates that these similarity-

based effects occur independently of the value or intrinsic preferences people have for the specific alternatives themselves.

Schrift, Parker, Zauberman and Srna explore sequential decision-processes in which options are selected one attribute at a time (i.e., a decision-tree). They find that the order by which attributes appear in the tree impacts how similar or dissimilar consumers construe the outside options (i.e., the forgone alternatives in the set) to the one they initially preferred. Such a categorization process substantially impacts consumers' replacement choices. Finally, Baskin, Novemsky and Dhar examine differences in consumption when consumers think about the current choice as being a unique opportunity versus having the outside option of future instances of a similar choice. The authors explain that viewing a choice as an opportunity shifts the attribution of choice process away from the self and towards the situation, which results in more vice consumption and less virtuous consumption.

This session ties together four ways of looking at how specific outside options affect preferences, and in particular, the role of similarity in these varied decision processes. The session remains focused while also advancing connections, as the researchers build from a diverse set of literature, from traditional choice theory to decision neuroscience.

The Role of Similarity when Considering Alternatives in Purchase Decisions

EXTENDED ABSTRACT

When deciding whether to buy an item, consumers sometimes think about other uses for their money. For example, a man who is considering purchasing a \$25 button-down shirt might first think about other ways to spend that money. The alternatives may be similar to the target item, such as a polo shirt or a tie, or different, such as gas or a video game. In the current research we explore how purchase decisions vary depending on whether consumers consider alternatives that are similar versus dissimilar to the target item.

Past research on consideration of alternatives has primarily focused on comparing situations where no alternative is considered to situations where an alternative is considered (e.g. Posavac et al., 2004). In consumer contexts, subtle reminders to think about alternative uses of money have been shown to decrease purchase incidence (Frederick et al 2009). However, while past research has explored whether people do or do not consider alternatives, and the broad effect of prompting them to do so, an open question is if and how behavior may systemically vary depending on which alternatives are considered.

In the current research, we explore how purchase decisions vary depending on the similarity of the alternatives considered to the target item. Specifically, we show that when consumers consider dissimilar alternatives, they will be relatively less interested in purchasing the target item, as compared to when they consider similar alternatives. Our results are explained by a difference in goal activation. Viewing the target option activates a focal goal. When consumers consider dissimilar alternatives, additional goals are activated, which decrease the importance of the focal goal, and in turn decrease purchase intent of the target option. In contrast, considering similar alternatives does not activate a new goal, so the focal goal remains important, and purchase intent of the target does not decrease to the same extent.

Study 1A tested our primary hypothesis, that purchase intent of a target option decreases more when dissimilar alternatives are considered than when similar alternatives are considered. All participants evaluated two target items: movie tickets and a massage, with the order counterbalanced. After viewing a picture, price and short description of the target item, participants were asked to briefly list three alternative ways of spending the exact amount of money as the price of the focal. There were four between-subjects conditions: Participants in the similar condition listed alternatives similar to the focal. Participants in the dissimilar condition listed alternatives NOT similar to the focal. Participants in the unspecified condition did not receive instructions indicating type of alternative to list, and participants in the control condition skipped the step of listing alternatives. All participants then indicated their likelihood of purchasing the target item a 9-point likert scale.

We found that the type of alternative considered had a significant impact on purchase intent for the target item. As predicted, participants in the control condition indicated the highest interest in purchasing the target ($M=5.9$), followed by participants in the similar condition ($M=4.8$), followed by those in dissimilar condition ($M=4.1$). Participants in the unspecified condition resembled those in the dissimilar condition in purchase intent ratings ($M=3.7$), as well as the type of alternatives they listed. The unspecified condition sheds light on the types of alternatives consumers might consider spontaneously, and offers evidence against the explanation that the difference in purchase intent between the similar and dissimilar conditions is due to similar alternatives already being taken into account in some capacity. Study 1B replicates these results using utilitarian rather than hedonic target items, and suggests that the effect is not limited to hedonic target items.

In study 2, we rule out an alternative explanation that the difference in purchase intent is driven by the attractiveness of alternatives, rather than by their similarity to the focal item. We use a 2 (attractiveness: more vs. less) \times 2 (similarity: similar vs. dissimilar) design, where we manipulate attractiveness by prompting participants to generate alternatives that are more or less attractive than the focal. We replicate our main effect of similarity, and find null results for the attractiveness manipulation.

In study 3, we examined a situation in which participants faced a choice between multiple target options (two shirts), rather than viewing one item in isolation, to test if considering alternatives impacts choice in the same way when multiple options are already available. There were 3 between-subjects generation conditions: similar, dissimilar and control. Like in study 1, participants in the similar and dissimilar conditions generated three alternatives before indicating whether they would buy one (or both) of the shirts, or choose to buy neither; participants in the control condition skipped the generation step. Consistent with previous studies, more participants chose not to buy a shirt in the dissimilar condition (54%) than in the similar condition (38%), and fewest in the control condition (14%).

Finally, study 4 explored a real world online shopping scenario in which marketers provide alternatives, rather than consumers generating the alternatives. Participants viewed a screenshot of a shopping webpage with the target option (wireless speakers) and its description. Beneath the speakers were two recommended products, which were either similar to the speakers (other music players) or dissimilar (two shirts). Participants were more likely to buy the speakers when the alternatives were similar ($M = 5.4$) than when they were dissimilar ($M = 4.9$). Moreover, we use a mediation model to investigate our underlying mechanism. We asked participants to specify the goal that the wireless speakers would fulfill for them, and subsequently asked them how important that goal was to them.

We show that the effect of similarity of the alternative considered on purchase interest of the target is mediated by goal importance. Participants in the dissimilar condition viewed the focal goal as less important, and in turn were less interested in purchasing the target.

Taken together, these results suggest that considering alternatives to purchase has an effect beyond merely taking them into account or not; the type of alternative considered can have a significant impact on purchase decisions.

The Impact of 'Display Set Composition' on Purchase Likelihood

EXTENDED ABSTRACT

Suppose you are shopping online, and deciding whether to buy a specific coffee maker. Are you more likely to click the "buy" button it when it is featured on its own product page, or when it is on a page that shows other recommended coffee makers? What if you came across it on a site advertising popular products from several different categories?

It's well established that changing the composition of a choice set can influence people's decisions and shift their preferences (e.g. Tversky and Simonson, 1993; Bettman, Luce and Payne, 1998; etc.). These studies often examine how increasing the options in a set will cause switching, or influence preferences for one item of interest in comparison to the others. However, it remains unclear how a buy/no buy decision about one particular item might be influenced by its display set composition.

Previous research has examined the impact of "phantom" alternatives, or choice options that are presented to an individual despite being unavailable (Pratkanis and Farquhar, 1992). Phantom alternatives create a range of biases dependent on several factors, including the degree of uncertainty about their unavailability (Farquhar and Pratkanis 1993). But when their unavailability is concrete, phantoms can create preference shifts similar to those observed with real alternatives (e.g. Doyle et al. 1999). Thus in the current work, we propose that the mere (viewable) presence of additional items in the display will impact perceptions of value and likelihood of purchase, even when the actionable "choice set" is held to a single target product.

Recent findings in decision neuroscience on "value normalization" mechanisms have shown that adding options to a set can create a net reduction in the perceived value of a preferred item in addition to making it less discriminable from other options (e.g. Louie et al. 2013, Webb et al., 2014). As a whole, these findings suggest that additions of display-only items may decrease the target's purchase likelihood by decreasing its perceived value. Furthermore, they predict that the effects may be strongest when the display items are comparable to the target.

Study 1 tested our basic hypothesis that display set composition can alter purchase intentions, as well as the predictions arising from value normalization. Participants ($n=225$) were asked to make four hypothetical buy/no-buy decisions. Those in the "alone" condition saw a labeled photo of the target product and its price. Participants in the "comparable" condition saw the same target product/price information flanked by photos of two products from the same general category (e.g. a target board game shown between two other board games). Participants in the "non-comparable" condition saw the products flanked by photos of two products from other categories (e.g. a target board game flanked by a Swiss army knife and a candle.) Participants were informed that the non-target products were only there as part of the display.

Comparing the three conditions, we found significant differences ($p < .01$), largely arising from whether the “display items” were from the same or different product categories. Average total purchase rates for the four products in the comparable condition ($M = 1.77$) were marginally higher than the alone condition ($M = 1.47$, $p = .08$), and significantly higher than the non-comparable condition ($M = 1.25$, $p < .02$). The difference between non-comparable and alone was not significant. Surprisingly, despite these differences in purchase intent, the display items did not change average liking rates for the target items, nor did they influence average willingness to pay for them.

Given the disparity between these results and the decreases in value predicted by value normalization, Study 2A tested how much the impact of display items depends on the specific products shown. We offered participants a single hypothetical purchase decision assigned via a counterbalanced 2x2 design that varied the type of target item (art poster vs. board game) and the category of the display items (comparable vs. non-comparable). Once again, we found a (main) effect in which purchase intentions were higher in the comparable compared to the non-comparable condition. There was no main effect of product type, nor interaction effects, suggesting that the increases in target purchase likelihood were not due to the display items themselves, but to their similarity to the target. Study 2B tested this question using a within-subject design where each participant made multiple incentive-compatible decisions about target products in both types of displays. We again found a significant benefit of comparable over non-comparable display sets on willingness to purchase.

Secondary regression analyses on data from Studies 1 and 2A did reveal that, pooling across conditions, preferences for the display items had a significant positive correlation with purchase intent towards the target item. This raises the question of whether our observed effects could be boosted or diminished by the relative value of the display items as compared to the target. Study 3 examined this by manipulating the display items’ a priori value (high vs. low) and similarity to the target item (comparable vs. non-comparable). We once again replicated our main similarity finding, but found that the value of the display items had no direct or moderating effects on purchase rates.

Overall, we find that adding items to the “display set” does indeed significantly impact buy/no buy decisions, but in a direction seemingly contrary to the predictions of value normalization models. Rather our results suggest that when the display set consistently reflects one category, it increases the likelihood of making a purchase from that category. One practical implication of this work is that retailers may be most effective at promoting a product by ensuring that it draws attention on the shelf among similar products rather than featured separately as one-of-a-kind.

Decision-Tree Structures and their Impact on Similarity Judgment and Replacement Choices

EXTENDED ABSTRACT

Consumers often seek replacement options when their preferred option is unavailable. The current research demonstrates that slight variations in the initial decision-making process—which do not affect initial preferences—significantly impact consumers’ replacement choices. Specifically, we focus on a hierarchical decision structure (i.e., decision-tree) in which alternatives are first screened on a single attribute and then further screened on other attributes, in a sequential process, until an option is chosen. Integrating research on preference trees and runner-up options, we find that the specific decision-tree structure (i.e., the order of attributes in the tree) impacts consumers’

replacement choices. Consumers tend to replace their most preferred option with alternatives from the same branch (i.e., stick with attribute levels that were chosen earlier in the tree).

Such patterns may, at first, appear contradictory to existing literature showing that consumers tend to deemphasize the importance of screening attributes, and over emphasize post-screening (or “selection”) attributes (e.g., Chakravarti et al. 2006; Diehl et al. 2003). According to these findings, one would expect that consumers would be more likely to stick to later attributes in the sequence when choosing replacement options. However, this previous work (i) did not explore replacement choices, (ii) did not manipulate order of attributes in the tree, and (iii) examined nested hierarchical decision-trees; that is, contexts in which the initial screening criterion (e.g., “beef” vs. “fish”) substantively alters the options available in the subsequent stage(s) (e.g., “steak or roast-beef” vs. “sole or trout”). The current work examines contexts in which all combinations are feasible (i.e., non-nested decision-trees) and whether the order of attribute decisions in such non-nested trees impacts replacement choices. We find that consumer’s preference for a replacement option is affected by the tree structure, and that consumers tend to stick with earlier decisions they made in the tree. Seventeen studies demonstrate this extremely robust effect. We explore different possible mechanisms underlying the effect and discuss relevant literature.

In Study 1 participants chose between different pens, each described in terms of color (5 levels) and material (2 levels), resulting in 10 available color-material combinations. In a between-subjects design, participants either directly chose one of the 10 pens (control), or made their choice in a two-stage decision process (color first then material vs. material first then color). After learning that their chosen pen was unavailable, participants chose their replacement option by either keeping their choice of color and replacing the material or vice versa. The decision-tree structure significantly impacted participants’ replacement decisions. Participants that chose material first were more likely to keep the pen’s material (64%) compared to those that chose color first (38%, $z = 2.72$, $p < .006$; control condition = 47%). Participants’ assigned attribute weights (using a constant-sum allocation task) showed a consistent and significant pattern. Eight additional studies replicated this robust effect across different decision contexts (e.g., cups, clocks, catering-services, food-items, hiring-decisions, paintings, visual-tasks). Additionally, the results were replicated with more than two hierarchy levels and when all attributes possessed the same number of levels. Further, the effect persisted in incentive compatible contexts and across different response and presentation modes. That is, participants tended to stick with their choice of initial attribute even when all alternatives were initially presented (screening, as opposed to choosing, format) and also when all replacement options were available for choice.

Exploring different potential mechanisms, we found the effect to persist when the initial choice was made for the participants either randomly (study 10) or by a third-party (study 11). That is, even when participants did not choose the original option, their choice of replacement option was still driven, in the hypothesized direction, by the decision-tree structure. Thus, choice-based explanations such as dissonance, self-perception, and reason-based choice, as well as explanations based on need for internal consistency or choice closure (suggested by Wright and Barbour 1977) do not fully account for the pattern of results (in Study 12 neither need for closure or internal consistency were found to moderate the effect).

Next, we examined whether the effect may be driven by inferences about attribute weights. In particular, previous literature suggested (and demonstrated) that decision makers attend to

attributes by order of their importance (e.g., elimination-by-aspect). Therefore, it is possible that when the order of attributes in the tree is externally provided, decision-makers infer that initial attributes are more important and therefore tend to stick with their originally chosen branch. In Studies 13 and 14 it was made extremely salient to participants that the order of attributes was determined randomly. In Study 15 participants were asked to choose among 4 tasks that were described on completely meaningless attributes (letters and colors). The effect persisted, indicating that inferring weights from the order in the tree is not the main driver of the results.

Finally, in Study 16 we explored whether the effect is driven by a categorization and similarity judgments (e.g., Goldstone 1994, 2001; Livingstone et al. 1998). We find that decision-makers perceive alternatives that belong to the same branch in the decision-tree as more similar and perceive the action of switching branches as more extreme (i.e., a greater change). As in Study 15, participants chose among 4 tasks that were described on completely meaningless attributes. However, when learning about the unavailability of their chosen task, participants either received a positive cue about this task (triggering a motivation to replace this task with a similar task), or received a negative cue (triggering a motivation to replace the task with a dissimilar task). The effect replicated in the positive but not in the negative cue condition. Thus, indicating that decision-makers associate the decision-tree structure with a similarity judgment between alternatives. In Study 17, we find that the motivation to replace the original option with either a similar or a distinct option mediates the effect.

In the current investigation we attempted to isolate the effect (which is theoretically and substantively important) using different paradigms. The results lend support to a categorization process in which consumers construe alternatives that share a branch on the decision tree as more similar.

Moderating the Effect of Self on Choice

EXTENDED ABSTRACT

Opportunity: A favorable combination of circumstances, time, and place

Merriam-Webster Dictionary (2014)

In both profit and non-profit sectors, marketers often position their products as an opportunity. For instance, Honda ran an ad campaign centered around a character named Mr. Opportunity who let viewers know that opportunity was knocking for them to buy a car. In the non-profit sector, many organizations position their volunteer and donation appeals as an opportunity to support their charity's mission. In fact, the five universities with the highest endowments all discuss charitable giving as an opportunity to make a gift to an institution of higher learning. Despite consistent use of the word, "opportunity," by marketers, relatively little is known about how thinking about a choice or decision as an opportunity affects consumer cognition and preferences.

We propose that when a choice is framed as an opportunity, the salience of the situation is increased. This increases the tendency to attribute the choice to the situation (Storms 1973). Generally, research has found that choices influence individuals' self-concept (Bem 1972) and these influences can be anticipated (Bodner and Prelec 2003). However, once the attribution shifts to the situation, choice attribution shifts to the situation and their impact on one's self-concept is reduced thus shifting preferences.

In many important choices, consumers are confronted with vices - tempting, impulsive options that have a negative association

with the self-concept (e.g., they make consumers feel that they are someone who has low self-control; Dhar and Wertenbroch 2012; Khan and Dhar 2006). We propose that when a vice is considered as an opportunity, the situation becomes the perceived basis of choice for the vice. This leads to fewer negative self-inferences if the vice is chosen since the reason for the choice can be attributed to the situation rather than the self. Lacking negative repercussions to the self-concept, preferences for vice opportunities increase.

It is important to note that the shift in attribution of the choice to the situation does not predict a general increase in an option's choice share when viewed as an opportunity. Rather, the change in preference depends on how choosing the option affects the self-concept. Consumers often face virtuous options - options linked to more positive, long-term aspects of the self-concept (Dhar and Wertenbroch 2012; Khan and Dhar 2007). Accordingly, when a virtuous option is framed as an opportunity, the choice of that option is more likely to be attributed to the situation, thus decreasing the positive benefits to one's self that would otherwise be received from choosing that option, and, therefore, preference for that option decreases.

To illustrate, consider a person who is deciding whether or not to choose an indulgent chocolate cake for dessert at a restaurant. Choosing to consume the chocolate cake may entail negative attribution about one's self-concept and hence may decrease the willingness to choose the chocolate cake (Okada 2005). However, if the choice of the same indulgent chocolate cake is an opportunity, the person might focus on the situation that brought about the chance for them to have chocolate cake. Thus, the negative costs to their self-concept from choosing the chocolate cake, such as thinking that they are unhealthy or have low self-control, decrease. Since the costs decrease and the benefits remain the same, it becomes more likely for the person to choose the chocolate cake.

Conversely, imagine a person who is called by their university alumni association for a donation. They might choose to donate because they want to signal something good about themselves when making their decision (Gneezy et al. 2012; Savary, Goldsmith, and Dhar 2014). However, the donation becomes a less diagnostic signal that the person cares about their alma mater when it is framed as an opportunity by the university. This is because the donation is attributed to the specific situation, such as the alumni officer calling them and asking for a donation. Thus, the donation's positive self-benefits decrease and therefore, the individual is less likely to donate.

The present research differs from previous research in several important ways. First, to the best of our knowledge, it is the first to demonstrate that framing a choice as an opportunity can influence attributional processes and subsequent preferences. Second, we show that this novel framing effect, i.e. opportunity framing, operates like a mindset and can persist and affect subsequent choices much like other mindsets. Finally, our research has important implications for any product whose choice results in either positive or negative self-attribution.

To explore the effects of opportunity frames on choice, we conducted six studies. Studies 1A and 1B show that preference for a vice increases when participants think about the choice as an opportunity. In support of our theory, the extent of the vice choice's dispositional attribution mediates this effect. Study 2 demonstrates that, in an opportunity frame, virtuous choices, such as donating to charity, become less preferred. Study 3 supports our underlying mechanism that opportunity framing of a choice increases situational attribution by putting participants in a strongly dispositional mindset and showing that this attenuates the effects of an opportunity frame. Next, we demonstrate that opportunity framing can lead to

a temporary mindset that carries over to unrelated choices. Study 4 shows that thinking about several events as opportunities prior to making an unrelated choice can cause that choice to be viewed as an opportunity. Finally, in study 5, we show that the use of the word opportunity in an advertisement is sufficient to induce an opportunity frame and generate both an increased preference for a vice and a decreased preference for a virtue.

SESSION OVERVIEW

Recent data from the National Center for Charitable Statistics shows that almost 3/4th of the contributions to nonprofit organizations come from private individuals. However, even with such high stakes, the charitable solicitations and other pro-social appeals used to solicit individual donations are rarely determined by empirical evidence. Therefore, it is important to systematically and scientifically investigate the various levers that can be used to influence pro-social behavior. In this session we bring together research both from the lab and from the field to shed light on the psychology of donation decisions and increase the efficacy of charitable appeals. The research in this session investigates the interplay between the structure of the appeal, information provided, and the social context of giving. We believe that these findings not only offer significant practical implications, but also leverage the setting of charitable giving to make important theoretical contributions for decision researchers.

Solicitation campaigns aiming to increase participation often employ some kind of incentive. Anik and Norton propose that highlighting the crucial role that an individual decision maker can play to *tip* a contingent reward to a higher level, affecting not only themselves but also other donors, can increase their motivation to participate. For example, informing a potential participant that getting a blood test would increase the amount donated for every participant from a baseline of \$x to a higher level of \$y, increased the likelihood of participation. The effectiveness of tipping points is driven by a sense of responsibility towards fellow participants. The intervention performs better than offering non-contingent financial rewards and is more effective at lower levels of contingent reward than at higher levels. This suggests that the intervention could be not only behaviorally effective but also economically efficient.

Morewedge and Carlin proposes another way to increase participation by instantiating the psychological state of the charity’s beneficiaries. This research demonstrates that empathy-invoking solicitations that invoke negative or unpleasant emotions to help the donor “feel the pain” of the beneficiary can be more effective than positive appeals, even when subjects evaluate both the appeals as equally important. Appeals that increase potential donors’ empathy for the targets can also potentially explain previously documented phenomena like the identifiable victim effect (Small, Loewenstein,

& Slovic, 2007) and martyrdom effect (Olivola & Shafir, 2013) and therefore has both theoretical and practical implications.

Extant research has documented that pre-set defaults have robust effects on choices, in consequential domains, including organ donation and retirement savings. However, the effect of an active-choice default on amount (as in charitable solicitations), which involves both the participation rate and average contribution, has not been systematically investigated. Using a large-scale natural field experiment, Goswami and Urminsky find that the effect of defaults on donation decisions is driven by two separate effects – designating a low amount as default *lowers the bar* and motivates more participants to contribute. However, participating donors *scale back* their contribution amount when faced with lower defaults. The net effect of these two conflicting forces determines the effect of defaults on donation amounts. The predictions of existing theories of defaults, suggesting either a direct default effect or a backlash against high defaults are both unsupported, suggesting the need to revisit our understanding of such useful nudges, particularly in the context of charitable giving.

Finally, Berman, Barasch, Levine, and Small examine how consumers make decisions regarding charities when effectiveness information (i.e., the total of good done per dollar donate) is available. The authors find that because consumers tend to believe that the choice of where to donate money is a subjective decision, they often weigh personal preferences at the expense of maximizing effectiveness. Specifically, they find that that consumers are less likely to use effectiveness information for charitable decisions than for investment decisions, and further, consumers are less likely to search by effectiveness ratings as compared to investments. They also find consumers use less effectiveness information when choosing between charities in a diverse rather than uniform choice set.

Taken together, we expect that this session will be of interest to a broad audience, facilitating connections among researchers interested in either pro-social behavior, judgment and decision making, persuasion and social influence, incentives or policy “nudges”. This session will also contribute to the diversity of research methods, featuring data from varied methodologies. We believe that understanding how decision makers think when confronted with a charitable solicitation identifying the conditions that yield optimal effectiveness is of crucial importance for both theoretical and practical reasons. We hope that this session will advance these connections and promote future research that improves our understanding of the science of charitable giving.

On Being the “Tipping Point”: Threshold Incentives Motivate Behavior

EXTENDED ABSTRACT

We explore and document a new intervention to motivate behavior: being the *tipping point*, the person whose contribution passes a threshold that kicks in a higher reward for the self and others. Anik, Norton, and Ariely (2014) showed that offering incentives contingent on other people’s behaviors is motivating: “If 75% of people engage in this behavior, we will increase the rewards for everyone.” Across three studies, we explore whether specifically being the person who tips that incentive is particularly motivating: “We are currently at 74% and you will bring us up to 75%.”

In Study 1, we asked participants to imagine a hypothetical scenario where donation would be made to a local health charity for each person who got a blood test. Participants were randomly assigned to a 2 (condition: *tipping* vs. *control*) X 3 (level of progress: *low*, *medium*, *high*) design. We told those in the *tipping* conditions that [9, 49, 89] people have gotten a blood test so far, and the amount to be donated per participant was [25¢, \$1.27, \$6.41]. If they agreed to get a blood test, since they would be the [10th, 50th, 90th] person, each donation would increase to [37.5¢, \$1.90, \$9.61], respectively. If they decided not to get a blood test, the per-participant donation rate would stay at [25¢, \$1.27, \$6.41]. We told those in the *control* conditions that [10, 50, 90] people have gotten blood tests so far, and the amount donated per person was [37.5¢, \$1.90, \$9.61]. If they also got a blood test, they would be the [11th, 51st, 91st] person, and each donation would still be [37.5¢, \$1.90, \$9.61]. Next, participants indicated their likelihood of getting a blood test using a 7-point scale (1 = *not at all likely*, 7 = *definitely likely*).

A 2 (condition: *tipping*, *control*) X 3 (level of progress: *low*, *medium*, *high*) ANOVA revealed a significant main effect of condition, $F(1, 286) = 17.41, p < .001$. The main effect for level of progress and the condition X progress interaction were both marginally significant, all $F_s > 2.52, p_s = .08$. Participants in the *tipping* conditions indicated a significantly higher likelihood of getting a blood test ($M = 5.37, SD = 1.81$) than those in the *control* conditions ($M = 4.44, SD = 1.91$), $t(290) = 4.30, p < .001$, suggesting that overall being the *tipping point* was indeed more motivating. A closer analysis revealed that at *low* and *medium* progress levels, participants' likelihoods of getting a blood test were significantly higher when they were the *tipping point*, all $t_s > 3.16$, all $p_s < .003$. However, for *high* progress level, being the *tipping point* was not more motivating than the baseline, $t(108) = .64, p = .53$.

One reason *tipping points* are more motivating when they are earlier, rather than later, could be that large contingent monetary incentives might have "crowded out" motivation (Deci 1975; Lepper, Greene, & Nisbett 1973). Therefore, in Study 2, we pit the impact of being the *tipping point* against small, non-contingent monetary incentives. The scenario used was very similar to the one in Study 1. Participants were randomly assigned to one of five conditions. The *tipping* condition informed participants that they could be the 10th person who tipped the donation from 50¢ to \$1 for everyone. Participants in the *non-tipping* condition were told that they could be the 10th person, and the donation would still be 50¢ per head. Finally, those in one of three *non-contingent incentives* conditions were not told about other's behavior, and were informed that [\$1, \$5.50 or \$10] would be donated to a charity on their behalf if they got a blood test. Participants indicated their likelihood of testing (1 = *yes*, 0 = *no*).

We replicated the effect that social incentives were more effective than nonsocial incentives ($M = 75.47\%$ vs. 58.67%), $\chi^2(1) = 3.98, p < .05$. Further contrasts revealed that percent of participants who agreed to getting a blood test in the *tipping* condition ($M = 85.71\%$) differed from the *non-tipping* condition ($M = 75.47\%$), $\chi^2(1) = 3.36, p < .07$, as well as from all three *non-contingent* conditions, $\chi^2_s > 4.49, p_s < .04$. Results show that being the *tipping point* in a social group is motivating above and beyond offering monetary incentives alone or providing only social information.

In Study 3, we ran a study with real consumer behavior where participants reviewed a restaurant experience in exchange for donations to a project that provided lunchbox to kids. There were three conditions: a *non-contingent incentives* condition offered a \$3 donation; a *tipping* condition grouped participants with two others, and by reviewing the restaurant, donations for all three participants would

jump from 50¢ each to \$1 each (a total of \$1 donated in total if the participant didn't respond to \$3 total if they did); and finally, a *social no-tipping* condition, where the amount donated for each participant was \$1, \$3 in total for the charity. Using a 7-point scale (1 = *not at all*, 7 = *a great deal*), participants answered a series of questions about how much responsibility they experienced towards other participants and towards the kids who would receive the lunchboxes and their feelings of altruism, impact, substitutability and guilt in general. Our dependent variable was the percent of participants who provided a review.

Again, we found that setting incentives contingent on social behavior led to a significantly higher percent of reviews than offering non-social incentives, ($M = 42.73\%$ vs. 33.83%), $\chi^2(1) = 2.13, p < .04$. Further analysis showed that the effect of social incentives was driven by the *tipping* condition as it resulted in participation significantly higher than in *social no-tipping* condition ($M = 50.00\%$ vs. 35.71%), $\chi^2(1) = 2.15, p < .04$. Finally, a mediation analysis revealed that the effect of being the *tipping point* on participation was mediated only by participants' feelings of responsibility towards fellow participants, rather than feelings toward the recipient or general feelings of altruism, guilt, substitutability or impact.

"I Feel Your Pain" The Efficacy of Instantiating States in Charitable Appeals

EXTENDED ABSTRACT

We examine the efficacy of charitable appeals that instantiate the psychological state of the target (the person helped by the charitable organization) in prospective donors in four experiments. Participants were more likely to donate a bonus to the same charity when presented with a more negative but empathy-evoking solicitation than a more positive informational solicitation stressing the importance of its work (Study 1). Participants were more likely to report they would participate in a fundraising event that was semantically related to the experience of the target than a semantically unrelated event (Study 2). Participants were more likely to report they would participate in fundraising events for causes of equal importance when the salient target of causes were possible to empathize with (people) than impossible to empathize with (abstract causes; Study 3). Finally, participants were more likely to report they would participate in a fundraising event for the same target when the event instantiated the state experienced by the target than when the event evoked an unempathetic state (Study 4). The results suggest a mechanism to increase charitable giving and that may help to explain the identifiable victim (e.g., Small, Loewenstein, & Slovic, 2007) and martyrdom effects (Olivola & Shafir 2013) that have been previously identified.

In Experiment 1, we assessed the effect of empathic (evocative) appeals on donation size. In this experiment, one cause (the Make-A-Wish Foundation) was selected and participants were assigned to an empathetic or an informative appeal. Participants in the empathetic appeal condition were given a salient target, an involved description of the suffering of the target, and the role of the charity in helping the target. In the informational condition, participants were provided with relevant information about the charity, their cause, who they help, what some of their events have included, and its fiscal responsibility and outside ratings. Both conditions were similar with respect to the amount of material they provided; the empathic appeal was more negative emotion inducing and positive emotion reducing in a pretest, $t_s(100) \geq 3.29, p_s \leq .01$. After reading an appeal, participants received a \$1 bonus and donated what they wished of it to that charity. Participants in the empathetic appeal condition donated sig-

nificantly more ($M = 32.2\%$; $SD = 29.4$) than did participants in the informational appeal condition ($M = 18.3\%$; $SD = 28.8$) and reported significantly higher levels of empathy for the target ($M_{\text{empathic}} = 6.04$, $SD = 1.50$; $M_{\text{informational}} = 5.25$, $SD = 1.87$), $t(100) = 2.05$, $p = .04$, and $t(100) = 2.36$, $p = .02$, respectively. Neither group deemed the cause more important, $t(100) = 1.32$, $p = .19$.

In Experiment 2, we compared the efficacy of participation in charitable events that would evoke empathy in the donor for targets (semantically related) to events that were pleasurable but unlikely to evoke empathy in the donor for targets (semantically unrelated). More specifically, in Experiment 2, we selected four causes (e.g., quality of life for nursing home residents) and then chose events that had been rated as semantically relevant or irrelevant to those causes (e.g., a bingo night vs. Texas hold'em night). Participants first rated their likelihood of attending all eight events (if they were not for charity). For the relevant condition, for each of the four causes, participants were shown a semantically related event to the cause and rated their likelihood of attending to support that cause. For the irrelevant condition, for each of the four causes, participants were shown a semantically unrelated event to the cause and rated their likelihood of attending to support that cause. Participants in the relevant condition reported feeling more empathy and connection to the targets, $t(116) > 4.03$, $p < .001$, and exhibited a greater increase in willingness to attend the events ($M_{\text{Attendance}} = 1.14$, $SD = 1.50$) than participants in the irrelevant condition ($M_{\text{Attendance}} = .58$, $SD = 1.40$), $F(1, 116) = 4.24$, $p = .04$.

In Experiment 3, we further tested the proposed process by presenting participants with a charitable fundraising event that was relevant to targets, but manipulating whether or not the salient target of the charity was capable of evoking empathy. Participants first rated their likelihood of attending six events. For a set of three causes, each participant then rated their likelihood of attending three of those events in support of related abstract targets (e.g., clean rivers) or related human targets (e.g., education for underserved school children), so that participants would be more likely to empathize with the target in the latter than in the former condition (Jenni and Loewenstein 1997). We found that participants exhibited heightened empathy and were more willing to participate in the event when the targets were human ($M_{\text{Attendance}} = 1.04$, $SD = 1.25$) than abstract ($M_{\text{Attendance}} = .34$, $SD = 1.02$), $t(138) = 3.63$, $p < .001$. In contrast, they rated both kinds of causes as equally important and cause-event pairings to be equally relevant across the two conditions, $t(138) \leq 1.26$, $p \geq .21$.

In Experiment 4, we manipulated the degree to which events elicited empathic understanding for targets. Participants were presented with semantically related charitable fundraising events for the same three targets (e.g., the hungry), which were designed to either evoke the state experienced by the target in the prospective donor (e.g., giving up lunch for a day) or designed to evoke a state inversely related to the state experienced by the target (e.g., a tasting menu at a Michelin star restaurant). In support of our hypothesis that understanding the target's state and "feeling his/her pain" drives empathy and charitable commitment, we found that the empathy-evoking events did evoke more empathy for the target, $F(1, 142) = 26.09$, $p < .001$, and increased the likelihood of participation in the fundraising event ($M_{\text{Attendance}} = .76$, $SD = 1.07$) relative to the non-empathetic event condition ($M_{\text{Attendance}} = -.28$, $SD = .93$), $F(1, 142) = 37.47$, $p < .001$. Events considered, however, did not influence the perceived importance of the causes, $F < 1$.

The Effect of Default Amounts on Charitable Donations. Evidence from a Large-Scale Field Experiment

EXTENDED ABSTRACT

When factors in the decision environment influence the choices people make, changes in those factors ("nudges") can be used strategically to influence people's choices. However, the research underlying nudges tends to point to the existence of psychological phenomena, rather than quantifying the effects of such nudges or identifying the optimal configuration. In this paper we investigate how an active-choice default option, a widely studied and much discussed "nudge", affects donations when used in fundraising appeals, and the implications for optimal choices of default amounts. Using a large-scale field experiment, we find evidence for two primary influences of defaults on donations: a "scale back" effect (lower donation amounts when a small donation amount is defaulted), and a "lowered bar" effect (more people donating when the small amount is defaulted). The interplay of these two effects determines the net effect of defaults on the amount raised from campaigns using a defaulted amount.

We conducted an experiment in the spring 2014 phase of the annual alumni fundraising campaign of a large Midwestern business school. In total, up to two mailings were sent to the 7917 prior donors who had not yet donated that year. Subjects were randomly assigned to one of the cells of a 4 (default level: Low, Medium, High, None) x 2 (reminder about prior donation amount: No, Yes) x 2 (number of options to designate what their donation would be used for: 2, 5) full-factorial design. The default amount was operationalized by highlighting a particular menu option with a different color and labelling it as 'suggested'. The menu options presented to the participants were customized based on prior donation behavior, with the middle menu-option being their previous donation amount. In total, the mailings yielded 76 donations, a 0.96% participation rate. The relatively low donation rate was due to targeting "colder" prior donors, who had not responded to appeals in the previous waves of that fiscal year's campaign.

Setting the low option as the default increased revenue compared to the no-default control ($M_{\text{Low Default}} = \2.60 vs $M_{\text{Control}} = \$1.87$), but that was not the case for the other default amounts. The medium and high defaults yielded similar revenue (\$1.75 and \$2.11, respectively) as control. Importantly, setting the high menu option as the default did not result in a revenue-reducing backlash effect in this context. These findings were confirmed in a series of regression analyses predicting the log of per-person revenue, controlling for lasso-selected covariates to avoid over-fitting. The effect of defaults on net revenue was robust across demographic and prior donation behavior differences, and was not moderated by the two other experimental manipulations (reminder of prior donation and the number of allocation options).

The effect of defaults on net revenues can be decomposed into the effect of defaults on participation and on average contribution among those donating. The low default significantly increased donation rates, relative to no default (1.6% vs. 0.7%, $c^2 = 10.23$, $p = .001$), and compared to medium and high defaults combined, low defaults resulted in a marginal increase in participation (1.6% vs. 1%, $c^2 = 3.06$, $p = .08$). Therefore, *lowering the bar*, by setting a lower default, encouraged more donors to participate in the campaign. The lower default may allow the donor to pay less without harming their pro-social self-image (Gneezy et al. 2010) and still experience the same good feeling as donating a larger amount, in effect obtaining "warm glow" (Andreoni 1990) at a discount.

Unlike participation, our inferences about average donations are under-powered, on account of the low number of donation incidences observed. Overall, the average amount donated was lower when an option was defaulted ($M = \$178$), compared to the no-default control ($M = \$283$). Among the default conditions, the average donations were consistent with a “*scale back*” effect: highest for the high default ($M = \$204$), \$25 lower for the medium default ($M = \$181$), and approximately \$20 lower for the low default ($M = \$162$). Therefore, increasing the default amount resulted in participants scaling back their donation amounts. This effect might arise from inferential reasoning about the norms or needs conveyed by the pre-selected default level. Additional lab-based studies demonstrate the “*scale back*” effect with actual choices.

Our findings did not provide support for the most optimistic prediction, a direct-default effect, in which simply setting one option as a default would consistently increase funds raised. However, we also found no support for the most pessimistic prediction, a backlash effect, in which setting a default (particularly a high amount default) would lead to rejection of the defaulted amount and lower revenue. The conflict between increased participation and lower donation amounts when using a low default points to both the difficulty of blanket policy prescriptions and the limitations of existing theories. In sum, the net effect of defaults on revenue is determined by the relative strengths of the “*scale back*” and the “*lowered bar*” effect. We are continuing to track donations, and will be able to also report the long-term effects of defaults on the subsequent year’s donations at the time of the conference.

Limits of Effective Altruism

EXTENDED ABSTRACT

Recent years have seen a rise in the “Effective Altruism” movement, which attempts to quantify the effectiveness of charitable organizations in order to better allocate resources to those in need. The Effective Altruism movement has gained followers from fields like economics and finance, which emphasize maximizing returns. Effective Altruism treats charitable giving as a social investment where the goal is to maximize social return, by donating to causes where one can do the most social good for each dollar donated (Baron and Szymanska 2011; Singer 2009).

We investigate how everyday consumers make decisions about where to donate their money. We argue that consumers do not naturally think about donation decisions as similar to investment decisions; their goal is not just to maximize an objective return. Instead, they think of the decision as relatively subjective, and therefore are often willing to compromise on effectiveness in order to satisfy their personal preferences. Studies 1 & 2 show that consumers are less likely to use effectiveness information for charitable decisions than for investment decisions. Study 3 shows that when searching for a charity, consumers are less likely to search by effectiveness ratings as compared to investments. Finally, Study 4 shows that presenting options in a relatively diverse (as opposed to uniform) choice set leads consumers to select a charity that fits their subjective preferences at the cost of maximizing effectiveness.

In Study 1 ($N = 201$), participants were told that they received a promotion for joining a local bank. In the Charity condition, the bank gave participants their choice to donate \$100 to one of three fictitious charities, and a description of each charity was provided (e.g., “Main Street Housing Fund: This charity builds residential homes for those in need”). In the Investment condition participants could invest \$100 into one of three fictitious companies (e.g., “Main Street Housing Corp: This company builds residential homes to sell

to individuals”). Participants were also provided with effectiveness information for each option on a 0 to 100 scale, with higher numbers representing more effective options. For the charities, effectiveness was defined as doing “the most good for each dollar donated” whereas for the investments, effectiveness was defined as providing “the best return for each dollar invested”. Results show that in the Charity condition, significantly fewer participants chose the most effective option (45.5%) than in the Investment condition (64.0%; $Z = 2.63$, $p = .009$).

Study 2 ($N = 214$) replicates these results in a more controlled setting. First, we changed the scenario so that the decision was self-directed and was not tied to a financial institution. Specifically, participants were told to imagine that they sought either to donate or to invest \$250 of their own money. Second, we presented participants with a wider range of options (15 options organized across 5 categories). Finally, to remove subtle differences that may exist between the investment and category options, participants only saw the name of option, its category, and effectiveness rating with no additional description (e.g., Arcadia Grocers, Category = Food, Rating = 85). Consistent with our previous findings, fewer participants in the Charity condition chose the most effective option (32.4%) than in the Investment condition (52.8%; $Z = 3.02$, $p = .003$).

We argue that for charitable decisions, participants weigh their subjective preferences greater than they do for investments. As a result, they are less likely to actively organize charity options by effectiveness ratings than they are for investment options. To test this, in Study 3, participants ($N = 401$) were given the same scenario as the previous study. However, before presenting participants with the choice set, we first asked whether they would like the options to be ordered by category or by effectiveness rating. Consistent with our expectation, fewer participants chose to order options by effectiveness in the Charity condition (67.8%) than in the Investment condition (83.4%; $Z = -3.63$, $p < .001$). Moreover, fewer participants in the Charity condition chose the most effective option (32.2%) than in the Investment condition (50.2%; $Z = 3.68$, $p < .001$). Finally, we find that the effect of domain condition (charity vs investment) on search mode decision (category vs rating) is mediated by participants’ feelings that their decision should reflect their personal beliefs (Indirect Effect = .68 95% CI = [.35, 1.08]), and is not mediated their desire for agency (Indirect Effect = .04 95% CI = [-.17, .25]), feelings of subjective knowledge in the domain (Indirect Effect = .04 95% CI = [-.01, .14]), or their belief that it is possible to rate options by effectiveness (Indirect Effect = -.03 95% CI = [-.13, .04]).

In Study 4 ($N = 304$), we manipulated whether participants were presented with a choice set in either a diverse or uniform set of options. We expect that when consumers compare charities from a diverse choice set, they choose less effective charities because the diverse set enables them to pick a cause that they personally prefer. Study 4 also utilizes a different effectiveness metric than the previous studies. Participants were presented with QALY (Quality Adjusted Life Years) ratings, which represents the number of fully healthy years of life that would be added to someone in need by a charity’s intervention.

Participants were randomly assigned to one of two conditions. In the Mixed Category condition, participants were presented with a list of three charities, each of which reflected a different category (Food, Medical, and International). In the Single Category condition, participants were presented with a list of three charities that all belonged to a single category (either Food, Medical, or International). We find that when choosing from a set of charities from different categories, participants picked the top rated option less often (69.3%)

than when choosing from a set of charities from a single category (84.1%; $Z = 3.05$, $p = .002$).

In sum, these studies show that when consumers decide where to donate their money, they often discount explicit effectiveness information, and instead consider their own subjective preferences.

SESSION OVERVIEW

Consumers make important financial decisions throughout their lives. How much should I spend given my income? How much debt is too much? What is the best way to reduce debt? How much should I be saving? Am I saving enough for retirement? How often should I monitor and readjust my investment portfolio? How much risk is too much risk? While such decisions were once thought the exclusive province of finance and economics, they also deserve great attention from consumer researchers. This is vividly illustrated by growing concerns about consumer debt as well as savings and retirement deficits and the huge fortunes made and destroyed in the stock market. Financial decisions have important influences on consumers' welfare as well as the economy as a whole. We feel strongly that consumer researchers have much to contribute to this area.

These papers seek to explore financial decision making in a variety of contexts using a variety of methods. Each paper tries to answer the following questions: What factors influence why consumers make poor financial choices? What underlying mechanisms are involved? What can be done to help consumers make wiser financial decisions? We believe that this session is uniquely poised to attract academicians, financial service providers and policy makers.

In our first paper, Michal Strahilevitz, Joseph Harvey, and Dan Ariely examine compulsive investor behavior using surveys of active investors. Results suggest significant correlations between trading frequency and many of the personality and emotional patterns associated with addictive behaviors. Specifically, trading frequency is found to be significantly correlated with impulsivity, intense positive and negative emotions, overconfidence, and a belief that most investors are addicted to trading. The paper also examines how both frequent stock trading and frequent monitoring of the market are related to overall physical and emotional health.

In the second paper, Grant Donnelly, Zoe Chance, and Mike Norton study consumer debt repayment in the realm of credit cards. They show that consumers who pay by the line item in their bill pay off significantly more in both items and amounts than consumers who pay solely by a set amount. Furthermore, consumers feel sig-

nificantly better about financial situation when paying off line item amounts.

In our third paper, Zoe Lu and Chris Hsee show how our perceptions of time alter our savings patterns. Over several experiments, they show how different manipulations of time perception and decision duration can alter savings behavior. They suggest both causal mechanisms and how manipulating the savings period might increase personal saving.

In our fourth paper, On Amir and Orly Lobel show how age interacts with savings decisions, adding an important and heretofore unexamined aspect to the study of consumer financial well-being. They find that older consumers make better financial decisions when resources are plentiful, but that when older consumers are constrained, their financial decisions are worse than those of younger consumers. They offer guidelines for designing financial products that are sympathetic to the interaction effects of age and cognitive resources.

The Relationship Between Frequent Stock Trading and Emotionality, Self Confidence and Self Control,

EXTENDED ABSTRACT

Frequent trading has been shown to have a strong negative effect on performance in the stock market (Odean and Barber 2000, Markiewicz and Weber 2013). Yet little has been done to investigate possible underlying causes for frequent stock trading. Our first study examines the relationship between trading frequency and a variety of psychological variables such as impulsivity, overconfidence and the tendency to experience intense positive and negative emotions, both related to trading and in one's daily lives. In a second study, we will examine the relationships between frequent stock trading, frequent monitoring of one's portfolio, use of mobile technology, self control, concern for achievement and several physical and emotional health measures including sleep quality, anxiety and a tendency toward unrelated addictions. The results illuminate potential causes and consequences of frequent stock trading and portfolio monitoring.

Study 1

Study 1 involves a survey of 149 active investors. Several significant findings suggest that frequent trading is not only related to overconfidence, but also to addiction, as opposed to a rational trading strategy.

Overconfidence in One's Skills and a Belief One is Luckier than Others

Although trading frequency is found to have no relationship with confidence in the future performance of US or global stock market, it is positively related to thinking one's own portfolio will do well in the future as well as to a greater confidence in one's overall investment skills. Trading frequency is also positively correlated with investors' tendencies to believe that they are smarter and better informed than the average investor. Outside perceptions of oneself as an investor, more frequent trading is correlated with thinking that one is generally luckier than the average person. Frequent traders are also more likely to attribute their investment losses to bad luck, and their investment gains to their strong research and skill as investors.

More Frequent and Intense Positive and Negative Emotions

We also found that frequent trading is associated with higher propensity to experience intense emotions, both related and unrelated to the stock market. Frequent traders rate both buying and selling stocks as more stimulating and more exciting than infrequent traders do. However, as is the case with several addictive behaviors, frequent trading is also correlated with a greater tendency to experience negative emotions such as regret, worry and self-doubt about one's decisions, both in regards to one's investments and in one's daily life.

Hedonic Dimensions to Frequent Trading

There also appears to be a thrill-seeking dimension to frequent stock trading, supporting the notion that frequent trading may be driven by a need for stimulation rather than a rational investment strategy. Specifically, frequent traders are more likely to see a fun day in the market as one where they realized gains by selling stocks. They are also more likely to see a dull day in the market as one where they did not sell or buy any stocks. In contrast, infrequent traders are more likely to agree that a fun day in the market is one where they see the value of their portfolio grow without any executions. Frequent traders also rate both buying and selling stocks as significantly more stimulating and more exciting than infrequent traders do.

Frequent Traders Are More Impulsive, Less Careful and More Likely to See Trading as an Addiction.

There are also several personality characteristics that are correlated with trading frequency. Specifically, frequent traders rate themselves as significantly less careful, both as investors and in their daily activities (unrelated to investing). Compared to infrequent traders, frequent traders also repeatedly rate themselves as more impulsive when buying stocks, selling stocks and making decisions unrelated to investing. Frequent traders are also more likely to indicate that they themselves are addicted to trading, suggesting some self-awareness. However, trading frequency is also correlated with significantly higher estimates of the percentage of all American investors who are addicted to stock trading.

Study 2

In Study 2 (in progress), we will examine the relationships between frequent monitoring of one's portfolio, use of mobile technology, and several physical and emotional health measures including anxiety, disordered sleeping, disordered eating, depression, and issues with anger and frustration. Because a connection has been found between intense emotions and several unhealthy compulsive behaviors (Kemp, Bui, Grier 2011), we consider identifying the connection between emotions and frequent trading to be particularly promising. The role of mobile technology is also of great interest, not only due to the huge growth in smart phones and tablet usage, but also based on previous work showing that access to gambling opportunities increases compulsive gambling behavior (Lester 1994). Based on prior findings connecting compulsive gambling with other addictions (Cowlshaw & Thomas 2011; Martin, Usdan, Cremeens, Vail-Smith 2014; Najavits, Meyer and Johnson 2010), we will also explore possible co-morbidities with addictions unrelated to the stock market.

Piecemeal Repayment: Paying Toward Specific Purchases Promotes Higher Repayments Toward Debt Balances

EXTENDED ABSTRACT

Consumers treat credit differently than other forms of payment. People spend more when using credit cards compared to cash

or checks (e.g., Rick, Cryder & Loewenstein, 2008). Possibly, the reason credit cards increase spending is because they allow the consumer to separate the pleasure of buying from the "pain of paying" (i.e., the discomfort of spending money; see Prelec & Loewenstein, 1998), and make the true cost of each purchase more difficult to evaluate by compiling all consumption in a monthly bill (Raghubir & Srivastava, 2008), reducing the total loss felt by a consumer (Thaler, 1985).

While this strategy has likely contributed to the accumulation of debt, recent research concerning debt repayment has suggested that aggregated debt balances are overwhelming and difficult to repay. For instance, when consumers are confronted with multiple debts they often prioritize the debt with the smallest balance first (even when this is not the most financially optimal strategy; see Amar et al., 2011). This tendency is aligned with the literature on sub-goals, suggesting that a short, proximal task will help fuel commitment toward subsequent larger tasks (Gal & McShane, 2012).

Given these conditions, this paper proposes that segregating losses by allowing consumers to make payments toward each individual purchase on a credit card bill could increase awareness of what the consumer is repaying. This awareness may increase the perceived impact the payment will make toward the debt balance, resulting in higher repayments.

In our first study, subjects were presented with a hypothetical purchasing scenario where they made purchases on a credit card totaling \$1,376.00. All participants were told they had \$800 to spend on a variety of expenses for the month (including their credit card payment). They then allocated the \$800 across these expenses. For the credit card bill, half of our participants were asked to make a payment toward the total debt balance, while the other half were able to make payments toward specific line items that composed their debt. Consumers who were able to repay toward specific purchases allocated more money toward debt repayment ($M = \$561.64$), than those who paid toward the aggregated balance ($M = \$473.50$), $p < .001$.

Our first study provides initial support for our hypothesis that individuals will repay more when able to make purchase-specific repayments. But would consumers prioritize repaying a debt that allowed piecemeal repayment over debts that allowed payment toward the total balance? In a second study, participants ($N = 180$) were presented with the same hypothetical purchasing task but were told that half of the purchases were made on a credit card that allowed payment toward the individual purchases (a total balance of \$688.00), while half were made on a credit card that allowed payments toward the total balance (\$688.00). Consumers paid significantly more toward the card that allowed repayment toward specific purchases ($M = \$333.01$), relative to the card that allowed repayment toward the total balance ($M = \$230.43$), $p < .001$.

In our third study we wanted to explore the underlying mechanisms of increased repayment. We programmed a debt repayment simulation where all participants ($N = 236$) were asked to evaluate a credit card statement that consisted of 10 items totaling a debt of \$888.44. Participants were asked to imagine that the debt was their own and that they had \$500 to put toward their debt repayment or keep for other expenses throughout the month. Participants were required to make a minimum payment of \$37, but could make any payment up to \$500. Participants were randomly assigned to one of two conditions: (a) in the whole balance condition, participants made a payment toward their total bill. In the piecemeal repayment condition, participants made repayment decisions toward specific purchases. Participants in these conditions were instructed to click a particular line item they wished to make a payment toward. Once the participant clicked on the line item a payment window appeared and

the participant selected their desired payment toward that line item. Participants could make a partial or full payment. In the instances where the line item was ‘paid off’ the item would disappear from the bill.

There was a significant differences in the amount paid toward the credit card balance, $t(235) = 5.33, p = .001$. Individuals in the whole balance condition paid significantly less ($M = \$189.60$) toward their debt than individuals in the piecemeal repayment condition ($M = \$283.18$). Participants were asked how much their payment method made them feel aware of what they were repaying and how much their payment made them feel that they made a significant impact toward their debt balance. The piecemeal repayment condition found higher reported awareness ($p < .001$) and feelings of impact ($p < .01$)

Next, we examined a mediation model, where awareness and impact were tested as a mediator of the link between payment condition and repayment decision. We found that (a) the piecemeal repayment condition significantly predicted higher awareness (i.e., path a; $\beta = .24; p < .001$); (b) awareness significantly predicted greater feelings of impact (i.e., path b; $\beta = .39; p < .001$); (c) impact significantly predicted higher repayment (i.e., path c; $\beta = 33.94; p < .001$); and (d) the link from piecemeal repayment to higher repayment (i.e., path d; $\beta = 13.06; p < .001$) was attenuated after awareness and impact were entered into the model (i.e., path $d' = .92$). The bootstrapping results indicate a significant indirect effect through awareness and impact, $b * c = 3.18, 95\% \text{ CI } [1.90, 5.06]$.

Across three studies, we have demonstrated that allowing consumers to make payments toward specific purchases results in significantly higher repayment. Given that recent research evaluating the effectiveness of the CARD Act has found no substantial positive effect on repayments (Navarro-Martinez et al., 2011), allowing for piecemeal repayment could be a relatively low-cost intervention that could save consumers a substantial amount of money in interest over time.

Low-Asking Heightens Demand and High-Asking Lowers Demand

EXTENDED ABSTRACT

Imagine the following. A bakery is running a promotion on cookies which can last one month. He displays an advertisement in front of the store for the product. Consider three alternative scenarios of what the advertisement says.

Scenario 1: “Buy for the whole month and save!”

Scenario 2: “Buy for the whole month and save! To decide how many to buy for the month, think about how many you will likely eat in one week.”

Scenario 3: “Buy for the whole month and save! To decide how many to buy for the month, think about how many you will likely eat in one year.”

Notice that in all the scenarios the advertisement includes a “suggesting statement” -- “Buy for the whole month and save.” In Scenarios 2 and 3, the advertisement contains an additional “asking statement” -- asking prospective buyers to think about their consumption quantity for either one week or for one year. The question we try to address in this research is: In which scenario will potential buyers buy the most, and in which scenario will they buy the least?

Our theory capitalizes on two psychological phenomena: low inter-person duration-sensitivity and high intra-person duration-consistency. Low inter-person duration-sensitivity suggests that if one person is asked to estimate her consumption quantity in a short duration and another person is asked to estimate her consumption quantity in a long duration, their estimates will be relatively close. For example, if one consumer is asked to estimate her cookie consumption quantity in one week and another to estimate her cookie consumption quantity in one month, the first person may say 10 for one week and the second person may say 20 for one month. The ratio of 20 to 10 ($=2$) is smaller than the ratio of one month to one week (≈ 4).

On the other hand, high intra-person duration consistency indicates that if the same person is first asked to estimate her consumption quantity in a short duration and then her consumption quantity in a long duration, her estimates will be roughly consistent with the difference in time. For example, if the same person is first asked to estimate her cookie consumption quantity in one week and then her cookie consumption quantity in one month, she may say 10 for one week and 40 for one month. The ratio of 40 to 10 is consistent with the ratio of month to week (≈ 4). (This is just a stylized example; in reality, we do not expect the two ratios to be exactly identical.)

Put together, low inter-person duration sensitivity and high intra-person duration consistency suggest that if one person is directly asked to estimate her consumption quantity in a long duration (e.g., one month), and another person is first asked to estimate her consumption quantity in a short duration (e.g., one week) and then her consumption quantity in the long duration (e.g., one month), the second person will estimate a higher consumption quantity for the long duration than the first person. So long as one’s purchase quantity roughly matches one’s estimated consumption quantity, the second person will also buy more for the long duration than the first person.

Hypothesis 1: (low-asking). Consumers will buy more units of a product for a given duration ($T_{purchase}$) if they are first asked to think about how many units of the product they will likely consume in a shorter duration (T_{asking}) than if they are not so asked.

Just as we propose low-asking will increase purchase quantity, we propose that high-asking will decrease purchase quantity. For example, if one person is directly asked to estimate her consumption quantity in a short duration (e.g., one month) and another is first asked to estimate her consumption quantity in a long duration (i.e., one year) and then her consumption quantity in the short duration (e.g., one month), the second person will arrive at a lower estimate for the short duration than the first person.

Hypothesis 2: (high-asking). Consumers will buy fewer units of a product for a given duration ($T_{purchase}$) if they are first asked to think about how many units of the product they will likely consume in a longer duration (T_{asking}) than if they are not so asked.

Our theory not only predicts that the counter-anchoring effect can occur, but also predicts when it disappears. The key moderator, we propose, is whether the prospective buyer has a specific purchase duration, $T_{purchase}$, in mind. If the prospective buyer does have a specific idea, the asking procedure will exert a “pushing” (contrasting) force and create the counter-anchoring effect. Otherwise, the asking procedure will exert a “pulling” (assimilating) force and generate the conventional anchoring effect.

Hypothesis 3: (moderator). If a consumer has a specific idea about the purchase duration ($T_{purchase}$), an asking procedure about a different duration (T_{asking}) will create the counter-anchoring effect, as posited in Hypothesis 1 and Hypothesis 2. If a consumer does not have a specific idea about the purchase duration ($T_{purchase}$), an asking procedure about a different duration (T_{asking}) will create the traditional anchoring effect.

We have conducted five experiments to test our theory. Together, Study 1 and Study 2 demonstrated that the presence of an asking statement could either increase or decrease purchase quantity depending on the length of T_{asking} relative to the length of $T_{purchase}$. Study 3 produced both the conventional anchoring effect and the counter-anchoring effect, and within the counter-anchoring effect, it demonstrated both the low-asking effect and the high-asking effect. Study 4 suggested that a long $T_{purchase}$ alone was unable to significantly boost purchase quantity, but a long $T_{purchase}$ coupled with a short T_{asking} was. Study 5, a field experiment, replicated the low-asking effect in a national chain store in the U.S.

A potential application of the low-asking effect is in savings. Asking individuals to estimate their annual need will potentially increase their estimate of the need for the rest of life, hence affecting their saving behavior. Meanwhile, a potential application of the high-asking effect is to nudge individuals to waste less.

Risk Management for the Future: Age, Risk, and Choice Architecture

EXTENDED ABSTRACT

How can regulation in an era of personal responsibility aid people to make the optimal decisions about their future risks, savings, and retirement? The current work aims to shed light on preferences for risk and retirement savings as a function of both age and the processes underlying the preference dynamics. Above and beyond rational reasons for varying preferences across different ages, such as differences in the life length of an investment, predicted career cycles or the proximity to retirement, there may be psychological differences among age groups. In order to disentangle these different effects, we designed a set of studies that presented various retirement-related decisions involving risk to people of various age groups. In order to shed light on the underlying psychological mechanisms, we manipulated the degree of available cognitive resources to try and mimic different decision conditions and states.

In the two sets of experiments involving large sample of a fairly representative population demographic and standard investment, savings, and insurance decisions, we observed age differences in judgment and decision-making pertaining to future savings and risk. In particular, we find that when deferring a tax rebate, younger and older people seem to be more patient than mid-age people when depleted of executive control resources, but no such effect in the control condition. With respect to savings, we find older participants more likely to opt-in to a Save-More-Tomorrow (SMT) program than younger ones, but not when they are depleted. We also find younger people to opt for an annuity over a lump-sum payoff, but this tendency is decreased when depleted. Furthermore, we find a general increased aversion to risk in an investment as people age, a general increase in risk taking as people are depleted of executive control resources, and a significant interaction, whereby, when depleted, older participants tend to take even more risk than their younger counterparts. This also manifests in selection of health insurance.

Overall, when cognitive resources are available, our findings show that older participants opt for more prudent savings choices. Although older people on average seem to choose the more rational options among available alternatives, in the sense of planning and saving, this pattern may not hold in situations that do not allow the luxury of executive control override, such as when tired, sick, distracted, or even after making a series of arduous other choices. In some instances, we also find the depletion of cognitive resources has an increased influence over older participants compared to younger participant. It is possible that older people not only rely more on executive control when making such decisions, but are also more susceptible the effects of depletion.

The findings that younger people are more likely to exemplify risk-taking behaviors while older people are more risk averse supports previous studies in the field, although the study of the interactions between age and risk tolerance has proven a challenge in the social sciences (Halek and Eisenhauer, 2001). The literature indicates that older investors tend to have different attitudes toward risk than younger age groups, and yet, many of the findings have been non-conclusive and even contradictory. At the turn of the century, it was widely believed to be true among financial planners that the older a person was the more risk averse (and less risk tolerant) they became. (Grable and Lytton, 1999; Gilliam et. al, 2010; Palsson, 1996; Bakshi and Chen, 1994). However, other studies have concluded that, after accounting for other variables, age either has little to no bearing on a person's risk tolerance (Hanna et. al, 2001), or that older generations may be even somewhat more risk tolerant than younger ones. (Wang and Hanna, 1997; Hanna et al, 2001). Our findings can help explain why previous research has mixed results when it comes to the effect of age on a person's financial risk tolerance.

At a theoretical level our findings suggest that much of the difference in financial choices between older and younger decision-makers lies in the ability of the decision-makers to override their intuitive and automatic responses (System 1) to such decisions. In other words, making more prudent financial choices appears to be a learned skill that relies on executive resources (System 2) for its execution. At a policy level, as the regulatory field is moving from command-and-control rules to the provision of menu options and choice architecture, our findings provide potential guidelines for better designing retirement and savings plans, such as the implementation of SMT-style programs and the encouragement of annuity over lump sum retirement benefits.

SESSION OVERVIEW

“Let me be surrounded by luxury, I can do without the necessities!”

-Oscar Wilde

With a revenue growth twice that of global GDP, the luxury industry, expected to reach €250 billion threshold this year, has received a lot of recent managerial and academic attention (Bain 2013). Particularly, central to researchers had been the question of what motivates people to consume luxury goods. Three main motivations for luxury consumption have been identified as (1) signaling status, (2) expressing one's identity, and (3) boosting self-contentment (Belk 1985; Han, Nunes, and Dreze 2010; Richins 1987; Veblen 1899). In this session, we seek to deepen our understanding of what motivates luxury consumption by bringing together four papers examining each of these drivers more in depth, from multiple perspectives.

The session will start with a focus on examining how motivation to signaling status impacts luxury consumption. The first paper by Kim, Park and Dubois, extends our current understanding on how status motivation impacts luxury consumption by distinguishing status-maintenance motivation from status-enhancement motivation and explores how the two status motivations interact with political ideology to impact luxury consumption. Grewal, Stephen and Coleman will then move the discussion forward to the second motivator, motivation to express one's identity. Using a highly marketing-relevant context, social media, the authors show that expressing one's ideal-self through online affiliations with luxury products on social media (e.g., Pinterest) reduces desire for luxury by enhancing psychological ownership of luxury brands.

Shifting discussion from non-owners to owners, the last two papers examine the role of the third motivator, self-contentment, in luxury consumption. In the third paper, Patrick and Prokopec propose that whether owning a downward-extended luxury product increases or decreases desire for luxury products depends on whether one's desire can be contented with owning a downward-extended luxury product (i.e., desire specificity). Finally, Bellezza and Keinan dem-

onstrate that low-fit downward brand extensions (e.g., Ferrari video game) as compared to high-fit downward brand extensions (e.g., Ferrari city car) enhance the brand image by boosting self-contentment for luxury brand owners.

Across an integrated set of four papers, we explore a coherent theme of what motivates one to consume luxury brands from multiple perspectives, building connections from one motivator to another and from non-owners to owners. Furthermore, we seek to advance connections with managers by presenting four papers that are highly practical and managerial. First paper explores a variable (political ideology) that is easy to be identified and utilized for managers while the second paper focuses on a highly marketing-relevant context, social media and the last two papers address the dilemma often faced by managers of luxury brands, namely, how to extend the market without diluting brand power. Altogether, this session raises a question of how different motivators interact with characteristics of consumers (e.g., political ideology and social media activity) and brand (e.g., brand structure and extension) to ultimately shape consumers' desire for luxury brands. We believe our session will attract audiences from diverse background including researchers in motivation, branding, conspicuous consumption and social class as well as managers of luxury brands.

Impact of Status Maintenance Motivation and Political Ideology on Luxury Consumption

EXTENDED ABSTRACT

In marketing, it is well established that people consume luxury goods to signal status (e.g., Han, Nunes, and Dreze 2010; Richins 1987; Veblen 1899). Accordingly, the use of status appeal is easily found in advertisements. For example, Audi tells consumers to ‘update your status’ with their car while BMW tells consumers that ‘the symbol on your hood is more than a logo—it's a reminder’. While the two luxury cars make similar appeals related to signaling status, the two differ in their messages greatly. Audi motivates consumers to improve and enhance their status with their car whereas BMW motivates consumers to remember and retain their status with their car. This distinction corresponds to what researchers in management have recognized as distinct dynamics of status (Chen, Peterson, Phillips, Podolny, and Ridgeway 2012) which we refer to as *status-enhancement motivation* and *status-maintenance motivation*. While prior research has recognized the two as distinct, little is known about how the two compare to each other, therefore, in this research, we fill this gap by exploring the two jointly in our studies.

Research on motivation has shown that focusing on discrepancy to the desired state is more motivating than focusing on the current state (e.g., Carver and Scheier 1990, 1998; Koo and Fishbach 2010). In our context, these findings suggest that consuming luxury brands to reach a desired state (i.e., status-enhancement motivation) would be more motivating than consuming luxury brands to keep the current state (i.e., status-maintenance motivation). Contrarily, in this research, we propose that this dynamic depends on one's belief system, political ideology which varies from liberal to conservative. According to Jost and his colleagues (2003), political ideology is a powerful belief system that stems from one's motivation to see the world as preferred and can have consequential impacts on variety aspects of life. Relevant to our theorizing, they have shown that political conservatism is adopted as motivation to keep the world sta-

bilized increases. Given that consuming luxury goods to maintain current status matches well with the core motivation of political conservatism, we posit that political conservatism enhances valuation for luxury brands when they are consumed for status-maintenance motivation as compared to status-enhancement motivation. Across four studies (three reported here), we demonstrate that status-maintenance motivation as compared to status-enhancement motivation increases one's preference for luxury goods as political conservatism increases.

In Study 1, we test our main argument that status-maintenance motivation as compared to status-enhancement motivation increases preference for luxury brands as political conservatism increases. Participants first indicated their political conservatism on a 7-point scale (1-extremely liberal; 7-extremely conservative). Afterwards, they were randomly assigned to one of the two status motivation conditions and wrote about 2-3 ways by which they can maintain (improve) their social standings. Subsequently, participants proceeded to a purportedly unrelated task on brand evaluations. Participants evaluated three luxury and three non-luxury automobile brands and indicated how much they desire purchasing a car from each brand. In the analysis of this study and all the studies afterwards, we controlled for variables which prior research has shown to influence preference for luxury such as age, gender, income, education and ethnicity, however, our results do not change with or without covariates (Chevalier and Mazzalovo 2012; Graham, Haidt, and Nosek 2009). As expected, the interaction between status-motivation type and political conservatism was significant ($p=.032$). More importantly, a floodlight analysis revealed that status-maintenance motivation increased preference for luxury brands significantly more than status-enhancement motivation when political conservatism was high, starting at .7 SD above the mean of political conservatism ($\beta=.31$, $p=.049$). However, this difference disappeared when political conservatism was low ($p=ns @-1SD$).

In order to address shortcomings that could arise with using real brands, in Study 2, we test our hypothesis using a hypothetical brand. The procedure was similar to study 1, except this time, instead of brand evaluation, participants read a print ad of a headphone framed as luxury versus non-luxury and indicated their willingness-to-pay for the headphone. A three-way GLM on WTP with status-motivation and product framing as categorical variables and political conservatism as a continuous variable revealed a significant three-way interaction ($F(1,295)=5.66$, $p=.018$). Crucially, the two-way interaction between status-motivation and political conservatism was significant in the luxury condition ($F(1,144)=9.25$, $p=.003$), but not in the non-luxury condition. Consistent with findings from Study 1, status-maintenance motivation increased WTP for a luxury headphone significantly more than status-enhancement motivation when political conservatism was high, starting at .3 SD above the mean of political conservatism ($\beta=26.45$, $p=.035$), but this difference disappeared when political conservatism was low ($p=ns @-1SD$).

Finally, we test our hypothesis using a real automobile purchase dataset from 38,939 automobile buyers who disclosed their political ideology. Building on prior research suggesting that higher SES individuals have motivation to maintain their current status whereas lower SES individuals have motivation to enhance their current status (Ellemers, van Knippenberg, de Vries, and Wilke 1988), we used current SES as a proxy for whether status-maintenance versus status-enhancement motivation is salient. Consistent with results from prior two studies, republicans purchased more luxury cars when status-maintenance as compared to status-enhancement motivation was salient (i.e., high current SES), but no such difference was found for liberals. In sum, we provide converging evidence for our argument

that status-maintenance motivation as compared to status-enhancement motivation leads to higher preference for luxury brands as political conservatism increases.

How Pinning Nordstrom Means Buying Macys: The Relationship of Social Media, Self-Concept, and Luxury Purchase Intentions

EXTENDED ABSTRACT

Past research has demonstrated that consumers use luxury products as a way to affiliate with desired reference groups and to signal self-concepts (Berger & Ward, 2010). With social media, consumers can affiliate with luxury brands online. As social media has been shown to fulfill a variety of social needs such as self-expression and self-presentation (Gosling et al., 2007), it stands to reason it can also fulfill ownership needs. Psychological ownership can provide many of the same benefits to consumers as traditional ownership (Pierce et al., 2003). Therefore, the rise of social media sites that allow consumers to engage with brands in visual and customizable formats has allowed consumers to curate self-images of themselves through luxury brands and products online.

The purpose of the current research is to demonstrate how social media allows consumers to engage with luxury brands in a way that promotes psychological ownership and identity signaling: lowering purchase intentions of luxury products. We believe that when social media enables consumers to visually curate their ideal-self through products and brands, this enhances psychological ownership of luxury products and fulfills identity signaling purposes that have been traditionally associated with luxury, negating the need for purchase.

Study 1 ($N = 52$) tested the effect of self-concept on WTP for luxury with a 2 group design (self-concept: actual, ideal). Participants were all Pinterest users who pinned 5 "luxury" items that represented who they actually are (actual-self) or who they wish to be (ideal-self). Afterwards, participants were shown a Louis Vuitton suitcase and asked to provide their WTP. Participants in the ideal-self condition were willing to pay significantly less for the suitcase compared to those in the actual-self condition, $B=-276.98$, $t(50)=-2.253$, $p=.029$. This study suggests that when consumers feel a general sense of luxury ownership, it will decrease preference for luxury goods only when they have made the connection of their ideal-selves to luxury.

Study 2 ($N=125$) explored the moderating role of public versus private signaling of luxury. In a 2 (self-concept: actual, ideal) x 2 (signaling: public, private) design, participants imagined engaging with a new Facebook feature that showcases brand preferences. The feature was described as either "private for their eyes" or "public to their whole social network". Participants then found 5 items that represented their actual or ideal-self that they would add to this feature. Afterwards, participants, in a seemingly unrelated survey, were shown a map of a regional mall. They were asked to indicate stores they wanted to shop at. Using a zero-inflated Poisson to analyze the number of luxury stores chosen, we found a significant interaction where participants in the ideal self-condition chose less luxury stores than those in the actual-self condition only when the new feature was public, ($B= -.707$, $\chi^2(4) = 5.10$, $p=.024$).

Study 3 ($N=330$) explored the role of network size on luxury purchase intentions. In a 2 (self-concept: actual, ideal) x 3 (signaling: full network, close network, private) design, participants engaged with the same stimuli as study 2. We had an additional "close network" condition where the app could only be seen by designated "close friends/family". We found a significant interaction for willingness to pay for the Louis Vuitton suitcase, $F(5,324)=4.385$, $p=.013$.

Looking at the simple effects, we found no significant differences in WTP for the private or close-network conditions. In the full-network condition, participants in the ideal-self condition were significantly less willing to pay for the suitcase ($M=148$) than those in the actual-self condition ($M=324$), $p=.002$. These two studies provide support for the idea that ideal-self presentation online only negatively impacts luxury purchase intentions when there is a public affiliation with luxury.

Study 4 ($N=49$) explored the moderating role of psychological ownership. Pinterest users interacted with their existing boards in a 2 group design (self-concept: actual, ideal). Afterwards, participants were asked about their sense of ownership of the board's contents and in a seemingly unrelated survey were then shown a mall to indicate store choices. Using a zero-inflated Poisson to analyze the number of luxury stores chosen, we found a significant main effect of self-concept. Participants in the ideal self-condition chose less luxury stores than those in the actual-self condition, ($B= -0.46$, $\chi^2(2) = 6.14$, $p=.013$). Testing the proposed moderation of measured psychological ownership for luxury purchase intentions, we found that the direct conditional effect of self-concept on purchase intention through psychological ownership was negative and significant but only at average and higher (+1SD) levels of psychological ownership.

Study 5 ($N=286$) explored varying levels of "ownership" online to determine what ownership is necessary for decreased luxury purchase intentions to occur. Pinterest users were randomly assigned in a 3(ownership: pin, like, control) x 2 (self-concept: actual, ideal) design. Participants found 5 pins that represented their actual or ideal-self; and were either allowed to pin them, like them, or paste them into our survey. We found a significant interaction for the WTP for the Louis Vuitton suitcase; $F(5,280)=3.091$, $p=.047$. Looking at the simple effects, we only found a significant difference in WTP for the pinning (i.e. full ownership) condition. Participants in the ideal-self condition were WTP significantly less for the suitcase ($M=248$) than those in the actual-self condition ($M=573$), $p=.018$. These two studies provide support for the idea that ideal-self presentation online only negatively impacts luxury purchase intentions when there is felt-psychological ownership of luxury.

To our knowledge, this set of studies represents a first attempt to consider how different consumer identities can impact luxury consumption preference based on online self-curation. These studies indicate self-representation online can impact luxury purchase intentions. Interestingly, representing one's ideal self-concept in social media appears to lead to lower purchase intentions specifically for luxury goods only when there is public signaling and a feeling of psychological ownership for luxury.

Quenching the desire for luxury: Successful lower-end luxury brand extensions satiate brand desire

EXTENDED ABSTRACT

The desire that luxury evokes makes consumers all over the world aspire for luxury products and contributes to the success of the nearly \$273 billion luxury industry (Reuters 2013). For luxury brand managers it is a balancing act to maintain the desire for a luxury brand on one hand and to expand and grow to be profitable on the other. One growth strategy managers have adopted involves the launch of lower-end line and brand extensions to expand the market and reach a larger consumer base (Kapferer and Bastien 2009).

Luxury products are those that provide extra pleasure and flatter the senses all at once (Kapferer 1997). Luxury brands, unlike functional brands, are fueled by desire and evaluated based on affective

considerations (Yeung and Wyer 2005) and the promise of pleasure (Hagtvedt and Patrick 2009). When managers introduce lower end extensions it is based on the assumption that when a consumer gets a taste of the luxury product, it simply whets her appetite, leaving her wanting more. The current research demonstrates the flaw behind this assumption to identify when this strategy might backfire.

We argue that a luxury brand can be diluted by a successful brand extension *when the lower-end extension is able to satiate the consumer's desire for the luxury brand experience*. Specifically, we identify two factors, *desire specificity* and *prior ownership* that influence whether a successful brand extension can dilute the luxury brand.

Desire specificity is defined as the fixation of consumers' desire onto a specific product/s in the brand portfolio. It is well established that when consumers focus on a specific desired object, little else can interfere with that yearning (Belk, Ger and Askegaard 1996, 2003; Belk 1997, 2000; Freund 1971, Baudrillard 1972). If desire for the brand is specifically focused on one or more products in the brand portfolio, then brand dilution is minimized. In contrast, if consumers' desire is generally directed to the brand, then the brand may be experienced through *any* lower-level extension, and the potential for brand dilution is heightened.

Prior brand ownership also secures brand desire. People value objects they own more than objects they do not, which affects the appeal of the good (Aggarwal 2004; Aggarwal and Law 2005; Belk 1988; Gawroski, Bodenhausen and Becker 2007). Consequently, successful extensions of luxury brands are more likely to result in decreased purchase intent for brand non-owners.

We investigate these assertions in a set of three studies (two reported here for space considerations). In study 1 ($N = 109$), desire specificity was manipulated between subjects. Participants were asked to imagine that Marie dreamed of owning the signature Chanel suit (anything from Chanel). All participants were told to imagine that Chanel introduced a new purse at a price of €210. We then assessed the likelihood to buy the desired, more expensive, Chanel product that they had always desired to own (1 = very unlikely, 7 = very likely). A repeated measures analysis with the likelihood to buy the desired parent brand before and after the introduction of the extension as the within-subject factor, and desire specificity as a between subject factor revealed a significant interaction, $F(1, 107) = 4.003$, $p < .05$. Simple main effects analysis revealed that there was only a significant drop in the likelihood to buy the originally desired parent brand for the participants in the no specific desire condition (5.84 versus 5.38, $p < .007$); participants in the specific desire condition did not experience any change (5.30 vs. 5.31, $p < ns$).

In Study 2 ($N = 106$), we operationalize desire specificity in terms of the presence or absence of a flagship product and use two luxury brands (Chanel and Chloe) that fit this criterion (based on a pretest). The design was a 2 (Desire specificity: Brand with Signature/Brand with No-signature) X 2 (Own: Yes/No) experiment, in which desire specificity was manipulated and ownership was measured. In the flagship condition (no-flagship condition), participants were told that they dreamed of owning the signature Chanel 2.55 bag (anything from Chloe). A Chanel/Chloe new leather bracelet at a price of €199 was introduced. All measures were similar to study 1. A repeated measures analysis with the purchase intent as a within-subject factor, and desire specificity and ownership as between subject factors. We observed a significant three-way interaction ($F(1,96) = 6.145$, $p < .015$); we observed that only the Chanel (flagship) owners did not experience any change in their likelihood to purchase the desired signature product in the future (5.58 vs. 5.42, $p < ns$). Chloe owners (no-flagship), Chanel non-owners and Chloe

non-owners experience a significant drop in their likelihood to buy the desired product in the future after seeing the new extension (5.00 vs. 3.73, $p < .01$; 6.09 vs. 5.18, $p < .025$; 5.05 vs. 4.49, $p < .008$). Diminished desire for the brand mediated the effect of desire specificity on purchase intent, using conditional process modeling (Hayes 2012; model 8). Results revealed that diminished desire mediated the effect of desire specificity (i.e. specific versus non-specific) on drop in purchase intent for non-owners but not for owners.

Given the current trend in the luxury industry to introduce low-end extensions, this research provides theoretically grounded and managerially relevant insights to this practice.

The Advantage of Low-Fit Brand Extensions: Addressing the Paradox of Exclusive Brands

EXTENDED ABSTRACT

Managing exclusive and luxury brands poses an inherent trade-off. Brand managers need to generate growth by extending the customer base to new segments and new markets; yet, this increased popularity and prevalence can paradoxically hurt the brand and threaten its prestige image. In particular, downward brand extensions of luxury brands may cause brand dilution and compromise the long-term equity of the brand. Indeed, several luxury brands (e.g., Burberry, Pierre Cardin, Bulgari, Gucci, Tiffany) extended their brands to multiple products and struggled with the resulting overexposure of the brand.

Contrary to the view that downward brand extensions and their users are a threat to brands, recent work (Bellezza and Keinan 2014) demonstrates that users of these extensions can enhance the brand's prestige when they are perceived as brand tourists (i.e., fans and admirers of the brand, who are not perceived to claim in-group status into the brand community). Building on the brand tourists' conceptualization and on research on brand membership, we consider responses to high-fit (same product category as the parent brand) versus low-fit (different product category than the parent brand) downward brand extensions of luxury brands. For example, we examine reactions to a Ferrari city car (high-fit) versus a Ferrari video game (low-fit). We propose that low-fit downward brand extensions can reinforce, rather than dilute, the brand image and generate a positive brand tourism effect because these extensions do not allow their users to claim membership into the brand community. We examine the conditions under which low-fit extensions serve as proof of value for the brand, making it more aspirational without compromising its attainability in the eyes of existing customers of the brand.

To ensure high external validity of our findings, the majority of our studies examine the reactions of real consumers to brands they actually own or use (e.g., Ferrari car owners, Harvard College students, Tough Mudder participants). Moreover, all of our stimuli are based on real branding dilemmas and brand extension scenarios.

In a pilot study conducted with 39 real owners of Ferrari cars (within-subjects) recruited at a luxury automobile event, we find that two low-fit extensions (a Ferrari museum and a Ferrari video game) are liked more and have more of a positive impact on the brand image than a high-fit extension (a Ferrari city car).

In Study 1 we investigate the reactions (between-subjects) of 350 participants who completed the Tough Mudder race (a 12 mile run with military-style obstacles). We find that Tough Mudders like a low-fit extension (Tough Mudder gear) more than two high-fit extensions (Soft Mudder and 5K Mudder races). Interestingly, we detect a significant interaction between the manipulation and the brand patriotism scale (Bellezza and Keinan 2014), a measure of attachment to the brand ($b = .69$, $t(346) = 33.07$, $p = .005$). The positive response

to low-fit extensions is driven by those Tough Mudders particularly attached to the brand (scoring high on brand patriotism). Moreover, in a mediation analysis, we find that the low-fit extensions elicit positive reactions among Tough Mudders because these products don't allow their users to claim membership to the Tough Mudders' brand community (indirect effect = .13; 95%CI = .028 to .296).

In a between-subjects design conducted with 238 lab participants, Study 2 controls for the specificities of the product category of extension. Participants are either assigned to being owners of Montblanc fountain pens or students at Oxford College. We then manipulate the category of extension (online course on the art of writing vs. ballpoint pen). As predicted, we find a significant cross-over interaction ($F(1, 232) = 23.3$, $p < .001$) such that for Montblanc the online course (low-fit extension) is liked more than the ballpoint pen (high-fit extension), whereas for Oxford University the ballpoint pen (low-fit extension) is liked more than the online course (high-fit extension).

Study 3 tests the reactions of 139 Harvard College undergraduates to three different sets of downward brand extensions: HarvardX, Harvard Extension School, Harvard Summer Program (3 high-fit); Harvard Magazine, Harvard reading glasses, Harvard ties (3 low-fit); Harvard shampoo, Harvard laundry bags, Harvard pajamas, Harvard sunglasses, Harvard chocolate, Harvard soft drinks (6 very low-fit). We find that low-fit extensions are liked more than high-fit extensions, as long as the level of fit is not ridiculously low ($F(2, 773) = 74.47$, $p < .001$).

Finally, in Study 4 we replicate the main effect and mediation results by manipulating (rather than measuring) the extent to which the users of the downward brand extensions can claim membership into the brand community. Even in this study, we use two existing brands (Louboutin for female and Bally for male) and assign participants (N. 297) to product ownership.

We are currently exploring two additional boundary conditions of the effect pertaining to the nature of the brand (luxury brand vs. mainstream brand) and respondents' ownership status (whether they own the brand or not).

In conclusion, our findings address the paradox of downward brand extensions for exclusive and luxury brands. We demonstrate that low-fit extensions can enhance the brand image in the eyes of the existing customers because these products do not allow their users to claim membership to the exclusive brand community.

Wen Wen, University of Texas at Austin, USA

SESSION OVERVIEW

Online sharing in the form of word-of-mouth (WOM) has become a prevalent and vital source of information for consumers (Chevalier and Mayzlin 2006; Dellarocas 2003), allowing them to share their own product and service experiences while learning about the experiences of others. Given that online reviews are inherently embedded in a social context (Hamilton, Vohs, and McGill 2014; Naylor, Lambertson, and Norton 2011), we suggest that seemingly ‘irrelevant’ information (e.g., language use) may serve as a critical social cue that leads consumers to make inferences about reviews or reviewers. The aim of this session is to examine such inferential processes in online WOM. Together, the four papers address the following questions: 1) What inferences do consumers draw from indirect cues in online reviews? and 2) How do these inferences impact review evaluations, product evaluations, and motivation to post reviews? Session attendees will learn how the subtle cues embedded in online reviews affect consumer inferences about both reviewers and reviews, thereby influencing their judgment and behavior.

The first two papers focus on how the language utilized in a review evokes inferences about reviewer characteristics. Kim, Moore, and Murray examine how linguistic negation style—contractions (e.g., isn’t) versus full negations (e.g., is not)—can alter perceptions of the reviewer. They show that the use of contractions leads to more favorable inferences about the reviewer’s warmth and knowledge, as well as more positive product evaluations. Hagen and O’Brien investigate the effect of linguistic temporal markers on review helpfulness. They find that the same review is less impactful when it is shared at a proximate point in time rather than a distant point in time (e.g., after one week vs. after one year), due to inferences that consumers draw about the reviewer’s emotionality and rationality. The last two papers investigate how inferences drawn from multiple reviews impact consumers’ judgment and motivation. Shoham, Moldovan, and Steinhart examine the role of the ‘unhelpful’ reviews in a set of reviews. They demonstrate that seemingly irrelevant negative reviews can lead consumers to infer that the worst is already known

about a product, boosting their product evaluations. Bond, He, and Wen explore reviewer motivation in free product settings (e.g., open-source software), and suggest that posting behavior in these settings is driven in large part by reciprocity. Using a real-world natural experiment, they present evidence that consumers use characteristics of existing reviews (e.g., quantity, variance) to infer whether posting will satisfy their reciprocity motivations.

Together, these papers highlight the diverse ways in which seemingly irrelevant cues in online WOM interact with consumer inference processes to yield unexpected consequences. We expect this session to be of interest to researchers in the areas of social connection and influence, WOM, language, and inference-making. Given the widespread applicability and implications of the issues discussed, we anticipate that the session will foster meaningful connections not only across research topics, but also across academics, practitioners, and consumers.

“Don’t Buy” or “Do Not Buy”? Negation Style and Product Evaluations

EXTENDED ABSTRACT

Online sharing in the form of word of mouth (WOM) is increasingly prevalent (Berger and Milkman 2012; Dellarocas 2003) and a significant body of work has demonstrated the impact of positive and negative WOM on consumers and firms (Chevalier and Mayzlin 2006; Dellarocas, Zhang, and Awad 2007; Richins 1983). Recent work has expanded beyond this focus on the valence of WOM by examining specific linguistic content. For example, specific emotion words (Yin, Bond, and Zhang 2014), abstract versus concrete language (Schellekens, Verlegh, and Smidts 2010), and explaining language (Moore 2012) can influence consumers’ product evaluations (Moore 2012), review helpfulness (Cao, Duan, and Gan 2011; Yin et al. 2014), and product choice (Kronrod and Danziger 2013). Yet while a growing body of work has examined linguistic content, or *what* is said, little research has examined linguistic style, or *how* things are said. We consider a prevalent and important aspect of linguistic style: negations. Building on the social agreement principle that governs online WOM, we investigate the novel question of how the use of different negation terms in online reviews can alter consumers’ product evaluations.

Specifically, we suggest that reviewers’ use of contracted negations (e.g., don’t) will lead consumers to have more favorable product evaluations than reviewers’ use of full negations (e.g., do not), due to the reduction in negativity communicated by contracted negations. Because the minimization of negatives in contractions better fits the socially communicative and interactive nature of online WOM (Berger 2014; Hamilton et al. 2014; Naylor et al. 2011), in which overt disagreement is curtailed and agreement is preferred (Schegloff, Jefferson, and Sacks 1977), the use of contracted negations should suggest a more favorable persona about the reviewer to consumers, resulting in more positive product evaluations than the use of full negations, which stress negativity (Yaeger-Dror, Hall-Lew, and Deckert 2002). Two studies test this hypothesis and show that consumers perceive a reviewer who uses contracted negations as warmer and more knowledgeable than one who uses full negations and evaluate the target product more favorably. A third study rules out processing fluency and language typicality as alternative explanations for this effect.

Study 1 tested whether negation style influences product evaluations. Undergraduates ($N = 85$, $M_{\text{age}} = 20.9$, $SD = 2.34$) read one of three identical online reviews about a digital camera. The reviews varied only in whether a sentence about the camera's ease of use contained a contraction ("wasn't easy to use"), a full negation ("was not easy to use"), or an affirmation ("was easy to use"). Participants reported their overall evaluations of the camera (e.g., bad/good, unfavorable/favorable; $\alpha = .89$) and their perceptions of how easy the camera was to use on 7-point scales. Participants in both negation conditions ($M_{\text{contracted}} = 4.33$, $M_{\text{full}} = 3.91$) evaluated the camera less positively than those in the affirmation condition ($M = 5.00$, $ps < .0001$), showing that both negations were attended to. However, participants who read the contracted negation evaluated the camera more positively than those who read the full negation ($t = 2.85$, $p < .01$) and rated the camera to be easier to use in the contraction condition ($M = 3.48$) than those in the full negation condition ($M = 2.79$; $t = 2.12$, $p < .05$).

To test the underlying mechanism, study 2 examined whether consumers' perceptions of reviewers' warmth and knowledge mediated the effect on negation style on product evaluations. Mechanical Turk participants ($N = 365$, $M_{\text{age}} = 33.1$, $SD = 11.64$) read an online review about a digital camera, the content of which was identical except for three sentences which contained either contracted or full negations (e.g., "the video menu wasn't/was not working properly"). Participants then evaluated the camera as in study 1 and rated the reviewer's warmth and knowledge (1 = not at all, 7 = very much). Participants in the contracted negation condition evaluated the camera more positively ($M = 4.26$) than those in the full negation condition ($M = 4.04$; $t = 1.95$, $p = .05$), and perceived the reviewer as warmer ($M_{\text{contracted}} = 4.84$, $M_{\text{full}} = 4.60$; $t = 2.03$, $p < .05$) and more knowledgeable ($M_{\text{contracted}} = 4.91$, $M_{\text{full}} = 4.62$; $t = 1.99$, $p < .05$). The effect of negation style on product evaluations was mediated by the reviewer's perceived warmth (95% CI: 0.001 – 0.082) and knowledge (95% CI: 0.005 – 0.101; Hayes 2013) individually.

Study 3 ruled out two alternative explanations for these findings. Contracted negations could lead to increased product evaluations not because of reviewer perceptions, but because they are more typical (Kronrod and Danziger 2013; Ling and Baron 2007) or more fluent to process (Alter et al. 2007) than full negations. Participants assessed the typicality (e.g., "How typical is this sentence for an online review?") and fluency (e.g., "How easy to read was this sentence?") of the sentences with contracted or full negations from study 2. We found that neither variable mediated the effect of negation style on product evaluations.

In sum, these findings suggest that beyond linguistic content, the linguistic *style* of negations can influence consumers. Specifically, consumers evaluate products more favorably and perceive reviewers as warmer and more knowledgeable when they use contracted rather than full negations. In contrast to prior work, which has focused on full negations (Grant et al. 2004), this research provides a nuanced understanding of negation style. By providing insight into how negations influence consumer judgments, this work contributes theoretically to marketing and psychology, and offers insight for marketers and consumers regarding online WOM.

Proximate Emotion and Distant Reason: Temporal Inference in Word-of-Mouth

EXTENDED ABSTRACT

Before purchasing, consumers often seek the opinions of others who have had personal exposure to the product. For example, many people browse customer reviews online. We find that the persuasive impact of these word-of-mouth (WOM) opinions depends on the

temporal context of the source: the same review is much less impactful when shared at "proximate" (i.e., soon after product purchase) versus "distant" (i.e., long after product purchase) points in time.

Surprisingly, this is not merely attributable to a perceived lack of usage experience on the part of quick review writers. Rather, this effect is driven by personality inferences about the reviewer, such that proximate reviewers are perceived as impulsive and emotional, rendering their opinion less credible and overall less helpful. The detrimental effect of proximate WOM is thwarted, however, when (a) the source's rationality is reaffirmed in other ways, (b) the review is emotion-relevant, i.e., about hedonic products, or (c) the audience is induced to value emotions. Five studies explore the phenomenon and establish process through mediation and moderation.

To begin, we showed the basic effect that proximate WOM is less impactful than distant WOM. First, a field study using real food processor reviews from Williams-Sonoma (Study 1a) leveraged ordinal length-of-ownership information reported by reviewers ("less than 1 week"–"over 5 years") to predict the proportion of readers rating the review as helpful ("I found this review: helpful vs. not helpful"). Regression showed that the more proximate the review to the purchase, the smaller the proportion of readers who rated it as helpful, even controlling for valence, word count, and concreteness.

Next, in a controlled laboratory experiment, participants read a positive or negative iPhone review labeled with a review date that was close (proximate) or far (distant) from the phone's reported release date (Study 1b). All other features of the review, including the content mentioned, were held constant. Participants rated on 1-7 scales how reliable, diagnostic, accurate, dependable, and helpful the review was, and how confident it made them feel ("Helpfulness Index," $\alpha = .95$). They also indicated to what extent the reviewer seemed like a person who is impulsive, emotional, rational (reversed), or has strong feelings ("Personality Index," $\alpha = .62$). As predicted, proximate reviews were seen as less helpful than distant reviews, despite identical review content. Further, proximate reviewers were perceived as more emotional types of people than distant reviewers, and this difference mediated the effect of time on review helpfulness (regardless of review valence).

Studies 1a and 1b showed evidence for the proposed effects, that is, that proximal reviews are less impactful, and that this is due to perception of proximate reviewers as impulsive and emotional. While Study 1b showed process evidence through mediation, we next examined moderators to further support our process hypothesis. Specifically, we tested whether reviews by patently unemotional reviewers (Study 2), for emotion-relevant products (Study 3), or read by an audience induced to value "gut" reactions and emotions (Study 4), would turn off the effect.

In Study 2, participants read positive Samsung Chromebook reviews written by a layperson or a professional product reviewer at a proximate or distant time after purchase. Here, temporal distance was manipulated by explicit mention of the specific timeframe of ownership. Again, participants completed the review "Helpfulness Index." To the extent that a professional product reviewer is perceived as unemotional (i.e., clearly writing the review based on logic and expertise), the effect of temporal distance on helpfulness should be muted. As predicted, reviews written by laypeople were much less helpful when shared soon versus long after purchase, but for reviews written by professional reviewers proximity did not undermine helpfulness.

Following the same design, in Study 3, participants read positive reviews written about a cook book or a food-art book at a proximate or distant point after purchase. As before, they rated the review on the "Helpfulness Index." Once more, we found the predicted interaction between temporal distance and product type: For the cook book (i.e., a product that does not involve immediate hedonic reac-

tions), proximate reviews were indeed much less helpful than identical reviews at a distant point. However, for the food-art book (i.e., a product for which immediate hedonic reactions are relevant), proximate reviews were seen as just as helpful as distant reviews.

Finally, in Study 4, participants read a positive review of a beverage mix written at a proximate or distant time after purchase. Crucially, before reading the review and rating the “Helpfulness Index,” half the respondents read a mock New York Times article about research evidencing the value of gut reactions and instinctual decisions (based on actual research, e.g., Gigerenzer 2007). To the extent that the article persuades people to value quick, feelings-based judgments, the effect of temporal distance on helpfulness should be muted. Indeed, as predicted, we found an interaction between temporal distance and attitude toward emotional reactions: Among control participants who read nothing beforehand, proximate reviews were seen as less helpful than distant reviews, replicating our basic effect. However, among those who read about the value of emotions, proximate reviews were seen as just as helpful as distant reviews.

Across field and laboratory studies, reviews shared soon after purchase were perceived as much less impactful than the same reviews shared at more distant points, because they made the reviewer seem too emotional to be taken seriously. These findings provide nuanced insight what consumers value in reviews: reasoned, thought-out opinions (even when shared quickly) are more persuasive than rather than sharing one’s initial emotion-based reactions. They also reveal that including temporal information in reviews can critically affect the persuasiveness of the review, and can strengthen its impact if the temporal relation matches the product. While firms may want to facilitate the reporting of temporal information, consumers themselves may strategically consider their use of temporal information to heighten their persuasiveness. Positive reviews might be bolstered by emphasizing the reviewer’s distance, just as negative reviews might be assuaged by emphasizing the reviewer’s proximity.

Positively Useless: Irrelevant Negative Information Enhances Positive Impressions

EXTENDED ABSTRACT

The current research examines the desirability and impact of irrelevant information, focusing on unhelpful online reviews. Positive and helpful user reviews typically increase evaluations and sales (Chevalier and Mayzlin 2006; Zhu and Zhang 2010). While negative reviews can increase product awareness (Berger, Sorensen, and Rasmussen 2010) and negative information can be beneficial in two-sided communications and reviews (Eisend 2006; Schlosser 2011), less is known about the effect of irrelevant information in the context of word of mouth and reviews. We suggest that unhelpful reviews can have a positive effect – if they are presented as being negative.

Online reviews are usually written by strangers, making it difficult to assess their value and relevance (Schlosser 2011). We propose that when consumers are uncertain of the best choice, they turn to the small number of available negative reviews, due to the perception that negative information is more diagnostic and valuable (e.g., Rozin and Royzman 2001). Irrelevant negative reviews do not provide the expected diagnostic value, so they are perceived as unhelpful, yet they lead consumers to infer that the worst is known and the product really is as good as advertised. This boosts the perceived usefulness of the positive information, resulting in more positive evaluations.

Past research has demonstrated that irrelevant information can have positive effects if it is valued by consumers (Carpenter, Glazer, and Nakamoto 1994), but also that it can reduce product evaluations if not valued (Brown and Carpenter 2000) or dilute the impact of

more relevant information (e.g., Meyvis and Janiszewski 2002). We build on this research and suggest that the way irrelevant information is presented can determine its impact. We predict that when irrelevant information, such as an unhelpful review, is framed *negatively*, it can lead to higher product evaluations and purchase intentions.

More specifically, we hypothesize that evaluations will be more positive when a review set includes an unhelpful review that is framed negatively rather than positively, and compared to sets without an unhelpful review. This hypothesis is confirmed in a series of five studies.

In study 1, participants evaluated an espresso machine and were assigned to one of three conditions: a set of four positive reviews only (control) or the same reviews with an additional unhelpful review, framed with either a positive or a negative rating (1 or 5 stars). This review provided general information about coffee rather than the specific espresso machine. As predicted, evaluations differed across conditions ($F_{(2, 74)} = 3.56, p < .05$). They were significantly higher when the review set included a *negatively* framed unhelpful review ($M = 5.81$) compared to the positive frame ($M = 5.04, t_{(48)} = 2.61, p < .05$) and control conditions ($M = 5.0, t_{(41)} = 2.41, p < .05$). The latter two conditions did not differ significantly.

Study 2 showed that the effect is moderated by familiarity with the reviewers. Student participants read comments about an elective course, supposedly provided by either friends or strangers. Once again, there were four identical positive comments and one unhelpful comment, framed either positively (“recommended”) or negatively (“not recommended”). The comment (that it fit the commenter’s schedule) was not perceived as useful by the participants. The expected 2-way interaction ($F_{(1, 91)} = 5.80, p < .05$) emerged: when the reviewers were strangers, evaluations were significantly higher if the set included a negatively framed unhelpful comment ($M = 5.68$) rather than a positive one ($M = 5.0, t_{(39)} = 2.35, p < .05$). When the reviewers were friends, the framing did not impact evaluations ($t < 1$). Bootstrapping analysis showed that the effect was mediated by greater perceived usefulness of the review set overall.

Study 3 sought to rule out two-sided persuasion as an alternative explanation, by showing that our effect derives from lack of negative diagnostic value rather than the inclusion of negative information. We added a condition with a weak but helpful negative review. As expected, we found a significant difference in evaluations of a camera ($F_{(2, 100)} = 4.71, p < .05$). Evaluations were significantly higher in the negative-unhelpful condition ($M = 5.76$) compared to the positive-unhelpful condition ($M = 5.15, t_{(64)} = 2.32, p < .05$) and the weak-negative condition ($M = 4.97, t_{(68)} = 2.91, p < .01$).

Study 4 demonstrated that the effect occurs when a negative review is personally irrelevant but not if it is relevant (and thus, truly negative). Participants read reviews of running shoes comprising either four positive reviews or the same reviews with an additional one-star review, which contained information relevant for women but not for men. The expected gender \times review set interaction emerged ($F_{(1, 80)} = 10.39, p < .01$). Men were willing to pay more for the shoes when the review set included the additional (irrelevant) review ($M = 86.97$) compared to when they saw only the four positive reviews ($M = 71.90; t_{(40)} = 2.14, p < .05$). Women, however, were willing to pay less when the additional (relevant) review was included ($M = 74.70$) than when it was not ($M = 89.68; t_{(40)} = -2.45, p < .05$).

In an additional study, participants chose a short video to watch as part of the experiment, based on user comments about each option. All participants actually saw the same video; however, those who chose a video that had an unhelpful negative review were more satisfied with their choice ($M = 5.38$) than those who did not ($M = 4.52; t_{(102)} = 2.73, p < .01$). This shows that the effect of unhelpful negative reviews extends into post-decision satisfaction.

The findings demonstrate that unhelpful reviews can have a positive effect on evaluations, and that they can boost the impact of positive reviews – if they are presented with a negative frame. Lack of negative diagnosticity, rather than the mere inclusion of negative information, is of key importance, making seemingly irrelevant information quite relevant with regard to evaluation and purchase decisions. While consumers and sellers may find some types of reviews and information unhelpful and irrelevant, these can nonetheless have unexpected positive effects.

Does Sharing Lead to Sharing? Evidence from Free Product Settings

EXTENDED ABSTRACT

Modern technology enables consumers to share product-related information, opinions, and experiences via platforms accessible to millions (social networks, retailer websites, review databases, blogs, etc.). As a result, online word-of-mouth (WOM) has come to represent a distinct communication channel, profoundly affecting consumer information search and decision making, while offering new challenges and opportunities for marketers (Chevalier and Mayzlin 2006; Schulze, Schöler, and Skiera 2014; Zhu and Zhang 2010). From a consumer and a practitioner standpoint, helpful WOM depends crucially on the willingness of consumers to share with one another; therefore, it is critical to understand the motivations underlying sharing behavior, so that such behavior can be facilitated, managed, and made sustainable.

Existing research on motivation for product-related WOM has focused almost entirely on retail WOM platforms and paid product settings (e.g., Dellarocas, Gao, and Narayan 2010; Lovett, Peres, and Shachar 2013). WOM in these settings is traditionally attributed to a self-focused, impression management motivation, whereby consumers seek to signal to others their expertise, status, conformity, uniqueness, etc. (Berger 2014). In contrast, our research examines drivers of consumer WOM in a setting where products are available for no (monetary) cost. This setting applies to a variety of modern marketplaces, especially in the technology arena, where ‘freemium’ business models are common (Niculescu and Wu 2014), and groups of enthusiasts produce high-quality goods and services for public consumption (e.g., smartphone apps, open-source software, webzines). Will WOM for free products follow the same social dynamics as for paid products, or will underlying motivations and sharing behavior differ?

Our primary argument is that an other-focused, reciprocity mechanism (Cialdini and Goldstein 2004; Gouldner 1960) is a prominent driver of WOM in free product markets. Our logic is based on the application of social exchange norms to producer-consumer relationships. In traditional (costly) product settings, buyers exchange monetary payment for the value that they derive from the products they consume. In free product settings, however, buyers must seek nonmonetary methods of compensating to avoid violating the norm of exchange. Given the limited options for doing so, we predict that consumers will view the provision of ‘helpful’ WOM as a practical and effective means of reciprocity.

To test of our hypothesis, we investigated a real-world, online review platform for free digital products (e.g., open-source software). To investigate our reciprocity mechanism and disentangle it from alternative accounts, we explored how the sharing behavior of prior consumers affected the sharing behavior of later consumers. In order for WOM to provide an effective means of reciprocating producers, consumers must infer that it provides meaningful value over existing WOM. Therefore, we predicted that likelihood of posting a review would depend on the quantity and dispersion of existing

reviews. Specifically: when the quantity of prior WOM is low (i.e., there are few existing reviews) or the dispersion of prior WOM is low (i.e., the content of existing reviews is similar), the perceived value of additional sharing for reciprocation will increase, resulting in a greater likelihood of posting. When the quantity or dispersion of prior WOM is high, the perceived value of additional sharing will decrease, resulting in a lower likelihood of posting. Importantly, these predictions contrast with the behavior implied by the ‘herding’ motivation often assumed in traditional review settings (Berger 2014; Moe and Schweidel 2012).

The basis for our natural experiment was a series of platform-wide reforms that resulted in the removal of a portion of existing reviews from the platform. Exploiting this exogenous shock, we used a difference-in-difference approach (Chevalier and Mayzlin 2006) to examine how changes to review distributions across products impacted sharing by subsequent customers. Because we could not directly observe individual posting behavior before and after the reform, we focused on the product level, and use changes to the quantity of posts as evidence that the intensity of posting motivation had changed. The sampling period began six months before the review system reform and ended seven months afterwards.

Analyses were performed via a series of conditional fixed-effect Poisson regressions. Results revealed consistent support for our hypotheses regarding reciprocity motivation. Contrary to the ‘herding’ prediction that a large quantity of WOM would invoke more sharing, we found that individuals became more likely to post a review as the quantity of existing reviews became smaller. Specifically, estimated coefficients suggested that a 10% reduction in the number of existing reviews would be expected to increase subsequent posting by seven to nine percent. Also supporting predictions, results indicated that propensity to share was impacted by the dispersion of prior reviews, such that greater dispersion (“mixed opinions”) reduced sharing. Specifically, estimated coefficients suggested that an increase of one standard deviation in existing review valence would be expected to decrease subsequent posting by twenty to twenty-seven percent. Offering further support for our model, follow-up analyses showed that the effects of both quantity and dispersion on posting were attenuated when there were other opportunities for reciprocation were available (e.g., a separate user feedback forum was present).

Together, our theory and findings contribute to current understanding of WOM by providing evidence for a heretofore understudied, reciprocity-based motivation. Moreover, they suggest potential means by which retailers, third-party forums, etc., might encourage customer conversations without resorting to pecuniary incentives that undermine trustworthiness (Stephen et al. 2013). For example, by framing a review request in terms of ‘giving back,’ and by highlighting specific aspects of existing product discussion (e.g., quantity or dispersion), platforms may be able to directly evoke reciprocity motivation among new users, increasing the likelihood that they will contribute to the discussion.

Paper #4: Excusing Selfishness in Charitable Giving: The Role of Risk

Christine Exley, Stanford University, USA

SESSION OVERVIEW

Consumer behavior researchers have been increasingly interested in consumer welfare, as testified by numerous recent publications on topics such as self-control (Wilcox and Stephen 2013), food consumption (Wansink and van Ittersum 2013), and promotion of healthy life-styles (Bolton et al. 2007). Consumer welfare can be improved by doing good not only for oneself but also for others: helping (Weinstein and Ryan 2010), volunteering (Petty and Hewitt 2001), or donating (Dunn, Aknin, and Norton 2014) have been shown to positively influence well-being.

This session investigates doing good both for self and others, and deals with a number of diverse phenomena: self-improvement, self-control, and prosocial behavior. The objective of the session is to examine factors that can unexpectedly facilitate or prevent doing good for the self and others. Surprisingly, factors generally considered as potentially damaging for consumer welfare, such as guilt and indulgence, end up being useful in fostering self-improvement and long-term healthier eating. Similarly, factors generally considered as beneficial for consumer welfare, such as malleable beliefs and a rational approach to giving, turn out to be detrimental to prosocial behavior.

The paper by **Allard and White** demonstrates positive consequences for the self of an affective experience generally considered as detrimental: guilt. The paper highlights that guilt activates a self-improvement motive, and therefore facilitates preferences for options enabling this self-improvement. The paper by **Gu, Klesse, Botti and Faro** illustrates how reaching closure with a choice of a *want* (e.g., chocolate cake) over a *should* (e.g., fruit salad) option lead to greater indulgence. This response, which is potentially self-damaging in the short term, has desirable long-term consequences in that it increases the likelihood to eat healthier in a subsequent choice.

These first two papers focus on factors that may have an unexpected positive impact on doing good for the self. The last two papers focus on factors that may have an unexpected negative impact on doing good for others. The paper by **Levontin and Johar** shows that belief in change, which is considered as valuable for the self, reveals

a dark side when it comes to doing good for others. Individuals who believe that personal qualities are malleable (“incremental theorists”) are less likely to help than those who do not (“entity theorists”). The fourth paper by **Exley** studies how potential donors use the perceived risk that their donations may have a low impact as an excuse not to give. Donors’ attention to the performance of non-profit organizations represents a sensible attitude toward charitable giving but can also justify the decision of not donating.

As a whole, these papers include studies that involve both hypothetical scenarios and actual experiences in the lab and the field. They raise questions such as: What factors considered as harmful for the self can foster doing good for others? What factors considered as valuable in prosocial settings can prevent doing good for the self? Focusing on doing good for yourself and others is expected to connect researchers interested in different topics such as consumer welfare, prosocial behavior, and self-control.

Cross-Domain Effects of Guilt on Desire for Self-Improvement Products

EXTENDED ABSTRACT

The current research highlights a novel downstream consequence of guilt—cross-domain preferences for choices enabling self-improvement. We propose that when opportunities to engage in actions directly aimed at addressing the source of the guilt are not available, guilt activates a general motive to improve the self. We show that guilt can lead to preferences for options geared toward improving important facets of the self, even in domains unrelated to the one where the guilt originated. Importantly, this increase in desire for self-improvement products is not observed in response to other negative emotions (e.g., shame, embarrassment, or sadness).

Past research shows that the experience of guilt often leads individuals to engage in actions allowing for reparation of the wrongdoing in a way that can *directly* resolve feelings of guilt (e.g., Ainslie 1975; Tangney and Dearing 2002). Guilt can also lead to behaviors aimed at *indirectly* addressing the feelings of guilt by reducing people’s negative mood either through mood-repairing behaviors such as prosocial actions or hedonic consumption (e.g., Bybee et al. 1996; De Hooge, Zeelenberg, and Breugelmans 2007; Konecni 1972) or through an avoidance of wasteful or immoral consumption choices that would further worsen their mood (e.g., chips or CDs; Khan and Dhar 2006; Kivetz and Keinan 2006; Zemack-Rugar, Bettman, and Fitzsimons 2007).

The current research introduces a third downstream consequence of guilt—its ability to induce a generalized desire for self-improvement. We suggest that because guilt is associated with a salient awareness of a failure to meet important self-standards (Miceli and Castelfranchi 1998; Tracy and Robins 2004), it can activate a general motivation to improve the self through consumption choices with self-improvement features. In sum, we propose that one additional response to guilt is to seek out options enabling self-improvement, even in domains unrelated to the source of the guilt.

Study 1 ($n = 169$, MTurk) utilizes a 2 (guilt vs. neutral) between-participants design and demonstrates our framework that guilt activates self-improvement strivings, which then lead to preferences for self-improvement products. Participants recalled either a time

when they let someone down and felt guilty about it or a neutral encounter. Afterwards, participants rated their general motivation to self-improve (four 7-point items; e.g., “I want to do better;” $\alpha = .82$). Participants were then asked to provide their likelihood of using a fitness-tracking app offering a number of self-improvement features including a pedometer, calorie counter, and sleep cycle visualization options (“very unlikely-improbable/very likely-probable,” $r = .98$), and controlling for fitness level. Participants in the guilt condition ($M = 5.68$) were more likely to use the app compared to those in the control condition ($M = 5.19$; $F(1, 166) = 4.01, p < .05$), and such effect was mediated by activated self-improvement strivings ($CI_{95} [0.01, 0.30]$).

Study 2 ($n = 166$, students) uses a mixed design with a 2-level between-participants factors (emotion: guilt vs. neutral) and a 2-level within-participants factor (pre-choice vs. post-choice measures of guilt and of desire for self-improvement). This study rules out an alternative explanation relying on mood-repair and instead tests that the selection of self-improvement options was serving a self-improvement function, through a steeper decline in the intensity of the self-improvement strivings for those who selected a self-improvement product.

After the emotional manipulation (same as study 1), participants reported the extent to which the event they described made them feel guilty (guilty, repentant, blameworthy; Tangney et al. 1996; 1 = not at all, 7 = very much; $\alpha = .96$) and their self-improvement strivings (see study 1; $\alpha = .84$). Participants were then shown a pack of sticky notes with the caption: “Sticky notes for effective knowledge retention—the secret weapon of students wishing to improve” and were offered the option to forgo (\$1) in exchange for the product. After making their choice, participants answered the two scales for a second time.

Participants were more likely to select the self-improvement product in the guilt (64.7%) compared to the control condition (49.4%; $\chi^2(1) = 3.98, p < .05$). For the guilt measure, a repeated-measures ANOVA revealed only a decay of the effect of the guilt manipulation over time (repeated measure by emotion interaction ($F(1,162) = 14.47, p < .001$), suggesting that choosing the self-improvement product (vs. not) had no influence on the magnitude of the guilt decay. For self-improvement strivings, results revealed a steeper difference between post minus pre self-improvement desire score by product choice (three-way interaction $F(1,162) = 3.57, p = .06$) suggesting that selecting a self-improvement product can address the guilt-heightened desire for self-improvement. Pre-choice self-improvement striving score also mediates the effect of guilt on product choice ($CI_{95} [0.08, 0.97]$). Thus, the results in this study appear to be driven by a desire for self-improvement, rather than a mood management motive.

Study 3 ($n = 157$, students) compares the effects of guilt (vs. neutral) on self-improvement against embarrassment, shame, sadness and controls for the alternative explanation of a punishment-seeking motivation (e.g., Nelissen and Zeelenberg 2009). Participants were first assigned to one of five emotional-recall conditions (short definitions of the emotions were provided). Then, participants read about the functional benefits of two herbal teas, the “Get Smart (self-improvement)” and “Get Happy (control)” flavors, and reported their willingness to pay for a box of each product. Participants also rated the extent to which they were currently seeking punishment using four 7-point items (e.g., “I want to deny myself rewards;” $\alpha = .89$). A repeated-measures ANOVA identified a significant interaction between product type and emotion on willingness to pay ($F(4, 152) = 2.43, p = .05$). Only participants in the guilt condition were willing to pay more for the self-improvement product compared to

the control product ($F(1, 152) = 4.25, p < .05$). In addition, this effect does not appear to be explained by desire for punishment-seeking.

Taken together, these studies provide converging evidence that the experience of guilt can lead to increased preferences for self-improvement consumption choices, even in domains different from where the guilt originated.

Choice Closure Increases Indulgence (But Only Once!)

EXTENDED ABSTRACT

Consumers frequently face a trade-off between what they want (e.g., chocolate cake) and what they should (e.g., fruit salad) choose. In such situations, consumers experience a conflict between highly desirable options that allow immediate pleasure (*want* options) and those that are less immediately appealing but provide more long-term benefits (*should* options) (Bazerman, Tenbrunsel, and Wade-Benzoni 1998; Thaler and Shefrin 1981). Literature has shown that choosing *want* options evokes negative feelings, such as guilt (Giner-Sorolla 2001; Kivetz and Simonson 2002), which may decrease the pleasure derived from the desirable consumption experience.

We propose choice closure—a psychological process by which decision makers come to perceive a decision to be complete (Gu, Botti, and Faro 2013)—as a means to reduce the negative feelings derived from choosing the *want* in place of the *should* option. Recent research (Gu et al. 2013) demonstrated that choice closure triggers (e.g., physical acts such as closing a lid and visual cues such as rejection signs) inhibit unfavorable comparisons between the selected and the rejected options, increasing satisfaction with the decision outcome in the context of difficult decisions. In the case of decisions that involve a *want* versus *should* conflict, we predict choice closure to inhibit the unfavorable feelings (e.g., Bitterly et al. 2014) induced by choosing the *want* option and, hence, enhance the pleasure individuals derive from their choice. However, by allowing consumers to maximize indulgence in the short-term, choice closure might reduce their desire to indulge again in the long term. Hence, consumers presented with a second conflicting choice might be more likely to choose the *should* option when they have reached closure on their first *want* option than when they have not. We test these predictions in four studies—three laboratory and one field study—utilizing different triggers of choice closure, and different manifestations of pleasure (e.g., intended consumption and enjoyment).

In Study 1 ($n = 153$), participants chose between M&Ms (*want* option) and grapes (*should* option) that were covered with a transparent lid. Initially, all participants were asked to remove the lid. To manipulate choice closure, half of them were asked to put the lid back on the rejected option after making their choice (closure condition) while the other half left the lid open (no-closure condition). Next, all participants poured as many M&Ms/grapes into their own cup as they wanted to eat. In line with our prediction that closure increases the tendency to indulge, participants in the choice closure condition poured more grams of M&Ms ($M_{closure} = 9.79$ versus $M_{noclosure} = 7.21$, $F(1,150) = 6.47, p = .012$). The amount of grapes poured was not affected by choice closure.

In Study 2 ($n = 120$), we replicated this finding by controlling for self-selection. Participants chose between two options—yogurt coated peanuts and chocolate coated raisins. Choice closure was manipulated as in the previous study. Regardless of their choice, participants in the *want* condition were provided some feedback describing their selection as superior on taste but inferior on healthiness. Participants in the control condition did not receive any feedback. Next, all participants poured as much as they wanted to eat of the chosen snack into their own cup. Utilizing square-root transforma-

tion, the results show that choice closure increased the amount of grams poured in the *want* condition ($M_{closure} = .73$ versus $M_{noclosure} = .51$, $F(1,128) = 4.84$, $p = .03$). The amount poured in the control condition was not affected by choice closure.

In Study 3 ($n = 332$), we measured indulgence by asking consumers' the level of enjoyment they expected to derive from their choice of chocolate cake (*want* option) or fruit salad (*should* option). Choice closure was manipulated by exposing half of the participants to a visual cue of closure after making their choice (i.e., a "rejected" sign attached to the rejected option) while the other half saw the pictures of both options without any additional sign. Choice closure increased the anticipated enjoyment for individuals that chose the chocolate cake ($M_{closure} = 7.94$ versus $M_{noclosure} = 7.55$, $F(1,330) = 4.74$, $p = .03$). The enjoyment of those that opted for the fruit salad was not affected by choice closure.

The results of these three studies denote that choice closure increases pleasure with *want* options manifesting itself in greater quantity poured for intended consumption or higher anticipated enjoyment. In Study 4 ($n = 111$), we investigated potential downstream consequences in a field setting. We predicted that consumers who reached closure over their decision to select a *want* option and fully enjoyed their experience would experience a lower desire to indulge again in a subsequent choice. Guests of a restaurant chose a dessert out of four options, two *wants* (i.e., Crème de Brûlée and chocolate cake) and two *shoulds* (i.e., yogurt and fruit salad). Notably, guests either received a two-page menu that could be closed (closure condition) or a one-page menu (no-closure condition) that could not be closed. For those guests that chose one of the *want* options, the waitress asked whether they wanted ice crème (*want* option) or berries (*should* option) on the side. Significantly fewer participants in the closure condition chose the ice crème as the side than in the no-closure condition (52.2% versus 71.4%, $c^2(1) = 4.02$, $p = .045$), indicating that reaching closure on a first indulgent choice decreases the tendency to indulge again in a subsequent decision.

Overall, these findings denote two positive consequences of choice closure when choosing between *want* and *should* options: closure increases the pleasure individuals' derive from their choice of a *want* option and it decreases their tendency to continue indulging in a subsequent decision.

"Serves you Right"? The Dark Side of a Malleable Mindset

EXTENDED ABSTRACT

Individuals differ greatly in their view about whether people's traits can adapt, change and grow over time (Chiu, Hong, and Dweck 1997; Levy, Stroessner, and Dweck 1998; Mukhopadhyay and Johar, 2005). Whereas "entity theorists" hold a fixed mindset of personal traits and characters, and do not believe that personal qualities can change much over time, "incremental theorists" hold a more malleable and dynamic view of traits and believe that personal qualities are changeable and can grow over time. An emphasis on growth has been found to increase intellectual achievement, advance conflict resolution between long-standing adversaries, decrease even chronic aggression, foster cross-race relations, and enhance willpower (Dweck 2012).

However, there is also a dark side to the belief in growth. Incremental theorists' behavior towards others stems from their belief that people can change their immoral behaviors and misfortunate situations. Thus, for example, incremental theorists are less forgiving than entity theorists, and this difference is explained by the incremental theorists' stronger tendency to appraise the transgressor as

responsible for causing the hurtful event (Ng and Tong, 2013). In this research we examine prosocial behavior towards victims of negative events. We hypothesized that incremental theorists make a default attribution that the victims are responsible for their plight. Being in need is a violation of incremental beliefs. The belief in growth suggests that everyone can grow and change their position in life. Thus, through the lenses of incremental theorists, those who are in need are responsible for their condition. Accordingly, they deserve less help, which results in what we call 'the dark side of malleable mindset.' Entity theorists hold a relatively fixed view of self and hence are likely to view the victims as unable to change what befalls them and less responsible for their plight. The results of two studies support this hypothesis.

In Study 1 ($n = 80$) participants first read a short paragraph (the well-established implicit theories manipulation, Chiu, Hong, et al. 1997) that presented research suggesting that personality is either fixed (entity condition) or malleable (incremental condition). Participants then read about the Williams family that is desperately poor, has no home and faces a threat of severe hunger. Participants reported whether they would be willing to donate money to help the Williams family, to volunteer helping families like the Williams family, and whether they believed that the Williams family are to be blamed for their condition. Note that blame for the Williams family's dire situation is ambiguous—it could be a result of dispositional or situational causes. As expected, following the entity manipulation participants were more willing to donate money and to volunteer ($M_{donate} = 5.38$, $SD = 1.68$; $M_{volunteer} = 5.33$, $SD = 1.72$) than following the incremental manipulation ($M_{donate} = 4.51$, $SD = 1.54$, $F(1,79) = 5.58$, $p = .021$; $M_{volunteer} = 4.74$, $SD = 1.31$, $F(1,79) = 2.84$, $p = .096$). Also as expected incremental theorists believed that the Williams family are to be blamed for their condition ($M = 3.26$, $SD = 1.29$) more than entity theorists ($M = 2.62$, $SD = 1.40$, $F(1,78) = 4.36$, $p = .040$). Mediation analyses (Hayes, model 4) using bootstrapping (Preacher, Rucker, & Hayes, 2007) with 5000 replications confirmed that blaming the victims mediates the effect of incremental (vs. entity) beliefs on participants' willingness to donate money (95% CI = $[-.678, -.019]$).

In Study 2 ($n = 234$) implicit theories were manipulated as in Study 1 and blame was also manipulated. In the high blame condition, the paragraph about the Williams family stated that Mr. Williams has lost their home in a gamble, whereas in the low blame condition the paragraph stated that the Williams family had lost their home in a hurricane disaster. Participants then responded to the same dependent variables as in study 1 as well as how many months they would be willing to volunteer. We predicted an interaction effect such that for entity theorists who attribute being in need to victims' fixed nature, blame would have little influence on prosocial behavior. However, incremental theorists would behave less prosocially in the high blame condition, replicating the results of Study 1.

Results showed a main effect for blame on participants' willingness to donate money ($F(1, 2228) = 19.08$, $p = .000$). More importantly, we found the expected interaction between blame and implicit theories ($F(1, 228) = 4.24$, $p = .041$). Entity theorists' willingness to donate money to the Williams family ($M = 4.37$, $SD = 1.81$) did not differ between blame conditions ($F(1,228) = 2.92$, $p = .089$). However, as expected, incremental theorists were less willing to donate in the high blame condition ($M = 3.54$, $SD = 1.68$) than in the low blame condition ($M = 5.00$, $SD = 1.58$, $F(1,228) = 19.02$, $p = .000$).

Finally, we found no main effects (F 's < 3.4), only the expected interaction between blame and implicit theories on participants' willingness to volunteer ($F(1, 228) = 4.25$, $p = .040$) and the number of months they were willing to volunteer for ($F(1, 228) = 8.05$, p

= .005). Entity theorists' willingness to volunteer ($M = 4.47$, $SD = 1.89$) and its duration ($M = 4.58$, $SD = 3.29$) did not differ between blame conditions ($F_{volunteer}(1,228) = .03$, $p > .250$; $F_{months}(1,228) = 2.62$, $p = .107$). However, as expected, incremental theorists were less willing to volunteer and volunteered for fewer months in the high blame condition ($M_{volunteer} = 4.26$, $SD = 1.70$; $M_{months} = 4.04$, $SD = 2.63$) than in the low blame condition ($M_{volunteer} = 5.20$, $SD = 1.72$, $F_{volunteer}(1,228) = 7.03$, $p = .009$; $M_{months} = 5.57$, $SD = 3.96$; $F_{months}(1,228) = 5.59$, $p = .019$).

The results of these two studies suggest that incremental theorists' belief in growth might sometimes lead them to be more judgmental of others and less generous compared to entity theorists. Research is under way to examine factors that can help mitigate incremental theorists' harsh judgments of those in need.

Excusing Selfishness in Charitable Giving: The Role of Risk

EXTENDED ABSTRACT

In the United States, 1 in 4 adults volunteer and 1 in 2 adults give to charities for an estimated combined value of \$500 billion dollars per year (<http://www.givingusareports.org>). An established literature documents potential motives for such giving; for instance, people feel good about themselves when they help others (Andreoni 1989, 1990) or value appearing nice to others (Harbaugh 1998a; Benabou and Tirole 2006; Ariely et al. 2009). These motives, as well as standard economic models, may easily explain a common finding in charitable giving: individuals give less when there is a greater risk that their donation will have less impact (Brock et al. 2013; Krawczyk and Lec 2010). In this paper, however, I investigate whether an additional mechanism is relevant: do people use the risk that their donation may have less than the desired impact as an excuse not to give?

Given that people are frequently asked to give, and an increasing push for individuals to "give wisely," it seems reasonable that individuals may use risk as an excuse not to give. Previous literature has documented the increasing "professionalization" and hence focus on performance in the nonprofit sector (Hwang and Powell 2009), and has demonstrated a large scope for motivations broadly related to excuses. For instance, people often behave more selfishly when they can avoid learning how their decisions affect others (Dana et al. 2007; Bartling et al. 2014), develop self-serving biases (Konow 2000; Haisley and Weber 2010), or rely on the possibility that their decisions did not influence the outcome (Dana et al. 2007; Andreoni and Bernheim 2009; Linardi and McConnell 2011; Falk and Szech 2013).

While this literature suggests a potentially large scope for excuse-driven behavior, it may be difficult to isolate excuse-driven responses from other responses to risk in charitable giving decisions, which often involve multi-faceted decision environments with no clear metric for risk. I thus begin by examining how individuals respond to objective risk in a laboratory study that allows for the necessary control. In particular, participants make a series of binary decisions between risky and riskless payoffs that may benefit themselves or the American Red Cross. A risky payoff is a lottery that yields a non-zero amount with probability P and \$0 with probability $1-P$. A risky payoff is a "charity lottery" if the corresponding outcome is given to the American Red Cross, or a "self lottery" if the corresponding outcome is given to the participant. A riskless payoff yields a non-zero amount with certainty. A riskless payoff is a "charity-certain amount" or "self-certain amount" if it is given to the American Red Cross or to the participant, respectively. In other

words, participants face four types of binary decisions that vary according to the payoff recipients - {self lottery, charity lottery} X {self-certain amount, charity-certain amount} - and these decisions imply valuations that allow me to distinguish between excuse-driven risk preferences and other responses to risk.

To begin, notice that participants do not face tradeoffs between payoffs for themselves and the charity when deciding between: (i) self lotteries and self-certain amounts, or (ii) charity lotteries and charity-certain amounts. In this no self-charity tradeoff context, excuses not to give are irrelevant as participants never decide whether or not to give - i.e., they cannot give in (i) or are forced to give in (ii). By contrast, participants always face tradeoffs between payoffs for themselves and the charity when deciding between: (iii) self lotteries and charity-certain amounts, or (iv) charity lotteries and self-certain amounts. In this self-charity tradeoff context, excuses not to give may be relevant.

I find that in the no self-charity tradeoff context, when excuses are not relevant, participants' responses to risk in charity and self lotteries are nearly indistinguishable. However, in the self-charity tradeoff context, when excuses not to give may be relevant, participants' responses to self risk and charity risk diverge. Consistent with excuse-driven risk preferences, participants act both more averse to charity risk and less averse to self risk. For instance, in response to introducing only 5% risk of a zero-dollar charity payoff, participants' valuations for charity lotteries decrease by 32% in the self-charity tradeoff context. The reduction is four times larger than the corresponding 8% decrease in the no self-charity tradeoff context. That is, participants appear to overweight the possibility that charity lotteries yield zero-dollar payoffs, using it as an excuse to choose self-certain-amounts over charity lotteries. These differences are robust across a range of risk levels, and to a variety of specifications, including simple comparisons of means and estimations that allows for participant-level fixed effects.

I infer from the observed treatment effects that individuals exhibit excuse-driven risk preferences. By exploiting the within-subject design of this study, additional results provide evidence for excuse-driven types of participants. First, there is a within-sample level of consistency: the same participants use both charity risk and self risk as excuses not to give. Second, there is an out-of-sample level of consistency: participants with excuse-driven risk preferences are more likely to engage in other excuse behavior in a separate incentivized "moral wiggle room" task, as developed in Dana et al. (2007).

Two additional laboratory studies document the potential prevalence of excuse-driven responses to risk. First, I find strong evidence for excuse-driven risk preferences when participants decide between payoffs for themselves and payoffs for another study participant, as opposed to payoffs for the charity. Second, I examine whether excuse-driven behavior arises in response to more commonly observed, although less precise, types of risk conveyed via charity performance metrics. Participants value charter schools with different college matriculation rates, animal shelters with different success rates, and charities with different levels of overheads costs. In line with lower charity performance metrics conveying higher risk of donations being used ineffectively or inefficiently, participants reduce their valuations for charities with lower charity performance metrics. In line with excuse-driven behavior, this reduction is larger when excuses not to give are possible, i.e., in the self-charity tradeoff context.

Paper #4: Self-Transformation and Performativity of Social Media Images

Joonas Rokka, NEOMA Business School, France

SESSION OVERVIEW

Although the term “selfie” has gained wide, and often inappropriate, currency in common parlance, the use of technologies to reflect images of the self is actually much wider than mere digital self-portraiture. Indeed, beyond the varieties of self-portrait shared through social media are technologies that reflect the self back to the self, mirror-like, as well as out to the world, broadcast-like, thus playing key roles in the complex contemporary construction of combined private-public selves. Conceptually emphasizing this self-reflective quality, its technological orientation, and its co-creative aspects, this session uses the term “the iMirror” to begin a research conversation about this potential new area. The “iMirror” theoretical conversation focuses not merely on particular manifestations, such as smartphone self-portraiture, but on the wider phenomenon of public-private self-related image sharing, including images of the self in consumption, and its implications for our understanding of self-in-culture and culture-in-self. Using consumer culture research on the vanguard of the phenomenon, this session is intended to highlight and begin to systematize the theoretical implications of these ideas.

Drawing upon multiple case studies interrelated by their self-reflective characteristics, the sessions explores different facets of the iMirror. First, Kozinets, Ashman, and Patterson use their longitudinal netnography of online food-sharing practices to conceptualize these different elements. Their study of food consumption photography blends technology consumption with food, self, and other in digital consumption “networks of practice”. Rob, Rachel, and Tony link these elements to notions of emancipation and participatory culture. But, showing that things are not so rosy, these notions are counterbalanced by a series of updated hegemonic and Weberian “iron cage” implications. Next, drawing on their ethnographic work with wearable camera technology, Dinhopf and Gretzel explore the notion of “soiveillance”, a widely used social media term that situates self-related digital technology practices within the context of surveillance. Building on notions of the panopticon and reconsumption, Anja and Ulli develop theory that helps add qualitative aspects to the quantified self. Belk then takes us on a journey to the center of theories of the self. Building from social psychology and sociology, he skillfully adapts them to the new digital world of iMirrors. Cooley’s notion of The Looking Glass Self and Goffman’s theories of presentation of self are confronted with Russ’s new realities of online tagging, comments, endorsements, and other such responses to consumers’ digital self-presentations. He shows nothing less than that the new digital

self-image is subject to a complex of old and new co-constructing responses of others. In the final paper, Rokka introduces notions of class and status. Joonas uses performativity theory to examine how champagne consumers are bounded by their own self-limits as they self-reflect their consumption online. Analyzing digital images reveals the disciplinary constraints that capital places on performative agency, and allows some speculation about what it might take to escape those limits, and engage in genuine self-transformation.

Each of these papers combines theory with fieldwork and observation. Each deals with the central topic of iMirrors. However, each assumes a unique perspective on the phenomenon—participation, surveillance, co-construction, and self-limitation. Combined into the session, this congerie of related themes reveals more than could any individual presentation. Although the session features consumer culture work, its central topics and constructs—the self and consumption—have wide appeal to those with self and social psychology orientations. The four papers were handpicked for their interrelated fit, offering different theoretical and site sampling angles on the phenomenon, but also with considerable depth. The session is well-suited to elicit and answer questions about new and existing constructs and theoretical relations to explain these new phenomena, such as: “Is there enough here to sketch out a nascent research area?” Technological and theoretical advancements and the nature of consumer-technology, consumer-consumption and consumer-consumer connection will be explored, “advancing” our understanding of consumer “connections” and also connecting “self” concepts across the field of consumer research.

Reflections of Self in Food Sharing Interactions and Experiences

EXTENDED ABSTRACT

Displaying representations of food is a widespread, global, and significant social media phenomenon with many aspects. This behavior is rooted in part in food photography and recipe books, but has grown to encompass and assume many new forms, such as recipe sharing and so-called “foodporn”. As it always has for scholars such as Pierre Bourdieu (1984) and Sidney Levy (1981), food consumption reveals a socially embodied structure of taste and distinction. Hence, we link the sharing of food related photography to a structure of ‘culinary capital’ (Lebesco and Naccarato 2012), a particular language and set of meanings that is both acculturated and immediately grasped. This research combines longitudinal netnographic work in the space of food and drink display with three years of in-person ethnographic and interview work.

In this paper, we demonstrate how a variety of styles of self-representation can inform our knowledge of the “iMirror”: public-private self-related image sharing, including images of the self in consumption, and its implications for our understanding of self-in-culture and culture-in-self. We note several major uses as consumers reflect consumption outwards, to others. Cosmopolitan and fashionable people like to be seen to eat the ‘correct’ foods, in the ‘correct’ restaurants and, as a consequence, gain admiration through display of their consumer status. However, until relatively recently, telling consumers what and where to eat has mostly been the preserve of food critics writing in newspapers. For many years, alongside the Michelin star system employed to assess haute cuisine restaurants, the system of food critics and evaluators legitimized particular per-

sons as the dominant purveyors of food knowledge. However, the disrupting disintermediation of traditional institutions of taste distribution is shifting, with voices being coopted alongside the emergence of new institutional voices (Dolbec and Fischer forthcoming; Jenkins forthcoming; McQuarrie et al. 2013; Scaraboto and Fischer 2013). In tandem with a broadening public sphere more open to exhibitionism through the sharing of intimate and personal revelations resulted in self representation which is outwardly directed and which both de-institutionalizes and re-institutionalizes consumption practices, identities, and characteristics.

The *iMirror* also exhibits consumption of the self to the self. The technological infrastructure equips people with unprecedented agency to reflect their own consumption to themselves through others. Although Web 2.0 technologies, according to the rhetoric at least, render a software-based architecture of participation that has led to consumer empowerment on a level previously unimaginable (Constantinides and Fountain 2008; Krishnamurthy and Kucuk 2008), we also, following Weber's famous metaphor, see this as a type of "Silicon Cage of Rationality". When media is marketplace, and when media are social, there is no escape from the gaze of the market. The implications for media scholar Henry Jenkins' (1991, forthcoming) notion of "participatory culture" is especially salient as it shows how participation in technology for consumption, even in boundary zones where it is not directly or immediately shared through social media, now performs not only a motivational function but also a pedagogical one. Emancipatory potentials are counterbalanced by marketplace hegemonies, and vice versa (Kreiss et al. 2011). Self-reflective technology teaches us how to consume, how to consumer better, hot to display and how not to consume/display. The resulting consumption process is thus much more than a simple addition of voices to an existing process. Instead, the connections enabled by social media create entirely new demands for new self-presentational practices and form of consumption. These work alongside economic and social processes requiring access to technology and a myriad of other products and services.

Although critics still exist and have (real world, and sometimes social media) klout, the creation and maintenance of food markets is therefore, to some extent, now dependent on networks of prosuming consumers, collectives composed of individuals capable of technologically-enabled production, consumption, and entrepreneurship (Moffitt and Dover 2013). Collectively, across a multitude of sharing sites, the depiction of food-related images plays an undeniable role in the arbitration of food tastes and restaurant choices. Typically, in excursions from home to restaurant, consumers are equipped with mobile phone cameras, which they use to capture and upload salivating pictures of restaurant-bought delicacies or homemade foodstuffs. These phones, and the cameras within them, made possible by the miniaturization of both electronic circuits and processors, often described as appendages of their bodies, directly linking them to social cuisine networks.

Appetites, tastes, and distinctions in such food sharing networks become complex market-community-industrial processes. Self-presentational practices in the *iMirror* play a vital role in these processes. Food sharing practices can include human bodies or no human bodies, depending upon the cultural codes conveyed. Patterns in distinct objectified edible objects are complex, and run from the pornographic to the sacralized. Food recipes are shared and tested regarding homemade cuisine. These recipes are subject to further elaboration and addition by other consumers, creating a collective co-creative process akin to networked new product development presaging, perhaps, such refinements in a maker movement of 3-dimensional "recipes". In addition, photographs, restaurants, recipes

and their resultant foodstuffs are ceaselessly rated, presenting a quantification of the gut that has distinctly material effects.

Throughout, the *iMirror*'s representation of the insatiably hungry and always-eating consumer is present, even when it is absent from photographs. In this netnography of online food photo networks, we find food consumption reflected back to self, food consumption reflected outwards to others, technology consumption reflected back to self, and technology consumption reflected out to others. The core categories of self and other—what anthropologists explore as "alterity" (Taussig 1993)—are present not only in every bite we take, but with every photograph we make.

Consumer Soiveillance: Observations of the Self by Means of New Media Technologies

EXTENDED ABSTRACT

Soiveillance is a term used in social media to situate self-related practices within the context of the "veillance" family (sur-, trans-, sous-, etc.) and refers to consumers' own observations of the self by the self by means of new media technologies. This paper will build on this term, examining how the consumption of new devices affords consumers increasingly complex ways to expose aspects of the self that are not visible unless tracked or recorded technologically. Wearable technologies, such as diet or activity trackers, in particular have become important tools in aiding consumers track and communicate aspects of their selves. Such user-generated data and technology not only allow insights into people, but give consumers agency: Technology acts as a digital mirror that enables consumers to engage in self-reflection (Lupton, 2013) and personalized interpretation of and interaction with data (Nafus and Sherman, 2014). Previous research on self-tracking has focused exclusively on users' interaction with 'objective' numeric data. Yet, consumers increasingly engage in self-tracking and self-reflection via new media technologies that deliver rich visuals.

Technology now affords consumers the opportunity to watch themselves and their own consumption experiences through video-recording their consumption experiences with wearable cameras. Wearable cameras that offer continuous, hands-free recording have become a global consumer phenomenon, specifically in the action and sports markets. Despite wearable cameras' innovation being the ability to record video from a point-of-view perspective, consumers often use accessories that enable them to record themselves to later rewatch their experiences (Dinhopl and Gretzel 2014). By rewatching their experiences, consumers engage in a variation of volitional reconsumption (Russell and Levy 2012), that is, the conscious seeking to relive their consumption experiences. This volitional reconsumption is not a simple hedonic re-experiencing but is mediated by and reflected upon through a technological lens. It is reflective reconsumption turned on its head: rather than engaging in reflective reconsumption to reflect on oneself at one's current point in life (Russell and Levy 2012), consumers engage in reflective reconsumption to reflect on their past self at the point of their (recorded) experience as well as in regards to their future consumption and social media represented future self.

The self and its consumption experiences thus become images and bits of data that are carefully monitored and scrutinized by consumers themselves or those with whom the records are shared. Self-tracking approaches have previously been linked to Foucauldian themes of surveillance (Albrechtslund 2013; Bossewitch and Sinreich 2013; Lupton 2012), and in this paper, we equally take a Foucauldian perspective to theorize consumers' practices of self-tracking via wearable cameras as both a classic panopticon (1977),

engaging consumers in a disciplinary gaze onto themselves, thereby governing consumer behavior, as well as an obverse panopticon (Kozinets et al. 2004), playing to consumers' enjoyment of being watched. We therefore seek to better/more broadly conceptualize surveillance with respect to consumption experiences.

Drawing from a year-long field study with wearable camera users (snowboarders, skiers, skateboarders, water park visitors, and cyclists), we explore the roles in which consumers use wearable technology for observations and reflections on the self. The camera performs at once as a neutral observer, a quasi-social actor, an arbiter, and an enabler of consumption. As a neutral observer, consumers use wearable cameras as sources of evidence to document their consumption. For example, cyclists mount wearable camera equipment to their bicycles to have visual proof of their innocence in case of traffic accidents. As a quasi-social actor, consumers use wearable cameras as a stand-in for their intended future audience, either themselves or others. They openly integrate the camera into their consumption by talking to it, or engaging in performativity (Larsen 2005, conceptualizing Butler's notion of performativity for the tourist context), for example, by 'mugging' for the camera. As an arbiter of consumption, consumers use wearable cameras to track their consumption, often related to the notion of progress to be critiqued by themselves or others. For example, skateboarders will film tricks and then (re)watch them to critique themselves and their consumption. As an enabler of consumption, consumers use wearable cameras as facilitators of the consumption experience in its own right. Filming consumption is prioritized over the consumption that is being filmed. In order to capture satisfying video, consumers engage in consumption behaviours they otherwise might not have enacted. For example, snowboarders will decide to jump over trees with snow on them for a more stunning visual.

The technology thus becomes both a digital mirror and an always-on panopticon through which consumers are able to reflect on and understand their own consumption experiences but also change their behaviours and self-perceptions. Consumers hereby respond as predicted by Foucault's panopticon with self-disciplining, but they also engage in the obverse panopticon (Kozinets et al. 2004), where they take pleasure in being recorded (and in recording) and being observed (by their future self or others). Indeed, while others may be involved in this process, the self-tracking phenomenon suggests that ever more technology is developed that supports new levels of self-reflection through quantitative and qualitative data: It allows consumers to watch their quantified selves consume, altering how they engage in reflective reconsumption. With this paper, we hope to prompt discussions on the role of technology for shaping consumption and reconsumption practices in the age of consumer surveillance.

Co-Construction of the Digital Self

EXTENDED ABSTRACT

One of five ways in which Belk (2013) contends that the extended self is modified in a digital era is through the co-construction of self that occurs online much more than offline. This paper is an extension and update elaborating on the observation that despite the vastly increased possibilities for representing the self online, there is also a welcome or unwelcome loss of control to known and unknown others whose online activity helps to shape the way we and others view our self. The idea that others help construct the way we see ourselves was formulated by Charles Cooley (1904/1964) who posited that our self presentation is interpreted and reflected back to us by others we encounter in daily life. Zhao (2005) takes up

Cooley's looking glass metaphor and suggests that online we have more resources available for self presentation (Goffman 1959) to telecopresent others: we are able to provide more information about our self online, engage in more self-disclosure, provide more elaborate self-narratives, and possibly present multiple and "retractable" selves untethered from our bodies.

But the sort of audience mirror that Zhao (2005) envisions online is passive one like a fixed mirror that reflects more or less what is presented. The co-construction of self that Belk (2013) envisions and that I pursue here involves a more active audience. Take the case of Justine Sacco, former Senior Director of Corporate Communications at IAC (InterActiveCorp). While on a long journey from New York to visit family in South Africa, she made a few quick Tweets from JFK and Heathrow airports, including these:

"Weird German Dude: You're in First Class. It's 2014. Get some deodorant? – Inner monologue as I inhale BO. 'Thank God for pharmaceuticals.'"

"Chilly – cucumber sandwiches – bad teeth. Back in London!"

"Going to Africa. Hope I don't get AIDS. Just kidding. I'm white!" (Ronson 2015).

She then wandered around Heathrow for half an hour and boarded the plane for the 11-hour flight to Cape Town. It was only while the plane was taxiing that she received a call from her best friend saying that she was the number one worldwide trend on Twitter. That's when the baffled woman had to shut off her smart phone for the flight. Although she had only 170 Twitter followers, the racist tone of her last comment caused great offence and led to viral follow-up messages like these:

"All I want for Christmas is to see @JustineSacco's face when her plane lands and she checks her inbox/voicemail."

"Oh man, @JustineSacco is going to have the most painful phone-turning-on moment ever when her plane lands."

"We are about to watch this @JustineSacco bitch get fired. In REAL time. Before she even KNOWS she's getting fired."

Someone even came to the Cape Town airport and posted a photo of her leaving the plane behind the scant disguise of sunglasses. Belk (2013) and Solove (2007) detail other such incidents of public Internet shaming. While social groups have long used shaming to gain conformity to social norms, such incidents are usually small scale and soon forgotten. Not so with the Internet.

If the power of the Internet to co-construct and alter identity in the blink of the eye is not already evident, consider the following account of a small dinner party by a *New York Times* columnist:

Over the course of the three-hour dinner, the poor sap eventually discovered, "my friends posted seven photos on Path, sent six Twitter messages (five with photos), six photos on Instagram and two people checked in on Foursquare. When I added up the collective follower counts of the people in the room, my little dinner party was potentially viewed by more people than watch *The Late Show* on CBS: over three million." (Two of his guests have large numbers of followers on Twitter.) And, to add insult to (self-inflicted) injury, a few days later he telephoned someone in a work-related call, only to be told by the other person – who has never crossed his threshold – how much he "just loved" the lamps hanging above the Bilton kitchen table (Naughton 2012). Not all of such co-construction is negative of course. But the point is that it is increasingly out of our control. We are becoming a character in our biography rather than its director.

The online "reputation economy" (Madden and Smith 2010; Zimmer and Hoffman 2011) works not only on individual identity on blogs, forums, sharing apps, and dating and rating sites (e.g., Schoeneman 2013), but also on corporate identity co-construction on

sites like Yelp, Urban Spoon, Angie's List, and Amazon. The shift in power to the consumer is well recognized in the commercial realm, but less so in the personal realm. We can see the potentially devastating effects of online others in the cases of revenge porn, sabotaging our social media pages by former partners who have our passwords (Gershon 2010), and cyberbullying. Surveillance by current or potential employers or schools can also dramatically affect lives and careers, as one rescinded early admission invitee to Bowdoin college learned when she Tweeted about their lame presentation.

Others can also initiate rather than respond to our digital self-presentations. They can post and tag us in photos, mention us in their social media pages, endorse our skills on LinkedIn (and expect us to reciprocate with our own "unsolicited endorsement"). Posting selfies when trying on clothes at a retailer can garner instant feedback shaping our self image and purchase likelihood before we leave the dressing room (Denton 2012). Even our pre-natal and post-mortem images can be shaped by others online (e.g., Carroll and Romono 2011). This talk addresses and illustrates these and other ways in which our digital self is very much a co-construction rather than simply a self-presentation. Cooley's looking glass is no longer the reflector of a scripted dramaturgical presentation of self as Goffman (1959) envisioned. In the digital era it has become an improvisational stage play with other actors who are often anonymous and unseen. Whether they are benign or malicious they introduce an entirely new facet to the mirror of old.

Self-Transformation and Performativity of Social Media Images

EXTENDED ABSTRACT

Recent debates on theories of 'performativity' (Butler 1990; Mason et al. 2015) have started to resonate among marketing scholars theorizing markets (e.g. Callon 1998), market(ing) practices (Kjellberg and Hagberg 2007), market research (Diaz-Ruiz 2013; Cluley and Brown 2015), branding (Lucarelli and Hallin 2015), and marketing devices such as advertising (Cochoy 2015). However, despite this apparent potential, applications in the field of consumer research are in many ways lacking. In this paper, the aim is to adopt a performative lens on consumer identity work and to analyze the ways in which consumer-made images shared online effectively partake in identity transformation and regeneration. The analysis stems from empirical materials gathered on the luxury and status-related consumption of champagne in order to assess the multitude of potentialities social media images open up for self/selves to emerge, abound and re-configure.

Similar way to both advertising (Cochoy 2015) and researcher-produced images (Bramming et al. 2010), consumer-produced images shared online can be understood as powerful articulation devices that not only represent realities but also effectively *perform* and consequently work on to produce and enact emergent social relations. Consider the consumer social media responses to Kim Kardashian's image that famously aimed to "break the Internet" by spurring such a volume of reactions. The image features a provocative 'champagne incident' where Kardashian pops open a champagne bottle landing on a glass perched on her bottom. While being deliberately staged, crafted, and photoshopped by a professional photographer, the image effectively created 'credible illusions' of the celebrity's extravagant life, but also opened her identity towards further new potentialities and emergence by provoking plentiful reactions, likes, dislikes and commentaries – even from those who chose not to view the image in the first place. In similar way, this paper aims to consider such visual expressive and performative capacities (Bramming et al. 2010; Co-

choy 2015) that social media images posted by consumers employ by way of acting in the world and in bringing about new relations and identities.

With an analytical focus on concept of self and the ways in which images of the self posted online may regenerate and transform the self through visual performances of consumption, this research hopes to extend prior work on consumers' online identity work (e.g. Schau and Gilly 2003; Belk 2013). Importantly, the aim is to use luxury self-consumption images to question identity as a relatively stable and holistic entity – not unlike Butler (1990; see also Cluley and Brown 2015) – by examining the ways in which identities are performed and enacted through various activities, such as selfies posted online. For Butler, whose work perfectly illustrates the usefulness of performative approach, the meaning of identity does not pre-exist beyond its performances. This is why the continuous online streaming of images we engage in and the ways in which these performances are intertwined with particular social, material and institutional relations and circumstances, produce who we are but also entail momentum of change. For example, in addition to consumers' own performances and doings, their identities are constantly shaped by a network of market actors and devices that "make up people" via market practices (Cluley and Brown 2015; Cochoy 2015).

Turning back to the performativity of images, it is important to acknowledge how images not only contain or capture meanings and representations but they express social-material-bodily configurations and ideologies through which images effectively perform, generate and project potentialities of the self. This ontology of images here is similar to Gilles Deleuze's (see Bogue 2003) view of the 'moving image' where a much greater emphasis is put on the expressive power of images as well as the potentialities of change showing the images to others may possibly generate. The empirical materials for this study consist of self-consumption images gathered from Instagram (popular social media photo-sharing device) featuring consumer images that tagged six of the most talked about champagne brands. These images were analyzed and read in relation to literature on status consumption (e.g. Eckhardt et al. 2014) and related identity transformation. The studied sample of images represent a "slice" of common champagne tagged images gathered over the span of six weeks in 2014.

Findings highlight in particular the heterogeneity of self-expressions that consumers employed in various status-related performances. These images, above all, project the self in relation to ideals of a good, affluent, happy, or "better" life. However, they also offer critical contestations of existing norms, boundaries, and the world of conspicuous consumption. Implications for studying consumer-produced online images are discussed.

Paper #4: Smart Phones, Bad Calls? In-store Mobile Technology Use and Consumer Purchase Behavior

Michael R. Sciandra, Fairfield University, USA
J. Jeffrey Inman, University of Pittsburgh, USA

SESSION OVERVIEW

In 2014, consumers spent a greater proportion of time on their smartphone than on any of their other technological devices (Millward Brown 2014). Although smartphones have become an integral part of consumers' everyday lives, there is currently little research examining the consequences of using this technology for consumer behavior. The objective of this session is to shed light on some of the implications of smartphone use for both consumers and marketers. As a group, the papers address the following question: How does smartphone use impact consumer psychology and decision-making in both online and offline consumption contexts?

The first two papers converge on a similar finding – that consumers react more favorably to smartphone-generated content than PC-generated content – and provide distinct but complementary accounts for this phenomenon. Across four studies, Melumad, Inman and Pham show that content generated on one's smartphone (vs. PC) contains more emotional language, and that this effect is driven in part by the physical experience of writing on each device. The authors also show that consumers react more favorably towards smartphone-generated content because of its heightened emotionality, which holds *regardless* of whether consumers are aware of the originating device. The findings suggest that smartphone use drives the creation of more emotional, and thus more influential, user-generated content.

Stephen and Grewal examine consumers' beliefs about online reviews generated on smartphones. Consistent with the results of Melumad et al., three studies demonstrated that consumers were more trusting of reviews that they *knew* had been written on smartphones (vs. PCs), and expressed greater purchase intention in response to the reviews. These effects were driven by consumers' belief that smartphone-written reviews are more accurate/thoughtful because reviewers are presumed to willingly exert greater effort to write on the device.

The second pair of papers examines the relationship between smartphone use and offline consumption contexts. Zubcsek, Katona and Sarvary examine whether consumers' offline location history can predict their responsiveness to mobile advertising efforts. While

many targeting methods for mobile advertising are based on consumers' proximity to a retailer, the authors find that targeting mobile ads based on consumers' location history enhances consumer response rates to promotions. Their results demonstrate that offline location history can be effectively used to reveal consumer preferences.

Sciandra and Inman examine whether decision-making in offline shopping settings is impacted by smartphone use. Across three studies, including two field studies, they find that smartphone use can distract consumers during a shopping experience resulting in greater omission of planned items and more unplanned purchases, but only when consumers use their smartphone in a manner unrelated to the shopping task. In contrast, using one's smartphone in a manner related to the shopping experience attenuates these errors.

Together, these papers employ a variety of methodologies and demonstrate that smartphone usage poses unique consequences for consumers in online as well as offline contexts. Overall, this special topic session should be of great interest to researchers and firms concerned with the implications of consumer smartphone usage, and for smartphone users in general.

The Distinct Psychology of Smartphone Use: Smartphone-Generated Content as Emotional Expression

EXTENDED ABSTRACT

Given the ubiquity of smartphone devices and the importance of word of mouth for consumer opinion and sales, it has become critical for firms to understand the impact of using one's smartphone to generate online content. One important consideration for firms is the emotionality of user-generated content, since increasing levels of emotional language in online reviews has been shown to increase customer conversion rates (Ludwig et al. 2013), and simply reading a text with affective content can influence consumers' opinions (Lau-Gesk and Meyers-Levy 2009). We predict that content generated on smartphones contains more emotional language than PC-generated content, and that consumers therefore respond more favorably to smartphone-generated word of mouth.

We examine one possible explanation for the increased emotionality of smartphone-generated content. Specifically, using one's smartphone is more cognitively taxing than using one's PC because of its smaller features (e.g., smaller screen and keyboard; Ghose, Goldfarb and Han 2013), which leads consumers to engage in more emotional processing when using their smartphone (e.g., Shiv and Fedorikhin 1999). We therefore propose that an increased reliance on emotional processing during smartphone use can carry over to the content generated on the device, resulting in the generation of more emotional content (vs. PC-generated content). Moreover, since people find emotional content to be more diagnostic and persuasive (e.g., Damasio 1994), we predict that consumers will respond more favorably to smartphone-generated content (vs. PC-generated content).

Study 1 tested the prediction that content generated on smartphones (vs. PCs) contains more emotional language. We conducted a text analysis on field data from UrbanSpoon.com, a popular online restaurant review forum, analyzing nearly 40,000 reviews of New York City-based restaurants. To control for region-specific characteristics that might confound the results, we also conducted a robustness check using over 20,000 reviews of Portland-based restaurants. Further, an alternative explanation for differences in content emotionality

ty is that unlike PC-users, smartphone-users tend to write during their restaurant experience so that their feelings are simply more “hot” or salient to them. To test the alternative explanation that increased emotionality is due to the time of review creation, we conducted an additional robustness check controlling for the temporal proximity between the experience and the creation of the review. As predicted, reviews written on smartphones contained more emotional language than PC-generated reviews, and this effect held across the two robustness checks. These results provide evidence that smartphone use increases the emotionality of online word of mouth.

The first objective of study 2 was to test the causal impact of smartphone use on content emotionality. As such, participants (N=367) were asked to write a review of a recent restaurant experience using either their smartphone or PC (randomly assigned). The second objective was to test the proposed mechanism underlying the effect: that users rely on more emotional processing – and thus create more emotional content – because using a smartphone is more cognitively taxing than using a PC. To test for the mediating role of ease-of-use, we asked participants to indicate how easy it was to write the review using their assigned device.

Smartphone-generated reviews were again found to contain more emotional language than reviews written on PCs. Moreover, a mediation analysis revealed that ease-of-use partially mediated the effect of the device on the amount of emotional language, which supports our proposition that the physical experience of using one’s smartphone (vs. PC) partly accounts for the increased emotionality of smartphone-generated content.

The main purpose of the next two studies was to explore users’ reactions to smartphone-generated word of mouth. In study 3 we conducted a content analysis on field data from the online social network of a large community of start-ups. Importantly, one of the features available on the network allows users to “vote” for posts on the newsfeed, which enabled us to test whether users respond more favorably to smartphone-generated content (vs. PC-generated content). Since the prior studies examined restaurant reviews, study 3 also tested whether the effects generalize to another type of user-generated content.

The results reveal that content generated on smartphones again contained more emotional language than content written on PCs, demonstrating that the effect holds not only for restaurant reviews but also for other forms of user-generated content (i.e. social media content). Importantly, smartphone-generated posts also received more votes relative to PC-generated posts, and this effect was mediated by the amount of emotional language in the content. These results suggest that smartphone-generated content is more emotional, and thus more appealing, to consumers.

The final study directly tested consumers’ reactions to smartphone-generated content vs. PC-generated content in an experimental setting, and examined the role of device knowledge on consumer opinion. Participants (N=135) were asked to rate a random selection of reviews (written by participants in study 2), half of which had been written on smartphones and half of which had been written on PCs. Further, while users of the social network in study 3 could not tell whether content had been posted from mobile devices, in study 4 we manipulated whether participants were informed about the device on which the reviews were written. In one condition, reviews were presented with labels indicating “via mobile” or “via PC,” while in the other condition no labels were presented. This allowed us to test whether knowledge of the originating device impacts consumers’ reactions to user-generated content.

We find that participants were more interested in trying restaurants that had been reviewed on smartphones (vs. PCs) *regardless*

of whether they were aware of the originating device. Moreover, as predicted, a mediation analysis reveals that smartphone-generated content is more persuasive (vs. PC-generated content) because of its greater perceived emotionality.

Our findings identify a unique consequence of smartphone use with important implications for firms concerned with online word of mouth. First, given its more emotional nature, smartphone-generated content might help firms more accurately gauge consumer opinion. Second, users respond more favorably to smartphone-generated content as a result of its increased emotionality (regardless of originating device knowledge), suggesting that smartphone use drives the creation of more impactful online word of mouth.

In Mobile We Trust: How Mobile Reviews Can Overcome Consumer Distrust of User-Generated Reviews

EXTENDED ABSTRACT

The use of mobile is ubiquitous with over half of the world using mobile devices. One common use of mobile devices is people reporting on their consumption experiences (e.g., posting a hotel review). The rising use of mobile has prompted a stream of research that attempts to understand the relationship between mobile and consumer behavior (Shankar et al. 2010; Bart et al. 2014). Here we consider how consumers perceive and respond to consumer-generated reviews when they are posted from mobile versus non-mobile devices. Consumers increasingly know this distinction because a trend among popular review sites (e.g., TripAdvisor) is to add labels to reviews from mobile devices (e.g., “via mobile”). We examine how this subtle additional information affects consumers’ perceptions of the review and purchase intentions.

We hypothesize that the extra effort that is required when writing reviews from mobile leads consumers to believe that, compared to reviews from non-mobile devices, reviews posted from mobile devices are more reflective of a reviewer’s true consumption experience. We posit this is because consumers think that to write a thoughtful review on a mobile device, more effort is physically needed, and once more effort has occurred, a review is perceived as more trustworthy (Ghose et al. 2013; Walther et al. 2005). Once a review has been seen as more trustworthy, we hypothesize that consumers will perceive higher accuracy. This higher accuracy is then expected to lead to higher purchase intentions or a greater consideration of the reviewed product or service provider. This is only expected to occur, however, when reviews are generally positive and, critically, when consumers are doubtful about the review or skeptical of the credibility of consumer-generated reviews in general. Thus, we propose that mobile reviews help consumers overcome skepticism that would otherwise lead them to discount a reviewer’s opinion, thereby allowing the review to have a stronger impact on a consumer’s attitudes. In three studies, participants were shown an actual consumer-generated hotel review from TripAdvisor where we manipulated aspects of the review (e.g., mobile vs. non-mobile) while holding constant the review itself.

Study 1 (N = 67) tested the effect of mobile vs. non-mobile reviews on purchase consideration with a 2(mobile, non-mobile) x 2(positive rating, negative rating) between-subjects design. To manipulate mobile versus non-mobile, a label said “via mobile” or “via desktop,” in line with TripAdvisor. To manipulate rating valence, the reviewer’s rating was either 4 (positive) or 2 (negative). After reading the review, participants indicated their interest in booking a stay at the reviewed hotel if they were visiting that location (1 =definitely not, 5=definitely yes). Results supported our prediction that mobile

reviews are associated with higher purchase intention, but only for favorable reviews. In the positive rating conditions there was a significant difference between mobile ($M = 3.60$) and non-mobile ($M = 2.86$) reviews (contrast $F(1, 63) = 6.96, p = .01$). There was no significant difference in the negative rating conditions ($M_{\text{mobile}} = 2.79$ vs. $M_{\text{nonmobile}} = 2.74$, contrast $F(1, 63) < 1, p = .83$).

Study 2 ($N = 56$) tested the proposed accuracy-mediated process with a 2(mobile, non-mobile) between-subjects design. The reviews in the positive rating condition from study 1 were used. We again measured purchase consideration and additionally measured perceived accuracy of the review with six items on seven-point Likert scales (e.g., “The information in this review was accurate,” $\alpha = .90$). These items were averaged to form a measure of the hypothesized mediator, perceived review accuracy. We also measured general skepticism, which was expected to moderate the hypothesized mediated process, with nine items measured on seven-point Likert scales (e.g., “I am skeptical of online user-generated reviews,” $\alpha = .93$). These items were averaged to form a general measure of skepticism of online consumer-generated reviews. We tested our predictions using conditional indirect effects analysis (Hayes 2013 model 15). The results confirmed our hypotheses. Specifically, the indirect effect of mobile versus non-mobile review on purchase intention through perceived review accuracy was positive and significant but only at higher (+1SD) levels of skepticism (indirect effect = .08, $SE = .06$, 95% CI = [.01, .26]). When skepticism was lower (-1SD) the indirect effect was not significant.

Additionally, we asked participants to indicate the extent to which they believed that mobile reviews are more likely to be written “in the moment” (1 = definitely not, 5 = definitely yes). This was intended to capture a lay belief that mobile reviews are more temporally proximate to the reviewed consumption experience. Participants held this belief, with 75% of participants selecting 4 or 5 on this scale. This suggests that mobile reviews are assumed less temporally distant from the reviewed experiences, which is a plausible explanation as to why mobile reviews lead to higher perceptions of review accuracy.

Study 3 ($N = 80$) examined perceived accuracy more closely. Participants read the same mobile review from the previous study and indicated their perception of review accuracy on the same six-item scale used previously. Additionally, perceived review-writing effort was measured with six items (e.g., “The reviewer put a lot of effort into writing this review” $\alpha = .88$), and perceived trust in the reviewer with six items (e.g., “The reviewer can be trusted” $\alpha = .85$). Results from a conditional indirect effects analysis (Hayes 2013 model 4) indicate that higher perceived review-writing effort leads to enhanced perceptions of reviewer trust, which in turn predicts higher perceived review accuracy (indirect effect = .29, $SE = .06$, 95% CI = [.18, .43]).

This research contributes to the literature on consumer-generated reviews and word of mouth referrals by showing how the context in which a review is written—mobile or non-mobile—affects consumers’ attitudes and purchase intentions. We show that consumers, particularly skeptical ones, perceive mobile reviews as more accurate and therefore have higher purchase intentions, and that this accuracy is associated with greater perceived effort in review writing and reviewer trust. Future research will examine this process in greater detail, and identify conditions under which mobile review writing is associated with higher effort.

Social and Location Effects in Mobile Advertising

Early research on location-based mobile advertising effectiveness focused on geo-fencing – sending consumers promotional of-

fers when they enter the vicinity of the retailer (Jagoe 2003, Schiller and Voisard 2004). Yet, while targeting based on store distance has been demonstrated to be quite effective in certain contexts (Ghose et al. 2012, Molitor et al. 2013), consumers’ location history may also be useful to marketers as it may hide rich information about their shopping behaviors and preferences (Hui et al. 2009, Shankar et al. 2010). In this paper, we explore whether targeting ads not based on the current location of prospects but their location history may enhance their response rates to promotions. We present a method that is able to demonstrate the link between the location history of consumers and their purchase behavior even in the absence of information on retailers’ exact locations (or other points-of-interest, POI). We discuss the implications of these findings for behavioral research.

Our data come from a pilot program of a mobile operator in a Pacific country. Participants installed a new app on their smartphone and were then regularly provided (independently from their current location) with digital coupons (“offers”) in four product categories. Information in coupons included the participating brand(s) and – if applicable – product(s), the discount value of the coupon ($M = \$4.58$) and the “when-you-spend” amount ($M = \$17.44$). After viewing these details, participants could receive the *in-store* discount after making the required purchase and showing the accepted coupon anytime during the validity of the offer ($M = 4.82$ days). (The exact time of response was not recorded.)

Our panel contains a total of 15,353 observations on 217 participants and 96 offers (registration was open throughout the duration of the pilot so some consumers did not see some offers). During the period studied, participants on average received less than two offers per day. To increase their engagement with the mobile app, they were also invited to participate in quizzes (brief surveys with questions) pertaining to a broad range of topics including personality traits, interests, lifestyle, work, and also preferences in certain product categories. Responding to quizzes was entirely optional and participants did not receive any reward for their answers.

Participants also agreed to have their GPS location information transmitted to the mobile operator every hour by the app (when both the location services were enabled and the device was able to detect the necessary satellite signals). For each hour during which there was no successful transmission, there is no location observation in the dataset. On average, we have 11.29 hourly location observations per day per participant in our panel. However, for about 40% of all observations, there is no location information on the participant. Further, we do not possess information about potential Points-of-Interest (POI) in the country where the study was conducted. Finally, we have data on referrals wherein a participant invited another to the program.

Our model builds on the idea that consumers’ location choices (albeit weakly) reflect their underlying preferences and that individuals who often attend the same venues have some commonalities in their taste. We construct a dynamically evolving network of co-location events – events when two or more participants were at the same place (a ca. 700-ft square on the map) during the same hour. Effects of network position in the so-derived co-location network are then simultaneously estimated with demographic and referral network effects on advertising response in a logit model with offer fixed and participant random effects (cf. Goel and Goldstein (2014)).

We capture both networks (co-location and referral) by 1. Including the average prior response rate of network neighbors in the category of the offer, and 2. Controlling for the number of network neighbors. Further, we control for participants’ *GPS activity* (the number of nonzero location observations available to us during the day preceding the launch of each offer).

The results (robust to a series of validity tests) show a significant positive link between the prior within-category response rate of co-located participants and their subsequent response to coupon-based promotions ($\beta=3.918, p<0.01$). This suggests that consumers who frequent the same locations indeed have correlated preferences. Whereas consumer-level demographic or psychographic variables may also be used to uncover such correlations in preferences, we find that the joint use of referral and location network variables is more effective than relying on traditional variables in predicting consumers' purchase behavior.

These are important results indicating that location history can be effectively used to reveal consumer preferences. Therefore, our method may provide a fruitful approach to complement current location-based advertising methods, which are mostly based on the geo-fencing approach.

Further, our findings pose new questions for behavioral research. Do the behavioral antecedents of location choices exhibit systematic patterns? Do certain environments affect consumer behavior (by causing consumers to converge to certain attitudes or brand preferences)? While the mobile behavioral platforms aiming to help testing these questions are still not commonly available, we have no doubt that in the coming years, controlled experiments will contribute more and more to our understanding of the mobile consumer.

Smart Phones, Bad Calls? In-store Mobile Technology Use and Consumer Purchase Behavior

EXTENDED ABSTRACT

One understudied factor impacting consumer decisions are mobile technologies such as cellphones and smartphones. As mobile devices continue to grow in popularity, the need is high for research explicating the impact of these devices on consumer decision-making. Recently, mobile technologies have been praised for helping consumers make better decisions (Shapiro 2012). However, research acknowledges unintended visual and cognitive impairments associated with these devices (e.g., Strayer et al. 2003; Strayer and Johnston 2001). Consequently, the use of mobile technologies in shopping environments may act as a double-edged sword with both positive and negative implications for shoppers.

We argue that the nature of mobile use (shopping-related vs. shopping-unrelated) will differentially impact consumer outcomes. When used in an unrelated manner (e.g., talking, texting, surfing the web), we predict that multi-tasking exhausts attentional resources and results in negative outcomes such as purchasing more unplanned products or failing to purchase planned items. When used in a related manner (e.g., checking prices, using shopping applications), we predict that mobile technologies can help consumers make better decisions and stay on track during the shopping trip.

In Study 1, we begin our investigation into in-store mobile device use by examining consumers' ability to accurately recall and complete an online shopping task while utilizing mobile technologies. In particular, we manipulate the duration (short vs. long) and intensity (low intensity use vs. high intensity use vs. no use) of device use to investigate recall of in-store displays and number of omitted planned items. We find that participants in the high ($M = 11.2\%$; $F(1, 193) = 4.69, p < .05$) and low ($M = 11.8\%$; $F(1, 193) = 4.79, p < .05$) intensity mobile use conditions exhibited lower recall of products on display compared to participants in the no mobile use condition ($M = 15.8\%$). Furthermore, we find that participants using their device for a long duration and high intensity demonstrated a higher percentage of omitted planned items ($M = 11.4\%$) than participants in both

the low intensity mobile use condition ($M = 5.4\%$; $F(1, 193) = 4.04, p < .05$), and the no mobile use condition ($M = 3.9\%$; $F(1, 193) = 6.76, p < .05$).

Study 2 and Study 3 use field data from Point of Purchase Advertising International to investigate in-store device use. In Study 2, data was collected in grocery stores while in Study 3 data was collected in mass merchandisers. In both studies, shoppers across the U.S. were interviewed before and after their shopping trip. In the exit interview, shoppers were asked to indicate if and how they used mobile technology during their trip. This information allowed us to partition consumers into three focal mobile usage categories: 1) no phone use, 2) shopping-related use (related), and 3) shopping-unrelated use (unrelated).

We find that in-store mobile technology use significantly alters the number of unplanned purchases and the number of omitted planned items. First, looking at unplanned purchases, we find that using mobile technology in an unrelated manner is associated with significantly more unplanned purchases ($\beta_{Study2} = 0.104, p < .05$; $\beta_{Study3} = 0.120, p < .01$) when compared to consumers not using phones. Furthermore, in Study 3 we find that shoppers using their phones for private conversation ($\beta_{Talk} = 0.111, p < .10$) and private text messaging ($\beta_{Text} = 0.151, p < .01$) are the main types of unrelated use that are contributing to the increase in unplanned purchasing. In comparison to shoppers not using a mobile device, individuals using a device in a related manner showed no difference in number of unplanned purchases ($\beta_{Study2} = 0.027, n.s.$; $\beta_{Study3} = 0.049, n.s$) when compared to shoppers not using a device.

While related device use did not exhibit a main effect on number of unplanned purchases, we do find that related device use can help mitigate unplanned purchasing, particularly, as shoppers basket size increases. We find a positive relationship between basket size and the number of unplanned purchases ($\beta_{Study2} = 0.082, p < .01$; $\beta_{Study3} = 0.116, p < .01$). Importantly, we find that using a mobile device in related manner attenuates this positive relationship ($\beta_{Study2} = -0.013, p < .05$; $\beta_{Study3} = -0.014, p < .05$). Furthermore, in Study 3 we find that shoppers using their phones to access a retailer's shopping application ($\beta_{Retailer App} = -0.044, p < .01$), access a digital list ($\beta_{Digital List} = -0.042, p < .01$), and use a calculator ($\beta_{Calculator} = -0.026, p < .05$), all contribute to this attenuation.

Next, looking at the number of omitted planned items, when compared to shoppers not using mobile devices, shoppers using their phones in an unrelated manner showed more omitted planned items ($\beta_{Study2} = 0.269, p < .05$; $\beta_{Study3} = 0.291, p < .01$). In Study 3, we find engaging in personal conversation to be the main driver of omitted planned items ($\beta_{Talk} = 0.204, p < .05$). This is consistent with our theorization that unrelated device use can distract consumers from the focal shopping task. Similarly, compared to shoppers not using mobile devices, shoppers using their phones in a related manner exhibited more omitted planned items ($\beta_{Study2} = 0.178, p < .10$; $\beta_{Study3} = 0.212, p < .01$). In Study 3, we see that shoppers using their device to access a calculator ($\beta_{calculator} = 0.373, p < .01$) to be the major contributor to this difference. This highlights a more conscious process in which the shopper passes over a planned item that might be too expensive or may cause the individual to exceed their acceptable budget.

In summary, we find that mobile device use can exert a distracting influence on consumers and interfere with shopping goals. Depending on use, mobile technology is associated with more unplanned purchases, more omitted planned items, and impaired recall of in-store stimuli. Further, based upon an exploratory study, it appears that consumers do not anticipate these effects. While consumers understand the positive implications of in-store mobile

technology use, they are unaware or overlook some of the negative implications of using mobile devices in stores.

SESSION OVERVIEW

The opinions of others often shape our beliefs about the world; these beliefs can in turn influence our inferences, predictions, and choices. In the information age we inhabit nowadays, the vast quantity of advice accessible to us—be it through online recommendation systems, social media, professionals and experts, or family and friends—renders it impractical to make decisions alone. Yet, research on advice and the wisdom of crowds (Larrick et al. 2012; Yaniv 2004) finds that consumers fail to fully exploit this wisdom. To address this, the proposed session discusses how people reason about advice in matters of taste: inferring others' preferences (Papers 1-2), seeking and incorporating recommendations to make predictions (Papers 2-3), and leveraging human and nonhuman sources of advice to ultimately improve prediction accuracy (Paper 3-4). In particular, the featured papers illuminate a range of faulty inferences that impede this goal.

Barasz, Kim, and John (Paper 1) begin by articulating a systematic prediction error when forming inferences about others' tastes. This "preference homogeneity bias," in which consumers believe others to possess less diverse preferences than themselves, may consequently affect how they seek and take advice from others. Next, Meng, Chen, and Bartels (Paper 2) examine how and when information from diverse others is used in inductive reasoning. Compared to predicting their own tastes, people were willing to sample advice from both similar and dissimilar others when they made more verifiable judgments and when they perceived a product category to represent matters of objective quality. Shen and Li (Paper 3) expand on the role of similarity by exploring how people value preference matching with online surrogates (users who have experienced a product) to guide preference predictions. They found a tendency to undervalue preference matching but overweigh surrogate advice, indicating a departure from Bayesian standards. Finally, Yeomans, Shah, Mullainathan, and Kleinberg (Paper 4) highlight a persistent aversion to algorithmic advice. Despite the superiority of collaborative filtering in accurately predicting tastes, humans remain skeptical about such recommendations.

In concert, these papers call attention to ways in which individuals commit prediction errors involving matters of taste. People falsely assume their own preferences to be more diverse than those of others (Barasz, Kim, and John) and are reluctant to seek diversity when predicting their future utility (Meng, Chen, and Bartels). They neglect base rates when taking surrogate advice (Shen and Li) and remain unreceptive to innovative sources of advice which can improve decisions and reduce search costs (Yeomans et al.). However, people do take into account others' opinions when nudged (Barasz, Kim, and John; Meng, Chen, and Bartels).

Listening to others is something we do habitually, and a closer examination of when and why we fail at doing so is crucial if we are to recommend effective remedies to these errors. Borrowing insights from multiple perspectives that span a variety of consumption domains, the substantive issues raised in this session may be especially useful for those interested in affective forecasting, inductive reasoning, advice and the wisdom of crowds, preferences, social influence, and word-of-mouth.

Mistaking Dissimilar for Dislike: Why We Underestimate the Diversity of Others' Preferences

EXTENDED ABSTRACT

Suppose you are asked to predict someone's preferences for certain items in a given category—say, types of vacation destinations or movie genres. Would the person like traveling to a bustling city? Would he enjoy watching an action-packed thriller? Lacking any specific information about that person's tastes, you might evaluate the items on their own merits, and for any popular or likeable options, sensibly predict that the other person would enjoy them.

But what if you had access to this other person's tastes for other items in the same category? Perhaps you discover the person recently vacationed at a lake house, or just attended the premiere of a documentary film. How might this change your predictions? Knowing the other person had previously chosen options seemingly unlike city vacations or thriller films, you might conclude he would not enjoy either. As this paper explores, upon finding out about others' preferences for one option, people have a recurring tendency to predict that others will dislike dissimilar options within the same category.

Is this inference correct? After observing another person's choice, we not only make assumptions about how much she likes the chosen option (Miller and Nelson 2002); we also make broader inferences about how much she likes—or dislikes—unchosen options. After learning of someone's choice—or their "background preference"—we show that people erroneously expect that others will *dislike* dissimilar ones. However, people hold this expectation despite recognizing that they, themselves, simultaneously like dissimilar options. For example, people readily indicate enjoying dissimilar vacation destinations (e.g., lake and city) and dissimilar movies (e.g., documentaries and thrillers), but predict that—for others—a preference for one precludes enjoyment of the other. Simply put, when predicting others' preferences, people mistake dissimilarity for dislike. In five experiments, we document this prediction error and show that it is driven by a false belief that others have a narrower, more homogeneous range of preferences than ourselves.

Study 1 demonstrates the basic effect: People mistakenly believe that others do not like items that are dissimilar from one another. Participants read about a consumer choosing between three

vacation destinations: Lake, Mountain, or City—the first two were similar, whereas the latter was dissimilar. Participants learned about the consumer's preferences for a reference choice (lake)—either that she *chose Lake*, *ruled out Lake*, or were given *no information*—and then estimated how much she liked each of the three options. Participants estimated positively correlated liking levels for similar options ($r = .56, p < 0.001$), but negatively correlated levels for dissimilar options ($r = -.42, p < 0.001$), as though these dissimilar preferences were mutually exclusive. In contrast, when reporting their own preferences, people's own preferences for dissimilar options were far less polarized ($r = -.10, p < 0.054$). Thus, Study 1 offers preliminary evidence that predictions and base rates are not aligned for dissimilar items.

Study 2 demonstrates the prediction error using a measure of dichotomous choice, shows it is specific to dissimilar items, and varies product ratings to gauge (actual/predicted) tradeoffs between quality and similarity. In a 2 (perspective: *actors* vs. *observers*) \times 2 (options: *similar* vs. *dissimilar*) design, participants either chose a movie genre for themselves (*actors*) or learned of someone else's choice (*observers*), as between two *similar* options (thriller/action adventure) or two *dissimilar* ones (thriller/documentary). Then participants made an "out-of-stock" tradeoff choice: a 3-star version of the chosen genre (e.g., 3-star thriller), or a 5-star version of the alternative (e.g., 5-star action adventure or 5-star documentary) genre. We predicted that, for themselves, most actors would rather have the higher-rated movie, regardless of genre; however, when predicting someone else's choice, we believed observers would correctly anticipate a tradeoff between similar items, but—mistaking dissimilar for dislike—would not predict a tradeoff between dissimilar ones. Indeed, when options were *similar*, most actors (74%) and observers (69%) chose the similar, higher-rated movie. However, when options were *dissimilar*, a significant gap emerged: most actors chose the dissimilar, higher-rated movie (64%), a choice predicted by few observers (18%; $p < .001$).

Study 3 elucidates the process underlying the effect: mistaking dissimilar for dislike is fully mediated by a (false) belief that others' preferences are homogeneous. We replicated the same design as Study 2's dissimilar condition, having people make a tradeoff (for themselves or someone else) between a 3-star similar movie and a 5-star dissimilar one. In addition, we measured actual/perceived range of preferences. Drawing on out-group homogeneity research (Judd, Ryan, & Park 1991), we showed participants 14 movie genres and asked them to select all the ones they (*actors*) or someone else (*observers*) liked. The results show that people infer a narrower, more homogeneous range of preferences for others: while actors reported liking 7 movie genres, observers estimated that someone else only liked 4. This fully mediated the choice of dissimilar movie in the out-of-stock scenario.

Study 4 shows that the effect persists even when predictors are financially incentivized for accuracy. Lab participants were partnered, assigned to be actors or observers. Actors chose between two dissimilar movies; observers learned of this choice. Both partners then encountered Study 2's trade-off choice. Observers were promised a bonus for correct prediction. While most actors (69%) chose the higher-rated but dissimilar option for themselves, again few observers (39%; $p < .001$) predicted that choice.

Finally, Study 5 found that the preference homogeneity bias is tempered by encouraging people to consider that others' preferences are varied (Critcher and Dunning 2013). Here, participants learned that either 1 person or 100 people had chosen a movie (thriller/documentary), then predicted a choice between a 3-star similar movie and a 5-star dissimilar one. Participants in the *single person* condition selected the choice they believed the other person made, while those

in the *sample population* condition estimated how many of the 100 people chose 3-star similar and how many chose 5-star dissimilar. Replicating previous results, only 27% of participants predicted that a *single person* would choose the higher-quality, dissimilar movie; however, for the *sample population*, observers predicted that 53% would choose the higher-quality, dissimilar movie, suggesting that the error can be mitigated when thinking more globally.

Valuing Dissimilarity: The Role of Diversity in Preference Predictions

EXTENDED ABSTRACT

People frequently incorporate the opinions of others to make predictions about the world, including their preferences for novel experiences. Consider a scenario where a person is deciding whether to see a new movie she knows little about. To predict how much she will enjoy it, she can solicit others' opinions. But whose advice does she value more—that of people with a wide variety of movie tastes, or that of only people who share her tastes? The current research asks how we integrate the opinions of those who are similar and dissimilar to us to inform predictions.

Similar others tend to be more influential on our judgments than dissimilar others (Festinger 1954; Heider 1958; Suls, Martin, and Wheeler 2002). Not only do people treat similar others as reliable and attractive sources of information, but they tend to discount advice from those less like them (Twyman, Harvey, and Harries 2008). However, there is reason to believe that people may value dissimilar others. The *diversity principle* from category-based induction states that evidence from diverse sources support stronger arguments (Heit 2000). These diverse samples create a stronger basis for generalization because they better *cover* the category of interest (Osherson et al. 1990). People also prefer to seek diverse, rather than similar, pieces of evidence when judging the validity of generalizations (López 1995; Rhodes, Brickman, and Gelman 2008). For example, when assessing whether an unfamiliar property (*has sesamoid bones*) holds for *all mammals*, participants would rather test whether it holds for *lions and goats* than for *lions and leopards*.

Further, the social influence literature has shown that people are more swayed by dissimilar others when more verifiable beliefs rather than values are involved (Goethals and Nelson 1973). The studies below explore whether and when people care about evidential diversity when predicting beliefs about preferences ("Will I like this movie?") as they do when predicting beliefs about facts ("Does a sea cucumber have condyloid canals?").

In Study 1, 156 MTurk respondents viewed positive evaluations of an unfamiliar movie from a pair of movie-goers, one who was similar to them and another who was dissimilar. When asked to describe how they would use this information to predict their enjoyment for the movie, 61% indicated that the dissimilar movie-goer's rating strengthened the likelihood that they would like the movie. Only 21% reported attending solely to the similar person. Hence, congruent opinions expressed by a diverse set of individuals may favorably influence predictions.

Study 2 examined whether these explicit self-reports matched how people seek advice to make preference predictions. Participants ($N = 201$) completed an evidence selection task where they solicited opinions from a panel of 12 "regular movie-goers" (reviewers) ranked by their similarity to the participant's movie preferences. We assigned participants to one of four conditions: People were asked to choose three reviewers whose opinions they would most like to get in order to predict (a) how much *they* would like a target mystery movie, (b) how much *the average person* would like it, (c) how *criti-*

cally acclaimed the movie would be, or (d) how *successful* at the box office it would be. We suspect diversity effects to emerge in the last three conditions, which constitute more verifiable judgments about the target movie.

For each individual, we calculated two indices based on her chosen distribution of reviewers: a “dissimilarity score,” capturing willingness to sample reviewers with *less* overlap to the participant, and a “diversity score,” capturing willingness to sample reviewers with *broader* overlap. Participants solicited both more dissimilar and diverse opinions when predicting more verifiable features of the movie than when predicting their own preferences. Whereas 44% of those in the self condition selected an advisor with a rank greater than 6 (higher ranks mean greater dissimilarity), 67%, 68%, and 55% did so in the average person, success, and critical acclaim conditions.

Study 3 ($N=161$) used an identical procedure, with one exception: Rather than elicit predictions about verifiable features, we varied the product category. Spiller and Belogolova (2015) argue that consumers hold discrepant beliefs about whether a set of products is “vertically differentiated” (differing on quality and intrinsic value, thus more verifiable) or “horizontally differentiated” (differing on taste and idiosyncratic value). A pretest of 35 product categories revealed significant inter-category heterogeneity in perceived differentiation. For example, respondents agreed that paintings, restaurants, and tattoos belonged to the realm of taste, while public transportation, blenders, and digital cameras concerned objective quality. We selected restaurants and digital cameras to represent two opposing ends of the taste-quality spectrum for Study 3. Results found that people sampled more dissimilar *and* diverse advisors for digital cameras relative to restaurants.

Studies 2-3 suggest that individuals are more likely to seek diversity when forming more verifiable judgments or when they perceive a category as vertically differentiated. Study 4 examined how they then use these opinions to update predictions. We assigned participants ($N=398$) to one of eight conditions in a 4 (prediction: self, average person, acclaim, success) \times 2 (advisor pair: similar, diverse) between-subjects design. Participants saw ratings from a pair of advisors sequentially, making one prediction after seeing each opinion. Half saw two similar reviewers, while the other half saw one similar followed by one dissimilar reviewer. In both conditions, the two advisors rated the movie highly. While participants contrasted their own predictions away from the dissimilar advisor, no contrast effects emerged for predictions pertaining to the average person, critical acclaim, or box office success. Thus, preference diversity appears to a negative cue only for judgments of personal preference.

Taken together, these results have implications for what information people might seek in different contexts. For example, if we were tasked with judging the quality of an ACR paper, we may prefer to poll conference attendees with both similar and dissimilar interests to our own. By contrast, if we wanted to determine which paper we should read for personal pleasure, we may only bother colleagues who share our taste in papers. Identifying precisely which factors affect how broadly we sample advice is an important topic of future research.

Are Advice Takers Bayesian? Preference Similarity Effects on Advice Seeking and Taking

EXTENDED ABSTRACT

Consumers today have access to far more information when making purchasing decisions than ever, thanks mainly to the proliferation of consumer-oriented websites and apps. When consum-

ers consider purchasing new products, they may try to forecast how likely they will like it. To better inform this “probabilistic affective forecast”, they may generally use two broad methods: 1) simulation of what it would be like to use the product based on product descriptions and pictures, and 2) surrogation—seeking word-of-mouth (WOM) or advice from surrogates (i.e., people who have direct experience with the product), for example, by reading their reviews on websites including Yelp, Amazon, and IMDb (Gilbert et al. 2009).

To date, little research has explored the more recent trend of online reviews becoming more social. For example, Yelp allows users to “friend” other users. On the other hand, social media websites such as Facebook and Twitter now provide users with product suggestions based on their friends’ ratings. Consumers now are able to take advice from someone who they at least partially know the preferences of, and thus have more information than before. However, previous research has yet to explore whether this additional information helps consumers make better decisions and rely more on WOM (He and Bond 2013).

The present research examines consumers’ affective forecasts when *taking* advice (WOM) from a surrogate whose preferences are at least partially known, and what determines whether consumers are willing to *seek* advice from these surrogates. We explore whether taking advice from online friends helps overcome systematic errors people often make in their affective forecasts of future experiences, findings that are well documented in previous research (Kermer et al 2009; Gilbert and Wilson 2000; Patrick, MacInnis, and Park 2007). Specifically, we directly manipulated the degree of *preference matching* (PM) with the surrogate to see how participants incorporate different PM levels into their affective forecasts and how PM affects advice seeking.

To assess the *normative* degree to which consumers should take advice from surrogates in the presence of PM information, we introduce a Bayesian framework that allows us to evaluate ex-ante prediction accuracy. There are two variables to consider when consumers incorporate a surrogate’s advice to predict their enjoyment of a future experience: 1) their general liking of similar experiences (i.e., the base rate), and 2) the relevance of the surrogate advice, which depends on PM (i.e., the diagnosticity of the advice). Therefore, it seems reasonable to draw an analogy between the advice-taking process and a Bayesian updating paradigm.

Two studies presented here directly manipulated PM with an unknown surrogate and measured the prediction accuracy using Bayesian prediction as the standard. We thus extend the research on affective forecasting, advice taking, and WOM to better understand the advice-taking process in the social media era.

Study 1 tested how perceived PM (PPM) affects consumers taking and further seeking advice from the surrogate. We mimic a complete decision process of making a probabilistic affective forecast (“how likely I will like it?”). Participants directly experienced PM by seeing “actual” ratings from a previous participant after rating each of 10 pieces of artwork, the trials that enable participants to recall their base rate preference and PM history with the surrogate. Then they saw the surrogate advice and made the prediction on the 11th piece of artwork. After seeing the 11th piece of artwork, they were asked to make a choice between surrogation information (previous participant’s rating) and reading a short description of the 12th piece of artwork. We used a 5 (PM: 50% vs. 70% vs. 90% vs. 100% vs. control) \times 2 (advice valence: 5 star vs. 1 star) between-subjects design.

We found that PPM is lower than the given PM, except for the 50% condition. This suggests that when consumers consider PM, the default is to assume low matching. Our study measured prediction

accuracy using Bayesian implicit PM (IPM), which is derived back from the actual prediction, representing the PM that a Bayesian predictor would have to reach this prediction, given the base rate. Comparing PPM with IPM reveals overuse of updated information (surrogate rating), as IPM that was actually used for predicting is higher than PPM. This is consistent with our expectation that although consumers perceive lower PM with a surrogate, they make an opposite decision that overweighs on surrogate advice.

After experiencing the target, more participants chose surrogate over descriptive information when the surrogate rating on the 11th painting agreed with their actual rating than when contradicted. Therefore, “useful” surrogate advice is particularly important for continuing to go to that surrogate for further advice. This contradicts the finding in previous research (e.g. Gilbert et. al. 2009) that people always prefer descriptive information over surrogate advice.

Study 2 switched domains to Dilbert comics, used a different range of PM (60%, 90%, and control) and changed the timing of choosing advice type. We enforced the choice before seeing the advice and making the prediction.

Participants reported lower-than-given PPM only in 90% condition. The PPM in 60% condition (57.84%) is similar to that in the control condition (57.04%), implying that people’s default of PPM is possibly around 60%. We found no difference in choice of advice type between the control condition and 60% condition, but significantly higher preference for surrogate rating in the 90% condition. A logit regression analysis shows that the PPM is the major predictor of the choice on advice type. Similar to Study 1, participants who chose surrogate rating overweighed surrogate’s advice across all three conditions based on the comparisons between IPMs and PPMs.

In summary, we explored how PM affects consumers using and seeking surrogate advice. To corporations who deal with massive online WOM, this research rationalizes their effort of socializing online reviews but also suggests that it may backfire. Providing PM information could benefit higher acceptance of online reviews, but may significantly reduce the intention of seeking advice once the advice quality is proved to be poor. Our proposition on Bayesian prediction could also help consumers to make better decisions using online reviews.

Recommenders vs. Recommender Systems

EXTENDED ABSTRACT

Recommendations can have a tremendous impact on welfare by guiding consumers towards better choices. Most often, they have been generated by other humans (experts, peers, loved ones, etc.) but recently, recommendations based on collaborative filtering algorithms have been introduced to many consumption settings (YouTube, Netflix, Amazon, etc.) These systems flourish because the costs of generating predictions are small. But costs aside, how beneficial are they for consumers, compared to the alternative? Can the algorithms make better predictions about preferences than other people? And which type of recommendation would people prefer to receive?

We conducted a series of experiments that compared human and machine recommenders, both on objective accuracy and on subjective consumer taste. We selected a domain where humans ought to have a natural advantage: Predicting which jokes other people will find funny. Strikingly, even in this domain, we find that computer algorithms are better recommenders than people, regardless of whether these people are making recommendations for complete strangers or close others. And yet, people would prefer to receive recommendations from other humans.

In Study 1 we tested whether human recommenders or computer algorithms were better at predicting people’s preferences. Our participants ($N=197$) predicted how much users of Jester (a website where people rate jokes) would like different jokes. We also developed a collaborative filtering algorithm to make these predictions. Each participant saw 4 jokes that a user had read and rated (e.g. this user rated joke A a 5.2, joke B a 1.4, and so on). Participants then read two new jokes and predicted which joke the user liked more, repeated for five users. On the machine recommender side, the algorithm took as inputs the user ratings. The algorithm then scanned a database of over 4000 Jester users and identified users who had made similar ratings for the four jokes. It then applied a kernel weighting function to develop a prediction of how much the current user would like a joke. Averaging across all five predictions the human subjects guessed correctly less often ($M=56\%$, $SE=1.6\%$) than the algorithm ($M=63\%$, $SE=1.5\%$).

Note that humans have one kind of advantage: They comprehend the subject and punchline of the joke, and they have direct insight into why it is funny. On the other hand, collaborative filtering doesn’t actually understand anything about the content of humor. Instead, they only scan for regularities in the pattern of ratings for those particular jokes. This is different from an actuarial model (Dawes 1979), which tries to reconstruct the human judgment process, using the same inputs. However, there are other sources of information (missing in Study 1) that human recommenders usually rely on in the real world—recommenders often know their targets personally, and know the context in which a joke will be heard. Would this make a difference?

In Study 2, we recruited pairs of people ($N=122$) who knew each other well (significant others, family members, etc.). Both people first rated 12 jokes for themselves. Then they each turned to making predictions about the other person. They saw a random sample of four jokes, along with their partner’s ratings for those jokes. Then they predicted their partner’s ratings for the other eight. Accuracy was scored as whether a recommender’s predictions matched the relative ranking of their target’s ratings, across all 28 possible pairwise combinations of two jokes. We find that even with personal and contextual information about their target, the humans ($M=56.8\%$, $SE=1.4\%$) were still less accurate than the algorithms ($M=62.4\%$, $SE=1.2\%$).

Study 3 was very similar to Study 2—people who knew one another well were recruited in pairs ($N=210$), with the added feature that some human recommenders were able to see the machine’s prediction before making their own. Even humans with this seeming advantage ($M=58.3\%$, $SE=1.4\%$) were not much improved from baseline ($M=58.0\%$, $SE=1.4\%$) and still less accurate than the algorithms ($M=62.8\%$, $SE=1.0\%$), and this pattern held whether participants were asked to make recommendations for their partner, or a stranger pulled from a database. These results demonstrate that even though machines are better at making recommendations, humans were reluctant to rely on their judgment when producing them.

Study 4 compared humans and machines from the perspective of a recommendation consumer. We first asked subjects ($N=100$) to log onto Jester, an online collaborative filtering engine for jokes. They rated eight sample jokes and saw the first five recommended jokes from the algorithm. Then we asked them to compare the algorithm to someone they knew well, or an unknown other participant (between-subjects). In both cases, fewer people thought the algorithm would be more accurate (known=17%; unknown=46%) and did not prefer to receive algorithm recommendations over the human alternative (known=15%; unknown=37%).

In Study 5 we measured accuracy and consumer taste in the same experiment. Subjects ($N=1300$) first rated ten “menu” jokes, then were assigned to receive recommendations from either a machine or a human. They rated three sample jokes, then saw which three jokes their recommender had chosen for them. Again, the target had given higher ratings to the jokes the machine chose ($M=2.8$, $SE=0.1$) than the jokes the humans chose ($M=2.5$, $SE=0.1$) but when asked afterwards, participants gave higher ratings to the performance of human recommenders ($M=4.1$, $SE=0.1$) than machine recommenders ($M=4.4$, $SE=0.1$). These results confirm that resistance to machine recommenders persists even when the accuracy difference is made explicit.

These results shine a light on a rapidly developing facet of consumer choice. Consumer resistance to machine recommendations has been well-documented (e.g. Dawes 1979; Sunstein 2014). This raises important questions about how to get consumers to actually take recommendations from a machine, which would improve choices and reduce search costs. Future research will examine these barriers to resistance, and extend our findings to other domains.

Paper #4: The Peculiarly Persistent Pleasantness of Bizarre Experiences

Robert Latimer, University of Toronto, Canada

SESSION OVERVIEW

Research on experiential consumption typically focuses on comparing the relative contributions of experiential and material purchases on post-consumption outcomes (e.g. happiness, identity, and regret). However, much of the rest of the journey regarding experiential consumption has been ignored. How do we decide what experiences we want, when we want them, and importantly, whether we made a good choice? In this special session, we combine four papers that address these unanswered questions.

While this session focuses on experiential purchases, our research differentially contributes to the existing literature by investigating one or more components of the experiential consumption process: (1) decision making, (2) consumption timing, and/or (3) post-consumption evaluations. Accordingly, our session promises to have broad appeal, as it advances connections from the information processing (Gallo, et al.), anticipation/intertemporal choice (Kumar and Gilovich), feature-richness (Miller, et al.), and consumer satisfaction (Latimer) literatures to research on experiential consumption. Furthermore, every paper in this session—all of which are at advanced stages in the research process—provides insights for: (a) consumers to improve their experiential decision making, and (b) managers to improve their experiential offerings.

In the first paper of this session, Gallo and colleagues contrast how consumers process information when making material and experiential purchase decisions. They show that consumers naturally use an intuitive mindset when comparing experiences and a deliberative mindset when comparing products. Additionally, they show that when consumers try to use the alternative mindsets, they make worse choices and anticipate more regret with the outcome.

In the second paper, Kumar and Gilovich examine how consumption timing interacts with purchase type, such that consumers prefer immediate consumption of material goods but delayed consumption of experiences. Furthermore, the authors demonstrate that consumers prefer an inferior product now rather than a superior product later but, conversely, prefer a superior experience later rather than an inferior experience now.

Miller, et al. extend the focus of consumers' inclinations for experiences to investigate pre- and post-consumption preferences for feature-richness. They find that, contrary to feature-fatigue, consumers prefer feature-poor experiences before consumption, but feature-rich experiences after consumption. Additionally, they identify several moderators that align consumers' pre- and post-consumption preferences.

Finally, Latimer examines a type of experience from which consumers derive increased enjoyment. He shows that, after consumption, bizarre experiences are more enjoyable than mundane experiences—even if the bizarre experience was less enjoyable during consumption.

This special session combines four papers that extend our knowledge of experiential purchases along different points of the consumption process. We believe the insights provided by this research will be helpful to consumers and timely for conference attendees given the many experiential offerings available in New Orleans.

The Heart and the Head: On Choosing Experiences Intuitively and Possessions Deliberatively

EXTENDED ABSTRACT

We examine the theoretical and empirical connections between recent work on intuitive and reflective processing (Evans and Stanovich 2013; Kahneman and Frederick 2002) and material and experiential consumption (Caprariello and Reis 2013; Carter and Gilovich 2010; 2012; Van Boven and Gilovich 2003). More specifically, we investigate whether people tend to weigh intuition more heavily when making experiential purchases and rational calculation more heavily when making material purchases. There are at least two reasons to believe they do.

First, it is often easier to isolate individual features of products and conduct a feature-by-feature comparison that is likely to cue rational processing (Inbar et al. 2010). Second, there are often more dimensions to consider when it comes to experiential purchases (Gallo and Sood 2014). A two-systems perspective seems to support the prediction that people will weigh intuition more heavily when it comes to experiential choices and rational calculation more heavily when it comes to material choices. Thus, examining how people choose to make these purchases provides an opportunity to test important postulates of a two-systems perspective.

This is not to say that people always choose experiences intuitively and material goods rationally. Our thesis is not absolute. The relative nature of our thesis is further mandated by the fact that the distinction between experiential and material purchases is not a clear-cut dichotomy. Both bicycles and television sets are undeniably material goods, but both are also vehicles for an experience. Still, the distinction is sufficiently clear and meaningful that, if our thesis is correct, people are more likely to weigh intuition more heavily when purchasing experiences and reason more heavily when purchasing material goods. All the stimuli used in the five studies we present were pretested so that, in each study, the material set of potential purchases was as desirable as the experiential set.

In study 1 we test consumers' processing style. Holistic processing involves the analysis of objects and entities taken as a whole (Nisbett et al. 2001), while analytic processing involves the evaluation of objects and entities attribute-by-attribute. We presented par-

ticipants ($n = 94$) with a material or experiential purchase decision (laptop, champagne flutes; weekend trip, dinner out) and asked them to select the format in which they would want to see the pertinent information. In line with our theoretical framework, those evaluating experiences selected a holistic or intuitive process (84%) more frequently than those evaluating material products (64%), $\chi^2(1, 187) = 6.20, p < .02$.

In our second study, we examine choice. Through an imbedded figure task (Monga & John 2008), we primed participants ($n = 167$) to process information holistically or analytically and then examined their preferences for material or experiential goods (laptop vs. weekend trip; dinner vs. champagne flutes). If people tend to think about experiential purchases holistically, then being in a holistic mindset should make experiential information easier to process and the experience in question more appealing. As predicted, participants induced to adopt a holistic mindset were more likely to choose the experiential option (68%) than those primed to adopt an analytic mindset (53%), $\chi^2(1, 334) = 6.71, p < .01$.

In study 3, we asked participants ($n = 25$) to rate the extent to which different purchase decisions (8 material and 8 experiential), should be made on the basis of intuition versus reason, on a scale from 1 to 9. As predicted, participants thought the material purchases should be based significantly more on reason ($M = 6.94, SD = 1.09$) than the experiential purchases ($M = 4.60, SD = 1.39$), paired $t(24) = 6.86, p < .001$.

Next (study 4), we tested whether processing style impacted consumer regret. Participants ($n = 20$) were informed that they would see a sequence (from study 3) of different types of potential purchases—one at a time—and they were to imagine that they were torn between two different options. They were also asked to imagine that their intuition led them to prefer one option and reason the other, and that their ultimate decision went quite badly so that they ended up regretting the choice they made. We asked them which processing style they would regret using more. As predicted, participants thought they would have significantly more regret going against reason for material purchases ($M = 4.80, SD = 1.96$) than for experiential purchases ($M = 3.30, SD = 1.87$), $t(19) = 3.032, p = .007$.

Finally, in study 5 we test whether choosing experiences intuitively and products deliberately leads to making better decisions. We checked this by testing for transitivity violations (von Neuman and Morgenstern 1947). We instructed some participants to make a set of pairwise choices intuitively and others analytically, and then we tabulated the number of intransitive preferences (paradigm from Rusou, Zakay, and Usher [2013]). We then presented participants ($n = 140$) with a variety of pairs of possible purchases (adapted from studies 3 and 4), and asked them to choose one option in each pair. As anticipated, participants told to make their choices deliberately showed more transitivity violations in the experiential condition ($M = 2.85, SD = 4.07$) than in the material condition ($M = 0.89, SD = 1.33$), $F(1,136) = 9.30, p = .003$. However, for those told to make their choices intuitively, participants in the material condition had more transitivity violations than those in the experiential condition (though this difference was not statistically significant).

These findings contribute to two growing literatures in social and consumer psychology. First, our results attest to the utility of a two-system model for purchase decisions. Second, our results add to the existing work on the psychological differences inherent in experiential and material consumption.

To Do or To Have, Now or Later? The Preferred Consumption Profiles of Material and Experiential Purchases

EXTENDED ABSTRACT

Van Boven and Gilovich (2003) asked a simple question: “To Do or To Have?” With respect to consumer satisfaction, their answer was clear—the hedonic return is greater for experiential than for material purchases (i.e. for money spent on doing rather than having). Here, we ask: *When?*

Nearly all of the research following the aforementioned seminal paper dealt with utility derived *after* consumption. More recently, however, Kumar, Killingsworth, and Gilovich (2014) found that there is a difference in the value derived from material and experiential purchases even *before* the good is acquired or the experience is consumed. The anticipation of future consumption tends to be more pleasant, more exciting, and less fraught with impatience for experiential than for material purchases. As Loewenstein (1987) has argued, the utility people get from anticipation can lead them to delay consumption. Accordingly, we investigated whether, as a result of this difference in anticipatory pleasure, people might prefer to delay their consumption of experiences, while preferring to consume products immediately.

In studies 1a-1c, we demonstrate that when asked to choose between an experience and a possession at different times, people show a marked preference for consuming the material purchase now and the experiential purchase later. As an initial assessment of whether people would rather delay their consumption of experiences than of material purchases, participants in study 1a ($N=97$) were presented with a choice between a possession now and an experience later or an experience now and a possession later. When they were told to imagine that they were given \$1500 to spend on two purchases in the scenario we gave them. 68% of participants indicated that they would rather have a \$750 gadget now and a \$750 beach vacation later, significantly different from indifference, $\chi^2 = 12.63, p < 0.001$.

One potential (but banal) explanation of these results is that people are more willing to put off consumption of an experience because most experiences are “time limited” but most material goods are not: that is, experiences are often over quickly and the only way to stretch out their enjoyment is to put off when they begin. Material goods, in contrast, can usually be enjoyed now *and* down the road. To deal with this issue, we conducted two follow-up replications using an experiential and material purchase that were matched on the degree to which they were time limited. In study 1b, 89% of participants reported that they would rather have a gadget now and a non-time-limited experience (a lifetime museum membership) later, $\chi^2(1, N=99) = 59.89, p < 0.0001$. 65% of respondents in study 1c indicated that they would rather have a time-limited gadget (a “loaner” pair of Google Glass) now and do a price-matched outdoor activity later, $\chi^2(1, N=100) = 9.00, p < 0.01$.

When forced to choose, consumers prefer to have their material purchases sooner and their experiential purchases later. Moving beyond forced choice, we extended these findings in study 2a ($N=98$) to a variety of purchases in a different paradigm in which participants simply stated their preferred time of consumption. Participants in this study were presented with 20 experiential and material purchases in a randomized order and were asked their preferred consumption time-frame for each purchase. Consumers reported that they would want to delay consumption of the 10 experiential purchases longer than the 10 material goods, matched pairs $t(97) = 5.70, p < 0.0001$. In a follow-up study (study 2b; $N=102$), we replicated this result using a material purchase and an experiential purchase

that could be consumed repeatedly, matched pairs $t(101) = 6.39, p < 0.0001$.

Ninety-five participants in study 3a were presented with a choice between a lesser purchase now and a superior purchase later on and we examined whether they were more likely to choose a lesser material possession now but opt to consume superior experiential purchases later. Respondents were asked to indicate a material/experiential purchase (between-subjects) they intended to make in the near future. They were then asked to imagine that 6 months from now, for the same price, they could get an “upgraded” version of that purchase. We then asked them to indicate their relative preference for the purchase that they could make right now versus the superior purchase in the future. Here, consumers exhibited more patience for experiential purchases, $t(93) = 3.38, p = 0.001$. Study 3b ($N=100$) used a similar paradigm to investigate whether the same pattern of results would emerge when the purchase was held constant and we varied whether participants were led to think of it in material or experiential terms. Here, a trip to New York was desired more immediately when the material aspects of that purchase were highlighted than when participants focused on its experiential elements, $t(98) = 1.95, p = 0.05$.

Study 3c ($N=97$) directly replicated these findings and conceptually replicated the findings from Kumar et al. (2014), showing that the greater value added by anticipation to experiential consumption mediates the differences found in intertemporal choices. Participants in this study indicated that they derived more anticipatory utility from a future experiential purchase, $t(95) = 2.36, p = 0.02$. Additionally, participants exhibited a stronger preference for an improved but delayed version of their purchase in the experiential rather than material condition, $t(95) = 2.50, p = 0.01$. Regressing intertemporal preference onto purchase condition and reported anticipatory utility showed that purchase condition was no longer a significant predictor of intertemporal choice ($p > 0.05$) whereas the amount of anticipatory utility associated with purchases did predict intertemporal preference, $\beta = 0.45, p < 0.01$ —indicating that anticipatory utility mediates this relationship. In a bootstrapping mediation analysis (10,000 samples), the 95% CI on the indirect effect did not include zero [0.05, 0.90].

Finally, in study 4 ($N=94$), we demonstrate that that our findings affect people’s real-life purchasing decisions. When participants were asked between-subjects about which purchases from their own lives they either couldn’t wait for or had delayed in order to savor, the delayed purchases were rated as significantly more experiential, $t(92) = 2.43, p < 0.02$.

Simply Desirable, Preferably Complex: Feature-Richness in Experiential Purchases

EXTENDED ABSTRACT

Previous research has differentiated between products and experiences in many ways (Van Boven and Gilovich 2003) and even though experiences generally provide more happiness than their material counterparts, researchers have primarily focused on studying the heuristics consumers use with material purchases. For instance, prior work finds that consumers prefer feature-rich products pre-consumption but feature-poor products post-consumption (Thompson, Hamilton, and Rust 2005). However, when it comes to experiences, which are intangible and have a finite usage time, will consumers still experience this “feature fatigue?”

In this research, we seek to understand how the number of features on an experience impacts pre- and post-consumption preferences. Prior work in the task complexity literature has shown that

as the number of events in a given task increases, the outcome of the task becomes more difficult to predict (Campbell 1988). As a result, consumers may prefer feature-poor experiences because they are perceived to have less uncertainty than feature-rich experiences (Trope and Liberman 2003). Post-consumption, however, there is evidence that consumers should prefer feature-rich experiences. For instance, a feature-rich experience should provide more opportunities for stories (Van Boven and Gilovich 2003; 2005), a better chance for a higher peak and end (Kahneman 1999), and less regret of inaction (Rosenzweig and Gilovich 2012).

In the current research, we show that consumers prefer feature-poor experiences pre-consumption, yet prefer feature-rich experiences post-consumption (the opposite of “feature fatigue;” studies 1 and 2) and that uncertainty mediates pre-consumption preferences. We also show that pre-consumption preferences can be moderated by changing the temporal distance associated with the purchase (study 3). That is, when temporally close we expect the same effect but when temporally distant, we expect consumers to have no preference for feature-rich vs. feature-poor experiences. Additionally, we suggest that Locus of Control (LOC; Rotter 1966) should impact how much consumers enjoy feature-rich (-poor) experiences (study 4) because it influences consumers’ initiation, effort, and persistence within an activity (Skinner 1996).

In our first study, we conducted a 2 (feature-rich vs. feature-poor) \times 2 (pre- vs. post-consumption) experiment. Participants ($N=290$) rated how much they liked, desired, and thought they would be satisfied with ($\alpha=.96$) a feature-poor versus feature-rich set of comedy videos. The comedy videos told exactly the same jokes and lasted about 10 minutes. In the “feature-rich” condition there were 19 individual segments, while in the “feature-poor” condition, there were only 3 individual segments. As anticipated, pre-consumption, participants preferred the feature-poor experience ($M_{\text{feature-poor}}=6.57, M_{\text{feature-rich}}=5.22, F(1,289) = 15.02, p<.01$), but post-consumption they preferred the feature-rich ($M_{\text{feature-poor}}=6.35, M_{\text{feature-rich}}=7.01, F(1,289)=4.18, p<.05$). Thus, we show that contrary to the case of material goods, consumers prefer feature-poor experiences pre-consumption, but feature-rich experiences post-consumption.

In study 2, we use more typical experiential stimuli—a day long trip—to replicate our findings from study 1 and test whether uncertainty concerns mediate the relationship between feature-richness and experiential evaluations. Participants ($N=181$) were asked to imagine that they were considering (pre-consumption) or just returning from (post-consumption) a feature-rich (6 activities) or feature-poor (2 activities) experience. We replicated our findings from study 1, where participants preferred the feature-poor experience pre-consumption ($M_{\text{feature-poor}}=7.34, M_{\text{feature-rich}}=6.49, F(1,180) = 6.57, p<.05$) and feature-rich experience post-consumption ($M_{\text{feature-poor}}=6.79, M_{\text{feature-rich}}=7.49, F(1,180) = 3.93, p<.05$). We also found that uncertainty mediates this relationship pre-consumption ($b = -.66 [-1.10, -.29]$), such that a feature-rich experience increases uncertainty which decreases evaluations of the experience.

Using a feature-poor (7 activities) and feature-rich vacation (21 activities), in study 3 we tested whether the temporal distance of the experience would moderate preferences for feature-poor experiences. We asked participants ($N=475$) to imagine they were going on a feature-rich (vs. feature-poor) vacation either next week or next year. Participants preferred the feature-poor experience when it was temporally proximate ($M_{\text{feature-poor}}=7.25, M_{\text{feature-rich}}=6.34, F(1,474) = 6.31, p<.05$), but feature-richness did not impact preferences when the experience was temporally distant ($M_{\text{feature-poor}}=6.64, M_{\text{feature-rich}}=6.71, F(1,474) = .1, p=.75$). We also found that uncertainty mediated this relationship in the temporally close condition ($b = -.55, [-.86, -.26]$).

In study 4, we test: (1) whether consumers' pre- and post-consumption preferences flip when they actually choose their own experience as well as (2) the moderating effect of locus of control on post-consumption evaluations. First, we asked participants to choose either a feature-rich (4 activities for 5 minutes in total) or feature-poor experience (one activity for 5 minutes in total). Overwhelmingly, participants (N=190) chose the feature-poor experience (160, 84%) rather than the feature-rich (30, 16%). However, after doing the experience of their choice, those that picked the feature-rich experience rated it higher than those that chose the feature-poor experience ($M_{\text{feature-poor}} = 5.93$, $M_{\text{feature-rich}} = 6.45$, $F(1, 189) = 3.86$, $p = .05$). Additionally, we found a marginally significant feature-richness x LOC interaction on post-consumption evaluations ($F(1, 189) = 3.16$, $p < .08$). Using a spotlight analysis, we found that participants with an external LOC exhibited the same flip in preferences that we previously observed, they enjoyed the feature-rich experience more than the feature-poor experience ($b = 1.14$; $t(189) = 2.22$, $p < .05$). However, because internal LOC participants want to control the outcomes of an experience, when they are engaged in a managed experience where they are not in control, we find no difference in their evaluations of feature-rich and feature-poor experiences ($b = -.08$; $t(189) = -.18$, $p = .86$).

In sum, consumers prefer feature-poor experiences pre-consumption and feature-rich post-consumption (the opposite of products). We also identify temporal distance as a pre-consumption moderator and LOC as a post-consumption moderator.

The Peculiarly Persistent Pleasantness of Bizarre Experiences

EXTENDED ABSTRACT

From the director of a cruise ship to the host of a dinner party, people strive to create experiences to which audiences will want to return. Not only must the audience enjoy the event, but they must remember the event as being enjoyable. Our project reveals one possible route to that goal: making an experience more bizarre. Bizarre stimuli tend to be processed and remembered differently from more mundane stimuli (Hunt 1995). This is true when stimuli differ from their local context, called *primary distinctiveness*, and also when stimuli differ from someone's entire life experience, called *secondary distinctiveness* or bizarreness (Schmidt 1996). In this project, we examine the impact of bizarreness.

While primary distinctiveness influences retrospective enjoyment largely by changing which parts of an experience are recalled later (Montgomery and Unava 2009), secondary distinctiveness has more extreme consequences for stimuli processing (Worthen 2006) and may have more direct effects on retrospective enjoyment. Bizarre elements of experiences may shift in valence over time as well as in prominence in memory. In this project, we demonstrate that bizarre experiences, compared to mundane experiences, are perceived as more pleasant in retrospect than during the initial experience.

The first two studies in our project provide correlational evidence that bizarre experiences become more enjoyable in retrospect. In study 1, 289 participants recounted an autobiographical event and reported their retrospective enjoyment of the event (3-item scale, $\alpha = .94$), the bizarreness of the event (3-item scale, $\alpha = .79$), and how long ago the event occurred.

The bizarreness and retrospective enjoyment of experiences were correlated $r = .32$, $p < .05$. Critically, regression analyses revealed that bizarreness was a better predictor of retrospective enjoyment for experiences further in the past, ($\beta_{\text{bizarre} \times \text{daysago}} = 1.3$, $p < .01$).

Study 2 (N = 185) replicated these results using students' retrospective enjoyment of research participation sessions.

In studies 3-5, we manipulated the presence of bizarre or mundane stimuli between-subjects and participants rated their initial and retrospective enjoyment of the stimuli, leading to a 2 (bizarre/mundane) x 2 (online rating/retrospective rating) mixed design. In study 3, 83 participants viewed a set of 12 paintings and sculptures from the MoMA: of which 2 paintings (pretested to be equally enjoyable) were either bizarre or mundane.

Participants initially reported equal enjoyment of either set ($m_{\text{bizarre}} = 47.4$, $m_{\text{mundane}} = 48.3$, $p > .1$), but after a 6-week delay participants who viewed the bizarre paintings reported greater retrospective enjoyment of the set ($m_{\text{bizarre}} = 54.1$, $p < .05$) whereas those who viewed the mundane paintings reported marginally lower retrospective enjoyment of the set ($m_{\text{mundane}} = 43.2$, $p < .1$; Interaction $p < .05$).

Studies 4 (N = 43) and 5 (N = 98) replicate the relative improvement of retrospective enjoyment for multiple different bizarre vs. mundane foods in scenarios where the bizarre experience (e.g., marmite) is initially less enjoyable than the mundane experience (e.g., butter).

While studies 3-5 show that bizarre experiences improved retrospective enjoyment *relative* to mundane experiences, studies 6 and 7 demonstrate that the *presence (vs. absence)* of a bizarre element in an experience increases retrospective enjoyment. In addition, studies 6 and 7 provide evidence for two mediating variables: how frequently participants discussed the experience after it occurred and the ease of recall during the retrospective evaluation.

Students enrolled in an introductory marketing class participated in three one hour research sessions one month apart. In each session, participants completed 6-10 different studies. We tracked 54 students' enjoyment of each study and the session overall for each of the three sessions. At the third and final session we asked for their retrospective enjoyment of the current, first, and second sessions. The manipulation of bizarreness was introduced in the second session by asking half the participants to complete a bizarre 5-minute "Apple Study" (the remainder left 5 minutes early). In the apple study, participants were instructed to stare at their computer screen for 160 seconds as the screen flashed varying shades of red, while varieties of apples (e.g., Fuji, Macintosh) appeared in 10 pt. white font in the center of the screen. They then went into a small room, lit with red light where they were asked to quickly rate the appearance of several apples.

The inclusion of the bizarre apple study did not change participants' initial enjoyment of the session, ($m_{\text{bizarre}} = 4.32$, $m_{\text{bizarre absent}} = 4.38$, $p > .1$), nor their mean enjoyment of the other studies in the session ($m_{\text{bizarre}} = 4.35$, $m_{\text{mundane}} = 4.20$, $p > .1$), and the apple study itself was no more enjoyable than the studies surrounding it ($m_{\text{apple study}} = 3.86$). After a one-month delay, however, participants who did not experience the apple study reported lower retrospective enjoyment of the second session as compared to their earlier evaluation ($m_{\text{bizarre absent}} = 3.63$, $p < .05$) as well as compared to those who did the apple study ($m_{\text{bizarre}} = 4.32$, $p < .05$; Interaction $p < .05$). The retrospective enjoyment of participants who completed the apple study was no different than initial enjoyment ($p > .9$). The interaction was mediated by both the reported frequency that participants talked about their second session in the lab and their ease in recalling the second session one month later ($ps < .05$).

Study 7 (N = 102) replicated the methods and results of study 6. However, instead of leaving the lab early, participants in the mundane condition completed a task in which they read about different apple varieties. As a result, instead of the bizarre condition persisting in its pleasantness while the mundane condition declined, the bizarre

condition became more pleasant in retrospect while the mundane condition was equally pleasant online and in retrospect.

To summarize, seven studies demonstrate that bizarre experiences become more enjoyable in retrospect compared to mundane experiences. Thus, if you want an experience to be fondly remembered, make it a little weirder.

SESSION OVERVIEW

Psychologists, economists, and marketing researchers spend significant amounts of effort thinking about risk preferences, and for good reason. It helps us develop normative theories about how we should use our time and money and descriptive accounts of how others actually do use theirs. But are researchers and practitioners focusing on the right things? What are we *really* capturing when we ask people to consider uncertain outcomes?

Risk assessment has traditionally been characterized by a mental balancing of probabilities and outcomes, and changing these parameters has been thought to influence our perceptions of a prospect. While this is certainly part of the story, we wonder what else changes simultaneously with risk than can cause shifts in preferences. How much of risk preference is really related to risk itself, and how much is caused by these other changes? The four papers in this session examine this more closely and propose alternative drivers of "risk preferences" beyond risk *per se*.

Why would putting a gift card inside of a box reduce its value by 30 percent? Mislavsky and Simonsohn propose that some forms of risk aversion are simply negative reactions to "weird" scenarios or unusual mechanisms. In four experiments, they show that, even in the absence of objective risk, mechanisms used to introduce uncertainty lower valuations.

When is a quarter worth less than nothing? Kelly and Simmons investigate why people would rather say "no" to a gamble than "yes" to \$0 and why giving up a gamble for \$0 is more attractive than giving it up for \$0.25. Ultimately, framing gambles differently (e.g., as a yes/no proposition or as a choice between action and inaction) and altering compensation for *not* gambling changes risk preferences in counternormative ways, in part because people believe that accepting different types of gambles says different things about their personalities.

Why would somebody prefer a drug that may cause cancer and constipation to one that may only cause cancer? Khan and Kupor show that "value atrophy" causes prospects to appear *less* risky when additional risky outcomes are added. This occurs because increasing the number of outcomes decreases the perceived probability of any individual outcome and holds in the domains of both positive and negative outcomes.

Why are people reluctant to pay for a sure thing? Frederick, Meyer, and Levis explore why people who are told that they will win

\$10 if a coin flip comes up *heads* pay significantly less than \$5 to also bet on *tails* (even though that purchase would guarantee them \$10). In fact, rather than being negatively correlated (as normative theory would predict) values of hedges are often *positively* correlated with their associated gambles.

Taken together, these papers cast doubt on current models of risk preference and provide new perspectives on the mechanisms behind "risk" aversion.

Risk is Weird: The Weirdness of Risky Transactions Causes "Risk" Aversion

EXTENDED ABSTRACT

What exactly do we mean when we talk about risk aversion? At its most basic, risk aversion exists when a person is willing to forgo an uncertain outcome for a certain one, despite the uncertain outcome having a higher expected value. That is, a risk-averse person may prefer getting \$30 for sure, rather than taking a 50% chance of winning \$100 (and a 50% chance of winning nothing). To date, most explanations of this phenomenon have focused on how we mentally balance the probabilities and magnitudes of positive and negative outcomes (Gneezy, List, & Wu, 2006; Kahneman & Tversky, 1979; Tversky & Fox, 1995), although recent accounts have suggested that uncertainty itself may have negative utility (Simonsohn, 2009).

However, we propose that much of what has previously been considered "risk aversion" has little to do with risk or uncertainty *per se*. It is instead caused by the specific mechanisms that are used to introduce uncertainty. For instance, buying a lottery ticket, flipping a coin with a friend, and sitting down at a blackjack table are all relatively typical ways to encounter risk in the world. In fact, these are generally domains where people show relatively little risk aversion and are often risk-seeking (Conlisk, 1993). On the other hand, betting on an experimenter pulling a red ball from an urn with an unknown ratio of black and red balls (Ellsberg, 1961) is much less common and may give pause to those asked to value the gamble. Unsurprisingly, this paradigm typically creates significant risk aversion (Fox & Tversky, 1995; Keren & Gerritsen, 1999).

We hypothesize that these weird risk-creating mechanisms would also reduce valuations even in cases with no objective risk. There are several reasons why this may occur. First, unusual mechanisms may introduce skepticism that everything will work as intended. Second, people may assume larger transaction costs as a mechanism's complexity increases, and risk aversion is merely an adjustment for these costs. Third, participants may believe that the mechanism is "biased against the person" (Keren & Gerritsen, 1999). That is, unless there is a compelling reason for increased complexity, participants may believe that the mechanism was specifically designed to produce unfavorable outcomes at the user's expense.

We conducted four studies to test our hypothesis. We primarily rely on scenarios similar to those used in studying the uncertainty effect (Gneezy et al., 2006). We used this paradigm because it has previously provided one of the more extreme demonstrations of risk aversion and allows for clean manipulation of both risk and weirdness. In prior uncertainty effect experiments, it was found that risky gambles are often valued *below* the value of the worst possible outcome.

Study 1 presented participants with one of three scenarios where they were asked to provide either (1) their willingness-to-pay (WTP)

for two gift cards (the *certainty* condition), (2) the chance to win one of two gift cards (the *uncertainty* condition), or (3) the chance to choose one of two gift cards (the *choice* condition). WTP elicitation in the *certainty* condition consisted of a simple question (e.g., “What is the most you would be willing to pay for this gift card?”), while the elicitation in the *uncertainty* and *choice* conditions involved a more elaborate scenario, which asked participants how much they would be willing to pay to open a box on a table and take one of two gift cards, which were either labeled (*choice*) or unlabeled (*uncertainty*). As demonstrated by prior studies of risk aversion and the uncertainty effect, participants provided a lower WTP in the *uncertainty* condition than in the *certainty* condition. However, they also provided a lower WTP in the *choice* condition, an objectively riskless condition where they would have had full control over the outcome and could have simply chosen their preferred gift card.

Study 2 replicated the results from Study 1, with one exception. The scenario in the *certainty* condition was modified to parallel those in the *uncertainty* and *choice* conditions. Instead of simply asking their WTP for a gift card, we asked their WTP to open a box and take the one gift card that was inside. We then used this as our baseline valuation to compare the *uncertainty* and *choice* valuations. We found no difference between valuations in any of the conditions. This suggests that, holding the distribution mechanism constant, risk or uncertainty do not necessarily lower willingness-to-pay.

Study 3 replicated the pattern of results from Studies 1 and 2, but with a different weird scenario, which involved the purchase and redemption of tokens but had the same basic elements of *certainty*, *uncertainty*, and *choice*. Study 4 used both the box and the token scenarios and incorporated outcomes of different objective values (\$50 and \$100 gift cards). We again find the same pattern of results, with participants showing significantly less risk aversion in the token scenarios than in the box scenarios.

Taken together, the results of these studies have significant implications for both researchers and businesses. Theoretically, these results suggest that prior experiments designed to measure risk aversion may have, at least in part, actually captured negative reactions to weird mechanisms and stimuli. Practically, this supports the idea that businesses should be wary of being “too weird.” Businesses that try to distinguish themselves by relying on overly novel methods may be lowering customers’ willingness to engage with their promotions or pay for their products. Instead, they may be better served by introducing changes or new features more slowly, so that customers have time to adjust to a “new normal.”

Gamblers Are Fun (But They Aren’t Risk Takers)

EXTENDED ABSTRACT

Mixed gambles are frequently used by researchers to assess people’s willingness to take risks across various contexts. However, we found that subtle differences in framing considerably affected people’s willingness to accept a mixed gamble. In our first experiment, we found that people are more willing to accept a mixed gamble when it is framed as a choice between two options (gambling vs. not gambling) than when it is framed as a choice to accept or reject a single option (i.e., the gamble). People are also more likely to accept nothing than next-to-nothing as an alternative to gambling.

We had 1,201 participants imagine they were offered a mixed gamble (50% chance of winning \$100 and a 50% chance of losing \$100) and indicate whether they would take the gamble in real life. Participants were randomly assigned to one of three conditions. In the first condition, the gamble was framed as the decision to accept or reject a single option (e.g., “Would you accept this option?”). In

the second, the gamble was framed as a choice between two options (the gamble versus “\$0 for certain”). The third condition was identical to the second condition, except that the alternative to the gamble was “\$0.25 for certain.” After participants made their choice, they rated how pleasurable it would feel to win \$100, how painful it would feel to lose \$100, and how pleasurable or painful it would feel to get the alternative outcome (\$0 or \$0.25). They also rated how exciting it would be to gamble and how boring it would be not to gamble.

Participants chose the gamble significantly more often when it was framed as a choice between the gamble and \$0 for certain (38.3%) than when it was framed as accepting or rejecting the gamble (25.1%), $p < .001$. More interestingly, however, is that they chose the gamble even more often when the alternative was \$0.25 (48.0%) than when it was \$0, $p = .007$. Therefore, by offering a trivially small alternative to taking the gamble, we nearly doubled the proportion of people willing to take the gamble relative to simply asking whether or not they would take it. This also suggests that people find the prospect of getting a \$0.25 reward *less appealing* than a \$0 reward. However, when we asked participants to rate how pleasurable or painful it would be to get the certain alternative, they rated that receiving \$0.25 would be significantly more pleasurable than getting \$0 under the two-choice framing, $p = .039$, and that getting \$0 under the accept/reject framing would be more painful than getting \$0 under the two-choice framing, $p < .001$. This pattern of results directly contradicts their choices. Furthermore, there were no significant differences between conditions in how participants rated the pleasure of winning \$100 or the pain of losing \$100.

What, then, can explain this pattern of choice? One possibility is that choosing a boring or uninteresting alternative feels worse than rejecting an interesting alternative. Our data provide partial support for this hypothesis. While there were no significant differences in ratings of how exciting it would be to take the gamble, participants in both two-option conditions rated *not* taking the gamble as more boring than those in the one-option condition, $ps < .001$. In sum, we find that people think that earning nothing is sometimes better than earning next-to-nothing, and that choosing an uninteresting option is worse than rejecting an interesting option.

Our second study ($N = 202$) further explored how people perceive these gambles. In addition to indicating whether or not they would take a mixed gamble (50% chance of winning \$100 and 50% chance of losing \$100), participants also rated the personality of a hypothetical person who rejected the gamble. Each participant was exposed to both the one-option (accept/reject a gamble) and two-option (choose between the gamble and \$0 for certain) gambles. To accomplish this, we embedded both framings of the target gamble in a set of eight filler gambles, randomizing the order of the one- and two-option framings of the focal gamble between participants.

In the personality judgment task, participants were asked to imagine that a person chose *not* to take the mixed gamble and then rated that person on whether they were more or less intelligent, wise, fun, boring, cautious, afraid of risk, and likable than average. The personality judgment task followed the same format as the choice task, and participants rated personalities for all gambles. The order of the gamble choices and personality judgment tasks were randomized between subjects.

We once again found that people were more willing to take the gamble when it was framed as a choice between two options (taking the gamble and getting \$0 for certain) than when it was framed as a single option (whether or not to take the gamble). Particularly noteworthy is that these are *within-subjects* effects, meaning that a significant portion of people accepted a gamble when it was framed

as a choice between two options (33.7%), then *rejected the same gamble* when it was framed as accepting or rejecting a single option (15.8%), $p < .001$.

We also found that the framing of the gamble significantly affected the perceived personality of a person choosing not to take it. A person who rejected a two-option gamble was seen as significantly less fun, less likable, more cautious, more afraid of risk, ($ps < .05$), and marginally more boring ($p = .075$), than a person who rejected the one-option gamble. Furthermore, a bootstrap mediation analysis revealed that changes in how fun and likeable a person who rejected the gamble seemed, but not changes in how cautious or afraid of risk they seemed, partially mediated the of single- versus two-option framing on willingness to gamble.

The Unattractiveness of Hedges: Implications for the Conception of Risk Preferences

EXTENDED ABSTRACT

Analyses of choice under uncertainty typically treat risk aversion as a primitive and stylized fact; the certainty equivalent of a gamble is nearly always below its expected value—indeed, this is routinely used as the *definition* of risk aversion. For instance, the typical person is indifferent between a sure \$3 and a coin flip for \$10.

Matthew Rabin and others have noted that this degree of (what we typically still call) "risk aversion" over small stakes violates Expected Utility Theory, because it implies a degree of curvature that is radically inconsistent with other choices. For instance, someone who is indifferent between \$3 and coin flip for \$10 "should" (i.e., would have to, for consistency) prefer a sure \$100 over a coin flip with an infinite payout. Prospect Theory attempts to accommodate such results by introducing a discontinuity at the reference point.

In this project, we investigate a different sort of inconsistency, by comparing subjects' valuation of *gambles* (e.g., a voucher which pays \$10 if HEADS obtains) with their valuation of *hedgies* (e.g., a second voucher that pays \$10 if TAILS obtains).

Logic requires three mutually entailed results: (1) The valuation of a *gamble* and the valuation of its *hedge* should sum to the prize. (Obviously, the joint possession of a \$10 HEADS and \$10 TAILS voucher guarantees \$10, and, hence, is worth \$10.) (2) The distribution of bet and hedge valuations should be perfectly negatively correlated; they should lie along the line $X+Y = \text{prize}$. (3) The valuation of a hedge should *exceed* its expected value. The local curvature invoked to explain why the certainty equivalent of a *gamble* falls below its expected value also demands that the certainty equivalent of the *hedge* exceed its expected value. Note that if a respondent is indifferent between \$3 and a coin flip that pays \$10 if the coin lands heads, they are effectively willing to sacrifice \$7 from the good state (coin lands heads) to ensure \$3 for the bad state (coin lands tails). Correspondingly, when faced with the opportunity to acquire a hedge, the strong desire to transfer wealth from a richer to a poorer state implied by their gamble valuation dictates a high valuation of the hedge; respondents should again be willing to sacrifice seven of the ten dollars if heads obtains to yield three if tails obtains.

Of course, none of these predictions are realized. Instead, gambles and hedges are *positively* correlated (between +0.4 and +0.6), they typically sum to less than the prize, and hedge valuations rarely exceed their expected value. Results hold across gambles with well specified probabilities (e.g. coin flips) and ambiguous probabilities (e.g. football games). Moreover, these logical violations are difficult to expunge. We presume that the symmetry between the *hedge* and the *gamble* coupled with an instinctive revulsion to valuing a prospect above its expected value suppress valuations of the *hedge*. We

explore several ways of describing the *hedge* (as "insurance," as an "upgrade," and so on), but none we've tried succeed in persuading even a significant minority of respondents to adopt a logical pair of valuations.

These results raise several fundamental issues. (1) If the gamble and hedge bets do not conform: no sort of utility function can be invoked to explain both choices—not even one suitably modified to accommodate extreme local curvature. This forces one to question what the traditional measures of risk aversion are actually measuring. (2) If gamble and hedge valuations are not (as they "should" be) redundant measures of the same construct, one should ask what each is, in fact, measuring and how each correlates with various types of real world behaviors that are traditionally associated with attitudes toward risk (e.g., ownership of equities, affinity for casinos, pursuit of professions with high variance outcomes, and so on). (3) To the extent that people can—somehow—be made to appreciate the normative relation between *gambles* and *hedgies*, in what way will their responses (or behaviors) change? We anticipated that repeated exposure to both types of questions will engender greater risk neutrality because respondents would be more averse to valuing a hedge *above* its expected value than they'd be to value a gamble *at* its expected value. However, initial results involving repeated play in the lab have not, thus far, supported this prediction.

Value Atrophy in Consumer Assessment of Risky Options

EXTENDED ABSTRACT

Normative theories as well as lay intuition suggest that adding additional negative (positive) prospects (i.e., probabilistic outcomes) should decrease (increase) the overall attractiveness of a risky option. For example, a prescription drug with a possible side-effect of a heart attack should be perceived as more threatening if it also poses the possibility of additional side-effects such as headaches and constipation, and a lottery offering an iPad should be viewed as even more attractive if it also offers other smaller prizes such as a mug and a T-shirt in addition to the iPad.

Contrary to the above normative view, we propose a "Value Atrophy" effect in risk assessment whereby a negative (positive) prospect can be perceived as less negative (positive) when additional smaller negative (positive) prospects are added to it. We propose that value atrophy occurs because people believe that larger prospects are less likely than smaller ones. As a result, the inclusion of smaller prospects by contrast makes a larger prospect appear less likely, and this reduction in the perceived likelihood of the large prospect decreases the perceived value of a risky option. We find support for value atrophy effect and the proposed mechanism across several studies.

In Experiment 1, participants perceived a pharmaceutical drug as more negative (i.e., more dangerous) when it had a single side effect of cancer, compared to when it had the same side effect of cancer in addition to several smaller side effects. Consistent with our proposed process, the presence of additional smaller side effects reduced the perceived likelihood of the larger side effect, and this reduction in the perceived likelihood of the larger side effect mediated the value atrophy effect.

Experiment 2 replicated value atrophy in a positive domain, thereby suggesting that the effect is unlikely to be due to motivated processing (in which people might be motivated to underestimate the likelihood of a larger side effect that might be more threatening and anxiety producing). Specifically, participants perceived a lottery drawing to be more attractive when it offered a single large prize compared to when it offered the same large prize in addition

to smaller prizes. Consistent with the mediation documented in Experiment 1, the presence of additional smaller prizes reduced the perceived likelihood of the larger prize, which in turn mediated the effect.

Our explanation of value atrophy hinges on the notion of lay belief that larger prospects are less likely than smaller prospects. In Experiment 3A we document existence of such lay belief. Participants indicated that they were more likely to experience a smaller prospect than a larger prospect in a variety of scenarios in both positive and negative domains (e.g., participants believed that they were more likely to find a \$1 bill than a \$100 bill on the ground, and more likely to sustain small rather than large damage from an earthquake). Providing convergent evidence, Experiment 3B similarly found that participants believed that both themselves and others would be more likely to obtain a small rather than a large prize from a lottery.

Because our theoretical framework suggests that value atrophy is in part driven by a contrast between smaller and larger prospects, we predict that value atrophy should only occur if a risky option contains a prospect that is relatively larger than the other prospects contained in it. Experiment 4 provides further support for our proposed theoretical account by testing this prediction. Participants viewed a pharmaceutical drug that either had a single minor side effect, multiple minor side effects, a single severe side effect, or the same severe side effects plus minor side effects. Value atrophy only occurred in the last two conditions when the magnitude of one prospect was larger than the other prospects.

If shifts in perceived probabilities underlie value atrophy, then the effect should not occur in contexts where there is no uncertainty regarding the likelihood of the prospects. In Experiment 5 we tested this prediction by manipulating whether the prospects were probabilistic or non-probabilistic. In the probabilistic context we told participants that they were choosing between two lotteries whereas in the non-probabilistic context we told them that they had earned additional compensation and were choosing between two certain compensation packages. We found value atrophy in the former context but not the latter. Specifically, we found that people chose a lottery offering a single large prospect over a lottery offering an equivalent large prospect plus a chance to win additional smaller prospects. However, we did not find this choice pattern in the compensation context.

The results are not only consistent with our proposed process, but also rule out several alternative possibilities. Specifically, value atrophy is unlikely to be driven by increased cognitive load or by decreased salience of the larger prospect. If increased load or decreased salience of the large prospect drove the effect, we would expect addition of prospects to produce value atrophy regardless of the prospects' magnitude and/or probability. In contrast, we find that value

atrophy occurs only in probabilistic options, and only when smaller prospects are included with a larger prospect. The effect also cannot be explained by an average value computation account whereby the overall value of a risky outcome is computed by averaging the magnitude of the prospects contained in it. This explanation is unlikely since the atrophy effect emerges only in probabilistic contexts and not in certain contexts where the perceived likelihoods of the prospects cannot shift.

Besides being theoretically interesting, the findings also have significant practical implications for marketers as well as policy makers since consumers evaluate the risks and benefits associated with their choices on almost a daily basis. Our research explains when bundling smaller prospects with larger ones may help or hurt marketing efforts. Our findings also have important implications for public policy. For example, consider FDA requirements to disclose all of a medical drug's potential risks. Current findings suggest that disclosing minor side effects may ironically make a drug appear less risky. Thus, this research has direct consequences for the design of advertisements, promotions and policy.

SESSION OVERVIEW

Reports abound in both academic and popular outlets on consumers' inability to ensure a secure and timely retirement (e.g., Munnell et al. 2009; Osterland 2014). Two major problems contribute to this retirement crisis. First, there is a savings *accumulation* problem related to the decisions consumers make when it comes to accumulating sufficient savings to retire comfortably. For example, the typical U.S. working household approaching retirement in 2013 had accumulated only \$111,000 in 401(k)/IRA balances (Munnell 2014). Second, there is a savings *decumulation* problem related to the complex decisions consumers reaching retirement age face of determining how and when to draw down retirement savings and pension benefits. Due to inadequate savings, ineffective financial planning, and increasing life expectancies many consumers are expected to outlive their retirement savings. For example, the Employee Benefit Research Institute estimates that 43% of Americans in the lowest-income quartile are expected to run short of money during their first year of retirement; and by the tenth year, an estimated 72% of them will be in this predicament (VanDerhei 2014). Retirement savings decumulation decisions are just as vital as decisions related to savings accumulation, yet very little consumer psychology research has been conducted to understand these decisions.

The objective of this special session is to explore the psychology of savings accumulation and decumulation decisions and their underlying processes. The first three papers in the session focus on the topic of savings decumulation, while the first and fourth papers in the session address the topic of savings accumulation. The first paper (Goldstein, Hershfield, and Benartzi) investigates how information architecture affects consumers' perceptions of wealth and intentions to save. Specifically, these authors examine whether people exhibit an "illusion of wealth" by which receiving a lump sum (e.g., \$100,000) can be perceived as larger or smaller than its annuitized monthly income equivalent (e.g., \$500 per month for life). The second paper (Salisbury and Nenkov) proposes that increased mortality salience while deciding whether to purchase an annuity may underlie the so-called annuity puzzle, leading consumers to avoid annuities

as a savings decumulation strategy. The third paper (Shu and Payne) investigates the impact of life expectation judgment framing, loss aversion, intertemporal impatience, and perceived ownership on decumulation decisions, such as when to begin claiming one's Social Security benefits. Finally, Zhao, Soman, and Kim focus on saving accumulation and examine how visual depiction of the (converging vs. diverging) flow between overall savings goals and multiple sub-goals can facilitate saving.

Together the papers in this session make important contributions to both theory and practice in financial decision-making, and savings accumulation and decumulation decision-making in particular. Further, this session embodies the 2015 ACR theme of *Advancing Connections*: it employs both controlled experiments and field studies and presents findings that offer both important theoretical contributions and useful practical implications for public policymakers, financial firms, and individual consumers. Given the growing size of the elderly population, these papers provide much needed insights into how to help consumers remain financially healthy and independent (Goldberg 2009; Yoon, Cole, and Lee 2009).

The Illusion of Wealth and Its Reversal

EXTENDED ABSTRACT

Research on choice architecture is now shaping policy around the world (Thaler and Sunstein 2008; Goldstein et al. 2008) touching on areas ranging from retirement economics (Benartzi and Thaler 2013), organ donation (Johnson and Goldstein 2003), end-of-life care (Halpern, Ubel, and Asch 2007), to environmental issues (Pichert and Katsikopoulos 2008). Recently, researchers and policy makers have started to pay more attention not just to choice architecture but also to information architecture: the format in which information is presented to people (Johnson et al. 2012). Research in information architecture has shown, for example, that the caloric content of food can be well appreciated in terms of the amount of exercise it would take to work calories off (Bleich and Rutkow 2013; Dowray et al. 2013), and the comprehension of cars' energy efficiency can be enhanced by presenting information in terms of gallons per 100 miles instead of miles per gallon (Larrick and Soll 2008). This paper investigates information architecture, though instead of addressing the consumption of calories or gasoline, we focus on economic consumption in retirement.

A timely policy debate concerns the information provided to the owners of approximately 80 million 401k retirement accounts. We focus on the Department of Labor (DOL) proposal that 401k statements display the money's worth of the account in terms of the projected lifetime income that the account can buy (Lifetime Income Disclosure Act 2011).

From a research perspective, our motivation is to investigate how people react to lump sums versus equivalent streams of monthly income. One question of interest is whether people exhibit an "illusion of wealth" by which a lump sum at retirement age (e.g., \$100,000) seems larger than its monthly equivalent (e.g., \$500 per month for life). We predict and test whether people exhibit the illusion of wealth as well as the opposite effect, by which lump sums seem smaller than their monthly equivalents.

We propose that the sensitivity to amounts of money is greater for monthly amounts than lump sums. We motivate this hypothesis using Decision by Sampling theory (Stewart, Chater, and Brown 2006), a relative of Range-Frequency Theory (Parducci 1965). This greater sensitivity to monthly amounts means that low monthly amounts are perceived as rather inadequate while high monthly amounts are perceived as rather adequate. In contrast, perceptions of lump sums change relatively little as the amount varies. This can lead to situations in which the two curves cross and monthly amounts are perceived as both less adequate and more adequate than lump sums, depending on the underlying amount. We show this in three experiments.

Study 1

A sample of 310 adults was recruited via Mechanical Turk ($M_{\text{age}} = 28.37$, $SD = 10.21$, Range 18-68, 40.3% women). We used a 2(Presentation: lump sum, annuity) \times 7(Amount: \$25,000, \$50,000, \$100,000, \$200,000, \$400,000, \$800,000, \$1,600,000) mixed design, with presentation as the between-subjects factor and amount as a within-subjects factor. In the lump sum condition, participants were asked to imagine that they would have a given lump sum to spend in retirement. In the annuity condition, however, participants were asked to imagine that they would have the equivalent monthly amount to spend in retirement. As predicted, people were less sensitive to changes in lump sums than to changes in monthly amounts. Also as predicted, monthly amounts were seen as clearly less adequate at low wealth levels, and clearly more adequate at high wealth levels. Models 2 and 3 in the appendix show that the predicted interaction between wealth amount and presentation format is significant.

Study 2

Study 2 replicates study 1 but with a between subjects design. A sample of 960 middle-aged respondents was recruited via a national survey panel ($M_{\text{age}} = 53.70$, $SD = 5.28$, Range 45-64, 52% women). To be eligible for participation, participants needed to have an annual household income between \$40,000 and \$150,000. Participants were then randomly assigned to one of eight conditions. We used a 2(Presentation: lump sum, annuity) \times 4(Amount: \$100,000, \$200,000, \$1,000,000, \$2,000,000) between-subjects factorial design. As in Study 1, people were less sensitive to changes in lump sums than to changes in monthly amounts, and monthly amounts were seen as strongly less adequate at low wealth levels, and strongly more adequate at high wealth levels. Models 5 and 6 in the appendix show that the predicted interaction between wealth amount and presentation format is significant.

Study 3

Study 3 had the same sample size and levels as Study 1, but was run on a new set of participants and had intentions to save as a dependent measure instead of perceived adequacy. As predicted, there was less sensitivity to lump sums. Furthermore, as predicted, low monthly amounts increased saving intentions more than low lump sums, and the effect reversed at higher wealth levels. Regression coefficients are omitted for space, but the expected interaction is significant ($p < .05$).

In conclusion, Studies 1, 2 and 3 support the possibility of an illusion of wealth and its reversal at higher monetary amounts. For smaller amounts of money, we found that middle-aged adults felt that a lump sum would be more adequate for retirement than an equivalent monthly annuity. They were also less likely to want to increase their saving behavior when exposed to a lump sum rather than an annuitized amount. We predicted and found a reversal of this pattern for larger amounts of money, consistent with the view

that people are more sensitive to amounts expressed as annuities, and less sensitive to lump sums, which they tend to assign intermediate ratings. Of social importance is the idea that the illusion of wealth might also contribute to the troubling tendency of Americans to claim their social security benefits at the earliest possible age and to cash out pensions.

Solving the Annuity Puzzle: The Role of Mortality Salience in Retirement Savings Decumulation Decisions

EXTENDED ABSTRACT

Consumers reaching retirement age face the difficult task of deciding how and when to spend the money they have saved for retirement. For five decades, economists have examined this savings decumulation problem and have argued that purchasing annuity products is an optimal decision strategy for most people when they reach retirement (Bernartzi et al. 2011; Yaari 1965). Economic theory argues that annuities mitigate the risk of outliving one's income, but very few individuals choose to annuitize their retirement savings, a phenomenon economists refer to as the *annuity puzzle*. In March 2014, U.S. retirement assets totaled \$23 trillion, with only 8.7% of that held as annuity reserves (Investment Company Institute).

The economic literature has examined the annuity puzzle within a rational choice framework. Several explanations for the annuity puzzle have been examined – such as low retirement savings (Dushi and Webb 2004), unfair annuity pricing (Mitchell et al. 2000), annuitization framing (Agnew et al. 2008; Brown et al. 2008), and desire to bequeath one's assets (Lockwood 2012) – yet none have been shown to fully account for it. Further, companies have adjusted their annuity products to accommodate proposed explanations and make annuities more attractive by introducing options such as fixed terms, bequeath features, and deferred start dates, with little effect on annuitization rates. As a result, some researchers have called for more work that moves beyond the fully rational paradigm and instead offers behavioral explanations for the annuity puzzle (Brown 2007). This research offers one such novel explanation. We propose that the task of choosing whether to buy an annuity evokes thoughts of death. We argue that, by forcing people to consider how long they have left to live, the annuity decision makes people's mortality salient, motivating them to escape the threatening awareness of their mortality by avoiding this option and choosing to self-manage their money instead.

Mortality salience (MS), defined as the increased accessibility of thoughts related to one's death, has been examined extensively by terror management theory researchers, who have shown that people defend against conscious death-related thoughts by using proximal cognitive strategies that remove these thoughts from consciousness and/or push the problem of death into the distant future (Pyszczynski et al. 1999). Drawing upon this literature, we argue that consumers avoid annuity products as a proximal defense strategy against experiencing thoughts of death evoked by the annuity choice task. To test this proposition, we conduct four experiments and a meta-analysis of our studies to estimate an overall average effect size.

In Experiment 1, we asked 161 participants to imagine they are age 65 and deciding whether to put their retirement savings into an annuity product (annuity condition) or into an IRA product (IRA condition). Spontaneous thought listing during each task revealed that the annuity decision evoked significantly more thoughts about death and dying than did the IRA decision ($z = 5.57$, $p < .001$), and purchase likelihood was far lower for the annuity (38.6%) than for the IRA product (63.4%; $z = 5.50$, $p < .001$).

In Experiment 2, we presented a hypothetical retirement scenario to 267 participants from an online panel and asked them to choose between a life annuity and self-managing their retirement savings at age 65. Participants were randomly assigned to a mortality salience or a control condition. We manipulated mortality salience using a well-established priming technique that asks participants to write about their own death (Burke et al. 2010; Greenberg et al. 2003; Greenberg et al. 1997). Participants in the control condition wrote essays about dental pain instead. As expected, participants were less likely to choose the annuity option when mortality salience was primed ($M = 20.69\%$) versus when it was not ($M = 31.79\%$; $\chi^2(1,267) = 4.41$, $p < .05$).

In Experiment 3 ($n = 469$), we tested a more subtle and practical MS manipulation by altering the annuity product description to make mortality more or less salient. A binary logistic regression analysis revealed that increasing mortality salience via either MS priming ($M_{\text{diff}} = -9.44\%$, $z = -2.31$, $p < .05$) or altering the annuity description ($M_{\text{diff}} = -10.31\%$, $z = -2.63$, $p < .01$) decreased the proportion of people choosing the annuity option, replicating our prior results.

In Experiment 4, we added a fixed term annuity with a bequeathable feature to the choice set and again replicated our findings with a sample of 314 older consumers closer to retirement age, demonstrating the robustness of the mortality salience effect. Results from a 2 (mortality salience: low/high) X 2 (choice set: with/without fixed-term option) between-subjects design indicated a significant negative effect of increasing mortality salience ($z = -2.01$, $p = .044$) and a significant positive effect of including a fixed-term annuity option in the choice set ($z = 1.94$, $p = .052$). Specifically, increasing mortality salience decreased the proportion of people choosing either annuity option ($M_{\text{diff}} = -10.19\%$, $z = -2.01$, $p = .044$), while adding a bequeathable fixed-term annuity increased the percent choosing an annuity ($M_{\text{diff}} = 9.83\%$, $z = 1.94$, $p = .052$). Further, the bequeathable fixed-term annuity appears to be shifting choice share amongst annuity products when mortality salience increases.

Finally, we conducted a meta-analysis to integrate findings across Experiments 2-4 and estimated that the overall mean effect of increasing mortality salience was an 11.2% point decline in annuity choice rate (see figure in appendix for meta-analysis results).

This research contributes to understanding the annuity puzzle by moving beyond prevalent economic explanations and instead offering a novel psychological explanation. It also adds to terror management theory (Greenberg et al. 1997), which has linked mortality salience to a broad range of behaviors (e.g., Arndt et al. 2004; Cai and Wyer 2014), but has not examined its effects on financial decisions like retirement savings. Finally, it contributes to retirement planning research and practice by providing insight into retirement savings decumulation – an increasingly important topic as 401(k) plans replace traditional defined benefit pensions and the size of the elderly population grows.

Psychological Factors in Savings and Decumulation Decisions

EXTENDED ABSTRACT

Every day 10,000 Americans reach age 65 and face one of the most expensive journeys of their life: retirement. As the largest source of retirement income for most Americans, the age at which to claim Social Security benefits is one of the most important financial decisions that they will ever make. Given substantial longevity risks and the financial benefits from delaying claiming, it has been suggested that later claiming should generally be chosen for most people (Shoven and Slavov 2012). Unfortunately, people may not be mak-

ing the wisest decisions about when to start claiming: most Americans start collecting at age 62, and eighty percent or more claim their benefits before the normal retirement age of 66. The studies reported here seek to better understand decumulation decisions, including Social Security claiming, by manipulating framing of life expectations judgments as well as by measuring individual differences in loss aversion, intertemporal patience, and perceived ownership.

The decision to delay claiming of Social Security benefits involves evaluating a complex option with multiple uncertain outcomes occurring over time. Recent work has documented the effects of question framing on individuals' judgments of their own life expectations, finding that asking questions in a "live to" frame rather than a "die by" frame can lead to an approximately ten year difference in predicted life expectation (Payne et al. 2013). Because life expectation is a key input to the claiming decision, it is important to understand how this type of question framing influences predicted claiming age. Another key psychological influence on claiming decisions is an individual's measure of loss aversion, due to the perspective that not claiming early may result in a loss of benefits relative to a breakeven calculation or one's own contributions into Social Security. We also predict that affective reactions such as perceived ownership ("I deserve the payments I contributed over my working life") can also be a strong driver of Social Security claiming decisions. Finally, since the claiming decision has implications that last for decades, individual measures of intertemporal patience should also predict whether individuals claim early or late.

We completed four online studies using national panels of over 4000 pre-retirement adults aged 35 to 65. Our first study focuses on the effects of life expectations judgments and loss aversion on a set of four retirement decisions including Social Security claiming. Studies 2 and 3 focus exclusively on the claiming decision, and show the effects of life expectations, loss aversion, perceived ownership, and intertemporal patience. Finally, in Study 4, we test whether using a "live to" or "die by" frame affects hypothetical retirement decisions by shifting attention to different aspects of the decision.

Study 1 is an online study of U.S. residents aged 35 to 65 ($N = 832$, 48.7% female) who were recruited and run online through internet panel company Survey Sampling International. We expose some participants to either a "live to" or "die by" frame prior to making a series of hypothetical retirement decisions to see how their life expectations judgments effect those later decisions. Specifically, participants were asked to estimate and report the chance that they would live to [die by] a certain age or older [younger] using a slider scale for the ages 65, 75, 85, and 95. As a control, other participants make the life expectation judgments after answering the retirement decisions. We collected four separate dependent variables, all of which capture whether the individual is being myopic about retirement income decisions. We also collect substantial additional information about each participant to use as covariates in our analysis, including age, gender, savings, social security solvency, life expectancy, loss aversion, subjective health, and numeracy. We find that subjective life expectancies are positively related to intentions to purchase a life annuity and to delay claiming of Social Security. This positive relationship is much stronger when the life expectancies are asked in a live-to frame rather than a die-by frame.

In Studies 2 ($N = 1432$, 49.8% female, aged 35-65) and 3 ($N = 1113$, 49.7% female, aged 40-65), we use only the "live to" frame and again manipulate whether judgments are collected before or after the claiming decisions. For participants who answer the live-to questions prior to claiming decisions, there is a significant and persistent effect of subjective life expectation judgments on predicted claiming age. Individual measures of loss aversion, perceived ownership,

solvency, and intertemporal patience are all significant predictors of intentions for early versus late Social Security claiming. Importantly, all of these individual difference measures operate independently of each other, suggesting that they can each contribute to the effectiveness of models of claiming behavior.

Finally, in Study 4 ($N = 831$, 49% female, aged 40 to 62), participants were randomly assigned to one of four conditions manipulating how claiming information was presented as well as whether life expectations were in a “live to” versus a “die by” frame. We again find that individual measures of life expectancy, loss aversion, perceived ownership, and intertemporal patience all significantly predict intentions for early versus late claiming. We also find a significant interaction effect: participants who think about their probabilities of living to older ages and then see an information table presented in a way that better highlights the benefits of later claiming indicate claiming ages delayed by around 5 months. Furthermore, life expectations are a more strongly significant predictor of claiming age for participants in the live-to framing condition. Individuals in the live-to frame appear to be more appropriately using their own predicted life expectancies, while those in the die-by frame are not integrating them in the same way. This may suggest something like an “ostrich effect” in which thoughts about dying result in an unwillingness to consider important choices related to retirement. One implication is that researchers hoping to gather behavioral measures that fully reflect respondents’ true subjective life expectations should be careful to use live-to framing (as in Studies 2 and 3). The choice of frame for life expectation information can be an important factor for helping individuals make retirement decisions.

Visual Depiction of Goal Structure and Financial Decisions

EXTENDED ABSTRACT

Helping consumers save has never been more important. Previous research has proposed different strategies to help consumers save such as the use of decision point (Cheema and Soman 2008), emphasizing goal specificity (Ülkümen and Cheema 2011), or earmarking on spending and saving (Soman and Cheema 2011; Thaler 1999). Recent research has also shown that focusing on one single savings goal increases saving compared with focusing on multiple savings goals (Soman and Zhao 2011). Given how common it is for consumers to have multiple goals for saving (e.g., saving for multiple purposes), we aim to explore how the visual depiction of the flow between overall financial goals and multiple sub-goals will facilitate saving.

We draw on the “fit” literature to develop our hypothesis. According to this literature, fit between external stimuli and consumers’ internal mindset creates fluency and enhances goal pursuit or persuasiveness (Higgins 2000; Kim, Rao and Lee 2009; Zhao, Dahl and Hoefler 2014). More directly related to the current research, recent work has shown that orienting a product toward consumers’ dominant hand in visual ad enhances fluency in product visualization and increases purchase intention (Elder and Krishna 2011). Drawing on these findings, we propose that visual depiction of the flow between overall financial goal and its sub-goals can facilitate goal pursuit when it creates a fit. Specifically, for saving which is an act of collecting, converging flow from multiple sub-goals to the overall savings goal creates a fit and increases saving compared with diverging flow from overall savings goal to multiple sub-goals. On the contrary, for donation, which is an act of giving out, this effect will reverse such that diverging flow leads to greater donation compared with converging flow. Four studies test our hypotheses.

In Study 1A which was a field study in India, we provided local workers an opportunity to join a new savings program and randomly assigned participants in five conditions. Participants in the three single-goal conditions were told to save more as it would help finance their children’s education, finance any healthcare needs they might have, or provide a nest-egg for when they retire, respectively. In the other two conditions, participants were reminded of all of these three sub-goals and were provided with a visual display of these goals. In the converging condition, the visual flow went from three sub-goals to the overall savings goal, whereas in the diverging condition, the visual flow went from the overall savings goal to the three sub-goals. Participants were asked to indicate their intention to join the savings program. The results showed a significant difference in percentage of people indicating intention to join the program ($M_{\text{single/children's education}} = 82\%$ vs. $M_{\text{single/healthcare}} = 71\%$ vs. $M_{\text{single/retirement}} = 72\%$ vs. $M_{\text{multiple/diverging}} = 36\%$ vs. $M_{\text{multiple/converging}} = 75\%$, $\chi^2(4) = 42.52$, $p < .001$). Consistently with Soman and Zhao (2011), we found that single goals led to greater intention to save than multiple goals. However, this effect was attenuated when the flow in the multiple-goal condition was converging. In Study 1B which was another field study in India, we replicated the effect of converging flow in terms of people’s self-reported saving six months after receiving the visual display of the flow between overall savings goal and multiple sub-goals ($M_{\text{diverging}} = \$20.44$ vs. $M_{\text{converging}} = \28.30 , $F(1,74) = 17.74$, $p < .001$).

In Study 2, which was a lab study, we seek to explore the underlying process. Participants were asked to imagine a scenario where they were thinking about joining a savings program. After introducing the savings program, the financial advisor reminded participants of their future financial wellbeing such as children’s education, future housing or retirement savings, and sketched the goal structure in either a converging (flow going from multiple savings goals and overall financial well-being) or diverging flow (reversed flow). After indicating their intention to join the program, participants were also asked to rate to what extent it felt right, good, pleasant and important to join this program. The results showed that converging flow indeed increased participants intention to join the savings program ($M_{\text{converging}} = 8.31$ vs. $M_{\text{diverging}} = 7.15$; $F(1,63) = 4.19$, $p < .05$), and made participants feel more “right” to join the program ($M_{\text{converging}} = 8.90$ vs. $M_{\text{diverging}} = 7.95$; $F(1,61) = 5.16$, $p < .05$). More importantly, feeling-right mediated the effect of visual flow in goal structure on savings intention.

In Study 3, we test whether the effect of converging flow on goal pursuit such as saving will be reversed for other financial decisions such as donation which is an act of giving out. In this study, participants were provided with an opportunity to make a donation with the \$2 that they received earlier in the study session. In both conditions, they could donate to either Daily Bread, Micro Skills or Habitat of Humanity, but the flow between overall goal of donation and the three sub-goals was either displayed in a converging (flow going from three organizations to overall donation goal) or diverging fashion (flow going from overall donation goal to three organizations). As a result, we found that participants in the diverging condition donated significantly more money than those in the converging condition ($M_{\text{diverging}} = \$1.49$ vs. $M_{\text{converging}} = \1.01 ; $F(1,48) = 3.96$, $p = .05$).

Taken together, these findings supported our hypotheses that visual flow in a financial goal structure can create a fit and facilitate goal pursuit. Specifically, converging flow enhances saving whereas diverging flow enhances donation because each type of flow is consistent with the goal act itself (collecting for saving vs. giving out for donating). This research contributes to prior work on financial decision making (Soman and Cheema 2011; Soman and Zhao 2011;

Thaler 1999) by providing a novel strategy to encourage consumer saving and donation. It also adds to the fit literature (Higgins 2000) and nudging research (Thaler and Sunstein 2008) by showing the impact of subtle contextual cues on fluency and financial decisions.

SESSION OVERVIEW

Conspicuous consumption, the public consumption of luxury goods in order to signal status to others, is now a well-understood phenomenon both in consumer research as well as among the general public. By consuming certain clothing and accessories, consumers can signal status and capitalize on the symbolic nature of goods. The research presented in this session offers a more nuanced and deeper understanding of how, when, and why certain brands and products act as signals, both to the public and to the consumer himself. Each of these projects takes a different perspective in examining the complex consumption choices involved in signaling status. Specifically, two of the projects consider the signals that consumers unknowingly communicate to themselves via the purchase and display of luxury and vintage products. The third and the fourth paper are rooted in consumers' motivation to signal status to others, via vintage products, and illustrate one manner in which lifestyle brands garner their high price premium. Together these four projects reveal the deep and complex relationship that exists between consumers and the brands and products they purchase.

These papers build on our existing knowledge of how consumers signal social status with the products they consume and display and how these purchases enable consumers to signal important aspects of self. First, **Wang, John, and Griskevicius**, argue that luxury consumers communicate status signals not only to others, but also to themselves. Four studies show how luxury consumption leads to consumers' own inferences of status, which induces them to behave more selfishly (studies 1 and 2), and, under certain conditions, more altruistically (studies 3 and 4). The second paper by **Sarial-Abi, Vohs, Hamilton, and Ulqinaku** also explores self-signaling through the lens of vintage consumption. Specifically, the authors identify one driver of consumers' preferences for vintage products: intertemporal connections (i.e. the desire to connect the past with the present and the future). Specifically, the authors examine the relationship between intertemporal connections and vintage consumption, showing that death awareness leads people to prefer vintage

products to modern products. The third paper, by **Townsend, Ward, and Nowlan**, also examines vintage consumption and suggests that products do not have to be from luxury brands in order to effectively signal status. In fact, the authors suggest that, unlike luxury, vintage consumption signals status in the form of fashion expertise, which is distinct from financial status. In line with this framework, study 3 manipulates fashion confidence to show that non-vintage consumers can be induced to prefer vintage products when their fashion confidence is increased. Lastly, **Ma, Hamilton, and Chernev** incorporate insights from consumer signaling theory to identify a factor that moderates the effect of product usage frequency on consumer judgments. Contrasting lifestyle and functional brands, the authors show across multiple studies that consumers are willing to pay more for lifestyle brands when their perceived usage frequency is lower; however this effect is reversed for functional brands.

In sum, these four papers advance our understanding of consumer signaling by providing insights into the motivations and consequences of symbolic consumption in the fashion domain. Importantly, the research presented in this session implicates tangible opportunities for marketers in fashion-related domains. As such, this session truly reflects the spirit of ACR's theme this year by advancing the connection between tenets of consumer psychology and marketing outcomes. This session incorporates a wide range of topics, including consumer signaling, luxury consumption, vintage consumption, and status-seeking behavior, thus we expect it to appeal to a diverse audience.

The Devil Wears Prada? How Luxury Consumption Influences Social Behaviors

EXTENDED ABSTRACT

Luxury consumption is skyrocketing and mounting to as much as \$525 billion per year in the United States alone (Bev and Zolenski 2011). When millions of people are using luxury products every day, what are the consequences of such consumption?

Surprisingly, with sufficient research in the luxury area, we still know very little to answer the questions raised above. Past research has examined people's attitudes, preferences, and motivations for acquiring luxury goods (Berger and Ward 2010; Han, Nunes, and Dreze 2010; Rucker, Galinsky, and Dubois 2012; Wang and Griskevicius 2014), leaving a blank for what happens to people when they actually use them. We investigate how luxury consumption influences psychology and behavior. We propose that the experience of using a luxury product boosts people's perceptions of social status and therefore it triggers self-interested behavior such as taking more resources for the self and becoming more willing to cut in line. In addition, we identify a theoretically-derived condition that reverses the negative effects of luxury consumption: it can lead people to behave in a self-interested manner by giving more to others, but only under specific conditions. Four experiments test these hypotheses.

In study 1, female participants (N=72) first walked around a busy area wearing either a luxury (Prada, retail price \$1890) or a non-luxury handbag (retail price \$75) for about 15 minutes. Afterwards, they were presented with an opportunity to behave in a self-interested manner. The first measure was based on the notion of selfishly taking the last desirable item from a group's common resources. The result indicated that people who wore the Prada handbag were far more likely to take the last desirable pen from com-

munal pen box compared to the control condition (61.8% vs. 30.3%; $\chi^2(1) = 6.67, p = .01$). The second measure involved willingness to share resources with another person. We found that participants in the luxury condition gave significantly more money to themselves than control condition ($M = \$7.44$ vs. $\$6.69; p = .02$).

Study 2 sought to conceptually replicate and extend the findings from study 1, and tested the psychological mechanism. Women ($N=42$) once again walked around campus with either a luxury or a non-luxury handbag. To assess whether wearing the handbag influenced people's perceptions of social status, participants filled out a short survey during their consumption experience. Embedded in this survey were items that measured participants' perceptions of their current level of social status. Finally, we examined women's self-interested behaviors across different situations such as cutting in line in a coffee shop and speeding ahead to get a parking space while another car is waiting for it. Responses to the four situations were averaged to form a selfish behavior index ($\alpha = .73$). Findings showed that participants in the luxury condition were significantly more likely to behave in a selfish manner than control condition ($M = 5.65$ vs. $4.24, p = .008$). Furthermore, a 10,000 resample bootstrap revealed a significant indirect effect of type of product on selfish behavioral intentions via sense of social status, $b = -.53$ ($SE = .32$), 95% CI [-1.38, -.06].

Although higher status is often associated with taking more for the self, it should be associated with acting in a generous manner when the behavior affords an opportunity to gain more status (Griskevicius, Tybur, and Van den Bergh 2010). Therefore, we predict that using a luxury (vs. non-luxury) product should make people more willing to donate money to charity in a public context. However, when there is no opportunity to display being helpful to others, luxury (vs. non-luxury) users will revert to selfish behaviors, which should result in donating less money to charity. Study 3 (2 (product type: luxury vs. control) by 2 (donation context: public vs. private) between-subjects designed) tested this hypothesis. The results showed that in the private context, women donated *less* money to charity in the luxury condition versus the control condition ($M = \$2.94$ vs. $\$3.93, p = .05$). However, in public, women donated *more* money to charity in the luxury condition compared to the control condition ($M = \$4.63$ vs. $\$3.20, p = .027$).

Study 4 sought to "turn off" the effect of luxury consumption by considering a situation in which luxury products should not influence social behavior – when other people have similar products, luxury consumption should not effectively increase social status. To do so, in one of the conditions (luxury *without status boost*), we placed multiple Burberry products (e.g., umbrella, wallet, tote bag) along the route where these participants walked while wearing the Burberry scarf around campus. We found that women in the luxury condition donated significantly more money to charity than women in the control condition ($M = \$4.35$ vs. $\$3.47; p = .047$). Thus, replicating the novel finding from study 3, women wearing a Burberry scarf became more charitable when they had an opportunity to donate in public. By contrast, wearing the same luxury scarf had no effect on donations when the luxury product did not enhance status. There was no difference in donations in the luxury *without status boost* condition and the control condition ($M = \$3.38$ vs. $\$3.35; p = .84$). Finally, perceived social status once again statistically mediated the effects ($b = .24$ ($SE = .13$), 95% CI [.04, .61]).

This research makes several important contributions. First, these studies are the first to examine the psychological and behavioral consequences of luxury consumption. Rather than measuring pre-purchase desires, our experimental approach involves actual use of luxury products and observations of behavior triggered by using

these products. Second, we show that luxury goods have an impact that goes beyond the luxury user alone, whereas prior work on luxury consumption has examined well-being from the standpoint of the consumer. Finally, this research contributes by showing that the social costs of luxury consumption are not inevitable. Instead, we show that under the right conditions the use of luxury products can spur behavior that benefits other people.

New Wine in Old Bottles: Vintage Consumption, Death Awareness, and the Desire to Connect the Past, Present, and Future

EXTENDED ABSTRACT

Why would anyone want old products, especially old products not even a part of one's own personal history? The concept of new has a special place in people's minds and preferences, a novelty preference that starts in infancy (Roder, Bushnell, and Sasseville 2000). The existence and value of vintage products stands in contrast to the deeply ingrained motivation for that which is new, suggesting that there are powerful motivations that give rise to a desire for that which is old. This paper investigated death cues as one such motivation.

The etymology of the word "vintage" comes from wine making, describing the year and location in which a particular wine was made. Now the term is applied to clothing, accessories, furniture, cars, and other artifacts from an earlier era. Within fashion circles, items between 20 and 100 years old are generally considered vintage (items older than this tend to be viewed as "antiques," Bardey and Cogliantry 2002; Cervellon et al. 2012). The term is especially applicable to items seen as emblematic or representative of a particular time period. For the purposes of this research, we limited our consideration to items more than 20 years old, previously owned, and in good, working condition (Veenstra and Kuipers 2013).

Vintage items, as pieces that have stood the test of time, represent the continuity of existence. We argue that this physical blending of elements from different times means that vintage items need not be merely evocative of the past, but instead can be symbolic of the connections across time. This notion led us to propose that vintage items can be viewed by consumers as meeting the need of perceiving connections among the past, present, and future. To be sure, a need to perceive intertemporal connectedness is not always active for consumers. We posited that one situation that stimulates it is thoughts about death.

According to the Meaning Maintenance Model (Heine Proulx and Vohs 2006), when meaning frameworks are perturbed, people seek to reassert meaning by finding, affirming, and reinforcing meaning in some other domain. Meaning challenges come in a host of forms. Hampered agency, social ostracism, and lacking knowledge are known meaning threats (Proulx et al. 2010). Death encompasses all of those — and more — and as such is probably the biggest, most pressing meaning challenge that people experience.

Responses to meaning threats likewise come in many forms. We proposed a new salve to the meaning challenge posed by death: bolstering perceptions of intertemporal connections. We posited that when death is salient, meaning that when time is perceived to be ending, facilitating intertemporal connections can represent symbolic connections across time and can be a way to cope with threats to meaning.

The proposition that thoughts about intertemporal connectedness mark attempts to see life as being meaningful is supported by recent empirical work. Seeing one's life as meaningful is one strategy that people can use to ward off the meaning threats associated

with death (Bassett and Connelly 2011), and the extent to which people reported that their thoughts were centered not only on the past but also the past and future predicted the degree to which they said their lives were meaningful (Baumeister et al. 2013). Hence our proposition that death cues arouse a need to quell a meaning threat, a need that vintage goods help to address due to aiding perceptions of temporal interconnectedness. That is, we posited that thoughts about temporal connectedness would account for preferences for vintage items caused by a reminder of one's own eventual death.

In summary, we predicted that reminders of death would lead to increased preference for vintage goods, relative to conditions where a person's mortality is not made accessible. We further predicted that this preference for vintage goods would be driven by an increased desire to perceive of time as interconnected following a death reminder.

We tested our predictions in five studies. The first study tested whether reminders of death altered people's liking of vintage products, relative to participants who did not receive a death reminder. The second study had a similar aim, this time taking our investigation to the field. Elderly residents of a nursing home indicated their liking of both vintage and non-vintage (modern) products. Mortality awareness was inferred based on an assessment of residents' physical health.

The third study tested the consequences of associating oneself with vintage goods after a death reminder. This study addressed the question of whether vintage goods can serve as an effective meaning maintenance tool by measuring differences in need for structure after associating with vintage goods (Thompson, Naccarato and Parker 1989).

The fourth and fifth studies tested the proposed mechanism. Study 4 investigated whether thinking about time being interconnected mediated the effect of mortality reminders on preference for vintage items. The fifth study provided an additional test of mediation by thoughts about time's connectedness, and used a novel behavioral indicator of preference for vintage goods. Participants were encouraged to handle vintage and non-vintage clothing items and accessories. Duration spent touching the items while looking at themselves in a mirror was the behavioral indicator of preference.

Vintage goods can appeal to customers for a variety of reasons, from relatively low prices to a sense of authenticity. We investigated the possibility that vintage goods can serve the psychological need to perceive time as interconnected. We argued (and found) that this desire increases after a death reminder. As a result, the preference for vintage goods increases when a consumer's mortality is salient.

Evidence for this effect was robust across different death reminder tasks (studies 1, 3, 4, and 5) as well as the proxy variable of physical ailments among an elderly population (study 2). We twice found evidence in support of mediation. Cuing people to think about death led their thoughts to attempt to integrate the past, present, and future, and the extent to which that happened predicted their preference for vintage items.

Don't Go Broke...Go Back in Time: Vintage, an alternative status symbol

EXTENDED ABSTRACT

Traditionally, social scientists have discussed luxury consumption as a way for consumers to signal social status (Bagwell and Bernheim 1996; Levy 1959; Veblen 1899). However, as consumers have increasing access to luxury products as well as recent market developments including cross-shopping (Skallerud and Korneliusen 2009) and the proliferation of counterfeit products (Gentry, Pu-

trevu, and Shultz 2006), displaying luxury products has become a less diagnostic signal of wealth, prestige, and connoisseurship. In response consumers have found other ways to signal status, such as through 'conspicuous conservation' (Griskevicius et al. 2010; Sexton and Sexton 2011), non-conforming behaviors (Bellezza, Gino, and Keinan 2014), and even the intentional targeting of non-luxury products (Geiger-Oneta et al. 2013). The present research identifies the consumption of vintage products—products from an earlier era that reflect the style of that era—as another such form of signaling. While prior research has linked vintage purchases with uniqueness and nostalgia (Carvellon et al 2012; Loveland et al 2010), consumer research has not fully investigated its social meaning nor the processes that underlie its social consumption. Drawing from perspectives in signaling theory, this work explores the similarities and differences between vintage and luxury products, and posits that, in contrast to luxury, vintage offers a stronger signal of area-specific (fashion) cultural capital. It follows that confidence in one's fashion knowledge is a key distinguishing factor between consumers of the two.

While luxury products traditionally signal financial wealth, recent research has identified ways in which consumers take more nuanced approaches to status signaling. In these cases, status is implied through the potential social costs to the consumer, rather than the monetary cost of the product involved. For example, Bellezza, Gino, and Keinan (2014) suggest that nonconforming behaviors are costly and visible signals that can increase perceptions of status. Berger and Ward (2010) show that consumers with more cultural capital prefer subtle signals of luxury to loud ones, despite the fact that fewer people will interpret them as status symbols. We argue that vintage products are unique as price alone does not reflect their desirability. As such, they pose a similar social cost to potential consumers, namely, when making a vintage purchase, a consumer cannot rely solely on trends or price to discern what is fashionable and what is not. In this sense, vintage purchases require expertise that is not necessarily required when selecting luxury purchases. It follows that, while less broadly appreciated, vintage offers a signal, not of status or wealth, but of area-specific (fashion) cultural capital. This suggests, that while vintage and luxury purchasers may share an interest and appreciation for fashion, vintage purchasers will feel more confident in their area-specific cultural capital.

Before investigating what drives consumers to prefer vintage products, we first explored how vintage consumers are perceived by others. In study 1 participants read a paragraph describing a woman in a public, everyday scenario and gave their evaluation of her. Depending on the condition, the woman was described as sporting either vintage, luxury, or undescribed (control) accessories. Consistent with theories suggesting that people consume as a means of communicating identity (Belk 1988; Berger and Heath 2007), our results show that both vintage and luxury consumers are perceived as interested in fashion, but that they differ with respect to their perceived uniqueness and affinity for taking fashion risks. Specifically, when described with vintage accessories the woman was perceived as more unique and more likely to take fashion risks than the woman in both of the other two conditions. Not surprisingly, when described with luxury accessories she was rated as wealthier, more status-seeking, more attention-seeking, and less humble than the woman in both of the other two conditions.

Verifying the differences in perceptions of vintage and luxury buyers found in Study 1, Study 2 provided evidence for differences in fashion confidence between actual vintage and luxury consumers. The participants (a group targeted for their fashion expertise) were asked about their clothing purchase habits and also answered

questions measuring their fashion confidence. Vintage purchase was positively correlated with fashion confidence ($r(125) = .46$ $p < .001$), while luxury purchase was negatively correlated with fashion confidence ($r(125) = -.19$ $p = .03$).

Next, in Study 3 we further investigated the differential drivers of vintage versus luxury purchase, and sought to increase non-vintage consumers' evaluations of vintage products. Specifically, we examined the role of fashion confidence by manipulating this variable by asking participants to consider their own fashion knowledge relative to an upward or a downward comparison (Collins 1996). Results indicated that non-vintage consumers who were made to feel more confident were more likely to select a vintage luxury product over an equivalent luxury non-vintage one, but only for relatively high income consumers. The moderating effect of household income highlights the fact that vintage is a status signaling alternative particularly for consumers who otherwise can afford luxury products.

Planned studies include examination of how desire for uniqueness also differentiates vintage from luxury purchases. Then building on both the fashion confidence and uniqueness differentiators of vintage, we will explore how marketing techniques signaling popularity (e.g. "best-selling") versus scarcity (e.g. limited time offers) differentially appeal to these different audiences.

This research contributes to the literature on how consumers select new identity signals as the traditional identity markers (e.g. luxury products) lose their ability to differentiate due to their ubiquity in the marketplace. Further, we offer the perspective that individuals might turn to more costly signals even at the expense of the positivity with which they are perceived by others.

The Impact of Usage Frequency on Lifestyle Branding

EXTENDED ABSTRACT

To increase sales, companies often promote product usage by encouraging individuals to consume their products more frequently and across different usage occasions (Wansink and Ray 1996). The underlying conventional wisdom is that more product usage gives consumers greater utility than less product usage. The logic of this argument is supported by economic theory, which argues that a greater number of usage occasions enhances consumers' willingness to pay (Marshall 2004). In this research, we challenge the universal validity of this approach and argue that under certain circumstances consumer willingness to pay can be enhanced by decreasing rather than increasing the number of usage occasions. We differentiate between two types of brands—functional and lifestyle—and argue that the type of brand influences the impact of varying product usage on willingness to pay.

In this context, we argue that limiting usage is likely to decrease willingness to pay only for brands that are high on functional attributes and that in the case of lifestyle brands this effect is reversed, such that limiting usage can increase rather than decrease willingness to pay. Our reasoning builds on the notion that consumers use brands to express their identity (Belk 1988; Fournier 1998) and that they are more likely to do so with lifestyle rather than functional brands. Specifically, we argue that in the case of lifestyle brands limiting usage frequency makes each usage occasion more special, which, in turn, increases customers' willingness to pay. This argument implies that consumers rely on usage frequency to determine the value of self-expressive brands, and that their willingness to pay increases with the decrease in the number of usage occasions. We attribute this effect to the self-expressive nature of lifestyle brands and predict that in the case of functional brands restricting usage frequency will have the opposite effect, decreasing rather than in-

creasing customers' willingness to pay. We tested this prediction in a series of four experiments.

Study 1

Study 1 provides evidence that limiting usage can enhance product value when the brand is lifestyle rather than functional. Specifically, this experiment examines the impact of usage on product value for either a functional brand (GAP) or a lifestyle brand (Victoria's Secret). We show that limiting the usage frequency of the functional brand decreases consumers' valuation of this brand (e.g., consumers were willing to pay less for GAP sleepwear that they could wear only twice a month as opposed to every day). In contrast, limiting the usage frequency of the lifestyle brand increases consumers' valuation (e.g., consumers were willing to pay more for Victoria's Secret sleepwear that they could wear only twice a month as opposed to every day).

Study 2

To support our proposition that the impact of varying product usage on product valuation is a function of the self-expressive nature of the underlying brands rather than other differences associated with different brands, Study 2 shows that positioning the same brand as functional vs. lifestyle can also switch the impact of usage on product value. Specifically, we show that when the positioning of a T-shirt brand centers on its comfortableness, limiting the usage of this brand to only once a week as opposed to every day significantly decreases consumers' willingness to pay for this brand. In contrast, when the positioning of this T-shirt brand centers on its self-designed features, limiting the usage of this brand to only once a week as opposed to every day significantly increases consumers' willingness to pay for this brand. This supports the proposition that the impact of usage on product valuation depends on the brand's self-expressiveness.

Studies 3 and 4

Studies 3 and 4 further examine the role of self-expression when usage is limited by comparing its effect on product valuation across consumers with high and low self-expressive needs. These experiments build on the notion that if the impact of usage on product value depends on the self-expressiveness of the brand, this effect should be stronger for individuals with a high need to self-express rather than a low need to self-express. In this context, **Study 3** shows that consumers with a chronically high self-expressive need, rather than a low self-expressive need, exhibit increased valuation of their favorite items from their most self-relevant brands when usage is limited as opposed to unlimited. Following this line of reasoning, **Study 4** shows that increasing consumers' need for self-expression increases their willingness to pay for lifestyle brands and that this effect is more pronounced when usage frequency is limited.

The findings from these four experiments provide convergent evidence that limiting usage frequency can have a differential impact on lifestyle versus functional brands, decreasing valuation of functional brands while increasing valuation of lifestyle brands.

Monica Wadhwa, INSEAD, Singapore
Amitava Chattopadhyay, INSEAD, Singapore

SESSION OVERVIEW

Indulgent behaviors are tempting because of their instant hedonic benefits, but carry with them the potential for delayed costs (Hoch and Loewenstein 1991). Much recent research has studied the factors that determine consumers' preferences for indulgent or hedonic consumption when they have conflicting long-term self-control goals and short-term desires (Laran 2010). The four papers in this session seek to extend the study of these problems from the one-off decisions which have been the focus of much of the literature, to the dynamics of indulgence within specific consumption episodes and goal-directed behaviors.

In the first paper, Oh, Huh, and Mukhopadhyay examine how the effect of nutrition information provided for entrées that consumers choose amongst can influence either their choice of entrée or their subsequent dessert consumption decision. Consistent with the emerging literature, when nutrition information is available (vs. not) for the initial entrée choice, it has no effect on whether consumers choose an indulgent (vs. healthy) option. However, there is a carry-over effect for restrained eaters, such that indulgent dessert consumption is indeed reduced.

In the second paper, Xu, Jin, and Zhang show that in order to manage motivation, consumers strategically exploit indulgent consumption opportunities over the course of goal pursuit. Before (after) attaining a focal goal, highly motivated consumers show higher (lower) preference for indulgent rewards that dampen their chronicle goal. This result suggests that consumers' preferences for indulgent consumption are affected systematically by their statuses during specific instances of goal-directed behavior.

In the third paper, Mead, Scott, and Hardesty then extend the discussion to the malleability of consumption episodes themselves, by asking how to reduce satiation from an ongoing experience (e.g., music) that can be either indulgent or virtuous. When consumers anticipate high (vs. low) variety in consumption, they satiate more slowly to a current consumption experience due to lowered negative affect. This effect is more pronounced for indulgent (vs. virtuous)

experiences, and among consumers with high (vs. low) emotional intelligence.

Finally, Kim, Wadhwa, and Chattopadhyay then broaden the investigation across consumption episodes by introducing the construct of subjective busyness. Results of lab and field experiments demonstrate that when subjective busyness is made salient, people are less likely to choose indulgent options. This effect occurs because people perceive themselves as important when being exposed to busyness appeals.

Considering the importance of indulgent and hedonic consumption in consumer research, and the diverse perspectives taken by four papers, we believe this session will attract audiences from diverse background including, but not limited to, hedonic consumption, motivation and well-being. Together, the four papers shed light on consumers' decision processes for indulgent consumption: these decisions depend upon stimulus-relevant information (papers 1 and 3) and self-relevant information (papers 2 and 4), whether consumption episodes are clearly-defined (papers 1 and 2) or not (papers 3 and 4). Together, this proposed session furthers the boundaries of a very much discussed in consumer research and raises a question of how researchers can broaden this area beyond conventional perspectives.

The Influence of Nutrition Information on Sequential Consumption Decisions for Indulgent Food

EXTENDED ABSTRACT

Prior research has shown mixed evidence regarding the effectiveness of providing calorie information to facilitate healthy food consumption (Bollinger et al. 2011; Downs et al. 2013). However, it is possible that consumers may change their subsequent consumption as a result of having nutrition information about what they just ate. In this research, we investigate whether the provision of nutrition information can have an influence either on an initial food choice (e.g., entrée), or a subsequent indulgent food consumption (i.e., dessert). We propose that restrained (vs. unrestrained) eaters tend to have smaller mental budgets for calories, and hence they should reduce subsequent consumption of indulgent food after having made a high-calorie unhealthy choice.

In a pretest, participants were categorized as either restrained or unrestrained eaters using the restrained eating scale (Herman and Polivy 1980; median-splitting is standard practice for this scale). We found that 58% of restrained eaters set calorie budgets but only 20% of unrestrained eaters did ($p < .01$). Moreover, restrained eaters set a smaller daily calorie budget ($M = 1,580$) than unrestrained eaters ($M = 1,998$; $p = .01$). These results suggest that restrained eaters have a tight budget that restricts themselves from further consumption if they had used up a large amount previously.

Study 1 examined how nutrition information provided for entrees influences either their choice of entrée or their subsequent dessert consumption. We used a 2 (nutrition information: absent vs. present) X 2 (restrained vs. unrestrained eaters) between-subjects design. Participants made a choice between a steak and a salad, with only half receiving nutrition information. All participants then rated the healthfulness and tastiness of both options, and estimated/recalled their caloric values. Then, they indicated how much ice cream they wanted to eat for dessert (0 – 100 scale). The choice of healthy food at time 1 (T1) was not affected by either nutrition information or restrained eating tendency. However, at time 2 (T2) there was a

significant three-way interaction between nutrition information, T1 choice and restrained eating on the consumption decision ($p < .05$). Only restrained eaters reduced T2 indulgent consumption after making an unhealthy choice at T1 as a result of nutrition information provision ($p < .01$). In contrast, making a healthy choice at T1 did not affect subsequent indulgence at T2.

Study 2 adopted the same design as study 1 to test whether the observed effect occurs when nutrition information is not salient at the T2 decision. The procedure was the same as in study 1 except that participants did not rate healthfulness, tastiness or calorie estimate/recall before the T2 decision. The T1 choice pattern remained the same as in study 1. However, unlike study 1, restrained eaters at T2 did not adjust consumption of indulgent food in the presence (vs. absence) of nutrition information (*ns.*). The results of studies 1 and 2 together suggest that nutrition information can have a prolonged effect on subsequent indulgence among restrained eaters, but the salience of nutrition information is necessary.

Study 3 aimed to test restrained eaters' use of small mental calorie budget in the presence of nutrition information. We employed the same design as Study 1 except that we added one more manipulated condition where participants were given a budget reference (e.g., average daily calorie intake of US population) along with nutrition information. Because the average calorie intake was higher (2,000 – 2,500) than their own range observed in our pretest ($M_{LowerBound} = 1,282$, $M_{UpperBound} = 1,899$), restrained eaters should not regulate themselves after having chosen a high-calorie option at T1. Consistent with study 1, the results replicated the interactive effect of nutrition information x T1 choice x eating restraint in that providing only nutrition information significantly reduced subsequent ice cream consumption among restrained eaters after an unhealthy food choice ($ps < .05$). However, providing average daily calorie intake information did not decrease subsequent consumption among restrained eaters compared to control after an unhealthy choice ($F < 1$).

The results so far showed that when consumers freely choose between unhealthy and healthy food (at T1), providing nutrition information does not influence on this choice but subsequent indulgence at T2 among restrain eaters. But what if the choice at T1 is imposed, rather than freely made? This is an important question as there have been increasing efforts to force healthier food consumption (e.g., Smart Snack provision of Hunger-Free Kids Act of 2010 in the US). Thus in study 4, we examined whether the prolonged effect of nutrition information still holds when the choice at T1 is imposed.

Study 4 employed a 2 (nutrition information: absent vs. present) X 2 (imposed food choice: unhealthy vs. healthy) X 2 (restrained vs. unrestrained eaters) between-subjects design. The study procedure and methods were identical to study 1 except that here we randomly assigned T1 choice to participants. Then, they indicated ice cream consumption as before. Surprisingly, regardless of eating restraint, there was an interaction only between nutrition information and prior food choice ($p = .01$). Participants who had been imposed with a healthy (vs. unhealthy) food increased subsequent consumption when no nutrition information had been provided for their imposed choice options ($p < .05$). However, when nutrition information for the imposed choice options had been provided (vs. not), those who had been imposed with a healthy food reduced subsequent indulgence ($p < .01$). The results suggest that although imposing a healthy choice backfires by increasing subsequent indulgent consumption regardless of eating restraint, providing nutrition information successfully undoes the backfire effect of imposing healthy choice.

To summarize, we demonstrate that although providing nutrition information has no effect on initial choice, it has positive prolonged effects on subsequent consumption decisions. Nutrition in-

formation provision helps restrained eaters to reduce indulgent food consumption at T2 after choosing an unhealthy option at T1 (studies 1 and 3). However, such effects are attenuated when nutrition information is not salient (study 2) and when an external reference for mental budget is provided (study 3). When a choice is imposed, providing nutrition information successfully eliminates backfire effects of imposing healthy food on subsequent indulgences.

Preference Reversal of Indulgent Rewards as A Dynamic Self-Control Mechanism

EXTENDED ABSTRACT

Consumers often set up an indulgent reward to motivate themselves to better pursue a goal. For example, researchers often think of luxurious trips to reward themselves for a semester's tough work when schools get really busy, and students make plans to indulge on a nice dinner when pulling those drowsy all-nighters in the library for exams. These incentives, however, often end up not being realized once people successfully attain the goals. Researchers might prefer to rest and finish up the unfinished reviews when semester actually ends, and students might realize that a better use of the money is to save up for the school supplies for next semester.

A large body of research has documented how people use incentives to motivate their goal pursuit and the effectiveness of these incentives (e.g., Cameron and Pierce 1994). In these works, the incentives are often treated as an external reward that individuals spontaneously choose to help them achieve important life goals. What remains relatively unclear, however, is how people choose these incentives and, once they help people achieve their goals, whether and how these incentives are consumed. In the present research, we propose a dynamic self-control mechanism that specifically examines the choice of indulgent rewards when people try to resolve self-control conflicts, and role of these incentives once the conflicts are resolved.

Drawing from the literature in multiple goal pursuit (Dhar and Simonson 1999; Kruglanski 2006), we define focal goals as goals that people are actively pursuing at the moment, and chronic goals as goals that are temporally neglected during the focal pursuit. We propose that because the pursuit of focal goals temporarily suppresses chronic goals into the background, indulgent options that violate the chronic goals would appear particularly appealing as the incentive for the accomplishment of the focal goal. However, once the focal goal is attained, chronic goals become prominent and focal, the appeal of these chosen options, ironically, decreases quickly. Four studies in two self-regulatory domains (dieting and academic) demonstrated the preference of indulgent rewards that undermine chronic goals reverses as the goal priority shifts.

Study 1 used a focal goal status (active vs. completed) x dieting goal (weak vs. strong) mixed design. Participants were asked to choose a reward (ice cream vs. movie) either in the midway or in the end of a prolonged survey. When the focal task was ongoing, greater commitment to the goal of being slim, ironically, increased the likelihood that people chose ice cream as their reward for completing the more urgent goal in hand ($\beta = 0.31$, Wald $\chi^2(1) = 4.09$, $p < .05$). However, once the focal goal was attained, the dieting goal negatively predicted the choice rate for the ice cream coupon ($\beta = -0.39$, Wald $\chi^2(1) = 4.84$, $p < .05$), suggesting a clear self-control pattern.

Study 2 tested for the observed effect using a within-subject design. Participants were first asked to choose a reward (Karaoke or food) in the middle of a number reduction task, and offered another chance to revise their choice after completing the task. The

results replicated the previous findings. Interestingly, the more the participants concerned about academic pressure, the more likely they would choose a time-wasting Karaoke coupon first and then changed their minds in the end, $\beta = 0.91$, Wald $\chi^2(1) = 8.48$, $p < .01$.

Study 3 tested the preference reversal for a Karaoke coupon either before the task began or when the task was ongoing. When the focal goal was not initiated, the greater one wanted to study the less likely he or she would choose a coupon for Karaoke ($\beta = -0.58$, Wald $\chi^2(1) = 4.68$, $p < .05$). However, when the focal goal was ongoing, a strong academic goal, ironically, increased the likelihood that people chose Karaoke as their reward ($\beta = 0.64$, Wald $\chi^2(1) = 4.05$, $p < .05$).

Study 4 explored whether the observed preference reversal was due to the suppression of chronic goals during the focal goal pursuit. Similar to study 1, participants encountered a choice between a coupon for a tempting cheesecake (indulgent option) and an entertainment voucher either during or after the task. We then reminded half of them of the dieting goal through presenting a health (vs. geography) magazine on the desk. In the control condition, the results replicated the previous findings. However, when the chronic goal was made salient via a health magazine, the observed preference reversal disappeared. People no longer preferred a cheesecake coupon even when the focal task was ongoing (*NS*).

In conclusion, during the focal goal pursuit, consumers prefer the reward that undermines the chronic goal to better motivate the pursuit of the focal goal; whereas, after the focal goal is attained, the chronic goal rebounds, consumers avoid the indulgent reward to maintain the chronic goal. This dynamic self-control process resolves the conflicts between a focal goal and a chronic goal.

What's Next? Anticipated Consumption Variety: Borrowing Affect From the Future To Slow Satiation in the Present

EXTENDED ABSTRACT

With enough repetition, even very enjoyable experiences eventually become tiresome and unfulfilling. That is, a consumer's first Hershey's Kiss is often more enjoyable than his or her fifth due to satiation (Galak, Kruger, and Loewenstein 2013). While satiation is often regarded as an inevitable side-effect of recurrent consumption (Brickman and Campbell 1971; Redden 2008), the ability to accelerate or slow the effect remains of great interest given the implications for consumer enjoyment, repeat purchases (McAlister and Pessemier 1982), and consumption regulation (Galak et al. 2014; Redden and Haws 2013).

Prior satiation research has primarily focused on how consumers perceive and experience stimuli during an ongoing consumption experience, often related to cognitive appraisals of consumption variety or repetition. For instance, item categorization level (providing general vs. specific descriptions) (Redden 2008), attention to consumption amounts (Redden 2008; Redden and Haws 2013), and mental imagery (Larson, Redden, and Elder 2014) have each been shown to influence consumer satiation rates during a present consumption experience. However, consumers attend to more than their present consumption experiences; they also anticipate the future. Past research has demonstrated the importance of present variety on consumer satiation (Redden 2008), and that anticipated variety represents an important aspect of future consumption (Ratner and Kahn 2002). For example, consumers often ponder dessert options throughout a meal or search for a new song while listening to a play list. How does anticipating more or less variety in the future influence consumer's satiety in the present? This research examines this

question: How and why does anticipating future consumption variety accelerate or slow present consumption satiation?

Anticipated experiences can produce emotional responses similar to actually experiencing the consumption event (Holmes and Mathews 2005). As such, anticipated experiences often produce a measurable effect on a range of consumer behaviors through the affect they evoke, from self-regulation (Nenkov, Inman, and Hulland 2008) to purchase decisions (Blair and Roesch 2013; Tsiros and Hardisty 2010). Despite being a seemingly common consumer phenomenon, little is known regarding how anticipated future consumption variety, and the affect it may generate, influences consumers' satiation responses in the present. Further, the moderating roles of product indulgence and consumer emotional intelligence are investigated in this research.

Central Hypothesis. We hypothesize that during a present consumption experience, consumers who anticipate more (less) variety in a future consumption experience will satiate less (more) quickly to a present consumption experience. We furthermore hypothesize that negative affect mediates the relationship between anticipated consumption variety and satiation rate during a present consumption experience, such that anticipated consumption variety reduces the amount of negative affect consumers experience during a present consumption experience, which leads to a decreased satiation rate.

Empirical Support. Four experiments support our theorizing. To test our hypothesis, experiment 1 utilized a 2 (anticipated consumption variety: more, less) x 15 (song clip exposure) mixed factor design. Anticipated consumption variety was between-subjects and song clip exposure was within-subjects. Participants were told that the study involved two listening tasks to evaluate songs for advertisements. Participants were informed that for the *first task* they would repeatedly evaluate the same song clip 15 times (procedure adapted from Galak et al. 2009). Participants repeatedly listened to the pretested song, "Hey Ho" by the Lumineers, and rated (15 times) their enjoyment of the 20-second clip. The description of the second task was our manipulation of anticipated consumption variety. Participants were told that after the first 15x listening task, their second task would be to listen to another [similar / different] style song from a [similar / different] style artist that most college students enjoy.

A 2 (anticipated consumption variety: more, less) x 15 (song clip exposure) repeated measures ANOVA was performed on present consumption enjoyment. Results revealed the expected song clip exposure main effect; participants found the song clip less enjoyable the more they listened to it ($F(14, 1176) = 122.45$, $p < .01$). The main effect of anticipated consumption variety also significantly influenced consumption enjoyment ($F(1, 84) = 5.44$, $p < .05$). This linear trend of decreased enjoyment with repeated consumption interacted with participants' experimental condition ($F(14, 1176) = 1.71$, $p < .05$); consumers who anticipated more consumption variety in the subsequent listening task satiated more slowly than consumers who anticipated less consumption variety.

Following a similar study design, experiment 2 replicates the effects of study 2, that is, participants who anticipated more consumption variety in the subsequent listening task satiated less quickly during their first listening task ($F(14, 1862) = 1.70$, $p < .05$). Experiment 2 also demonstrates that negative affect fully mediates the relationship between anticipated consumption variety and enjoyment (time 15), [95% CI: .59 to 7.22]. Finally, this experiment shows that the effect holds above and beyond alternative explanations (e.g., variety seeking, attention to consumption).

Studies 3 and 4 reveal two important moderating effects: perception of product indulgence (study 3) and consumer emotional intelligence (study 4). These studies also use different music selec-

tions to further generalize the findings. In experiment 3, we predict and find support for the hypothesis that the effect of anticipated consumption variety on consumer satiation is magnified (attenuated) for vice (virtue) products. In experiment 4, we predict and find support for the hypothesis that the effect of anticipated consumption variety on consumer satiation is magnified (attenuated) for consumers with higher (lower) levels of emotional intelligence.

Too Busy to Lose Control: Impact of Busyness on Indulgent Consumption Behaviors

EXTENDED ABSTRACT

In the last few decades, ‘busy’ has become one of key descriptors of modern consumers as an increasing number of people report that they are busier than ever (Adam, 2013; Hochschild, 1997; Schor, 1991). Accordingly, the use of time-oriented appeals to empathize with today’s busy consumers has been growing in marketing (Gross, 2004; Gross and Sheth, 1989). For example, Apple’s popular Siri ad featuring Martin Scorsese focuses on the busy day of the celebrated director. Similarly, Dunkin’ Donut ads position their food as the real food for “busy lifestyle”. Despite an increasing number of such marketing appeals targeted at busy consumers, relatively little is understood about how such marketing appeals impact consumers. Some research examining the role of time pressure shows that time pressure leads consumers to primarily rely on affect and choose more myopic and indulgent options (Cohen, Pham and Andrade, 2008; Siemer and Reizenstein, 1998). In the context of busyness-oriented marketing appeals, therefore, this stream of research would suggest that such appeals should increase indulgent consumption behaviors.

Contrarily, we argue that busyness-oriented marketing appeals reduce indulgent consumption behaviors by making subjective busyness—thoughts of oneself as a busy person—salient. Drawing upon research suggesting a link between subjective busyness and positive self-view (Perlow, 1999; Schor, 1991), we propose that subjective busyness (hereafter, referred to as busyness) enhances one’s perception of self-importance. Since busyness also signals that one has not completed all the tasks yet, we posit that busyness would enhance self-importance without eliciting feeling of pride or achievement. Therefore, building on literature showing that enhanced view of self has positive impact on self-control (e.g., Bandura, 1989; Mischel, Shoda and Peake, 1988; Schmeichel and Vohs, 2009), we predict that busyness would reduce indulgent consumption behaviors by enhancing self-importance.

In Study1, we tested our main argument that busyness reduces indulgence in the context of ad. If our hypothesis is valid, we should observe that busyness-oriented appeals reduce desire for indulging brand (McDonald’s), but not for non-indulging brand (Subway). Busyness was manipulated by varying a tagline in the ad: ‘Good-to-go, for Busy Americans’ (busyness) vs. ‘Good-to-go, for Americans’ (control). Participants were randomly assigned to view one of four ads (McDonald’s-busyness, McDonald’s-control, Subway-busyness, Subway-control) and indicated their desire for the food on the ad on a 7-point scale. As hypothesized, desire for McDonald’s was significantly lower when busyness appeal was used ($M_{\text{busy}} = 3.21$, $SD = 2.39$) as compared to when it was not used ($M_{\text{control}} = 4.68$, $SD = 2.02$, $p < .05$), however, no such difference was found for Subway.

In Study2, we provide support for our underlying process by demonstrating a mediating role of self-importance. Participants were randomly assigned to a condition and asked to recall recent time when they were busy (vs. not-busy) and write about how they felt during that time. Subsequently, they indicated how important they feel and answered various mood and arousal measures. Finally, they

completed a delayed discounting task adapted from Thaler (1981). Since myopic view is linked to indulgence, if our hypothesis is correct, we should observe participants in the busy condition to discount less. As predicted, participants in the busy condition reported feeling more important, and discounted future value less as compared to those in the not-busy condition. More importantly, a bootstrap analysis revealed a significant mediation by feeling of self-importance on discounting rate ($CI_{\text{lower-bound}} = -1.89$, $CI_{\text{upper-bound}} = -.03$). No difference was found on mood and arousal measures.

In Study3, we provide further support for the underlying process by demonstrating that negative impact of busyness on indulgence is attenuated when self-importance is dampened in an intervening task. Summer students were recruited and randomly assigned to one of four conditions (busyness: salient vs. not x self-importance: dampened vs. not-dampened). Participants in the busyness-salient (busyness-not salient) condition were told that a recent study we’ve conducted revealed that students who stay on campus during summer are busier (tend to engage in different activities) than students who leave campus and asked to write two or three things that keep them busy (they do). The next question asked participants to think about how many people in their lives consider them an important person and indicate their answer on either a scale that ranged from 1-5 (not-dampened) or 10-50 (dampened). This manipulation was based on the logic that responding toward the top or the bottom of a scale could lead responders to make corresponding inferences about themselves (Schwarz, 1999). Therefore, participants responding on the 10-50 scale should feel less important, and the feeling of self-importance induced by the busyness manipulation should be attenuated. Finally, participants were asked to choose between an apple (healthy option) and a brownie (indulgent option). A logistic regression revealed a significant effect of the interaction term between busyness and self-importance on the choice of snack (Wald(165) = 4.20, $p < .05$). Specifically, when busyness was made salient, a significantly higher percentage (65%) of participants chose an apple, compared to when busyness (38%) was not made salient. This effect of busyness appeal was attenuated when the self-importance was dampened in an intervening task.

Finally, in a field study that lasted over three weeks at a main dining hall of a large university, we found that making busyness salient in the environment reduced the percentage of fat calories taken compared to when busyness was not salient. In sum, we provide a converging support for our argument that busyness reduces indulgent consumption behaviors by enhancing perception of self-importance.

SESSION OVERVIEW

The rise of the sharing economy is discussed in the popular press as a significant social and economic trend (Botsman and Rogers 2010; Gansky 2010). Within consumer research, recent work examines the emergence of a gift economy within the Napster community (Giesler 2006) and temporary communities forming around collaborative gifting and generalized exchange at the Burning Man Festival (Kozinets 2002). But other research suggests that forging commercial sharing models of exchange, such as Zipcar, do not always facilitate the development of community or feelings of social integration (Bardhi and Eckhardt 2012).

In this session, we seek to broaden and deepen our theoretical understanding of the sharing economy. All of the presentations in this special session are devoted to understanding the emergence of successful systems of sharing as well as key impediments. These studies span commercial, nonprofit, and governmental sharing systems and draw on diverse methods including case study, survey, experiments, and field research. All of the presentations present new theoretical insights grounded on empirical data such as exploring the role of emotion in sharing, trades-offs between individual and collective goals, and the darker side of sharing. Several of the papers delve into a domain that has received scant attention--cooperative pooling, which is a form of sharing where consumers combine resources that are redistributed based on need (e.g., a blood bank).

First, Giesler, Veresiu, and Siebert draw on a rich case study of the controversial ride-share system Uber. They adopt a more managerial perspective providing concrete advice on managing tensions among different stakeholders with opposing interests. Foregrounding the role of empathy, they articulate four theoretical processes for legitimizing sharing markets offering guidance on the strategic use of emotions for redesigning institutional networks.

Second, Lambertson, Rose, and Rose seek to build a broader theorization of how systems of sharing blend both utility maximization (e.g., Bardhi and Eckhardt 2012) and mutuality (e.g., Giesler 2006). Using survey and experimental data, they examine two sharing systems based on pooling of resources (i.e., a state leave pooling

system and the Affordable Care Act). They explore insights on how consumers' interests in participating in sharing systems vary across system-level attributes of individual possessiveness and mutuality.

Third, Appau, Ozanne, and Klein advance our understanding of the complexity, morality, and darker sides of a sharing system focusing on cooperative pooling (Sahlins 1972). In an ethnographic study of a Christian church community in Ghana of mostly poor members, they explore competitive and exclusionary forces at play that challenge the conventional wisdom that generalized exchange increases cohesion.

Fourth, Rose and Arnould use ethnographic data exploring consumer-to-consumer pooling as a form of resource sharing at craft beer festivals. Drawing upon a comparison of the Pacific Northwest indigenous potlatch ritual, they articulate benefits that accrue to both firms and consumers drawing upon the theory of the gift.

Designing a Sharing Economy Through the Process of Market Empathization

EXTENDED ABSTRACT

How is a sharing market created? The rise of the so-called sharing economy, "an economic model based on sharing underutilized assets from spaces to skills to stuff for monetary or non-monetary benefits" (Botsman 2013, 6; Lessig 2008; Sacks 2011) or simply stated a cooperative pooling of specific resources, is receiving considerable scholarly attention. As a construct, sharing has been theorized "as a pervasive, overlooked, and fundamental consumer behavior process" (Belk 2010, 729) that increasingly relies on online platforms and is thriving in multiple industries from transportation to education to hospitality. The entrepreneurs responsible for creating sophisticated sharing technology platforms are commonly heralded as being at the forefront of a powerful paradigm capable of stimulating the economy, fostering communities, and overall creating value (e.g., Belk 2014; Botsman and Rogers 2010; Curtis 2014; Lambertson and Rose 2012; Sacks 2011).

At the same time, however, managers of sharing technologies are often confronted with harsh criticism and resistance from important stakeholder groups, including regulators and consumers. Accordingly, prior work in marketing and consumer research is beginning to highlight the importance of effectively managing the institutional environment to enable and ensure the success of sharing businesses (e.g., Cannon and Summers 2014; Lambertson and Rose 2012). When the biggest risk for sharing firms does not emanate from technology issues or competition, but rather from stakeholders' passionate objections, understanding how sharing markets are created requires an in-depth investigation of how marketers of sharing technologies can win over multiple skeptical stakeholders.

To address these underexplored theoretical concerns, we bring sociological work on the strategic use, and shaping of, emotions in economic contexts (Hochschild 2003; Illouz 2007; Pedwell 2012) to bear on an institutional investigation of the company Uber, the leading sharing technology firm in the transportation industry. Uber's path to success nicely illustrates the controversial rise of sharing markets, and is described by co-founder and CEO Travis Kalanick as a "political race [that] is happening in every major city in the world" (Dalenberg 2014, 2), with Uber as the candidate that needs to "win." Since 2011, we have collected both online and offline data

on a discursive level (Uber-related news reports, court, and policy documents, as well as video materials, advertising, pamphlets, and worker guidelines) and a practical level (interviews with Uber management, drivers, and consumers, as well as policy makers, union representatives, legal experts, journalists) across major European and North American cities. We analyzed the complete dataset using the longitudinal hermeneutics approach (Giesler 2008; Thompson 1997).

Our findings suggest that Uber's main criticism can be organized into four distinct stakeholder groups, each with a dominant main issue: consumers with safety and privacy concerns; workers with social justice complaints; city regulators with structural integrity concerns; and journalists with accountability issues. This resistance arises from sharing markets' potential to challenge established balances between economic and social interests (e.g., justice, safety), and to shift agency and mandates from larger institutions such as unions and regulators to individual market actors.

To manage this shift, our analysis further reveals that Uber engaged in a strategic process that we call "market empathization," a fourfold process through which "a cultural good" is repositioned from the institutional domain to the domain of individual market-mediated empathy. We identify four processes that address each of the stakeholder complaints and establish a sharing market. In the first process of *humanization*, empathy is used to position (complaints against) the sharing technology away from bureaucratic, mechanistic, and rigid structures and towards more self-regulating, flexible, caring, and organic structures. In *universalization*, empathy is heralded as the true ideal through which all issues, including those of structural integrity, justice, accountability, and safety can be resolved. Third, *prototyping* refers to the education of individuals in the sharing network to act respectfully and caringly towards one another by creating role models and circulating their success stories (e.g., of empathetic consumers who are helping individual Uber drivers and their families). Last, in *contracting*, empathetic contracts with stakeholder groups are established by writing concrete policies, such as worker safety guidelines, and creating mutually beneficial partnerships, in favor of a system that prioritizes individual, self-regulating ethical conduct over formal social regulation.

This study provides both managerial and theoretical implications. The four processes of empathization equip managers with an organizational tool (e.g., Cutcher 2008; Strangleman 1999) to render sharing markets as desirable and effective to realign economic and social issues, while other demands (e.g., for protection of existing industries) are cast as undesirable. As such, we theoretically contribute to the growing literature on the sharing economy by addressing Lambertson and Rose's (2012, 123) call to "adopt a broader view of sharing systems," and by explaining the active role of marketers in sustaining the success of sharing business models over time. Second, we theoretically contribute to the literature on market creation (e.g., Humphreys 2010; Giesler 2012) by unpacking how sharing economy firms (re)design their institutional network through the strategic use of emotions.

Disambiguating Sharing Economies: How Economic Tropes Affect Attitudes

EXTENDED ABSTRACT

In keeping with recent scholarship on the matter (Arnould and Rose 2015), we maintain that the consumer responses to so-called sharing systems (Belk 2010) are a function of structural differences in the mode of resource circulation present in the various forms of these systems. Any given economy will be characterized by a blend-

ing in various proportions between two dominant tropes—possessive individualism and mutuality (Giesler 2008). The degree to which each trope is prominent in the economic system is, we argue, determinative of the nature and function of that system. Thus, researchers studying market-mediated systems such as Zipcar, the use of which is effectively a market transaction, have observed that there is little social consideration amongst users (Bardhi and Eckhardt 2012; Lambertson and Rose 2012). But given that possessive individualism is concerned predominantly with utility maximization and one-off transactions, this is unsurprising (Arnould and Rose 2015). Conversely, one could (and does) see a sense of community evolve out of online file sharing systems, and this is expected given that such systems are heavily formulated by the ideas of mutuality, which is far more socially driven than possessive individualism (Giesler 2006).

Despite several studies of the sharing economy set in very different contexts, none have yet drilled down into how these macro distinctions (i.e., in the form of the economic blending between individualism and mutuality) systematically affect behavior and beliefs of individuals within them. This is our purpose in organizing the present research. The questions motivating the work are, "What factors drive interest in participating in sharing systems, and how do those factors vary based on the degree to which sharing systems differ in two prominent system-level characteristics, possessive individualism and mutuality?"

To frame our answers to these questions, we employ gift theory and the tradition of anti-utilitarian social science to explicitly label two resource pooling contexts in terms of their blending of individualism and mutuality (Arnould and Rose 2015; Giesler 2008). Marketers, both commercial and political, can position sharing systems as emphasizing individualism or mutuality through integrated communications efforts, including public relations and paid media. We expect these system-level differences in turn to invoke different ideological positions depending on the cultural context in which the mode is deployed. In this case, we have limited our studies to the US. Thus, we would expect modes characterized more heavily by possessive individualism to be more attractive to ideological conservatives (in the contemporary American sense) while those characterized by mutuality would be the subject of antipathy, and vice-versa for ideological liberals.

We collected data that address, at the micro level, how behavior and beliefs in the various contexts are affected by those ideological prompts. For instance, in mutuality-oriented systems, social factors such as trust, fairness, and equity would likely assume greater prominence in judgment than economic self-interest; vice-versa, contexts characterized by a high degree of possessive individualism would foster a focus on utility over relationships. These distinctions may, in turn, affect the extent to which prospective or current consumers in these markets would be incentivized or de-incentivized by social factors such as the ability to designate those who may benefit from resources in the sharing pool. Our data to address these issues are based on two different contexts, marked by differences in their formulation between mutuality and individualism.

The first set of data was gleaned from a cross-sectional survey of employees in a state-managed leave sharing system of a state in the southeast US. Here, participants may donate their leave time to a shared pool that may be debited by other participants and themselves. This particular context is characterized by a moderate degree of mutuality as it is public and equitable; it is available to all in equal measure. But it is not fully so, as the anonymity present reduces the potential for sociality as a function of the gift giving (i.e., contributions to the pool).

The second set of data was collected in the wake of the Affordable Care Act (ACA) and assesses comparable issues as the first instrument. This context is a hybrid in that risk is dispersed amongst all participants via government mandate, but the system is managed by private interests (i.e., insurance firms) and is effectively a mandatory market transaction. Thus, the ACA context is one characterized by considerable ambiguity and may be particularly susceptible to propaganda intended to activate possessive individualism or mutuality.

Given the timeliness of research involving the ACA and the ubiquity of hybrid sharing systems, we then extend our survey findings by conducting two experiments in which the ACA is positioned in terms of either mutuality or possessive individualism, and measuring the effects of these variations in system-level positioning on the relative importance of social and economic factors in driving system attitudes. Thus, our expected contributions lie in addressing systematic influences of various forms of economy on the attitudes of consumers within those markets, as influenced by ideological cues. We also extend marketing and consumer research literatures on the sharing economy to new contexts involving the sharing of health and financial risks, not tangible products.

The Dark Side of Sharing: Social Exclusion within Donation Pooling

EXTENDED ABSTRACT

Generalized exchange is widely held to increase social integration (Malinowski 1920; Sahlin 1972). Contemporary examples include people donating to blood banks or consumers posting product reviews online. The indirect structure of generalized exchange, where exchange is separated in time and by different trading partners, creates opportunities for trust to develop that can help unite people (Molm 2000). One form of generalized exchange, pooling, involves individuals unilaterally giving to a common pool of resources that are redistributed later based on need (Ekeh 1974; Sahlin 1972). Although infrequently studied, consumer researchers also stress that pooling promotes social cohesion and mutuality (Arnould and Rose 2015; Gielser 2006; Kozinets 2002).

In an ethnographic study of the Salvation Baptist Church (SBC) in Ghana, we examine religious donations as a form of cooperative pooling. Data collection spanned 5 months involving participant observation and 34 interviews with 21 informants all of whom experienced poverty extreme enough that meeting basic needs was a struggle and restricting calories was a common coping strategy. Since Carol Stack's (1974) classic study, researchers stress how pooling resources is an important survival strategy of poor consumers (Hill and Stamey 1990). Extremely impoverished communities do not have resources aplenty. Instead, they have scarcity to share (Sachs 2005; Banerjee and Duflo 2011). The orientation here then is pooling "our little," rather than pooling "our lot."

We find a wide range of different logics of pooling that do inspire social integration, but also promoted competition and even social fragmentation. At SBC, we documented no fewer than 17 donation funds where money was pooled. These ranged from compulsory (e.g., tithing) to voluntary (e.g., pastor's appreciation), varied in frequency (e.g., weekly tithing, monthly funeral dues, and annual harvest fund), were requested publically (e.g., building fund) or privately (e.g., welfare fund), and ranged in meanings from secular (e.g., bus fund) to sacred (e.g., pledge fund). The logic of sharing was complex and varied. Tithing was one of the most important funds integrating members in their shared sacred duty to support the church. However, far from providing social integration, the "birth day thanksgiving fund" involved members competing to raise the

most money on their day of birth. Winners preened and everyone mocked the losers who were born on the day with the smallest contributions.

More troubling is that the very poor were excluded from funds both compulsorily and voluntarily. For example, no matter what one's donation history, if you did not pay or missed payments to the funeral fund then you were excluded from receiving benefits. Poor members were often in conflict between contributing to pools and feeding their family.

The very public nature of many of these donations was also pertinent. The church has a ritual of collection to fund the church. At all formal tri-weekly meetings, members contribute money into a bowl placed in front of the congregation. Members leave their seats by rows guided by an usher to drop their monies in the collection bowl. Members without money must remain seated marking them as unable to pay. The social stigma is so great that very poor members like Bertha will not attend when they have no money: "I will feel embarrassed if everybody is giving collection and you don't get up to give, it is very disturbing. (Bertha, F, 36).

Contributing money and the amount given is generally voluntary, except for the tithing fund, where everyone is expected to give. However, Dede offers an explanation of how failing to give can lead to scorn and exclusion.

God has protected you from Monday to Saturday, so are you trying to say you don't even have 10 pesewas [less than 1¢] on you? Even if you don't have anything on you, give 10 pesewas as collection so that God will see what He has done for you. But if you always come to church and people have to by-pass you to give their collections while you are seated, then it means you always spend the money you get without giving some to God. (Dede, 44, F)

As Dede points out, even in a group where scarcity is prevalent, it is unacceptable to have nothing to give. Scarcity is scantiness, not absence. Moreover, this specific pool is not a utilitarian redistribution system but a normative one expressing morality. When pooling transcends the secular into the sacred domain, then failure to contribute is not just wrong—it is sacrilegious. A member who is unable to contribute to the collection fund offends God, the group, and the group's very reason for existence. Thus, poor members self-exclude themselves by staying home to avoid this pooling ritual at church and its attendant stigmatization effect on non-contributors.

Our contribution is to highlight the complexity, morality, and dark sides of co-operative pooling and sharing. We provide empirical support exploring the integrative, competitive, and exclusionary influences of different pooling systems.

Strategic Implications of Consumer-To-Consumer Resource Pooling

EXTENDED ABSTRACT

We contribute to the literature on alternative modes of circulation by examining the extent to which consumer-to-consumer pooling can be deployed by small businesses as a marketing mix element. That is, we look at the manner and efficacy of affording consumers the opportunity to engage in resource pooling. Firms themselves need not be active participants in the pooling—instead, they can provide the context (or frame). We uncover the ways in which this benefits both hosting firm and participants. Thus, our research question is, "How and to what extent does providing opportunities for consumer-to-consumer pooling benefit the host firm?"

To address this question, we conducted ethnographic research at craft beer festivals. We selected ethnographic methods due to the exploratory nature of the research. We wanted to see if, and how resource pooling operated in a context, part trade show, part ludic entertainment. A deep cultural exploration of an uncharted consumer practice within an industry noted for its festivals was thus apposite.

Several reasons motivated the choice of context. The first is the growth of the industry and concomitant diversification of segments. Investigation among industry leaders, who by definition are successful, strengthens conclusions based on exploratory data. The second is that festivals are an industry hallmark. That is, firms in this sector offer festivals as element of their value proposition. In festivals, consumers come together at brewery-hosted events to share products from the host brewery, other breweries, and even homebrews. Third, all firms, as craft beer producers, conform to standard limits on production volume. This commonality strengthens the generativity of our conclusions as all firms in the segment fall into a comparable range of operational size and scope.

Five breweries were visited over two and a half years—each more than once. Each visit took place during a single brewery hosted festival. This way, multi-brewery sponsorships do not muddle firm-level attributions. At each brewery, the lead author engaged in participant observation, making jottings, collecting artifacts, and taking photos as a participant before writing up formal notes. For the sake of comparison, firms were visited in California (The Bruery), Michigan (Founders), Indiana (3 Floyds), Florida (Cigar City), and North Carolina (Foothills). The resulting dataset included nearly 400 pages of written accounts as well as photographs and artifacts.

At each festival, we observed consumers engage in “bottle shares.” In bottle sharing, consumers pool beer—setting out a diverse product array in a common space to be tasted in ritualized fashion. For analysis, we drew on the theory of the gift. This presented two key opportunities. First, the literature on the gift has an elaborate history both in social science as well as in consumer research and marketing. Still, only a few studies of gift stores have looked at how the gift economy may be leveraged—enhanced understanding will provide practical managerial tools. Second, the rise of the so-called sharing economy has garnered much attention, but contention remains as to how best to understand alternative modes of resource circulation. The theory of the gift provides a comprehensive framework that productively contributes to current debate.

Our data reveal insights for firms wishing to mobilize alternative modes of resource circulation by providing contexts for consumer pooling. First, for example, is that consumer pooling operates very much like the famous “potlatch” detailed in classic anthropology and recent consumer research. Here, the firm plays the role of Big Man as understood in gifting societies. Firms on the craft brew festive circuit reap benefits as a result of providing contexts for consumer-to-consumer gift exchange. Whereas Big Men accrued honor and prestige, craft breweries accrue brand-related boons. These include loyalty, brand ambassadorship, and active purchase intentions. This is due to a second finding of note. Consumers who engage in pooling also amass benefits beyond those related to enjoyment and accrual of brand knowledge. Pooling produces membership and identity affirmation within a brand and product community. Of note is that festivals attract both local international patronage.

To summarize, our contributions include detailing how firms may leverage the gift, how setting the context for pooling as a strategic practice is beneficial to firms, and further elucidating how an ostensible sharing-oriented phenomena can be better understood within the theory of the gift.

SESSION OVERVIEW

What drives how people speak when they talk about products? And what are the consequences of the language consumers use in word of mouth settings? While it's clear that word of mouth shapes consumer behavior (Chevalier and Mayzlin 2006; Chintagunta et al. 2013), and some work has begun to uncover behavioral drivers of word of mouth (Berger 2014), there has been less attention to the underlying role of language in these processes (cf. Moore 2012; Packard and Wooten 2013). This session integrates a variety of perspectives to shed light on how people talk about products in word of mouth and how these linguistic choices shape word of mouth's influence on people.

Packard and Berger examine the language different types of consumers use to endorse products and how this can, paradoxically, lead word of mouth recipients to make worse choices. A combination of field data and laboratory experiments show that novices tend to use stronger, more persuasive, "I recommend" endorsements than expert consumers. This, in turn, leads word of mouth recipients to follow objectively inferior recommendations. While paying for online reviews might seem like a good idea, **du Plessis and Dubois** demonstrate that it actually undermines review persuasiveness. Two experiments show that the language used in paid (vs. unpaid) reviews produces heightened recipient perceptions that the sender is uncertain about their attitudes, increasing recipients' own doubt of the product's quality and decreasing their purchase intentions. A subsequent study demonstrates that incentive size moderates the effect and that paying senders a small (versus no or large) incentive makes them more uncertain of their attitudes because they feel less legitimate.

Tohidinia and Lurie leverage linguistic theory and text analysis to derive personality profiles based on the language people use in over 65,000 online reviews. This data and subsequent lab studies show, for example, that reviews containing language evincing neuroticism are particularly valued by word of mouth recipients, while those from linguistically agreeable reviewers are less so. Finally, **Chen and Schlosser** shed light on how language use in reviews impacts the reviewer. Using logical rather than vivid language impairs subsequent product memory. Subsequent studies demonstrate that this is due to the extent to which the different writing styles impact rehearsal of the reviewer's original product experience.

Taken together, these papers offer insights highlighting the importance of new research examining *how* people talk about products. Given the increasing visibility of consumer language in online contexts, this session should appeal to a broad array of researchers, including those examining service interactions (e.g. email or live forum service), online brand communities, and social media. Beyond these directly relevant settings, ACR's information processing contingent (e.g. advertising researchers) may wish to hear about new approaches to analyzing language use at the level of the word, clause, sentence or corpus. Finally, the papers may be of interest to those interested in discovering conceptual links between language and knowledge, certainty, memory, and personality.

We hope to engage the session audience in discussion about these papers and how researchers can examine consumer behavior through linguistic analysis. The following questions are offered to this end: How can researchers link prominent theories relevant to consumer behavior to linguistic analysis? How do communication modes (oral vs. written) impact language use in word of mouth? When does the linguistic sophistication of a speaker help or hurt interpersonal persuasion? In what ways does the interaction between speaker and audience states/traits influence language use in persuasion settings?

Following the Blind: How Expertise and Endorsement Style Impact Word of Mouth Persuasion

EXTENDED ABSTRACT

Word of mouth is thought to help consumers make better choices (Berger 2014; Hennig-Thurau and Walsh 2003). Few companies will say their own products are terrible though, so relying on advertisements or company-generated communications isn't always useful. Consequently, consumers turn to others' opinions to help them select good options and avoid bad ones. But could the way consumers endorse products actually lead word of mouth recipients to make *worse* choices than they would have otherwise?

This paper examines the endorsement language consumers' use, and the consequences such language has on word of mouth recipients. Sometimes people assert their positive product evaluation by saying "I like it" while other times they might say "I recommend it." We suggest that these different "endorsement styles," or implicit versus explicit expressions of product approval (McCracken 1989), shape the persuasive impact of word of mouth. People should be more likely to choose something someone else recommended rather than liked because recommendations are expected to come from authority and signal expertise (Brodsky et al 2010; Oxford 2015; Pornpitakpan 2004).

Importantly, however, we also suggest that consumer knowledge should influence the endorsement styles people use. Less knowledgeable consumers—that is, consumers with less category experience or expertise (Alba and Hutchinson 1987) should be particularly likely to explicitly "recommend" products to others because they are less aware that others' tastes may differ from their own (i.e. preference heterogeneity; Feick & Higie 1992). Taken together, novices' tendency toward more explicit endorsements, and social perceptions of explicit endorser's heightened expertise, may lead word of mouth recipients astray. Five studies, including a mix of field data and laboratory experiments, test these predictions.

Study 1 analyzes nearly 1,000 real consumer online reviews to examine whether more experienced consumers are less likely to use explicit endorsements (e.g. “I recommend”). While more experienced consumers (+1SD in book purchase experience) explicitly recommended books only 6.5% of the time, this jumped to 35.7% among less experienced book consumers (-1SD; $p < .001$).

Study 2 tests this relationship in the lab, and examines the hypothesized mechanism behind the effect. Participants in one condition were reminded that, “people have very different preferences when it comes to this kind of hotel” to prime preference heterogeneity. All participants were then asked to write a review of a hotel they had stayed at and enjoyed. Replicating Study 1, in the no prime condition, novices (-1SD in tested hotel expertise) were significantly more likely to “recommend” the hotel ($M = 53.8%$) than experts (+1SD $M = 31.2%$; $p < .05$). Reminding participants of preference heterogeneity, however, wiped out this difference ($p = .36$).

Study 3 examines how explicit (“I recommend”) versus implicit (“I liked” or “I enjoyed”) endorsement styles impact persuasion, and the proposed mechanism (perceived expertise) underlying this effect. As predicted, a friend who provided an explicit (“I recommend it...”) restaurant endorsement was seen as more expert than an implicit (“I enjoyed it...”) endorser ($p < .05$) and led people to believe they would be more likely to choose the restaurant ($p < .001$). Bootstrap results confirm mediation of the impact of explicit endorsements on persuasion by perceptions of sender expertise (95% CI: .02, .17).

A final pair of studies uses a yoked design to test whether novices are more likely to use explicit recommendations, and whether when this is combined with their tendency to choose worse products, can lead to sub-optimal choices by word of mouth recipients.

In Study 4, we asked participants to choose between two wines. Both wines had three positive attributes, but to make one inferior we added three additional attributes pretested to be undesirable (e.g. “bottle contains clay sediment”). Experts should notice this and avoid the bad wine. However, low knowledge consumers use attribute numerosity as a cue for quality (Alba & Marmorstein 1987), and as a result should pick the inferior wine. Consistent with this expectation, novices (as measured by a wine knowledge test) were nearly twice as likely to pick the inferior wine as experts (55.3% vs. 30.3%; $p < .01$).

Next, participants were asked to imagine that they enjoyed the wine they chose, and wanted to tell others about it. They indicated whether they would be more likely to say, “I recommend” or “I liked” the chosen wine. Novices were again more likely to use strong endorsements than experts (60.9% vs. 47.3%; $p < .05$). In sum, wine novices both (1) picked an inferior product and (2) used a stronger endorsement style than experts to share their opinion about it.

Finally, in Study 5 we examined the impact of these endorsements on others’ choices. Participants were given the same wines as Study 4, but in addition to product information, half the participants (word of mouth condition) were also shown the aggregate percentage of consumers from Study 4 that “liked” or “recommended” as a summary of consumer opinion. As predicted, the word of mouth condition led to inferior choices. Compared to the product information only condition (41.9%), seeing how many others liked or recommended the wine led more people to choose the inferior wine (53.07%; $p = .02$).

This research demonstrates that how people endorse products has important—and potentially aversive—consequences for word of mouth recipients. By looking at the mismatch between the drivers of endorsement style and their impact on recipients, this paper deepens

our understanding of how and why language use impacts consumer attitudes and behaviors.

When and Why Paid Reviews are Bad Investments: The Impact of Monetary Incentives on Review Certainty

EXTENDED ABSTRACT

Many companies increasingly provide incentives to consumers for participating in advocacy programs or posting product reviews online. In a recent study, Amazon found that, of its 1,000 most active reviewers, 85% are incentivized and 92% of incentivized reviewers write reviews about the free products they received (Pinch and Kesler 2010).

How do incentives influence review effectiveness and effort? On the one hand, studies have found a significant positive correlation between incentive size and task performance (e.g. Heyman and Ariely 2004). Other works showed that people do not exert effort on a task unless it contributes to their own economic well-being (e.g. Lock et al 1980; Eisenhardt 1989; Gerhart et al 2009). A survey of top executives in different industries ($N = 23$) confirmed that 70% of them believe that paying for reviews increases review effectiveness. Taken together, these findings suggest that monetary incentives may lead to higher quality reviews. On the other hand, researchers have argued that external rewards can be ineffective (see Pfeffer 1998) possibly because incentivized reviewers invest less effort in the review writing process (e.g. Lepper et al 1973; Deci et al 1999; Gneezy and Rustichini 2000; Vansteenkiste et al 2004; Gerhart and Fang 2015). These findings suggest that monetary incentives might decrease review effectiveness.

Beyond the role of effort, this research proposes that monetary incentives can alter the content of reviews by affecting how legitimate review writers feel when generating their review. Money is a social cue which signals reward in a similar manner to praise (Izuma et al 2008; Zink et al 2008; Saxe and Haushofer 2008). Furthermore, research has shown that the social meaning of money can be transferred to the self (Vohs, Mead and Goode 2006; Vohs, Mead and Goode 2008; Yang et al 2013). As such, word-of-mouth (WOM) senders may interpret monetary incentives as social signals. Specifically, we propose that the size of the incentive can influence senders’ feelings of legitimacy and result in shifts in their expressed uncertainty. In particular, we expect that low monetary incentives can trigger low feelings of legitimacy, compared to significant monetary incentives or no incentives. In turn, because feeling legitimate is a key antecedent to certainty – the sense of conviction that one’s attitudes are correct (Rucker et al 2014) – we hypothesize that low legitimacy will induce consumers to express greater uncertainty in their reviews. We propose that when people are paid, they rely on the reward to feel legitimate. A low reward might trigger consumers to lose their feelings of legitimacy, increasing expressed uncertainty. In contrast when consumers are not given an incentive (i.e., when social cues are absent) or when monetary incentives are significant (i.e., social cues are adequate), consumers might rely on their experience, resulting in greater certainty (Rucker et al 2014).

Three experiments tested the effect of monetary incentives on the certainty expressed in review content. Importantly, across experiments, WOM receivers were blind to whether senders had been paid or not, or how much they had been paid.

In study 1, participants ($N=86$) were either paid a bonus of \$1 or no bonus to write a review about an online game. These reviews were later rated by 975 MTurkers (± 11 raters per review) on review positivity, objectivity and reviewer certainty. Random effects regression showed that unpaid WOM senders expressed more certainty in

the content of their reviews than paid WOM senders ($p < .001$). Importantly, the reviews did not differ in positivity or objectivity (all p -values $> .05$).

In study 2, 716 MTurkers were randomly presented one of the reviews from study 1 and rated how doubtful they were of the quality of the reviewed product, in addition to how uncertain they believed the reviewer was based only on the language used in the review. Random effects regression showed that people perceived paid senders to be more uncertain of their opinions than unpaid senders ($p < .05$). Importantly, paying the sender (vs. not paying) had a significant positive indirect effect on the receivers' product quality doubts through perceptions of reviewer uncertainty (95% C.I. = .01, .18). In other words, paying senders to write a review increased receivers' perceptions that senders were uncertain, based only on the language used in the review, which in turn made the receiver doubt the quality of the game.

In study 3 we test whether increasing the size of the incentive reverses the effect of incentive provision on attitude uncertainty. In addition, we also tested if legitimacy mediates the effect of providing a small incentive on attitude uncertainty. 205 Dutch students took this study in exchange for course credit and were randomly assigned to receive no payment, 10 cents or €10 as a bonus payment for writing a review. Participants were told to use a set of headphones to watch two videos, write a review of the headphones and then answer questions. We measured how uncertain people felt about the opinions they expressed in their review. Results revealed that paying a WOM sender a small (i.e., 10c) versus no or high (i.e., €0 or €10) incentive increased senders' uncertainty ($p < .05$). Senders who received a small incentive (versus no incentive or a significant incentive) also felt that their opinion was less legitimate ($p < .0001$). Moreover, legitimacy mediated the effect of receiving a small incentive on attitude uncertainty (95% C.I. = [.03, .16]). Reviewers who were paid a small incentive were more uncertain of the opinions in their review than those who did not receive an incentive or received a large incentive, because the small incentive made them feel less legitimate.

Overall, the results contribute to the literatures on incentives, WOM, and certainty. First, we demonstrate that the quality of a review may stem from feelings of legitimacy and that providing an incentive shifts the source of legitimacy from one's experience (internal) to the size of one's reward (external). Second, we contribute to a growing body of work showing that uncertainty in WOM content can decrease consumers' attitudes and purchase intentions (Dubois, Rucker and Tormala 2011). Third, we contribute to past work on consumers' certainty by documenting for the first time how monetary incentives affects consumers' certainty by affecting their feelings of legitimacy. Managerially we demonstrate how incentive size can affect the content of the review and its effectiveness.

Write and Write Alike: How Personality Affects the Value of Word of Mouth

EXTENDED ABSTRACT

Online word of mouth is considered a valuable source of information (Zhu and Zhang 2010); but not all word of mouth has an equally persuasive effect on consumers. Prior research shows that review characteristics; such as valence (Chevalier and Mayzlin 2006), length (Mudambi and Schuff 2010), product type (Forman et al. 2008; Zhu and Zhang 2010) and the presence of words indicating temporal contiguity between product experiences and review writing (Chen and Lurie 2013); affect the influence and perceived value of online reviews. However less has been done to explore whether

and how reviewer characteristics, such as personality, affect the perceived value of online word-of-mouth.

Personality influences language content and word choice (Pennebaker and King 1999). Recent research shows that personality dimensions can be successfully extracted through automated text analysis based on words used in different long text collections such as blogs, emails, or stories (Tausczik and Pennebaker 2010; Cohn et al. 2004; Yarkoni 2010). However, there have been few attempts to extract personality from a single review. Prior research has shown that dimensions of personality can have positive as well as negative effects on message persuasiveness in face-to-face settings (Oreg and Sverdlik 2014); yet little is known about the persuasive role of personality in online word-of-mouth, a setting in which cues to personality beyond language use are often absent. In addition, there has been almost no effort to examine how the match between sender and receiver personalities affects persuasion. Using secondary data as well as lab experiments, we examine how reviewer personality, as expressed through language use, affects the perceived value of online word-of-mouth. We further examine how the interaction between writer and reader personalities influences review value.

In Study 1, we utilized Linguistic Inquiry Word Count (LIWC; Pennebaker et al. 2001) to analyze over 65,000 Yelp restaurant reviews. Personality scores for each review were calculated using weights from prior research on the relationship between LIWC word categories and the Big Five personality dimensions (Schwartz et al. 2013). The relationship between expressed personality scores and word-of-mouth value was assessed through a negative binomial distribution model in which value was measured by a count of the number of people who found the review useful. The results of this study show that extracted personality dimensions are significant predictors of review usefulness. Greater extraversion, conscientiousness, and openness have a significant positive relationship with review usefulness. Somewhat counter-intuitively, greater neuroticism also has a significant positive relationship with review value, while greater agreeableness has a significant negative relationship with review value.

Study 2 extended Study 1 to examine the effects of expressed personality on word of mouth value in a lab setting. In line with Study 1, openness and neuroticism had a positive effect on review usefulness while agreeableness had a negative effect on review usefulness. Further analysis shows that review valence, as proxied by the star rating (on a scale of 1-5, with 5 indicating a very positive experience) that accompanies the text of each review, mediates the relationships between neuroticism and review value as well as between agreeableness and review value. Greater neuroticism is associated with more negatively valenced reviews. Conversely, agreeableness is associated with more positive reviews. Consistent with prior research (Basuroy et al. 2003; Chen and Lurie 2013), negative reviews are perceived as more useful than positive reviews.

Study 3 examined whether compatibility between writer and reader personalities impacts review usefulness. This study also examined whether the extracted personality dimensions of writers are consistent with those perceived by readers. Dimension of writer personality were extracted from online reviews. Dimensions of reader personality were extracted by asking readers to compose either a short email or a short review—we found similar results regardless of writing type—and a reader-writer personality similarity index was calculated using the mean of absolute differences between reader and writer on the Big Five (Setterlund and Niedenthal 1993). Readers also assessed reviewer personalities using the 10-item Big Five scale (Rammstedt and John 2007). Results show that greater similarity between expressed writer and reader personalities positively

impacts the perceived value of online word-of-mouth. Results also show that, except for openness, reader perceptions of reviewer personality are consistent with those extracted from reviews.

This paper shows that personality, extracted from a single online review through automated text analysis, is an important predictor of the value of online word-of-mouth. In addition to removing the need to measure personality through traditional scales, this approach is less subject to exaggeration and social desirability biases (Bearden et al. 1993). Our findings show that personality dimensions can influence word-of-mouth persuasiveness in unexpected ways. Although neuroticism is generally perceived as an undesirable personal attribute that reduces persuasion (Costa and McCrae 1980; Oreg and Sverdluk 2014), in word-of-mouth contexts it enhances value by being associated with more negative reviews. Conversely, conventional thinking holds agreeableness to be a favorable personal trait that enhances persuasion (McCrae and Costa 1987; Oreg and Sverdluk 2014); yet it decreases review usefulness by being associated with more positive reviews.

Transmitting Well-Reasoned Word of Mouth Impairs Memory for Product Experiences

EXTENDED ABSTRACT

A growing stream of research examines how word of mouth (WOM) affects consumers and product performance (e.g. Chevalier & Mayzlin 2006). The influence of engaging in WOM on the speaker, however, has been largely ignored. Although some recent research has examined how transmitting WOM affects senders' attitudes (Moore 2012), little is known about how transmitting WOM affects senders' memories for product experiences. Research in eyewitness testimony (Loftus 2003) and verbalization (Schooler and Engstler-Schooler 1990) suggest that the act of talking about an experience can change people's memory of the experience. Yet, it is unclear how and why different verbalization motivations affect memory. This work thus attempts to both contribute to a better understanding of how WOM affects reviewers and also provides insights into understanding how and why verbalization affects memory.

Reviewers often aim to be logical when writing reviews. Indeed, this behavior is often encouraged by many review websites (e.g. Amazon, Yelp, Yahoo). For example, Yahoo Movie prompts reviewers for rationales: "Tell us if you liked or disliked the film, but also why you liked or disliked it. Compare this film to others - why is this better or worse?"

We theorize that writing reviews can affect memory by influencing how people rehearse the original product experience. When reviewers write reviews in general, especially when prompted to write logical reviews, they search for well-reasoned arguments for their opinions rather than rehearse the original product experience (which is encouraged by imagery-based instructions). As a result of this search, those who write logical reviews are likely to suffer memory issues. Removing reviewers' ability to engage in this reason-seeking process – via cognitive load – should then improve memory to a level comparable to those writing imagery-based reviews. A series of five studies test and confirm these ideas.

In study 1, all participants watched the movie "Oktapodi," a short (2 minute) animation, and then were randomly assigned to a sender or receiver condition. Senders were instructed to write a review about the video to another student. Each receiver was yoked to one sender and read a randomly-assigned review after viewing the film. This provides a delay between watching the film and the memory test, and allows us to assess whether it is the act of writing a review or the actual content of the review that affects memory.

All participants completed a recognition task that had seven true statements and seven false statements about the movie. Memory is measured by summing correct acceptances and correct rejections. Results show that reviewers had worse memory for the underlying film than those who did not write reviews (e.g. receivers). Study 1 provides initial evidence that writing reviews can impair memory.

In the subsequent studies, to test the underlying process, we focus on senders and directly manipulate the goal to write logic-based versus imagery-based reviews. In study 2, after watching *Oktapodi*, participants were randomly assigned to write a logic-based review (i.e., to be well-reasoned and logical) or imagery-based review (i.e., to visualize and describe the film). Participants then completed the same memory test used in study 1. Manipulation checks supported the effectiveness of the manipulation. Confirming our theory, those who wrote logic-based reviews had worse memory than those who wrote imagery-based reviews. These results are consistent with the idea that searching for rational arguments may be responsible for subsequent memory deficits.

Study 3 further documents the negative effect of writing logical reviews and shows that the magnitude of this impairment is comparable to not being able to consolidate the product memory in the first place. Participants were randomly assigned to one of three between-subject conditions (logic-based review, imagery-based review vs. interference task). The procedures were the same as study 2 except that instead of writing a review, those in the interference condition completed an unrelated (anagram) task that prevented them from further thinking about the film. All participants then completed a 14-item memory test. Results reveal that those who wrote logic-based reviews had worse memory than those who wrote imagery-based reviews. Importantly, those who wrote logic-based reviews did as poorly on the memory test as those who experienced memory interference. This study not only reinforces earlier results but provides insights into the magnitude of the deficit: writing logic-based reviews is akin to preventing consolidation of the original memory.

In study 4, we test people's memory for a camera to examine the robustness of our effect in a different product category (i.e., a search rather than experience good). As before, participants were first shown a video of a camera, asked to write a logic- or imagery-based review for the camera and then answered 14 true/false statements. The results replicate earlier findings and show that writing logic-based reviews impairs memory for search products as well.

If memory impairments are indeed caused by people searching for rational arguments (instead of reflecting on the original experience), then preventing people from this search should attenuate our effect. Study 5 tests this with a 2 (logic- vs. imagery-based review) x 2 (no vs. high cognitive load) between-subjects design. The procedures were the same as study 4 except that those in the high cognitive load condition were asked to remember a roster of names while writing the review (after watching the movie; Elder & Krishna, 2010). Immediately after writing the review, the load was removed. Results show that when there is no load, the results replicate earlier findings. For those under cognitive load (i.e., prevented from searching for argument) while writing their reviews, there was no difference across logic- and imagery-based conditions.

In summary, we show that writing reviews-- logical reviews in particular-- can make people more susceptible to memory issues for the reviewed product. This work provides theoretical insight into how and why verbalization affects memory, as well as managerial insights given that many websites encourage consumers to write logic-based reviews.

Paper #4: Performance Brand Placebos: How Brands Improve Performance and Consumers Take the Credit

Aaron M. Garvey, University of Kentucky, USA
Frank Germann, University of Notre Dame, USA
Lisa E. Bolton, Pennsylvania State University, USA

SESSION OVERVIEW

Brands serve many roles in the modern marketplace. They function as indicators of products' manufacturers, containers of associations, signals of quality, and cues of compatibility, among others. The papers in this session advance knowledge on brand roles by focusing on the capabilities of brands, the underlying processes that enable them, and the unintended consequences that emerge from their typical usage in today's world. In doing so, the papers answer fundamental questions such as: "What does it mean to be a brand?" and "What do brands do for us?" Our answers bear consequence not only for the theory of brands, but also for consumers engaging in daily interaction with brands, firms building and managing brands, and policy makers regulating brand activities.

In the first paper, Rahinel, Otto, Clarkson, and Grossman study how decision making is affected by the presence of brands. Specifically, they find that brand exposure makes subsequent decisions easier. Process evidence shows that brand exposure cues a cognitive readiness for decision making, which leads to greater ease in decision making.

In the second paper, Acikalin, Watson, Fitzsimons, and Platt study brand preferences in rhesus monkeys. They find that pairing brand logos with sex- and status-based images builds brand preferences consistent with evolutionary principles. Thus, although though more elaborate cognitive systems in humans allow sophisticated rationalizations for brand preferences, those preferences may in fact simply result from associative conditioning.

In the third paper, Coary examines the effect of brand labels in symbolic complementary settings where a consumed product (e.g., beer) is paired with a supporting product (e.g., glass). He finds that enjoyment of the consumed product is heightened when its brand matches that of the supporting product. Process evidence supports brand involvement as an underlying process for the effect.

In the fourth paper, Garvey, Germann, and Bolton examine the underlying processes and consequences of brand placebo effects. They find that performance brands heighten the self-concept, which lowers state anxiety, and subsequently improves performance. Furthermore, consumers attributed enhanced performance to themselves, apparently ignoring the role of brand in this process.

These projects, all in advanced stages, offer new insights into general capabilities that extend across all brands. Notably, they also appeal to a broad audience, as they not only intersect with but also tackle central questions in variety of other popular areas in consumer behavior such as decision making, evolutionary behavior, performance outcomes, and consumption enjoyment. Finally, the novel methodologies, interesting outcomes, and fresh perspectives on the topic promise to facilitate dialogue amongst session attendees and ultimately advance connections.

Brand Exposure Makes Decisions Easier

EXTENDED ABSTRACT

Brand exposure has profound impacts on behavior. Subliminal exposure to thrift brands like Wal-Mart makes people choose thriftier options (Chartrand, Huber, Shiv, and Tanner 2008), exposure to the Apple (vs. IBM) brand logo makes people generate more creative ideas (Fitzsimons, Chartrand, and Fitzsimons 2008), and finally, using a Red Bull car in a video game makes players race more aggressively and recklessly (Brasel and Gips 2011). Brands apparently cue behavior in line with their core associations.

In the current work, we broaden this line of inquiry by studying brand exposure effects of a general nature. That is, we ask the question: "What are the consequences of exposure to brands *of any kind*?" Our point of departure from this question comes from the simple notion that the most consequential use and consideration of brands by consumers occurs during decision making episodes, such as product choice (Jacoby, Speller, and Kohn 1974; Jacoby, Szybillo, Busato-Schach 1977; Mela, Gupta, and Lehmann 1997). We propose that, akin to classical conditioning processes (Pavlov 1927; Rescorla 1988), such pairing leads brand exposure to prompt a cognitive readiness for decision making. Although this is the first work to instantiate the notion of decision readiness, its conceptualization draws from other forms of cognitive preparation in the domains of task performance (Carlson and Lundy 1992; Monsell 2003; Sohn and Carlson 1998), behavior anticipation (Hull 1951; Spence 1937), and motor control (Haggard and Eimer 1999; Libet et al., 1983; Wohlert 1993). Consistent with the findings in such literatures, we further propose that decision readiness makes the experience of subsequent decision making easier. That is, brand exposure makes decisions easier by cueing a cognitive readiness for decision making. We test this framework in a series of three studies.

The objective of study 1 was to conduct a test of the basic effect with real brands. Participants completed a 15 item quiz about either brand logos or driving signs (in the control condition). There were two forms of each quiz to counteract any effects produced by the specific brands or driving signs chosen. We then told participants that we sometimes give away small gifts instead of course credits in exchange for completing their studies, and that the we were interested in determining students' preferences these types of gifts. Participants indicated which of six small, non-branded gifts they would choose. We measured several constructs: option similarity, decision ease, decision confidence, and decision deliberation. We also measured the subjective difficulty of the quiz, as well as demographic information, including age. We measure subjective difficulty of the manipulation as well as participant age (which may co-vary with both readiness and ease) at the end of each study, and control for them in all analyses. Preliminary results demonstrated

that there were no differences between forms within each condition, so we collapsed them within condition. There was no effect of exposure condition on the particular option chosen, perceived option similarity, decision confidence, or decision deliberation. However, there was the predicted effect of brand (vs. driving signs) exposure on decision ease, with those exposed to brands (vs. driving signs) expressing greater ease in their product decision.

In study 2, we sought to replicate the effect using a different manipulation and provide evidence for the underlying mechanism via mediation. In the brand condition, participants evaluated 30 designs which we told them were potentially new brand logos for brands about to enter the mainstream market. Each “logo” was rated on a scale from 1 = terrible brand logo to 7 = excellent brand logo. In the control condition, participants evaluated the same 30 designs as in the brand condition, but were instead told that the designs were abstract art designs by local college students. Each art design was rated on a scale from 1 = terrible art piece to 7 = excellent art piece. After the exposure manipulation, participants saw the same choice set and cover story as in study 1. We measured decision ease and decision readiness (e.g., “I felt prepared to make a choice”). We also sought to rule out rival mechanisms by measuring other constructs: number of attributes considered, comparative processing, random choice, and choice satisficing. Results replicated the core effect from study 1, and the same pattern of data held for the decision readiness measure. Furthermore, a mediation analysis showed that the effect of brand (vs. art) exposure framing on decision ease was mediated by decision readiness. Alternative mechanisms did not mediate the effect.

In study 3, we aimed to conceptually replicate the effect using a different choice set and provide more evidence for the underlying mechanism via moderation. Participants completed the same brand exposure manipulation as in study 2. They were then told to imagine that they had an hour of free time, and to choose one of six activities (e.g., take a walk, take a nap) to do during that time. Decision ease was measured using the same items as in studies 1 and 2. We then measured decision readiness as a dispositional variable using four items (e.g., “I am always prepared to make decisions”). We tested our core hypothesis by regressing decision ease on brand exposure, chronic decision readiness, their interaction, and control measures. There were positive main effects of both decision readiness and brand exposure. More importantly, there was a significant interaction such that brand exposure strongly increased decision ease for those chronically low in decision readiness, whereas there was no effect of brand exposure for those high in decision readiness, who all experienced relatively high decision ease. Looking at the interaction another way, there was a significantly positive effect of decision readiness for those in the control exposure condition, whereas there was no significant effect of decision readiness for those in the brand exposure condition, since brand exposure presumably increased readiness for participants anyway. Overall, these results document an important general effect of brand exposure and highlight readiness as a key consideration in the study of decision making.

Sex and Status Sell to Monkeys: Social Advertising Creates Brand Preferences in Rhesus Macaques

EXTENDED ABSTRACT

Over the course of human evolution, natural selection shaped psychological tendencies that promote survival and reproduction within an intensely social context (Kenrick et al., 1994). Today, these cognitive biases continue to influence behavior, including virtually all consumer settings. Social rewards, including depictions

of sex and social status, reliably elicit innate motivational drives, and their use in motivating behavior is a favored strategy in advertising. Consumers respond more favorably to attractive ads with models from the opposite gender (Baker and Churchill, 1977), and physiological studies in humans find that nudity in advertising indeed elicits strong physiological responses (Belch et al., 1982). Association of products with an individual of high social status is another common advertising strategy. In some cultures, more than half of all advertisements feature celebrities (Choi, 2005). Notably, sexuality and celebrity endorsements in advertisements are appealing across cultures, suggesting these strategies tap into universal human characteristics (Paliwoda, 2009; Praet, 2001). This observation suggests that the psychology underlying the formation of advertising-driven brand preferences could have deep evolutionary roots.

Exactly why and how sex and social status in advertising influences consumer behavior remains unknown. Some theories rely on high-level cognition of the consumer, such as the attribution of beliefs of a celebrity spokesperson about the desirability of the product (Silvera and Austad, 2004; see Erdogan, 1999 for review). Conversely, a simple association between a product, a social reward, and the cognitive and physiological state this reward induces in the consumer, may be adequate to bias preferences toward the product.

Visual depictions of sex and status influence preferences in monkeys, suggesting that social rewards could be used to alter preferences for objects paired with them (Deaner et al., 2005; Watson and Platt, 2008). Because old world monkeys and humans diverged 25 million years ago, the presence of a cognitive bias in both families suggests evolutionarily ancient origins. Shared brain circuits mediating social perception and valuation in rhesus macaques and humans provide a mechanism by which this bias may be translated into preferences for brands associated with sex and status (Chang et al., 2013; Pearson et al., 2014). Here we experimentally test whether a sex- and status- based ad campaign can elicit brand preferences in adult rhesus monkeys.

Three stimulus sets were used as *models* in an ad campaign in which social images (female *perinea*, *dominant* male faces, and *subordinate* male faces) or their corresponding control images were paired with brand logos.

Monkeys were exposed to a series of *advertisement trials* interleaved with *decision trials* that allowed assessment of logo preference. During a decision trial, monkeys had to tap on a central fixation square, and then tap on a brand logo image of their choice. Advertisement and decision trials were randomly interleaved. The orders of presentation for the three different ad campaigns and for the two logos for each campaign (Social vs. Control image) were drawn randomly with replacement. Each session consisted of seventy ad trials and thirty decision trials. Each monkey (n=5 males and n= 5 females) completed 100 *baseline* decision trials prior to the beginning of the experiment, and demonstrated no pre-existing preference for any logo before exposure to the ad campaign ($p>0.7$).

Because ads are known to lose impact over repeated viewings (Campbell and Keller, 2003; see Pechmann and Stewart, 1988 for review), the efficacy of each ad campaign was evaluated during the initial phase (trials 1-20 for each ad) of the experiment. Specifically, analysis in Study 1 was restricted to decisions made up until each monkey had seen 10 control and 10 social advertisements from each stimulus set (dominant, subordinate, perinea).

A logistic regression analyzing decision outcome as a function of ad campaign category (*SPORTperinea*, *CARDominant*, or *PIZZAsubordinate*) and sex of the monkey subject revealed a significant interaction between ad campaign category and sex. Specifically, male monkeys, but not female monkeys, were more

likely to choose *SPORTperinea* over *SPORTcontrol* while, female monkeys, but not male monkeys, were more likely to choose *CARDominant* over *CARcontrol*. These findings show that male monkeys develop an advertising-induced bias (AIB) for brand logos paired with sexual images of female monkeys, and that female monkeys develop a preference for brand logos paired with faces of dominant male macaques. To determine how advertising efficacy changed over repeated exposures to ads, we next regressed the cumulative AIB over the number of relevant non-scrambled advertisements seen for each category, with the intercepts fixed to zero based on our baseline results. These results show that male monkey preferences for the *SPORT* logo paired with sexual images increases with repeated ad exposure, and that female monkey preferences for the *CAR* logo paired with high status images increases over repeated ad exposure. These findings also show that female monkeys show decreased preference for the *PIZZA* logo repeatedly paired with low status images, while male monkeys show an increased preference for the *PIZZA* logo paired with low status images with repeated exposure.

Here we show that monkeys develop preferences for logos after social advertising campaigns. Female sexual images increase brand preference in male monkeys, and high status male faces increase brand preference for female monkeys. Finally, pairing images of subordinate males with logos decreases brand preference for females and increased brand preference for male monkeys across our trials. In the context of human marketing and advertising research, our findings endorse the idea that innate, evolutionarily ancient mechanisms mediate socially induced brand preferences.

Symbolic Brand Synergy: When 1 is Greater Than 2

EXTENDED ABSTRACT

Consumers are often exposed to multiple branded products during their consumption experiences. Sometimes these products are consumed together in a functional fashion (e.g., cake and frosting) while other times only one is consumed while the other plays a symbolic role (e.g., drinking a beer out of a branded glass). In a functional setting, Rahinel and Redden (2013) found that consumers enjoyed the experience more when the products' brands matched (vs. mismatched), since matching brands cued inferences that the products were designed for each other. This research studies whether such an effect might occur in a symbolic consumption setting, where inferences of product coordination are likely to be muted.

I posit that brand matching in symbolic complementarity setups indeed leads to greater utility for the consumed product under specific circumstances. Specifically, people with a high need for internal consistency may receive utility from brand matching, as these consumers prefer consistency in their lives, including their consumption experiences. Furthermore, I hypothesize that the effect is also bounded to brands high in perceived quality, as the brand matching of the second product can reinforce the quality of the primary product that is being consumed. Such reinforcement of the brand through a secondary product increases a consumer's brand involvement, which subsequently leads to a better consumption experience. I tested this framework in a series of three studies.

The goal of Study 1 is twofold: to demonstrate that the effects of brand synergy extend beyond functional complementarity to symbolic complementarity and to investigate one's need for internal consistency as a moderator for these effects. A one-way two level between subjects design was utilized. Brand synergy was manipulated by having participants drink Coca-Cola out of a Coca-Cola branded cup or a Solo cup. Results reveal that symbolic

brand synergy has a significant effect on attitudes towards the soda, consumers' interest in drinking more, and their likelihood to purchase. These effects are moderated by an individual's need for consistency, where consumers with a high need for consistency have higher attitudes and behavioral intentions for brand synergy than those with low need for consistency.

Study 2 investigates the quality of the brands as a potential moderator for the effects of symbolic brand synergy. To further test the strength of symbolic brand synergy, water was utilized as the experimental product. Consumers have a difficulty in evaluating the quality of the actual water and rely solely on the brand name for perceived quality. A pretest confirms the quality (1-9 scale) manipulation of the two brands utilized, (Fiji High Quality vs. Arrowhead Low Quality). The experimental procedure was similar to that utilized in Study 1. To further investigate the effects of brand synergy, the amount of water consumed was measured as the dependent variable. Regression results reveal a significant main effect for brand synergy, a significant main effect for quality, and a significant interaction. There was a significant difference in the amount of water consumed for the high quality brand, but no significant difference in the amount of water drunk for the low quality brand. These results suggest that only high quality brands are significantly affected by symbolic brand synergy.

The purpose of Study 3 is to investigate the underlying process driving the effects of brand synergy and investigate the effects in another product category, thus expanding its generalizability. A one-way three level design was utilized manipulating brand synergy. Dunkin Donuts were utilized with a Dunkin Donut napkin, Starbucks napkin, or control (plain white) napkin. Comparing the Dunkin Donuts vs. Starbucks first; results demonstrate a significant main effect for brand synergy on attitudes towards the food and on taste evaluations. To investigate the proposed mediating mechanism (brand involvement) for brand synergy on attitudes towards the food, Hayes's (2013) PROCESS procedure was utilized, and it was demonstrated that brand involvement significantly mediated the effect. Similar results occur between the Dunkin Donuts and control (plain white napkin) condition.

Three studies demonstrate that the effects of brand synergy occur during symbolic complementarity products not just functional products as found in previous research. These studies suggest that brands can benefit from increased attitudes and increased consumption by providing their consumers with a secondary branded product (glass, napkin, plate, wristband, etc.) during consumption of the primary product.

Performance Brand Placebos: How Brands Improve Performance and Consumers Take the Credit

EXTENDED ABSTRACT

Firms frequently promise consumers that use of their brands will improve performance outcomes. Claims of superior materials, craftsmanship, design, or other components can be quite convincing, and certainly true in some instances. However, when products or services are functionally homogenous, could the simple belief that a particular brand is effective at enhancing performance actually improve objective performance? To answer this question, we develop and test a framework for performance brand consumption by drawing on the literatures on placebo effects (Plassmann et al. 2008; Shiv, Carmon, and Ariely 2005; Waber et al. 2008), performance anxiety and stress responses (Crum, Salovey, and Achor 2013; Eysenck et al. 2007), and self-attributions (Malle 2006). In doing so, our

research increases knowledge at the intersection between branded consumption and consumer performance outcomes.

Our research focuses upon the implications of performance brand consumption for the consumer's mental and emotional state in influencing task outcomes. We demonstrate that performance brand consumption has objectively measurable effects upon performance due to purely perceived and illusory (i.e. immaterial) brand differences, consistent with a placebo effect (Shiv et al. 2005). Paradoxically, although this performance brand placebo emerges most strongly when consumers believe the branded offering impacts performance, consumers tend to credit any positive gains to the self, rather than the brand. We provide evidence for the psychological mechanisms through which both effects upon performance and attribution emerge. Specifically, we propose that consumption of a performance branded product serves to reduce the experience of state anxiety as the result of a bolstered self-concept. The experience of state anxiety has been demonstrated to redirect attention and cognitive resources away from consciously pursued outcomes (Eysenck et al. 2007), and to increase ruminative thought (Carver and Scheier 1988), thereby interfering with performance in achieving those outcomes. Consumption of a performance branded product will serve to reduce such debilitating state anxiety, thereby improving performance. This effect emerges through the impact of brand consumption upon the self-concept. To the extent that the brand is congruent with an idealized self, it should re-enforce that positive self-view and accordingly bolster the self-concept (Berger and Ward 2010; Fournier 1998; Muniz and O'Guinn 2001). A bolstered self-concept will in turn reduce task induced anxiety (Baumeister et al. 2003; Koivula et al. 2002; Langendörfer et al. 2006), thereby improving performance. Furthermore, a bolstered self-concept should increase attributions for improved performance to the self, rather than the performance brand.

Support for a performance brand placebo is observed in four studies across a variety of brands, product categories, and athletic and cognitive performance contexts. Study 1 was a field experiment that utilized an athletic context and examined how the salience of performance brands alters exercise behavior, as well as downstream attributions for athletic performance. A two-group between subjects design manipulated the salience of performance brands worn by members of a health club. Participants in the salient performance brand condition performed their workouts significantly longer than those in the control condition. Furthermore, salient performance brands increased attributions for workout performance to the self.

Study 2 replicated these effects in a golfing context while exploring the underlying process role of experienced anxiety. Participants were members of a health club that agreed to help test a golf putter by performing a series of actual golf putts. The putter was manipulated to be either a strong (Nike) or weak (Starter) performance brand. Participants who used the strong performance brand required fewer strokes to successfully complete a putt. Mediation analysis revealed that participants using the strong performance branded experienced less state anxiety while putting, thereby requiring fewer putts to succeed.

Study 3 demonstrated the performance brand placebo in a cognitive performance context. A three-group design was employed that included a performance brand salience condition (participants described worn brands and reflected upon implications for performance), non-performance brand salience condition (participants described worn brands), and control condition. Participants in the performance brand salience condition demonstrated higher scores on a test of five questions (Frederick 2005) versus those in the non-performance brand salience and control conditions. Serial mediation analysis revealed that performance brand salience heightened the self-

concept, which in turned lowered state anxiety, thereby improving cognitive performance. The heightened self-concept simultaneously increased attributions to the self rather than the performance brand. Notably, the performance brand placebo emerges only when brands relevant to performance are made salient. Finally, study 4 (details omitted for brevity's sake) further explicated the role of state anxiety by examining stress mindset (Crum et al. 2013) as a theoretically relevant boundary condition for a performance brand placebo.

In summary, this research expands upon the literatures examining placebo effects, performance anxiety and stress responses, and self-attributions to explain how branded offerings systematically improve (or undermine) consumer outcomes in a variety of cognitive and athletic contexts. Whereas prior work examining placebo effects has developed theory concerning subjective outcomes (e.g., perceived pain reduction), with limited findings for objective performance outcomes, our work explains how objective outcomes are systematically improved or harmed by performance brand consumption, and through mechanisms distinct from traditional, subjective placebo effects. We shed insight into the psychological underpinnings of this performance enhancing effect by proposing and providing empirical support for an anxiety-reduction mechanism, which is driven by a bolstered self-concept. Furthermore, we reveal how consumers tend to credit themselves, rather than brands, for performance gains. Thus whereas prior research has demonstrated that branded consumption that bolsters the self-concept improves consumer-brand connections, we find that consumers do not acknowledge the role of performance brands in determining outcomes.

SESSION OVERVIEW

Prosocial motivations and actions are pervasive in consumer contexts. For example, a corporation's perceived social responsibility alters consumer responses to its products (Bodur, Gao, & Grohmann, 2014; Torelli, Monga, & Kaikati), and prosocial motivations may lead consumers to seek out socially responsible brands or charitable giving opportunities. Markets also have social dimensions, as consumers may rely on advice from or their impressions of other people. Prosocial actions, however, depend upon complex underlying psychological processes, and no single experimental approach can encapsulate these rich phenomena. Therefore, insights from multiple methods and disciplines must be combined in order to advance understanding of prosocial behavior in consumer contexts.

This session incorporates a diverse set of methods to elucidate the underlying psychological processes guiding prosocial behavior, including findings from pharmacology, functional neuroimaging, and field data. At the heart of these different approaches, however, is a common set of questions derived from, and building on, laboratory experiments on human prosociality. The first presentation by Ming Hsu, Ignacio Sáez, and Andrew Kayser addresses a core question in the study of prosocial behavior: are prosocial actions relatively automatic and reflexive, or are they relatively effortful and controlled? Employing a pharmacological approach in conjunction with a social decision making task, Hsu and colleagues demonstrate that controlled, as opposed to automatic, processes appear to enable prosocial behavior.

The second presentation by Crystal Reeck, Nina Mazar, Dan Ariely, Rita Ludwig, and Malia Mason examines prosocial behavior in the context of conflicts of interest. Combining functional magnetic resonance imaging (fMRI) with a conflict of interest task, the authors demonstrate that activation in neural regions involved in self-control predicts variability in the extent to which judges respond selflessly when confronted with potential conflicts of interest. These findings

suggest that those seeking to curb the negative consequences of conflicts of interest should focus on enhancing self-control among those whose judgments might be biased by self-interest.

In the third presentation, Alexander Genevsky and Brian Knutson assess which affective processes predict microlending decisions. Using fMRI to predict market-level outcomes, the authors examine how responses to those requesting microfinancing predicts decisions to lend. Positive affect as indexed by behavioral and neural measures predicts both individual and market-level lending decisions. These findings provide greater insight into how marketing actions by loan applicants can influence their outcomes.

The final presentation by Alex Imas, Elizabeth Keenan, and Ayelet Gneezy uses a combination of laboratory and field experiments to examine how prosocial incentives motivate effort. The authors demonstrate that explicitly linking efforts with charitable outcomes improves their impact compared to standard self-benefiting incentives.

This session will advance connections among these different approaches, which is critical for both developing richer theories at the mechanistic level and enhancing predictive power as a result of these insights. What predictions for market outcomes emerge from understanding biological phenomena, and vice versa? How can marketing agents improve consumer experiences or promote better outcomes? How can prosocial motivations be enhanced to promote charitable giving, honest advice, or social responsibility?

The Controlled Nature of Prosociality: Pharmacological Enhancement of Prosocial Behavior

EXTENDED ABSTRACT

Prosocial motivations often form an important part of consumers' decision-making process. Charitable giving in 2013, for example, reached more than \$400 billion, or around 1.9% of personal income (The Hudson Institute 2013). More recently, prosocial motivations have become an increasingly important element of marketing strategy aimed to promote customer engagement and satisfaction (Duclos and Barasch 2014).

At the psychological level, considerable debate exists regarding the specific mechanisms that enable prosocial behavior (Gino et al. 2011; Rand, Greene, and Nowak 2012). In particular, it remains largely unknown the extent to which prosocial actions are a product of automatic or controlled processes. That prosocial behaviors result from the interaction of these two processes has come from several difference sources. Behaviorally, a number of existing experimental studies have shown changes in prosocial behavior following taxing control processes using time pressure, cognitive load, or ego-depletion manipulations (Gino et al. 2011; Rand et al. 2012; Shalvi, Eldar, and Bereby-Meyer 2012). More recently, studies using functional brain imaging techniques have provided direct insight into the engagement of prefrontal cortex-dependent cognitive control mechanisms in decisions that require tradeoff between self-interested and prosocial motivations.

However, it is much less clear whether control is exercised in the service of promoting self-interested or prosocial actions. In particular, behavioral studies have resulted in conflicting findings such that both increases and decreases in prosociality have been observed (Gino et al. 2011; Rand et al. 2012; Shalvi et al. 2012). Likewise,

neuroimaging evidence is limited by their inherently correlational nature. More generally, this highlights the limits of traditional methodological approaches that rely on indirect manipulation of internal psychological processes.

To address these questions, we sought to provide novel causal evidence by using a pharmacological approach that allows direct manipulation of the brain regions known to subservise control processes (Badre 2008; Baumgartner et al. 2011). Specifically, we conducted a within-subject, double-blind, placebo-controlled, crossover study using the brain-penetrant drug tolcapone to manipulate prefrontal functioning by inhibiting the degradation of prefrontal dopamine. Although widely associated with motivation and reward, it has long been known that dopamine in the prefrontal cortex serves a critical role in cognitive control through its influence on plasticity of activation states in prefrontal regions (Cools 2008; Aarts et al. 2014). In previous studies, enhancement of prefrontal dopamine via tolcapone have been associated with improved cognitive control and reducing impulsivity (Apud et al. 2007; Kayser et al. 2012), but its effects on social behavior have not been characterized.

Over two visits, we administered either placebo or a single 200mg dose of tolcapone to 35 healthy volunteers (Mean age 32.5; SD 9.0 years). Following administration, each subject participated in a continuous version of the Dictator game with an expanded choice space (Andreoni and Miller 2002; Camerer 2003). As in the standard Dictator game, the participant in the position of the dictator received an endowment consisting of T tokens and could unilaterally choose to give some portion T_o to an anonymous recipient while keeping the remaining T_s tokens. In addition, we manipulated the relative cost and benefit of giving on each trial by independently varying how much each token was worth to the dictator (r_d) and the recipient (r_r). For example, under a 3:1 exchange rate, a token could be worth \$3 if kept by the subject and \$1 if given to the recipient. Under the 1:1 exchange rate, our task reduced to the standard Dictator game.

First, we assessed how tolcapone administration affected behavioral sensitivity to inequity in our participants. Specifically, we conducted a paired comparison in mean inequity, calculated as the absolute difference between the participant's payoff and those of the recipient, under tolcapone versus placebo. We found that tolcapone administration resulted in a highly significant mean reduction in overall inequity—from $\$87.08 \pm 3.45$ in the placebo condition to $\$80.16 \pm 3.3$ in the tolcapone condition—with a paired difference of $\$6.92 \pm 2.43$ (paired random effects t-test, $p < 0.001$).

Next, we separately examined mean changes in advantageous and disadvantageous inequity. If tolcapone administration resulted in a general increase in behavioral sensitivity to inequity, we should expect to see a decrease in both advantageous and disadvantageous inequity. Consistent with this hypothesis, we found that advantageous inequity decreased from $\$128.36 \pm 4.34$ to $\$112.04 \pm 4.44$ ($p < 0.01$, two-tailed t-test), and disadvantageous inequity from $\$131 \pm 8.27$ to $\$74.99 \pm 10.23$ ($p < 10^{-4}$, two-tailed t-test; Fig. 3B). Importantly, this concomitant reduction in both types of inequity, across all exchange rates, further argues against the hypothesis that tolcapone directly increases the reward value attached to the payoff of others, which would instead predict a reduction in advantageous inequity and a corresponding increase in disadvantageous inequity.

Finally, to assess the robustness of our results to potential confounding variables such as order of drug and placebo administration, gender, and body mass index (BMI), we performed a repeated-measures ANOVA including these measures, as well as their interactions with the drug condition, as covariates of no interest. We found that none of these factors exerted a significant influence on behavior

($p > 0.1$ for all tests), and that the drug effect on inequity is robust to their inclusion ($p < 0.01$).

Taken together, our results support the idea that cognitive control is engaged to curb self-interested motives, at least in the case of the dictator game. Future studies combining this approach with additional experimental manipulations can shed light on prosocial motivations in other behavioral domains. More generally, our approach highlights the ability of pharmacological manipulations in providing direct causal insight into psychological mechanisms underlying behavior.

Neural Mechanisms Promoting Selflessness in Potential Conflicts of Interest

EXTENDED ABSTRACT

Self-interest is fundamental to neoclassical economic models of human reasoning, which assume that individuals are utility maximizers. Yet people occasionally act against their own self-interest. Sometimes they do so because of external reinforcement, including social scorn and reputational concerns, which promotes seemingly selfless, virtuous behaviors. Sometimes, however, they behave selflessly even when external reinforcements are minimal, as when they leave generous gratuities at restaurants they only visit once (Kahneman, Knetsch, & Thaler, 1986), donate organs to strangers (Jacobs, Roman, Garvey, Kahn, & Matas, 2004), or disclose mechanical problems while selling used vehicles to strangers (Akerlof, 1970). Moreover, people occasionally act against their own interest even when the "proper" response is ambiguous. In circumstances where the proper course of action is difficult to determine and the external consequences of selfish behavior are minimal, what distinguishes people who continue to choose the principled course of action from those who act selfishly? What explains such extreme righteousness?

Conflicts of interest (Cain, Loewenstein, & Moore, 2011) present a particularly important context for examining righteousness, as they have been shown to undermine a broad range of professional judgments that consumer rely upon, such as doctors' espousal of self-interested medical guidance (Dana & Loewenstein, 2003) and investment recommendations from financial professionals (Mullainathan, Noeth, & Schoar, 2012) at the expense of patient or client welfare. In particular, as the objectively proper course of action becomes more ambiguous, higher-order ethical commitments no longer prescribe a particular action clearly and people's tendency to pursue self-interest becomes more pronounced (Babcock & Loewenstein, 2004). Therefore, understanding what predicts who is most likely to act on their self-interest as the appropriate response becomes more unclear is important to avoiding negative outcomes for those who rely on their advice.

To investigate whether internal reward or control processes explain individual differences in righteousness behavior, the present experiment employed a conflict of interest task in conjunction with functional neuroimaging (Mazar, Amir, & Ariely, 2008b). On each of 150 trials, participants ($N = 27$) viewed an image that contained 100 dots and a vertical line dividing the image into left and right halves. Although participants were instructed to indicate which side contained more dots accurately, they were paid more (\$0.10 per response) when they indicated there were more dots on the right than when they responded there were more dots on the left (\$0.02 per response). Thus, trials that consisted of more dots on the left, lower paying side represented a potential COI between giving the correct response or giving an incorrect response in exchange for higher pay (incentivized error trials). As previous research has demonstrated that selfish behaviors are more common in response to ambiguity

(Argo & Shiv, 2012; Mazar, Amir, & Ariely, 2008a), ambiguity was manipulated such that on half the trials the discrimination was difficult and uncertainty about the correct response was relatively high. Not surprisingly, we find that incentivized responses occurred more frequently than disincentivized responses, $F(1, 26)=21.93$, $p<.001$. Importantly, there was a significant interaction between response incentive and ambiguity, $F(1, 26)=13.016$, $p=.001$. Pairwise comparisons revealed that incentivized responses were provided more frequently than disincentivized responses when the correct response was more ambiguous, $t(26)=5.544$, $p<.001$. This same pattern of results was also observed in error rates, with participants making more selfish, incentivized errors on more ambiguous than less ambiguous discriminations, $t(26)=4.882$, $p<.001$. Overall, participants did allow motives for personal gain to color their judgment, and this self-serving bias was more common when the appropriate response was more ambiguous.

A network of neural regions putatively involved in cognitive control exhibited greater activation in individuals who did not increase their self-interested responding when the proper response was more obscure, including lateral prefrontal cortex, dorsal parietal cortex, and temporoparietal junction. Importantly, these regions discriminated those who responded in a self-serving fashion from those who did not, specifically on trials in which the correct response was more ambiguous and self-interest was most likely to influence judgments. Conversely, activation in reward processing regions did not predict individual differences in selflessness when confronting potential conflicts of interest. The parietal regions and temporoparietal junction have been previously implicated in directing attention and other controlled processing (Corbetta, Patel, & Shulman, 2008). The correlation between lateral prefrontal cortex and righteousness may reflect the role of this region in resolving competition between competing responses, rules, or representations (Botvinick, Braver, Barch, Carter, & Cohen, 2001; Kerns et al., 2004; MacDonald, Cohen, Stenger, & Carter, 2000) and resisting temptation by implementing self-control (Hare, Camerer, & Rangel, 2009; McClure, Laibson, Loewenstein, & Cohen, 2004).

Taken as a whole, these findings advocate a central role for self-control and not reward in determining who will continue to subvert their own self-interest when the “proper” action becomes more difficult to determine. In light of the present findings, interventions seeking to limit the negative consequences of conflicts of interest should focus on enhancing self-control among those whose judgments they seek to insulate from self-interest.

Affective Mechanisms in Microlending Decisions: Using Internet Data and Neuroimaging to Predict Market-level Behavior

EXTENDED ABSTRACT

Humans sometimes share with others whom they may never meet or know. These acts elude the scope of theories that assume that people choose according to pure self-interest. Microlending, or individual choices to make small low-interest loans to strangers, represents an example of this phenomenon. While incentives like repayment with interest motivate traditional institutional loans, individuals often fund microloans that return little or no interest while incurring significant opportunity costs. The psychological mechanisms underlying lenders’ decisions remain unclear, however, as does the question of whether the influence of those mechanisms extends beyond individual choice to account for aggregate behavior. In two studies, we demonstrate that neural affective mechanisms influence microloan request success. These findings highlight affective neuro-

science’s potential to test theories about neuropsychological mechanisms that drive microlending, to predict market-level behavior, and to enhance the effectiveness of loan requests.

Successful loan requests that impose opportunity costs may recruit some of the same psychological mechanisms as appeals for charitable gifts (Harbaugh, Mayr, and Burghart 2007; Genevsky et al. 2013) and has been proposed to partly depend on affect. By soliciting charitable donations from human subjects during behavioral and neural (i.e., functional magnetic resonance imaging). Therefore, we sought to examine whether neural affective mechanisms implicated in charitable giving might also promote microlending. The current research specifically aimed to determine whether affective mechanisms could account for microlending in a large internet dataset involving significant financial incentives, as well as to test whether neural and affective responses in a neuroimaging sample could predict microlending not only at the group level, but also at the market level.

A first internet study explored the impact of affective loan request features on loan request success in a large online microloan dataset (obtained from Kiva.org; $n=13,500$). Two features of loan requests were identified as potentially having affective impact: (1) a text description introducing and describing each borrower’s individual circumstances and needs, and (2) a photograph of each borrower prominently displayed at the top of each loan request. If microloan requests and charitable giving appeals are similar, we predicted that photographs’ positive affective impact should promote loan request success, while also testing the alternative possibility that negative affective impact might enhance loan request success.

Study 1 analyses indicated that positive arousal ratings of photographs were positively associated with loan funding rate. The effect of negative arousal ratings of photographs and the percentage of both positive and negative words in the text was not associated with loan request success (Appendix 1a). Further, analyses indicated that requests with photographs classified as ‘happy’ received a higher rate of funding than those with photographs classified as ‘sad’. To establish the financial impact of these effects, we explored descriptive and predictive aspects of models of loan request success. Photographs in the top versus the bottom decile of positive arousal ratings were funded at \$8.04 (8.2%) more per hour.

While the internet study focused on whether loan request features could elicit affect and promote loan request success, it could not specifically test whether affective responses increased lending, since affective responses were assessed in a separate group of subjects who rated borrowers’ expressions rather than their own experience. In a second neuroimaging study, we aimed to determine whether the experiential and neural affective responses of a neuroimaging sample to loan requests could account for aggregate loan request success, even beyond overt behavioral measures. Thus, we scanned a neuroimaging sample ($n=28$) as they chose whether or not to lend to borrowers.

We predicted that activity in brain regions implicated in anticipatory affect (e.g., NAcc and anterior insula; Knutson & Greer, 2008) technical limitations have made it difficult to determine whether anticipatory affect influences subsequent choice. Recent advances in the spatio-temporal resolution of functional magnetic resonance imaging, however, now allow researchers to visualize changes in neural activity seconds before choice occurs. We review evidence that activation in specific brain circuits changes during anticipation of monetary incentives, that this activation correlates with affective experience and that activity in these circuits may influence subsequent choice. Specifically, an activation likelihood estimate meta-analysis of cued response studies indicates that nucleus accumbens (NAcc

might scale to predict internet loan request success. Anticipatory activity in regions drawn from predicted volumes of interest (NAcc, AIns, MPFC) as well as whole brain group analysis (anterior MPFC, amygdala, precuneus, and temporal gyri) were correlated with internet loan request success (as in Berns & Moore, 2012). Of these regions, only NAcc activity significantly and positively correlated with aggregate loan funding rates. Model comparisons indicated that neuroimaging sample brain activity explained more variance in internet funding rate than choice despite penalties for additional predictors. Further, in a combined model that included choice, affect, and neural variables, only NAcc activity and positive arousal remained significantly associated with internet funding rate (Appendix 1b).

These findings collectively suggest that neural affective mechanisms promote microlending, both at individual and market scales. While a growing number of studies suggests that neural responses can predict individual behavior (e.g., financial risk taking or purchasing; Knutson & Greer, 2008) technical limitations have made it difficult to determine whether anticipatory affect influences subsequent choice. Recent advances in the spatio-temporal resolution of functional magnetic resonance imaging, however, now allow researchers to visualize changes in neural activity seconds before choice occurs. We review evidence that activation in specific brain circuits changes during anticipation of monetary incentives, that this activation correlates with affective experience and that activity in these circuits may influence subsequent choice. Specifically, an activation likelihood estimate meta-analysis of cued response studies indicates that nucleus accumbens (NAcc, only a handful have explored whether group brain activity can predict aggregate behavior (Falk et al. 2011; Berns and Moore 2012). No studies, however, have initially used findings from aggregate data to infer a neurobehavioral mechanism, and then assessed that mechanism in an independent group to reciprocally classify aggregate behavior.

This research makes a number of novel contributions. First, the findings implicate specific neural affective mechanisms in microlending across both individual and aggregate scales. By demonstrating that psychologically “hidden” mechanisms can account for aggregate choices better than behaviorally “revealed” choices, the findings empirically address a challenge from economic theorists. A second contribution of the current findings is that they help distinguish between different theoretical accounts of which psychological mechanisms promote microlending, and specifically support an anticipatory affect account. While previous research on charitable giving has presented mixed evidence of the impact of positive versus negative affect (Andreoni 1990; Small and Verrochi 2009), by simultaneously assessing affect at both internet and laboratory levels of analysis, the current studies provide clear evidence that photograph-elicited positive arousal most powerfully promoted loan funding rates and outcomes. A third contribution of the current findings is that they validate neuroimaging technology as potentially providing useful practical information about how to enhance loan request success.

Opportunities exist for further developing models that can specify when and how neural mechanisms account for aggregate behavior. The present findings thus raise the hope that integrating neuroscience evidence across levels of analysis can ultimately improve theories of choice. Together, these findings highlight affective neuroscience’s potential to test theories about neuropsychological mechanisms that drive microlending, to predict market-level behavior, and to enhance the effectiveness of loan requests.

Prosocial Incentives: Limits and Benefits of Working for Others

EXTENDED ABSTRACT

Optimizing incentive schemes to increase effort provision is an important design question for firms, governments, and other organizations. However, standard self-benefiting monetary incentives have been shown to backfire, particularly when the payments are low (Ariely, Bracha and Meier, 2009; Deci, 1971; Gneezy and Rustichini, 2000; Heyman and Ariely, 2004). Recent work has demonstrated that individuals report greater happiness when spending money on others than when spending on themselves (Dunn, Aknin, and Norton 2008). Building on these findings, we use two field experiments to compare the effectiveness of prosocial incentives, where effort is tied directly to charitable contributions, to standard, self-benefiting. We hypothesize and show that when incentives are low, individuals will exert more effort under a prosocial incentive scheme than under a standard incentive scheme. However, when incentives go up, individuals work harder under standard incentives but do not adjust effort when the money is donated to others. Additionally, we demonstrate that individuals are more likely to select into prosocial incentive schemes—especially in public.

In study 1 we used an online labor spot market, Amazon Mechanical Turk, to advertise a task requiring workers to populate an image database with pictures in a particular domain (e.g., wildlife). The advertisement featured the basic details of how these images should be collected, as well as the flat fee for completing the task, which entailed collecting ten links to images from the web. It also included a link to learn more information and to sign up. Once workers (N=872) clicked on the link, they were randomized into one of four conditions, which varied the incentive (Low/\$0.01 per 10 images vs. High/\$0.05 per 10 images) and the beneficiary (For Self vs. For Others, where the Others is one of six charities). This design allowed us to test how many workers selected into completing the task under the incentive scheme, as measured by the ratio of those who began and finished the task to those who clicked on the link. In line with our hypothesis, when incentives were Low, workers were more likely to begin and finish the task under the prosocial incentive scheme (62% For Others) than in the standard incentive scheme (53% For Self, $p=.04$). This difference disappeared when the incentive increased: workers were just as likely to begin the task under the prosocial incentive scheme (64% For Others) as under the standard one (61% For Self, $p=.45$).

Recent studies suggest that although individuals often choose to act prosocially when having to make this choice, they may intentionally avoid such decisions if possible (Andreoni, Rao and Trachtman, 2012). In light of this evidence, to assess the effectiveness of prosocial incentive schemes in practice, it is critical to determine whether they discourage or encourage participation. In study 2, we ran a field experiment in the context of a recycling drive to study whether individuals will be less likely to participate in a campaign that uses a prosocial incentive scheme, and to test the effect of making the decision public. We made announcements for an upcoming recycling drive in 12 classrooms, and asked students (N=846) to indicate on a slip of paper their intention to participate in the drive. Students saw one of two incentive schemes for bringing in recyclables (For Self or For Others), crossed with one of two levels of visibility: students either opted-in privately by marking a sheet of paper and slipping it into an envelope, or publicly by raising their hands after marking the paper and bringing it to the front of the room. Students were told the procedure prior to making their decisions. Results showed that individuals were significantly more likely to participate in the

recycling drive when money from recyclables went to charity rather than themselves. The prosocial incentive scheme had a significant main effect on participation, with 19.1% of students agreeing to participate in the For Others treatments compared to 7.4% in the For Self treatments ($p < .001$). Pairwise comparisons show significantly more sign ups in both the public and private For Others treatments (23.9% and 15.1%, respectively), compared to sign-ups in the public and private For Self treatments (6.79% and 8.09%, respectively), though the difference between private For Others and private For Self was marginally significant ($p = .06$). Making participation public had a significant effect on sign-ups, but only in the prosocial treatment: 23.9% signed up in the For Others public treatment compared to 15.1% in the private treatment ($p < .05$). In contrast, making the act public had no significant effect on participation in the For Self treatments (6.79% vs. 8.09%, n.s.).

SESSION OVERVIEW

The objective of this session is to bring together research that contributes to better understanding and addressing important social problems. In keeping with the conference theme "Advancing Connections," the four papers in this session not only advance our theoretical understanding of consumer behavior, but also generate practical and policy implications, each aimed at increasing consumer welfare:

Sugary consumption is a major contributor to the societal problem of obesity. Therefore, some have argued for a restriction on the size of sugary beverages. In the first paper, John and Roberto examine the consequences of a possible firm response to a portion size cap: bundling products in order to continue to offer larger sizes. The authors conducted an incentive compatible experiment and found that bundling soda beverages (2 x 12 oz instead of 24 oz) caused people to order *fewer* ounces of soda, in line with the goals of proposed policy.

In the second paper, Robitaille, Mazar and Tsai focus on the problem that the vast majority of individuals support organ donation yet many do not take action and register. The authors tested interventions aimed at increasing organ donation rates in a large-scale randomized control trial. These interventions aimed at counteracting psychological barriers that could discourage individuals from registering. The authors found that 1) providing information to satisfy the due diligence heuristic, 2) promoting cognitive perspective taking and 3) promoting first-person emotional perspective taking to induce a sense of social responsibility, each significantly increased actual donor registrations.

While the first two papers show that interventions improve behavior while in place, less is known about extended effects, once interventions end. In the third paper, Mochon and colleagues examined the extended effects of a behavioral health intervention with a voluntary 6-month commitment contract. The authors found persistence of

the positive behavioral change, no negative substitution effects and no effects on customer loyalty once the intervention was removed. These findings support the notion that incentives can drive long-term change, and therefore be valuable tools for improving health.

In the fourth paper, Donnelly and colleagues examine an untapped source of consumer happiness, their disposal choices. They focus on 'social recycling' (disposing still useful items to be reused by others). Across four studies, they found that social recycling resulted in increased positive and reduced negative emotions. Moreover, social recycling encouraged people to reduce product retention (which may help alleviate hoarding), and significantly reduced the number of items placed into trash and recycling, which is important because the average American generates 4.5 pounds of trash daily.

Together, these papers highlight the impact of simple behavioral interventions and their positive influences on both individual and societal wellbeing. At the same time, from an applied perspective, they raise the questions when such interventions may and may not be ethically justified, and how they may be used to empower people to be able to regulate their own conduct rather than enforcing specific behaviors.

This session should facilitate connections among consumers, academics, practitioners, and public-policy makers alike – consumer research for the greater good.

Setting the Record Straight on Sugary Drink Portion Cap Policies

EXTENDED ABSTRACT

We test the effect of portion size caps on people's propensity to buy sugary drinks. This intervention stems from the behavioral economic notion of constructed preferences – that people have difficulty knowing what they want, and therefore turn to contextual cues to try to resolve this uncertainty. In food consumption, this translates into "mindless eating" – instead of relying on their bodies to tell them when they're full, people rely on contextual cues, such as an empty plate, to tell them that they are full. Consistent with this perspective, Brian Wansink and colleagues have conducted a series of ingenious experiments in which, for example, people eat fewer chicken wings when the remnants of the eaten wings (i.e. bones) are left on the table, as opposed to when they are continually cleared away. The bones serve as a cue reminding people of how much they've eaten, in turn curbing consumption. Therefore, we thought that reducing the portion size of soda may serve to reduce consumption, while at the same time preserving individual choice – people are free to order as many sodas as desired.

Although there is reason to suspect a soda cap policy to reduce consumption, this intervention has been met with considerable public and political resistance. In 2012, the New York City Board of Health prohibited restaurants from selling sugary drinks (i.e. soda and juice) over 16 ounces. However the policy was never implemented because it was overturned by city council. Contributing to the opposition has been an influential piece of research concluding that limiting sugary drink sizes will have adverse unintended consequences (Wilson, Fantino, & Fantino, *PLoS One*, 2013). Specifically, these researchers argued that in response to such a policy, firms will start to offer bundles. For example, banned from offering a large-sized 24 ounce soda, the authors contend, firms would offer the large size as 2x12

ounce sodas. Moreover, the authors argue that framing a 24 ounce soda as 2x12 ounce sodas will *increase* consumption.

However, the study design did not resemble the way in which this policy would *actually* be implemented, and thus, the authors' conclusions are unwarranted. Specifically, the study was hypothetical, underpowered, and conducted online. Thus participants did not actually order drinks and hence, consumption was not measured. It would seem that giving participants the opportunity to actually buy drinks would be a minimal design requirement to test the effect of soda cap policies. Given that sugary consumption is a major contributor to the societal problem of obesity, assessing the true effect of this possible firm response is of critical importance.

We therefore conducted a large-scale, well-powered experiment in which we assessed the effect of soda caps on people's propensity to order and consume soda. We also tested whether the effect of soda caps might depend on the type of restaurant: whether it is self-serve or full service. One could imagine that bundling might be particularly effective at curbing consumption in a self-serve context, for it capitalizes on the embarrassment and inconvenience people face in having to carry two sodas to their table. The study was therefore a 2x2 between-subjects design in which we manipulated bundling (single unit vs. bundled) and service style (self-serve vs. served).

Participants ($N=297$) were endowed with forty cents, which they could use to buy sugary drinks. All participants had the choice of purchasing either nothing (in which case they could keep all 40 cents), a medium (16 ounce) drink for 20 cents, or a large (24 ounce) drink for 30 cents. To encourage drink buying, we kept prices low and offered a choice between two different (sugary) drinks: iced tea or lemonade. In the single unit condition, the choice was simply between one 16 ounce cup or one 24 ounce cup. In the bundled condition, the large option was presented as two 12 ounce cups. Thus in the bundled condition, the medium size was presented as one 16 ounce cup, whereas the large size was presented as 2x12 ounce cups. In the served condition, the soda was delivered directly to the participant's table; this condition mimicked a sit-down restaurant in which sodas are delivered to patrons by waiters. In the self-serve condition, participants had to walk over to a booth to pick up their order. Critically, at the time of making their purchase decision, participants were aware that they would either be served the soda (served condition) or would have to personally pick up the soda (self-serve condition).

Results indicated that regardless of service style, bundling caused people to order fewer ounces of soda: In the single unit condition, approximately 45% of participants ordered the large size, compared to only 20% of participants in the bundled condition ($p=.03$). There was no effect of service style, nor did service style interact with bundling. In ongoing research, we are testing other possible firm responses that could substantively impact the effectiveness of soda size cap policies; for example, offering free refills.

Nudging to Increase Organ and Tissue Donor Registrations

EXTENDED ABSTRACT

On average, 18 people in the United States die every day waiting for an organ transplant because of a growing shortage of donated organs (organdonor.gov 2014). Over 100,000 individuals are currently on the transplant waiting list and the gap between those needing transplants and those receiving them continues to widen. While the vast majority of individuals acknowledge the urgent need for more organ and tissue donors and support organ and tissue donation, it is puzzling that many of them do not take action and register.

Behavioral scientists have started to investigate the shortage of registered organ donors and explore ways to encourage individuals to register their consent. For example, Johnson and Goldstein (2003) demonstrated that countries with a presumed-consent default – individuals are automatically registered as donors unless they explicitly opt-out – have, on average, 60% more of the population registered as donors compared to countries with an explicit-consent default – individuals are not registered as donors unless they explicitly register their consent. The takeaway of this research is that one way to address the low number of registered donors may be to change the organ donation policy default from an explicit-consent system to a presumed-consent system. In spite of the positive evidence for the presumed-consent default, ethical concerns have been raised with this approach. Further, recent empirical evidence showed that changing the default may be ineffective at increasing registrations (Ammann 2010). Therefore it is important to identify potential psychological barriers to donor registration in explicit-consent systems and develop corresponding countering interventions to increase the number of registrations in these systems.

The aim of this research is to apply theories from behavioral science to develop interventions to nudge individuals into action and increase organ donor registration rates in the field. By carefully examining the registration processes in explicit-consent systems and drawing on the literature from behavioral sciences we propose that there are at least three psychological barriers that are inherent in explicit-consent systems that are hard for people to overcome and that contribute to the low sign-up rates. These psychological barriers include hassle cost – the hassle of actually registering one's consent (e.g., Bettinger, et al. 2012; Bertrand et al. 2006), the due diligence heuristic – individuals may feel they have not put in adequate effort to make an informed decision (Tsai and McGill 2011; Schrift et al. 2011; Sela and Berger 2012), and low sense of social responsibility (Slovic 2007; Wallach et al. 1964). We propose that these psychological barriers are likely operating together, contributing to low sign-up rates. Therefore, we designed and tested a number of interventions in order to overcome these barriers, and in turn increase the number of registered donors.

We conducted a large-scale ($N = 10,043$) randomized controlled trial on organ and tissue donor registrations in order to test the effectiveness of our behavioral interventions, each aimed at counteracting a psychological barrier that could discourage individuals from registering. Our field experiment was conducted in collaboration and consultation with several participating government agencies and departments within one North American jurisdiction. The experiment itself was conducted at one of their service center locations. During the experiment, we measured the daily number of new donor registrations at this location over an eight-week period.

The experiment had nine conditions in total: two control conditions (one pre-experiment and one post-experiment), two acclimation conditions that served to expose the staff to our new forms and process as well as examine the effect of giving the staff specific instructions, and five focal treatment conditions designed to establish the most effective interventions to increase organ and tissue donor registration rates. These interventions sought to reduce the hassle cost (through simplifying the registration form; treatment condition 1), increase feelings of due diligence (through handing out a brochure; treatment condition 2), and induce a sense of social responsibility (through using nudge statements that prompted emotional and/or cognitive perspective taking; treatment conditions 3-5). All interventions were accompanied with more time for the individuals to think about the donation.

In order to examine the effect of condition on an individual's likelihood of registering as an organ and tissue donor, we employed a logistic regression analysis with each of the conditions and business days dummy-coded, and fixed-effects for the customer service representatives. The dependent variable was whether or not an individual registered as an organ and tissue donor. To test the effectiveness of our interventions, we examined the odds ratios of individuals registering as organ and tissue donors in each of our five focal treatment conditions and compared them to the pre-experiment control condition, with a donor registration rate of 3.04%.

We find that three of the five focal treatment conditions significantly increased the likelihood of an individual registering as an organ and tissue donor (overall model: χ^2 (DF=13) = 106.89, $p < .001$): handing out a brochure, handing out the registration form with a cognitive perspective taking nudge statement that has been successfully used online in the UK (Behavioral Insights Team 2013) and handing out the registration form with a first-person emotional perspective taking nudge statement. Individuals' odds of registering as organ and tissue donors were more than two times higher when visiting the service center during these three treatment conditions than during the pre-experiment control condition.

Together these findings contribute to our understanding of how to motivate individuals to act for the greater good. In our field experiment, we significantly increased registrations by: 1) providing more information to satisfy the due diligence heuristic, 2) promoting cognitive perspective taking and 3) promoting first-person emotional perspective taking. Each of these interventions more than doubled an individual's likelihood of registering. In addition, our paper demonstrates the power of relatively costless nudges, grounded in behavioral science research, and their profound influence on behaviors significant to economic and individual wellbeing.

Gain without Pain: The Extended Effects of a Behavioral Health Intervention

EXTENDED ABSTRACT

Financial incentive programs are increasingly employed to improve people's health (Gneezy, Meier, and Rey-Biel 2011). While research shows that many incentive-based interventions can effectively improve a specific health behavior while in place, less is known about the extended effects for both the participants and the host firms once the intervention ends. These effects are essential to understand from both a theoretical and policy perspective because an intervention that has positive effects on a targeted behavior during the intervention, but leads to negative consequences once the program ends, or shows negative substitution effects in other domains, may not be a sustainable marketplace product.

This research begins to address this question by examining the extended effects of a behavioral health intervention: a voluntary 6-month commitment contract that significantly improved the health of grocery purchases (Schwartz et al. 2014). Member households who were already receiving a 25% discount on healthy food grocery purchases, put that discount on the line by precommitting to a 5-percentage-point increase above their household healthy food baseline. Those who met the goal kept their discount, those who did not forfeited it.

Since this precommitment intervention was run within the context of an overall health rewards program, we were able to examine the commitment device's impact beyond the specific time period and targeted behavior (nutrition). Specifically, we examined whether the effect persisted once the penalty was removed, whether the program lead to substitution effects while the incentives were in place (i.e.,

healthier nutrition behavior leads to less exercise) and, finally, the impact of the intervention on the overall relationship between the customers and the firm running it.

Persistence effects: For the committed households we specifically tested whether the intervention led to habit formation (Charness and Gneezy 2009) or whether the penalty associated with the precommitment led to crowding out effects whereby less healthy purchases re-emerged once the penalty was removed (Benabou and Tirole 2003; Lepper, Greene, and Nisbett 1973). Consistent with the habit formation prediction, the committed group continued to make healthier grocery purchases during the 6-months post-intervention ($\beta = 2.84$, $SE = .95$, $p < .01$). This persistence effect was strongest for the most loyal customers, as well as for participants who had the most money to lose during the commitment period. This result demonstrates that incentives can be catalysts to long term change, and therefore be valuable tools for improving health.

Substitution effects: One concern with health interventions targeting a specific behavior, is that they may lead to negative substitution effects in other domains, either because exerting self-control is depleting (Baumeister et al. 1998) or because of licensing effects (Khan and Dhar 2006). We tested for substitution effects by examining all logged exercise activity (e.g. going to the gym) during the precommitment period. In other words, we tested whether eating healthier food lead consumers to exercise less. Our results show no evidence of substitution effects. Committed households exercised slightly more (though not significantly more) than the control group ($\beta = .07$, $SE = .05$, *n.s.*). Interestingly, we found a significant positive effect on exercise when examining participants who had the most money on the line during the commitment period, ($\beta = .23$, $SE = .07$, $p < .01$). These are important findings since data limitations have prevented previous research from examining this important question about substitution effects. Our results further reinforce the value of incentives as a tool for improving health, by suggesting that they do not lead to negative consequences in other domains, and may even lead to positive spillovers for at least a subset of the population.

Loyalty effects: While penalty-only commitment contracts may improve targeted health behaviors, this may come at the cost of customer loyalty and thus make it difficult for private firms to offer such programs. We test the effect of the intervention on customer loyalty by examining involvement with the health rewards program during the year after the commitment contract ended. We do this by testing the participants' change in status level in the program relative to the prior year. Positive numbers indicate higher status, and therefore a better relationship with the firm. Our result show that committed households showed a positive (though non-significant) change in status during the year after the intervention ended ($\beta = .07$, $SE = .12$, *n.s.*). This is an important finding since most committed households forfeited their discount at least once, which could have translated into negative firm reactions. Consistent with this finding, the results of a follow-up survey suggests that committed households did not blame the firm for failures. Indeed, 68% assigned more blame to themselves than to the firm for failing to meet the precommitment goal (only 15% assigned more blame to the firm). This suggests that consumers took responsibility for their own actions, and consequently for their own failures, which mitigated any negative feelings towards the firm. Interestingly, when asked whether they would be willing to participate if the precommitment was offered again, a full 66% said that they would put their discount on the line as a means of improving self-control while grocery shopping.

From Garbage to Gift: 'Social' Recycling Promotes Happiness

EXTENDED ABSTRACT

Researchers are becoming adept at identifying ways to extract maximal happiness from the consumption process. For example, research has demonstrated that acquiring experiences make us happier than acquiring goods (Goodman, Nicolao & Irwin, 2009), and that spending money on others can yield greater happiness than spending money on oneself (Dunn, Aknin & Norton, 2008). While important, such work focuses primarily on acquisition and consumption.

In the present research, we argue that disposal choices represent an untapped source of consumer happiness. As such, we focus on social recycling, a relatively new form of 'recycling' one's possessions to others, which happens when consumers allow used goods to be acquired by an unspecified other.

As a first study, participants ($N = 279$) were given a list of 20 household items (i.e., a coffee mug) to sort into different boxes that represented disposal options. Participants were randomly assigned to a: (a) trash and recycling bin, (b) trash, recycling, and social recycling bin, or (c) trash and social recycling bin. The social recycling bin was described as a bin to 'place things you no longer want, but others might. All items placed into this box will be taken to the street on trash day, and made available to your neighbors. All untaken items will be removed.' This design allowed us to test the potential benefit of a social recycling bin, and to see if differences exist because of a third disposal option. Following the sorting task, participants reported their affective state, and impressions of how their disposal decisions impacted the environment and other people.

The presence of a social recycling bin significantly reduced the number of items placed in the trash ($p < .001$), and recycling ($p < .001$) bins, increased positive affect ($p = .08$), reduced negative affect ($p < .001$), increased feelings of helping the environment ($p < .001$), and others ($p < .001$) regardless of the number of disposal options. Perceptions of helping mediated the relation between social recycling and positive affective benefits.

Given that perceptions of helping others influenced positive affect, we ran a second study ($N = 298$) to evaluate the significance of the recipients of socially recycled items. We followed the same design as Study 1, however all participants sorted items into: (a) a trash bin, (b) a recycling bin or (c) a social recycling bin. We manipulated the recipients of the socially recycled items. Participants learned that socially recycled items would be made available to a family making an annual income of either (a) \$20,000, (b) \$40,000 or (c) \$100,000. The average income of our participants was \$32,634.12 ($SD = \$25,820.58$), so these income categories represented populations that made less, about the same or significantly more than our sample. While sorting decisions were no different based on the recipients, affective states were influenced. Individuals whose items went to a family making \$20,000 reported significantly more positive affect than those whose items went to a family making \$100,000 ($p = .02$). While there were no differences in perception of helping the environment, participants who gave to families making \$20,000 or \$40,000 reported higher feelings of helping others. Again, perceptions of helping others significantly mediated the social recycling and positive affect relation.

In our third study ($N = 222$), we investigate the differences between social recycling and donations. We hypothesized that social recycling is a more convenient form of donating, leading to less retention and trashing of items, and more prosocial exchange. In this study, participants listed ten possessions they no longer wanted, but other people may want or benefit from. Participants assigned to the

donation condition were asked to sort each item into (a) trash, (b) keep it, or (c) take it to the nearest donation center. Those in the social recycling condition were asked to sort each item into (a) trash, (b) keep it, or (c) social recycling bin. Like our other studies, participants then reported their affective states and their perceptions of helping others and the environment.

As hypothesized, social recycling was deemed much more convenient relative to taking items to a donation center ($p < .001$), and resulted in fewer items placed into the trash ($p < .001$), fewer items kept ($p = .003$), and more items prosocially disposed of ($p < .001$). Social recyclers also reported greater positive affect ($p = .05$), less negative affect ($p = .006$), and higher perceptions of helping the environment ($p < .001$), but no differences in helping others ($p = .60$).

In a fourth study ($N = 182$) participants sorted *real* items that would actually be trashed, recycled or made available to others. Participants came to a university laboratory and were randomly assigned to one of three conditions: (a) trash and recycling, (b) trash, recycle and social recycle, or (c) a taker of a socially recycled item. Takers did not sort; they only took items that had been socially recycled by others. When arriving to our lab, participants rated how happy they felt on a 1 (not at all) to 5 (very much) scale. They then were asked to sort 18 items placed on their desk into the available bins. Participants in the social recycling condition then took items placed in the social bin to a 'share shelf' which made the items available to participants assigned as 'takers'. Sorters then rated their current happiness after this task, while takers took an item and then reported their happiness.

Participants in the social recycling condition sorted fewer items into the trash ($p < .001$) and recycling ($p < .001$) bins. While there were no significant differences in happiness between conditions at time 1 ($p = .23$), at time 2 social recyclers were significantly happier ($p = .003$). Traditional disposers and takers did not experience any differences in happiness from time 1 to time 2 ($p = .35$).

Across four studies, we find support for our hypothesis that social recycling can boost consumer happiness, likely because of increased feelings of helping.

SESSION OVERVIEW

The study of consumer-brand relationships has been a central focus of research in the recent past (Fournier 1998; Escalas & Bettman 2003; Batra, Ahuvia, and Bagozzi 2011). Aligning with the conference's theme of "Advancing Connections," this session provides a holistic view of consumer-brand connections by exploring different antecedents of these connections as well as their downstream consequences. The papers in this session explore motivational-emotional, as well as collective, processes underlying the formation of consumer-brand connections, as well as some of the consequences of such connections for consumers' views of the brand (i.e., their response to negative brand information) and others (i.e., attributions based on the connections other people form with brands). Collectively, the papers here provide a broader framework to understand the antecedents and consequences of consumer-brand connections.

Rodas and Torelli explore the motivational-emotional process of falling in love with a brand by applying the self-expansion model (Aron et al., 2013) to consumer-brand relationships. This model suggests that novel and exciting activities, as well as direct acquisition of resources, can trigger self-expansion, which in turn can result in positive feelings or love for the brand. The authors demonstrate that consumption experiences that are novel and exciting, or that provide direct resources to consumers (in terms of information) result in greater love for the brand, and this effect is mediated by feelings of self-expansion.

Torelli and colleagues focus on the role of self-relevant collective identities in shaping self-brand connections. They find that a brand's cultural symbolism impacts the strength of the consumer-brand relationship. Stronger bonds with culturally symbolic brands are more likely to emerge when cultural identities are chronically or temporarily salient, as a result of identity salience heightening the valuation of culturally symbolic brands.

Camurdan and colleagues investigate how self-brand connections interact with consumers' mindsets to impact their evaluations of brands under the presence of negative brand information. Findings from two studies show that consumers in a mastery mindset tend to

find negative brand information more diagnostic and hence become more susceptible to brand dilution when they have a strong self-brand connection, whereas consumers in a performance mindset tend to find negative brand information more diagnostic when they have a weak self-brand connection.

Finally, Park and John study how consumer-brand connections impact people's views of other consumers. The authors examine how brand signals are perceived by others. They find that not all consumers perceive brand signals in the same way. Only entity (not incremental) theorists appear to form judgments about other people based on the brands they use. Furthermore, this process is mediated by their perception of brands as diagnostic information when judging others.

In keeping with the theme of the conference ("Advancing Connections"), the papers in this special session build connections across the growing field of consumer-brand connections to provide a holistic view of its antecedents and consequences. The papers in this session should appeal specially to scholars interested in branding, brand signals, negative publicity, as well as generally to those interested in the psychological processes underlying self-brand relationships.

The Self-Expanding Process of Falling in Love with a Brand

EXTENDED ABSTRACT

Brand love, a construct that assesses consumers' passionate emotional attachment to particular brands, has experienced a surge in research in the recent past (Batra et al., 2012). The focus has been on conceptualizing and measuring the construct and on exploring the downstream consequences of brand love, such as WOM, loyalty, and protection against brand failures (e.g., Carrol and Ahuvia, 2006). However, there is little research that explores the underlying process of falling in love with a given brand. There are potentially several ways in which consumers fall in love with brands (e.g., finding a match between what the brand signals to others and what consumers want to signal), but our research explores a novel antecedent of brand love, namely that feelings of self-expansion can result in love for a brand.

According to the self-expansion model (Aron et al., 2013), people have a fundamental motive to expand their selves and one way of achieving this is by forming close relationships in which each includes the other in the self. Self-expansion can occur by directly acquiring resources from the other person (e.g., through sharing and learning from each other), or by sharing novel and challenging experiences, which is arousing and thus provides a sense of expansion. As such, the self-expansion model posits that when a potential relationship partner is associated with arousal or new resources (material, cognitive or psychological), the partner is viewed more positively, or loved more, because of this link to self-expansion.

There is initial psychological and neurophysiological evidence that the self-expansion model can be applied to self-brand relationships (Reimann et al., 2012). However, this research focuses on already established relationships with brands and their impact on emotional arousal, without addressing the questions of how the love towards the brand emerged and whether the link between brand love

and arousal is bidirectional. To address these questions, we propose and find evidence that arousal (in the form of exciting and novel activities) can lead to falling in love with a brand (study 1) and that this process is mediated by self-expansion (study 3). Furthermore, we find evidence that another path to self-expansion, namely the direct acquisition of resources (in the form of information), also leads to brand love (study 2).

In order to explore whether engaging with a brand in a novel/challenging way leads to higher levels of brand love, 165 U.S. participants reviewed information about an ostensible new brand of athletic shoes, *FastForm*. They were randomly assigned to one of two conditions. In the 'exciting' condition, they wrote a positive review about an imaginary exciting experience while wearing the athletic shoes; whereas in the 'control' condition they wrote about a pleasant experience. After this, they all rated their love for the brand (Carroll & Ahuvia, 2006). As predicted, writing about having an imaginary exciting/novel experience with the brand resulted in greater love towards the brand than writing about an imaginary pleasant experience ($M=4.88$ and $M=4.31$, respectively, $p<.005$).

Study 2 was designed to explore the extent to which directly acquiring resources from a brand (another proposed process of self-expansion) results in higher brand love. To do so, 63 U.S. participants rated an ostensible new campaign by an unfamiliar brand (*Ten Acre*, a relatively new brand of potato chips in the U.K.). The campaign consisted in printing fun facts inside the chips' bags. Past research has shown that reading more (vs. less) novel, exciting and interesting facts leads to self-expansion (Mattingly & Lewandowski, 2013). Based on this notion, participants were randomly assigned to either a 'novel' condition presenting novel/exciting facts (e.g., "butterflies taste with their feet"), or to a 'control' condition including similar, but less novel facts (e.g., "butterflies begin life as a caterpillar"). After this, they indicated their love for the brand. Results showed that including more (vs. less) novel and exciting facts led to higher levels of brand love ($M=4.17$ and 3.72 respectively, $F(1, 60) = 3.631$, $p<.05$). This effect emerged even after controlling for brand familiarity.

In study 3, we assessed directly the extent to which feelings of self-expansion mediate the past effects. 166 U.S. participants were asked to directly interact with the brand. Under the cover story of studying the effects of multitasking on people's judgments, we asked the participants to review an unfamiliar brand (*The Fruit Factory*, a brand of fruit gummies in the U.K.) while using their motor skills. In the 'control' condition, participants spent 90 seconds reading about the brand while eating as many gummies as they wished out of a cup. In the 'novel/exciting' condition, participants did the same, except that they ate the gummies using easy chopsticks. After this, participants indicated their love for the brand. A one-way ANOVA with condition as a fixed factor revealed significant differences between the control and novel conditions ($M=3.63$ and $M=4.08$, respectively, $p\leq.05$). Additionally, we counted the gummies left in the cup as a behavioral measure of enjoyment (i.e., less gummies left=more enjoyment) and there were also significant differences between the control and novel conditions ($M=14.30$ and $M=11.12$, respectively, $p<.05$). To measure self-expansion, at the end of the session, participants were asked to draw two circles on a sheet of paper: one representing them and one representing their current context. We used the ratio of the diameter of the 'self' circle divided by that of the 'context' circle as a measure of self-expansion—a greater ratio means a more expanded self. Results of a mediation analysis suggested that greater self-expansion mediated participants' higher levels of love towards the brand in the novel (vs. control) condition (mediated effect = .207, SE = .105, 95% CI = .04 to .46).

This research contributes to the emerging literature of self-expansion in consumer-brand relationships by providing evidence that interacting with a brand in an exciting and/or novel way or directly acquiring resources from it can result in brand love, and that this process is mediated by self-expansion. Furthermore, and more importantly, this work sheds light onto the process of falling in love with a brand.

Salient Cultural Identities and Consumer Relationships with Culturally Symbolic Brands

EXTENDED ABSTRACT

Brands are used by consumers to signal self-relevant characteristics (Levy 1959). Thus people tend to prefer and connect with those brands that match their self-relevant personalities and values (Aaker 1999; Torelli et al. 2012). Although the impact of personal traits and characteristics on brand attitudes is well established, relatively less is known about the role of self-relevant collective identities in shaping self-brand connections. This research attempts to fill this gap by identifying the role that a brand's cultural symbolism plays in the long-term bonds that consumers establish with brands.

Consumers don't always act according to culturally-prescribed norms, and the effects of culture on persuasion are often only evident when consumers engage in little deliberation (Briley and Aaker 2006). However, consumers who are reminded of their cultural identity tend to think and behave in identity-consistent ways (Oyserman 2009). This explains why making a consumer's social identity salient can result in more favorable evaluations of hypothetical products that are promoted in identity-relevant terms (e.g., Reed 2004). Because acting according to cultural mindsets seems to be highly context-dependent, it is still an open question whether cultural identities shape the long-term relationships that consumers establish with brands. We propose that because chronic identification with a cultural identity should increase the likelihood that the identity is salient when evaluating a brand, highly identified consumers should exhibit more favorable attitudes toward brands that symbolize a valued cultural group (i.e., culturally symbolic brands). Over time, this should lead highly identified consumers (more so than those low in group identification) to establish stronger bonds with culturally symbolic brands. Four studies with participants from different cultural groups were conducted to test these hypotheses.

Study 1 tested the basic prediction that consumers high (vs. low) in their identification with a cultural group exhibit more favorable attitudes toward brands high in cultural symbolism (CS) for the group. Male and female participants in the U.S. and China ($N_{U.S. Males} = 56$, $N_{U.S. Females} = 50$, and $N_{Chinese Females} = 51$) evaluated two pairs of brands (from pretests) chosen to be either high or low in CS for the group (*Budweiser* and *Harley-Davidson* [high-CS] and *Jansport* and *American Express* [low-CS] for American men; *Special K* and *Aveda* [high-CS] and *Jansport* and *American Express* [low-CS] for American women; *Gege Qipao* and *Yuesai* [high-CS] and *Swatch* and *Jeanswest* [low-CS] for Chinese women). After completing some filler tasks, participants also rated their identification with their corresponding cultural group (i.e., Bem Sex Role Inventory for American men and women, Bem 1974; or the Chinese Sex-Role Inventory for Chinese women, Zhang et al. 2001). Fitting a multi-level linear model to the brand evaluations data (evaluations for the two types of brands are nested within participants, which in turn are nested within each cultural group) showed that, for all cultural groups, individuals having high (vs. low) identification with the group exhibited more favorable evaluations of brands that are high in symbolism of abstract group characteristics. In contrast, evaluation

of brands low in cultural symbolism is unrelated with cultural group identification ($p > .16$).

Salience of a cultural identity can occur spontaneously due to a chronic tendency to view the self in terms of the cultural identity (i.e., strong cultural identification), or can be triggered by contextual cues (Forehand, Deshpandé, and Reed 2002; Torelli 2013). Studies 2a and 2b were designed to assess the extent to which favorable responses to brands high (vs. low) in cultural symbolism are indeed driven by the salience of cultural group identity. Minnesotan participants read an article aimed at making the Minnesotan identity salient or completed a neutral task. After this, participants in study 2a were informed about a promotional activity that consisted in paying college students to carry a brand logo on their backpacks. Half of the participants were told that the brand involved in the activity was “Target” (Minnesota-symbolic brand), whereas the other half were told it was “Dasani” (Minnesota-neutral brand). Participants indicated the amount in dollars that they would require as a payment to participate in this promotional activity. For Study 2b, participants were presented with an actual set of poker chips with the “Target” logo stamped on each chip and indicated the dollar amount that they would be willing to pay for it. Results showed that when the Minnesotan identity was made salient, participants were willing to receive *less* money for promoting a Minnesota-symbolic brand (“Target”), and also to pay *more* money for a product that carried the brand’s logo, as compared to participants in the baseline condition. No such effect emerged when the brand was low in association with the salient identity (“Dasani”).

Finally, study 3 assessed directly the long-term relationships that consumers establish with brands that vary in their cultural symbolism as a function of their cultural group identification. A sample of 320 American and Chinese participants were prompted to spontaneously elicit their favorite brand and assessed the extent to which they were likely to elicit a brand that was high (vs. low) in cultural symbolism. We also assessed the extent to which their perceptions of self-brand connections (SBC) were influenced by the congruity between their own chronically salient cultural identity and that of the brand. Identity salience was measured via identification with their cultural group for two different samples (American and Chinese). Results showed that participants with a chronically salient cultural identity (i.e., those highly identified with their cultural group): (a) were more likely to spontaneously list a brand that was strongly associated with their salient cultural identity schema; and (b) reported a higher level of SBC for brands high in CS. No such relationships emerged for participants low in identification with the cultural identity.

Results from this research demonstrate that a brand’s cultural symbolism impact the strength of the consumer-brand relationship. Stronger bonds with culturally symbolic brands are more likely to emerge when cultural identities are chronically or temporarily salient. This occurs because identity salience heightens the valuation of culturally symbolic brands.

When Strong Self-Brand Connections Don’t Protect Brands: Achievement Mindsets and Brand Dilution

EXTENDED ABSTRACT

Instances of the spread of negative information about brands are becoming increasingly common (Monga & John, 2008), especially now that social media facilitates the share of unfavorable brand experiences. One of the main reasons why consumers are attentive to negative brand information, and hence become more susceptible to brand dilution, is because they tend to perceive negative brand

information as more diagnostic (Ahluwalia & Gurhan-Canli, 2000). Having a strong connection to a brand protects the brand against negative information. This research expands past theorizing by focusing on achievement goal theory. We demonstrate that consumers’ differential views of competence that can be salient in a branding context alter the diagnosticity of negative information, and hence affect consumers’ susceptibility to brand dilution. Furthermore, we demonstrate this effect even under the influence of a strong self-brand connection.

According to achievement goal theory, there are two different ways in which individuals interpret competence: mastery and performance. While some individuals focus on competence with the aim of outperforming themselves (mastery mindset), others focus on competence with the aim of outperforming others (performance mindset) (Elliot, McGregor, & Gable, 1999). Thus, there are differences in how individuals in each mindset perceive negative feedback. Individuals in a mastery mindset welcome negative feedback, as it hints diagnostic cues about possible ways for improvement (Dweck & Leggett, 1988, Cron et al., 2005). In contrast, individuals in a performance mindset emphasize normative performance, thus perceiving negative feedback as a threat to one’s perceived ability and worth (Cron et al., 2005).

Prior literature suggests that, when consumers integrate a brand into their own self-concept, there is a strong link between how individuals view information about themselves and how they view information about the brand (Escalas & Bettman, 2003). According to Cheng, White and Chaplin (2012), when consumers strongly connected to a brand encounter negative information about the brand, they react to it as they would respond to negative information about themselves. We propose, and find evidence across two studies, that when consumers have high self-brand connections, those in a mastery (vs. a performance) mindset tend to find negative brand information more diagnostic and hence become more susceptible to brand dilution. In contrast, when consumers have low self-brand connections, those in a performance (vs. a mastery) mindsets tend to find negative brand information more diagnostic and hence become more susceptible to brand dilution.

Study 1 was designed to explore how people in different achievement mindsets perceive the diagnosticity of negative brand information, as well as to assess the extent to which self-brand connection moderates these perceptions. To do so, achievement mindset was manipulated by asking participants to recall a time in their lives in which they tried to outperform themselves (for mastery mindset) or others (for performance mindset). Then, participants read a fictitious newspaper article stating that the industry experts and some selected consumers already had a chance to evaluate a Google product and the reviews came in highly negative. Afterwards, participants were asked to assess the diagnosticity of the newspaper article (how useful/relevant was the newspaper article; Ahluwalia, 2002) and rated Google in terms of self-brand connection. Using Preacher and Hayes’s (2013) method of calculating standard errors and 95% confidence intervals of the effect of self-brand connection on achievement mindset, the results suggest a significant achievement mindset x self-brand connection interaction ($\beta = -.48$, $t = -2.80$, $p < .01$). We used Johnson-Neyman technique to decompose this interaction and we found that when self-brand connection is high, consumers in a mastery (vs. a performance) mindset are more likely to find negative information to be diagnostic. In contrast, when self-brand connection is low, consumers in a performance (vs. a mastery) mindset are more likely to find negative brand information to be diagnostic.

In study 2, we used a different brand (Sony) to further explore people's susceptibility to brand dilution under different achievement mindsets, as well as to assess the extent to which diagnosticity of information mediates the interactive effect of self-brand connection and consumer mindset on susceptibility to brand dilution. We measured participants' evaluations of the Sony brand. Next, participants read a fictitious newspaper article with negative information on the Sony brand (adapted from Monga & John, 2008). Afterwards, participants rated Sony using the same items as before, assessed the diagnosticity of the newspaper article and completed the self-brand connection scale. We subtracted the post-exposure mean of brand evaluation index from pre-exposure mean of brand evaluation index to create the brand dilution measure. Using Preacher and Hayes's (2013) method of calculating standard errors and 95% confidence intervals, we found a significant achievement mindset x self-brand connection interaction ($\beta = -.32$, $t = -2.76$, $p < .01$). Johnson-Neyman analysis showed that when self-brand connection is high, consumers in a mastery mindset are more susceptible to brand dilution than consumers in a performance mindset. In contrast, when self-brand connection is low, consumers in a performance mindset are more susceptible to brand dilution than consumers in a mastery mindset. To examine whether information diagnosticity mediated the effect of achievement mindset and self-brand connection interaction on brand dilution, we used Preacher and Hayes's moderated mediation model. The index of moderated mediation was significant ($\beta = -.08$, $CI = -.214$ to $-.016$) suggesting that information diagnosticity is mediating the effect of achievement mindset on brand dilution when self-brand connection is taken into account.

Our findings contribute to theory in several different ways. First of all, we extend the brand dilution literature by demonstrating achievement mindsets' differential effect on brand dilution. Second, to our knowledge, this research is the first one to examine achievement mindsets in a marketing context. Third, we extend the literature on self-brand connection by demonstrating that strong self-brand relationships do not always protect the brand from negative information. Lastly, this research contributes to the achievement goal theory by demonstrating that when individuals in mastery/performance mindsets see the target of the information as an extension of their selves, they treat negative information in the same way they treat negative personal feedback.

The Brand Company You Keep: When People Judge You by the Brands You Use

EXTENDED ABSTRACT

One of the most pervasive findings in the branding literature is the existence of strong connections between consumers and the brands they use. Consumers use brands to express themselves, communicate who they are to other people, and signify membership in a group. A common theme of much of this work is that consumers use brands to signal aspects of themselves—such as their personalities, interests, and status—to other people.

Surprisingly, there has been little research on whether these brand signals are received as intended. For example, if I wear a Rolex watch, will other people view me as successful? If I own a Mercedes, will other people perceive me as sophisticated?

In this paper, we examine how brand signals are perceived by others. We focus our efforts on the following question: Do all consumers perceive brand signals the same way—or, are some types of consumers more likely to use a brand signal to draw inferences about a brand user? We predict that there are individual

differences in consumers' propensity to use brand signals, and draw upon research on implicit self-theories as a starting point. Implicit self-theories are lay beliefs regarding the malleability of personal qualities. Two types of implicit self-theories have been identified: incremental and entity theory (Dweck 2000). Individuals who endorse *entity theory* ("entity theorists") view personal qualities and abilities as fixed, whereas as individual who endorse incremental theory ("incremental theorists") view personal qualities and abilities as malleable.

We reason that individuals who are entity theorists are more likely to use brand signals to make inferences about a brand user. Because they believe that everyone's traits are fixed, and that one's behavior is indicative of those traits, entity theorists make judgments of others based on very limited information (Plaks, Stroessner, Dweck, and Sherman 2001). Thus, simply seeing someone using a particular brand is sufficient to ascribe certain personality traits to that person. In contrast, incremental theorists believe everyone's traits are malleable, and therefore, one's behavior at one point in time is not necessarily diagnostic of their traits (Plaks et al. 2001). Thus, they are less likely to use brand signals as sufficient evidence of someone's traits.

We find support for our predictions in three studies. In the first study, we tested whether entity theorists (but not incremental theorists) judge the personality of a stranger by using the brand he or she uses. Participants were asked to view the pictures of two people that showed a moment of their daily lives, and to report their general impressions of each person by rating them on five personality domains (Aaker 1997; sincerity, excitement, competence, sophistication, and ruggedness). The first picture was a filler picture showing a woman talking on the phone. The second picture was the target picture showing a man who was reading a pamphlet about Mercedes Benz cars (brand information) or a magazine about cars in general (no brand information). After rating the target person on the five personality domains, participants completed an implicit self-theory measure. As expected, entity theorists perceived the target person to be more sophisticated (associated with Mercedes Benz) when the brand information was provided than when it was not. Such a difference was not found in other personality domains. Further, incremental theorists were not influenced by the brand information provided.

In the second study, we extended our findings by using a different brand (Godiva), changing the gender of the target person (female), and showing the image of the target person actually consuming the brand. Also, we manipulated beliefs in entity versus incremental theory (Chiu, Hong, and Dweck 1997) prior to seeing the target person's image. As predicted, participants in the entity theory condition perceived the target person as being more sophisticated (associated with the Godiva brand) when she consumed Godiva chocolates than when she consumed regular chocolates (no brand information). However, incremental theorists were not influenced by the brand information provided.

In a third study, we examined the mechanism underlying reliance on brands in judging others found among entity theorists in the first two studies. Entity theorists, who use brands as an important signal of the self, are likely to view brands as diagnostic information when judging others. However, if entity theorists have a chance to reflect the target person's life as if they were the person (which facilitates people to ascribe self-descriptive traits to the target person; Davis et al. 1996), they will put more weight on self-descriptive traits than a brand the person uses when judging the person. We thus predicted that when taking the perspective of a stranger, entity theorists will reduce their reliance on brands when judging him or her.

Participants were told that we were interested in people's ability to construct life-event details from visual information alone. They were asked to take a moment to look at the man reading the pamphlet about the Mercedes in the picture, and then to write a short narrative essay (2 pages) about a typical day in the life of the person in the picture. Participants in the perspective-taking condition were asked to write an essay about a typical day of that person while imagining as if they were that individual. Participants in the no perspective-taking condition were asked to write objectively without reflecting on their own life. Prior to the perspective-taking manipulation, we measured implicit self-theory. As expected, entity theorists perceived the target person to be less sophisticated (associated with Mercedes Benz) in the perspective-taking condition than in the no perspective-taking condition. However, incremental theorists were not influenced by the perspective-taking manipulation. More importantly, results from a *mediation analysis* showed that perspective taking decreased the belief that the target person used the brand (Mercedes Benz) as a way to signal and communicate his identity, which led to reduced reliance on the brand when judging the target person.

In sum, not all consumers perceive brand signals in the same way. Only entity theorists appear to form judgments about other people based on the brands they use.

SESSION OVERVIEW

Sharing is a fundamental consumption behavior that only recently has started to gain academic attention (Belk 2010). As consumers, we share our possessions, knowledge, experiences, time, and other resources with selected others. Sharing is defined as anti-materialistic, prosocial, communal behavior, which bridges interpersonal boundaries by linking us to other people, with no expectations of reciprocity (Belk 2010 ; Benkler 2004). However, very little is known about how the perception of others affects our willingness to share our possessions and resources with them.

This special session aims to further our knowledge of sharing as a social phenomenon. The authors explore diverse forms of sharing, including experiences, decisions, social relationships and possessions, in a variety of social contexts, and use multiple research methods and data from multiple countries, including Russia, France, Canada and the US.

Hellwig, Belk and Morhart open the session with an exploration of the sociality of shared moments in monetary (AirBnB) vs. non-monetary (CouchSurfing) peer-to-peer hospitality platforms. Using qualitative data, they study how shared experiences are created, shaped and evaluated through the prevailing material or non-material context. They conclude that when sociality is perceived as authentic it comes closest to the ideal of prototypical sharing.

Barakshina and Malter examine a different kind of sharing – shared decision-making, in the context of patient-doctor decisions during pregnancy and childbirth. Their survey data from Russia and the US and interviews with patients and their doctors show that patients often feel they are sharing decisions with doctors, as well as family, friends, and peers online, but the same treatment decisions are typically perceived by medical practitioners as not “shared” at all. Medical outcomes are felt most acutely by the patient (and her baby) and only to a lesser extent by others who shared in the decision.

Gentina, Shrum and Lowrey aim to bridge apparently contradictory concepts - sharing and materialism. Transcending the traditional view of materialism as acquisition of objects, they examine a

different type of materialism - as shared experiences. Using network analysis of adolescents’ social relationships with peers, they find a positive relationship between centrality of social standing and sharing materialism (but not with acquisition materialism) and between sharing materialism and happiness.

Finally, Ruvio, Mandel and Gentina focus on the fundamental question, “With whom do we share?” Two experiments suggest that consumers strategically choose with whom to share possessions, and tend to share more with individuals perceived as superior to them in terms of social comparison. This behavior seems motivated by anticipation of future gain, challenging the view of sharing as a non-reciprocal act.

Each of these papers highlights a different view of sharing as a social phenomenon. Together they expand our understanding of sharing as a consumption behavior and help push the boundaries of this emerging concept. This session offers potentially fruitful avenues for future research, and will appeal to ACR attendees interested in sharing, consumption and pro-social behavior, possessions and self-identity, and shared decision-making, among others.

Shared Moments of Sociality: Embedded Sharing within Peer-to-peer Hospitality Platforms

EXTENDED ABSTRACT

Many welcome the “new sharing economy” for its transformative impact, lower prices, and increased convenience. But there is also growing criticism of its rampant neoliberalism, its marginal illegality, and its business practices that support tax fraud and undermine workers’ rights and social security (Cagle 2014; Morozov 2013). In fact the business practices of many prominent “sharing businesses” have little to do with the romantic ideal of sharing as “joint (psychological) ownership, pro-social intentions and the absence of expectations of reciprocity” (Belk 2010).

Given the dominance of economic treatments of business it is not surprising that much existing research focuses precisely on the redistribution of idle capacity and thus on purely economic efficiency within a system labeled sharing (Bardhi and Eckhardt 2012; Lamberton and Rose 2012). Many of the findings of such studies thus revolve around how participants perpetuate a traditional capitalist mindset by presumably maximizing their utilities under the guise of a socially romantic label - a practice that has sometimes been called “sharewashing.” However, if a socially romantic aspect within material sharing systems is to be found, it is not advisable to focus solely on economically efficient behaviors, but on the opposite: on economically “inefficient” behaviors, namely participants’ spending time and congeniality with each other even though the redistribution of physical resources would not require it.

Among the plethora of peer-to-peer service offerings, two popular cases in the new sharing economy appear particularly well-suited for investigating the sociality of shared moments: the hospitality platforms CouchSurfing and AirBnB. The latter is based on monetary exchange while the former is based on non-monetary exchange. We use a multi-method and multi-sited collection of qualitative data over a three year period in order to understand how the notion of sociality is produced and shaped through these market or non-market based sharing ideologies. We draw on fourteen qualitative in-depth interviews with AirBnB and CouchSurfing hosts (some do both) in

Sharing Difficult Choices

EXTENDED ABSTRACT

Europe and the Americas. Besides participant observation we analyze online content such as member profiles and forum discussions.

Granovetter's (1985) discovery that social embeddedness is pervasive in business transactions is especially germane in the "hospitality industry" because it relies not only on providing concrete accommodations, food, and drinks, but also the social interaction between hosts and guests. But although the two hospitality platforms studied were both founded upon the idea of offering strangers the use of unused home facilities, they differ substantially in how they deliver the material and non-material components of hospitality. As summarized in table 1, the sociability aspect of hospitality is the core offering of CouchSurfing while in AirBnB the core offering is the accommodation.

In CouchSurfing, comforts beyond a simple place to sleep are perceived as an "added value" that is not decisive in choosing a host. In AirBnB, it is sociability among guests and hosts that is the not expected source of added value (Ikkala and Lampinen 2015). In AirBnB, the economic exchange of money for accommodation is explicitly stated in the contractual agreement between host and guest and both have legal rights for mutual compliance. In CouchSurfing by contrast, there is an implicit agreement for social engagement in which claims for mutual sociality are embedded. This is illustrated by the disappointment, anger and frustration that were expressed by the CouchSurfer informants in cases where such implicit agreements for time and attention broke down. The opposite is true of attractive accommodations; AirBnB'ers have a legal right to them, while for CouchSurfers having their own rooms and comfortable beds is a nice extra.

However, when social interactions between AirBnB hosts and their guests DID occur, they added unexpected autotelic benefits external to the economic exchange. This points to the insight that, ironically, when it comes to sociality, AirBnB sometimes comes closest to the idea of "true sharing" without underlying expectations or obligations (Belk 2010, 2013). In contrast, in the case of non-monetized CouchSurfing, sociality is an "expected benefit". The interactions are obligations and entitlements that suggest "demand sharing" (Belk 2010; Price 1975; Woodburn 1998) of attention and time. Materially, CouchSurfing is clearly closest to true sharing; but non-materially, such demand sharing is institutionalized and expected, even though it is often freely given and autotelic.

Thus, we find that what changes the perception of sociability in both platforms is whether they are part of the core offer, or whether such social moments occur as "added value" beyond the agreement. The sometime occurrences of social interactions in AirBnB are unsolicited and when they do take place they are not driven by reciprocal expectations. They are the extra embeddedness that Granovetter (1985) finds in other business transactions. In CouchSurfing by contrast, such social embeddedness is the sine qua non of the expectations of both hosts and guests.

We conclude that sociability comes closest to the ideal of prototypical sharing whenever it is perceived as autotelic. This is mostly (but not exclusively) the case when moments of social togetherness are not overtly expected or induced by the system. Sociability seems to be perceived as more autotelic when time is perceived as something that is not in limited supply. While research on consumption practices in the so-called sharing economy mostly examines how existing material resources are redistributed among individuals, we look at how shared experiences are also created and shaped through the prevailing material or non-material context.

The medical domain represents a unique and important class of consumption decisions that are not only high-stakes, high-risk and high uncertainty, but also rely on advice and guidance from expert service providers. Medical practitioners often decide for patients, even when medical evidence does not clearly support a specific option. We study the effect of sharing "preference-based" patient-doctor decisions during pregnancy and childbirth when more than one treatment option is medically justified (Wennberg 2004) (e.g., choice of epidural anesthesia during labor). In contrast, medical decisions are "evidence-based" or "effective care" when benefits clearly outweigh potential harms (O'Connor et al. 2007) (e.g., emergency C-section when there is a sudden change in the baby's heart rate).

In the U.S., the concept of shared decision-making (SDM) between a doctor and patient was first proposed several decades ago. SDM may occur when neither party carries the focal decision power or is predisposed towards one course of action; hence the decision is made collectively, combining the doctor's medical expertise and patient's view of desired outcomes. By adding consumer input to the decision-making process, SDM may improve patient outcomes (Gravel, Legare and Graham 2006). While SDM has received vocal support from many U.S. practitioners, implementation is still far from widespread. Multiple factors, from a paternalistic tradition in healthcare (Coulter 1997) to practical limitations, such as brief duration of doctor visits, have prevented wider adoption of SDM. In developing countries, including Russia, SDM is still in its initial stage.

In marketing and consumer research, healthcare has been studied as high-stakes decisions (Kahn and Luce 2003) from the perspective of emotional load, affect and stress associated with these decisions (Isen 2001), positive and negative consequences resulting from freedom of choice (Markus and Schwartz, 2010; Botti, Orfali and Iengar 2009), uncertainty-seeking by avoiding risk and responsibility (Leonhardt, Keller, Pechmann 2011), and the effect of social power exercised by physicians on patient satisfaction and compliance (Friedman and Churchill 1987). Personality and social psychology research links investigation of "decisions for others" and self-others decision-making to level of construal theory (Polman and Emich 2011). While making decisions for others, people tend to be less loss-averse compared to making decisions for themselves (Polman 2012). In the medical literature, Frosch et al. (2012) found that many patients feel compelled to play socially predetermined roles and defer to physician decisions during clinical consultations even for preference-based decisions. Bernstein et al. (2012) show that women's decisions in favor of elective repeat C-section are largely due to lack of objective information and essentially follow the medical provider's preference.

Our research aims to bridge the gap between clinical evidence from healthcare studies and studies of consumer perspectives on decision-making processes for difficult decisions. Specifically, we examine how and when shared decision mode between patient and doctor affects emotional outcomes of decisions, such as post-decision regret.

We surveyed 394 females from the U.S, ages 18-50, regarding their youngest child. Respondents were recruited through a paid online panel, and identified medical procedures they decided to undergo (or not) during pregnancy. For decisions described as "preference-based," respondents rated and evaluated the emotional difficulty of each decision. Participants reported the decision mode (patient-made, doctor-made, or shared) and degree of agreement with the treatment decision. Post-decision regret was measured on

a scale commonly used in the medical decision-making literature (Breahaut et al. 2003).

We find that patient involvement in decision-making (patient-made or shared decisions) minimized post-decision regret. Decisions made only by medical doctors had the highest level of regret. The U.S. results were replicated with a second sample of 177 women in Russia. Findings were consistent for Russia and the U.S., despite contrasting medical traditions (authoritative vs. patient-centered). A similar pattern was found for treatment decisions of low versus moderate emotional difficulty.

A key issue may be the degree of decision-making match or mis-match between patient and physician. The patient's perception of decision control often contradicts the physician's perception (Adams and Drake 2006). To test this assumption, we are conducting a long-term study – also in the maternal care domain – in the U.S., to measure patient-doctor correspondence in dyadic assessment of decision control.

Our current paper highlights the complex and multi-faceted nature of factors contributing to decision-making approaches that optimize emotional outcomes of highly-consequential consumer health-care decisions. The consumer behavior perspective helps enrich the medical approach by looking at patients in their diversity. For decisions when medical outcomes are positive, some consumers feel happy and experience no regret thinking about the decision process, while others become completely alienated from the medical establishment. Our research suggests that patient empowerment through shared medical decisions is a robust factor driving emotional outcomes of medical decisions. Shared decision-making, distinct from joint decisions, deserves a status of a standalone concept, making an important difference and improving medical service consumption experiences globally.

A Social Network Analysis of Adolescent Social Standing, Sharing and Acquisition Materialism, and Life Satisfaction

EXTENDED ABSTRACT

Materialism plays a central role in many aspects of everyday life. Research has overwhelmingly focused on the negative consequences of materialism that may result from emphases on products over experiences (Van Boven and Gilovich 2003) or trade-offs between social relationships and material pursuits. This focus may ignore important positive functions that materialism may serve for some people. Recent conceptualizations of materialism have expanded the targets of materialistic acquisition to include not only products and services, but also shared product experiences based on social relationships (Shrum et al. 2013, 2014). Our research explores the implications of this new perspective.

Because the process of developing materialistic values is particularly critical during periods of identity transitions, we focus on adolescence, which is one of the most crucial transitions in one's life, because it is the time when adolescents emerge from the family setting in order to construct their personal identities. To do so, they increasingly rely on their peers, who help them to construct their social identity. More specifically, to reinforce their social identities, adolescents may seek strategic positions in a social peer network: some adolescents are isolated whereas others are socially integrated within their peer group.

This research aims to expand the view of materialism and develop an integrative model that identifies two social determinants of materialism (loneliness and social position within the peer group) and its consequences (life satisfaction). We focus on two subtypes of

materialism that play different roles in adolescents' and life satisfaction: materialism as acquisition of objects and materialism as shared experiences.

Method

Because school is where adolescents interact every day with their peers, we used school class as the unit of analysis to identify peer networks. A questionnaire was distributed to 984 adolescents across 33 school classes. This sample was then randomly divided into two sub-samples. The first sample served to validate the measurement scales. The second sample was used to test the model.

To measure adolescent's social network integration, we created a peer-reported measure of teenagers' social position by asking teenagers to nominate their five closest friends in their school classes. In such networks, the most central teenagers are those most frequently considered by others as being the more active. This "in-degree" centrality measure was chosen because it is less subject to social desirability bias, and thus provides the most accurate instrument to identify the most active teens in the network using sociometric data (Lee et al. 2010). Some adolescents are situated on the extreme periphery and have few contacts; others have many contacts and thus exhibit a greater degree of centrality.

Life satisfaction and materialism as acquisition of objects were measured using Diener et al.'s (1985) and Goldberg et al.'s (2003) scales, respectively. Loneliness was measured with Russell, Peplau, and Cutrona's (1980) scale. To measure sharing practices with others, we proceeded in two stages. First, semi-structured interviews were conducted with 10 adolescents, who were asked to answer the following question: "What are the objects that you share more often with others at school?" This qualitative study enabled us to list 15 shared objects during adolescence. Next, a quantitative study of 150 adolescents was conducted. Among these 15 shared objects, only three were selected (movies, games, and files) because they were those most often shared. Sharing, defined as the extent to which adolescents engage in sharing practices with friends, was measured with a 3-item scale. Confirmatory factor analyses (using AMOS) on the first sample indicated good fit statistics and good composite reliability coefficients.

Results and Discussion

Structural equation modeling was used to test the structural model. The results of this analysis revealed the following. First, consistent with expectations, in-degree centrality was positively related to materialism as shared experiences but unrelated to materialism as acquisition of objects. In contrast, loneliness was positively related to materialism as the acquisition of objects but unrelated to materialism as shared experiences. Importantly, materialism as shared experiences was positively related to life satisfaction whereas materialism as the acquisition of objects was unrelated to life satisfaction.

There are concerns that today's teenagers are more materialistic than ever, because of the material resources they have to achieve a specific, positive social identity through their consumption. In contrast, our results revisit the fundamental question of the extent to which adolescents should be considered materialistic consumers in the conventional sense of the term. This research offers a new conceptualization of adolescents' materialism that refers not only to the acquisition of objects but also to shared experiences, which contributes to adolescent life satisfaction. We provide evidence that adolescents suffering from loneliness seek to acquire objects to compensate for their isolated status, whereas socially integrated adolescents seek to share experiences with their peer group. Their purpose is not merely to "have," but rather to "be" or even to "become."

With Whom Do People Share? The Effects of Upward and Downward Social Comparisons on Willingness to Share Possessions

EXTENDED ABSTRACT

Imagine that you are a college student preparing for an important exam, and a classmate asks to borrow your notes. Would you be more likely to share with one of the top students in the class, or one of the bottom students? The answer may seem unclear, because you would have both more to gain (e.g., future favors) and more to lose (e.g., class standing) by sharing with a top student.

Individuals must often decide whether and with whom to share their most important material possessions. In this research, we experimentally investigate the role of social comparison in sharing: Are people more likely to share with someone who rates higher or lower than them on a dimension of interest, such as academic performance?

People often compare themselves to others on dimensions such as intelligence, appearance, or status (Festinger 1954). An upward comparison is a comparison to an individual who is superior on that dimension, and a downward comparison is a comparison to an individual who is inferior on that dimension. Upward comparisons can sometimes trigger similarity testing, in which the individual and target are seen as similar to each other, leading to assimilation (Mussweiler 2003). If this assimilation occurs, sharing with the upward comparison target may feel almost like sharing with oneself. Indeed, individuals are more likely to share possessions such as computer files with others with whom they are psychologically or geographically close (Wiese et al. 2011). Moreover, people may prefer to share with upward comparison targets for strategic reasons. Sharing is a communal act that connects us to other people (Belk 2010), and the sharer may wish to ingratiate him/herself with an upward comparison target in order to feel socially closer, or to benefit in the future.

Based on the reasoning above, we predicted that individuals would be more likely to share a significant possession with an upward comparison target than a downward comparison target. We also predicted that several factors might moderate these results. First, we expected to find stronger effects in situations where the shared product was non-relevant to the comparison dimension (such as sharing an apartment with an academic superior) than in situations where the shared product was relevant to the comparison dimension (such as sharing notes with an academic superior, in which case the sharer might lose academic standing). Second, we predicted that when individuals were in a competitive mindset (Toma et al. 2009), they would be less willing to share with anyone, but in particular they would be less willing to share with an upward comparison target, because sharing would potentially allow the target to get even further ahead on the comparison dimension.

The goal of study 1 was to examine the effects of social comparison and product relevance on likelihood to share. Study 1 utilized a 3 (comparison target: upward vs. downward vs. neutral) X (shared product: relevant – class notes, computer vs. non-relevant – sandwich, apartment) between-subject design with 607 participants. For the social comparison manipulation, participants read a scenario about Michael/Michelle, who was a very successful (upward comparison), very unsuccessful (downward comparison) or average (neutral) business student in the same class as the participant (Mussweiler et al. 2004). We matched the gender of the target to the gender of the participant to control for the effects of mating motives. Participants indicated their willingness to share their possession with Michael/Michelle. We pooled the two relevant products and two non-relevant products for analysis purposes. There was a main effect

of social comparison, indicating that participants were more willing to share with an upward versus downward comparison ($M = 5.32$ vs. 4.09 , $F(2, 601) = 31.56$, $p < .001$), with neutral in the middle ($M = 4.59$). There was also a main effect of product relevance, indicating that participants were more likely to share non-relevant versus relevant products ($M = 4.94$ vs. 4.39 , $F(1, 601) = 18.63$, $p < .001$), but these two variables did not interact. Consistent with our theorizing, participants believed they had more to gain from sharing with an upward target ($M = 4.53$ _{upward} vs. 3.94 _{same} vs. 3.6 _{downward}, $F(1, 601) = 34.61$, $p < .001$), and this perceived gain mediated the relationship between social comparison ($r = .30$) and sharing ($r = .44$).

The purpose of study 2 was to examine the moderating role of competitive mindset. Undergraduate students ($N = 128$) participated in a 2 (comparison target: upward vs. downward) X 3 (mindset: competitive vs. cooperative vs. control) experiment. Participants read the same social comparison scenario as in study 1. Then they wrote a short paragraph about a situation where they competed/cooperated with another individual or group of individuals (Toma et al. 2009), or went grocery shopping (control condition). Finally, they indicated their willingness to share their class notes. Results demonstrated a significant main effect of social comparison ($M = 4.12$ downward vs. 5.53 upward, $F(1, 122) = 24.89$, $p < .001$), replicating the findings in Study 1, and a significant comparison X mindset interaction ($F(2, 247) = 3.15$, $p < .04$). Participants were more likely to share with an upward target when they were in a cooperative mindset ($t = 2.50$; $p < .02$) than either a competitive or control mindset ($t = 2.50$; $p < .02$), whereas they were more likely to share with a downward target when they were in a competitive mindset than either a cooperative ($t = -3.09$; $p < .003$) or neutral mindset ($t = -3.77$; $p < .001$).

The goal of study 3 (currently underway) is to further probe the reasons why individuals prefer to share with upward comparison targets. In other words, what exactly do people stand to gain by sharing with their superiors? We designed study 3 very similarly to study 2, but with several follow-up questions about what the participant expects to gain from sharing, including knowledge, favors, respect, trust, and reputational gains. In doing so, we hope to establish a more precise explanation for our findings.

Paper #4: Can A “Fresh Start” Help Consumers Achieve Their Goals?

Ainslie Schultz, University of Arizona, USA
Linda L. Price, University of Arizona, USA
Robin Coulter, University of Connecticut, USA

SESSION OVERVIEW

Wellbeing as a consumer pursuit is one of the most important discourses of our time (Sointu, 2005). Indeed, wellbeing is tied to a myriad of choices and actions taken in pursuit of immediate and far-reaching goals. Consumers’ aspirations to be healthy, wealthy and wise affect choices and goals related to exercise, diet, finances and education. Despite the call to help consumers in their pursuit of wellbeing (Aaker, 2014; Baumgartner and Pieters, 2008; Mick et al. 2012), much remains to be done.

The papers in this session focus on tools that consumers can use to lead adaptive lives and achieve their goals. In the first paper, Daphna Oyserman, Sheida Novin, George C. Smith, Kristen Elmore, and Cecile Nurra use identity-based motivation theory to explain why some people give up and others keep going when they experience difficulties. Based on the results of several experiments, they offer a tool that urges people to, “interpret experienced difficulty as implying that a task is both important and not impossible.” In the second paper, Joan Ball and Cait Lamberton take a different path to answer why some people persist in the face of frustrating consumption experiences, while others give up. Drawing on both qualitative and quantitative findings, they focus on consumer resilience as a tool, arguing that resilient individuals “use plans as guides for maintaining progress.” In the third paper, Yelena Tsarenko, Yuliya Strizhakova, and Cele Otnes, using a case method approach to present their qualitative results, examine a related question of how do consumers respond to disappointments and transgressions. Specifically, they investigate how forgiveness can be used as a tool to help consumers conquer ruminating thoughts. They uncover key goal pursuits that motivate forgiveness, observing that “consumers consider a variety of personal and relational goals” in deciding to forgive. The fourth

paper investigates a tool for helping consumers begin anew and move beyond failure and disappointment. Ainslie Schultz, Linda Price, and Robin Coulter extend their prior research on “Fresh Starts” to demonstrate across several experiments that a “Fresh Start” can be an important adaptive strategy for taking up new goals following failure and re-energizing and renewing engagement with a current goal.

Together, these papers provide a broadened perspective on how consumers interpret and move beyond difficulties, disappointments, and failures to persevere, try again, do different and do better, to improve their wellbeing. Consistent with the conference theme of advancing connections, the papers interplay to create a lively conversation across methodologies and disciplinary boundaries about the everyday utility of these tools for enhancing consumer wellbeing. The topic is likely to have broad appeal and serve as a rich petri dish for future investigations.

From Difficulty to Possibility: Interpretation of Experienced Difficulty, Motivation and Behavior

EXTENDED ABSTRACT

People sometimes dig in and other times disengage after experiencing difficulty. To understand why that might be, we use identity-based motivation theory to articulate two different interpretations of what experienced difficulty might mean for engagement in difficult tasks. Prior research has documented that what ease or difficulty implies depends on the situation at hand. We propose that in the situation of school or work, accomplishing tasks with ease can be interpreted as meaning that the tasks are possible with the implication that experienced difficulty is a signal that the tasks may be impossible. However, in the same situations, ease could also be a signal that a task is mundane or trivial, with the implication that experienced difficulty implies that the task is important.

Four experiments test and support our predictions. People led to consider experienced difficulty as implying impossibility were less task focused than those led to consider experienced difficulty as implying importance. When asked to describe their possible selves and strategies, they were less focused on school and academics and instead included a variety of other possibilities and social roles (Study 1). When asked to what extent they would sacrifice to attain their goals, they were less likely to agree that they would (Study 2). Lack of focus translated into worse performance (Study 3 intelligence test, Study 4 standardized writing test). In the first four studies the method used, random assignment to reading either four statements inducing one to consider whether difficulty implies impossible or importance, implies that both interpretations of experienced difficulty are likely represented in memory. Both have everyday utility, facilitating engagement and task switching, by focusing on whether a task is important (as opposed to trivial) or impossible (as opposed to possible). Moreover, much as has been found in stereotype threat research, inducing people to consider the interpretation yielded an effect, it was not necessary that people endorsed the proffered interpretation – endorsement did not moderate the effect of the prime. The initial studies documented that the interpretation of experienced difficulty that was on one’s mind mattered.

In follow-up studies, we assessed the two interpretations of experienced difficulty. This allowed us to examine the extent to which the two interpretations of experienced difficulty were correlated with

each other or with other popular measures of persistence and engagement, in particular, self-reported persistence or ‘grit’ and the belief that ability is fixed and not changeable with effort. Across studies correlations varied but were consistently small, implying that each of these constructs captures unique aspects of the motivation and engagement process. One can persist because one is a “persister”, because one believes that skills are malleable and not fixed, or because difficulty itself cues engagement – implying that the task is important and not impossible. In two final studies we tested this possibility by looking at the relationship between interpretation of experienced difficulty, belief in malleability of skills, and value-expectancy (self-efficacy and self-competence) measures. Here too we find that each of the interpretation difficulty and malleability constructs have independent effects on the value and expectancy constructs.

Across studies the implication is that one of the ways to keep going, stay focused, and succeed when experiencing difficulty is to interpret the experienced difficulty as implying task importance. Interpreting experienced difficulty as task impossibility has an undermining effect and our correlational studies imply that this is independent of the positive consequences of interpreting experienced difficulty as task important. Thus the best possible strategy may be to interpret experienced difficulty as both implying that a task is important and not impossible.

What happens once a task has been interpreted as impossible, at least for the moment? Is it possible to forgive oneself or be given a ‘fresh start’ so that one can re-engage and once more reap the benefits of interpreting difficulty as importance? Our studies did not tackle this important question, but the next set of papers do just that.

Rising Every Time They Fall: The Importance and Determinants of Consumer Resilience

EXTENDED ABSTRACT

Nelson Mandela famously pointed out that, “the greatest glory in living lies not in never falling, but in rising every time we fall.” Indeed, academic research has shown that this ability to rebound from failure, also known as resilience, is critical in individual well-being (Scoloveno, 2014; Tugade and Fredrickson, 2004) and can lead to an enhanced sense of life purpose (Rutten et al., 2013). Much resilience research considers the construct in either pathological settings or in the context of extraordinary events where resilience leads to acts of true heroism (see Fletcher and Sarkar, 2013 for review).

We suggest that the next wave of resilience research will consider the ways that resilience is manifest in everyday experiences. Specifically, we propose that *consumer resilience* is a key factor in successful consumption experiences.

We began our study of this topic with an experiment designed to see if trait resilience might have important impacts on marketplace outcomes. This study was conducted using an online panel ($n = 185$, $M_{age} = 32.63$ years, 63% male) who took part in the study in return for a nominal payment. Participants read about two service experiences that involved potential dissatisfaction: one that involved relatively low stakes (a bad haircut) and one that involved much higher stakes (the failure to find an effective medical response to a health problem).

Respondents then used a 1 (not at all likely) to 5 (very likely) scale to report their propensity to respond to this situation in a number of ways, including a way that would signal persistence (asking the stylist to keep working on the haircut with them), the use of coping strategies (making a joke), negative feelings or emotional labor (feeling angry, hiding the feeling). Participants also reported their likelihood of returning to the same service provider (1 = not at all

likely, 7 = very likely), and their likelihood of recommending this service provider to a friend. They then completed a filler task that took approximately 3 minutes, consisting of rating a number of pictures, and then completed the other scenario.

After an additional filler task, participants completed the resilience scale (Campbell-Sills and Stein, 2007), a 10-item measure that includes items such as “I am able to adapt to change” and “I tend to bounce back after illness and hardship,” with responses anchored at “Not at all true of me” (1) and “True of me nearly all of the time,” (5).

We observe a range of trait resilience ($M = 3.74$, range 1.3 to 5). Using this index to predict participants’ likelihood to engage in various responses to the frustrating service experience, we find similar patterns regardless of context. In both low and high-stakes situations, more resilient individuals were significantly more likely to keep working with a service provider to identify a solution or to return to the same service provider, less likely to feel anger or to hide their feelings, and either marginally (low stakes) or significantly (high stakes) more likely to recommend the service provider to others.

Given these findings, we next designed a study to capture the habitual thoughts and behaviors of individuals with a range of trait resilience. A sample of 594 US consumers ($M_{age} = 34.2$ years, 51.6% female) provided both qualitative descriptions of their own resilient and non-resilient behavior and quantitative response to the same Trait Resilience measure used in study 1. They also provided responses related to their experience of life stressors (Holmes and Rahe, 1967), subjective well-being, susceptibility to sunk cost effects, and their use of structure and schedules (make lists and plan) and approaches to goals.

In both qualitative and index measures, we again observed a range in resilience; qualitative responses will be discussed at the conference. The trait measure demonstrated that more resilient consumers tend to experience similar levels of life stress as less resilient consumers. However, regression analyses also showed that more resilient people tended to use structure and plans in their lives more than did less resilient people. Rather than seeing such plans as means of restricting freedom, resilient individuals seemed to use plans as guides for maintaining progress. Further, we find that resilient people do not hold systematically different goals than do other consumers; they simply have a higher degree of optimism that can fulfil them. This finding suggests that firms need not expect resilience only among certain goals segments, but rather, that resilience can be of benefit in a wide range of domains. Interestingly, we also see a greater susceptibility to sunk cost effects among resilient consumers, suggesting that there may be some situations in which consumers’ tendency to persist can become suboptimal – a finding that has not been suggested in prior resilience research.

A third experiment, to be completed by ACR, will build on our finding that planning is a means of fostering resilient behavior. In this experiment, we provide some participants with planning prompts and structure (i.e., “you can make a plan to support the United Way – do a task a day!”), others with salience cues (i.e., don’t forget the United Way!) and some with freedom cues (“support the United Way any way you want, anytime you want.”) To make this donation, participants need to complete a number of tasks over the course of a week, some of which present substantial challenge. We anticipate that resilient participants will be more likely to complete the donation process than less resilient participants. We also anticipate that planning prompts will be more effective than salience or freedom prompts in helping chronically non-resilient participants to complete the donation process, as planning can help promote resilience.

In sum, we argue that *consumer resilience* is a critical yet unrecognized element in successful consumer experience. Given the importance of resilience in a wide range of domains, we believe this work will inspire researchers to focus on its operation in the consumer realm, while also prompting marketers and policymakers to target its development in the individuals they serve.

Many Goals – One Choice: Understanding Consumer Forgiveness

EXTENDED ABSTRACT

Within the sociocultural structures of the marketplace, consumers can be wronged by individuals, groups, institutions, or other forces. In response, consumers engage in coping behaviors (Duhachek, 2005), complain (Dunn and Dahl, 2012), badmouth transgressors (Zhang, Feick, and Mittal, 2014), seek revenge (Bechwati and Morrin, 2003), switch providers (Ganesh, Arnold and Reynolds, 2000) or choose a more positive outcome, such as reconciling with the transgressor (Joireman, Grégoire, Devezer, and Tripp, 2013). Previous research also suggests some consumers may choose to forgive transgressors (Grégoire and Fisher, 2006; Zourrig, Chebat and Toffoli, 2009). However, noticeably absent is a focused exploration of why and how consumers choose to forgive marketplace transgressions.

Our paper explores consumer forgiveness as a socially grounded choice to marketplace transgression and makes several important contributions. First, we illuminate consumers' forgiveness experiences in light of service transgressions as goal-directed, socioculturally-grounded gestalts, and demonstrate how this gestalt approach informs and enhances the psychological perspective that dominates extant consumer literature on the topic. Second, our research demonstrates that consumers not only pursue their general well-being but multiple goals in choosing to forgive transgressions. Third, we highlight the salience of marketplace influences in shaping consumers' forgiveness choices. Finally, we explain why some transgressions that might be perceived as relatively mild may lead consumers to terminate relationships with service providers, and equally paradoxically, why some choose to maintain relationships after transgressions that might be perceived as very severe.

Marketplace transgressions are of interest to researchers due to their profound effects on consumers and subsequent implications for marketers. Broadly, such transgressions result in either anti-firm (negative word-of-mouth, third-party complaining, exit, and revenge) or pro-firm (positive word-of-mouth, patronage, and reconciliation) outcomes, complaining to management, and general consumer coping with the elicited distress. Consumer research that explores the various outcomes of marketplace transgressions suggest that emotions, appraisals of the transgressor, reparation and recompense, transgression severity, consumer/provider relationships, personality traits, demographics, social influences and industry structure (manifest through availability of alternatives and switching costs) impact consumer responses to transgressions.

Consumer forgiveness as a possible response to marketplace transgressions receives far less attention. In studies on consumer revenge, authors either speculate that forgiveness may explain instances of low or attenuated effects of revenge (Bechwati and Morrin, 2007; Joireman et al., 2013), or advise firms to explore responses promoting forgiveness as a means of avoiding consumer revenge (Johnson, Matear, and Thomson 2011). In addition, Grégoire and Fisher (2008) find that high-quality relationships with providers do not guarantee forgiveness, but may instead backfire. A few other studies within consumer behavior discuss the mediating role of forgiveness (Fournier, 1998; Tsarenko and Tojib, 2012; Xie and

Peng, 2009). Two qualitative studies explore forgiveness as one of outcomes of consumer responses to conflicts. Ringberg et al. (2007) show that relational consumers (i.e., those focusing on emotional ties with providers) tend to exhibit forgiveness, whereas oppositional consumers (i.e., those who hold oppositional views on the provider) are least likely to forgive. Further, Beverland et al. (2010) discuss forgiveness as dichotomous outcome of conflict resolution (i.e., one either forgives or holds grudges).

To explore consumer forgiveness, we conducted phenomenological, semi-structured interviews with 35 people who had experienced marketplace transgressions with service providers within the two years prior to interviews in the healthcare and financial sectors. Transgressions ranged in severity from minor problems to life-threatening crises. Nevertheless, informants regarded even the less traumatic incidents as impacting their lives. Although informants often discussed their transgression experiences holistically, they attributed the offenses to either service providers at large, or to specific individuals. To present our findings, we rely on the case method approach.

Our interview analyses resulted in four gestalts of forgiveness as a choice which are differentiated by the underlying ruminative strategy. Forgiveness as grace (Victor) is defined by empathetic ruminations shaped by key cultural and social dimensions. As a professional service provider, an athlete and a loving husband/father, Victor's choice to forgive allows him to achieve consistency and harmony in his life, ensure his family's well-being, and act as a role model. Forgiveness as analgesic (Janine) is driven by self-healing ruminations. Her choice to forgive is bounded by the transgression severity and her relationship insecurity that stems from her dependence on future medical care and a limited number of skilled professionals. Janine chooses to forgive to achieve the goals of regaining her most basic life functions (similar to other consumers facing dire choices; Pavia and Mason, 2004) and of adapting to future uncertainty given her disability. A relational goal—being a role model to her family—also motivates her choice. Forgiveness as fate (Frank) is driven by cynical ruminations regarding the industry structure. Frank's identities both as a young yet knowledgeable employee and a devout Christian guide his choice to forgive. Bound by industry constraints, Frank chooses to forgive to follow Christian values—but awareness about a lack of better marketplace alternatives also guide his choice. Finally, forgiveness as atonement (Tracey) is driven by justice ruminations. Tracey's identities as a career woman, a respected networker and a recent immigrant guide her choice to forgive. Tracey chooses to forgive to achieve her personal goals of restoring self-respect and serenity, as well as a relational goal of achieving justice.

We offer a more holistic understanding on forgiveness than a purely psychological perspective allows. In contrast to social-psychological research that focuses on the health benefits of forgiveness or the desire to maintain relationships with transgressors, our research demonstrates that consumers consider a variety of personal and relational goals in making their choice. Interestingly, and in contrast to incidences of interpersonal forgiveness, consumers' choices to forgive are not necessarily associated with their desire to preserve transgressor relationships. When no solution exists to resolve the transgression, the choice to forgive may be the only option for consumers, to restore their basic life functioning. Because these marketplace mistakes are too risky to be repeated, reconciliation is frequently not associated with forgiveness. We further show how some aspects of culture, religion, family and friends play an important role in consumer-forgiveness cases.

Can A “Fresh Start” Help Consumers Achieve Their Goals?

EXTENDED ABSTRACT

Belief in the power of “Fresh Starts” to help people move past failures, engage with and achieve lapsed or new goals has a long history in folklore and religious rituals. “Fresh Starts” also have a prominent role in popular culture featured in movies, blogs, ad campaigns and products. Everyday consumers pursue new beginnings related to diet, exercise, financial wellbeing and personal growth. We know that conceptual metaphors such as “Fresh Start” can often be powerful tools for reframing problems and motivating behaviors (Coulter and Zaltman, 1995; Lakoff and Johnson, 1980; Landau, Keefer and Meier, 2010; Thibodeau and Boroditsky, 2011). However, research has not examined whether “Fresh Starts” can indeed help consumers achieve their goals. In prior research, we define a “fresh start” as consumers’ pursuit of new beginnings, and develop a reliable, valid measure distinct from related constructs such as optimism, hope, entity theory and psychological closure (Schultz, Price, and Coulter, 2014; 2015). We find consumers pursuing new beginnings focus on the future optimistically, construe the future abstractly, have intentions to improve and change behaviors in health, finances, organizing and disposition, and are likely to make novel choices.

This research investigates whether and how “fresh starts” affect goal achievement. Fresh starts may incite action toward goals by shifting focus from the past to the future, widening the gap between a past and future self and building confidence in the ability to reach goals—enabling the new self to act different (Libby and Eibach, 2002). Related research finds that people who feel they are making embodied progress forward are more inclined to reach their goals (Natanzon and Ferguson, 2012) and that people who experience positive affect during a goal increase their odds of achieving that goal (Carver and Scheier, 1990). Across four studies, we show that a “fresh start” helps consumers move past goal failure to succeed at goals similar or different from an initial failed goal, and boosts performance between contingent tasks.

Study 1 asks whether a “Fresh Start” affects goal-directed behavior following failure on a similar independent task. We used a 2 (fresh start, control) x 2 (self-affirmation, no self-affirmation; as self-affirmation is a commonly used strategy to improve goal pursuit following failure) between subjects design (n=136). Undergraduate students first engaged in a five-minute RAT task (Griskevicius et al., 2006; Mednick, 1962), and upon completion received (false) feedback saying they performed worse than average. Then half the participants were affirmed by writing about their top-ranked value and half not affirmed by writing about their 7th ranked value (Steele, 1988). Before completing task 2, in the fresh start condition participants read, “Start anew” and clicked to the next page; those in the control condition simply clicked to the next page. Participants again completed a five-minute RAT, and the number of correct items served as our dependent variable. The analysis revealed the predicted main effect of the fresh start condition, $F(1, 136) = 5.32, p = .02$, with those participants in the fresh start condition significantly outperforming others on the second RAT ($M_{\text{fresh}} = 3.49$, vs. $M_{\text{no fresh}} = 2.68$), suggesting that a “fresh start” helps participants move past failure. We note no significant difference in performance between the self-affirmed and control group $F(1, 136) = .23, p = .63$.

Study 2 extends study 1. In particular, we ask whether following failure if consumers who make a fresh start are better able than controls to succeed at a task in a separate, unrelated domain. Study 2 also provides mediational evidence for the role of positive affect in fresh starts. Undergraduates (n=114) took a five-minute math in-

telligence test (difficult GMAT problems). Upon completion, participants received false feedback, saying they performed worse than average. Participants then solved as many of 8 Remote Associations (RAT), as possible within six minutes with the number answered correctly serving as our dependent variable. Next, participants answered the PANAS scale (Watson, Clark, and Tellegen, 1988). As expected, participants with stronger (vs. weaker) fresh start feelings performed significantly better on the RAT task following failure at an unrelated task, $b = -7.86, t(1, 114) = -1.88, p = .06$. Hayes bootstrapped confidence intervals for mediation analysis revealed that, controlling for positive affect (mediator), a fresh start was no longer a significant predictor of performance, $\beta = .16 [.04 \text{ to } .36]$ as the confidence interval did not contain 0, providing support for the fully mediating role of positive affect.

Study 3 examines whether Fresh Starts are useful when tasks are contingent. In this experiment, we tested to see whether a fresh start could boost performance following failure on a first task where one’s overall performance is based on both tasks. Sixty-six (29 men) undergraduate participants were randomly assigned to the fresh start condition or control condition and provided 8 RAT questions to answer in 4 minutes. Participants graded their own answers. The answer key contained a false standardized curve such that all participants fell in the bottom quartile. In the fresh start condition participants read, “Start anew” and clicked to the next page; control condition participants simply clicked to the next page. Next participants decorated pumpkin-shaped cookies with the goal of creating a creative cookie. Once finished, participants rated each other’s cookies on a scale from 1 (“Very uncreative”) to 7 (“Very creative”) and answered general questions about the study, including, “I am good at decorating cookies.” An ANCOVA with fresh start as the between-subjects factor and “I am good at decorating cookies” as a covariate revealed a one-tailed significant main effect of the fresh start condition on participants peer assessments of creativity, $F(1, 60) = 3.17, p = .04$. Simple effects tests showed that overall participants considered cookies decorated by participants in the fresh start condition ($M_{\text{fresh}} = 4.53$) as more creative than cookies decorated by participants in the control condition ($M_{\text{control}} = 4.27$).

Lastly, a field study demonstrates a “fresh start” improves performance across contingent tasks toward an overall goal. Thirty undergraduates participated. Exam 1 occurred after the first month of class, with the intervention a week before exam 2. In the fresh start intervention participants were motivated to move forward and approach exam 2 as a fresh, new exam, while in the control condition, participants were encouraged to learn from exam 1 and apply those lessons to exam 2. As expected, participants in the fresh start intervention performed significantly better on the second exam than participants in the control intervention ($M_{\text{fresh}} = 107.067, M_{\text{control}} = 102.433; F(1, 30) = 5.97, p = 0.02$; out of 120 possible exam points).

Across four studies, we show that making a fresh start not only aids consumers in pursuing new goals, but also helps them move past goal failure to succeed on similar or different independent goals and on contingent tasks and goal progression.

SESSION OVERVIEW

Since Dichter's (1966) seminal article on word-of-mouth (WOM) communication, extensive research has looked at what motivates consumers to share product and brand related messages (Berger 2014). Less clear, however, is how WOM recipients ascribe motives to a source and how these motive inferences impact the recipients' attitudes and behaviors. In fact, the general consensus is that consumers trust the motives of WOM sources (Brown, Broderick, and Lee 2007). Literature on skepticism of communicator motives has generally focused on inferences of the persuasive intent in firm-to-consumer communications (Friestad and Wright 1994). However, such suspicion of communication motives is likely to occur for WOM sources too especially when motives for sharing are ambiguous. The papers in this session use different methodologies to examine the consequences of inferring different types of WOM motives, both on attitudes and behaviors towards sources as well as the products and brands mentioned in the WOM communication.

The first paper, by Elanor Williams and Mary Steffel, examines consumers' intuitions about their own and others' WOM communications on social media. Consumers see their own communications as stemming from their status as fans of a brand and as equally genuine regardless of whether they were incentivized to share them, but perceive others as more likely to be influenced by incentives and their incentivized communications as less indicative of their true preferences. This research shows that both marketers and social media users may be miscalibrated about the effects of incentives on perceptions of WOM.

Bragging via mentions of high status brands on social media is the focus of the second paper by Tejvir Sekhon, Barbara Bickart, Remi Trudel and Susan Fournier. This research examines strategies whereby the extrinsic motive inferences that recipients make based on brand mentions on social media can be attenuated. They show that consumption-related bragging does not lead to negative evalua-

tions if the communication includes cues signaling attachment to the mentioned brand since such cues lead to intrinsic (relative to extrinsic) motive inferences for brand mentioning.

The third paper by Grant Packard, Andrew Gershoff and David Wooten examines self-enhancement by WOM sources in online reviews and the importance of trust cues in the impact of such boasting on social persuasion. They show that while negative trust cues signal self-interest and impede persuasion by boastful reviewers, positive trust cues signal expertise and enhance persuasion.

Whereas the first three papers consider individual-level motivations and inferences, the fourth paper explores the social aspects of the phenomenon as indicated in brand community-based motivations and consequences of WOM sharing. Mina Seraj, Robert Kozinets, and Aysegul Toker show how extensive sharing on social media can create pods of communally-conflicted tension as is the case with the conflict between Apple and Android brand communities.

This session offers a holistic understanding of the nature and effects of sharing, and explores ways in which suspicions about motives for WOM sharing can be enhanced or attenuated. Papers in this session raise important questions: 1) As persuasion knowledge leads to suspicion of firm-initiated communication, what is the content of consumers' knowledge about WOM motives that leads to discounting of WOM communication? 2) How are the cues impacting motive inferences for WOM communication similar (such as financial incentives) or different (such as brand attachment) than those for firm-initiated communication?

Does Sharing Signal Caring? Asymmetric Interpretations of the Informativeness of Own and Others' Social Media Communications

EXTENDED ABSTRACT

Social media has brought many changes to the way people communicate. Because the effort, care, and intentions behind such communications are hidden to other users, there may be self-other asymmetries in how those communications are interpreted. These asymmetries may be especially prominent when businesses attempt to incentivize consumers to share brand-related content on social media. This research examines how well people believe their social media communications reflect their own or others' true preferences and whether self-other asymmetries arise when marketers incentivize those communications.

There are two ways in which people might interpret their own and others' social media actions differently. One possibility is that consumers may interpret others' communications as genuine reflections of their true preferences but acknowledge that their own communications might be motivated by instrumental reasons. Consistent with pluralistic ignorance, they may assume that others' behavior matches their preferences but realize that their own preferences and behavior may not correspond (Prentice and Miller 1993). Alternatively, consumers may believe that their own communications are genuine and free from bias by external incentives but that other people are more susceptible to the lure of an incentive, as people think others are more prone to bias than themselves (Ehrlinger, Gilovich, and Ross 2005; Pronin and Kugler 2007). Consumers may believe that their own communications reflect their true preferences no mat-

ter what prompted them, but that others are more likely to misrepresent their preferences in exchange for an incentive. In a series of experiments, we test whether consumers draw stronger inferences from their own or others' communications when those communications are incentivized.

In a pretest, we examined people's intuitions about why they or other people like brands on Facebook. Participants ranked the degree to which several reasons motivated them or others to like brands and businesses on Facebook. They believed being "a true fan" had a greater influence on their decisions to like a brand ($M = 2.97$, $SD = 1.40$) than their friends' decisions ($M = 3.34$, $SD = 1.42$; $t(235) = -2.06$, $p = .04$), but being incentivized had more influence on their friends' decisions ($M = 2.45$, $SD = 1.30$) than their own ($M = 2.95$, $SD = 1.33$; $t(235) = 2.93$, $p = .004$). This suggests that people's interpretations of their own and others' shares are more akin to a bias blind spot, in which people believe that their own communications are motivated by their preferences whereas others can be swayed to misrepresent their preferences. Studies 1 and 2 test this hypothesis.

Study 1 investigated whether people believe that their own or other people's social media actions are more revealing, especially in the presence of an incentive. MTurk participants imagined they were shopping with a friend, Jill, and stopped at a chocolate shop. This shop was debuting some new cake pops. The shop encouraged them to retweet an announcement about the cake pops on Twitter, which either they did or Jill did, depending on condition. Further, for half of participants, this request included an incentive, the chance to win a \$100 gift card; for the other half, there was no incentive, simply the request. Then participants imagined that they were considering buying either the cake pops or some chocolate-covered pretzels as a treat for the person who retweeted the announcement (themselves or Jill). Participants were less likely to choose the cake pops for Jill when she retweeted the ad with an incentive ($M = 4.97$, $SD = 1.89$) than without one ($M = 5.85$, $SD = 1.33$; $t(181.35) = 3.86$, $p < .001$). However, they were equally likely to purchase the cake pops for themselves regardless of whether or not there was an incentive ($M = 4.86$, $SD = 1.96$, and $M = 5.03$, $SD = 2.05$, respectively; $t(199) = -.60$, $p = .55$). Thus, people indicate that an incentive can lead others to misrepresent their preferences, but that they are not likely to be so swayed.

Study 2 examined whether people believe that others are less likely to behave in line with their professed preferences than they themselves are, when those preferences are elicited by an incentive. Participants imagined they were planning on attending a music festival with a friend, and they or their friend shared a photo on Facebook to spread the word about the festival. Half of the participants knew that the event sponsors were offering discounted admission for sharing the photo; for the other half, there was no mention of a discount. Participants indicated how likely the person who shared the photo would be to buy an advance ticket to another, similar music festival. Participants rated their friend as less likely to attend the second event when an incentive was offered to share the photo ($M = 4.93$, $SD = 1.50$) than when no incentive was offered ($M = 5.59$, $SD = 1.28$; $t(200) = -3.38$, $p = .001$). However, participants indicated they were equally likely to attend the second event regardless of the incentive ($M = 4.79$, $SD = 1.81$ and $M = 4.87$, $SD = 1.75$, respectively; $t(197) = -.30$, $p = .77$). Consumers believe they are more likely to behave in line with their social media shares regardless of circumstance, whereas only others' unincentivized shares are indicative of future behavior.

Our findings show that consumers believe their own social media communications reflect their true preferences regardless of whether those communications were incentivized, but others convey less about their true preferences when they are incentivized than

when they are not. Further, they believe that future brand interactions will follow this same pattern: one's own behavior will match their social media actions, whereas incentives distort others' messages so that they are not predictive of their behavior. This research will help researchers and practitioners understand what drives consumers to share brand-related material via social media, and the inferences they draw from others' such shares. This work will shed new light on the nature of social media and what people share and believe they are sharing with the world.

I Do It Out of Love! The Role of Brand Attachment Cues in Consumption Related Bragging

EXTENDED ABSTRACT

In line with Veblen's (1899) conceptualization of conspicuous consumption, the consumption literature has mainly focused on self-presentation via conspicuous 'display' of status signaling possessions to an immediate audience (Han, Nunes, and Dreze 2010). With the advent of social media, however, consumers have an opportunity to craft their self-presentations for a much wider audience via explicit mentions of brands (Schau and Gilly 2003). We define consumption related bragging as conveying an association with a brand that signals status to a particular reference group by mentioning the brand in a message. While consumption-related bragging can create desired status associations, it can also lead to less than favorable impressions of both of the communicator and potentially, of the brand itself (Ferraro, Kirmani, and Matherly 2013). In this research, we examine one way to attenuate the negative evaluations that others make based on consumption related bragging. Specifically, we show that mentioning a high status brand in social media communications does not lead to negative evaluations if the message includes cues signaling attachment to the brand.

Research has shown that if the communication context provides an explanation for bragging, then negative evaluations become less likely (Holtgraves 2002). Kirmani and Zhu (2007) also demonstrated that certain message cues can provide context to a communication making ulterior motives less salient. We suggest that people interpret consumption related bragging in the context of the communicator's relationship with the mentioned brand. Fournier (1998) showed that consumers can form strong relationships with brands. The strength of the bond connecting the brand with the self is defined as brand attachment (Park et al. 2010). Consumers are attached to brands that are inherently tied to their self-concept and thus, these brands are likely to be mentioned for self-expression purposes (Thomson, MacInnis, and Park 2005). People have an inherent tendency to express themselves and self-expression is intrinsically rewarding (Tamir and Mitchell 2012). When brand attachment is conveyed in a message, the audience may infer that the communicator is authentic and is attempting to express his true self. Therefore, inclusion of cues indicating attachment to the mentioned brand leads an audience to infer intrinsic motives (such as self-expression or personal enjoyment) and not extrinsic motives (such as status signaling). These intrinsic inferences mitigate any negative evaluation the audience might have made in the absence of the attachment cues.

To test these hypotheses, we conducted three studies in the context of tweets mentioning high status brands. Based on our exploratory research (Sekhon et al. 2015) and reviews of the literatures on brand attachment (Park et al. 2010), and consumer brand relationships (Batra Ahuvia, and Bagozzi 2012; Fournier 1998), we identified and pretested cues that indicate a consumer's attachment to a brand. In study 1, we tested the effect of attachment cues on the impressions of consumers who mention the high status brand Mer-

cedes in social media communications. MTurk participants ($n=239$) were asked to imagine that they were checking their Twitter feed and saw a tweet from a casual acquaintance named Pat. Then they saw a tweet either with or without attachment cues and responded to a series of questions regarding perceptions of Pat's attachment to the brand, an assessment of Pat's motives for tweeting and attitude towards Pat. We manipulated absence (*presence*) of attachment cues with the tweet—"It (*She*) is looking so good after a wash #MyCar (#MyLove) #Mercedes pic.twitter.com/26WiMSe5v". As hypothesized, presence of attachment cues led to more positive attitude towards the communicator ($M=4.9$) as compared to the no cue condition ($M=4.4$; $p<0.05$). Inferred motives for tweeting were marginally more intrinsic in the cue condition. The effect of attachment cues on attitude was partially mediated through inferred motives.

Study 2 followed the same procedure as Study 1 with the only difference being that the tweet the participants saw either mentioned a high status (Mercedes) or a low status (Ford) car brand based on a pretest. MTurk participants ($n=98$) read the same tweet mentioning either Mercedes or Ford, and either with or without an attachment cue. Then, they responded to the same series of questions as in study 1. We found that the attitude towards the communicator mentioning Ford was not different in the cue ($M=5.12$) and the no cue ($M=5.24$) condition. However, attitude towards the communicator mentioning Mercedes was significantly more positive in the cue condition ($M=5.4$) as compared to the no cue condition ($M=4.1$; $p<0.01$). Similarly, the inferred motives for tweeting were perceived as more intrinsic in the cue condition ($M=3.9$) as compared to the no cue condition ($M=2.9$; $p<0.01$). We also found evidence for moderated mediation such that the presence of attachment cues led to inference of intrinsic motives, which subsequently impacted the attitude towards the communicator mentioning Mercedes but not towards the communicator mentioning Ford.

In study 3 ($n=301$), we replicated the results across multiple high status car brands (Mercedes, BMW, and Audi) with a different set of tweets. We manipulated absence (*presence*) of attachment cues with a different tweet—"Driving around on Friday night #Mercedes/BMW/Audi (#LoveMyMercedes/LoveMyBMW/LoveMyAudi). Presence of attachment cues led to more positive attitude towards the communicator ($M=5.6$) as compared to the no cue condition ($M=4.9$; $p<0.01$). There was no main or interaction effect of the brand suggesting that this effect holds true for mention of any high status brand. Similarly, the inferred motives for tweeting were perceived as being more intrinsic in the cue condition ($M=4.4$) as compared to the no cue condition ($M=3.3$; $p<0.01$). The indirect effect of attachment cues on attitude towards the communicator through inferred motives was significant. However, there was no direct effect of attachment cues on attitude.

Overall, our findings show that brand attachment cues lead to intrinsic motive inferences for brand mentioning mitigating negative evaluations. Future studies will examine the boundary conditions of this effect pertaining to the communicator, the recipient and the communication medium. This research can be a first step towards developing a theory that can guide practitioners on how to encourage brand mentions in ways that can enhance brand value.

Trust Me, I Know! The Impact of Source Self-Enhancement on Persuasion in Word-of-Mouth

EXTENDED ABSTRACT

By some accounts, boasting online has become a social epidemic (Bernstein 2012). For example, over half of people in one recent survey indicate they boast about their travel exploits online even

before they return home (Travelmail Reporter 2012). A recent book documents the pervasiveness of online 'humblebrags'—people who post information using false modesty as cover for their self-enhancing boasts (Wittels 2012). What's more, a growing body of evidence suggests that self-enhancement is a central motive in the transmission of word of mouth information (cf. Berger 2014 review). For example, a consumer returning from a vacation may post a review of a hotel that includes self-enhancing (i.e. boastful) information about herself, such as positive boasts of her travel expertise or experience.

But what are the consequences of source boasting on word of mouth recipients? Much research finds that people have negative perceptions of people who make self-enhancing statements about their own abilities (Godfrey, Jones, and Lord 1986; Robinson, Johnson, and Shields 1995; Sedikides, Gregg, and Hart 2008). This suggests that self-enhancement might decrease the persuasiveness of a boastful source of product information. Yet other work reveals that people seldom perceive 'ulterior motives' in consumer word of mouth sources (Dellarocas 2003; Hennig-Thurau and Walsh 2003), suggesting that boasting could be idle in this context. However, it is also plausible that consumers might perceive information that comes from a boastful source as especially useful. Boastful claims of consumer experience or status might enhance persuasion by influencing perceptions of source expertise, important information that is generally scarce in technology-mediated settings (Dellarocas 2003). To sum, consumer boasting in word-of-mouth transmission may be idle, impede or even improve word of mouth persuasion.

The present research predicts that trust cues are central to determining the meaning of source self-enhancement in word of mouth persuasion. We leverage and extend the persuasion knowledge model (Friestad and Wright 1994), arguing that in addition to negative trust cues, positive trust cues can have an important impact on recipient perceptions and persuasion. First, because consumer (firm) persuasion agents are perceived as normatively other- (self-) interested (Friestad and Wright 1994; Hennig-Thurau and Walsh 2003), boasting will have a null (negative) effect on their persuasiveness. Similar to firm persuasion agents, self-enhancing consumer sources of word of mouth information will be perceived as motivated by self-interest in the presence of a negative trust cue, impeding their persuasion. However, because trustworthy endorsers are likely to be unthinkingly accepted (Priester and Petty 2003), given a positive trust cue, self-enhancing consumer boasting will be accepted as a signal of source expertise, enhancing persuasion. Three studies examine these predictions.

Study 1 provides an initial test of whether the normative motives inferred for different sources of product information (firm vs. consumer persuasion agents) act as trust cues resulting in different baseline responses to persuasion attempts. Participants were presented with an online product opinion in a 2 (source boasting: high, low) x 2 (source: consumer, firm agent) design. Boasting decreased persuasion when the source was normatively associated with distrust (firm agent). However, the same boastful statements failed to impede persuasion when the source was normatively associated with trust (consumer).

Study 2 tests our prediction that the valence of a trust cue may have important consequences in interpersonal persuasion. The study manipulated a known cue of trust in word of mouth: source-recipient similarity (Karmaker and Tormala 2009; Rogers 1995). Participants were presented with a consumer product review in a 2 (source boasting: high, low) x 2 (source-recipient similarity: high, low) design. Given high (low) demographic similarity between the reviewer and recipient, trust was heightened (attenuated), leading to increased (decreased) persuasion by a boastful reviewer.

In Study 3, we directly manipulate the trustworthiness of the source to isolate the process through which trust cues moderate the impact of self-enhancement on persuasion. We predict that the presence of trust cues result in a “change of meaning” (Friestad and Wright 1994) of source boasts of consumer expertise. Trust was manipulated to high or low levels using a “rate the reviewer” score for the source prior to the source’s product review, which was either high or low in source self-enhancement. Given high manipulated trust, the consumer accepted the boastful source’s claims of category expertise with less scrutiny than in the low trust condition (as measured by processing time; Priester and Petty 1995), leading to heightened persuasion. Under low trust, recipients rejected the source’s boastful claims of consumer expertise and their persuasion attempt. Bootstrap tests confirm moderated mediation of the relationship between boasting, trust cues and persuasion by recipient perceptions of source expertise.

Overall, the results suggest that modesty is not in itself a virtue--nor immodesty a vice--when it comes to interpersonal persuasion. Trust cues modify the recipient’s perceptions of source boasting, determining whether self-enhancement is idle, impedes, or increases persuasion. We hope our research may help inform consumers as they evaluate word of mouth information and managers who wish to optimize online social persuasion, and guide future research exploring the impact of source self-enhancement on consumer judgment and decision-making.

Sharing Turns to Scaring: Explaining Apple versus Android Brand Community Conflict

EXTENDED ABSTRACT

Social media creates extensive sharing possibilities for people to act in collective fashion. This sharing has been widely noted in the online interactions and experiences of people who assemble virtually around common consumption interests, causes, or brands (Husemann, Ladstaetter, and Luedicke 2015; Kozinets 1997; Rheingold 1993; Von Hippel 2005). Online deeds related to sharing knowledge, experience, ideas, and emotions intensify through the proliferation of online communal engagement; yet these sharing practices also trigger occasions of conflict. Why, we ask in this research, do members of one online group attack the members of another? What motives can we infer?

Although intra-communal conflict has been discussed in a peripheral sense in research focusing on communities related to distance running (Thomas, Price, and Schau 2013), culinary practices (de Valck, van Bruggen, and Wierenga 2009), and premium cola consumption (Husemann, Ladstaetter, and Luedicke 2015), the discussion of inter-communal conflict where divergent communities challenge and attack each other’s consumption choices, convictions, and even identities is an emergent field.

Muniz and O’Guinn (2001) provide relevant conceptualization for the activity in their discussion of consciousness of kind and its apparent consequence, oppositional brand loyalty. Oppositional brand loyalty is defined as a social process that propagates the members of a community to demarcate themselves as different and unique by defining their identities based on their brand utilization as well as their anti-brand attitudes and avoidance of rival brands. This “us” vs. “them” theme is developed in the discussion of cola wars by Muniz and Hamer (2001). However, there is still much conceptual work to be done to follow these pioneering efforts. In particular, we seek to define inter-communal tension as well as the factors that aggravate the reciprocated practices of virtual violence among opposing brand communities.

Our research uses a 38-month long participative netnographic and ethnographic engagement with the phenomenon to study the conflict between Apple and Android brand communities. The engagement encompasses both online and face-to-face settings. The Apple versus Android site provides a clear, contemporary, and technology-brand driven example of inter-communal brand conflict. Personal relationships between people turn into collective conflict through an aggressive rhetoric that is exacerbated by the idealized personality differences that manifest within Apple and Android communities.

How can this brand-related aggression be so widespread and so vitriolic? Certainly, the tension between Apple and Android users can be partly explained by out-group/in-group tensions, social identity and realistic group conflict theories (Tajfel and Turner 1979; Campbell 1965; Husemann, Ladstaetter, and Luedicke 2015; Levine and Campbell 1972). The norms of these relationships have also been culturally shaped and shared by identity-centric mass advertising communications such as Apple’s Mac versus PC guy commercials and the Samsung ads mocking iPhone’s ‘next big thing’ followers. Consistent with advertising portrayals, Apple users tends to be more sociable, loyal, and elitist, while Android users are more individualistic, curious, frustrated and aggressive in nature.

The product of this cultural engineering is that adversarial and oppositional brand relationships in this technology sphere are both attractive norms and behavioral frames. Community members build on these tensions, enjoying the escalating tension in rhetoric that facilitates the community to further define its ethos and identity through conflict as well as to augment its intellectual, social, and cultural value through increasing the possibilities for multidimensional human engagement, including aggression. Thus, autotelic brand violence provides its participants not only with hostility and anger, but humor, identity, communality, and pleasure as well.

Our conceptualization draws on Schinkel (2004), who discusses the concept of autotelic violence as a phenomenon where the means and ends to violence merge. In autotelic violence, violence becomes a performance, aggressive acts happen for the sake of its own intrinsic pleasure rather than in order to reach a specific objective. We hypothesize in this research that social media tendency to reflect and represent personalities amplifies the tendency for autotelic violence to occur. Because individuals are performing for their community, which acts as their audience, a charged and intensified inter-communal brand rivalry is created, where differences are salient and aggressive interaction the norm. Unlike oppositional brand loyalty, challenges in these personal and social media settings occur not only for the sake of challenging brand choices of opposite groups or daring to convert them to the supported brand, but also as entertainment.

From this, we theorize that the conflict we observe is motivated by autotelic violence, a culture of widespread oppositional ideologies, and capitalistic competitive mind-sets. As each side is prodded to respond, conflict endogenously generates and distinguishes opposing idealized communal personalities that reciprocally elicit both auxiliary inter-communal conflict and consistent brand identity-related responses.

The research provides theoretical contributions to brand and consumer research literatures in two broad areas. First, it refines our conception of oppositional brand loyalty by developing the concept of inter-communal conflict based in autotelic violence. Second, it explores the relationship between advertised brand identity and communal personality differences, specifically locating them in the context of social media reciprocal conflict. Why do members of one brand using group attack members of another? A culturally informed answer is that they do it because they identify with oppositional

brand images in advertising, they internalize oppositional brand identities, they are empowered by their brand communal audience, and because they find the aggression entertaining.

SESSION OVERVIEW

It is now widely accepted that “people’s preferences are often constructed in the process of elicitation” (Tversky, Sattath, and Slovic 1988), but despite four decades of research, our understanding of preference construction processes is still far from complete. Whereas most prior research has focused on task characteristics and information processing, the current session explores the role of decision-makers’ intuitions and implicit motives.

Why are people sometimes motivated to deliberately distort their preferences as they construct them? How is the choice construction strategy people use influenced by their intuition? And if intuitive preferences do, in fact, exist outside of the construction context, how might they be best revealed? Four papers explore these and related questions as they look to deepen our understanding of consumer preference construction processes.

The first two papers examine, in different ways, the role of implicit intuitions in the preference construction process, and the notion that certain preference intuitions may exist independent of the elicitation context. **Morvinski and Amir’s** paper shows that consumers intuitively associate preferred options with prominent labels or cues. They further show that incorporating such cues in the preference construction context can decrease system-2 bias and susceptibility to certain context effects. The paper by **Sela and Simonson** examines how the preference construction strategy (i.e., lexicographic vs. tradeoff-based) is impacted by a subjective “feeling of preference,” which can be triggered by situational cues even before any options or attributes are encountered.

The next two papers focus on the dynamics of the construction process itself. The paper by **Schrift, Kivetz, and Netzer** shows that the ingrained intuition that positive outcomes are the fruits of an effortful and diligent decision process may drive people to distort and thereby complicate the process by which they construct their preferences and choice. In the fourth paper, **Liu and Simonson** examine the dual role played by preference instability and preference affirmation in a process called Evolving Front-runners (EF), in which preference is constructed gradually.

Much prior work on preference construction has demonstrated effects of task characteristics and information processing goals and constraints, but little is known about how preference construction is impacted by consumers’ intuitions and implicit motives. Taken

together, the four papers in this session present novel findings that further our understanding of the elusive nature of the mechanisms by which consumers construct their preferences. The session should be of interest not only to researchers who study consumer preference and choice, but also those who are more broadly interested in heuristic and systematic decision making, information processing, and metacognition. Consistent with this ACR’s theme – Advancing Connections – this session incorporates multiple methodologies and speaks to audiences that include theory-inclined academics, consumers, policy-makers, and marketers.

Liking Goes with Liking: An Intuitive Measure of Preferences at a Flip of a Coin

EXTENDED ABSTRACT

In a series of five experiments, we explore congruence between preferred products to prominent labels. We find that people intuitively relate high evaluative judgments, such as preferred products, to prominent labels, but this effect is not symmetric as no similar relation was found between low evaluative judgments and non-prominent labels. We discuss the link between prominence and preference and suggest a fluency-based congruence explanation between two positively judged ends. Lastly, we demonstrate an important implication of our finding in which our intuitive measure of relative evaluative judgment helps de-bias compromise effect, an established system-2 bias.

In the initial demonstration of the effect (Experiment 1), participants played a game in which they saw two alternative DVD movie rewards and tossed a virtual coin to determine which movie they hypothetically win. Before tossing the coin, participants decided on the reward they will win in each of the coin-toss outcomes, but the question was framed using the prominent label of heads (Schelling 1960; Bar Hillel et al. 2014), i.e., “In the case of head, which movie will you win?” When the movie “The Alamo” was presented together with a least preferred movie [“Superbabies: Babies Geniuses 2”] as was determined by a pretest from the same population, 81% of the participants assigned heads to this movie. However, when the alternative was a more favorite movie [“Forrest Gump”], only 34% of the participants indicated they want to win the movie “The Alamo” in case the coin landed heads up. Therefore, keeping the reward constant, participants in our study associated the same reward with a prominent label when it was their preferred choice but not when it was their least preferred choice. In Experiment 2, we explored the asymmetry property of the effect in which framing the same assignment task with tails (a non-prominent label) instead of heads, did not yield the reverse results. The likelihood that our participants assigned their least preferred movie to tails did not differ from chance (53%, $p = .78$). This finding also rules out a simple rank-matching explanation (i.e., polarity alignment principle). Additionally, participants in the heads assignment condition, compared to those in the tails assignment condition, did not feel more control over the winning outcome, nor did they feel they had a better chance of winning their preferred reward. In Experiment 3, participants performed 20 consecutive choice tasks, each comprised of a different pair of rewards. After examining a pair of rewards for 5 seconds, one of the rewards started to blink after which participants had only one second to assign either heads or tails to the blinking reward. The results showed a similar pattern of behavior. That is, whether the task involved assign-

ing a choice to a label (Experiments 1-2) or vice versa (Experiment 3) did not change our participants' behavior. More importantly, we replicated our initial findings even when participants had only one second to submit their choice, suggesting that the preference-prominence link is intuitive, not requiring long deliberate thinking. Experiment 4 extended our findings to other prominent labels (i.e., even/odd, card ranks). Lastly, Experiment 5 was designed to demonstrate how the use of the coin-flip task (based on preference-prominence congruity) can help reduce a System-2 bias, a bias that occurs when System 2 processing is inferior to more intuitive judgment. Utilizing the Compromise Effect, a well-established System-2 bias, we demonstrated how the bias significantly decreases when we replaced the standard choice task with the coin-face assignment task. Compared to a 33% bias in the focal product market share in the regular choice task condition, the bias was reduced to 15% in the assignment task condition. It is worth noting that even in the assignment task condition, the compromise effect did not completely disappear and participants' assignments of heads to their "favorite" product differed significantly from chance.

Together, our findings demonstrate that people intuitively relate high evaluative judgments to prominent labels. As one of our online participants bluntly commented: "I chose the item that I thought I would want more: Heads I win, Tails you lose". We refute alternative explanations such as simple rank-matching and subjective probability. We propose that prominent labels are processed more fluently compared with non-prominent ones. Existing evidences support the link between fluency and likable (E.g., Reber, Winkielman & Schwarz 1998) and the fact that fluent cues are hedonically marked (Winkielman et al. 2003). Therefore, high congruence is achieved because both prominence and preference carry positive affective reaction. Consumers are affectively evaluative matching in the same manner as they associate positively valenced stimuli (e.g., positive words) with positive responses (e.g., familiar, known). That is, like goes with like (but not the reverse). We drew our conclusions from existing literature that support the idea that it is pervasive human characteristic to prefer fluent cues such as known to the unknown and familiar to unfamiliar. For example, psychologists have long observed that repeated, unreinforced exposure results in an increased evaluation of stimulus (Zajonc, 1968). On the other hand, things that deviate from the usual and expected are curiosity arousing and under most condition will be positively evaluated (Mandler 1987). We also try to explain the asymmetry property using the concept of markedness. We discuss our findings in light of the existing literature from economic and psychology on focal point (Schelling 1960), perceptual fluency (Reber et al. 1988), hedonic familiarity, and hedonic marking of fluency (Winkielman et al., 2003), as well common used implicit measures of preferences.

Our work concludes with a suggestion for those who are about to make a decision via a coin toss: choose the option you have assigned heads to regardless of the coin toss outcome. Most likely, this is your most preferred option.

The Feeling of Preference

EXTENDED ABSTRACT

As has been well established, consumers often do not have well-defined preferences and they construct their preferences on the fly, using ad-hoc decision strategies determined by salient decision goals, processing constraints, and task characteristics (Bettman, Luce, and Payne 1998).

We propose that the construction of preferences is also influenced by a previously unexamined factor, the "feeling of prefer-

ence," which is the sense that one has or should be able to form a preference in a given domain. The feeling of preference (FOP) can be triggered by situational cues pertaining to the ability to formulate or retrieve a preference (e.g., the perception of prior experience), regardless of actual preference retrieval, cognitive ease (i.e., fluency), or a motivation to express a preference.

Unlike the feeling of knowing (Koriat 1993), the feeling of preference can be triggered independently (and is therefore not a by-product) of the preference formation process or experiences of cognitive ease (fluency). Because it is independent of – and can be triggered prior to – the formation of a preference, FOP is also distinct from certainty (Rucker et al. 2014), which is conceptualized as a property of a particular attitude, preference, or judgment.

We demonstrate how FOP impacts the construction of choices from non-dominated, two-attribute, three-option choice sets ("compromise sets"). We use compromise sets because research has shown that, whereas choice of the middle (compromise) option often reflects a tradeoff-based strategy and/or difficulty forming a preference (Dhar and Simonson 2003; Levav, Kivetz, and Cho 2010), choosing one of the extreme options indicates that the decision maker prefers one attribute over another, reflecting more of a lexicographic strategy. We expected that activating a FOP would increase choice of extreme options and decrease compromising. In a series of studies we test alternative mechanisms that trigger and underlie the feeling of preference.

Study 1 activated FOP by manipulating perceived experience. Participants completed a series of choices from several "compromise sets" that are characterized by a high share of the middle option (portable grills, lawnmowers, and flashlights) and before seeing the choice options, rated on a 7-point scale how many times they had made a choice in each domain. We manipulated FOP by varying the anchors of the scale: 1="never"/7="a few times" in the high relative experience condition and 1="a few times"/7="multiple times" in the low relative experience condition. Consistent with our prediction, believing one is experienced and therefore should be able to form a preference increased the tendency to choose extreme options in all three decisions.

Study 2 activated FOP by priming people with preference-related words (e.g., opinion, attitude) or control words (e.g., bird, color). Consistent with our prediction, priming preferences increased choice of extreme options and decreased compromising in two separate choice problems (lawnmowers and microwave ovens). Casting doubt on an alternative account according to which our priming activated certainty, we found no effects of the prime on several measures of certainty and choice confidence (in fact, certainty was slightly lower in the preference prime condition).

One could argue that, rather than activating a general feeling of preference, our prior manipulations activated or brought to mind preexisting preferences in the respective domains. To rule out this possibility, Study 3 used a choice context in which participants could not possibly have had prior preferences. First, we primed preferences by asking half of the participants to describe a situation in which their decision was strongly influenced by personal beliefs, values, or principles. The other half served as control. Then, participants saw a decision problem consisting of a fictitious product ("skimbles") with fictitious attribute names ("atmority" and "predorsity"). Despite the fact that participants could not possibly retrieve preferences for skimbles, priming preferences significantly increased choice of extreme options and decreased compromising. This provides a strong test of our proposition regarding the impact of a general feeling of preference on choice construction, as well as rules out an ease-of-re-

trieval (fluency) account. We again found no differences in certainty or confidence between conditions.

In addition to ruling out preference retrieval and certainty as alternative explanations, Study 3 provides insight into the underlying process. After making their choice, we asked participants to explain their decision in their own words, and then to classify their responses as most closely corresponding to one of five general statements (identified in a pretest). Four statement options pertained to lack of preference and/or an attempt to choose what seemed like a balanced product, whereas the fifth statement read "I had a vague intuition that the option I chose was somehow better or that one attribute was more important than the other". Consistent with our suggestion that priming preferences activated a general feeling of preference that is independent of specific knowledge or attributes, participants were significantly more likely to mention preference intuition as an explanation in the preference prime condition, and this was correlated with choice of extreme options (i.e., "non-compromising").

We further argue that the feeling of preference reflects consumers' perceptions rather than any motivation to have or display a preference. Study 4 tested this motivational explanation by varying whether choice was public (i.e., evaluated by others) or not. We used the same choice task and manipulation of experience from Study 1, but we also varied whether participants thought their choices would be shown to other respondents who will judge the quality of the choices made by the participant (Maimaran and Simonson 2011; Simonson and Nowlis 2000). If our manipulation activated a desire to have or display a preference then expecting to be evaluated should strengthen its effect. Casting doubt on this alternative account, the results revealed a main effect of FOP priming, without an experience x evaluation interaction.

Taken together, the findings show that preference construction (e.g., non/compromising) can be influenced by a feeling of preference: a sense that one has or should be able to form a preference in a given domain. The studies illustrate several situational cues that can activate such a feeling, and show that it can operate independently of retrieval processes, motivation, cognitive ease, and preference certainty.

Complicating Decisions: The Effort-Outcome Link and the Construction of Effortful Decision Processes

EXTENDED ABSTRACT

The ethos that effort and hard work yield desired and positive outcomes is ingrained in our lives and many cultures. Whether through bedtime stories at a young age (e.g., *Three Little Pigs* and *The Little Red Hen*) or popular slogans such as "no pain, no gain," the link between effort and positive outcomes is essentially hard-wired into the way we think and behave in many situations. This belief may be functional and serve an important and fundamental purpose, such as fostering the sense that one can impact the world in predictable ways (e.g., the just-world hypothesis; Lerner 1980). However, can the belief in the effort-outcome link (hereafter EOL) impede decision-making when important decisions seem too easy?

In this paper we postulate that since decision-makers believe that positive outcomes are the fruits of effortful decision-making processes, when confronted with a decision that feels too easy, decision-makers will artificially construct more effortful choice processes (i.e., complicate their choice). The notion that decision-makers complicate their choices under certain conditions is consistent with recent findings (e.g., Schrift, Netzer, and Kivetz 2011; Sela and Berger 2012). In particular, Schrift et al. demonstrate that decision-makers seek to attain compatibility between the effort they anticipate

in a certain decision context and the effort they actually exert. Building on these findings, the main contribution of this research is to (i) delve deeper into the mechanism that triggers complicating behavior, namely belief in the EOL and (ii) demonstrate additional and unique ways by which decision makers complicate their impending decisions.

In Study 1 participants were first asked to rate 10 fictitious company logos on their level of attractiveness. In the second part of the study we manipulated participants' strength of EOL beliefs using a well-established (and pretested¹) paradigm of manipulating meta-cognitive experiences (Schwarz et al. 1991). In the third and final section of the study participants imagined that they had recently created their own new company, and read an excerpt emphasizing the importance of choosing a company logo. Participants then received (in a between-subjects design) a choice between two fictitious logos at varying degrees of choice difficulty (based on participants' own pre-measured preferences). Prior to making their choice, participants were asked to re-rate the attractiveness of the logos, enabling us to examine the degree and direction by which participants distorted their preferences. We find that when facing a relatively easy decision, participants distorted their preferences in a manner that intensified their conflict in choice² (after controlling for statistical artifacts possibly arising from the test-retest design). Further, consistent with our hypothesis, we find that strength of EOL beliefs moderate such tendency to complicate³.

In Study 2, participants reviewed information about 12 job candidates before deciding whom to hire for a senior position in their company. Later, participants were asked to choose one of two candidates and were given partial information of that they originally reviewed about the candidates. Based on the available information, one candidate was clearly superior over the other. Aside from choosing, participants were also asked to recall the missing information from memory. In this study, three factors were examined. First, we measured participants' chronic tendency to link effort with positive outcomes using the Protestant Work Ethic (PWE) scale (Mirels & Garrett, 1971). Second, we manipulated (between subjects) the stage in which participants were asked to recall the missing information (pre-decisional vs. post-decisional stage). Finally, we also manipulated the degree to which the decision was framed as important (based on Jecker 1964). We find that when decisions are relatively easy, individuals with stronger PWE beliefs distort the information they recall about potential dates (Study 2a) and job candidates (Study 2b) in a manner that artificially increases their choice-conflict (i.e., complicating behavior). Consistent with our motivational account and inconsistent with several rival accounts (e.g., market-efficiency inferences and conversational norms) such patterns were (i) observed only in the pre-decisional stage (and not after the choice is made) and (ii) were more pronounced when the decision was framed as important⁴.

In Study 3 we again manipulate perceptions of the EOL using a pretested⁵ priming procedure (based on Quinn & Crocker 1999) and demonstrate that decision-makers not only distort the information they recall, but also selectively interpret incoming information about the alternatives. We find that participants distort and interpret other consumers' recommendations in a manner that detracts from the superior car, thus increasing conflict in choice. Further supporting a motivational account (and inconsistent with inferential processes), such distortions were observed only when participants were facing a decision and not when such evaluations were done outside the context of an impending choice⁶.

In Studies 4 and 5 we examine whether individuals with a stronger EOL beliefs would actively exert more effort in choice by

seeking more information and spending more time before finalizing their decision. In Study 4, when choosing either a difficult or easy choice of a company logo, decision-makers spent more time and searched for more information before finalizing their choice compared to when the decision was moderately difficult. That is, we find a U-shape pattern of decision time and information search as a function of choice difficulty⁷. Moreover, the tendency to conduct this superfluous information search when facing easy decisions was more pronounced for individuals with stronger EOL beliefs⁸. In Study 5 a similar pattern was observed for individuals that chose different models (to advertise their company's brand)⁹.

To summarize, whether choosing which job candidate to hire, which person to date, or which property to buy, sometimes an apparently easy choice is indeed ripe for the making. In this article, we argue that a belief that positive outcomes are attained only through diligent and effortful decisions may backfire and cause people to artificially construct a more effortful decision even when such choice conflict is unwarranted. Such superfluous deliberations may waste valuable resources, cause people to miss out on opportunities, and even lead to inferior choices. Six studies validate the EOL as the underlying mechanism, rule out several rival accounts, and demonstrate unique ways in which individuals complicate their choice.

Evolving Front-runners: Choice under Gradual Construction

EXTENDED ABSTRACT

How do people make a choice among a larger set of options (of more than two or three)? Although much previous research examines choice sets of two or three options, when there are more options, less is known about the process by which people sort through the choice set to arrive at a final decision, especially when options are introduced not all at once. For example, do people mentally keep all options in mind, or do people engage in interim comparisons and eliminations, and if so, how? And furthermore, how does the choice outcome change depending on the process involved? In this research, we examine one process that people might use to make a choice among multiple options, namely, the Evolving Front-runners (EF) process. We argue that even though in real life people might not engage in a pure version of this process, choices among multiple options can often have an EF component. In 17 experiments we study the EF process. Our findings have implications for understanding preference construction in larger choice sets.

The EF process works as follows: Imagine a consumer is looking to buy a dress from a designer. There are 10 new dresses this season, and she will be presented with the dresses sequentially. Further, she will be advised to make eliminations as she goes along. Specifically, she will first see two dresses, and will decide which of the two she prefers. The preferred dress will be held for her, whereas the other one will be eliminated from her consideration. The person is then presented with the third dress. She now compares this third dress to the one held. If the third dress is better than the one held, the third dress will be held to be compared to the fourth dress, while the old incumbent is eliminated. If the third dress is not better than the one held, then the third dress is eliminated, and the held dress will still be held, and will be compared to option 4. The process goes on whereby a newly introduced option is always compared to the current incumbent, and can either "beat it" and replace it, or fail and let the incumbent live on. Finally, the last option is revealed, and the person makes a choice between this option and the final incumbent, and the chosen option is the final selection for the entire set.

Thus in this EF procedure, a newly introduced option needs to compare to only one of the previous options, namely, the incumbent, as opposed to all earlier options. This greatly cuts down the amount of processing required to make a selection. This process may be used when a decision maker does not wish to carry information of all options in one's mind, but instead just focuses on a forerunner at any stage.

Our research focuses on the following questions: what are the properties of this choice process? Is it accurate? Does it create systematic preference shifts compared to a default simultaneous choice? And do decision makers like this procedure?

We answer these questions in 17 real incentive experiments. We find that preference instability plays a large role in choice outcome under EF. Further, an incumbent often gets compared to a number of new options, and this creates a process of repeated preference affirmation for the incumbent. We find preference affirmation to have a positive effect on subsequent preferences. The combined effect of preference instability and preference affirmation leads to systematic shifts in preferences compared to a default simultaneous choice. Specifically, options introduced late are the most advantaged, whereas middle options are the most disadvantaged. Implications for understanding preferences in larger choice sets are discussed.

SESSION OVERVIEW

People routinely face financial challenges that may impede their financial and overall well-being. For example, chronic and situational financial deprivation can result in costly errors involving consequential decisions: when to repay debts, whether to borrow, and how much to save. While much research has explored such pitfalls, relatively less well-understood are the psychological mechanisms associated with these obstacles and how people aim to overcome them. To this end, this session explores causes and consequences of economic challenges such as feeling poor and bearing the burden of debt repayment. The featured papers impart insights into the psychological and behavioral consequences of experiencing financial challenges and suggest some recommendations for combating them. In particular, attention is focused on uncovering process evidence underlying the relationship between financial constraints and suboptimal behavior (Papers 1 and 2) as well as the routes people take in the face of environmental obstacles (Paper 3).

The session opens with a discussion of potential causes of impaired decision-making among the financially constrained. Gneezy and Imas (Paper 1) examine the role of feelings of helplessness on impulsivity and risk taking. Specifically, they find that lower-income increases perceived helplessness, which in turn engenders higher discount rates and risk taking. Johar, Meng, and Wilcox (Paper 2) implicate another source of suboptimal behavior among the poor: that of cognitive rumination. While the poor are more likely to chronically suppress and express thoughts about financial concerns than the rich, rumination seems to better explain their heightened impulsivity and lower cognitive performance. Paper 3 investigates how people manage resources in the face of external financial constraints and shocks. Zhang, Hsee, and Sussman find evidence of an “urgency bias” whereby people choose to repay debt faster when they know the interest rate will increase in the future compared to when they know the rate is already at a high level.

Together, these papers combine secondary data, lab experiments, and field studies to raise important questions about (1) how affective and cognitive processes can impair behavior among the poor, as well as (2) the effect of exogenous factors that influence how we manage our financial resources in anticipation of the future. Papers 1 and 2 examine how economic constraints influence decisions from both an affective perspective (Gneezy and Imas) and

an information-processing perspective (Johar, Meng, and Wilcox). Complementarily, Paper 3 investigates how consumers prepare for their financial future (Zhang, Hsee, and Sussman). Diving into the causes and consequences of financial challenges, this session aims to contribute to improved ability to understand and counteract some of the detrimental effects associated with these obstacles.

Poverty as Helplessness: How Loss of Control Affects Impulsivity and Risk-Taking

EXTENDED ABSTRACT

Research has shown that individuals living in poverty display greater impatience and elevated valuation of high-risk prospects such as lottery tickets, leading to choices that further undermine their chances to emerge from poverty (Lawrance 1991; Haisley, Mostafa, and Loewenstein 2008; Lynch and Zauberman 2006). One line of research posits that the poor are mired in a “culture of poverty” in which biased preferences and deviant values such as myopia and increased risk-seeking cause them to become, and remain, poor (Banfield 1970; Lewis 1970). However, recent work suggests that it is the state of living in poverty that changes individuals’ preferences and behavior (Mani et al. 2013; Vohs 2013). In outlining a mechanism for how poverty shapes preferences, Rabow, Berkman and Kessler (1983) argue that feelings of helplessness endemic to living in poverty give rise to the elevated levels of impatience and risk-seeking the poor often display.

The helplessness theory of poverty suggests that the scarcity inherent in being poor severely restricts individuals’ choice sets, resulting in a loss of agency and feelings of not being in control of one’s life. This state of helplessness increases impulsivity and risk-seeking that drive suboptimal decisions such as buying lottery tickets, gambling, and taking payday (Kane 1987). The result is a grim cycle in which individuals’ choices further reinforce their abject states, creating poverty traps in which those who become poor stay poor. However, although helplessness is often comorbid with an increased preference for immediate rewards and high-risk prospects, studies have yet to establish the causal link between these constructs—critical for the helplessness account of poverty. This paper combines insights from marketing, sociology and behavioral economics to present the first causal evidence for the role of helplessness in relative greater discounting of the future and increased preference for high-risk rewards.

We first establish a link between low income and an increased sense of helplessness using a large data set from the World Values Survey comprised of 60,094 individuals from 48 countries. To capture sense of helplessness, we used participants’ responses to the question of how much free choice and control they have over their lives. We used responses on income class as a measure of *relative* income. Running a fixed-effects regression of the helplessness measure on relative income, our analysis revealed the predicted significant relationship between income and helplessness, with poorer individuals reporting feelings of having less control over their lives ($\beta = -.31$; $p < .001$).

To first demonstrate a relationship between poverty and impatience, we elicited and compared the discount rates of poorer individuals and those who are financially better off. The first group

comprised of unemployed individuals approached around an unemployment-benefits center in City Heights, a low-income neighborhood in Southern California. The second group comprised of employed individuals in the same area. We elicited time preferences by having participants respond to a series of 27 hypothetical choices between receiving a smaller amount now or a larger amount later (Kirby, Petry, and Bickel 1999). Indeed, the unemployed individuals displayed greater impulsivity, choosing the smaller-sooner reward on average 61% of the time, whereas the employed individuals from the same low-income neighborhood chose the smaller-sooner reward 48% of the time ($p=.03$). Estimating parameter k of a hyperbolic discounting function revealed that unemployed individuals discounted the future to a significantly greater extent than the employed group (mean $k=.020$ vs. $.008$, respectively; $p=.015$).

To directly test the effect of helplessness on time preferences, we manipulated sense of control over an aversive stimulus in a standard laboratory subject pool and then elicited their time discount rates. Using a novel experimental paradigm based on the classic learned helplessness studies (Alloy and Abramson 1982; Hiroto and Seligman 1975), we induced helplessness by exposing participants to aversive, uncontrollable noise, and empowered about half of them with the option to control the noise, thereby increasing their sense of control. Critically, we made the ability to exercise control costly, discouraging empowered participants from actually changing the level of noise, resulting in helpless and empowered participants experiencing the same aversive stimulus. After being exposed to the noise, we elicited time preferences using the same set of 27 choices over time. Our analyses revealed that inducing helplessness exogenously generated a similar shift in time preferences as financial scarcity: those in the Helpless treatment chose the smaller-sooner reward 60% of the time, whereas Empowered participants chose it only 50% of the time, $p=.002$. The mean hyperbolic discounting parameter k of the Helpless group ($M=.015$) was significantly higher than that of the Empowered group ($M=.007$; $SD=.01$), $p<.01$.

Similar to the first study, we sought to demonstrate a link between low income and greater risk-seeking by eliciting valuations of high-risk, high-reward prospects from two groups of individuals that differed in their level of wealth. The first group comprised of unemployed individuals approached in a low-income neighborhood in Pittsburgh (PA) and the second group comprised of employed individuals in the same neighborhood. We elicited participants' willingness to pay for either a high-risk prospect or a low-risk prospect, each with the same large reward. Adopting the protocol of Rottenreich and Hsee (2001), the gamble was either a 1% or a 99% chance of winning a European vacation. Indeed, unemployed individuals reported a significantly higher willingness to pay for the high-risk lottery ($M=24.31$) than the employed individuals ($M=13.16$), $p=.021$. However, we found no significant difference in willingness to pay for the low-risk lottery ($M=194.12$ vs. $M=241.22$), $p=.45$. To show that inducing helplessness generates a similar shift in risk attitudes, we used the same helplessness manipulation as in the previous study and then elicited participants' willingness to pay for either the low or high-risk gamble. Indeed, participants in the Helpless treatment reported significantly higher willingness to pay for the high-risk lottery ($M=41.86$) compared with Empowered participants ($M=18.13$), $p=.038$. At the same time, participants' willingness to pay for the low-risk lottery was not affected by experimental treatment ($M=377.08$ vs. $M=352.87$), $p=.70$.

Thinking About Financial Deprivation: Rumination and Decision Making Among the Poor

EXTENDED ABSTRACT

Why are the poor often susceptible to impaired decision-making? Recent work demonstrates that people who face scarce financial resources make suboptimal decisions and perform worse on a variety of cognitive tasks compared to those who do not face such constraints (Mani et al. 2013; Shah, Mullainathan, and Shafir 2012). The current research aims to illuminate the precise cognitive mechanism potentially responsible for these impaired decisions in order to derive implementable interventions.

Aversive thoughts about money are likely to be more accessible for the poor than the rich; given this, the poor may be predisposed to ruminate on, or dwell upon, their financial concerns. Indeed, a pilot study found that lower-income individuals were more prone to agree with statements such as "I have thoughts that I cannot stop" and "My thoughts frequently return to one idea" than the rich (select items from the White Bear Suppression Index, or WBSI; Wegner and Zanakos 1994). A large body of work has implicated the role of rumination in negative mood and a host of psychopathologies, including depression, anxiety, binge eating and drinking, and self-harm (Nolen-Hoeksema, Wisco, and Lyubomirsky 2008). In two field studies, we examine the effect of income on rumination about financial concerns in particular and highlight some downstream negative consequences of rumination on decision making. A third study investigates the efficacy of interventions such as suppressing thoughts about financial concerns, versus encouraging their free expression, on impulsivity.

Study 1 used a representative U.S. panel ($N=517$) to test the mediating role of rumination on impulsivity and cognitive function. Participants completed a monetary intertemporal titrator composed of 11 choices between a smaller, immediate reward and a larger, delayed reward (Green, Fry, and Myerson 1994), followed by a measure of cognitive performance and ability (Cognitive Reflection Task; Frederick, 2005). We then administered the WBSI and an adapted financial rumination scale (Scott and McIntosh 1999), along with alternative mediators hypothesized *ex ante* to be psychologically relevant (i.e., self-efficacy, desirability of control, self-control, and tightwad-spendthrift scores).

To analyze impulsivity, we interpolated an indifference point for each individual and estimated a discount rate parameter assuming a hyperbolic value function (Mazur 1987). The results demonstrate that the poor—both when classified as having incomes below \$40,000 and on a continuous scale—discounted the future more (i.e., chose smaller-sooner rewards more often) and ruminated more on their finances than the rich. Rumination fully mediated the relationship between income and impatience. A similar pattern obtained for CRT scores (after controlling for numeracy). In additional, rumination mediated the relationship between income and several consequential financial behaviors: namely, the likelihood of having taken a payday loan in the past, using a pawn shop, being able to raise \$2,000 for an emergency, and spending more than one's income over the past year.

Study 2 ($N=949$) extends these findings using a naturally occurring event to create conditions that would make the poor more likely to ruminate on their finances. Previous research finds that the poor tend to display impaired decision-making just before they receive a windfall gain. This tendency is best illustrated by Mani et al. (2013), who found that farmers' cognitive function was impeded immediately before harvest compared to after harvest. We recruited participants (all with annual household incomes below \$40,000) and compared rumination among those who claimed the Earned Income

Tax Credit (EITC) on their 2014 tax return relative to those who did not plan to claim EITC. Results reveal that compared to those who did not plan to claim this credit, rumination was higher among people who either received, were awaiting, or were planning to file for the EITC. Again, rumination significantly mediated the relationship between EITC status and impatience, as well as between EITC and CRT scores. These patterns suggest that the effects of rumination hold even when there is no variation in real income—in other words, the mediating role of financial rumination may generalize to situations involving both chronic and situational (or perceived) poverty.

If the poor focus too much on their financial concerns, one solution is simply to encourage them not to. However, literature on the “ironic processes” of mental control has shown that inhibiting attention to a target thought often backfires, triggering the very thoughts we wish to suppress (if I tell you not to think about a white bear, you will invariably think about a white bear; Wegner et al. 1987). From this perspective, suppressing thoughts of poverty when it is the “white bear” in the room may lead people to do worse—by overborrowing, say, or engaging in other reckless behaviors. A third study found, however, that while financial rumination exacerbated impulsivity, thought suppression did not produce significant gaps in time preferences between the poor and the well-off. Specifically, 538 Amazon Mechanical Turk participants were told to either (a) freely type their thoughts, including any financial concerns (express condition), (b) freely type their thoughts, excluding any financial concerns (suppress condition), or (c) list the names of streets near their hometown (control). Discount rates were imputed using the same monetary intertemporal choice titrator from Studies 1 and 2. As anticipated, the poor discounted the future more than the rich. Further, while no differences by condition emerged among higher-income individuals, the poor exhibited much higher discount rates only in the express condition. Hence, simply allowing for the free expression of money-related thoughts and scarcity caused the poor to behave more impulsively.

In sum, our findings suggest that the poor are chronically more disposed to ruminate on their finances, and that this tendency may in turn give way to myopic preferences (higher discount rates) and cognitive decrements (lower scores on the CRT). If rumination, then, is to blame for “worse” decisions among the poor, what actionable steps can we take to attenuate or eliminate its negative effects? As a next step in this research program, we plan to test the efficacy of different interventions that reduce rumination on financial concerns to try to correct for the detrimental downstream consequences on impulsivity and other decisions.

An Urgency Effect in Responses to Future Rate Increases

EXTENDED ABSTRACT

Total consumer debt outstanding has been increasing since 2010 and reached over 3 trillion dollars in 2014 (Federal Reserve, 2014). Existing literature in financial decision making has shown that consumers have trouble dealing with their debts, understanding their credit card use and optimizing their repayment plans (e.g., Amar et al. 2011; David and McShane 2012). Studies have also shown that consumers have trouble figuring out how interest rates affect their finances and underestimate the effort required to pay off their debts (e.g., Soll, Keeney, and Larrick 2013).

The current research focuses on debt repayment behavior. Specifically, we examined how knowledge of the timing of future interest rate increases influences a person’s decision about when to repay their debts. We found that when the interest rate is already high, or is expected to increase in the very near future, people pay their debts

more slowly than when it is currently at a lower level and expected to rise in the (not very near) future. We also investigated the underlying mechanism of this pattern, uncovered boundary conditions, and sought to generalize the pattern beyond debt payments to other domains of consumer behavior.

In Study 1, we asked 60 MTurk participants to imagine that they had taken out a loan last year. The interest rate on the loan was flexible and would increase from 2% to 5% at some point. We manipulated when the interest rate increased. In the rate-already-increased condition, we told participants that the lender had notified them that the rate had increased three months ago. In the rate-will-increase condition, we told participants that the lender notified them that the rate will increase in three months. Then, participants stated when they would like to pay back the loan. Participants in the rate-will-increase condition decided to pay off the loan significantly faster than those in the rate-already-increased condition ($M=10.27$ vs. 7.27 months, $p<.01$), despite the fact that the accumulated interest (total cost) was higher in the rate-already-increased condition.

Study 2 aimed to replicate the basic effect we found in Study 1 and to show that the effect goes beyond past-future asymmetry (i.e., valuing future events more than equivalent past events, Caruso et al. 2008). In Study 2, we asked participants when they would pay back a loan, varying when in the future the interest rate would increase: immediately (this coming month), in a certain future time (four months from now) or in an uncertain future time (sometime between this month and 12 months from now). We found that participants in the certain-future ($M=6.41$ months) and uncertain-future ($M=7.69$) conditions decided to pay off the loan significantly faster than participants in the increase-immediately condition ($M=11.17$ months, $p<.01$ for this month vs. four months; $p<.05$ for this month vs. uncertain future).

One possible explanation is that overly aggressive goals might bring counterproductive consequences (e.g., Locke and Latham 2006; Soman and Cheema 2004). Participants may adopt the temporal cue (i.e., when the rate increases) as a deadline and automatically set up a goal to pay the money back before the deadline, but this only happens when the temporal cue is achievable. Therefore, when participants knew that the rate would increase in the coming month, that temporal cue did not trigger either the setting of an automatic goal (a deadline) or the motivation to pursue it, because they did not consider the goal achievable. They would otherwise repay the debt following their own pace. However, deadline-setting cannot fully explain why participants decided to repay sooner in the uncertain-future condition.

Another possible explanation is an “urgency bias.” Research has shown that people are more sensitive to changes than the status quo (Kahneman and Tversky 1979). People should normatively prioritize their repayment effort according to the interest rate. However, the rate increase looms larger than the objective amount of that rate in people’s decisions. In other words, people perceive the anticipation of an increased rate to be more urgent than a static high interest rate. Therefore, they pay more attention to the urgent cue (increasing tendency) than the important cue (interest rate) when making decisions.

In Study 3 and Study 4, we proposed two ways to draw consumers’ attention back to the interest rate. Study 3 tested whether evaluation mode (Hsee and Zhang 2010) would moderate the urgency bias. We manipulated perceived urgency (rate has increased vs. rate will increase) and evaluation mode (single vs. joint evaluation). We replicated the basic effect in single evaluation, but found that participants were more rational in joint evaluation: participants decided to pay off the rate-has-increased loan faster than the rate-will-increase

loan when the two loans were presented side by side. Study 4 tested whether contemplating on the interest rate would alleviate the urgency bias. Results showed that the urgency bias went away when we asked participants to focus on the rate itself and consider whether the increased rate was too high or too low before they made their decisions.

The urgency bias exists not only in financial decision making with punitive interest rates, but also in other consumer behavior domains. In Studies 5 and 6, we looked at consumer purchasing behavior when the price of the product changes. We found that consumers purchased more when they received a discount for only one item than if they received a discount for four items. We have tested this effect with hypothetical scenarios (e.g., buying oysters, renting a bike) and are now running studies involving real consequences.

The above studies showed that when the interest rate is already at a high level, or is expected to increase in the very near future, people pay their debts more slowly than when it is currently at a lower level and expected to rise in the (not very near) future.

SESSION OVERVIEW

The objective of this session is to promote the use of pragmatism within consumer research. This topic is particularly important and relevant to the conference theme of ‘Advancing Connections’. Pragmatism maintains the demand for rigor but allows a range of methods and techniques to be employed within research, offering no preference or predetermination in this area. This means that academics are more likely to be interested by, and appreciate of, work taking a different approach to their own, as opposed to vying for credibility with them. Further, pragmatism contains certain similarities with both ends of the methodological spectrum and so would not be completely alien to anyone within the community.

The enhanced emphasis on developing workable solutions to practical problems could also help to strengthen connections with practitioners, public policy makers and consumers. Here the focus on usability of findings and the style of work produced means that impact becomes a natural part of the research process, rather than something to be searched for at the end of a project. The topic therefore speaks to a range of key consumer research context areas that span the methodological divide, for example sustainability, ethical consumption, health, well-being, finance, poverty, as well as inequality reduction more generally.

Each paper in the session is either dedicated to, or strongly influenced by, pragmatic research philosophy. Dan Silcock’s paper reviews pragmatic philosophy and contributes by delineating previous literature into three distinct versions of pragmatism. He also details several advantages to a wider adoption of pragmatic thought, including potential for improving the connection between research camps. Richard Varey’s contribution relates pragmatism to a specific area of consumer research, highlighting problems within the field of sustainability and how pragmatic new science could help solve these issues.

Iain Davies’ article centres on using pragmatism to improve connections between theory and practice, exploring how consumer research theory could be operationalized into ‘knowledge’ given the pragmatic understanding of this term, and illustrates this process with work on ethical consumption. The final paper from Ronika Chakrabarti and Katy Mason provides a concrete case where pragmatic inquiry has advanced knowledge, relating to consumer-led market design, and shows how such an approach could be utilized to inform other socio-politically pertinent areas.

The session raises several challenging questions, for instance, can pragmatism appeal to a wider selection of consumer research

scholars? And imperatively given the current research climate, can consumer research afford not to take the pragmatic path?

Marketing Pragmatism: A Constructive Review of Pragmatic Philosophy and Implications for Consumer Research

EXTENDED ABSTRACT

This paper promotes pragmatism as a viable middle ground philosophy for consumer research. This is not in itself a novel or new suggestion, indeed numerous leading figures within marketing have either promoted or utilized pragmatist thought (e.g. Brown, 2012; Chakrabarti & Mason, 2014; Firat & Dholakia, 2006; Hatch, 2012; Thompson, Stern & Arnould, 1998; Varey, 2012), and these ideas are gaining considerable momentum outside of marketing (e.g. Corley & Gioia, 2011, Johnson & Duberley, 2000; Kellemen & Rumens, 2013; Kitcher, 2012; Morgan, 2007, 2014; Suddaby, 2006; Tsoukas & Chia, 2002; Weick, 1995, 2001).

However pragmatism remains stricken with internal variation and this has been a major factor in holding back its popularity and uptake. Therefore rather than suggesting another singular vision of pragmatism that should be adopted, this article contributes by delineating previous literature into three distinct versions of pragmatism. These versions are introduced within this abstract, explained in detail in the full paper, and presented in a form that can be taught and applied.

The article additionally outlines several advantages to a wider adoption of pragmatism within consumer research, namely the improvement of connections between methodological camps, potential influence on policy, the development of theory, and enhancement of the PhD process. Finally the paper provides a framework for understanding the evaluation of pragmatic research. The remainder of this abstract includes a brief overview of each section.

The history of pragmatism is covered first, from the ‘pragmatic maxim’ (Peirce, 1878) and the popularisation of ‘pragmatism’ by James in 1898, to Dewey’s (1929) ‘warranted assertions’ and ‘practical adequacy’. The central tenets to pragmatism are then explored, and here the rejection of correspondence theory is not unique, but this in combination with an emphasis on the practical nature of knowledge distinguishes pragmatism from other philosophical schools.

The three versions of pragmatism identified share similar epistemological considerations (accepting the socially constructed *and* practical nature of knowledge); however they are separated by the occupation of varying ontological positions. The first could be described as ontologically neutral, asserting that ontological considerations are not actually that important or useful (in fact suggesting that these become a hindrance), and is most predominantly associated with William James (e.g. 1897, 1907). The second is termed ontologically realist, believing in a single transcendent reality that bounds and limits our social constructions, and is mostly drawn from some of the work of John Dewey (e.g. 1929). The third is named ontologically relativist, where there are as many realities as there are constructions, and this view is most prominently advocated by more modern authors (e.g. Rorty, 1979, 1982). Each version has been followed or pursued by different authors and these are highlighted throughout. It is worth noting here that this paper does not advocate

any one version over the others, and all share the potential to provide a series of advantages.

Within each version of pragmatism the data collection methods and analytical techniques to be used in a study are not predetermined by the philosophical persuasion, rather the emphasis is simply on what methods and techniques will produce the most useful findings in relation to the particular questions or problems being addressed (Feilzer, 2010; Hanson, 2008; Rescher, 1977). This is not only beneficial for individual projects but has wider positive implications. The freedom offered within pragmatism fosters an environment where academics develop a thorough understanding of a variety of methods and techniques from across the philosophical spectrum. This encourages the ability and desire to read, draw from, and constructively critique contextually relevant work from differing methodological perspectives. Such an environment could therefore facilitate connections that would allow a more combined progress on key managerial, societal and political issues, as opposed to the situation where completely separate streams of research attempt to tackle the same problem.

The practical focus within pragmatism makes it particularly appealing given current trends within research in relation to policy, engagement and impact. With practical outcomes embedded into the whole research process, engagement and impact opportunities are a natural consequence of pragmatic research, not a supplementary consideration. In fact, a situation where a piece of research had no potential for engagement or impact would be very unlikely to occur in the first place. This practical focus would certainly not denigrate marketing's ability to generate original, novel and influential theory. In contrast, it is argued that this might be more likely, that the applied nature of marketing research makes theory better not worse, and that acknowledging this could actually lead to a more equal theoretical exchange with other disciplines.

Another advantage outlined relates to the experience of new PhD students, who are still often presented with an either/or decision in regards to research philosophy. This is possibly the most difficult and complex scholarly problem that they will ever face, and yet they are expected to make this decision, which has serious and significant connotations for the rest of their career, within the first few months of their studies. Pragmatism provides another option for this decision, which is possibly more palatable, and would leave emerging scholars equipped with enough methodological understanding to be able to either confirm, or change, their persuasion as they go through further intellectual development.

An associated problem for the expansion of pragmatism relates to the evaluation of research findings. While positivism and interpretivism both now offer widely accepted procedures and systems for evaluating research, few middle ground philosophies can boast such a weapon. This paper therefore additionally provides a framework for understanding the evaluation of pragmatic research in an attempt to help rectify this situation.

Pragmatism, New Science and Sustainability

EXTENDED ABSTRACT

For how long and to what extent is consumer culture sustainable? An ethic is needed that provides moral limits on consumption and directs production into a less harmful path, while still allowing consumer experience to nourish and enrich human existence. What is needed is a reconceptualization of the relationship between humans and nature.

Rogene Buchholz, in 'Reforming Capitalism: The Scientific Worldview and Business' (2012), urges readers to question the costs

to both themselves and society of maintaining the classical scientific worldview of 'normal science' in economics. Buchholz argues that the classical scientific worldview brings values into aspects of life – ethics, economics, politics, culture, and our relationship with nature – such that we are deprived of true meaning. The characteristics of classical science are reductionism, atomism, quantification, determinism, and the assumption of mechanism. The meaning of the parts provides meaning of the whole. This science is supposed to be passive and disinterested; there are only facts, and there are no values. The normal scientific worldview objectifies nature as a useful resource for humans to manipulate to their interests; otherwise it is of no value. In terms of use(-up) and waste disposal, the environment simply poses a challenge to continued economic growth.

Buchholz (2012) proposes a 'new science', based on Pragmatism, which shows a view of a world that is organic and holistic. The meaning of the whole is the basis for the meaning of parts. There is a fact-value distinction, and both are necessary for understanding the multitude of environments in which business is embedded. The way in which business relates to these multiple environments has profound implications for the society in which businesses operate. Re-thinking science in a holistic, relational philosophy treats ordinary lived experience as a form of knowledge, and does not reject scientific knowledge, but crucially accepts morality as essential in human experience. General characteristics of Pragmatism (originated by Charles Pierce, William James, John Dewey, C I Lewis, and George Herbert Mead) are therefore emergence, holism, continuity, quality, and indeterminism.

In Pragmatism's understanding of our world, knowledge emerges through intelligent reflection on experience within nature, and is thus fallible and tested by its consequences in experience. The nature of value is not considered real (i.e. objective) knowledge in a scientific worldview – it is no more than a subjective feeling. In Pragmatism, values emerge out of human experience in interaction with the environment in which humans live. Things experienced possess qualities (for example fulfilling or stultifying, appealing or unappealing) that are real emergents in the context of interactions with cultural and natural environments; 'valuing experiences are not the experience of evaluating experience from the outside . . . but arise from the immediate "having" of experience' (Buchholz 2012, p. 142). Further, 'valuings are turned into the valuable by the organizing activity of the mind in the ongoing course of experience as experimental' (p. 143).

Recent work on sustainability presents a striking picture: use of natural resources has already surpassed sustainable limits (Heinberg, 2011; Senge Smith, Kruschwitz, Laur & Schley, 2010), marketing theory and practice has contributed to this problem (Lawson, 2009; Smart, 2010), and fundamental shifts are needed (Belz & Peattie, 2009; Ophulus, 2011; Sheth & Sisodia, 2012; Varey, 2012). Changes are beginning to occur, both in practice (Benett & O'Reilly, 2010) and in theory (Martin & Schouten, 2012). Pragmatic thought can help the field inform policy makers who wish to see such change accelerate by providing workable solutions to real-world problems.

The consequences of adopting a 'New science' approach have profound implications for business. Industrial capitalism can no longer power prosperity. The mass society worldview is giving way to individualisation. The 'standard enterprise logic' is challenged. Marketing has operated as an attention technology for sellers competing to capture customers. However, in an intention economy buyers are a scarce commodity, and it is intentions that drive production for specific needs. Change in marketing is overdue. Despite increased social disharmony and the mounting evidence of looming environmental disasters, progress is stagnant and often negative, as market-

ing exacerbates the problem by misallocating negative value goods. The commonality in the contemporary crises of financial meltdown, humanmade climate change, economic inequality, distrust of government, and the social corrosion of consumerism, is the moral limit of markets in civic society. Sustainable living provides the higher purpose of marketing: well-being and human flourishing. Sustainability is a socio-cultural, inherently ethical, respectful, intellectual construct for a life of careful and equitable resource use within limits and inter-dependencies. It is not the antithesis of competitive business, indeed business can flourish by competing on, and being rewarded for, the accomplishment of enduringly valuable outcomes.

“Theory” into “Knowledge”: Operationalizing Consumption Research into Behavioral Change with Pragmatism

EXTENDED ABSTRACT

As a former fair trade marketer and now marketing ethics scholar operating around changing consumption markets and behaviors I find myself increasingly frustrated by the abstract nature of scholarly exploration in consumption research. Schaefer and Crane (2005) highlighted the polarisation of the ethical consumption field into rational information processing approach vs. socio-anthropological approach, highlighting the void between both fields and lack of research on the reality of changing consumption patterns. A decade on, and despite the emergence of Transformative Consumer Research (Mick, 2006), little has changing in ethical consumption, and disappointingly in consumption research generally.

The rational approach is underpinned by the assumption that consumers cognitively translate their concerns towards society or the environment into expressed buying behavior (Andorfer and Liebe 2012; Carrington et al. 2010; De Pelsmacker et al. 2005; Fukukawa and Ennew 2010; Gleim et al. 2013; Shaw, Shiu and Clark 2000), often drawing on linear behavioral models such as The Theory of Reasoned Action / Planned Behavior (Fishbein and Ajzen 1975; Ajzen 1991). However, the de-contextualization of this stream of research has made it all but irrelevant to our understanding of how and why consumers consume sustainable products (Eckhardt et al. 2010; Foxall 1993).

In contrast, the socio-anthropological school focuses on consumption as a means of self-identity creation and here sustainable consumption is often framed as a mechanism for demonstrating resistance to the mainstream, as a method for gaining in-group membership, or as part of an identity project (Craig-Lees and Hill 2002; Fournier 1998; Kozinets and Handelman 2004; Price and Penalzo 1993; Rumbo 2002; Thompson and Arsel 2004), with notable examples including voluntary simplicity (Craig-lees and Hill 2002), political purchasing (Connolly and Prothero 2008; Prothero et al., 2011), economic voting (Gabriel and Lang 1995), and anti-consumption (Zavestoski 2002).

Following this line, resisting one type of consumption often forms the basis for another type of consumption - sustainable consumption (Arnould 2007; Holt 2002; Hollenbeck and Zinkhan 2006; Kozinets 2002). Therefore the socio-anthropological literature frames the ethical consumer as on the fringe (Eckhardt et al. 2010; Shaw and Riach 2011; Thompson and Coskuner-Balli 2007), radical (Bezenco and Blili 2010; Kozinets and Handelman 2004; Luedicke, Thompson and Giesler 2010), or anti-corporate (Thompson and Arsel 2004). However, from a pragmatic stand-point, it is hard to envision the consumption of a fair trade KitKat, H&M organic clothing, or Ben and Jerry's Ice-cream, as resistance to the mainstream.

William James (1842-1910) coined the phrases tender-minded and tough-minded to classify the differing schools of philosophical/scientific thought of his day. He typified the tender-minded as intellectualistic, idealistic, optimistic, free-willist, monistic, and dogmatic; insisting on going by principles, whereas the tough-minded were sensationalistic (understanding the world through senses), materialistic, pessimistic, fatalistic, pluralistic, and sceptical; insisting on going by facts. Setting aside the alternative meanings these words have developed of the last century, James highlighted, over the course of 8 public lectures on philosophy, the biases and misdirection inherent in rigid adherence to either school. However as I turn the pages of our hallowed scriptures in leading marketing periodicals I return time and again to James' observation: "You want a system that will combine both things, the scientific loyalty to facts and willingness to take account of them, the spirit of adaptation and accommodation, in short, but also the old confidence in human values and the resultant spontaneity, whether of the religious or of the romantic type" (James, 1907: 8).

Our subject has polarized with the emergence of required publication tariffs, making volume more important than quality. We have thus isolated ourselves into competing schools that do not inter-relate or talk with each other. At the extremes we see the burgeoning dominance of lab-based experimentation seeking abstracted generalizations which would never stand up to contextual reality, and on the other we have extreme contextual reality, often explicitly operationalized with outlier samples, masquerading as theory. Both may be producing relevant learning which would benefit the other, but neither is producing what Dewey (1938) referred to as "Knowledge".

Knowledge, to a pragmatist, is the ultimate set of truths which lead us to take better action in context. In essence, it is what a theorist may refer to as a universal theory. However, knowledge must be active; used for a purpose. Therefore information which does not lead a protagonist to achieve a specific goal in its employment is not useful - or knowledge. Yes "There is nothing so practical as a good theory" (Lewin, 1951: 169), but how do we interpret these words in a modern consumer research space?

Kurt Lewin, as social psychologist, obviously had a certain world view underpinning these words. I borrow here from Greenwald (2012: 99), another social psychologist, who provides this interpretation: "When a theory is 'good' ... its rules of correspondence go beyond assigning conceptual labels to laboratory research procedures. They extend the theory's concepts and principles to the non-laboratory world—in other words, to the possibility of useful applications." In other words, 'good theory' is nascent 'Knowledge'.

In this paper I explore what it would mean to operationalize the existing field of ethical / sustainable consumption into a field of Knowledge rather than a field of academic contribution. Taking Pierce's (1878: 300) proposition that "Different minds may set out with the most antagonistic views, but the progress of investigation carries them by a force outside of themselves to one and the same conclusion", I outline what we "know" about influencing consumption habits and explore means of investigating the subject more effectively in the future. I discuss what it means to conduct pragmatic research in a modern consumer research and publication environment, looking at steps in the research process and the process of pragmatic inquiry. I then go on to explain the pros and cons of taking a pragmatic approach in a discipline and employment environment which does not always favour the expansive, mixed-methods, multi-disciplinary, longitudinal approaches required for true Knowledge generation.

Can the Pragmatist Logic of Inquiry Inform Consumer Led Market Design?

EXTENDED ABSTRACT

We are interested in how the pragmatist notion of inquiry and experimentation proposed by John Dewey can inform consumer led market design. In Dewey's (1938) vision of political philosophy he advocates logic as a method of inquiry firmly grounded in *experience* aimed at improving human lives and social progress. As a key concept in pragmatism, *experience (or intelligent action)* holds both personal and contextual accounts of reality. In order to understand reality (or how to organize things in reality), the pragmatists focus on how reality is experienced. They consider how experiences are used to gain an understanding about what is happening in the world or to envision what ought to be happening (Keulartz et al., 2004). As such, Dewey claims that democracies are forms of organized intelligence and social action from where to pursue socio-political ideals. In a similar vein, markets are also viewed as practical outcomes of organizing efforts (Araujo et al., 2010) that are always 'in the making' and being constructed (Latour, 1987).

If reality is an existence verifiable to inquiry then questioning free imagination and intellectual possibilities are necessary to shape it. Since pragmatic philosophy recognizes the contingent and changing elements of livelihoods based on the 'experiences', it has important implications for understanding how patterns of inquiry can inform consumer learning and how we can be en-cultured within a consumer environment. By understanding how consumer practices can inform market design through a process of inquiry and experimentation; we can begin to make sense of 'what matters are' from a consumer perspective and create space for what markets could be. In Dewey's logic, methods of inquiry are applicable to real problems, which he calls an "indeterminate situation" (Dewey, 1929; 1938). What constitutes a situation to be undetermined is essentially a state of doubt or a felt difficulty (Dewey, 1910) or imbalance within an ecological environment. For Dewey, a critical difference exists between the state of 'knowing' and 'the known'. If what is known is based on previous inquiries (or facts) then what is to be known (or knowing) is more eventual and in a process of becoming. Knowing is therefore inquiry that is directed to what is indeterminate (or of concern) and also significant within a situation. At the heart of his pragmatist theory is a resolution for an indeterminate situation.

Inquiry can then only really end when an original indeterminate situation becomes more determinate (Dewey, 1938). This 'in-determination' offers a unique methodological lens from which to view the nature of inquiry as a series of phases: (1) *The Antecedent Conditions of Inquiry: The Indeterminate Situation (i.e. questionability)*; (2) *Institution of a Problem (how a problem is conceived, defined, observed and located)*; (3) *The Determination of a Problem-Solution (as "ideas" or "suggestions")*; (4) *Reasoning (or the equating of "ideas")* and (5) *The Operational Character of Facts- Meanings (or the interaction of facts and ideas and the need for experiments)*. We proffer that using Dewey's logic of inquiry could offer unique insights into both current and imagined market futures in consumer research. For example, by considering bottom-up market design as an unfolding process of inquiry (See Chakrabarti and Mason, 2014) we show how a process of inquiry can imagine and introduce new objects to configure market actors' practices in ways that make imagined markets at the subsistence level become real (Araujo et al., 2010; Cochoy, 2008). As the notion of practices allows for a recursive performance, bottom-up design enables this performance to continue to happen and democratize what new social norms will be in the market. Therefore, problematizing and designing are im-

portant for the bundling of practices and to create the right kind of market for the poor.

Dewey's arguments on pragmatism and democracy question how a democratic view of the world can be construed and interpreted to ensure that 'intellectual warranty' is achieved through judgments of practice. These judgements of practices are informed by multiple agencies and the connections that they make. For example, the intellectual warranty of consumers may invoke other forms of expertise essential to market design - regulators, NGOs, scientists, technologies etc. In this way Dewey's inquiry foregrounds the consumer but does not restrict it to the consumer alone. Instead, his approach offers not only a democratic view but one that is mobilising of collective action. In terms of future research, it would be interesting to explore through a processes of inquiry how markets are being shaped by the rise of important actors (e.g. the consumer-producers (Karnani, 2007)) who are influencing public policy discussions and new modes of governmentality. By using a process of inquiry in wider 'indeterminate markets' we may stand to unfold market designs that work well for both the communities and institutions that perform them and offer insights from a consumer research perspective into how inquiry might lead to new and better ways of doing things. We encourage scholars to use a pragmatist logic of inquiry to further explore markets that engage vulnerable consumers (cf. Piacentini et al., 2014), those in the arts, social care, war zones, ecological high risk zones (i.e. the need for low-carbon and renewable energy consumption), healthcare etc. that in times of austerity and socio-political insecurities are threatened by the nature of their indeterminate realities.

Paper #4: We'll Always Have Paris (Though We May Not Think of It): Consumers Overestimate How Often They Will Retrospect about Experiences

Stephanie Tully, University of Southern California, USA
Tom Meyvis, New York University, USA

SESSION OVERVIEW

The unique set of experiences that people accumulate over the course of their lives comes to define who they are as individuals. Recalling the memories of these experiences can increase one's sense of meaning and well-being (Wildschut et al. 2006; Holbrook 1993). Accordingly, people engage in certain actions in the present to create memories they can draw on in the future (Elster and Loewenstein 1992; Keinan and Kivetz 2011). They also strongly value opportunities to preserve and protect their memories (Zauberman, Ratner, and Kim 2009; Baumgartner, Sujan, and Bettman 1992). Given that memories of experiences are so valuable, it is important to understand what factors affect the formation and recollection of these memories, and how these memories impact future decisions.

The first two papers in this session focus on how factors present during the experience can influence memory of the experience. **Zauberman, Silverman, Diehl, and Barasch** investigate how taking photos during an experience can affect memory accuracy for different aspects of the experience. They find that taking photos improves recognition of visual aspects of the experience, but impairs recognition of auditory and higher-level information present during the experience. **Mantonakis, Schwarz, Wudarszewski, and Yoon** examine how using different ways to rate experiences affects memories of these experiences. They show that using bipolar (vs. unipolar) scales leads to more extreme ratings of taste attributes, such as concentration of a beverage, and that memory for the experience subsequently follows these ratings. For positively valued attributes, such recollections can heighten evaluations and willingness to pay for future taste experiences.

The final two papers focus on the role of memories of experiences in consumers' lives. **Martin, Reimann, and Norton** examine how memories for experiences affect whether consumers are risk seeking or risk averse when choosing future experiences. They show that for experiences, consumers recall more extreme experiences as

references points, leading them to become risk averse for negative experiences but risk seeking for positive experiences. Finally, while consumers may intend to revisit memories of experiences to make future decisions, **Tully and Meyvis** show that they systematically overestimate *how much* they will retrospect on any given experience. The authors show that unless tangible reminders cue people's thinking, they are unlikely to do so as frequently as they expect.

Experiences are the building blocks of people's lives, and remembering them is not only essential for personal identity and satisfaction (Singer and Blagov, 2004; Van Boven & Gilovich, 2003), but also integral in consumer decision-making (Bettman 1979). Together, this session highlights the diverse ways in which memories of experiences impact our daily lives. All four projects are working papers with at least three studies completed. Given the widespread applicability of the issues discussed, we expect this session to attract researchers interested in memory, experiential purchases, risk preferences, picture-taking, taste, and measurement tools. In the spirit of the conference theme "Advancing Connections," we hope that the diverse approaches to studying this topic will generate a lively and fruitful discussion.

Photographic Memory: The Effects of Photo-Taking on Memory for Auditory and Visual Information

EXTENDED ABSTRACT

Memory plays a key role across a wide range of contexts such as childhood development (Nelson and Fivush 2004), the formation of self-identity (Howe and Courage 1997), and decision-making (Lynch and Srull 1982; Alba and Hutchinson 1987). Since memory is fallible, people frequently create external memory records such as lists and diaries to capture knowledge and experiences (e.g. Block and Morwitz 1999). Today, photography in particular plays an integral role in how we document our experiences for the future. Given the prevalence of the behavior, it is important to understand how the act of taking pictures itself influences people's memory of their experiences, even *without* revisiting those photos.

Prior work on memory and photography has focused on the role photos can play in cueing past memories (Neisser and Libby 2000; Wade et al. 2002; Glenberg and Grimes 1995). However, this work has focused on the role of revisiting photos after the event. Only one recent paper (Henkel 2014) examined the effect of photo-taking on memory and showed that being directed to take pictures can impair visual recognition of objects. However, by instructing people when to take photos, this paper was unable to examine how freely deciding when and what to take pictures of affects memory. This autonomy is integral to photo-taking and may be crucial in examining its effect on memory. On one hand, taking photos may cause people to remember more from their experiences. Photo-taking has been shown to make people more engaged in their experience (Barasch, Diehl, and Zauberman 2015), which could cause people to remember more details. On the other hand, taking photos may lead people to remember less about their experiences; the photographer may pass off the responsibility of remembering the details to the photos, much like people can shift their memory of information to computers when they expect to access it later (Sparrow, Liu, and Wegner 2011). Additionally, retaining other aspects of the experience (e.g. auditory information) may be particularly important as that information is not documented by photo-taking. In general auditory and visual stimuli are recalled

at similar rates (Brand and Jolles 1985) and recall of auditory and visual memories occur along the same neural pathway (Buckner et al. 1996). However, due to its visual nature photo-taking may focus photographers more on the visual aspects of an experience to the detriment of other aspects.

In four studies we examine the effect of photo-taking on visual and auditory memory. We find that photo-takers consistently remember visual information better but remember auditory information worse.

In studies 1 through 3, lab participants use a unique computer interface that allows them to “experience” an event by watching a first-hand video and taking pictures by clicking a button. This procedure provided consistency across experiences in each condition, thus ensuring high internal validity.

In study 1, we examined how taking photos affects visual memory. 251 MTurk participants took photos during, or simply experienced, a bus tour of London. This video contained only instrumental background music without any auditory information in order to eliminate any chance for auditory cues to influence participants’ photo-taking behavior or their memory. After watching the bus tour, participants answered 11 visual recognition questions.

We found that taking photos affects memory for visual information; in a two-way ANOVA, participants in the camera condition remembered more of what they had seen ($M=58.1\%$, $SD=20.3$) compared to participants in the control condition ($M=52.8\%$, $SD=19.7$, $F(1, 249)=4.46$, $p=.036$).

In study 2, we shifted our focus from visual to auditory information. 171 lab participants were randomly assigned to take pictures during, or simply experience, the Hershey Park factory tour ride. Afterwards, participants answered 10 auditory recognition questions.

Contrary to our findings for memory of visual information, a two-way ANOVA reveals that participants who took pictures remembered less ($M=51.5\%$, $SD=26.2$) than participants who were not given a camera ($M=58.6\%$, $SD=26.1$, $F(1, 169)=6.27$, $p=.013$).

In study 3 we examined on the effect of photo-taking on both visual and auditory memory simultaneously, as would be expected in a real life experience. 306 MTurk participants were randomly assigned to take pictures, or simply experience, three narrated tours of three different art galleries. Participants then answered 7 visual and 8 auditory recognition questions about the experience.

In a mixed ANOVA, there is a main effect of type of question ($F(1,63)=114.44$, $p<.001$), such that participants remembered more visual than auditory information. There is also a significant interaction between type of question and condition ($F(1,304)=461.28$, $p<.001$). While participants in the camera condition remember significantly more visual information ($M=87.2\%$, $SD=18.5$) than participants in the control condition ($M=76.3\%$, $SD=23.3$, $F(1,304)=20.46$, $p<.001$), participants in the camera condition remember significantly less auditory information ($M=43.9\%$, $SD=21.7$) than those in the control condition ($M=56.0\%$, $SD=21.3$, $F(1,304)=24.54$, $p<.001$).

To assess the external validity of our lab findings, we conducted a field study in a museum exhibit. 203 participants were given a map and audio guide and were randomly assigned to take photos as they wished, or simply experience, a self-guided tour of an exhibit. Afterwards, they answered 9 visual and 9 auditory recognition questions (time 1). A week later, 142 participants answered 7 visual and 5 auditory recognition (time 2).

In a three-way mixed ANOVA, participants remember more at time 1 ($M_{\text{time 1}}=72.5\%$, $SD=15.9$; $M_{\text{time 2}}=63.8\%$, $SD=21.3$) and more visual information ($M_{\text{visual}}=73.6\%$, $SD=16.6$; $M_{\text{auditory}}=65.4\%$, $SD=20.1$). Replicating the previous studies, there is a two-way interaction between condition and type of question ($F(1,200)=11.33$,

$p<.001$); participants in the camera condition remember more visual information than participants in the control condition ($M_{\text{camera}}=72.5\%$, $SD=1.4$; $M_{\text{control}}=68.2\%$, $SD=1.7$) but less auditory information ($M_{\text{camera}}=59.4\%$, $SD=1.6$; $M_{\text{control}}=64.4\%$, $SD=1.8$). There is also a two-way interaction between time and type of question ($F(1,200)=7.64$, $p=.006$); participants remember less at time 2, but the decrease is significantly larger for auditory memory ($M_{\text{time 1}}=68.7\%$, $SD=1.4$; $M_{\text{time 2}}=55.1\%$, $SD=1.9$) than for visual memory ($M_{\text{time 1}}=73.5\%$, $SD=1.2$; $M_{\text{time 2}}=67.3\%$, $SD=1.7$).

Overall, we find that photo-taking improves visual recognition but hinders auditory recognition. These results hold when participants’ auditory and visual memory are tested individually or simultaneously, and in an externally valid field study.

Malleability of Taste Perception: Biasing Effects of Rating Scale Format on Taste Recognition, Product Evaluation, and Willingness to Pay

EXTENDED ABSTRACT

Subjective experiences are fleeting and poorly represented in memory; people resort to reconstruction strategies shortly after an experience (Schwarz, 2007). As in other domains of autobiographical memory (Schwarz & Sudman, 1994), people will draw on any accessible piece of information that may be useful to reconstruct the experience, including general knowledge about the domain and memorable features of the episode related to the experience. We propose that the same logic applies to taste experiences: the experience itself is fleeting and not well represented in memory; hence, consumers can introspect on it while they are having the experience, but need to reconstruct it later on. This leaves the door open for systematic errors of memory for taste that can affect downstream intentions and behaviors.

According to sensory testing experts, tasters are typically asked to indicate their experiences on rating scales (S. Kirkmeyer, personal communication, August 3, 2011), and remember them later or compare them with the taste of other samples. Similarly, consumers who sample products need to remember their sensory experiences for later purchase decisions. Whereas potential biases on sensory perceptions arising from non-sensory information like the brand (Hoegg & Alba, 2007), color (Garber, Hyatt & Starr, 2000), price (Plassmann, O’Doherty, Shiv, & Rangel, 2008) or information about the ingredients (Lee, Frederick, & Ariely, 2006) have been examined, other likely sources of bias have gone unnoticed, such as the format in which consumers report their taste experience.

Suppose that consumers at a winery taste a new ice wine and rate its attributes along rating scales. In one condition, an 11-point scale ranges from “not at all sweet” = 0 to “very sweet” = 10; and in the other condition, it ranges from “not at all sweet” = -5 to “very sweet” = +5. Previous research on social judgments (Schwarz, et al., 1991) showed that the latter set of values results in more extreme ratings. Would this effect of rating scales also apply to a product that is tasted?

In **Experiment 1**, participants sampled an unlabeled orange juice. Depending on condition, they were assigned to rate attributes of the juice on either a bipolar (-5 to +5) or unipolar (0 to 10) scale. Participants then completed a taste recognition task. They sampled three orange juices and attempted to identify the one they had tasted earlier; the original sample was presented along with a more concentrated one as well as a less concentrated one. We predicted that the sampled drink would receive higher attribute ratings when participants were given a bipolar than unipolar scale (**hypothesis 1**), and that participants in the bipolar scale condition would be more likely to misidentify the more concentrated test sample as the one

they had originally tasted, consistent with the higher taste attribute ratings they provided (**hypothesis 2**).

As predicted (hypothesis 1), participants gave higher attribute ratings on the bipolar ($M = 7.16$) than on the unipolar ($M = 6.31$) scale, $F(1, 126) = 6.11, p < .01$. This confirms the success of the scale manipulation (Schwarz et al., 1991). Accuracy at identifying the correct orange juice as the one sampled earlier was higher in the unipolar ($M = .53$) than the bipolar condition ($M = .46$), z -contrast = 4.72, $p < .01$. As predicted (hypothesis 2), the error was systematic: the more concentrated juice was more likely to be misidentified as the one sampled earlier when participants had made the initial attribute ratings along a bipolar ($M = .23$) rather than unipolar scale ($M = .17$), z -contrast = 3.11, $p = .01$.

We predicted that this this biased reconstruction will also influence subsequent evaluations of the product (**hypothesis 3**), and affect consumers' subsequent WTP (**hypothesis 4**). We tested these ideas in **Experiment 2**, where we extended the range of dependent variables to consumers' overall product evaluations and willingness to pay.

Attribute ratings were higher on the bipolar ($M = 6.05$) than on the unipolar ($M = 4.90$) scale, $F(1, 163) = 20.96, p < .001$. Supporting hypotheses 3 and 4, respectively, participants rated the standard sample of orange juice more highly when they had rated its attributes on bipolar ($M = 6.05$) rather than unipolar ($M = 4.28$) scales, $F(1, 163) = 22.24, p < .001$. The former participants were willing to pay more for the juice ($M = \$2.38$) than the latter ($M = \1.67), $F(1, 163) = 25.87, p < .001$.

Accuracy at identifying the correct sample as the one sampled earlier was higher in the unipolar ($M = .56$) than the bipolar ($M = .43$) scale condition, z -contrast = 3.69, $p < .001$. Again, the more concentrated juice sample was twice as likely to be misidentified as the one sampled earlier in the bipolar ($M = .29$) than unipolar ($M = .14$) rating conditions, z -contrast = 4.26, $p < .001$.

We expect that these influences are less pronounced for experts than for novices in a given product domain (**hypothesis 5**), because they would be less biased by the scale. In **Experiment 3**, we gave participants wine to sample, and to rate attributes of it on either a bipolar (-5 to +5) or unipolar (0 to 10) scale. Next, we gave participants questions pertaining to the wine (e.g., "How much would you be willing to pay for a bottle of this wine?"), and their level of wine expertise.

Ratings on the 4 attributes were combined to produce a single evaluation index. We examined mean differences between the conditions, with expertise as a covariate. Evaluation was higher for the bipolar ($M = 7.14$) than the unipolar condition ($M = 6.53$), $F(1, 77) = 5.51, p < .03$. To examine whether the numerical values manipulation affected WTP, we examined mean differences between the conditions, with expertise as a covariate. WTP was higher for the bipolar condition than the unipolar condition (WTP means = \$17.51 and \$15.05; log(WTP) means = 2.80 and 2.61; $F(1, 77) = 4.07, p < .05$).

Thus, managers may be able to influence purchase-related variables such as willingness to pay by using the right response scales.

Risk Preferences for Experiences, or How Desserts Are Like Losses

EXTENDED ABSTRACT

How can we predict, when people make choices in everyday life, whether they will be risk-seeking or risk-averse? If these choices relate to money, we know the answer fairly confidently; extensive research has been devoted to risk preferences for money, demonstrating that people are risk-seeking when choosing between monetary

losses and risk-averse when choosing between monetary gains (e.g., Kahneman & Tversky, 1979; Rabin & Thaler, 2001; Stewart, Chater, Stott, & Reimers, 2003; Wang & Johnson, 2012). Despite this well-documented research on risk preferences for money, surprisingly little attention has been paid to risk preferences for non-monetary experiences, either negative (disgusting foods and visits to the dentist) or positive (desserts and visits to the movies). Facing a choice between seeing a "safe" movie that receives many 3-star ratings and a "risky" movie that receives many 5-star but also many 1-star ratings, how do people evaluate the potential risks and rewards? Generally speaking, how will memories of experiences influence the way we form risk preferences?

Given the established contrast between risk preferences for positive and negative gambles, valence offers an intuitively appealing prediction about risk preferences for experiences: negative experiences (e.g., dentist visits) might be similar to monetary losses, while positive experiences (e.g., desserts) might be similar to monetary gains, implying risk-seeking for negative experiences and risk-aversion for positive experiences. However, we propose and provide convergent evidence stemming from six experiments reported below that people are generally risk-seeking for positive experiences and risk-averse for negative experiences, the mirror image of choices for money: people gamble on desserts, but not on dentists.

We suggest that this reversal is because the reference points that are commonly drawn upon when making decisions about experiences and money are based on different types of memories. Reference points are critical to understanding risk preferences because they serve as the basis against which possible outcomes are compared; outcomes are treated as losses whenever they fall below some reference point but as gains when they exceed that reference point (March & Shapira, 1992; Payne, Laughhunn, & Crum, 1980). For monetary prospects, zero change in wealth (i.e., the status quo) serves as a salient reference point, such that monetary gambles with positive values are typically treated as gains and those with negative values are treated as losses (Kahneman & Tversky, 1979; Rabin & Thaler, 2001; Tversky & Kahneman, 1992). For experiences, on the other hand, research shows that reference points may be determined not by neutral memories but rather by extreme memories (e.g., the best dessert and the worst dentist visit): individuals asked to recall *typical* instances of past experiences in positive and negative domains in fact recall the *most extreme* positive and negative experiences they have had in those domains (Gershoff, Mukherjee, & Mukhopadhyay, 2003; Morewedge, Gilbert, & Wilson, 2005), and these readily available memories offer convenient reference points (Koszegi & Rabin, 2006; Novemsky & Dhar, 2005; Thaler & Johnson, 1990). Should the memory of the best dessert one has ever eaten serve as a reference point when choosing between desserts, then ironically many of the available options, despite being positive experiences, will be treated as comparative losses – precisely because they fall below the salient reference point (Kahneman & Tversky, 1979). Similarly, should the memory of the most burdensome chore come to mind when choosing which chore to tackle, many of the available options – despite being negative experiences – will be treated as comparative gains.

This account suggests several interrelated hypotheses, which we test in six experiments. In Experiment 1a, we find support for our first hypothesis that people are generally more risk-averse for negative categories of experience and risk-seeking for positive categories of experience, a reversal of the relationship between valence and risk preferences observed for money. In Experiment 1b, we assess external validity by employing an incentive-compatible experiment with a real choice. In Experiment 2, we document that this reversal in risk preferences is due to a fundamental difference between risk

in the quality of experiences and risk in quantities of money. Indeed, we observe similar risk preferences for quantities of experiences and quantities of money of the same valence, but again the opposite pattern for experiential quality. In Experiment 3, we rule out alternative explanations relating solely to the way that people use rating scales for experience quality. When participants list equivalent experiences and monetary outcomes, from which we construct “equivalent” risky choices, they exhibit different risk preferences depending on whether these choices are expressed as experiential outcomes or their monetary equivalents. In Experiment 4, we assess the reference points that individuals use to make choices; reference points for gambles are closer to zero, whereas reference points for experiences are closer to extremes. In Experiment 5, we show that subjective utility functions are convex for positive experiences and monetary losses, but concave for negative experiences and monetary gains, consistent with extreme reference points for experiences; these utility curves also predict risky choices across all four domains.

“We’ll Always Have Paris (Though We May Not Think of It): Consumers Overestimate How Often They Will Retrospect about Experiences.”

EXTENDED ABSTRACT

People enjoy retrospectively about past experiences and appear to do it quite often. Past research suggests that we spend upwards of 50% of relaxed, social conversation talking about our experiences (Dunbar, Marriott, and Duncan 1997) and that sharing information about ourselves and our experiences is intrinsically rewarding (Tamir and Mitchell 2012). Memories also appear to be one of the reasons why consumers are happier with their experiences than with their material goods (Van Boven and Gilovich 2003). Furthermore, consumers seem to anticipate the future retrospection that experiences provide as they sometimes choose experiences as a function of their retrospective value (Keinan and Kivetz 2011; Ratner, Kahn, and Kahneman 1999). But how accurate are consumers at predicting the extent of their retrospection?

Because sharing one’s experiences is intrinsically rewarding, people should want to talk about their experiences. However, given the abundance of experiences people live through, people cannot and do not continue to talk about all of their experiences indefinitely. Memories of experiences are less likely to come to mind over time. Indeed, the majority of memories that people remember and think about have recently occurred (Crovitz and Schiffman 1974). Yet, since consumers have a strong desire to retrospect about their experiences, they may underestimate the difficulty of bringing past experiences to mind. In support of this idea, a recent study found that people were not able to remember details of a previous conversation despite a previous belief that they would be able to (Zhang et al. 2014). We therefore expect consumers to systematically overestimate how much they will retrospect about an experience. We show that this overestimation is not the result of misconstrual of the event (it persists after the experience occurred), is moderated by the positivity of the experience, and is attenuated when physical reminders are present to facilitate retrospection.

In a first study, participants were asked to consider an experience that had occurred 3-6 months in the past or that would occur 3-6 months in the future. After describing the experience, participants indicated how often they did (past condition) or would (future condition) think about and talk about the experience during the two months following the experience. Next, they rated the experience on a number of dimensions. As expected, participants in the future condition predicted greater retrospection than participants in the past

condition actually recalled ($F(1,157) = 15.08, p < .001$). This result held when adjusting for differences in participants’ perception of their experience ($F(1, 154) = 8.18, p = .005$) and when adjusting for the type of experiences people wrote about ($F(1,117) = 8.79, p = .004$). Thus, people considering a future experience predict more frequent retrospection than participants report having actually engaged in after a past experience.

Study 2 was designed to rule out misconstrual of the future experience as an explanation for the overestimation of future retrospection. To this end, attendants of the U.S. Open tennis tournament were asked to predict their future retrospection a day *after* they attended the tournament. Two months later, we measured their actual retrospection. As expected, participants predicted they would talk about their U.S. Open experience more often than they reported having done at time 2 ($F(1,139) = 259.62, p < .001$). This overestimation was moderated by their willingness to recommend the experience ($F(1,138) = 10.46, p = .002$). These findings indicate that the overestimation is not simply misconstrual of a future, unknown experience, and that it is more pronounced for people who feel more positively about the experience—suggesting a motivated reasoning process.

In study 3, we replicated the results of study 2 with an experience for which retrospection should be a particularly important contributor to the value of the experience. A group going on an African safari completed the survey days after returning to the U.S. and completed a follow-up survey two months later. In this study, we measured the estimated frequency of looking at pictures of the event rather than the estimated frequency of thinking about the event, since the former should be easier to objectively recall at time 2. Replicating earlier studies, participants overestimated how much they would retrospect about the safari ($F(1,26) = 21.42, p < .001$). In line with a motivational explanation, this overestimation was moderated by how much participants reported wanting to talk about the trip at time 1 ($F(1,25) = 6.078, p = .021$).

We have proposed that the overestimation of retrospection occurs because people want to recall experiences, but do not recognize the difficulty of spontaneously recalling previous experiences. In the last 2 studies, we examined this latter proposition by demonstrating that overestimation is attenuated when physical objects serve as reminders to cue retrospection.

In a fourth study, participants in an obstacle course fun run completed a survey in the days following the run and completed a follow-up survey two months later. In addition to indicating their frequency of talking and looking at pictures, respondents indicated whether they had purchased a souvenir. Replicating previous studies, people overestimated how much they would retrospect about the race ($F(1,152) = 97.24, p < .001$). However, a significant time by souvenir interaction showed that this overestimation was attenuated for people who purchased a souvenir ($F(1,152) = 4.32, p = .039$): souvenirs increased actual, but not predicted retrospection (people do not intuit their impact).

In the final study, participants predicted how much they would talk and think about a purchase that was either an experience or a material good. A month later, participants indicated how often they did in fact talk and think about the purchase. Since material goods persist physically, we expected that the overestimation would be unique to experiences. As predicted, overestimation depended on purchase type ($F(1, 73) = 8.41, p = .005$): participants (marginally) overestimated how often they would talk and think about their experiences ($F(1, 73) = 3.25, p = .076$), but *underestimated* how often they would talk and think about their material purchases ($F(1, 73) = 5.16, p = .026$), indicating that people’s overestimation is specific to experiences.

SESSION OVERVIEW

Incentives can be especially powerful in driving desirable behavior. However, social psychology and consumer behavior have found that people respond differently to different incentive structures and framing of rewards (Gneezy, Meier, & Rey-Biel, 2011; Goldsmith & Dhar, 2013). In addition, people are sensitive to cost structure, fairness, and how benefits are redistributed (Fehr & Gächter, 2000; Kahneman et al., 1986). Thus, it is important to understand the effectiveness of incentive structures and distribution of benefits in encouraging behavior change. This session contributes to this literature through novel experimental research that explores how individuals' sensitivity to incentives and their perception of the fairness of incentive structures can be harnessed to increase collective welfare.

The first two papers focus on people's sensitivity to different incentive structures and the distribution of benefits and its implications to personal and public wellbeing. **Olivola, Kim, Merzel, Kareev, Avrahami, and Ritov** use a Volunteer's Dilemma Game (VDG) to explore how varying the number of players, the size of the benefits associated with volunteering, and the certainty of these benefits influences prosocial contributions. The results indicate that people are sensitive to the size and the certainty of welfare impact, but this sensitivity varies across cultures and gender. **Sussman and O'Brien** demonstrate that low income consumers are more motivated to pay off debt in accounts that incentivize repayments with lottery prizes than with a known payoff of equal expected value. Additionally, the concreteness of the goal to repay debt can make people particularly sensitive to certain lottery incentives. These two papers show how designing incentive schemes not only enhances personal welfare but also increases the distribution of benefits to others through contributions.

While the first two papers examine how people's sensitivity to incentives can increase contributions, the last two papers explore

how people can be incentivized when they know how costs and benefits will be distributed. **Mohan, Buell, and John** show that disclosing favorable or unfavorable variable costs associated with a good's production increases purchase interest and sales because of brand attraction. However, this result only holds when the price is a fair markup. **Srna, Zauberan, and Schrift** investigate how people's effort, satisfaction, and perceptions of fairness in response to different flat tax rates and the redistribution of tax money are counter to intuitions in an experimental pay-per-performance setting. These two papers demonstrate the importance of sharing cost information, and find that fairness is an important contributor to people's willingness to invest.

Taken together, these four projects highlight the importance of sensitivity to different incentive structures and the distribution of benefits to understanding consumer perceptions and behavior in four different domains of banking, volunteering, sales, and taxation. In line with the conference theme "Advancing Connections," the widespread applicability of these papers' findings could attract researchers interested in incentives, prosocial behavior, consumer behavior, and financial decision-making and have a broader impact on policy and practitioners. This session will create a productive discussion because of the theoretical and practical implications of each presentation.

Taking One for the Team: Motivating Prosocial Volunteering by Varying the Size and the (Un)Certainty of its Impact on Collective Welfare

EXTENDED ABSTRACT

What factors motivate or deter volunteering? This paper explores how culture, gender, and welfare impact, jointly influence prosocial decisions in a special type of social dilemma: The volunteer's dilemma game (VDG; Diekmann, 1985). The VDG provides a controlled experimental method for studying volunteering behaviors in an anonymous interactive environment (e.g., Barron & Yechiam, 2002; Diekmann, 1993; Murnighan, Kim, & Metzger, 1993).

Each player in the VDG is given a starting budget and has to decide whether or not to pay a fee in order to improve the final payoff (i.e., welfare) of all players. The contribution of one player is sufficient to produce the collective benefit but every player who chooses to pay must do so—irrespective of what the other players chose. Thus, if no one volunteers then no one receives the benefit; if a player does not volunteer but someone else does, the player receives the full benefit; and if a player volunteers, that player receives the benefit minus the cost of volunteering. All players make the decision (to volunteer or not) simultaneously. Critically, while all players benefit from one person volunteering, these benefits do not increase further if more than one player volunteers. Therefore, there is a coordination and efficiency problem to be solved in the VDG: every player prefers to volunteer if no one else will, but volunteering becomes pointless if at least one other person is already going to do so. In other words, it is suboptimal if no one volunteers (as it represents a missed opportunity to increase final payoffs), but it is inefficient if several people volunteer (as it implies wasted "effort" on the part of every additional player, beyond the first, who volunteers).

We developed six variations of the VDG, in which we manipulated the number of players in the game (and thus the number of potential benefactors of volunteering), the size of the welfare benefits associated with volunteering (i.e., how much people benefit from one's decision to volunteer), and whether volunteering led to certain or merely probabilistic increases in welfare (i.e., whether or not volunteering is sure to be effective), all while holding its expected value constant. We administered these 6 variations to economics students in five different cultures: Bali, England, India, Israel, and Java (total $N = 603$).

Overall, participants were sensitive to the welfare benefits of volunteering, but this sensitivity varied across cultures. Specifically, we found that Balinese participants' decisions to volunteer were less influenced by the returns to volunteering. This can be explained by the fact that Balinese culture places a strong emphasis on communal volunteering, as a sacred value (Veszteg & Narhetali, 2010), which could lead to scope insensitivity regarding the perceived benefit of volunteering. In contrast to the size of the welfare benefits, volunteering decisions were unaffected by the number of players present. This could be because the increased welfare benefits of volunteering when more players are involved were offset by the diffusion of responsibility that comes with more players (Darley & Latané, 1968; Latané & Darley, 1968; 1970; Latané & Rodin, 1969). Finally, we found that culture interacted with the (un)certainly of the benefits associated with volunteering, to influence volunteering decisions. Specifically, we found that, whereas Balinese, English, Israeli, and Javanese participants were equally likely to volunteer when doing so was associated with certain vs. uncertain welfare benefits, Indian participants were much more likely to volunteer when the returns to doing so were uncertain (albeit, with the same expected benefits, on average). Additional analyses showed that this tendency was unrelated to their general risk preferences, however.

Beyond culture, we found two other predictors of volunteering: religiosity and gender. First, we found that religiosity increases volunteering, and this was true for all major religions represented in our study. To the best of our knowledge, this is one of the first studies to show that religiosity increases prosocial choices in social dilemma games (Galen, 2012). Second, we found that men are less likely (than women) to volunteer when the returns to doing so are certain. By contrast, men and women are equally likely to volunteer when the welfare benefits of doing so are uncertain. To the best of our knowledge, this is only the third study to examine the effects of gender on volunteering in a controlled social dilemma experiment (Rapoport, 1988; Vesterlund, Babcock, & Weingart, 2014).

In sum, we investigated several determinants of volunteering. In particular we examined interactions between culture, gender, and welfare impact, on decisions to volunteer in an experimental social dilemma game. We show that, in deciding whether to volunteer, people are sensitive to the size of the welfare impact of volunteering and whether this impact is certain or uncertain. However, this sensitivity to size and (un)certainly varies across cultures and genders.

Using Gambling to Incentivize Prudent Financial Decisions

EXTENDED ABSTRACT

US consumers struggle with their finances—both building savings and paying down debt. Despite the importance of savings as protection against financial shocks, a large percentage of households hold little to no saving (Lusardi, Schneider, and Tufano 2011). Additionally, US consumers carry over \$800 billion dollars of credit

card debt in aggregate, despite high financial and psychological costs associated with debt.

Prize-linked savings accounts have been used effectively to increase savings among consumers throughout the world (e.g., Kearney et al., 2010). These accounts are similar to traditional savings accounts except account-holders forgo (some or all) interest dividends in return for the chance to win lottery-like payouts. They are particularly appealing to low-income individuals, and evidence suggests that investment in this product can serve as a substitute for lottery or casino gambling (Cole, Iverson, Tufano, 2014; Cookson, 2014). Importantly, legislation passed in late 2014 will allow prize-linked savings accounts to be offered by banks and credit unions in the US.

Although prize-linked accounts have previously been used only in the context of building savings, we propose that a similar incentive structure could be used to help consumers reach another important financial goal—repaying their debt. Prize-linked debt products may be particularly attractive as an incentive in the context of consumers who hold nonperforming loans and may otherwise be unlikely to repay the full amount of the loan. Across four studies, we examine interest these products (prize-linked debt and savings), investigate differences in beliefs about savings and debt that would make each product appealing, and explore how considering goal-setting can be used to recommend specific design parameters.

Study 1 investigated whether consumers would express any interest in a prize-linked account to assist with debt repayment, and how this interest would compare to interest in prize-linked savings. 52 online participants were told to imagine that they had \$10,000 to allocate across four different options: (1) a traditional savings account (2) prize-linked savings account (3) repaying credit card debt with a constant bonus and (4) prize-linked debt account. In the two debt accounts, the cards were described as offering a promotion where consumers received a bonus for making payments on their debt. The expected value of bonuses was equated across all four account types. A 2 (credit vs savings) x 2 (traditional vs lottery) within-subject ANOVA revealed that participants put significantly more money towards credit repayment (\$5,716) than savings (\$4,283, $p < .05$). Participants were more likely to put more money towards the traditional (\$8,341) than lottery-based products (\$1,658, $p < .05$), but they were as attracted to the prize-linked debt account (\$1,077) as the prize linked savings account (\$593, *ns*), suggesting that the novel prize-linked debt account may be an effective remedy for debt repayment in some populations.

Study 2 examined relative interest in prize-linked savings versus debt products relative to traditional accounts by asking 100 participants to allocate funds across prize-linked savings versus traditional savings or prize-linked debt repayment versus traditional debt repayment options, in a between-subjects design. Results showed that the prize-linked debt account garnered significantly more interest (\$2,402) from participants than the prize-linked savings accounts (\$1,051, $p < .05$) when compared to their respective traditional accounts.

Study 3 moved to a national sample with overrepresentation from low-income households, to determine characteristics of people interested in each type of product. This study included a large range of individual difference measures. Relying on a study design similar to Study 1, results revealed that overall interest in lottery-based products was predicted by liberalism, gender, age, race, income, risk tolerance, and propensity to play the lottery. Additionally, we examined a range of attitudinal measures to better understand perspectives towards savings and debt. Among other factors, we found that having a plan for reaching one's debt goal was a positive predictor of

lottery use while having a plan for reaching one's savings goal was a negative predictor, and that the importance of debt repayment is a significant predictor of the relative preference for the debt lottery relative to the savings lottery. To better understand the appeal of a prize-linked credit account (relative to prize-linked savings), we also examined differences in beliefs about building savings and repaying debt. This analysis revealed that participants considered building savings to be a more gradual process than repaying debt, and that people have more concrete views of their debt goals relative to savings goals.

Leveraging insights gained about the psychology of debt repayment, Study 4 aimed to understand how the presence of concrete savings goals and beliefs that debt repayment is not always gradual could help with product design. One way debt differs from savings is that many people may have the same, concrete debt-goal (i.e., become debt free) whereas savings goals are more personalized and amounts are malleable (e.g., have enough money to retire). This suggests that a debt product that offers the opportunity for a consumer to clear her debt could be particularly compelling, while no exact parallel exists in the savings domain. To test this hypothesis, 100 participants read a scenario in which they had a preset amount of credit card debt and choose between a consumption (TV purchase) and lottery-based debt repayment opportunity (1-7 Likert scale). Each of the debt repayment options included several \$1,000 payouts. This amount was either (a) insufficient for repaying all outstanding debt (b) equal to outstanding debt or (c) described as eliminating all of the winner's debt (rather than stating an amount, equivalent to \$1,000 in the scenario provided). Participants in the explicit debt elimination condition were significantly more likely to repay their debt ($M_c=5.93$) than those in either of the other two conditions ($M_b=4.77$, $M_a=4.88$, $p_s<.05$). These findings suggest that (holding expected value constant) allowing for the possibility of clearing a customer's total debt, and highlighting this feature, may be most effective in encouraging debt repayment.

Overall, we provide additional insight into existing prize-linked savings accounts. More importantly, we introduce a new product to help consumers repay their debt, demonstrate interest in this product, and recommend using goals to encourage take-up.

Lifting the Veil: The Benefits of Cost Transparency

EXTENDED ABSTRACT

A firm's costs are typically tightly-guarded secrets. However, a significant body of literature on the social psychology of disclosure suggests that those who disclose intimate information can be seen as more likeable and attractive (Collins & Miller, 1994; Laurenceau, 1998; Moon, 2000). We suggest that cost transparency – revealing a firm's variable costs of production – is a particularly intimate form of disclosure by a firm to the consumer. Using six laboratory experiments and a field study, we examine the effect of cost transparency on consumer purchase behavior.

Our first study was a natural experiment with an online accessories retailer. We found that the addition of a 'cost transparency' graphic denoting the variable costs of producing a wallet significantly increased sales over a two-month period. Using the estimates from a fully-specified model, we calculated that the introduction of the cost transparency infographic increased daily unit sales by 88.1%.

In study 2, we tested the effect of cost transparency on consumers' willingness to buy in a simulated online retail environment. Participants saw an online shopping interface featuring a model wearing a t-shirt. This interface served as the baseline in all of our experiments. In the operational transparency condition, an additional

infographic depicted six operational steps to produce the t-shirt – cotton, cutting, sewing, dyeing, finishing, and transport. In the cost transparency condition, the true cost of each of the six operational steps was also provided, i.e., \$2.75, \$0.35, \$1.35, \$0.50, \$1.25, and \$0.50 respectively. Participants indicated their willingness to buy the t-shirt on a 7-point scale. Willingness to buy was greater in the cost transparency condition relative to both the control condition ($M_{\text{cost}} = 4.16$ vs. $M_{\text{control}} = 3.31$, $t(177) = 2.95$, $p < 0.01$) and the operational transparency condition ($M_{\text{operational}} = 3.57$, $t(180) = 2.10$, $p = 0.04$).

In study 3, we tested whether a weak form of cost transparency – simply divulging the total summed cost to produce the product – is sufficient to be beneficial. Cost transparency was found to be more effective in boosting purchase interest in a \$10 t-shirt than summed cost alone ($M_{\text{cost}} = 4.91$ vs. $M_{\text{sum}} = 4.07$, $t(185) = 3.45$, $p < 0.01$), which was not significantly better than the control condition ($M_{\text{none}} = 4.15$, $t(197) = 0.77$, $p = 0.90$).

Importantly, Study 3 also explored the process underlying the beneficial effect of cost transparency. We measured a potential mediator, attraction to the brand, using a modified version of Moon's 4-item (2000) scale ($\alpha = .93$). Relative to control, brand attraction was significantly higher in the cost transparency condition ($M_{\text{cost}} = 5.40$ vs. $M_{\text{control}} = 4.86$, $t(200) = 5.33$, $p < 0.01$). Consistent with previous research on disclosure and attraction, the effect of cost transparency on willingness to buy was fully mediated by consumers' attraction to the disclosing firm (95% CI: 0.32, 0.81); we replicated this finding thrice in the following studies.

It is possible that the beneficial effect of cost transparency in studies 1-3 was driven by the specific allocation of costs among the different cost components. In study 4, we tested whether the results generalize to unfavorable cost allocations (i.e. when costs of intangible components – such as transportation – are relatively high). Relative to control, willingness to buy was significantly higher in both favorable and unfavorable cost allocation conditions (p 's < 0.01). The difference between disclosing favorable and unfavorable cost allocations was not significant ($M_{\text{favorable}} = 4.90$ vs. $M_{\text{unfavorable}} = 4.86$, $p = 0.60$). Thus, we found that the capacity for cost transparency to boost willingness to buy persists even when costs are allocated in a relatively undesirable way.

In study 5, we tested whether cost transparency substitutes or complements consumer-brand relationships. Participants were told that a brand was either a familiar or new brand. There was no interaction between brand relationship and transparency ($(F(1,325) = 0.32$, $p = 0.57)$). Thus, we found that brand relationship does not moderate the effect of cost transparency on willingness to buy – cost transparency is appealing to consumers regardless of their prior relationship with a brand ($M_{\text{cost}} = 4.52$ vs. $M_{\text{control}} = 3.96$, $t(327) = 2.65$, $p < 0.01$).

Of course, not all disclosure leads to attraction; prior research suggests a curvilinear relationship between disclosure intimacy and liking (Cozby, 1972). In study 6, we tested how revealing high profit margins (i.e., a high price relative to cost) moderated the effect of cost transparency on a consumer's willingness to purchase a good from a firm. We used the online website of a popular department store to determine a relevant range of t-shirt prices (\$10-\$100), and manipulated the price of the product while keeping costs constant. As expected, willingness to buy decreased as price increased ($F(1,954) = 121.2$, $p < 0.01$). Moreover, there was a significant interaction between price and cost transparency on willingness to buy ($F(1,954) = 6.05$, $p = 0.01$) The benefits of cost transparency weakened – but did not reverse – when a firm disclosed higher prices relative to cost.

When might cost transparency backfire? Although consumers understand and accept that firms must make profits (Bolton, Warlop, & Alba, 2003; Kahneman, Knetsch, & Thaler, 1986), they pun-

ish firms that violate established norms of price fairness (Campbell, 1999; Xia, Monroe, & Cox, 2004). In study 7, we tested whether making a markup more salient would diminish the effectiveness of cost transparency. For instance, we noted that a similar shirt sold by a competitor is priced at \$25, a 3.7X markup over the estimated cost of production. Thus, at the \$30 price point, the firm's markup of 4.5X was higher, and therefore, less desirable than that of its' competitor. Relative to the control, willingness to buy was significantly lower versus the control when an undesirable markup was made salient ($M_{\text{markup}} = 2.17$ vs. $M_{\text{control}} = 3.34$, $t(60) = 2.37$, $p = 0.02$). This suggests that when markups are counter-normatively high compared to competitors, cost transparency diminishes purchase intentions.

The provocative implication of this research is that by revealing costs – typically tightly-guarded secrets – marketers can potentially improve both brand attraction and sales.

The impact of income tax and redistribution of tax money on productivity, satisfaction, and perceptions of fairness

EXTENDED ABSTRACT

Consumers face different levels of taxation, which have potentially important implications for their perceptions and behavior. Existing experimental evidence suggests that people are tax averse, causing them to avoid costs associated with taxes beyond equivalent costs in their purchase and policy decisions (e.g., Hardisty, Johnson, & Weber, 2010; Sussman & Olivola, 2011). This research proposes that people indeed predict they will be income tax averse, but their actual behavior in response to income tax is not nearly as extreme and is influenced by how tax money is redistributed.

Perceptions of tax policy might affect people's decisions, including residence decisions and voting on policy. Therefore, it is important to understand people's intuitions about the impact of income tax and redistribution schedules. In the first two studies, participants predicted how they (Study 1a) or an average "Joe" (Study 1b) would behave and feel if their task earnings were subject to an income tax and redistribution schedule. In Study 1a, participants (N=202) read about a hypothetical study that taxed their earnings and were asked to predict their own behavior and feelings. The study design was within participants and compared tax levels of no tax, 10%, 40%, and 55%. Participants were instructed that tax money was either evenly redistributed among all participants or withheld to support research. Participants predicted that they would be less productive the higher the tax ($p < .001$) and reported lower satisfaction ($p < .001$) with the task and payment fairness ($p < .001$). Participants also predicted that they would be more productive with an even redistribution of tax money than when it was withheld to support research ($p < .001$). In order to determine the results' robustness, Study 1b replicated Study 1a using third-person rather than first-person framing. Thus, in Study 1b, participants (N=201) predicted how an average "Joe" would behave and feel when his earnings from a task were subject to different tax and redistribution schedules. We find the results of Study 1a extend to this context.

Given the results of Studies 1a and 1b, we sought to test participants' intuitions in a controlled incentive compatible experiment. While these experiments do not mirror taxes' complexities in the real world, the incentives, taxation, and redistribution of tax money are real, and thus give important psychological insights. Participants' (N=627) earnings were taxed at 10% or 40% such that participants made the same amount after taxes regardless of the tax rate and participants were told that the tax money either supported research or was redistributed evenly among participants. When the tax money

was evenly redistributed, each participant received an equal share regardless of earnings. After working on an incentive-compatible task, participants received their payment information. Contrary to intuitions, the results suggest that participants are slightly more productive with higher tax rates ($p = .03$) possibly because they compensate for lost wages by working more. There were no differences in satisfaction with task, payment, or payment structure fairness due to higher taxes ($\alpha = .83$, $p = .87$). Despite higher satisfaction with an even allocation of tax money ($p = .002$) and receiving redistribution money, participants were less productive when tax money was evenly redistributed ($p = .03$). Consistent with public goods literature, our findings suggest that in this context people also reduce effort when benefits can be received with no contribution (Fehr & Gächter, 2000).

Admittedly, it could be argued that participants' insensitivity to different tax rates was because 10% and 40% tax rates fall within the realm of normal income taxes, or alternatively, that participants were unclear regarding what constitutes a "normal tax rate" in this scenario. Thus, in Study 3 we held constant before tax earnings in order to make sure participants were actually experiencing the penalty of taxation. To ensure there was no ambiguity about the task and payment structure, Study 3 employed a two-stage design where all participants (N=488) first worked on a task taxed at 0%, 10% or 55%, (manipulated between participants). After completing the first task, participants either predicted how much they will work or actually worked on the second target task, which was also taxed at 0%, 10% or 55% (both factors were manipulated between participants). We find that participants were less productive (correctly complete 7 less problems on average) and satisfied on the second task when taxes were raised from 10% in the first task to 55% in the second task and were more productive (correctly complete 1 more problem) when taxes were lowered from 55% to 10%. Furthermore, participants predicted much higher productivity on the second task than they actually performed ($p < .0001$). The study's results, however, cannot determine whether the change in productivity is because of tax aversion or a change in compensation.

In order to address this question, Study 4 compared after tax earnings with or without the mention of taxes. Participants (N=484) worked on two different tasks in which they were either taxed or not. In the first and second tasks, they were either subject to a 0%, 10%, or 55% tax or were paid the equivalent after tax amounts with no mention of taxation. We find participants' difference in productivity between the tasks is due to changes in incentives for both tasks ($p < .001$) but not from being averse to the mention of taxes. Thus, the results show that taxation does not have a differential impact on productivity beyond that of an equivalent decrease in incentives. This finding is inconsistent with participants' intuition that they would exhibit tax aversion in this study.

In summary, people intuit that higher taxes and no distribution of tax money among participants decrease productivity and satisfaction beyond the impact of lower payments. However, our results provide evidence that, while people are sensitive to incentive schemes and how tax money is redistributed, their actual effort is not tax averse. We discuss the important implications of these findings to psychology, consumer research, and public policy.

Darren Dahl, University of British Columbia, Canada

SESSION OVERVIEW

Consumers employ a variety of strategies to select gifts that will enable them to please and connect with their intended recipients, with varying results. Whereas some of these strategies can lead to success, others are more likely to lead givers astray. The purpose of this symposium is to identify the strategies that givers use to imbue gifts with value and meaning, understand how givers come to develop deft or daft intuitions, and predict how such strategies are likely to affect recipients' appreciation for the gifts they receive as well as for the givers who gave them. Together these four papers address those key questions.

First, Evan Polman and Sam J. Maglio propose that one way in which givers attempt to please and connect with recipients is by "companionizing" their gifts – whereby givers gift something that they also buy for themselves. This strategy generates greater feelings of closeness among recipients toward givers and increases their appreciation for their gifts, even when such gifts are less-than-desirable.

Next, Lisa Cavanaugh, Francesca Gino, and Gavan Fitzsimons examine another strategy that givers use: givers choose socially responsible gifts (e.g., a charitable donation in the recipient's name) to make recipients feel good about supporting a worthy cause. Although this intuition is generally well-founded, givers underestimate close others' appreciation for socially responsible gifts and overestimate distant others' appreciation for such gifts.

Mary Steffel, Elanor F. Williams, and Robyn A. LeBoeuf investigate another way in which givers mispredict recipients' preferences: by choosing gifts that are more specific and less versatile than what recipients prefer. Givers focus on recipients' stable traits and choose gifts that are specifically tailored to those qualities, whereas recipients focus on their multiple, varying wants and needs and prefer gifts that can fulfill whatever those might be. This mismatch is greatest when givers choose gifts for close versus distant others and can lead to gift nonuse.

Finally, Laurence Ashworth, Katherine White, and Darren Dahl show that, whereas givers may find it intuitive to convey to recipients why they chose certain gifts on their behalf, this strategy may often

backfire. In the absence of an explanation, recipients tend to naturally attribute gifts to symbolic or sentimental motives. Thus, the presence of information that provides another possible reason for why the gift was chosen (e.g., the gift was on sale) can undermine the symbolic value of the gift and reduce recipients' appreciation for it.

Together, these studies contribute to consumer theory by illuminating how consumers strive to gratify and connect with other people through the gifts that they give them, how such efforts may come to be well-placed or misguided, and how recipients respond to these gestures. It further identifies factors—such as relationship closeness, perspective taking, and behavioral attributions—that may bias givers' perceptions and contribute to givers' success or failure. This research is of broad interest to researchers in consumer psychology in general and to researchers in gift giving, prosocial behavior, and judgment and decision making in particular.

Ensouling Gifts with Closeness

EXTENDED ABSTRACT

When it comes to gift-giving, consumers often experience ambivalent feelings: Many relish the opportunity to buy gifts because gift-giving offers a means by which to build stronger bonds with one's closest peers (Ward and Broniarczyk 2011), yet consumers are often inaccurate in what they think will delight their peers (Baskin, Wakslak, Trope, and Novemsky 2014; Flynn and Adams 2009; Gino and Flynn 2011; Steffel and LeBoeuf 2014). Typically, such deficits are discussed in terms of givers struggling to take the perspective of recipients (Zhang and Epley 2012) – indeed, much research has found that people are susceptible to egocentrism, social projection, and multiple attribution errors (Ross 1977).

In our research, we take a different approach to this topic. Rather than examining the effects of givers' egocentrism dampening recipients' satisfaction, we develop links between gift-giving and the separate literature streams on interpersonal closeness and a special type of sharing that we refer to as "companionizing." In marketing research, sharing is usually viewed as jointly consuming something, like sharing the same dessert, or sharing a meal together – however, other instances of sharing have been documented as well. For example, sharing can also mean to use, occupy, or enjoy something jointly with others (e.g., sharing a house together in the Hamptons); to tell someone about something personal (e.g., sharing a secret); or to possess something in common with others (e.g., sharing the same sweater as someone else). It is this last example that is the focus of our work.

Broadly, we document a new type of sharing that results of owning the same product as others. Specifically, our studies build on past work on interpersonal closeness by proposing that this type of sharing also may play an important role in gift-giving. As a general pattern, sharing "goes hand in hand with trust and bonding" (Belk 2010, 717) – it is for this reason that when consumers want to *fit in* with others, they appropriate the same items as those others (Mead, Baumeister, Stillman, Rawn, and Vohs 2011); similarly, it is for this same reason that when consumers want to *stand out* from others, they deliberately avoid buying the same items as those others (Berger and Heath 2007, 2008). These examples show that sharing creates closeness – from sharing attitudes with others, to birthdays, or clothes, people feel closer to those similar others (Gentina 2014;

Liang, Hoegg, Dahl, and Chattopadhyay 2010; Miller, Downs, and Prentice 1998).

We applied this idea of sharing to the context of gift-giving. In three studies in which participant-recipients evaluated gifts ranging from blankets, bonsais, books, bourbon, to bowls, we investigated whether companionizing – whereby givers gift something that they also buy themselves – generates a higher valuation for gifts.

In study 1, we investigated participants' valuation of 10 gifts. We randomly presented participants with one of two conditions; the companionized condition, which accompanied this message, *Imagine you receive a gift for a special occasion. You open the present, and inside is a new [gift], with a card that reads, "I hope you like the [gift] -- I got myself the same [gift] too!"* and the control condition, which accompanied this message, *Imagine you receive a gift for a special occasion. You open the present, and inside is a new [gift], with a card that reads, "I hope you like the [gift]!"*. Then, participants rated the gift, on scales of likability, thoughtfulness, and considerateness – we collapsed these items into one item, valuation ($\alpha=.89$). We found that participants in the companionized condition valued their gift more ($M=4.87$, $SD=1.38$) than participants in the control condition ($M=4.56$, $SD=1.56$), $F(1, 9.87)=10.60$, $p=.009$.

Quite possibly, the results to study 1 could be because participants inferred that companionized gifts are high quality. In study 2, we aimed to investigate this possibility. The procedure was the same as study 1, except we used different gifts and added a quality condition which accompanied this message, *"Imagine you receive a gift for a special occasion from a friend. You open the present, and inside is a [gift], with a card that reads, "I hope you like the [gift] -- it got great reviews online!"*. We found a significant difference between conditions, $F(2,4.56)=11.95$, $p=.015$. Specifically, post hoc analyses (LSD) revealed participants in the companionized condition valued their gift more ($M=4.55$, $SD=1.42$) than participants in both the control ($M=4.22$, $SD=1.52$) and quality condition ($M=4.05$, $SD=1.49$), $ps<.054$.

Thus, in study 2, we ruled out an interpretation based on quality; in study 3 we aimed to rule in an explanation based on social bonds. In this study, we precisely measured the closeness receivers report with givers, and tested if this feeling mediates the relation between companionizing and the value receivers ascribe to their gifts. The procedure was the same as in study 1, except we used different gifts and added a mediator item, asking "How close would you feel to the giver of this gift?". We found participants in the companionized condition valued their gift more ($M=4.74$, $SD=1.35$) than participants in the control condition ($M=4.26$, $SD=1.38$), $F(1,2.39)=14.73$, $p=.046$. Additionally, participants in the companionized condition felt closer to their givers ($M=5.00$, $SD=1.29$) than participants in the control condition ($M=4.23$, $SD=1.511$), $F(1,2.55)=42.23$, $p=.012$. Furthermore, we tested mediation using bootstrapping while controlling for gift (Hayes, 2013). One thousand resamples were taken from the data to compute the indirect effect ($\beta=.55$, $SE=.17$). This indirect effect was estimated to lie within the non-zero-containing 95% confidence interval, 0.22 and 0.86, suggesting that companionizing a gift increased the felt bond between recipient and giver, which in turn led recipients to value their gifts more.

Our investigation suggests a rather easy way to improve the feeling one has when receiving a gift. Beyond highlighting a straightforward way that anyone can use to boost a recipient's gift valuation, we further discuss the theoretical, economic and environmental implications of our research, as well as suggest boundary conditions. Quite possibly, to the extent that people have the ability to buy experiential gifts for others they may be just as well off if they bought sentimental, material gifts.

When Doing Good Is Bad in Gift Giving: Mispredicting Appreciation of Socially Responsible Gifts

EXTENDED ABSTRACT

As a socially important phenomenon, gift-giving helps individuals signal their commitment and caring in social relationships (Belk 1976; Caplow 1982). Individuals face numerous occasions in which they need to choose gifts for others with whom they have a personal (family, friends, neighbors) or professional (assistants, bosses, interns, co-workers) relationship. Often consumers find themselves in situations where they need to choose a gift for someone whose explicit preferences are unknown. An increasing number of gift givers are turning to "gifts that give twice"—that is, gifts supporting a worthy cause (Maciejewsky 2008). Such gift choices are often motivated by people's desire to "do good" (Andreoni 1990) and identification with moral identity (Aquino and Reed 2002). We examine whether such gifts have the expected outcomes.

Most research on gift giving has focused on gifts that benefit the recipient directly, such as products, monetary gifts, or gift certificates. Past research has examined how a variety of gift characteristics impact appreciation, including whether a gift is requested (e.g., gift registry; Bradford and Sherry 2013; Gino and Flynn 2011; Ward and Broniarczyk 2011), expensive (Flynn and Adams 2009) or material vs. experiential (Van Boven and Gilovich 2003). Socially responsible gifts, such as a charitable donation made in the recipient's name, do not benefit the recipient directly; rather, they are intended to produce an indirect psychological benefit to the recipient, namely a sense of satisfaction and happiness from helping a third party in need (e.g., a charity) and perhaps connoting recognition of an altruistic or moral identity. Moreover, socially responsible gifts are often intangible and their cost transparent (e.g., \$50 donation in your name). As such, socially responsible gifts provide an interesting context for understanding when symbolic meaning is most likely to impact givers' predicted and recipients' actual appreciation.

Building on prior work documenting mispredictions in gift-giving (e.g., Adams, Flynn, and Norton 2012; Flynn and Adams 2009; Gino and Flynn 2011; Zhang and Epley 2012), we argue that, under certain conditions, socially responsible gifts are substantially less appreciated by recipients than givers anticipate. We propose that reactions to socially responsible gifts and interpretation of their meaning largely depend on *relational closeness* between the gift giver and the receiver. Specifically, we find that givers consistently mispredict appreciation of socially responsible gifts, underestimating appreciation for *close* and overestimating appreciation for more *distant others*.

Our research is the first to explore 1) whether socially responsible gifts are appreciated, 2) what socially responsible gifts communicate in the minds of those giving vs. receiving them, and 3) when mispredictions of appreciation are most likely to occur. We identify relational closeness as an important moderator to documented mispredictions in appreciation of symbolic gifts. We present four studies that support our hypotheses, comparing non-tangible, socially responsible gifts (e.g., a charitable donation in the recipient's name) to both tangible and non-tangible gifts that produce direct benefits to the recipient (e.g., a gift basket or a gift certificate).

Study 1A & 1B

Participants (N=154) randomly assigned to a giver (vs. receiver) condition were asked to imagine that they (or a close friend) had selected a birthday gift: a \$50 donation to Oxfam to support coffee growers. They then completed dependent measures for feelings of appreciation, thoughtfulness (Flynn and Adams 2009), offensiveness,

favorability, and symbolizing commitment to the recipient on 7pt scales. Study 1B (N=311) provided a conceptual replication with a 2 (role: giver vs. receiver) X 2 (alternative gift option: known vs. unknown) design and different gift stimuli. Results show that, in close relationships, givers do not accurately predict how much recipients will appreciate socially responsible gifts whether the alternative gift options are known or unknown (all $p < .01$).

Study 2

To investigate the role of relationship closeness as an important moderator, participants (N=151) were randomly assigned to a 2 (role: giver vs. receiver) X 2 (relational closeness: close vs. not close) design. Results revealed the predicted role X relationship closeness interaction on all measures: appreciation, thoughtfulness, favorability, offensiveness and the gift symbolizing commitment to the relationship (all $p < .002$). On all measures, givers predicted that the recipient would appreciate the socially responsible gift much more in the case of a distant rather than a close friend ($p < .001$). However, in close relationships, givers underestimated how much recipients would appreciate socially responsible gifts ($p < .003$). Moreover, givers believed receivers would appreciate the donation more when the recipient was a *distant* rather than a *close* friend.

Study 3

To test the generalizability and external validity of our findings, we examined the phenomenon using real gifts and real relationships (close and distant). University students (N=245) were randomly assigned to a 2 role (gift giver/ gift recipient) X 2 relationship closeness (close/ not close) X 2 gift type (socially responsible gift/ traditional gift) design, described as a gifting study in exchange for credit or \$5 gift-card. In advance of their lab session, participants identified multiple friends, and we randomly selected and contacted one of the listed friends. Friends were contacted via email and asked to make a \$25 gift choice from six options for the person named. After making their choice, gift-givers completed all the same dependent measures. When student participants arrived at the lab for their in-person session, the gift chosen by their friend was presented to them. After collapsing across gift type (traditional vs. socially responsible gift), results showed that 39.1% of givers chose the socially responsible gifts and 60.9% chose traditional gifts for friends. We found a significant relationship closeness by gift type interaction ($p < .03$) and a significant three-way role by gift type by relationship closeness interaction ($p < .02$). The simple role by relationship closeness interaction was significant for socially responsible gifts ($p < .02$), but not traditional gifts ($p < .44$). Probing with the Johnson-Neyman technique showed that givers significantly overestimated recipients' appreciation for socially responsible gifts at low levels of closeness (below 3.1030), i.e. distant relationships. Together these four studies show that givers mispredict appreciation for socially responsible gifts, and that their mispredictions depend on the nature of their relationship to the recipient.

Overly Specific Gift Giving: Givers Choose Personalized But Less-Versatile And Less-Preferred Gifts

EXTENDED ABSTRACT

Gift givers often fail to anticipate that the gifts they prefer to give are not necessarily the ones recipients prefer to receive. We propose that one way in which givers misgauge recipients' preferences is by favoring gifts that are specific and personalized to recipients but are less versatile than what recipients prefer to receive.

Givers frequently tailor gifts to recipients, as it is not just the act of giving a gift, but the meaning of that gift, that matters (Belk 1996; Schwartz 1967). When selecting and tailoring gifts, givers may focus on recipients' stable and unique traits to select what seem like the most appropriate gifts, but recipients may be more aware that what they want may depend on the situation and may frequently change (e.g., Jones and Nisbett 1971; Nisbett et al. 1973). As a consequence, givers may gravitate toward gifts that are tailored to recipients' traits but are too specific to meet recipients' varying wants and needs.

Studies 1a, 1b, and 1c examine whether givers tend to choose gifts that are more specific than recipients prefer to receive. In study 1, participants imagined either giving or receiving a gift card and chose between a Visa gift card or a gift card for the recipient's favorite store. Recipients were more likely to want to receive the Visa gift card than givers were to give it ($\chi^2(1, N = 294) = 44.50, p < .001$). Study 1b illustrates the generality of this discrepancy by showing that recipients are more likely than givers to prefer a gift card meant for several stores over one meant for a single store ($t(115) = -2.36, p = .02, d = .43$), a gift card over a gift ($t(117) = -2.73, p = .007, d = .50$), and cash over a gift ($t(118) = -4.05, p < .001, d = .74$). Study 1c shows that this discrepancy extends to tangible gifts as well: recipients preferred a multi-purpose gift over a single-purpose gift more than did givers ($t(268.28) = -5.08, p < .001, d = .61$).

Study 2 investigates whether givers persist in choosing overly specific gifts even when they first consider what they themselves would prefer to receive. Indeed, givers chose overly specific gift cards even when they assumed the roles of both recipient and giver sequentially (paired $t(341) = 12.66, p < .001, d = .71$). Study 3 shows that this is because givers and recipients have different ideas about which gifts are more thoughtful and better liked. Recipients were more likely to consider a Visa gift card to be more thoughtful (relative to a store gift card) than were givers ($\chi^2(1, N = 238) = 21.20, p < .001$). Additionally, recipients liked the Visa gift card more than givers thought they would ($t(236) = 4.04, p < .001$), and liked the store gift card less than givers thought they would ($t(213.36) = -2.77, p = .006$).

Studies 4a and 4b show that this discrepancy is rooted in the tendency for givers to focus on recipients' stable traits and for recipients to focus on their own variable wants and needs. In study 4a, givers rated themselves more likely to consider what their friend was like as a person when choosing a gift than recipients were to consider what they were like as a person when suggesting gifts they would want to receive ($t(169) = 5.58, p < .001, d = .84$). And, givers were less likely than recipients to consider the recipient's current wants and needs when choosing gifts ($t(169) = -2.30, p = .02, d = .35$). In study 4b, givers rated themselves more likely to choose a Visa gift card over the store gift card when they first thought about what their recipient *would like* than when they first thought about what their recipient *was like* ($t(206) = 2.33, p = .02, d = .32$).

Study 5 shows that givers are more likely to choose overly specific gifts for close than distant others, presumably because they are especially motivated to be thoughtful and personalize gifts for close others. Givers preferred giving a tailored store gift card over a Visa gift card to a greater extent for a romantic partner than a friend ($t(197) = 4.01, p < .001, d = .57$), but recipients' preferences between the gift cards did not vary based on their relationship to the giver ($t(180.31) = .74, p = .46, d = .11$).

Studies 6a and 6b show that this giver-recipient discrepancy can contribute to gift non-use. In study 6a, participants recalled a gift card that they gave [received] and indicated how long it took the recipient [them] to redeem it (if at all). Gift cards were coded for specificity based on the number of product categories for which they could be

redeemed. Recipients took longer to redeem gift cards (if at all) the more specific they were ($\beta = -.31, t = -4.08, p < .001$), but givers failed to anticipate this ($\beta = -.13, t = -1.61, p = .11$). In study 6b, we analyzed all gifts that were given in 2013 and redeemed via Gifty, a service that allows givers to give gift cards with a suggestion of what to get and where to get it and allows recipients to receive their gifts as a credit to their credit card or PayPal account. Controlling for gift value and method of receipt, recipients took longer to redeem gifts that came with a specific suggestion of an item or place where the gift should be used than ones that did not ($F(1, 9,355) = 75.89, p < .001, \eta_p^2 = .008$).

This research contributes to a growing body of research showing that givers often fail to accurately anticipate what recipients would most like. It further suggests that giver-recipient discrepancies in judgment may be one reason why so many gift cards go unredeemed. It also suggests a solution: focusing on what recipients would like may encourage givers to choose gifts that are more likely to be used and appreciated.

How Reasons Can Undermine the Symbolic Value of Gifts

EXTENDED ABSTRACT

Consumers' spend a great deal of money on gifts – by some estimates, over 4% of household income (Caplow 1982; Garner and Wagner 1991). A fair amount of research has explored the social function of gifts (e.g., Sherry 1983). Less, however, has examined how receivers respond to the gifts that they receive. The current work examines an attributional framework for understanding recipients' reactions. Our basic premise is that recipients typically attribute gifts to positive giver sentiments. This makes recipients relatively forgiving when it comes to the quality of the gift, but it also means they should be sensitive to information that suggests alternative reasons for the givers' choice. We examine this idea in the context of discounts, where we suggest that knowing a gift was bought on sale provides an alternative reason for the givers' choice that undermines recipients' appreciation.

Choosing the right gift is a difficult task. Givers appear to routinely misjudge what recipients would like (Flynn and Adams 2009; Gino and Flynn 2011), resulting in a deadweight loss (Waldfogel 1993) and many returned gifts (NRF 2015). Despite this, current evidence suggests that gift recipients are nevertheless appreciative of the gifts that they receive. Gino and Flynn (2011) found that recipients were happier to receive a solicited (vs. unsolicited) gift than givers believed they would be. Flynn and Adams (2009) found that recipients were insensitive to cost, despite givers' beliefs that more expensive gifts would convey greater thoughtfulness. In short, recipients appear to be more appreciative of a wider variety of gifts than givers appear to recognize.

One suggestion for this is because recipients may be relatively unlikely to contemplate an alternative gift. Instead, they may compare their gift to the counterfactual of receiving no gift at all (Flynn and Adams 2009). This implies that recipients' will be appreciative of a wide variety of gifts because relative to no gift, it is a thoughtful gesture. However, this also suggests that recipients might be sensitive to information that suggests alternative reasons for the givers' behavior. Consistent with principles of attributional discounting (Morris and Larrick 1995), competing accounts of the behavior should undermine any one explanation. Specifically, we predict that recipients will discount their assumption that the gift reflects positive giver sentiments when there is information that suggests other reasons for givers' choice. We test this in the context

of discounts, where we predict that a discount provides an alternative reason for givers' choice which should reduce the symbolic value of the gift, undermining recipients' appreciation. Two studies test this basic prediction.

Study 1

Two-hundred and six students participated in a 2 (Price: \$20 vs. \$40) x 2 (Discounted: Yes vs. No) between-subjects experiment. Participants read a scenario in which they received a gift from a friend at their birthday party. The following day participants happen to see the gift while shopping for \$20 (vs. \$40) and discounted by 50% (vs. not). Six items measured participants' happiness with the gift ($\alpha = .90$). Consistent with past research, price did not affect happiness ($F(1, 202) = .01, p > .90$). The discount, however, did reduce happiness ($M_s = 4.62$ vs. 6.01 ; $F(1, 202) = 97.75, p < .001$). A significant interaction ($F(1, 202) = 5.08, p < .05$) indicated this was enhanced for the more expensive gift ($M_{\$40s} = 4.47$ vs. 6.18 ; $M_{\$20s} = 4.77$ vs. 5.84). Note that a gift discounted from \$40 to \$20 was less appreciated than a non-discounted \$20 gift ($M_s = 4.47$ vs. 5.84 ; $p < .001$). Overall, there was no evidence that the absolute amount spent mattered (at least within the price range examined), but a discounted gift did lower recipients' happiness.

Study 2

Study 2 examined whether the negative effect of the discount would be reduced in situations where the giver was less responsible for the discount. This was manipulated by having the gift come from the recipients' wish list (vs. not). Some work suggests that recipients should be sensitive to this information, although the correspondence bias suggests they might not. Ninety-three students participated in a 2 (Wish List Item: Yes vs. No) x 2 (Discount: Yes vs. No) between-subjects experiment. The gift always cost \$20 and was discounted from \$40 (vs. not). Happiness with the gift was measured with the same items ($\alpha = .90$). Consistent with the previous study, a discounted gift reduced recipients' appreciation relative to a non-discounted gift ($M_s = 4.90$ vs. 5.59 ; $F(1, 89) = 10.38, p < .01$), even when the gift came from the recipient's wish list (no other effects were significant). Overall, discounted gifts reduced recipients' appreciation. This occurred regardless of the price of the gift, and even when the recipient chose the gift.

SESSION OVERVIEW

Creativity permeates today's consumption environment. Consumers increasingly engage in various creative activities, from co-creating with companies to consuming creative products (Burroughs and Mick 2004; Dahl and Moreau 2007). Thus, it is critical to understand what factors enhance consumer creativity and what downstream consequences engaging in creative thinking engender. This session seeks to provide new insights into creative cognition. The first paper, by Sellier and Dahl, examines the effect of an ethical mindset versus a moral mindset on creativity. In contrast to prior work suggesting a bidirectional positive relationship between creativity and dishonesty, this research proposes that creativity can also be positively associated with morality. Results show that compared to a moral mindset and a neutral mindset, an ethical mindset facilitates individual creativity through elevating autonomy. In contrast, when a creativity task requires teamwork, a moral mindset enhances creative performance as compared to an ethical mindset because it fuels group cohesion during the creativity production process. The second paper, by Tian and Häubl, examines when self-regulatory resource depletion helps versus hinders creativity. They posit that while resource depletion has been documented to be maladaptive and harmful, it can be beneficial under certain circumstances by facilitating creative ideation. Results demonstrate that resource depletion enhances creativity in terms of divergent thinking by weakening cognitive inhibition and promoting a broad search of individuals' associative networks. Conversely, resource depletion jeopardizes creativity in terms of convergent thinking, which calls for a strongly constrained search process and cognitive inhibition. The third paper, by Xu and Mehta, investigates downstream effects of creative engagement on prosocial behavior. Reconciling conflicting predictions suggested by prior literature, they show that whether creative engagement increases or decreases prosocial behavior depends on the thinking style adopted in a creative task. Specifically, engaging in a creative task involving divergent thinking promotes prosocial behavior by activating a deliberative mindset that triggers open-mindedness, whereas engaging in a creative task involving convergent thinking hinders prosocial behavior by activating an implemental mindset that decreases open-mindedness.

Unified by a focus on creativity yet built on diverse theoretical bases, the three papers deepen our understanding of creativity by providing new, interdisciplinary insights into its causes and consequences. This session echoes the theme of ACR 2015 by connecting creativity with seemingly unrelated factors and providing academics,

consumers, marketers, and public policy makers with suggestions for promoting and making good use of creativity.

The Light Side of Creativity: Moral Reminders Can Boost Creativity

EXTENDED ABSTRACT

Considerable consumer research has established that a critical area of study is the investigation of contextual factors that enable consumers to be creative (e.g., Moreau and Dahl 2005). Alarming-ly, recent research documented that creativity can negatively affect ethical behavior (e.g., Gino and Ariely 2012; Gino and Wiltermuth 2014). This research flips this perspective to show that creators reminded of moral intuitions can enjoy greater creativity (study 1 and 2). We further show that reminding creators of the moral law can similarly serve as a creative boost (study 3). In sum, "good" can increase creativity.

We examine how contextually reminding creators of their moral intuition (e.g., being good) versus the moral law (e.g., following a dogma) shapes subsequent creative cognitive processing. Prior research pinpointed constraints as a critical antecedent of creativity (e.g., Dahl and Moreau 2007). Both moral intuitions and the moral law constrain the creative process in that they both increase the salience of a set of moral rules that are internally (moral intuitions) versus externally produced (moral law). Further, reminding creators of moral intuitions increases their perceived autonomy, because moral intuitions allow the internal justification of one's actions. By contrast, the moral law stifles autonomy—it is the law. For these reasons, we expect that reminders of moral intuitions will foster individual creativity more than reminders of the moral law and than a non-constraining, neutral mindset.

We tested this prediction in a first study in which 92 students (45 men, age = 20.1 years) completed creative tasks after having been primed with moral intuition-related, moral law-related, or neutral words. They were told that they would take part in two studies. The first study was a word search task. We varied the list of words, so that most of the words either related to moral intuitions, the moral law, or were neutral. Participants subsequently reported how creative, original, novel, inspired, artistic, and innovative they perceived their alien to be (1-7; not at all/very), their mood, and other measures. Next, participants participated in an ostensibly unrelated creativity study. Their first task was to be as creative as possible in drawing an alien (Ward 1994). Next, they were given the Duncker candle task, for which only one solution exists.

Once all data from creators were collected, 16 peers independently rated each alien's creativity, indicating how creative, original, novel, inspired, artistic, innovative (1-7; not at all/very; α for the averaged creativity score across peers = .99) the aliens were. Subsequently, they rated each alien's attractiveness (6 items, all α 's > .85). Seven participants did not follow the study instructions, and were therefore excluded from the sample. We report our analyses for the remaining 85 participants. We computed a self-perceived creativity index by averaging creators' creativity ratings ($\alpha = .91$), and subjected this index to an ANOVA. We found a significant impact of Mindset, $F(1, 85) = 3.15, p < .05, r^2 = .04$, such that creators reminded of moral intuitions perceived their aliens to be significantly more creative than creators reminded of the moral law ($M_{\text{moral intuitions}}$

= 4.10 vs. $M_{\text{moral law}} = 3.44$, $t(82) = 1.94$, $p = .05$, $r^2 = .04$); and than creators in the control condition ($M_{\text{control}} = 3.28$, $t(82) = 2.34$, $p < .03$, $r^2 = .06$). Moral law and control creators rated themselves as equally creative, $t < 1$.

Next, we computed an objective creativity index by averaging peers' creativity ratings (all $as > .85$). An ANOVA using this index as the dependent variable showed a significant impact of Moral Prime, $F(1, 85) = 3.16$, $p < .05$, $r^2 = .04$, such that the moral intuitions aliens were judged more creative than the moral law aliens, $M_{\text{moral intuitions}} = 4.34$ vs. $M_{\text{moral law}} = 3.77$, $t(82) = 2.27$, $p < .03$, $r^2 = .06$; and than the control aliens, $M_{\text{control}} = 3.81$, $t(82) = 1.94$, $p = .05$, $r^2 = .04$. Moral and control aliens were rated as equally creative, $t < 1$.

Focusing on the Duncker candle problem, we found that 54% of participants reminded of moral intuitions found the correct answer, a greater performance than participants reminded of the moral law (29% solved correctly, $\chi^2 = 3.62$, one-tail $p < .03$), and than control participants (30%, $\chi^2 = 3.24$, one-tail $p < .04$). We found no influence of mood or peers' alien attractiveness ratings on our results, all p 's $> .08$.

In a second study, we replicated the creativity findings in study 1 with a different task, one in which creators were asked to develop a new product solution for eating while at the wheel. In addition, study 2 demonstrates that the process through which creators reminded of moral intuitions have a creative advantage over creators reminded of the moral law is because reminders of moral intuitions activate creators' autonomy.

A third study examines when reminders of the moral law can boost creativity above and beyond reminders of moral intuitions. Following research in moral psychology (Haidt 2007), we suggest that the moral law (vs. moral intuitions) will foster greater creativity when creators work in groups, because it activates group cohesion and facilitation processes during the creative process. In contrast, because they boosts autonomy, reminders of moral intuitions compromise group cohesion. We primed 90 participants with moral intuitions or the moral law as in study 1, before they worked on designing a new product as in study 2. Subsequently, they rated the extent to which they felt the group worked well and enjoyed cohesion. We found that moral law groups produced more creative products than the moral intuitions groups, $p < .05$. Further, we found that groups' ratings of how well they worked together mediated this effect.

Together, our results suggest that, if creativity can lead to dishonesty, honesty can also produce a creative advantage.

Does Self-Regulatory Resource Depletion Reduce or Enhance Creativity?

EXTENDED ABSTRACT

Consumers often have to engage in self-control in order to attain their virtuous goals by overriding impulsive responses that are immediately gratifying yet deleterious in the long run. Prior research suggests that all acts of self-control rely on a common, limited pool of resources, which can be temporarily depleted after an initial exertion of self-control, thus undermining subsequent self-control endeavors (Baumeister et al. 1998; Muraven, Tice, and Baumeister 1998). It is well documented that self-regulatory resource depletion gives rise to a variety of undesirable consequences, including overeating (Vohs and Heatherton 2000), increased impulse buying (Vohs and Faber 2007), impaired task performance (Schmeichel, Vohs, and Baumeister 2003), reduced prosocial behavior (DeWall et al. 2008), inappropriate sexual responses (Gailliot and Baumeister 2007), ineffective self-presentation (Vohs, Baumeister, and Ciarocco 2005), and heightened unethical behavior (Gino et al. 2011). However, recent

work (Lisjak and Lee 2014) suggests that self-regulatory resource depletion may not always be harmful or maladaptive. This raises the question of how, given the prevalence of depletion in daily life, consumers might take advantage of, as opposed to merely avoiding falling prey to, a depleted state? The present research tackles this question in the domain of creative cognition, and it does so by examining under what circumstances self-regulatory resource depletion promotes (vs. hinders) creativity.

Prior research indicates that self-control acts and other acts of executive function (e.g., decision-making) draw on the same finite pool of resources (Pocheptsova et al. 2009; Schmeichel 2007; Vohs et al. 2008). Thus, acts of self-regulation deplete a common resource that is required for the exercise of various executive functions. This suggests that, cognitive inhibition, an important executive function, may be weakened after self-regulatory resource depletion. Cognitive inhibition refers to the capacity to withhold (seemingly) irrelevant, distracting information from ongoing mental processes (Bjorklund and Harnishfeger 1995), and it is central to selective attention and working memory functioning (Hasher and Zacks 1988). Consequently, reduced cognitive inhibitory functioning is accompanied by impaired ability to ignore unrelated or peripheral information and to selectively attend to information most pertinent to dealing with current tasks, thereby leading to divided or diffuse attention. According to prior research on creativity, creative individuals are characterized by a lack of cognitive inhibition (Eysenck 1993; Carson, Peterson, and Higgins 2003; Martindale 1999), and diffuse attention is associated with creative ideation (Kasof 1997; Rawlings 1985; Takeuchi et al. 2011). Thus, resource depletion that decreases cognitive inhibition may lead to diffuse attention and a broadened attention span, thereby lifting unnecessary constraints imposed on individuals' thinking process and promoting a broad search of their associative networks. As a result, depletion may facilitate divergent thinking, a key aspect of creativity, which involves flexible switching among a broad range of categories (Nijstad, De Dreu, and Rietzschel 2010) and allows people to generate as many target-related responses as possible (Guilford 1967). Specifically, we propose that self-regulatory resource depletion *boosts* creativity in terms of divergent thinking, and that this effect is the result of reduced cognitive inhibition. However, creativity can also be driven by convergent thinking, which involves following a particular set of logical steps to arrive at a single correct solution to a problem (Guilford 1967). As this is a constrained search process, convergent thinking requires cognitive inhibitory abilities and therefore consumes executive resources. Thus, we posit that self-regulatory resource depletion *undermines* creativity in terms of convergent thinking.

Evidence from three studies provides support for these propositions. Study 1 examines whether resource depletion facilitates divergent thinking. It has been shown that resolving trade-offs in choices depletes self-control resources (Wang et al. 2010). First, participants made a series of product choices involving either difficult trade-offs (depletion condition) or no trade-offs (control condition). Then, participants performed a divergent thinking task (Alternate Uses Task (AUT), Guilford 1967), in which they were asked to identify as many unusual (yet feasible) uses of a brick. As hypothesized, depleted participants generated significantly more unusual uses of a brick ($M = 4.76$) than non-depleted participants ($M = 3.84$; $F(1, 144) = 4.07$, $p < .05$).

Study 2 provides a conceptual replication of the creativity-enhancing effect of resource depletion using a different depletion manipulation, and it sheds light on the mental process underlying this effect. Participants first completed an essay-writing task that served as a self-control depletion manipulation (Schmeichel 2007), and then

performed the same divergent thinking task as in study 1. In the writing task, participants were instructed to write about what they had done the previous day without using any words containing the letters “A” or “N” (depletion condition) or “X” or “Z” (control condition). As predicted, participants in the depletion condition generated significantly more creative uses of a brick ($M = 5.89$) than those in the control condition ($M = 4.39$; $F(1, 91) = 4.77, p < .05$). Moreover, the results reveal that reduced cognitive inhibition fully mediates this effect (95% CI [.0525, 1.1878]).

Study 3 contrasts the effect of resource depletion on creativity in domains where divergent versus convergent thinking is required. After making a series of product choices as in study 1, participants performed either a divergent thinking task (AUT) or a convergent thinking task (Remote Associates Test (RAT), Mednick 1962). As hypothesized, depleted participants demonstrated greater divergent thinking ($M = 4.25$) than non-depleted participants ($M = 3.55$; $F(1, 118) = 4.24, p < .05$), whereas depleted participants exhibited less convergent thinking ($M = 5.63$) than non-depleted participants ($M = 6.67$; $F(1, 118) = 4.48, p < .05$), indicating that depletion facilitates divergent thinking but inhibits convergent thinking.

This research presents the first empirical investigation of the influence of self-regulatory resource depletion on creativity. Our findings bridge the self-control literature and the literature on creativity by demonstrating that depletion can either enhance or hinder creativity, depending on whether divergent thinking or convergent thinking is required by a creativity task. Moreover, these findings deepen our understanding of self-regulatory resource depletion by showing that depletion does not necessarily lead to maladaptive behaviors, and that it can instead be beneficial – under certain, predictable circumstances.

Good or Bad? Exploring Differential Effects of Creativity on Pro-social Behavior

EXTENDED ABSTRACT

Previous research examining the effects of being creative on social behaviors has produced conflicting results. A part of research has shown positive effects of being creative, like enhancement of sense of autonomy and competence (Dahl and Moreau 2007), prevention of automatic stereotyping (Sassenberg and Moskowitz 2005), and conflict resolution (Gruber 2000). Yet another stream of research suggests just the opposite and demonstrates negative effects of being creative on personal and social behaviors, like threatening of social connection and relationships (Ardnt et al. 1999), and increased dishonest behaviors (Gino and Ariely 2012).

The present work aims to resolve this existing inconsistency in the literature by illuminating the cognitive processes through which creative engagement may affect social behaviors in general and pro-social behaviors in particular. Specifically, we propose that the style of creative thinking (i.e., divergent versus convergent thinking; Guilford 1957; Cropley 2006; Runco 2003) consumers adopt during creative engagement uniquely affects their pro-social behavior. We suggest that engaging in divergent versus convergent thinking induces competing mindsets, which in turn differentially impact subsequent pro-social behaviors. In particular, thinking divergently (convergently) while engaged in a creative task, we propose, induces a deliberative (implemental) mindset that in turn enhances (reduces) pro-social behaviors (Gollwitzer and Bayer 1999).

Divergent thinking requires individuals to engage in broad cognitive search in different directions and being receptive to all available information (Guilford 1959; Chermahini and Hommel 2012). Such cognitive processes that require broad search and deliberation

of information induces a deliberative mindset (Gollwitzer 1990). On the other hand, convergent thinking requires individuals to engage in a constrained information processing and focus on the implementation of potential solutions, which we propose induces an implemental mindset (Chermahini and Hommel 2010; Cropley 2006). Further, we argue that when a deliberative (implemental) mindset is activated, individuals are more open-minded (closed-minded), which allows them to take perspective of others and be more empathic to others (Nelson 2009), and positively affects their pro-social behavior (Eisenberg and Miller 1987). We test our hypothesis in a set of five studies as detailed next.

Study 1A and B tested our focal hypothesis, that is, whether engaging in different thinking styles differentially affects one’s pro-social behavior. In study 1A participants completed either a divergent thinking task (draw an alien; Ward 1994), or a comparable control task (draw a human). In study 1B participants completed either a convergent thinking task (Remote Associates Test; Mednick 1962), or a comparable control task (proofreading; Mehta and Zhu 2009). After completing the subject tasks, participants in both studies were presented with an advertisement seeking donations and asked to indicate their likelihood of donating money at that moment in time. Supporting our hypothesis, one-way ANOVA revealed a significant main effect of thinking style on pro-social behavior in both the studies. In study 1A participants in the divergent thinking condition ($M = 4.55$) indicated higher likelihood to donate as compared to those in the control condition ($M = 3.46$; $F(1, 44) = 4.28, p < .05$). In study 1B, however, participants in control condition indicated higher likelihood to donate ($M = 4.75$) as compared to those in the convergent thinking condition ($M = 3.81$; $F(1, 61) = 5.99, p < .05$).

Study 2 directly examined the effect of the two different creative thinking styles on pro-social behavior. For the thinking style manipulation, participants were presented with the shoe-shine problem (Burroughs and Mick 2004) and asked to either come up with as many creative solutions as possible (divergent thinking) or one most creative solution (convergent thinking). The participants then indicated an amount they would be willing to donate in response to a donation appeal. As hypothesized, those who engaged in divergent thinking ($M = 11.52$) reported higher donation amounts than those who engaged in convergent thinking ($M = 5.38$; $F(1, 47) = 4.03, p = .05$).

Study 3 tested for the proposed mechanism. Participants engaged in either divergent thinking (they were presented with one word and were asked to come up with at least three words that were related to the mentioned word) or convergent thinking (they were presented with three words and were asked to come up with one word that was related with all other words) and completed deliberative versus implemental mindset measures (adapted from Magee 2009). All participants then responded to four scenarios measuring pro-social behavior (Rushton, Chrisjohn, and Fekken 1981). People thinking divergently indicated marginally higher willingness to engage in pro-social behavior than those thinking convergently ($M_{\text{divergent}} = 4.32$ vs. $M_{\text{convergent}} = 3.84$; $F(1, 98) = 6.03, p = .07$). More importantly, mediation analysis revealed that indeed deliberative vs. implemental mindset mediated this relationship (CI = [.05, .51]).

Study 4 manipulated both thinking style (divergent vs. convergent thinking) and mindset (deliberative vs. implemental mindset; Büttner et al. 2014) and found a significant two-way interaction between the two for willingness to donate measures ($F(1, 157) = 6.44, p = .01$), with all four contrasts being either significant or marginally significant.

To sum, this research promises to make several contributions. First, it offers to reconcile an apparent inconsistency in the litera-

ture on how being creative affects pro-social behaviors. Next, this research adds to the limited literature aimed at understanding the consequences of being creative and further illuminates the processes through which being creative may influence social behaviors. This current work also advances the creativity literature by providing new insights on divergent and convergent thinking; on how these two types of creative thinking may induce competing mindsets and thus differentially impact subsequent social behaviors. Finally, this research adds to the mindset literature by suggesting type of creative thinking as an antecedent of deliberative versus implemental mindset.

Paper #4: Feeling Like an Expert: Subjective Expertise and Consumption Enjoyment

Troy H. Campbell, University of Oregon, USA
Dan Ariely, Duke University, USA

SESSION OVERVIEW

Human lives are a collection of experiences and an extraordinary amount of money is spent acquiring hedonic experiences. In 2013 alone, Americans spent twenty two billion dollars on bars and nightclubs, \$140 billion on hotels, bed and breakfasts, and hostels, \$15 billion at amusement parks, and well over \$400 billion eating at restaurants (IBISWorld 2013). Given the prevalence of experiences, understanding how consumers' form evaluations of experiences is increasingly important. The goal of this session is to re-examine factors currently understood to influence the evaluations of experiences and to uncover new factors that influence such evaluations. Examining both established and novel factors, the papers included in this session offer important new insights to better understand how consumers form evaluations of experiences.

The first two papers re-examine one of the most well-established findings in the current literature: the peak-end effect, which suggests that people over-weight the peak (i.e., most intense) and end (i.e., final moments) of an experience when forming evaluations. These re-examinations provide greater clarity on if and when such moments are indeed over-weighted. First, Tully and Meyvis systematically re-examine existing evidence for the end effect. This paper did not set out to identify moderators or boundary conditions, but rather to re-examine the existence of a basic end effect. The findings in this paper indicate that endings are not inherently over-weighted in retrospective evaluations. Their results demonstrate that prior demonstrations attributed to an end effect are in fact the result of other processes associated with the end under specific conditions. In the second paper, Robert Latimer demonstrates when peaks are over-weighted in evaluations providing a boundary condition as well as offering a mechanism to better understand previous findings. He demonstrates that the heterogeneity of an experience influences whether people use global or local processing which in turn impacts whether the experience is stored as a prototype representation affecting the extent to which a peak is weighted in evaluations.

The other two papers reveal new factors that systematically impact evaluations of experiences. Complementing the findings of the second study, the third paper also demonstrates that processing style affects evaluations. However, instead of examining the peak of a unitary experience, this research examines multifaceted experiences (experiences that consist of multiple components simultaneously). Their results suggest that, compared to using a destructionist mode

where components are appreciated independently, the constructionist mode, where components are evaluated holistically (e.g., globally), increases overall evaluations above the rating of either of the individual components. The last paper, by Campbell and Ariely, pieces together existing findings on expertise and consumption enjoyment to identify subjective expertise (i.e., feeling like an expert in the "experience" area) as an important influence that differentially impacts consumption and process enjoyment of experiences. Their findings suggest that subjective expertise increases process enjoyment and consumption enjoyment of high quality experiences. However, for low quality experiences, subjective expertise increases process enjoyment, but not consumption enjoyment.

Questioning the End Effect: Endings Do Not Inherently Have a Disproportionate Impact on Evaluations of Experiences

EXTENDED ABSTRACT

This research adds to the existing understanding of how the structure of an experience affects its overall evaluation, by reexamining one of the most basic findings in this area: the end effect. The end effect suggests that people over-weight the final moments when evaluating an experience (e.g., Fredrickson and Kahneman 1993). Although demonstrations of the end effect abound, prior research also has identified several boundary conditions under which the effect fails to obtain (e.g., Miron-Shatz 2009). Rather than examining boundary conditions, the current work revisits the basic effect to test if the end of an experience is in fact inherently over-weighted. While we certainly acknowledge that endings can have a disproportionate impact on retrospective evaluations at times, our findings suggest that people do not readily over-weight the end of an experience in evaluations.

In study 1, participants listened to one of two sound clips of a vacuum cleaner noise. The clips were identical, but reversed in sequence, such that the ending was either softer (better-end) or louder (worse-end) than average. Participants in the better-end condition rated the end of the clip as significantly better than participants in the worse-end condition ($F(1, 294)=273.67, p<.001$). Despite this effective manipulation, there was no significant difference in their overall irritation ratings ($F< 1$). In this study, the sample size was sufficiently large to detect a small effect (Cohen's $d=.2$) with a 93% probability. The remaining studies reconcile our inability to find an end effect here with previous demonstrations of the effect.

We first turned to previous demonstrations that retrospective evaluations of an aversive experience improve when a better end is added to it. We tested whether this effect was due to an improvement in the average of the experience rather than an over-weighting of the end. In study 2, participants were assigned to listen to one of three noise profiles: better-middle, better-end, and added-end. The better-middle and better-end sound clips were equally long but differed in whether a less aversive (i.e., better) segment was positioned in the middle or the end. The added-end clip consisted of the better-middle clip, adding an additional, less aversive segment to the end. Thus, the better-middle and added-end clips differed in both average intensity and the intensity of the end (as in previous demonstrations), whereas the better-middle and better-end clips had the same average intensity and only differed in the intensity of the end. Replicating previous demonstrations, participants in the added-end condition reported less

irritation with the noise than participants in the better-end and better-middle conditions ($F(1, 220)=4.43, p=.036$). However, there was no significant difference in irritation between the better-middle and better-end ($F<1$), indicating that the intensity of the end didn't matter when average irritation was held constant.

Study 3 conceptually replicated study 2 using positive stimuli by creating compilations of music. Since the overall experience was positive, we added a less enjoyable component to the compilation for some participants, and varied the positioning of this component. Participants in the control condition enjoyed the music compilation more than did participants who had a less enjoyable part added, either to the end or to the middle ($F(1, 880)=4.37, p=.037$). There was no significant difference between the last two conditions ($F<1$). Thus, while adding a less enjoyable component lowered evaluations, the positioning of this component did not matter. In sum, studies 2 and 3 indicate that adding a better (or worse) end changes evaluations by changing the average, rather than by changing the final moments.

We next turn to prior research that has observed end effects within-subjects. We examined whether providing multiple experiences that vary only in structure compels people to incorporate opinions of the structure into evaluations. In study 4, participants listened to two aversive sounds that were identical, but reversed in sequence, such that one ended well and one ended poorly. The order of the sounds was counterbalanced. The within-subject analysis replicates previous demonstrations of the end effect: participants rated their better-end experience as less irritating than their worse-end experience, $F(1, 199)=73.45, p<.001$. However, the between-subjects analysis showed no difference in ratings of the better-end and worse-end sounds at time 1 ($F<1$). It was only at time 2 that participants who listened to the better-end reported less irritation than those who heard the worse-end sound ($F(1, 198)=53.44, p<.001$).

Study 5 replicated study 4 using positive stimuli. The within-subject analysis replicated the end effect as demonstrated in prior research ($F(1, 488)=15.52, p<.001$). However, between-subjects analysis indicated that, at time 1, there was no difference in enjoyment between participants who received the worse-end experience and those who received the worse-middle experience ($F<1$). Only at time 2 did participants who received the worse-end experience rate their experience as less enjoyable than those who received the worse-middle experience ($F(1, 487)=5.10, p=.024$). In other words, the end effect did not appear until participants were exposed to both experiences.

Finally, in study 6, participants listened to two aversive sounds that varied in structure, with one sound ending relatively better and one ending relatively worse. However, half of the participants heard two sounds of the same type (e.g., a vacuum) while the other half heard two different types (e.g., a vacuum then a drill). Thus, the same-sounds condition differed only in the intensity of the end as in previous within-subjects demonstrations of the end effect whereas the mixed-sounds condition varied in both intensity of the end and sound type. As predicted, there was a 3-way interaction ($F(1, 298)=4.163, p=.043$). Again, there was no end effect at time 1. Further, in line with our predictions, the end effect was only significant at time 2 for people in the same-sounds condition—for whom the structure was the only aspect available to differentiate ratings of the first and second sound. For those in the different-sounds condition—who had another aspect to consider—there was still no end effect at time 2. Thus, the end effect may only occur when people evaluate multiple experiences that only differ in structure which encourages a reliance on the intuitive preference for improving sequences.

Experience Heterogeneity Moderates the Peak Effect in Retrospective Evaluations

EXTENDED ABSTRACT

We explore how the heterogeneity of an experience changes the influence of the most intense moment of an experience (peak) on retrospective evaluations of the experience as a whole. Prior research has shown the peak is a powerful predictor of overall evaluations (Fredrickson, 2000). This phenomenon—described by the peak-end rule—is an example of judgment by prototype (Kahneman, 2003) or gestalt (Ariely & Carmon, 2000). Instead of representing the entirety of an experience in memory, people instead store an abstraction of the experience drawn from a few key moments. In this paper we manipulate the heterogeneity of experiences in order to change reliance on a prototype representation.

Two streams of research suggest that heterogeneity of an experience may moderate the peak effect. Replications of the peak-end rule across different types of experiences reveal that the peak effect is less robust for long, complex experiences such as vacations (Kemp, Burt, & Furneaux, 2008) or the events of a week (Ben-Zeev, Young, & Madsen, 2009) or day (Miron-Shatz, 2009). This pattern is consistent with the literature on categorization. Prototype models tend to perform best for simple stimuli such as patterns of dots (e.g., Smith & Minda, 2002). Exemplar models, in which every stimulus is stored in memory, better predict categorization for complex, feature-rich stimuli such as imaginary creatures (Yamauchi & Markman, 2000). If heterogeneity increases the complexity and feature-richness of an experience, people should shift from using a prototype representation to an exemplar representation. This shift may reduce the peak's impact on retrospective evaluations.

Study 1 ($N=930$) was designed as both a pretest and an opportunity to test the effect of heterogeneity on the predictive power of peaks and ends. Participants viewed and rated their liking of 20 paintings and each painting's similarity to the other paintings in the set. Participants viewed either 20 paintings of the same style (homogenous condition, 9 style replicates) or 20 paintings drawn randomly from all 9 styles (heterogeneous condition). Finally, participants indicated their overall enjoyment of the set.

Following Kahneman and colleagues (e.g., Shreiber & Kahneman, 2002; Fredrickson & Kahneman, 1993), we tested the peak-end rule by examining the correlations between online and retrospective evaluations. Both peak and end liking ratings were more closely correlated to overall enjoyment in the homogenous condition ($z_{\text{peak}} = 3.8, p < .0001$; $z_{\text{end}} = 4.11, p < .0001$; Steiger, 1980).

Study 2A ($N=386$) demonstrates that the addition of a highly enjoyable peak (vs. moderately enjoyable peak) produces greater retrospective enjoyment for participants viewing a more homogenous set of art. Participants viewed 10 paintings for 20 seconds each. As in Study 1 heterogeneity was manipulated by presenting participants with paintings of the same style (homogenous) or 2 paintings from each of five styles (heterogeneous). Both conditions had five replicates that were collapsed together during the analysis. In all conditions, eight of the paintings were selected to be moderately liked based ratings in Study 1 ($M_{\text{background}} = 45.3$). For half of the participants we added two highly liked paintings ($M_{\text{hipeak}} = 74.2$) and for the remaining participants we added two moderately liked paintings ($M_{\text{lopeak}} = 59.8$). Participants in the homogenous condition indicated a greater increase in retrospective enjoyment due to the higher peak ($M_{\text{hipeak}} = 68.2, M_{\text{lopeak}} = 54.6$) than participants in the heterogeneous condition ($M_{\text{hipeak}} = 64.0, M_{\text{lopeak}} = 59.3$) ($F(1, 382) = 5.21, p < .05$).

In Study 2A, participants in the high peak condition also experienced a set with a higher mean liking rating. Study 2B corrected

this by changing the 8 moderately liked paintings across conditions to keep the mean consistent despite the changing intensity of the peak ($M_{\text{overall}} = 51.1$). The same high and low peaks were used as in Study 2A and the remainder of the procedure was identical. Replicating Study 2A, participants in the homogenous condition indicated a greater increase in retrospective enjoyment due to the higher peak ($M_{\text{hipeak}} = 74.8$, $M_{\text{lopeak}} = 63.4$) than participants in the heterogeneous condition ($M_{\text{hipeak}} = 65.6$, $M_{\text{lopeak}} = 67.4$) ($F(1, 609) = 6.80$, $p < .01$).

In Studies 1 and 2, heterogeneity was achieved by mixing art from disparate styles. However, the styles themselves also vary in how similar one painting is to the next. Using the similarity ratings from Study 1, we selected the styles for which paintings were most similar to one another (Pollock Drip) and most different from one another (Watercolor Portraits). For just these styles, participants in Study 3 ($N = 562$) were presented with sets containing either high or low peaks, as in Study 2B. Participants with the more similar set indicated a greater increase in retrospective enjoyment due to the higher peak ($M_{\text{hipeak}} = 74.8$, $M_{\text{lopeak}} = 63.4$) than participants with the less similar set ($M_{\text{hipeak}} = 65.6$, $M_{\text{lopeak}} = 67.4$) ($F(1, 558) = 8.32$, $p < .01$).

In Study 4 ($N=784$), we manipulated the perceived homogeneity of a set with processing style. Participants viewed a series of 8 Navon figures—large letters made up of many smaller letters—(Navon, 1977) and were prompted to respond with either the large letter (global processing) or the smaller letter (local processing). Local processing may reduce the perceived similarity between stimuli, in turn reducing reliance on prototypes and decreasing the magnitude of the peak effect. In all other aspects Study 4 replicates the homogenous condition of Study 2b. Participants in the global processing condition indicated a greater increase in retrospective enjoyment due to the higher peak ($M_{\text{hipeak}} = 78.8$, $M_{\text{lopeak}} = 69.8$) than participants with the less similar set ($M_{\text{hipeak}} = 68.3$, $M_{\text{lopeak}} = 64.5$) ($F(1, 558) = 8.32$, $p < .01$).

Over four studies we demonstrate that high peaks have a larger influence on retrospective evaluations of experiences when those experiences are more homogenous or are processed more globally. Our results both provide evidence for the mechanism underlying the peak effect—prototype representations of experiences—and suggest boundaries—heterogeneous experiences. Although we happily concede that other mechanisms may also produce peak effects (e.g., distinctive, memorable peaks represented as exemplars, Montgomery & Unava, 2009).

Modes of Enjoyment for Multifaceted Experiences

EXTENDED ABSTRACT

Consumer experiences are typically multifaceted. For example, an overall experience (e.g., a night at the cinema) is comprised by constituent parts that are enjoyed simultaneously (watching a movie while eating popcorn). If the movie is more enjoyable than the popcorn, how much do people enjoy the overall cinematic experience? On the one hand, overall enjoyment could be *greater* than the utility that either the movie or the popcorn alone could provide. On the other hand, overall enjoyment may lie somewhere *between* the utility derived from a highly-liked movie and from middling popcorn.

Through four studies, we demonstrate that either of these results are possible depending on the mode of enjoyment consumers use while having a multifaceted experience. First, consumers can use a Constructive Mode, wherein the individual components are fused and are seen as one inseparable Gestalt whole. As a result, using a Constructive Mode means that overall enjoyment is greater than the enjoyment gained from having either of the components alone.

Second, consumers can use a Deconstructive Mode, which leads to the perception that the individual components are seen as separable, distinct entities. Consequently, a Deconstructive Mode leads to a preference for having the better-liked component by itself, because overall enjoyment is dragged down by the presence of a less-liked component.

Imagine eating cheese that has great taste but mediocre texture. Although early attitude models viewed a product's attributes as separable drivers of liking, this does not necessarily follow for hedonic psychology. It is difficult to cognitively separate taste and texture and arrive at a rational evaluation of the cheese. Taste and texture are interwoven, resulting in a composite hedonic response. In this way, we predict that people often use a default Constructive Mode when evaluating experiences. We further predict that this Constructive Mode leads people to enjoy an overall experience more than either of its components alone. These predictions are supported by research in cognitive psychology, which suggests that people are equipped with the ability to perceive an object as either a unified whole or as the smaller parts that comprise it (Palmer 1977). Although the use of these processing strategies can change depending on how stimuli are presented (Kimchi 1992), people are often better equipped to use the former strategy (Navon 1977; Kahneman, 2003), favoring the forest over the trees. In contrast, we predict that people will use a Deconstructive Mode when experiences are broken apart and attention is drawn to the individual components. This will lead people to enjoy a better-liked component more than the overall experience, which is being "dragged down" by the lesser-liked component. We conducted four studies to test these ideas.

Study 1 tested our core prediction as stated above. 146 participants received a (pretested) lesser-liked music sample and a better-liked chocolate. We manipulated whether participants experienced these two components combined or separately. All participants indicated their enjoyment of the individual components. Combined-experiencers indicated their enjoyment of the overall chocolate-music experience; separate-experiencers predicted how enjoyable this combination would be. We found that combined-experiencers rated the overall experience as more enjoyable than the chocolate alone and the music alone. However, separate-experiencers predicted that the overall experience would be less enjoyable than chocolate, but more enjoyable than music. This is consistent with our theorizing: Combined-experiencers exhibited a Constructive Mode of enjoyment (because the components were interwoven), whereas separate-experiencers exhibited a Deconstructive Mode (because the components were fragmented).

Our second study sheds more light on the proposed process. 211 participants received (pretested) lesser-liked music and better-liked artwork. Whether the components were combined or separated was manipulated. Our DV was how much participants preferred to have the artwork with or without the music. Participants also answered, "How similar (different) were the art and the music?" which served as the proposed mediator. Results were consistent with the theory. Combined-experiencers (compared to separate-experiencers) had a stronger preference to have artwork with music, and this effect was fully mediated by the perception of similarity between the components. Essentially, having a multifaceted experience elicited a Constructive Mode of enjoyment (seeing components as interwoven), where overall enjoyment was greater than individual components alone. Breaking up an experience promoted a Deconstructive Mode (seeing components as independent), where a highly-liked component was perceived to be more enjoyable than an overall experience.

Study 3 provides more process evidence. 68 participants were given the same stimuli and DV from Study 2. Afterward, they filled

out the Attention to Detail subscale (Baron-Cohen et al. 2001), which determines the extent to which participants naturally deconstruct an experience into constituent parts. The scale was found to be correlated with our outcome variable. Participants who naturally use a Deconstructive Mode (Constructive Mode) were more likely to prefer having highly-liked artwork alone (artwork and music together).

Our final study elicits the core finding using a different manipulation. All participants enjoyed music and art simultaneously. During the experience, half of the participants were told to alternate their focus between components; the remaining participants were given no instructions. Finally, all participants were asked to indicate whether they preferred to have the music and the art together, the art by itself, or the music by itself. The results showed that participants who were given no instructions used the default Constructive Mode, overwhelmingly preferring to have the music and the art together. However, when participants were asked to break up the experience and alternate focus (eliciting a Deconstructive Mode), more participants preferred to have the better-liked component (artwork) by itself.

In sum, these four studies advance the idea that people have two fundamental ways of thinking about multifaceted experiences. They can either see an experience as components coming together (Constructive), or as components existing independently (Deconstructive). Although hedonic psychology has experienced a surge of interest in the last decade, there is no previous research that has explored what happens when consumers enjoy more than one thing at a time. Our research seeks to be the first to fill this void by proposing a unique intersection between cognitive and hedonic psychology.

Feeling Like an Expert: Subjective Expertise and Consumption Enjoyment

EXTENDED ABSTRACT

Past findings show that beliefs and expectations are some of the most powerful forces that affect consumption enjoyment. Fortunately, these forces are within the feasible capability of marketers and consumption designers to influence. For instance, marketing materials that highlight a wine as expensive improve consumers' enjoyment of the wine (Plassmann et al., 2008). Similarly, meats and sweets taste better to consumers when marketed with delicious and less healthy sounding labels (Wasnink and Van Ittersum, 2006). Across many studies, marketing researchers have found alteration of external beliefs and expectations about products' qualities (e.g., how well-crafted a wine is) affect consumption enjoyment.

In this project, we explore a similar but new question; how do internal beliefs about one's own consumer expertise (e.g. one's belief in their personal ability to detect qualities of a well-crafted wine) affect evaluations of a consumption experience. Specifically we explore subjective expertise, defined as consumers' beliefs about their ability and knowledge in a consumption domain (Alba and Hutchinson 2000; Hadar, Sood, and Fox, 2013).

We join a general trend that has spanned marketing (Mochon et al. 2012), psychology (Deci and Ryan 2010), and management literatures (Grant and Parker, 2009), that seeks to examine the effects of subjective expertise on various outcomes. We add to the existing body of literature by illustrating the nuanced effect subjective expertise has on evaluations of a consumption experience. Doing so allows researchers to better understand the importance of expertise as a construct and provides useful knowledge for managers since this is a type of expertise that can often be feasibly influenced by external factors.

In this investigation, we draw an important distinction between two different sources of enjoyment: item-enjoyment (the enjoyment

of an item's qualities such as liking an item's flavor, appreciating its qualities) and process-enjoyment (the enjoyment of consumer processes such as thoughtfully evaluating an item's flavor or other engagement processes). Such a distinction is related to many larger perspectives on procedural versus non-procedural elements (McFarlin and Sweeney, 1992), engagement versus satisfaction (Calder, Malthouse, and Schaedel 2008; van Doorn et al. 2010), and recent work on enjoyment of consumer processes such as assembly (Dahl and Moreau 2007; Mochon et al. 2012, Prahalad and Ramaswamy, 2004). However, empirical research in marketing has not widely examined when these two types of enjoyment diverge from one another and the specific and variable effects subjective expertise can have on them—for instance across items of high versus low quality.

We conducted eleven experiments using multiple online panels and a lab (individual cell $n_s > 30$ in all experiments but one). In each experiment, we first manipulated participants' subjective expertise of a single specific consumption domain using a classic test plus false feedback manipulation. Next, in general participants consumed content from that consumption domain, which depending on the experiment involved watching a film clip, reading literary excerpts, drinking tea, or perusing stylish branded advertisements. Next we measured enjoyment of these consumption experiences (and in two separate experiments the predicted enjoyment of a film and wine).

Next, the findings are reported with reference to the three dependent variables assessed, rather than by experiment. Every time each dependent variable was assessed across the experiments, we mention the findings. All reported differences and interactions had $p_s < .05$, unless otherwise noted.

Item-Enjoyment. All eleven experiments measured and provided significant support that subjective expertise in a domain increases item-enjoyment of items in that domain (example measure: how much did you enjoy the qualities of item itself). Feedback that indicated high expertise lead to more consumption enjoyment compared to conditions with either low or no feedback. Further, one experiment tested and found that the effects of the subjective expertise manipulation are domain specific and do not affect enjoyment in other domains.

Three experiments demonstrate that the effect on item-enjoyment is dependent on quality. When domain items were noticeable low in quality either due to an explicit label or other traits about the item (e.g. a known low quality author), subjective expertise did not increase item enjoyment (a null effect). Meditational analyses found that participants increased feelings of general domain subjective expertise and specific perceived ability to distinguish unique qualities in of the certain specific stimuli items mediated the experimental effect of subjective expertise on item enjoyment.

Improvement Processes. Two experiments tested and found that subjective expertise leads people to be significantly more likely to engage in actions to improve consumption, such as taking the time to properly stir a hot tea to "improve the taste."

Process Enjoyment. While watching a movie, a consumer may not enjoy the qualities of the movie but may enjoy aspects of the consumption process (e.g. critiquing the movie). We investigated this type of process enjoyment: the process of consuming/critiquing enjoyment. The measurement of this enjoyment involved: both asking people to post hoc reflect on their enjoyment of critiquing during a consumption experience for which no direction to critique had been given, and separately by directly asking participants to engage in a critiquing consumption process and measuring enjoyment of the process. Although subjective expertise only increased item enjoyment for high quality items, subjective expertise increased process enjoyment for both high and low quality items. Meditational analyses (me-

diator: generalized feelings of subjective expertise) supported this three-way interaction of manipulated subjective expertise by item quality by type of enjoyment (item or process).

Summary. The current research pieces together existing findings on expertise (Dahl and Moreau 2007; Deci and Ryan 2000; White 1959) and consumption enjoyment (Loewenstein 1999; Vohs et al. 2013) to distinguish subjective expertise as an important, distinct, and nuanced influence on evaluations of a consumption experience. The findings help researchers to make better predictions regarding how subjective expertise will affect different types of enjoyment, under what conditions these patterns will vary, and what behaviors subjective expertise might encourage.

SESSION OVERVIEW

“Every Moment is an Experience”—J. Roberts

Experiences tend to provide more enduring satisfaction than material possessions (Van Boven and Gilovich, 2003; Nicolao, Irwin, and Goodman, 2009) and come to constitute a fundamental part of the self (Carter and Gilovich 2012). However, very little is known about what influences how events are experienced in the moment. While some research has measured experiences in the moment (e.g. Wirtz et al. 2003), such research did so to explain the experience as a whole. The papers in this session specifically focus on how experiences in the moment are affected by information that consumers have *prior* to an event, as well as information that they receive *during* the event. Further, the four papers employ an array of methodologies that allow a deeper understanding of how experiences unfold over time.

The first two papers, in particular, examine how experiences are shaped by information consumers receive prior to the experience. **Valsesia, Diehl, and Nunes** explore how the veracity of a narrative, the belief that a story did or did not happen in reality, affects consumer experiences. They find that knowing a movie plot is based on true events alters viewers' moment-to-moment reactions to the movie. Further, using secondary data, they show that such beliefs also lead to more positive review ratings. **John and Norton** show that consumers' knowledge that they are experiencing a “revised” (as opposed to an “original”) version of an experience influences how the experience is evaluated. They find that consumers have a “revision bias” – modified experiences are perceived as being of higher tastiness and higher quality than versions they were told were “originals.” **Rifkin, Chan and Kahn** show that information that consumers receive *during* the experience also influences the experience itself. They find that enjoyment of an ongoing experience can be negatively affected when one becomes aware of concurrent social events (e.g. via social media) due to what they call “Fear of Missing Out”. Finally, the work by **Lovett and Peres** complements these papers by examining mobile diaries as valid tools to measure experiences in the moment. The authors study mobile diaries in the context of TV viewing which allows them to compare self-reported diary

with metered (PeopleMeter) viewing records. The authors observe a high correspondence between diary and metered records for longer metered TV viewing experiences (e.g., >30 minutes).

Taken together, these working papers shed light on how events are experienced in the moment. They do so using an array of methodological approaches (ranging from moment-to-moment ratings and mobile diaries, to retrospective evaluations and secondary review data).

Given the primacy of experiences in consumers' lives, we expect this session to generate interest among researchers studying experiential purchases, social judgment, consumer decision-making, entertainment and cultural goods, as well as measurement tools. In the spirit of the conference theme “Advancing Connections,” we believe that the diverse background of the authors as well as the varied methodological approaches will provoke a discussion at ACR that is both fruitful and engaging.

Based on True Events: The Effects of Veracity on the Consumption Experience

EXTENDED ABSTRACT

Movies, books and even songs are often marketed as being “inspired by” or “based on true events.” While this familiar disclaimer is a frequent and long-established practice for dramatic movies, today, even horror movies (e.g. “The Possession”) and sitcoms (e.g. “Fresh off the Boat”) use the tagline “inspired by a true story.” Marketers apparently believe that promoting a story in this way will be beneficial to their success. Indeed, prior research suggests that, *a priori*, consumers expect stories described as reality-based to be more emotionally intense (Ebert and Meyvis 2014). However *following* the experience, the effect does not manifest for people's recollections of the emotional intensity (Ebert and Meyvis 2014) or reported enjoyment (Argo et al 2008).

In this work, we propose that the apparent contradiction between marketers' beliefs and academic evidence is driven by the fact that not every narrative benefits from being labeled as reality-based. We suggest that only those stories that lack verisimilitude - defined as a low likelihood the events actually may have happened (Leary et al 2014) - benefit from a veracity claim such as “based on a true story”. Verisimilitude is known to increase positive feelings if the story is one people can imagine (Busselle and Bilandzic 2008). We propose that veracity claims have a positive effect on an experience only when there is a lack of verisimilitude.

We first examine secondary movie data for evidence of a positive effect of being labeled as reality-based on both critics' and consumers' evaluations. We then examine experimentally the extent to which consumers' reactions to reality-based stories depend on the story's verisimilitude. Across these different methodological approaches we find that veracity claims lead to more positive reviews, but the effect is limited to narratives that lack verisimilitude and would otherwise be deemed implausible by consumers.

We begin by examining the role of veracity claims on review ratings in the real world. Consumer ratings are widely publicized and are an important driver of consumer choice, particularly in the movie industry (Liu 2006). In study 1, we utilize a unique, real-world data set to understand whether reality-based (as opposed to fictional) movies receive different ratings by consumers as well as critics. The data include information about the 1,000 movies that entered the Top

100 Box Office ranking from 2003 through 2012. Each movie was dummy-coded based on whether or not it was promoted as being based on true events. Our main dependent variables are the average rating each movie received from both consumers and critics. Consumer ratings were obtained from the IMDB website and ranged from zero to ten stars. Critic ratings were taken from metacritic.com and ranged from 0 to 100. We find that being based on a true story has a positive effect on consumers ($\beta = 0.49$, $t = 3.37$, $p < .01$) and critics ($\beta = 10.18$, $t = 4.21$, $p < .01$) while controlling for genre, budget, star power, MPAA ratings, and year. Further, we find that reality-based movies are also more likely to garner industry recognition in the form of winning Academy Awards for Best Picture ($\beta = 1.54$, $Wald = 13.89$, $p < .01$).

This data suggests that veracity claims do affect the way movies are evaluated by lay consumers as well as experts. However, we argue that this effect is driven by movies low in verisimilitude actually receiving and benefitting from such a label. Hence in Study 2, we test for the moderating role of verisimilitude. One hundred and fifty-one participants read a short story based on the film *Compliance*. Details of the story were changed in order to vary verisimilitude ($M_{High} = 6.03$, $M_{Low} = 4.76$, $F(1,148) = 8.78$, $p < .01$). We manipulated the veracity claim along with verisimilitude. We find that, in line with our expectations, knowing a movie is reality-based increased consumers' attitudes towards the story in the low-verisimilitude version ($M_{True} = 5.78$ vs $M_{Fictional} = 4.61$, $t(1,148) = 2.64$, $p < .01$), but not in the high-verisimilitude version ($M_{True} = 5.63$, $M_{Fictional} = 5.56$, $t(1,148) = -.18$, $p = .86$).

Study 3 overcomes a potential limitation of study 2, namely that we modified some details of the narrative to vary its plausibility. In study 3 all 442 participants watched the same short movie, *Giving*. Once again, we manipulated the veracity claim associated with the video. We expected that characteristics of the respondent (i.e. ethnicity) would affect perceived verisimilitude and hence moderate the effect of veracity claims on attitudes. The movie was set in Asia and featured Asian protagonists. We a priori expected that Asian respondents would find the story more plausible to start with and hence that non-Asian (but not Asians) would be affected by learning that a story is reality-based. Indeed, non-Asians found the narrative to be less plausible compared to Asians ($M_{Non-Asian} = 5.20$, $M_{Asian} = 5.66$, $F(1,440) = 3.72$, $p = .05$). More importantly, ethnicity moderated the effect of veracity claims ($F(1, 438) = 4.86$, $p = .03$). As predicted, knowing the movie is reality-based increased attitudes for non-Asian respondents ($M_{True} = 7.56$ vs $M_{Fictional} = 7.17$, $t(1,438) = 2.20$, $p = .03$) who deemed the story on its own less plausible. However veracity claims did not affect attitudes of Asian respondents ($M_{True} = 7.41$, $M_{Fictional} = 7.79$, $t(1,438) = -1.25$, $p = .21$) to whom the story was more plausible to start with. Additionally, part of the respondents also rated their moment-to-moment (MTM) enjoyment while watching the video. We observe the same pattern of effects on this measure; enjoyment was greater when the video was described as reality-based, but only for Non-Asians ($M_{True} = 63.52$ vs $M_{Fictional} = 57.19$, $t(1, 182) = 2.22$, $p = .03$) and not for Asians ($M_{True} = 57.50$, $M_{Fictional} = 58.95$, $t(1, 182) = -.30$, $p = .77$).

Using a multi-method approach, this research contributes to our understanding of when and how information about the veracity of a narrative influences consumer attitudes. Further our research contributes to research emphasizing the importance of understanding how consumers experience events in the moment.

The Revision Bias: Preferences for Revised Experiences Absent Objective Improvement

EXTENDED ABSTRACT

Many authors (academic and otherwise) have felt that although critics and reviewers preferred revised versions of their work, the original version was the better product – that reviewers preferred the revision simply because it was revised, rather than improved. In three experiments, we offer empirical evidence of this “revision bias”: people prefer experiences and products that have been revised over time, regardless of whether newer versions are objectively better than their predecessors. Moreover, we show that the revision bias is independent of the input bias (Chinander and Schweitzer 2003), which refers to the confounding of effort with quality – people, often sensibly, think that the more effort that is put into producing something the higher the quality (see also Buell and Norton 2011; Kruger, Wirtz, Van Boven, and Altermatt 2004).

In Study 1, we document the revision bias in an experiential context in which participants ($N = 239$) consumed two gummy candies. The study was a within-subjects design in which participants were told that one of the candies used a refined recipe and were given no such information about the other candy. Specifically, participants were given a candy and told that it was the “final, market-ready version of the recipe” but that “before the recipe was finalized, the company had tried several different recipes before finalizing the current formulation” (*revision condition*). Participants then ate the candy and rated its quality and tastiness. They were given another candy and simply ate it and rated its quality and tastiness (*control condition*). As control factors, between-subjects, we randomized the order of candy version and the ascription of candy to version; these factors had no effect on ratings, and so we collapse across them. As predicted, participants deemed the revised version to be better tasting and of higher quality than the control version, $t(238)=2.41$, $p=.017$. These results held even when we controlled for participants' perceptions of the effort that the candy manufacturer put into making the candy.

In Study 2, we extend the revision bias to a new context: writing. Participants ($N = 199$) were shown two versions of a person's resume – a “first draft” and a “revision” – and rated the overall appeal of each. Critically, the only difference between the two drafts was trivial, the font: one of the resumes appeared in Times New Roman while the other resume appeared in Arial. We manipulated the ascription of font to draft: for some participants, the “first draft” was in Arial whereas the “revision” was in Times New Roman, while the reverse was true for other participants (we collapse across this factor in our analyses). As predicted, participants rated the revised version as significantly more appealing relative to the first draft, $t(198) = 4.02$, $p < .0005$. We find this effect particularly surprising given that the triviality of the revision was fully transparent: the two versions were presented side-by-side on the same page of the survey. Therefore, participants could plainly see that the resumes were not substantively different but nonetheless rated the revision to be better.

In Study 3, we differentiate revision bias from input bias (Chinander and Schweitzer, 2003). The preference for the revised resume in Study 2 could arise because the total effort put into it is necessarily greater than that put into the first draft (since the revised draft represents the sum of all effort put into the first draft, *plus* that put into the revision). Study 3 addresses this alternative explanation by pitting effort (operationalized by the total amount of time the candidate has spent on the resume drafts) against revision status. As in Study 1, participants ($N = 210$) rated the appeal of a resume. Between-subjects, we manipulated the total amount of time spent on the drafts (*10 minutes* versus *30 minutes*) and revision status (*first draft* versus

revision). As in Study 2, the two versions differed only in font. As predicted, we found only a main effect of revision status, $F(1, 206) = 4.52, p = .035$. Regardless of effort, participants found the revised resume more appealing. Indeed, participants rated a revised resume on which a person had ostensibly spent a total of 10 minutes as more appealing than a first draft on which a person had spent a total of 30 minutes.

Taken together, these experiments suggest that authors' feeling that reviewers prefer revisions simply because they are revisions may – at least in some cases – be warranted. Controlling for the actual quality of both foods and resumes, people rated revisions as being of higher tastiness and higher quality than versions they were told were “originals.” While in these experiments we did not ask participants themselves to give feedback on originals and then sample products revised in response to their concerns, we suspect that people are likely to rate revisions on which they have provided input as particularly stellar – again, independent of any actual improvement.

FOMO: How the Fear of Missing Out Leads to Missing Out

EXTENDED ABSTRACT

Fear of Missing Out (FOMO) is defined as “a pervasive apprehension that others might be having rewarding experiences from which one is absent” (Przybylski et al., 2013). This research explores FOMO's antecedents and consequences, and how it is driven by social belonging uncertainty. We establish that seeing social media photos of a missed social-group event triggers a two-pronged “FOMO effect”: a decrease in enjoyment of one's current experience, and an increase in expected enjoyment of the missed experience.

In Study 1, we asked 198 participants, “What does FOMO mean to you?” and coded their responses. We found that 75% of participants mentioned their social group or friends. Of the participants who mentioned when they experienced FOMO, the majority (54%) reported experiencing FOMO during a missed event, compared to before (22%) or after (30%) an event. Finally, subsequent questions revealed that more active social media users experience FOMO more frequently ($r = .23, p = .001$), and that FOMO occurs most often in social situations with friends (84.4%), compared to with family members (48.3%) or coworkers (53.7%).

In Study 2, we examined how social media photos affect experience enjoyment by experimentally manipulating whether one saw Facebook photos of a missed event and whether one posted photos of one's concurrent event. Ninety-one participants imagined they faced a social dilemma: attend a “once-in-a-lifetime” concert with a friend, or a regularly-scheduled party with their social group. All participants were told that they chose the concert (confirmed by pre-test to be the most realistic choice). Participants rated their pre-event expected enjoyment of both the concert and party, and then were randomly assigned to one of four conditions: While at the concert, they saw [did not see] photos of the party on Facebook, and they posted [did not post] their own concert photos. Following the photo manipulations, participants rated their enjoyment of the current event (concert) and their expected enjoyment of the missed event (party); participants also rated their post-event retrospective enjoyment. We analyzed enjoyment ratings in a 2 between (Viewed Photos: see, do not see party photos) \times 2 between (Concert Photos: post, do not post) \times 2 within (Event: concert, party) \times 2 within (Time: before-to-during, during-to-after) mixed ANOVA. Results revealed a significant interaction of Viewed Photos, Event, and Time, $F = 24.90, p < .0001$. Seeing (vs. not seeing) party photos produced the two-pronged “FOMO effect”: decreased current event enjoyment ($M_{concert, party\ photos}$

$= -0.40$ vs. $M_{concert, no\ party\ photos} = -0.06$), $F = 4.09, p < .04$, and increased missed event expected enjoyment ($M_{party, party\ photos} = 0.31$ vs. $M_{party, no\ party\ photos} = -0.41$), $F = 18.02, p < .0001$. Notably, the FOMO effect was observed even though participants perceived the concert as more enjoyable than the party ($M_{concert} = 6.47$ vs. $M_{party} = 5.25, t = 7.32, p < .0001$). Finally, we found that posting one's own concert photos did not mitigate FOMO, suggesting that FOMO is not driven by the desire to “keep up” with others' social media activity.

Study 3 used the concert-versus-party scenario from Study 2, but also included an additional “Viewed Photos” condition (a friend posting conference photos) to rule out the alternative explanation that FOMO is caused by distraction. Submitting participants' ($N = 179$) over-time enjoyment ratings of the current and missed events to a mixed ANOVA, we replicated the FOMO effect (Viewed Photos \times Event interaction, $F = 6.59, p < .002$): Seeing (vs. not seeing) party photos decreased participants' current event enjoyment ($M_{concert, party\ photos} = -0.49$ vs. $M_{concert, no\ party\ photos} = -0.12$), $F = 6.96, p < .009$, and increased their missed event expected enjoyment ($M_{party, party\ photos} = 0.12$ vs. $M_{party, no\ party\ photos} = -0.24$), $F = 6.47, p < .02$. Further, as predicted, seeing conference photos did not elicit FOMO (changes in concert and party enjoyment $ps > .2$), indicating that distraction is not sufficient to elicit FOMO. We also measured participants' proclivity to worry about missed events using a trait FOMO scale (Przybylski et al., 2013). A Viewed Photos \times trait FOMO mixed ANOVA predicting concert enjoyment revealed a significant interaction, $t = 2.34, p < .03$, with those higher in trait FOMO experiencing sharper declines in current event enjoyment after viewing photos of the missed social event.

Study 4 tested our theory that FOMO is driven by uncertainty about social belonging. Participants ($N=147$) first listed the name of a social group they belonged to, then reported how uncertain they felt about their group belonging (measured as feeling the need to protect their status as a group member). Next, participants read the concert-versus-party scenario from Study 2, and imagined they saw [vs. did not see] party photos. Participants rated their enjoyment and expected enjoyment both before and during the events. Replicating the FOMO effect (Viewed Photos \times Event interaction, $F = 31.35, p < .001$), we found that seeing (vs. not seeing) party photos decreased current event enjoyment ($M_{concert, party\ photos} = -0.47$ vs. $M_{concert, no\ party\ photos} = -0.07$), $F = 12.6, p = .001$ and increased missed event expected enjoyment ($M_{party, party\ photos} = 0.26$ vs. $M_{party, no\ party\ photos} = -0.36$), $F = 18.00, p < .001$). We also found a significant Viewed Photos \times Social Belonging Uncertainty interaction on current event enjoyment, $t = 2.76, p = .007$: Among those who saw party photos, higher social belonging uncertainty was associated with lower current event enjoyment.

These studies demonstrate that seeing social media photos of a missed social-group event produces “FOMO”: decreased enjoyment of the current event, and increased expected enjoyment of the missed event. FOMO was triggered even when the current event was considered more enjoyable and experienced with a friend (Studies 2-3), and it was exacerbated by social belonging uncertainty (Study 4). FOMO was not triggered when social media photos were unrelated to the social group (Study 3), nor attenuated by posting one's own photos to social media (Study 2). This research thus shows how exposure to social media photos can negatively affect one's experiences and reveals the underlying role of social belonging uncertainty.

My Phone is My Diary: Using Mobile Diaries for TV Viewing Measurement

EXTENDED ABSTRACT

Consumer diaries have been a popular tool for capturing behaviors, habits, communication, and consumption over time. The ubiquity of mobile phone makes them a natural platform for diary studies. Such studies are increasingly used in medical and communication research (e.g., Bolger, Davis, and Rafaeli 2003; Broderick 2008; Shiffman, Stone, and Hubbard 2008), and mobile panels have been gaining increased popularity among marketing practitioners. However, their use in academic marketing research is still relatively scarce.

We study mobile diaries in the context of TV viewing measurement with two goals. First, we investigate the level and nature of the accuracy of self-report mobile diaries compared to observable PeopleMeter data. This goal leads us to provide insight into how to best apply and analyze long diaries lasting multiple weeks. Second, we provide substantive results about how these mobile diaries can complement PeopleMeter data to better understand television viewing. Although PeopleMeter measurement has undergone considerable validation (e.g., Danaher and Beed 1993), it continues to face controversy as technology and viewing changes (Carter and Steel 2014).

Our data include a mobile diary for a representative sample of 1702 respondents who reported viewing and communications about prime time TV for 3-6 weeks during the fall season of 2013. The respondents were given random alarms twice during the day and three times during prime-time hours and they were allowed to self-initiate entries at any time. Response to alarms was 47% on average and self-initiated reports accounted for 33% of all reports. The patterns of reporting suggest that daytime and prime-time participation reasonably matches the frequency of alarms, but that weekends have lower participation. Interesting, during less frequently alarmed daytime period self-initiation consisted of 48% of entries, and during prime-time with more frequent alarms, self-initiation was 26% of entries.

For a subsample of 146 respondents, we also have their Nielsen PeopleMeter (NPM) records. We examine each direction of the match between NPM records and mobile diary entries.

For the link from NPM records to the mobile diary entries, only a subset of the entries/records are relevant. First, the instructions for the diary suggest a limited time window (prime time with incentives for only 3 weeks of diary). Second, PeopleMeter captures viewing minute by minute, whereas diary entries are reported only when a viewing is long enough to warrant it. We find that viewings less than 3 minutes long had very low reporting rates, but that as the viewing length increased so did the reporting rate. Third, our data indicate a response pattern in which individuals were either active or inactive in their viewing reports on particular days. By focusing on the active days, reporting completeness increases by over 15%. Finally, respondents on occasion reported that they watched multiple episodes (5% of diary entries) in a single record. We accumulate viewings of the same program to control for this "binge-viewing" concern and find that reporting completeness increases another 8% on average. As a result, for shows on prime time viewed more than 30 minutes during the first 3 weeks of the diary and reported on active days, over 70% of PeopleMeter records have corresponding diary entries.

Considering how the completeness varies, we found little correlation with demographics or reporting activity, but day of the week has a distinct and significant pattern (e.g., Saturday is lowest). Interestingly, the reporting completeness rate is quite stable for the first 4

weeks of diary tenure (and only the first 3 weeks are incentivized). This suggests even longer mobile diary studies are possible and that incentives need not be as large.

We now start from the mobile diary entries and examining whether matching NPM records exist. We find that 67% of mobile diary viewing entries have a matching NPM viewing and another 7% were diary viewing reported as not on TV (i.e., no NPM match is expected). Hence, 74% match well with expectations. However, despite instructions to complete entries during or after viewing, 6% of the matching entries were completed before the viewing and 60% during the airing.

The unmatched cases include two categories--diary viewing on TV that has no matching NPM record (14%) and diary viewing that has an NPM record at the same time, but for a different program (12%). In both cases two possible explanations exist. First, the entries or records could be incorrect. For example, diary entries could be made in error or NPM records could incorrectly identify the household member who is watching. Second, the unmatched cases could reflect viewing not captured by the NPM on un-metered devices (TVs out of the home or un-metered in the home).

These unmatched entries are relatively concentrated with 17% of respondents accounting for 50% of the unmatched cases. These cases are more likely to come from younger people, during non-prime time hours, and from self-initiated reports. All three relationships are consistent with accurate, but non-metered viewing (e.g., viewing away from home during daytime). Further, intuitively, the self-initiated diary entries would on the surface seem most likely to be accurate.

These findings have implications for the use of mobile diaries and their ability to complement PeopleMeter viewing measurement. First, we suggest not only that mobile diaries are reasonably complete and accurate, but that even lengthy mobile diaries can achieve these completeness rates if properly accounting for activity levels and the exact instructions for the diary. While the completeness rates may not be high enough for some purposes, for other purposes there is no other way to obtain the data. Second, we argue that mobile diaries are able to identify both viewing that is not metered (on other devices or out-of-home) and viewing that could be inaccurate (e.g., household ID's not accurately entered). At the same time, mobile diaries can track other useful information about communications that shape viewing behaviors, yet PeopleMeter is unable to track. We do not suggest mobile diaries as a replacement to PeopleMeter, but they could augment the existing viewing measurement system.

SESSION OVERVIEW

An individual engaged in the process of food consumption is exposed to myriad subtle cues and pieces of information, each of which may or may not be attended to and incorporated into the consumption experience. Extant research has shown that even irrelevant information (e.g., the size and color of dinnerware; the color of juice one consumes; Hoegg and Alba 2007; Van Ittersum and Wansink 2012) has important impacts on consumption. Yet, several ubiquitous aspects of consumption contexts, such as product numerosity and nutritional information, remain relatively less explored—particularly from a perspective of non-usage or non-consumption.

The authors in this session focus on how the usage vs. non-usage of subtle features of the consumption environment affects a range of consumption-relevant outcomes. In particular, we shift our focus away from the typical emphasis on how what *is* consumed affects consumption experiences, to instead ask: How do features of the consumption environment that are *not* consumed or *not* attended to affect consumption experiences?

In the first paper, Davis and Haws show that not receiving nutritional information impacts consumers' enjoyment of hedonic foods, an effect they term "motivated ignorance." Their studies show that consumers who are lower in eating self-control seek less and spend less time evaluating nutritional information relating to unhealthy foods to avoid the hedonic cost of this information and increase predicted and actual enjoyment of the foods.

Ilyuk and Block show that packaging may affect the perceived and actual efficacy derived from products such as energy-enhancers and medication. Their studies show that consuming the same amount of such products from a single-serving (vs. multi-serving) package may lead to greater product efficacy due to the perception of consuming all available resources (vs. a fraction of all available resources), respectively.

While the presence of non-consumed products hurts efficacy in some cases, VanBergen, Irmak, and Sevilla show that present but non-consumed products can improve efficacy in others. In particular, their results show that consumers who are unfamiliar with an energy-

enhancing product derive greater benefits from a single consumed unit if the consumed unit is alongside several non-consumed units. Consumers familiar with the product show the opposite pattern of results, performing better in the absence of non-consumed products.

Finally, Tal and Wansink show that satiety—an outcome explicitly related to food consumption—can be influenced by the way the units of a food item are presented. Their studies show that consumers feel fullest when food is divided into more units and spaced closely together. More distal spacing makes the consumed food appear smaller relative to the total food space (i.e., the sum of consumed and non-consumed area), reducing perceptions of satiation.

Together, the authors in this session provide insight into the variety of ways that non-consumed aspects of the consumption environment affect the experience of food consumption. Given the growing importance of health and wellness research, we believe this session has implications for consumers and practitioners alike and will interest a wide audience of researchers studying aspects of food consumption, nutritional information, and numerosity.

Motivated Ignorance: The Hedonic Cost of Nutritional Information

EXTENDED ABSTRACT

Prior research has suggested that disclosure of nutritional information is only effective in reducing obesity when consumers are motivated to seek out and process such information (Howlett et al., 2009). Since consumers generally believe that unhealthy items taste better (Ragunathan, Naylor, & Hoyer, 2006), there may be a substantial hedonic cost when objective nutritional facts are known to the consumer. Research has shown that consumers are sometimes willfully ignorant of easily obtainable product attributes when these attributes conflict with goals and generate negative emotions (Ehrich and Irwin 2005). Due to heightened conflict with hedonic goals, we propose and examine across four studies that individuals low in eating self-control will be motivated to ignore available nutritional information for indulgent foods, and doing so will heighten their enjoyment.

Study 1 introduced 128 participants (54% female) to a product evaluation task involving relatively healthy Baked Ruffles potato chips or relatively unhealthy Doritos, depending on condition. The packaging for the chips was shown on-screen including the nutrition facts panel. Participants were asked to carefully review the packaging and time spent doing so was recorded. Next, we captured an individual difference measure self-control (SC) using Tangney et al.'s (2004) scale items. The interaction between the condition and SC was significant in predicting the time spent reviewing the packaging ($F(1,124) = 6.96, p < .01$). A spotlight analysis at 1 SD above and below the SC mean revealed the effect of the experimental condition on time spent reviewing the packaging to be marginally significant at both one SD below ($\beta = -8.99, SE = 4.62, p = .05$) and above the self-control mean ($\beta = 8.30, SE = 4.61, p = .07$). Individuals lower (higher) in self-control tended to pay less (more) attention to nutritional information for unhealthy Doritos relative to healthier Baked Ruffles.

In study 2, we examined the effects of information choice on downstream enjoyment. Specifically, 103 participants (34% female) were asked to choose to view or skip nutritional information for a large slice of chocolate cake. Those who chose "view" were shown

that the large indulgence contained 960 calories and 52 grams of fat. Regardless of whether they chose to view or skip, participants next imagined eating a bite of cake and rated enjoyment on a 9-point scale. In a logistic regression, we found that lower levels of self-control corresponded to a greater likelihood of skipping the nutritional information ($\beta = .55, p < .001$). Importantly, we found a significant interaction between information choice and self-control ($F(1,99) = 6.96, p < .01$). A spotlight analysis at 1 standard deviation below the self-control mean showed that individuals lower in self-control who chose to skip nutritional information anticipated significantly higher enjoyment for the chocolate cake dessert relative to those who viewed ($\beta = 1.85, p < .01$). High self-control participants at 1 standard deviation above the mean did not show significantly varying enjoyment between the choices ($\beta = -.43, NS$).

In study 3, 170 participants (47% female) were instructed to evaluate chocolate truffles that were present at their workstations. Each participant ate two truffles and, depending on experimental condition, viewed nutritional information either before consuming the first truffle or between consuming the first and second truffles. Enjoyment was measured after each truffle was eaten. Self-control tendencies and demographics were collected at the end of the session. Our analysis revealed a significant interaction of the timing of nutritional information and SC in predicting the enjoyment differential between the first and second truffle ($F(1,162) = 7.58, p < .01$). Measured enjoyment of the first and second truffle varied significantly between experimental conditions for those lower in self-control ($\beta = .89, p < .01$) but not for those higher in self-control ($\beta = -.19, NS$). Individuals lower in self-control experienced a significant drop in enjoyment when viewing nutritional information between the first and second truffle, supporting our prediction that such information produces a hedonic cost.

We next investigated whether hedonic costs result in reduced consumption in study 4. Participants ($n=194$, 62% female) were asked to sample one chocolate-covered almond and then choose whether to view nutritional information or customer reviews for the product. After viewing the information they selected, they were invited to consume the chocolate-covered almond snack (up to 40g) as they watched a video. Our analysis revealed a significant interaction between information choice and self-control ($F(1,181) = 4.12, p < .05$), such that those low in self-control consumed marginally more of the snack when they chose to view customer reviews vs. nutritional information ($\beta = 3.26, SE = 1.80, p < .08$). Those higher in self-control did not significantly differ in consumption for the two information types ($\beta = -1.77, SE = 1.82, NS$). Additionally, an indirect effect of eating enjoyment linked the information choice and self-control interaction to the quantity of almonds consumed ($\beta = -1.53, SE = .79, 95\%$ bias-corrected bootstrap $CI: -3.18, -.08$).

Across four studies, we examine the efficacy of providing nutritional information by exploring whether individuals lower in self-control tend to avoid available nutritional information for more indulgent foods and whether such exposure influences consumption. We measured tendencies to view nutritional information through time spent looking at packaging (study 1) and explicit choices to view or not view nutrition facts (studies 2-4). Further, we find that people with low self-control tend to consume more unhealthy food when they avoid nutritional information (studies 2 and 4) and enjoy unhealthy food more (less) when avoiding (viewing) nutritional information (studies 2-4). These findings, using different food stimuli and various formats of information, show that nutritional disclosure may be a promising intervention for individuals lower in self-control but there are obstacles to clear in getting these consumers to view and process the information provided.

The Influence of Package Formats on Consumers' Perceptions of Product Adequacy and Efficacy Responses

EXTENDED ABSTRACT

Marketers offer products in a variety of package formats—from large containers to smaller, single-serve, individually-wrapped and travel-size alternatives. Although much of prior research has focused on the effects of portion, serving, and package size on consumption of foods (for a review see Zlatevska, Dubelaar, and Holden 2014), little inquiry has been made into the effects of product packaging on consumers' perceptions of product efficacy. In this research, we build on extant research on the effects of resource availability and product packaging on consumption (Morewedge, Holtzman, and Epley 2007; Wansink 1996) and implicate package format—single-serve vs. multi-serve packages—as a source of product efficacy experiences and expectations.

During consumption, a product's package necessarily defines the accessible "resource inventory" and the serving/dosage defines the consumption quantity. Although the ratio of consumption quantity to resource availability is, in and of itself, uninformative to product efficacy inference, we suggest that consumers may erroneously rely on the size of the resource inventory when making efficacy judgments when processing capacity (herein PC) is limited. We propose and demonstrate that consuming a particular serving/dosage of a product from a smaller resource inventory (i.e., the entirety of a single-serve package, a "whole") may subjectively feel *more adequate* than consuming the *same amount* from a larger resource inventory (i.e., a multi-serve package, namely one containing many servings/doses). Across three studies, we used a 2(Package Format: Single-Serve vs. Multi-Serve) X 2(PC: High vs. Low) between-subjects design; PC was manipulated by imposing a cognitive load.

In study 1, participants were given 1-ounce of *Gatorade G-Series Pro 02 Perform* powder to mix into a water bottle from either an individually-wrapped, 1-ounce, packet (single-serve condition) or a 32-ounce container (multi-serve condition). They were asked to drink the mixture (purportedly capable of increasing mental acuity) as needed while they performed a verbal GMAT task; actual efficacy experiences were captured by task performance (Ilyuk, Block, and Faro 2014; Shiv, Carmon, and Arieli 2005; Wright et al. 2013). As hypothesized, an ANCOVA revealed a significant package format by PC interaction on task performance, controlling for how much participants drank and how well they usually perform on standardized tests ($F(1,93)=5.44, p<.05$). Contrast analysis indicated that when PC was low, task performance was higher when participants were given Gatorade powder from the single-serve package ($M=50.33\%$) than an equivalent amount from a multi-serve package ($M=40.01\%$; $F(1,93)=4.21, p<.05$). However, when PC was high, there was no difference in task performance between the two package conditions ($M_{\text{single-serve}}=43.38\%$ vs. $M_{\text{multi-serve}}=49.40\%$; $F(1,93)=1.56, p=.21$). Perceived product adequacy exhibited a similar pattern: when PC was limited, perceptions of having an adequate quantity were higher for those who received 1-ounce of powder from a single-serve ($M=5.65$) than from the multi-serve package ($M=4.78$; $F(1,95)=3.80, p=.05$). However, when PC was high, there was no significant difference in perceptions of adequacy ($M_{\text{single-serve}}=4.85$ vs. $M_{\text{multi-serve}}=5.48$; $F(1,95)=2.18, p=.14$). Moderated mediation analysis showed that perceived product adequacy mediated the effect of package format on task performance in the low (CI[-3.3866,-1.206]) but not high PC condition (CI[-.0368,2.9676]).

In study 2, we held package size completely constant while varying the resource inventory (number of servings). All participants were given a packet of Sport Beans® (caffeinated jelly beans); they

were asked to eat one serving of 5 Sport Beans® and to perform three cognitive tasks. We manipulated the quantity of servings in the packets prior to distribution: those in the single-serve condition received a packet containing 5 Sport Beans® whereas those in the multi-serve condition received a packet containing 15. Analysis of task performance for all three tasks replicated the pattern found in study 1: when PC was low, task performance was higher in the single-serve, 5-pack condition, than in the multi-serve, 15-pack condition. However, when PC was high, there was no difference in performance between the two package conditions. Further, perceived product adequacy exhibited a similar pattern: when PC was limited, perceptions of having an adequate quantity of Sport Beans® were higher for those in the single-serve ($M=5.36$) than in the multi-serve condition ($M=4.11$; $F(1,108)=10.61$, $p<.005$). However, when PC was high, there was no significant difference in perceptions of adequacy ($F<1$). Analyses of moderated mediation for each task revealed that perceived product adequacy mediated the effect of package format on task performance in the low but not high PC condition.

In study 3, given the inability to test the effects on actual efficacy experiences due to the nature of the utilized product (pain medication), we gauged product efficacy *expectations*. Participants imagined experiencing a painful headache. They were given a description of a popular OTC pain reliever—Advil®—and asked to imagine taking a dose of 2 tablets from either a 2-tablet travel-size packet (single-dose condition) or a bottle (multi-dose condition); an image was provided in both conditions. In line with the results of the previous studies, contrast analysis showed that in the low PC condition, efficacy expectations (5-items; $\alpha=.85$) were higher when participants imagined consuming the medication from the single-dose packet ($M=4.96$) than from the multi-dose bottle ($M=4.30$; $F(1,98)=4.59$, $p<.05$). However, in the high PC condition, there was no difference in efficacy expectations ($F<1$). Similarly, when PC was limited, perceptions of product adequacy (to relieve the symptoms) were higher for those in the single-dose ($M=5.19$) than in the multi-dose condition ($M=3.90$; $F(1,98)=6.53$, $p=.01$); in the high PC condition, there was no significant difference in perceptions of adequacy ($M_{\text{single-dose}}=4.08$ vs. $M_{\text{multi-dose}}=4.64$; $F(1,98)=1.23$, $p=.27$). Perceived product adequacy mediated the effect of package format on efficacy expectations in the low (CI [-.2254, -.0043]) but not high PC condition (CI [-.0139, .1417]).

Together, these studies document a new bias in which consumers rely on the quantity of servings within a package to infer whether a fixed amount (serving/dose) is adequate to produce the desired result. Accordingly, we introduce a previously unexplored antecedent to efficacy perceptions/experiences: feelings of (in)adequate consumption. Also, whereas prior work has shown how available resources may change consumption levels, this research demonstrates how available resources affect behavioral outcomes when consumption is *fixed*. We suggest that this research has implications for consumer health and well-being.

Present but Not Consumed: The Interaction of Assortment Size and Product Familiarity on Expected and Actual Product Efficacy

EXTENDED ABSTRACT

The use of performance-enhancing products (e.g., energy drinks) has been increasing rapidly over the past decade (Wong 2013), a trend accompanied by increasing numbers of health-related conditions related to over-consumption of these products (SAMHSA 2014). While knowledge of the physiological effects performance-enhancing products (PEPs) have on consumers is obviously critical,

it is also necessary to understand the psychological factors influencing consumption of PEPs, given that consumption depends heavily on perception and expectations (Hsee 1996; Shiv, Carmon, and Ariely 2005).

Building on extant research on the effect of expectations on actual product efficacy (Irmak, Block and Fitzsimons 2005; Shiv et al. 2005), this research contributes to our knowledge of the psychological influences of perceptions on experiences involving PEPs. Specifically, we examine how the number of products included in an assortment from which consumers take a product influences consumption experiences. In so doing, we show how an often-neglected but ubiquitous aspect of consumption—the presence of products that are *not* consumed in an assortment—affects the experience of consumption.

Extant research provides some insight into the ways that non-consumed products will impact product efficacy. Individuals often rely on quantitative heuristics as they evaluate products (Josephs, Giesler, and Silvera 1994; Pelham, Sumarta, and Myaskovsky 1994). One such quantitative heuristic likely implicated in expectation formation is the number of products available for consumption. Individuals often use the proportion, rather than the absolute amount, of material used or consumed as the basis for judgments of product efficacy (Silvera, Josephs, and Giesler 2001). When this proportion is higher, consumers perceive greater product effectiveness. Applied here, this implies that PEPs present but not consumed in an assortment will detract from the efficacy of consumed PEPs.

Importantly, however, we argue that individuals' familiarity with the consumed PEP will impact their product efficacy judgments and, hence, actual product efficacy. Specifically, we propose that a consumer unfamiliar with a PEP will form greater product efficacy expectations when more units of the PEP are present in the assortment. This is because when consumers are unsure of a product's efficacy, a larger assortment size will enhance perceived availability and, thus, credibility of the product, leading to greater expected and actual product efficacy. When consumers are familiar with the PEP, on the other hand, consuming one unit of the product from a large assortment will lower performance as the non-consumed units in the assortment will reduce the perceived proportion consumed. We test these predictions in three studies and find consistent support.

In our first study, we tested the impact of non-consumed products on performance for a highly familiar product: Red Bull energy drinks. We asked participants to imagine they were up late studying for an exam and decided to have a Red Bull. We showed participants a picture of a single can of Red Bull (vs. a 24-pack of Red Bull cans) and asked them to imagine they purchased (one of) the can(s) they were shown. We then asked the extent to which they believed their physical performance would improve as a result of consuming the can of Red Bull. As expected, individuals expected to derive a greater benefit from this familiar product when they imagined consuming a lone can vs. the can from a large assortment ($p = .05$).

Our second study built on study 1 in two important ways. First, we used a product that is familiar to some participants and less familiar to others. Second, we showed that actual behavioral performance, not only expectations, is affected by consuming energy-enhancing products taken from small vs. large assortments. To achieve these goals, we asked participants to consume a single Gatorade Energy Chew (a relatively new product at the time of the study) taken from a baggie containing either one single chew or six total chews. After consuming the chew, participants completed two measures of performance, one requiring speed and accuracy (correctly identifying the number of dots shown on a screen in under two seconds) and the other drawing more on cognitive resources (rearranging letters

in a 10-letter word to form new words). After completing the tasks, we asked participants how familiar they were with Gatorade Energy Chews (1 = *not at all familiar*; 9 = *extremely familiar*). We expected that individuals who were familiar with the product would show better performance in the single-chew condition, while less familiar individuals would show better performance in the six-chews condition.

Results on both measures of performance supported our expectations. Participants' score on the word task showed a significant 2-way interaction between condition (1 vs. 6 chews) and mean-centered product familiarity ($p < .05$): Participants more familiar with the product performed better in the 1- vs. 6-chew condition, while the opposite pattern was observed for less familiar individuals. Similar 2-way interactions were seen on participants' reaction times (2-way interaction $p = .05$) and the number of correct responses on the dot task (2-way interaction $p = .08$).

Finally, in study 3 we extended the generalizability of the effect by using a different type of "product": classical music. Research on the "Mozart Effect" suggests that listening to classical music can enhance performance (Angel, Polzella, and Elvers 2010). We thus asked participants to listen to a 4-minute composition by Mozart that was either accompanied by five other song titles on the screen or not. After listening to the song, participants completed a different measure of performance. Afterwards we asked whether or not participants had heard of the Mozart Effect before the study. As expected, a significant 2-way interaction ($p < .05$) showed that, for participants who had (had not) heard of the Mozart Effect, performance was better when the song they heard was the only (one of six) song(s) presented on the screen.

Together, these studies show that consumption and product efficacy experiences are not only affected by what *is* consumed, but also by what is *not* consumed. These results have both practical (e.g., packaging considerations, particularly for new product introductions) and theoretical implications in the areas of food consumption, numerosity, and product efficacy.

In Pieces:

Food Is More Filling when Served in Several Pieces

EXTENDED ABSTRACT

Would eating a bagel cut into pieces make it more filling? Satiety, or the sense of how full one is, is driven by psychological, as well as physiological, factors (Wansink 2007; Redden and Galak 2013). People feel full or empty, and assess their need to eat more, based not only on how much they've eaten, but on external cues as to quantity eaten, as well on their perspective regarding the meal, for instance whether it counts as a meal or a snack (Wansink et al. 2010). Broadly speaking, if people *think* they ate a more substantial meal, they feel fuller.

Eating behavior in general is affected by external cues (Wansink 2004). People clear off the food from their plate, and take the amount of food on the plate to imply the quantity they should eat. Accordingly, while there is food on the plate, people tend to continue eating (Wansink et al. 2005). Accordingly, eating from bigger containers tend to lead to increased consumption (Young & Nestle 2002; Wansink & Kim 2005).

Such behavior may be partially driven by perceptual distortions, whereby people's judgment of the size of their meal is affected by contextual variables such as how big the food portion appears relative to their plate (van Ittersum and Wansink 2012). Labeling products as larger can also lead people to think that they are eating more. Thinking that less was eaten can in turn lead people to consume more food (Aydinoğlu & Krishna, 2010).

The perception of quantity can affect not just how much one would eat, but their sense of psychological satiety (Redden and Galak 2013). For example, seeing one's leftovers may serve as an indication as to how much one has eaten, increasing satiety (Wansink 2007). Even cues to quantity eaten that do not in fact indicate how much one has eaten may lead to increased reported satiety (Tal and Wansink 2014).

In the current work we explore the notion that the number of units one thinks they have eaten affects their satiety. A prior study (Wadhera et al. 2012) found that having a bagel cut into 4 pieces led to decreased food consumption in a subsequent meal compared to eating a bagel whole. The authors conjectured that perceptions of the volume of the bagel on the plate increased satiety. A bagel cut into 4 pieces fills the plate to a greater extent, leading to increased volume perception, and consequently a sense that one has eaten more.

In the current study, we examine whether volume perceptions indeed affect satiety by providing an additional condition. In one of our 4-piece conditions the bagel is spread across the plate, to fill up more volume. In another, the pieces of the cut bagel are kept together. We conjectured that it is the perception of number of units eaten, rather than volume perception, that increases satiety, and that spacing the pieces of the bagel, rather than increasing satiety, would in fact reduce satiety since it makes the size of the bagel pieces appear smaller. We also employed a direct measure of felt satiety, rather than consumption in a subsequent meal.

Participants (N=43) were randomly assigned to one of three groups. All groups ate a mini bagel with cream cheese in a lab setting. One group got the bagel in one piece. The other two groups got the bagel cut into four pieces: for one group pieces were spread out on the plate, and for another the pieces were kept together. Participants reported on their fullness across 3 measures: hunger, fullness, and satiation, all measured on 9 point likert scales. They reported fullness before and after eating the bagels. We created a summary satiety score, and calculated the difference score between pre and post eating fullness as our dependent measure.

Increased satiety was highest when participants received the pieces close together (4.77). Satiety was higher in this condition than when participants received the bagel whole (3.75). However, receiving the 4 pieces spread apart led to reduced satiety (2.18). Differences were significant at a .04 level: $F(2,41)=3.26$. Participants report greater satiety when eating a food cut into several pieces, but only when those pieces are close together.

This result was subsequently replicated with a larger sample (N=72). In this study, we examined whether liking for the bagel moderated our results. Liking was measured on a 9-point likert scale. We analyzed results in a GLM model with difference in satiety as the dependent measure, and bagel condition, rated tastiness, and the interaction of the two as independent variables. There was a significant effect of condition on satiety: $F(2,64)=4.21, p=.02$. Having the bagel cut to 4 increased satiety (3.29) relative to eating the bagel whole (2.63). Those who received the cut bagel spread on the plate reported the least increase in satiety (1.72). There was also a marginally significant interaction of liking and condition: $F(2,64)=3.02, p=.056$. Those who expressed greater liking for the bagel were less influenced by condition.

Together, the studies attest that food is felt to be more filling when eaten in several pieces. However, the effects of eating the food in pieces are mitigated if the pieces are spread apart such as the serving appears smaller (each piece would appear smaller when separated from the others, creating an overall appearance of a smaller serving). In other words, it appears that eating more pieces increases satiety, as long as the perception of volume is maintained.

Further research should corroborate the mechanisms behind this phenomenon. For example, research could measure consumers' self-reports of perceived volume of the serving as well as quantity eaten. Research could also examine whether the effect increases as the number of servings increases. Finally, research could examine whether splitting the pieces but keeping them in close proximity such that the gestalt appears larger would enhance, rather than decrease, the effects of cutting.

These findings have clear implications for public health. Serving food in pieces would create a sense of increased satiety. This would allow consumers to feel full with less food, reducing consumption.

SESSION OVERVIEW:

The papers in this session explore the issue of marketplace access for stigmatized consumers. More specifically, they examine access in transition. Capturing moments of access is consequential, as these instances represent the attainment of more equal terms in society often following prolonged histories of exclusion and devaluation. Stigmatized consumers, or those possessing a discrediting attribute that taints or discounts (Goffman 1963), often face marketplace neglect, or even explicit rejection (Coskuner-Balli and Thompson 2013, Scaraboto and Fischer 2013, Adkins and Ozanne 2005, Sandikci and Ger 2010). Our session spans the experiences of transgender individuals, multiracial families, same-sex couples, and feminists who face various levels of exclusion from the marketplace. As the works in this session demonstrate, however, marketplace access is often evolving and at times even increasing for marginalized consumers. Focusing attention toward these situations of increased access enables exploration into the processes and players that shape these transitions as well as consumers' diverse responses to marketplace evolution.

Situating stigmatized consumers within their institutional environment, these works join others to explore how shifting social systems composed of rules (regulatory), morals (normative), and understandings (cultural-cognitive) impact legitimacy (Arnold, Kozinets, and Handelman 2001; Handelman and Arnold 1999; Humphrey 2010a, 2010b, Sandikci and Ger 2010; Scaraboto and Fischer 2013). Efforts to acquire legitimation—"a generalized perception or assumption that the actions of an entity are desirable, proper, or appropriate" within a particular context (Suchman 1995, 574)—can (but do not always) result in increasing marketplace access, which raises important questions: 1) How does the institutional environment (influence consumer legitimacy and shape marketplace access for stigmatized groups? To what extent do the different forms of legitimacy – regulatory, normative, cultural-cognitive – impact evolving access? 2) Does greater legitimacy necessarily result in greater marketplace

access? What factors complicate this relationship? Taken together, the papers address these questions by looking at the relationship between access and legitimacy. Paper 1 (Velagaleti and Epp) studies the recent unprecedented shifts in public opinion and regulatory gains around same-sex marriage, the subsequent increased attention from the marketplace, and same-sex couples' responses to this increased access. In contrast, Paper 2 (Harrison, Thomas, and Cross) examines how multiracial families with long-established regulatory gains can still face such limited marketplace access, owing to slow progress in achieving cultural validation as a family form. Paper 3 (Crosby, McKeage, and Rittenburg) investigates how transgender individuals with limited legitimacy in all forms and almost non-existent marketplace representation still find moments of temporal reprieve, when their social transgression is condoned or even celebrated. Lastly, Paper 4 (Coleman and Tuncay Zayer) looks at discursive access, tracing how stigmatizing associations have called into question the legitimacy of feminism, resulting in constrained accessibility to feminist discourse in the marketplace.

In the spirit of the conference theme, "advancing connections" these papers promote an intersectional approach to understanding marginality in society, by considering various aspects of identity across papers – gender, sexuality, and race. Similarly, our discussion will focus on looking across papers to think more broadly about how forms of legitimacy and stigmatized identity shape marketplace access.

Pursuing Marriage Equality in the Marketplace: Stigmatized Consumers' Responses to Mainstream Marketplace Access

EXTENDED ABSTRACT

Stigmatized consumers, or those possessing a discrediting attribute that taints or discounts (Goffman 1963), often lack access to the mainstream marketplace. Examples include limited plus-sized clothing options (Scaraboto and Fischer 2013) and scarce childcare accessories for at-home fathers (Coskuner-Balli and Thompson 2013). As "a social process implicated within relations of power" (Sandikci and Ger 2010, 17), however, stigma's status or impact can change with a shift in the beliefs of powerful groups or by altering power dynamics that allow these groups "to make their cognitions the dominant one" (Link and Phelan 2001, 381). The marketplace – as a domain where power is reproduced and contested – is not immune to these changes (Sandikci and Ger 2010, 17). More specifically, a stigmatized population or practice, once restricted from the mainstream marketplace, can gain increasing access.

An example can be found in the context of same-sex couples' pursuit of marriage. Although those who identify as lesbian, gay, bisexual, and transgender (LGBT) have faced prolonged stigmatization, a cultural shift has occurred in the past decade, reflected in part by increased public support for the legalization of same-sex marriage as well as legislative action to secure it (Freedom to Marry; McCarthy 2014; Pew Research). Public backing and regulatory victories alter the power dynamics and lessen the ability and desire of dominant parties to enforce stigma through institutional channels, including the marketplace. One implication of these power shifts is increased

marketplace access for same-sex couples as marketers respond to a commercial opportunity around marriage.

This study explores shifting access through two central questions. First, how do stigmatized consumers interpret and respond to newfound access? Specifically, what diversity exists within their perceptions and actions? Second, how might the heterogeneity within a stigmatized group contribute to variation in responses to access? In terms of capital or resources, while LGBT consumers as a whole arguably still lack its symbolic form (e.g. social recognition, status), other varieties (cultural, social, and economic) exist, though differentially distributed among its members. Bourdieuan applications in consumer research explore how differences in distributions of capital within marginalized communities impact their marketplace experiences and coping mechanisms (Adkins and Ozanne 2005; Coskuner-Balli and Thompson 2013; Saatcioglu and Ozanne 2013; Scaraboto and Fischer 2013). We extend this work by exploring the impact of resource heterogeneity in contexts of mainstream access. In line with this focus on heterogeneity, we also incorporate stigma theory and its mechanisms – such as discrimination – to ensure recognition of how same-sex couples generate intragroup diversity in the understanding, experience, and impact of a stigmatized identity.

Using in-depth interviews with 30 same-sex couples with varying responses to access (e.g. receptive, ambivalent, or resistant) and ethnographic observation at wedding expos, we developed a theoretical framework that demonstrates how within-group heterogeneity generates diversity in responses to increased marketplace access. More specifically, it details how heterogeneity in individual experiences with tensions, stigma identity, and social capital impact consumers' responses. The framework conceptualizes increasing access as a continuum, with earlier periods being typified by inconsistency. Marketplace visibility is constrained to socially legitimized aspects of the community. Service provision is restricted, as it is often unclear which vendors are willing to serve stigmatized consumers and rejection is common. Product and service offerings remain dominant-group-centric, and updates to marketplace infrastructure (e.g. forms) and prior logics (e.g. heteronormative and gender-normative assumptions) are neither automatic nor uniform.

Responses to access include consumers' approaches to the marketplace and reactions to constraint. Consumers describe engagement with the marketplace as a constant "coming out" to vendors, and vigilance is exerted to minimize experiences with discrimination or rejection. For instance, consumers avoid unfamiliar retailers, choose not to disclose their stigma status, assess a retailer's position before disclosing, or simply prepare for rejection. Another aspect of approach is the types of resources utilized. Despite being seen as marginalizing, mainstream resources are heavily leveraged to normalize same-sex couples' performance of marriage. In contrast, "alternative" (not limited to LGBT-specific) resources are utilized by those in search of non-traditional ideas and are presumed to be more accepting. Variation also exists in consumers' reactions to constraint, including strategies such as correcting vendors through education, affording marketers the opportunity to "recalibrate," discontinuing use, accepting limitations as a product of early-stage access, ignoring constraint, or compensating for resource deficiencies.

Diversity in responses to access is, in part, the result of heterogeneity in individual experiences of tensions, stigma identity, and social capital. For instance, tensions – including liberation from tradition versus desire to normalize (Tension 1) and celebrating visibility versus apprehension in disclosure (Tension 2) – shape which resources are used as well as a consumer's approach to their use (e.g. decisions to disclose stigma status or correct). In addition, how one experiences a stigma identity – the result of an individual's unique

history of discrimination along with his/her interpretations of the label (e.g. liability) – shapes expectations of marketplace treatment and the degree of caution exercised. Lastly, social capital protects, facilitates, and legitimizes in the context of increased marketplace access. It protects through identifying inclusive vendors. It facilitates by securing resources not readily available in the marketplace. Lastly, it legitimizes through others' recognition and collaboration. Social capital also connects to stigma identification, with support combatting fears of rejection, while its absence reinforces them. Social capital can also motivate tensions around normalization, encouraging inclusion of traditional practices or objects in order to create a "relatable" ceremony. Within-group variability in response to access has consequences. More assertive approaches generate visibility for consumers as well as the privilege to provide marketplace instruction on how to cater to stigmatized entrants. This finding reflects Bourdieu's (1986) idea of the logic of representation, as more assertive consumers shape the marketplace's perception of the greater "LGBT consumer." It also suggests what Goffman (1963) terms codes or "certain standard manners" that define the "desirable pattern of revealing and concealing" (109) – in this case, how consumers and marketers can "appropriately" handle marketplace access.

Problem or Opportunity: Marketplace Access and Legitimacy for the Multiracial Consumer

EXTENDED ABSTRACT

"*Loving* [vs. Virginia case] marks the moment when our families, families that transgress law and the color line, became legitimated, permissible, cognizable dimensions of our national landscape. *Loving* said something powerful and new about our parents and the choices they had made about whom to love and with whom to make a family." (Professor Martha S. Jones, University of Michigan, Michigan Law's Martin Luther King Jr. Day lecture, 01/19/2015)

The struggle to legitimize multiracial identity has been long and arduous. However, in recent years we have witnessed several gains towards legitimation. In 1967, anti-miscegenation laws in the U.S. were overturned by the Supreme Court ruling in the landmark *Loving vs. Virginia* case, which declared that all US couples could marry regardless of their racial backgrounds. This case provided regulative legitimacy to multiracial couples (Scott 1995). In 2000, regulative legitimacy was extended to the offspring of multiracial couples when the U.S. Census expanded its racial categorization system to include a multiracial option. Since the Census change, the Selig Center for Economic Growth, which tracks the buying power of several U.S. consumer segments, has also begun to do so for multiracial Americans. Recent Selig Center data states that there are more than nine million multiracial Americans that hold a combined buying power of \$161 billion. The tracking and reporting of such data provides multiracial individuals with newfound cultural-cognitive legitimacy, as they are collectively represented as a viable consumer segment.

Even with these achievements, it is debatable whether members of multiracial families have achieved full marketplace access and legitimacy as consumers. According to Professor Martha Jones (2015) co-director of the Program in Race, Law and History at the University of Michigan, who grew up in a multi-racial household: "There will be more anecdotes and ways to think about how courts, legal culture, and our culture at large think about and grapple with the fact, the possibility, the problem that mixed-race people represent." The virulent online comments against the 2013 Cheerios commercial featuring a Caucasian mother, African-American father, and their biracial daughter raised concerns that many in society still deny full legitimacy to multiracial individuals and their families. Over the

past decade and increasingly in the last few years, when attempts are made to recognize this consumer segment, there is still considerable consumer backlash. Thus, it is clear that while multiracial individuals have made significant strides in attaining regulative legitimacy, they continue to struggle to gain normative and cognitive/cultural legitimacy in the marketplace and society at large.

Full legitimization of multiracial groups may bring with it a range of public policy and marketplace issues. For instance, adoption of multiracial as a legitimate racial category by government entities (e.g. US Census) has impacted how governmental funds and resources are distributed, particularly among racial/ethnic minority populations (Williams 2006). Additionally, representation of multiracial consumers in commercial media can be problematic. Due to the ubiquitous nature of marketing communication, if marketers utilize a narrow range of phenotypic characteristics and body types when representing multiracial populations, a myopic and essentialized understanding of who is (and is not) multiracial can result. Such a situation could not only negatively impact the development of multiracial individuals who reside outside the narrowly constructed boundaries of “multiracialness,” but may also affect their consumption behavior and overall retail experience in adverse ways. Thus, from a broader societal perspective, multiracial individuals’ socialization experiences as consumers and members of society may differ markedly from the experiences of their mono-racial counterparts. It is therefore even more important that we understand how multiracial consumers learn and, by their very presence, define the expectations of marketers, retailers, and public policy administrators.

This paper explores the experiences of multiracial consumers in this paradoxical environment. We ask the following key research questions: 1) What are multiracial consumers’ perceptions of current marketplace practices? 2) What is the experience of multiracial consumers and their family units as legal recognition transfers to marketplace legitimacy and societal acceptance? We focus on adult female offspring of multiracial unions. We employ a phenomenological approach emphasizing their lived experience both individually and within their family units, by studying “the totality of human-being-in-world” (Thompson et al. 1989, 135). We conducted interviews with 21 mixed-race women between the ages of 19-25. “Mixed race” was defined as having both a black and a white U.S.-born parent. Socio-historically, this racial combination maintains the highest level of social juxtaposition and therefore offered the greatest opportunity to investigate the dynamics of multiracial identity development (Rockquemore and Brunnsma 2008). Interviews spanned 60-75 minutes, were audiotaped and transcribed, and were analyzed following phenomenological procedures (Moustakas 1994).

Findings reveal that in spite of legal and census policy changes which have attempted to remove societal and marketplace barriers, longstanding views make such emancipatory policies particularly complex for the multiracial consumer. While multiracial consumers may be members of the U.S. multicultural marketplace, their lived experiences, socialization processes and perception by society make them different from others who share the same multicultural classification. The process of constantly moving between two disparate worlds, not fully accepted by either, may cause some individuals to focus their efforts on one world or the other. In an attempt to successfully navigate between their heritage backgrounds, multiracial individuals consume (or eschew) the symbolic value of marketplace commodities, using brands and marketplace access to enhance (or suppress) association with specific aspects of their racial backgrounds. For example, identity markers, such as uniquely textured hair, which we coin “the mighty ringlets,” emerge as a key visual representation of multiracial identity for the vast majority of infor-

nants. For this particular identity marker, hair products and self-help hair care books, specifically marketed to and for multiracial women, legitimize their liminal racial space.

Marginalization, Resistance, and Stealth Shopping: Subalternity in the Gendered Marketplace

EXTENDED ABSTRACT

The concept of gender is socially constructed and pervasive (West and Zimmerman 1987). Gendered products and services include clothing, hairstyles, cosmetics, bags (totes, purses, etc.), colors, toys, and books. Within the dominant social discourse, individuals are expected to conform to the gender norms that are associated with their biological sex. People that violate this norm often experience stigmatization (Gagné and Tewksbury 1998, Kosenko et al. 2013). They are devalued and face social exclusion in many aspects of their lives, including the marketplace. In this research, we explore transgender consumers’ experiences in the market by addressing the following research questions: (1) How does the market marginalize transgender consumers? (2) How do these individuals cope with this marginalization?

Transgender is “an umbrella term for people whose gender identity differs from . . . the sex they were assigned at birth” (GLAAD 2013, 1). We conducted 24 depth interviews with informants having a wide range of gender identities. For the purposes of this research, we focus on those who identify as the opposite gender from what they were assigned at birth. Respondents also constructed collages depicting their gender identity. The interviews generated more than 775 pages of text along with 24 collages. In analyzing the data, we searched for emergent themes while engaging in dialectical tacking (Strauss and Corbin 1998).

Our findings concerning how the market marginalizes transgender consumers echo Baker, Gentry, and Rittenburg (2005) who argue that consumers can experience powerlessness in multiple marketing contexts. Many of our informants perceived the market as unfriendly, and reported four major areas of marginalization: (1) products, (2) service, (3) retail space, and (4) advertising. In the product area, informants discuss having limited options. For example, transgender consumers often have difficulty finding clothing and shoes in appropriate sizes. Clothing is a significant factor in communicating gender, so limited product options can stifle consumers’ ability to express their identity. Service providers also play a key role in market experiences. Informants report that service providers have treated them poorly in the marketplace after realizing that they are transgender. For example, a store employee insisted that one informant try on clothing in a back room rather than the store’s dressing room. Others report salespeople making fun of them and in some cases calling them derogatory names. Informants also discuss how the retail space itself is uninviting and in some cases hostile, with accessing the correct gendered spaces safely (such as bathrooms and dressing rooms) being a constant struggle.

Lastly, media and advertising can marginalize transgender consumers. Advertising significantly contributes to the social construction of gender (Pollay 1986). Informants point out that these stereotypes are difficult to meet, making it even harder for them to be accepted as their true gender. The need to conform in order to have one’s gender read correctly has implications for discrimination, harassment, and personal safety. Therefore, some of these consumers can be extremely susceptible to marketing promises of fitting in and looking “right.”

Marketplace marginalization can leave transgender consumers feeling powerless and as if they do not belong. Informants often dis-

cuss being devalued and discriminated against. Related to Baker et al.'s (2005) regulating emotions, some informants report trying to use marginalizing episodes as teaching opportunities, especially with service providers. However, having to constantly do this is exhausting for many who do not want to have to always defend themselves. Often due to the marginalization, transgender consumers withdraw from the market. In some cases, this can be seen as a form of resistance. Similar to other findings, these consumers actively work to escape the restrictive and in some instances oppressive marketplace (e.g., Murray and Ozanne 1991, Firat and Venkatesh 1995, Kozinets 2002). They may band together to fulfill their consumption needs within the gender nonconforming community. It is important to note that these individuals are not just resisting the market because they find it exploitative or restricting in general; they are resisting at least in part because of the significant marginalizing practices.

Informants also use other adaptive strategies to cope with the marginalization. Some transgender consumers engage in stealth shopping. For example, several informants discuss shopping for clothing around Halloween when an individual perceived as male can buy women's clothing (or vice versa) without fear of stigmatization as it could be a costume. What is generally seen as a gender transgression becomes legitimated by society. Informants discuss the immense relief to be able to purchase items without the cloud of stigmatization over them during this temporary window of time. Many also make purchases online for access to a wider range of sizes and to limit market interaction where they are constantly misgendered. While the Internet may provide a safe place, it also further isolates these consumers from the bricks and mortar marketplace and increases feelings of disenfranchisement and dissatisfaction. These negative feelings and responses to the marketplace can also increase feelings of marginalization.

Transgender consumers' negative responses seem especially regrettable given that in many cases the issues that these consumers encounter in the market do not have to be there. They are, rather, a result of relatively unthinking and unquestioned habits and assumptions. Currently, the market is starting to manifest shifts toward gender-free spaces and products that respond in a more thoughtful manner. Ultimately, transgender consumers ask marketers to think, question, and change the marketplace in ways that are more inclusive and will benefit all consumers.

Ban the Word Feminist? Control and Subversion of Stigma in Social Movements and Consumer Culture

EXTENDED ABSTRACT

The feminist label, with its contested meanings (Bennett 2014; McRobbie 2008), has long carried a stigma that is deployed to discredit (Goffman 1963) those identified as feminists and the underlying tenets of feminist movements (Lind and Salo 2002; Jaworska and Krishnamurthy 2012). In a 2014 poll, *Time* magazine proposed a ban on the word "feminist," arguing it had become a celebrity buzzword. With help from online anti-feminist campaigns, "feminist" was winning (Merlan 2014). This example evokes enduring discourses surrounding the "feminist" stigma. For years, high-profile women from entertainers Madonna, Beyonce, and Taylor Swift to Supreme Court Justice Sandra Day O'Connor, despite supporting gender equality, would not "cop to the F-bomb" (McDonough 2013). Yet some of these same women—Beyonce and Taylor Swift to name two—have recently labeled themselves feminist (Bennett 2014; Thomas 2014), a move some have argued legitimizes feminism for the masses (Bennett 2014). These discourses are further reflected in consumer culture and marketing. A recent *Ad Age* article argues social media has

facilitated change, and marketers "now subject to the social media jury" are "challenging cultural norms and notions about how we talk about—and to—women" (Zmuda and Diaz 2014). Yet despite recent attention to empowerment marketing, go-girl marketing, and femvertising (Davidson 2015), "marketers are being careful not to label themselves or their marketing messages as feminist" (Zmuda and Diaz 2014). In this way, possibilities have opened up for conversations about feminism, yet "feminism" as a label may be restricted in discourses and representations in marketing.

Drawing from Kozinets's (2010, p. 39) argument that "online communities change the way that people seek to change their world," we examine transition in discourses on feminism through communicative acts that consumers perform online. In the context of social media, which has been touted as a democratizing force, and stigmatization, which involves power and dis/empowerment (Sandikci and Ger 2010; Kozinets 2001), we examine stigmatization and subversion in communicative acts surrounding discourses of feminism. We ask: To what extent do different forms of legitimacy influence evolving access to feminist discourses and representations online? What is the nature of discourses and representations evident in these communicative acts?

Following Kozinets's (2010) recommendations on netnographic analysis, we examine two sets of online conversations, both emerging feminist discourses. One is in the context of American socio-political events and the other in the context of a brand. The Twitter movement #YesAllWomen initially sought to bring attention to violence against women in response to the May 23, 2014 killing spree by a young man near the University of California Santa Barbara campus. Before killing himself, the shooter posted a YouTube video discussing his hatred towards women who rejected him, among other things. #YesAllWomen morphed into a larger movement seeking to highlight the ubiquitous sexism that all women face in their daily lives and in part to counter #NotAllMen ("not all men are like that"). Within five days, there were one million tweets using #YesAllWomen. We collected over 750 tweets using the hashtags #YesAllWomen and #NotAllMen in the days following the California shootings, which feminist voices such as Rebecca Solnit (2014), activist and contributing editor at *Harper's Magazine*, called a "watershed moment in the history of feminism."

In June 2014, the brand Always launched their Like a Girl campaign. The brand sought to tackle negative connotations surrounding the phrase "like a girl" (e.g., throwing like a girl), while also utilizing the hashtag #likeagirl. Their agency Leo Burnett later placed the ad during Super Bowl 2015, where it garnered significant media attention. We collected more than 2,300 tweets during the first five days of the launch of the original campaign and immediately following Super Bowl spot. Additionally, we collected more than 800 tweets using the hashtag #likeaboy. #likeaboy emerged online shortly after the Super Bowl and was reported to be a response by some men who found #likeagirl to be "exclusionary and sexist" (Chittal 2014), reminiscent of arguments stigmatizing feminists as "man-haters" (Cavanagh 2014).

Our initial analysis of both sets of data reveals the emergence of online voices who employ stigmas as a way to control and divert the conversation, a tacit others claim (e.g., Zimmerman 2014) that is a common response to feminist arguments. With regard to institutional forces, while substantial legal measures regulate various levels of marketplace participation for women in some areas of the world (e.g., Coleman 2012), cultural-cognitive and normative forces are utilized to regulate feminist dialogue in both the socio-political events surrounding #YesAllWomen and Always's branding campaign with #likeagirl. Yet we find that attempts to participate, and

to some extent control, discourse go both ways. Where #likeaboy was used to control the conversation of cultural gender norms, the #YesAllWomen movement was in part a response to the #NotAllMen discourses that position sexism as an individual issue, rather than a structural and institutional one. It is, in part, a collective effort (Scaraboto and Fischer 2010) in an emergent online conversation to subvert stigma. Our analysis of #likeagirl/#likeaboy considers previous critiques that the prevailing message of consumer culture is anti-feminist (McRobbie 2009), taking feminism “‘into account,’ while simultaneously dismissing it” (Myers 2013, p. 198). Thus, feminist language is given attention and simultaneously marginalized. Understanding stigmatization of and subversion through feminist discourses in the two online environments in this study is important for several reasons. Scholars note that media help fashion gender role norms (Jhally 1987). Moreover, emergence of social media has altered the manner in which people seek to change the world and how they serve as social agents of change (Kozinets 2010, p. 39). Exploring stigmatization and legitimization of feminist discourse merits attention, particularly for consumer researchers as feminism has received renewed attention (Shirk 2014) from the market and brands are embracing female empowerment discourses for the 21st century. Research should examine whether online social movements and brand discourses evoking variations of feminist themes (e.g. go-girl marketing, femvertising) affect substantial social change as individuals engage with them on social media.

SESSION OVERVIEW

Consumers face uncertainty in a wide range of choices that they encounter daily. Some of these reflect risks, in which people are well informed about the likelihoods of possible outcomes, though those outcomes are uncertain. Others involve ambiguity, in which people have little, or incomplete, information about a situation with uncertain outcomes. It is well known that consumers find many instances of such uncertainty and/or ambiguity aversive, making these decisions difficult and frustrating. This can lead to an array of biases, or even simply avoidance of important choices in uncertain realms. The papers in this session explore the mechanisms underlying uncertain decision-making, how they change with experience, and how they impact real (incentivized) choices. Specifically, we seek to address the following questions: (i) do simple measures of decisions under uncertainty like loss aversion predict real world decisions? (ii) how do consumers use information to reduce uncertainty across various situations, and (iii) how they might learn from their experiences to improve the quality of decisions.

The first paper from Payne and colleagues explores loss aversion as a key construct that predicts how individuals react to uncertainty. They show that a simple measure of loss aversion reliably predicts consumer financial preferences for retirement savings investments, Social Security claiming, and life annuity preferences. In the second paper, Karmarkar and Peysakhovich examine how people incorporate partial or incomplete information as it is added in uncertain situations, depending on its valence. Though loss aversion might suggest that individuals give more weight to unfavorable information, they find that people appear to overweight favorable information when estimating the worth of uncertain financial prospects. Notably, this net behavioral effect arises from a complex set of mechanisms involving how information impacts *feelings* of certainty.

While adding information can be seen as one type of “updating”, Venkatraman and colleagues demonstrate the adaptive nature of decision-making across decision contexts using eye-tracking. They

show that the decision-making strategies are consistent even for decisions under ambiguity, where individuals have to learn the underlying probabilities through experience. In the final paper, Hsu and colleagues take a neural perspective on adaptive types of changes, also focusing on how people behave in dynamic situations where ambiguity can be reduced over time. Using fMRI, they show that the updating process involves more cognitive regions unlike traditional decisions under ambiguity, which have been associated with more emotional processing.

This session will appeal to researchers interested in motivation, goals, situation/context effects, and self-control as well as risk and uncertainty. In accordance with the “Advancing Connections” conference theme, these papers bring together data from a wealth of methodologies including laboratory experiments, eye-tracking, large-scale field surveys, and neuroimaging to better understand the processes involved in decision-making in uncertain situations and the dynamics of how these processes develop and change with experience over time. As such, these findings have important implications for designing choice architecture in used in marketing and public policy. They additionally speak to issues regarding the welfare of individual consumers, particularly in the realm of consumer financial decision-making.

Development of an Individual Measure of Loss Aversion

EXTENDED ABSTRACT

Many of the complex, and difficult, consumer financial decisions we face such as choices for mortgages, health insurance, and when to collect Social Security benefits involve options that have multiple “mixed” outcomes in the sense that there is both risk of loss and opportunity for gain. A key concept in explaining such decisions is loss aversion. Kahneman (2011) defines loss aversion in terms of the direct comparison of gains with losses - the idea that “losses loom larger than gains” - and makes it clear that individuals will differ in their loss aversion. For marketers of financial services, or public policy experts who may wish to nudge individuals’ risky decisions, having a simple and easy to use individual loss aversion measure is useful for customizing their advice.

Given the importance of loss aversion in explaining behaviors, several approaches for measuring it at the individual level have been developed. Most of the approaches assume an underlying model of decisions under risk (Kahneman & Tversky, 1979), and use simple 50:50 two-outcome gambles. While sophisticated model-based estimation techniques have much to recommend them, we offer an alternative approach that is model-free and based on choices made between slightly more complex mixed three-outcome gambles. In particular, our loss aversion measure is based on ideas presented in Brooks and Zank (2005). They offer several reasons for adopting a more model free approach to measuring loss aversion, including the avoidance of 50:50 gambles; we also note that a choice between two options differing on two dimensions of value (gain versus loss) evokes more System 2 thinking (Kahneman, 2011). Many important “real-world” consumer decisions under risk involve more than simple two-outcome gambles.

To obtain a precise measure of individual differences in degrees of loss aversion we present participants with a series of gamble

choices. Participants are asked at each step to choose between two mixed three-outcome gambles, A and B. Each gamble has one positive outcome at 45% chance, a zero outcome at 10% chance, and one negative outcome at 45% chance. We find, for example, that most respondents (often above 70%) express some degree of loss aversion by preferring a loss averse (LA) gamble (\$400, .45; \$0, .10; -\$400, .45) to a matched gain seeking (GS) gamble (\$600, .45; \$0, .10; -\$600, .45). Building on this base gamble, we go beyond prior literature and systematically change the amounts to be gained (or lost) for either A or B in each pair. The different pairs of gambles with different levels of gain vs. loss tradeoffs are presented to the respondents in random order. The ultimate result is that this series of simple paired comparison choices yields an overall measure of loss aversion per participant.

We report on the results of a meta-analysis that tests this measure of loss aversion with over 7,000 participants from online studies with national survey panel companies. All of the results presented are for respondents whose choices satisfy first-order stochastic dominance. We focus on four main questions: (1) whether the individual measures of loss aversion collected from participants match the typical overall distribution of loss aversion found in other studies; (2) how individual loss aversion measures correlate with other individual differences such as gender, age, and time preferences; (3) whether these measures are predictive of other behaviors and choices, especially within the realm of consumer financial decision-making; and (4) the predictive power of our loss aversion measure relative to traditional measures of risk taking.

To summarize our results, we find that the overall pattern of loss aversion scores we collected is consistent with the results found in other studies. We check robustness by testing the measure with different probability values; the similarity in responses across different probability amounts suggests that respondents are focusing on comparisons between gain and loss amounts and not simply expected value differences. Next, we find that other individual differences are correlated with our loss aversion measure in meaningful ways, such as females indicating higher loss aversion. More importantly, we find that this choice-based loss aversion measure is highly predictive of a range of expressed preferences for financial decisions. For example, we consistently find that higher levels of loss aversion predict individuals' preference for claiming Social Security benefits early. We also find that loss aversion is predictive of decisions about retirement savings, life annuities, and investment preferences, such choices between bond and stock funds.

Lastly, we have studied the predictive power of our loss aversion measure against other traditional measures of risk taking. In an online study with 99 participants, we tested risk likelihood and risk perception for a series of gambles under different choice brackets (narrow, broad) and gamble types (positive EV mixed, negative EV mixed, and strictly negative). We then collected individual measures of loss aversion via our nine-point scale, loss aversion using the DEEP measure (Toubia et al 2013), subjective risk aversion, and a measure of risk aversion from the economics literature (Kapteyn & Teppa 2011). We find that our loss aversion measure is significantly positively correlated with the DEEP loss aversion measure ($r=.35$, $p<.05$). On the other hand, it is not significantly correlated with either subjective risk aversion ($r=-.04$) or economic risk aversion ($r=-.20$) measures, suggesting that loss aversion is capturing a different construct from risk aversion. Importantly, our loss aversion measure has a significant negative effect on choosing to gamble ($B = -0.07$, $p = 0.03$) across all gamble choices, even after controlling for risk perception (the greatest predictor of risk-taking in the extant literature). This finding suggests that our loss aversion measure has predictive

value over and above what risk perception captures; specifically, it suggests that loss aversion measures aspects of risk-taking preference that are not completely captured by subjective beliefs about the level of risk in a financial gamble. Many financial services firms currently employ generic risk perception questions when working with new clients; this new loss aversion measure offers them the ability to gather individual information that is more predictive of actual financial choices.

Biases in Using Information to Evaluate Uncertain Financial Prospects

EXTENDED ABSTRACT

Consider a trader contemplating the value of a stock, or an individual choosing where to invest a windfall. Often they have *some* relevant favorable and unfavorable information, but their overall knowledge is incomplete. Unlike risky situations, in which the likelihood of a good vs. bad outcome is known, ambiguous situations like these arise from uncertainty about outcome probabilities (e.g. Ellsberg 1961). Since people are disproportionately averse to losses and negatives in general (e.g. Kahneman and Tversky 1979; Baumeister et al. 2001; Rozin and Royzman 2001) one might predict that a decision-maker would overweight unfavorable information. Instead, across a series of experiments, we show that favorable information is "overweighted" when determining the value of uncertain financial prospects. We find that this bias is driven by the interaction of multiple mechanisms.

In our first study, individuals indicated their willingness-to-pay (WTP) for gambles where one poker chip was randomly drawn from a bag of 100 red and blue chips. Participants read the following: "This bag contains at least X red chips and at least Y blue chips," and learned that a red chip resulted in a monetary payout, and a blue chip had no payout. Thus X represented the amount of favorable information available while Y represented the amount of unfavorable information, and both could be varied independently ($X=\{0, 25, 50\}$; $Y=\{0, 25, 50\}$). Regression analyses demonstrated that unfavorable information had much less impact on WTP than favorable information (absolute magnitude=5% of favorable, test for equality of regression coefficients $p<.01$.) This bias persisted when tested in the domain of losses, that is, even when unfavorable information signaled a distinct monetary loss as opposed to merely absence of a win.

In such "constrained" ambiguity experiments, participants were aware of the limited total number of chips (and thus the total amount of information possibly available). Addressing this, we tested WTP for gambles with more subjectively interpretable, or "unconstrained" situations based on trivia questions. Participants continued to overweight favorable information and even overclassify information as being favorable towards their desired outcome.

Though these findings suggest a bias arising (only) from engagement with favorable information, we hypothesized a second mechanism based on individuals' aversion to feelings of ignorance and ambiguity (e.g. Fox and Tversky 1995). We considered that information can be used both to estimate the probability of winning, and to reduce the uncertainty felt about those estimates. We conducted a study in which participants indicated their WTP, their estimate of the likelihood that a red or blue chip would be drawn, and their certainty in that estimate. This multi-trial, incentive compatible experiment replicated the net bias in WTP. From a mechanistic standpoint, we found that that favorable information increased perceived likelihood of winning, and unfavorable information appropriately decreased it. However, favorable *and* unfavorable information significantly increased felt certainty. And in turn, both likelihood and

certainty variables explained a significant amount of the positive effect of information on WTP. Put another way, we show that people will pay more when they feel more certain, even when that certainty comes from negative information.

Thus we find a complex set of mechanisms driving biases in how favorable and unfavorable information is used to estimate value and make decisions. In financial situations, though unfavorable information decreases the estimated likelihood of a desired outcome, it also increases felt certainty about this estimate. These elements act in opposition, minimizing the effects of unfavorable information, and deepening the asymmetry in information processing. This multi-mechanism framework is supported by preliminary fMRI data showing that valenced information is represented in different ways across multiple neural loci when individuals are making incentive-compatible decisions under uncertainty.

Our findings demonstrate a real and robust role for subjective, or felt certainty in these types of financial decisions. While increasing easily interpretable information can increase certainty in the financial domain, it has been shown to have more complex effects when the information is more complex (Hadar, Sood and Fox, 2013) or when people are choosing romantic partners (Norton, Frost and Ariely, 2007). We discuss how our insights about certainty relate to these findings, and can be extended across various choice domains.

Overall Probability of Winning Heuristic in Decisions Under Uncertainty and Ambiguity

EXTENDED ABSTRACT

Over the past few decades, there has been considerable debate about the role of inherent preferences that are stable and time-invariant versus constructed preferences, which are influenced by the context and cognitive resources. Several studies in behavioral economics, consumer behavior, and judgment and decision-making have shown that people adaptively make judgments and decisions depending on different descriptions and procedures of given tasks or choice options (Tversky & Kahneman, 1986), which seem to support the preference construction framework. However, those adaptive behaviors have been studied mostly with risky decision-making tasks where outcomes and probabilities are known, but relatively less has been investigated under ambiguity where the outcomes and/or probabilities are unknown (Fox & Hadar, 2006; Knight, 1921). Here, we explore further the adaptive nature of preferences under uncertainty and ambiguity by two different decision-making paradigms across three studies (Hertwig, Barron, Weber, & Erev, 2004; Ludvig & Spetch, 2011).

We report findings from three independent studies. All studies were approved by Temple University IRB, and participants received course credit in exchange for their participation. In study 1, 29 participants completed a series of risky-choice problems involving mixed gambles (Venkatraman et al., 2014), while seated in front of a Tobii T60XL eye tracking system. In each trial, three gambles were presented in the form of a 4x4 grid, with the columns rank-ordered from the highest gain to greatest losses. The probabilities occupied the top row. Each gamble consisted of three outcomes (one gain, one loss and one intermediate), each with its own probability. One alternative was associated with the highest gain outcome (Gain maximizing or Gmax), one alternative was associated with the lowest loss outcome (loss minimizing or Lmin) and the third alternative was associated with superior value for the intermediate outcome. Trials were classified as either OP (overall probability) available or OP unavailable. In the OP available trials, the intermediate alternative was associated with a greater overall probability of winning (Pwin) compared to the

other alternatives. In the OP unavailable trials, there was no change in overall probability of winning across all alternatives.

A total of 30 additional participants completed a follow-up Study 2. Here, we varied the presentation formats (fixed, random), such that the columns were no longer rank-ordered in some trials. Therefore, most common attribute-based decision-making strategies (e.g., lexicographic, take the best) were unavailable on certain trials. In Study 3, a total of 47 participants ($M = 21.75$, $SD = 2.98$; $Male = 16$) completed a similar risky-choice task with mixed gambles. However, no probability information was presented for each of the gambles and participants had to learn this information by repeatedly sampling the outcomes from each of the gambles (Camilleri & Newell, 2013; Hertwig et al., 2004). Three boxes (corresponding to the three gamble alternatives) were presented on the computer screen. Participants could sample one gamble at a time by pressing the corresponding button, and a randomly chosen outcome (based on the underlying probabilities) from that gamble was revealed within that box for 500ms. They could sample each gamble as many times as they wanted without any restriction in the sampling order. When participants felt that they had sufficient information to make their decision, they could indicate their choice. In all studies, we were primarily interested in the relative preference for the overall probability of winning option (Venkatraman et al., 2014).

In Study 1, participants showed a strong preference for the intermediate outcome only when it changed the overall probability of winning (53%), but not in the OP unavailable trials (34%). In Study 2, we replicated the findings from Study 1 with participants showing a strong preference for Pwin choices in OP available trials. Crucially, we also found a strong effect of presentation format. In trials where the information was presented in a randomized format, the preference for Pwin choices increased (64%) for OP available trials. Strikingly, the introduction of random trials lead to systematic changes in decision-making strategies as indexed by eye-tracking measures, even for fixed trials when compared to similar trials from Study 1. In Study 3 for decisions under ambiguity, initial analysis indicated that participants showed a reduced preference for Pwin choices when information had to be learned through sampling unlike Studies 1 and 2, but these preferences still adapted with trial types. We next investigated whether the effects could have been masked by the actual samples experienced. We used a conditional logistic regression to determine the effects of predefined overall probability of winning (set-OP) and experienced overall probability of winning (exp-OP) on choice. The result showed that set-OP negatively influenced the choice of an option ($b = -0.39$, $SE = 0.12$, $p = .001$, $e^b = 0.67$), while exp-OP positively influenced the choice of option ($b = 0.99$, $SE = 0.14$, $p < .001$, $e^b = 2.69$), and the effect of exp-OP was significantly greater than the effect of set-OP ($e^b = 0.25$, $SE = 0.06$, $z = -5.70$, $p < .001$). These findings suggest that participants demonstrate a bias for the overall probability of winning even when making decisions under ambiguity.

We show that both preferences and decision-making strategies are systematically influenced by format in which information is presented, consistent with the notion of constructed preferences. Crucially, we extend the recent developments from the decisions-from-experience paradigm for risky choice to show that such adaptivity may also extend to decisions under ambiguity - situations where the probabilities are unknown and need to be learned from experience, but only if information about learning is integrated into the models.

Updating Under Ambiguity: Insights From Neuroscience

EXTENDED ABSTRACT

Some of the most important decisions consumers make involve ambiguity where probabilities of potential outcomes are unknown or partially known. Empirically, behavioral experiments have repeatedly shown that in gambling decisions most participants are averse to ambiguous bets involving unknown probabilities, e.g., an urn containing 100 balls with unknown proportions of red and black, compared to risky bets with known probabilities, e.g., an urn containing 50 red balls and 50 black balls (Ellsberg 1961; Slovic and Tversky 1974; Sarin and Winkler 1992).

This aversion to ambiguity has important implications for a number of aspects of consumer decision-making, among others timing of purchase, brand choice (Muthukrishnan 1995). Scientifically, it has resulted in a rich literature on psychological antecedents to ambiguity (e.g., Curley, Yates, and Abrams 1986; Fox and Weber 2002; Trautmann, Vieider, and Wakker 2008). In particular, these studies have suggested the importance of emotional processes associated with consideration of ambiguous options, such as the fear of negative evaluation (FNE) by others (Curley et al. 1986; Trautmann et al. 2008).

More recently, these accounts have received support from neuroscientific studies that allow researchers to directly access psychological processes underlying behavior. In particular, consistent with accounts of bias resulting from emotional systems, these studies have implicated regions involved in emotion processing in decisions under ambiguity, in particular the amygdala and the lateral orbitofrontal cortex (Hsu et al. 2005; Levy et al. 2010).

In contrast, much less is known about how people behave in dynamic situations where ambiguity is reducible over time. Such an understanding is important for developing marketing strategies, such as those involving new brand and product introduction decisions. One possibility is that the same systems involved in choices under ambiguity are also involved in updating, such that updating, like choice, would be colored by emotional processes. An alternative account is that updating will engage analytical regions of the brain, such as frontoparietal circuits engaged in more sophisticated forms of Bayesian reasoning processes (Botvinick, Niv, and Barto 2009; Gläscher et al. 2010) in the form of a reward prediction error (RPE), and that the influence of emotional processes are restricted to choice.

To provide direct evidence of the constructive process behind updating of behavior in ambiguous settings, we conducted a functional neuroimaging study using a series of decisions involving the so-called Ellsberg's Three-Colored Urn problem. In the Three-Color Urn problem, an agent is presented with an urn containing some number balls of three possible colors—yellow, red, and green. Furthermore the agent knows about the exact number of balls in one color (referred to as the “risky color”), but not in the other two colors (“ambiguous colors”). For example, if the yellow ball is risky, it means the green and red are ambiguous. The agent wins some monetary prize if the drawn ball matches a pre-determined “winning” color, for example green. We next introduce updating to this decision problem in the form of an “observed draw”. A ball is randomly drawn from the urn, observed by the agents and returned back, before the gamble is resolved. Valuation for the urn both before and after the observed draw was elicited as willingness to pay to play the gamble (WTP).

A total of 20 participants made 90 decisions over a series of 12 different three-color urns while undergoing functional magnetic resonance imaging (fMRI). Behaviorally, we first examined how participants updated WTP under three types of information condi-

tions in our experiment: (i) “good news” in cases where the observed draw was an ambiguous ball matching the winning color, thereby improving one’s likelihood of winning, (ii) “bad news” where the observed draw was an ambiguous ball that did not match the winning color, therefore lowering one’s likelihood of winning, and (iii) “no news” where the draw was a risky ball. We found that the direction of WTP changes overwhelmingly conformed to prediction (chi-square test of independence, $\chi^2(4) = 1493.4, p < 10^{-10}$), such that WTP values changed positively (negatively) under good (bad) news, and did not change when there was no news.

Next, we investigated how the brain responded to these different types of information. Specifically, we sought to characterize brain regions that responded to (i) updating of information of urn contents and (ii) updating of the value of the urns. We found that a set of frontoparietal regions responded to updating of information of urn contents, in particular bilateral dorsolateral prefrontal cortex and intraparietal sulcus ($p < 0.001$). In contrast, we found that the updating of urn value was correlated with brain activity in the ventromedial prefrontal cortex.

Compared to previous findings involving choice under ambiguity, these results provide striking contrast in the dissociations observed between these processes. That is, unlike *choice* under ambiguity which engages brain regions known to subservise emotion-related processes, *updating* under ambiguity engages an entirely different set of frontoparietal systems thought to subservise sophisticated reasoning processes (Daw et al. 2011). This has potential implications for marketing strategies involving new brand and product introduction decisions. It suggests that although initial introduction are likely to be met with emotion-related ambiguity-averse responses that suppress demand for new brands and products, they may be mitigated by the use of more reason-based strategies in subsequent interactions that allows consumers to overcome the initial aversion. Future studies are needed to assess whether this also holds for real products.

SESSION OVERVIEW

The tenet that preferences are constructed underlies much of consumer behavior research and marketing practice. Consumer preferences for goods and services can be influenced through advertising, the choice context, the way preferences are elicited, etc. Consumer preferences for risk, in contrast, are typically treated as consistent. Consumers are either assumed to be risk-averse or to follow the fourfold pattern of risk aversion suggested by prospect theory (Tversky & Wakker 1995). Neither risk preference pattern, however, can account for some consumers actively seeking risk in some domains (e.g., recreation, gambling, finance) and at the same time avoiding risks of similar magnitude and consequences in other domains (health, safety, social; cf., Weber, Blais & Betz 2002; Blais & Weber 2006). The proposed session provides evidence that revealed risk preferences—like preferences for goods and services—are malleable, and hence inconsistent (as has been argued by Loewenstein et al. 2001). Three papers demonstrate inconsistent risk preferences, and the fourth paper shows a novel instance of inconsistent preferences under risk.

The first paper by Meyer, Hundtofte, and Frederick demonstrates that risk preferences are context dependent. Using historical odds from multiple sports betting markets, the authors show that independent gambles within a reference class, for example two bets involving a heavy and a slight underdog, are perceived as too similar. As a result, market betting returns are biased such that returns of bets on heavy (slight) underdogs are too low (high). The second and third paper show that consumers can be risk-seeking and risk-averse for the same risky prospect. Moon and Nelson demonstrate that participants are willing to pay less for a risky prospect than for its worst outcome (i.e., the uncertainty effect, Gneezy, List & Wu 2006), but at the same time expect to enjoy the risky prospect as much as its best outcome, a pattern consistent with risk seeking. Vosgerau and Peer show that consumers are willing to pay (WTP) and ask to be paid (WTA) to take on the same risk. Such opposing revealed risk preferences are shown for hypothetical and real gambles, and when WTP and WTA are manipulated within-subjects and are elicited incentive-compatible. The fourth paper by Paolacci and Vosgerau shows that probability of occurrence not only affects consumers' valuation of a risky prospect, but also the valuation of the prospect's outcomes.

Less likely outcomes are valued less, leading to preference reversals when valuing risky and riskless outcomes.

Together, the four papers demonstrate new conditions under which risk preferences and preferences under risk are inconsistent. Risk preferences are influenced by the context (Meyer et al.), and consumers can be risk-seeking and risk-averse for the same risky prospects (Moon & Nelson, Vosgerau & Peer). Finally, risk not only affects valuations of risky prospects but also valuations of their constituent outcomes (Paolacci & Vosgerau). The findings deepen our understanding of how consumers evaluate risk, and may contribute to designing new interventions in marketing and public policy aimed at influencing how consumers evaluate health, environmental, and financial risks.

Contextual Gambles Bias Odds in Sports Betting Markets

EXTENDED ABSTRACT

We examine historical odds on sporting events in multiple markets and find that the valuations of independent gambles within a reference class are too similar to one another. We argue that this compression of odds within a reference class reflects an effect of irrelevant context on gambler choice: comparisons to the returns of other similar and salient gambles make a particular gamble seem more or less appealing.

We presented participants with two independent sporting events and asked them to place a hypothetical bet on each. For each event, participants chose whether to bet on the “favorite” or on the “underdog.” The odds on the second event were fixed across conditions while the odds on the first event varied by experimental condition.

Participants were more likely to bet on the favorite in competition 2 when the favorite in competition 1 offered a \$110 return than when the favorite in competition 1 offered a \$170 return. We assume that the “favorite” and “underdog” column headers in the experimental materials created two “reference classes” within-which participants judged the appropriate returns for members of the class; \$130 seems like a good return for a favorite when compared to \$110, but a bad return for a favorite when compared to \$170.

Sports betting markets are an ideal real-world context in which to document this effect on actual consumer choices. If actual gamblers were influenced by contextual gambles in the way that our experimental participants were, demand for a bet would increase when it was presented alongside similar bets offering lower returns, and decrease when it was presented alongside similar bets offering higher returns. In response, bookmakers would lower potential returns when a bet was presented alongside similar bets offering lower returns, and raise potential returns when a bet was presented alongside similar bets offering higher returns. Within a reference class, these adjustments would cause high return bets not to be high enough, and low return bets not to be low enough. All returns within the reference class would be slightly compressed toward the center of the class. The actual rates of outcomes provide fundamental values against which to measure this pricing bias, and the dates on which competitions take place allow us to create a proxy for the reference point.

In addition to laboratory demonstrations of the context effect, we examine two historical datasets of market closing odds: one on 3,597 Mixed Martial Arts (MMA) fights scheduled to take place

from June of 2007 to February of 2013, and one on 94,221 European soccer games scheduled to take place from June of 2000 to January of 2013. In the MMA dataset, notational differences between the presentation of favorite and underdog odds suggest comparisons within those types of bets. In the Soccer dataset, the layout of the betting card suggests three types: home team, away team, and draw. In both cases, we assume that bettors compare odds to bets of the same type from the previous week. This proxies for the reference class. We then take the median odds within the reference class to proxy for the reference point.

Consistent with the bookmaker's best response to the experimentally observed bias, we find that within a reference class, high return bets are particularly unprofitable for the bettor, and low return bets are more profitable than they should be. Incorporating our class compression framework into a simple out-of-sample test of a betting strategy can lead to positive returns approaching 5% per bet placed. Our estimates are robust to controls for the well-known longshot bias, in which high return bets are particularly unprofitable without respect to reference class (see Griffith, 1949; Snowberg & Wolfers, 2011).

In addition to the primary compression, our causal hypothesis makes a number of secondary predictions. Compression toward bets likely to have been presented to bettors within the same time period should be greater than compression toward a historical class midpoint, and compression toward the odds on past gambles should be greater than compression toward future gambles. We find support for both. Further, compression should be greater when the reference class is clearer. For example, in Soccer, we follow the layout of the betting card to assume win-bet reference classes of Home and Away. But some bettors may instead (or also) be comparing favorites to favorites and away teams to away teams. Because these two comparisons sometimes predict cancelling biases, we should find smaller estimates of compression for these win bets than for bets to draw, where there is only one reasonable reference set: other bets to draw. We find this as well.

The prices that we observe are set by a bookmaker. But we assume that the observed pricing bias reflects a response to a bias in bettor choice, rather than a biased bookmaker himself. In the MMA dataset, we observe market opening prices before bettor demand can influence price. We find no evidence of compression there, suggesting that bettor demand is necessary to create the bias. Further, we directly observe compression over the course of the market: mean absolute distance from the assumed reference point falls by over 17% from market open to market close.

We follow up with more laboratory experiments, showing that the bias on gambler choice can be easily moderated by slight changes to the experimental materials. Two simple changes each halve the effect of the referent: presenting the referent return in different units than the focal return, and employing different syntax to describe the referent gamble than to describe the focal gamble.

In conclusion, we demonstrate that sport market betting odds are biased by simple context effects. Bookmakers respond to the effect of context on betting volumes, which leads to biased returns in the market place.

When and Why Do Consumers Devalue Risky Prospects?

EXTENDED ABSTRACT

In 2006, Gneezy, List, and Wu discovered a perplexing phenomenon they called the "uncertainty effect" (UE): people valued lotteries less than their worst possible outcomes. In particular, participants were asked to report their willingness-to-pay (WTP) for ei-

ther: (1) a \$50 Barnes & Noble (B&N) gift certificate, or (2) a lottery ticket that would for sure provide them with a reward of a \$50 B&N gift certificate or a \$100 B&N gift certificate with equal probability. Participants were WTP around \$38 on average for the \$50 gift certificate, but surprisingly, they were only WTP around \$28 for the lottery between the \$50 and the \$100 gift certificates. This effect held in both hypothetical and real-stakes scenarios, with other goods (e.g., a field experiment with baseball trading cards) and notably, using other elicitation methods (i.e., choice between the prospect and \$25 in cash).

Why does the UE occur? Although Gneezy et al. (2006) hypothesized that the effect is due to risk aversion, a plethora of other explanations have been tested and ruled out, such as: (1) disappointment aversion (Newman & Mochoch, 2012), (2) joint evaluations in the lottery versus separate evaluations in the certain conditions (Simonsohn, 2009), and (3) misunderstanding of instructions (Simonsohn, 2009; Rydval et al., 2009; Keren & Willemsen, 2009). Therefore, despite numerous alternative explanations that have been proposed for the UE, without clear-cut opposing evidence, the default explanation is that of "direct risk aversion" (coined by Simonsohn [2009]). Specifically, people simply dislike uncertainty which leads them to devalue risky prospects.

Seemingly contrary to this explanation, Yang, Vosgerau, and Loewenstein (2013) found that when the uncertain prospects were framed as uncertain gift cards, people were WTP just as much for the uncertain prospect as the lowest possible outcome. Furthermore, they found that this framing influenced WTP but not willingness-to-accept (WTA). Yang et al. (2013) proposed that the UE was explained by an aversion to bad deals, which led buyers to be more sensitive to cues of risk (e.g., lottery rather than gift card) than sellers. Though this explanation is not entirely incompatible with the direct risk aversion explanation, it provides another explanation as to why the UE may occur.

In several studies, we provided more direct tests of both the direct risk aversion and the bad deal aversion accounts of the UE. To test the direct risk aversion account, Studies 1A, 1B, and 2 examined how uncertainty influenced expected enjoyment. To test the bad deal aversion account, Study 3 examined whether eliminating the bad deal aspect of a risky prospect would also eliminate the UE.

Study 1A. 201 undergraduates watched trailers for two upcoming movies and ranked them. After being randomly assigned to one of two conditions: Certain (told which movie they would watch) or Uncertain (not yet told which movie they would watch), participants rated their expected enjoyment of the movie.

Inconsistent with the UE, Uncertain participants expected to enjoy the movie ($M=4.83$, $SD=1.29$) as much as those who were told that they would watch the movie they ranked higher ($M=5.18$, $SD=1.32$; $t(154)=1.61$; $p=.11$), and significantly more than those who were told that they would be watching the movie they ranked lower ($M=3.78$, $SD=1.54$; $t(144)=4.30$, $p<.001$).

Study 1B. Using a similar procedure as Study 1A, Study 1B replicated the UE with WTP using these stimuli ($N=156$).

Study 2. 303 MTurk participants completed an online study using a 3 (Certainty: Certain – Match vs. Certain – Mismatch vs. Uncertain) x 2 (DV: Enjoy vs. WTP) between-subjects design. After watching trailers for two movies and ranking them, participants were randomly assigned to one of three certainty conditions: Certain - Match (asked about movie they liked), Certain - Mismatch (asked about movie they did not like), or Uncertain (asked about a lottery between the two). Participants either reported their expected enjoyment or WTP.

Replicating Study 1A, Uncertain participants expected to enjoy the movie ($M=5.78$, $SD=1.15$) just as much as Certain - Match

participants ($M=5.79$, $SD=1.14$, $t(105)=.05$, $p=.96$, and significantly more than Certain – Mismatch participants ($M=3.74$, $SD=1.68$; $t(92)=6.95$, $p<.001$ and $t(97)=7.22$, $p<.001$, respectively).

Replicating the UE, Uncertain participants were WTP less ($M=\$2.25$, $SD=\$2.10$) than Certain – Mismatch participants ($M=\$5.48$, $SD=\$2.98$; $t(107)=6.26$, $p<.001$).

Study 3. 203 MTurk participants completed an online study using a 2 (Certainty: Certain vs. Uncertain) x 2 (Refundable: Non-Refundable vs. Refundable) between-subjects design. The Non-Refundable conditions were the same as those of the original UE. The Refundable conditions stated that there was a 30-day return policy; for the Uncertain Refundable condition, the return policy allowed the consumer to return the lottery ticket *even after* finding out the outcome. This should considerably reduce the worry of paying for a bad deal. Participants first stated their WTP for the prospect, then they rated how worried they were about the prospect being a bad deal on a 7-point Likert scale (1 = Not At All, 7 = Extremely).

For ratings of bad deal, there was a significant interaction effect, $F(1, 199)=6.65$, $p=.01$. There was no effect of refundability for the Certain conditions; however, there was an effect for the Uncertain conditions: the lottery was deemed less of a bad deal when it was refundable ($M=2.59$, $SD=1.56$) than when it was not ($M=3.84$, $SD=2.08$).

For WTP, there was only a main effect of Certainty, such that participants in the Uncertain condition were WTP significantly less ($M=\$40.80$, $SD=\$10.35$) than participants in the Certain condition ($M=\$29.33$, $SD=\$21.77$), $F(1, 199)=22.8$, $p<.001$. Even when the lottery was less of a bad deal, people were not WTP as much as the worst possible outcome.

Across several studies, we tested two different accounts of the UE. Studies 1A, 1B, and 2 demonstrated that though people are less WTP for risky prospects, they expect to enjoy the same risky prospects, which provides evidence that consumers may not dislike uncertainty. Study 3 found that even when uncertain prospects are not “bad deals,” people still exhibit the UE. Taken together, these studies suggest that another explanation for the UE is needed. We offer some alternative accounts based on our studies.

Malleability of Revealed Risk Preferences

EXTENDED ABSTRACT

All theories of decision making under risk presume (revealed) risk preferences to be stable such that for identical risky prospects, people are either risk seeking or risk averse. Classical expected utility models, for example, assume general risk aversion expressed by the diminishing marginal utility of wealth (Rabin 2000). In prospect theory, a four-fold pattern of risk seeking/aversion emerges from the interplay of the subjective value and probability weighting functions (Tversky & Wakker 1995). In the perceived relative argument model (PRAM) by Loomes (2010), risk preferences are determined by the comparison of risky prospects' outcome and probability ratios.

Weber, Blais, and Betz (2002), however, suggest that people can be risk seeking in one domain (e.g., finance) and risk averse in another (e.g., social). We argue that risk preferences—like preferences for riskless prospects—are to a large extent constructed (cf., Ariely, Loewenstein, & Prelec 2006; Loewenstein et al. 2001), and may thus be inconsistent even within the same domain. In six experiments with hypothetical and real gambles, we show that people ask to be paid (WTA) and at the same time are willing to pay (WTP) to play the same gamble. All six experiments involved gambles with a 60% chance of winning \$X, and a 40% chance of losing \$X. Both the

stake X in the gamble and whether WTA or WTP were elicited was manipulated between- and within-subjects.

In Experiment 1 (N = 308, MTurk), participants indicated their WTA or WTP for two hypothetical gambles, where X = \$10 (small stake) or X = \$100 (large stake; WTA/WTP and stakes were manipulated btw-sbj.). For both small and large stake gambles, over 85% of participants asked to be paid (i.e., indicated a WTA > \$0), and over 68 % were willing to pay (i.e., indicated a WTP > \$0) to play the gambles. Thus, participants were more risk-averse in the WTA conditions (over 85% indicated WTA > \$0) than in the WTP conditions (only 32% indicated WTP = \$0; all $p < .001$), indicating that risk-preferences differed across WTA/WTP conditions. Such risk preference reversals were observed for both small and large stake gambles. Experiment 2 (N = 149, MTurk, hypothetical) replicated these findings with stakes manipulated within-participants.

Since the WTA/WTP measures are truncated at \$0 (i.e., any amount greater than \$0 is interpreted as evidence for a risk preference change), our results may not necessarily indicate true risk preference reversals but represent a demand effect or stem from participants' misunderstanding of the scales/instructions. We tested this possibility by a) manipulating WTA/WTP within-participants, b) playing gambles for real, and c) setting the WTA/WTP default to \$0 and reminding participants that they can set their WTA/WTP to \$0.

In experiment 3 (N = 485, MTurk, hypothetical), we manipulated WTA/WTP within-participants, thereby exposing participants to opposing experimental demands. Each participant indicated her WTA for the low stake and her WTP for the high stake gamble (same gambles as in experiment 1) or vice versa (order was counterbalanced). Again, the majority of participants asked to be paid (> 85%) and was willing to pay (> 70%) to play the gambles, demonstrating more risk-aversion in the WTA (over 85% indicated WTA > \$0) than the WTP conditions (only 30% indicated WTP = \$0; all p 's < .001). Furthermore, WTA and WTP correlated positively ($r = .49$, $p < .001$), the more participants asked to be paid to take on risk, the more they were also willing to pay to take on risk. Note that if risk preferences were based on a stable underlying construct, WTA and WTP should have correlated negatively.

In experiment 4 (N = 101) and 5 (N = 53), WTA/WTP (btw-sbj.) were elicited with the Becker, De Groot, and Marschak (1964) incentive-compatible procedure, and gambles were played out for real. In experiment 4, X = \$0.10 or X = \$1.00 (btw-sbj.), in experiment 5 X = \$7. In both experiments (and in all stake conditions), risk preferences reversed, participants were more risk averse in the WTA (over 85% set their WTA > \$0) than the WTP conditions (max 50% set their WTP = \$0; all p 's < .01).

Experiment 6 tested a boundary condition for the observed risk preference reversals. In the WTA conditions, WTA can be used to hedge against a potential loss. At the extreme of setting WTA = X (the stake in the gamble) the decision maker is completely insured against the possibility of losing X. As a consequence, WTA should increase proportionally to increases in X. The opposite holds for the WTP conditions, the higher WTP the more a decision maker hedges against a potential win, at the extreme setting WTP = X which ‘insures’ the decision maker completely against the possibility of winning X. Hence, as X increases WTP will not increase proportionally but quickly reach a maximum. To test this, in experiment 6 (N = 425, MTurk, hypothetical) WTA/WTP was manipulated between-subjects. To make sure participants understood that they can enter any amount including \$0, participants were presented with a scale ranging from \$0 to \$1000, with the scale pointer positioned at \$0 by default. In addition, participants were reminded that they could indicate \$0. The stake X was manipulated within-subjects at three lev-

els: \$10 vs. \$100 vs \$1000. Significant risk preference changes were again observed across the WTA/WTP conditions for all three levels of X (all $p < .001$). WTA increased almost linearly in X (X = \$10, $Median_{WTA} = \$10$; X = \$100, $Median_{WTA} = \$100$; X = \$1000, $Median_{WTA} = \$709$; nonparametric $p < .001$), whereas WTP increased much less in X (X = \$10, $Median_{WTP} = \$2$; X = \$100, $Median_{WTP} = \$9$; X = \$1000, $Median_{WTP} = \$14$; nonparametric $p < .001$). The results suggest that assessing consumers' WTA/WTP does not make losses/gains or winning/losing probabilities more salient, or trigger avoidance/approach motivation. Rather, the WTA/WTP manipulation appears to truly change revealed risk preferences, risk-averse consumers become risk-seeking.

Less Likely Outcomes are Valued Less

EXTENDED ABSTRACT

A risk-neutral decision maker would—according to expected utility theory (Von Neumann & Morgenstern 1944)—value a 50% chance of obtaining a \$50 gift certificate at \$25. Both entities, probability and outcome, are assumed to be independent; the likelihood of occurrence does not depend on the desirability of the outcome, and the desirability of the outcome does not depend on the outcome's likelihood. More recent theories of decision making under risk have relaxed the first assumption (e.g., Quiggin 1982; Tversky & Kahneman 1992), and can hence accommodate wishful thinking-type of anomalies where desirability of outcomes increases the subjective likelihood of their occurrence (cf., Krizan & Windschitl 2007; Vosgerau 2010). Interestingly, the opposite possibility of probabilities influencing the desirability of outcomes—first proposed by McGuire (1960)—has received scant attention. In the only empirical investigation to date, Pyszczynski (1982) found participants being less attracted to a prize when it was uncertain whether they would obtain it.

In four studies, we tested whether the mere presence of uncertainty reduces outcome valuations. Specifically, we tested whether such devaluation is observed a) when valuations are elicited incentive-compatible, b) for high, moderate, and low probabilities, and c) for gains and losses. The latter manipulation allowed us to test two competing explanations for the devaluation of outcomes, anticipated disappointment and psychological distance.

In Study 1, participants (MTurk, N = 203, incentive-compatible) were informed that one participant would be selected at random and endowed with a \$50 bonus payment. Willingness to pay (WTP) for an outcome was elicited incentive-compatible with the Becker, De Groot, and Marschak (1964; BDM) procedure. Participants were randomly assigned to one of two conditions. In the *certain* condition, participants were asked about the highest amount they were willing to pay for a \$50 Amazon certificate. In the *10% probability* condition, participants were told that there was a 10% probability that they would be eligible to buy a \$50 Amazon certificate. Participants were then asked "If it turns out that you can buy the gift certificate, what is the highest amount you would be willing to pay for it?" As hypothesized, WTP was lower in the *10% probability* condition ($Median = \$25.00$) than in the *certain* condition ($Median = \$30.50$; $p = .004$; we report p -values of non-parametric tests throughout; results are qualitatively identical with parametric tests.)

In Study 2 (MTurk, N = 401, hypothetical), we employed a 2 (gift certificate: \$80 Amazon vs. \$100 Overstock) x 2 (uncertainty: certain vs. 10% probability) between-subjects design using the same (but hypothetical) scenario from Study 1. Replicating our previous result, participants valued both gift certificates less when probability of obtaining them was uncertain ($Median_{certain} = \$70.00$; $Median_{uncertain} = \$51.00$; $p < .001$). This led to preference reversals when

purchase of one gift certificate was uncertain. Participants valued the Amazon gift certificate ($Median_{\$80\text{-Amazon}} = \70.00) more than the Overstock certificate ($Median_{\$100\text{-Overstock}} = \50.00 , $p = .007$) when it was uncertain whether they could buy the latter. In contrast, participants valued the Amazon certificate ($Median_{\$80\text{-Amazon}} = \60.00) less than the Overstock certificate ($Median_{\$100\text{-Overstock}} = \75.00 ; $p < .001$) when it was uncertain whether they could buy the former.

In Study 3 (MTurk, N = 401, incentive-compatible), we varied between-subjects the probability of being eligible to purchase the \$50 Amazon gift certificate (10% vs. 50% vs. 90% vs. 100%). WTP varied significantly across conditions (independent-samples Kruskal-Wallis test $p < .001$), with probability predicting WTP in a linear regression with robust error estimation ($B = 0.088$, *robust SD* = 0.021, $p < .001$; see figure, the dashed lines show 95% confidence intervals).

There are two possible explanations for the results of Studies 1-3. When valuing an uncertain outcome, people may anticipate the disappointment of not obtaining the outcome, and reduce this disappointment by decreasing the value of the outcome (Zeelenberg et al. 1998; 2000). Alternatively, uncertainty may increase the psychological distance to the outcome, which—like increases in temporal distance—would lead to lower valuations of the outcome (Prelec & Loewenstein 1991, Todorov et al. 2007, Weber & Chapman 2005; Chandran & Menon 2004). In Study 4, we tested these two competing explanations by manipulating the valence of the outcomes (gains versus losses). For gains, both theories predict that uncertainty will lead to lower valuations of outcomes. For losses, anticipated disappointment increases with the likelihood of the negative outcome occurring (van Dijk & Zeelenberg 2006). As disappointment can be reduced by devaluing the outcome, WTP to avoid the loss should be lower the more likely the loss is. Probability as an instance of psychological distance, in contrast, predicts the opposite pattern. Because uncertain negative outcomes are perceived as less threatening (Chandran and Menon 2004), WTP to avoid a loss should be lower the lower the outcome's probability is.

Study 4 (MTurk, N = 401, hypothetical) employed a 2 (certain vs. uncertain) x 2 (gain vs. lose gift certificate) between-subjects design. We used the same gain scenarios as in Study 1. For losses, participants were told to imagine that they owned a \$50 Amazon gift certificate, and were asked how much they were willing to pay to avoid losing it. We replicated the effect of uncertainty for gains ($Median_{certain} = \$40.0$ vs. $Median_{10\%} = \$25.0$, $p < .001$). The same pattern was observed for losses, uncertainty reduced WTP to avoid losing the certificate ($Median_{certain} = \$13.0$ vs. $Median_{10\%} = \$10.0$, $p = .022$). These results support the hypothesis that less likely outcomes are valued less because they are perceived as more remote.

Devaluation of uncertain (positive and negative) outcomes bears theoretical and practical implications. Theoretically, the extent of risk aversion in previous studies may have been underestimated if less likely outcomes are valued less. Practically, consumers' reluctance to alter their behavior in face of potential negative outcomes (e.g., cancer due to smoking, sea-level rises and extreme weather due to pollution) may be partly driven by consumers believing these outcomes to be less severe as long as they are not certain.

SESSION OVERVIEW

The concept of “paying it forward” is prevalent in game theory, psychology, and popular culture. This concept is a simple one: A is kind to B, and B—rather than paying that kindness *back* to A—pays it *forward* to C. C then pays that kindness forward to D, D pays it forward to E, and so on, creating a never-ending chain of good will.

However, reality is not so simple. On any given day, consumers may receive not just kindness, but also cruelty. They may be motivated by self-interest, pressured by social norms, or influenced by individual differences. In this session, we look at how various internal and external factors may influence the likelihood of paying forward both positive and negative outcomes. In so doing, we shed light on how greed and generosity, fairness and unfairness, and prosocial and antisocial behavior may spread through social networks.

The first paper (Ward, Norton, and Gray) investigates how two potential incentives—material gain and reputational concerns—may influence the likelihood of paying forward both positive and negative outcomes; results suggest that adults use sophisticated cognitive abilities to maximize material benefits while minimizing social costs.

The second paper (Jung, Nelson, and Kurtisa) analyzes the separate influences of reciprocity and generosity on paying-it-forward; results from this work shed light on multiple components motivating pay-it-forward behavior and suggest that prosocial behavior may often be motivated by misguided beliefs about the effects of one’s actions on others’ happiness.

The third paper (Janakiraman, Yang, and Winterich) investigates how individual differences in communal vs. exchange orientation and differences in potential recipients’ perceived needs interact to produce different levels of paying-it-forward; results from this work indicate that individuals who are sensitive to others’ needs are affected by the salience of these needs, while those who are relatively insensitive to others are not.

Finally, the fourth paper (Yang, Janakiraman, and Ward) investigates the perceived importance of individuals’ actions in a

different light. This work suggests that longer chains of recipients—which objectively increase the potential effectiveness of a prosocial action—ironically reduce the likelihood of paying forward positive outcomes due to a diffused sense of moral responsibility.

Together, these papers add to a growing area of research acknowledging that prosocial (and antisocial) behavior such as giving (and taking) is often determined by social context; both the outcomes people experience and the impact they believe they might have feed into their decisions about how to treat others. These data provide evidence that consumer behavior cannot be considered in a social vacuum; rather, pay-it-forward chains connect consumers’ actions to the actions of those around them.

Social and Material Concerns in Paying it Forward: People are Selfish, But Only in Secret

EXTENDED ABSTRACT

Daily life is filled with opportunities to be greedy or generous, cruel or kind, antisocial or prosocial. A growing body of research suggests that one of the most powerful influences on people’s choices between these alternatives is the way they have been treated in the immediate past (e.g., Gray, Ward, and Norton 2014; Leimgruber, et al. 2014), and that people may be more likely to pay this treatment *forward* (AàBàC) than to pay it *back* (AàBàA) (e.g., Herne, Lappalainen, and Kestilä-Kekkonen 2013; Stanca 2007).

In two experiments, we investigate the effects of both material (financial) and social (reputational) concerns on paying forward both positive and negative outcomes. These experiments add to a growing body of literature that recognizes the potential ripple effects of both pro- and antisocial interactions (e.g., Gray, Ward, and Norton 2014), contribute to theory by providing new insights into the determinants of paying-it-forward (PIF), and reveal broad principles for both maximizing prosocial and minimizing antisocial PIF behavior—principles that may be particularly relevant in a world increasingly defined by anonymous interactions.

Each participant in each experiment served as the central link in a PIF chain of financial allocation decisions. Participants first played the role of “receiver,” accepting some amount of money left to them by a previous participant, then played the role of “decider,” choosing how much money from a second endowment to leave for a future participant. Participants’ behavior in the “decider” phase served as our measure of “paying it forward.”

Both prior treatment and social/reputational concerns were manipulated within each experiment according to a 2 (receive: *negative, positive*) × 2 (anonymity: *anonymous, non-anonymous*) design. Participants in the *anonymous* condition never saw the future participant. Participants in the *non-anonymous* condition experienced only minimal contact with the future participant; they stood in this person’s presence for a few seconds, but were not introduced or allowed to speak.
